Some have maintained that the commission to baptize was addressed by Jesus only to the apostles; and hence they argue that none but apostles and apostolical men, their successors, have any right to administer baptism. But it has been asked by others, is it not a true fact that during the lives of the apostles, none but they baptized? Philip the deacon baptized the Samaritans (Acts xviii. 14); there was no apostle at Damascus when Paul was baptized, but he was baptized by a certain disciple named Ananias. Acts ix. 18. Rom. vi. 4. See also Acts xviii. 2, 26. Acts x. 23. It is also inquired further by persons of this latter class, who are the successors of the apostles? and whether or not Jesus instituted a priesthood or any order of men to succeed the apostles? It is, however, a fact which cannot be contended, that in the earliest age of the Christian church, the bishop only, or the priests by his permission, administered baptism; as, with his leave, they also performed any other of his functions: but it appears from Tertullian, that in his time laymen had in some cases the power of baptizing. This baptism, nevertheless, seemed to have required the confirmation of the bishop, and would not be allowed but in case of necessity, as at the approach of death, &c. At a synod at Elvin, in 306, it was allowed, that a layman, provided he had not been married a second time, might baptize catechumens in case of necessity; but it was ordered, that if they forewroth they should be brought to the bishop for the imposition of hands. Afterwards, when the bounds of the church were much enlarged, the business of baptism was left almost entirely to the priests, or the country bishops; and the bishops of great fees only confirmed afterwards. It seems, however, to be decent and proper, that baptism should be administered only by the teachers and ministers of the church, where their attendance can be had; not only because it appears that these were the persons by whom it was administered in the New Testament, but because, ceteris paribus, they must be most capable of judging who are the fit subjects of it.

Great doubts were raised in early times about the validity of baptism as administered by heretics. Tertullian, before he became a Montanist, wrote a treatise to prove that heretics, not having the name God or the name Christ with the orthodox, their baptism was not valid. Cyprian called a synod at Carthage, in which it was determined, that no baptism was valid out of the Catholic church, and therefore, that those who had been heretics should be re-baptized. But Stephen, the bishop of Rome, did not approve of this decision; and by degrees his opinion, which continued to be that of the church of Rome, became every where prevalent. Indeed, when so much stress was laid upon baptism itself, it would have introduced endless anxiety, if much doubt had remained about the power of administering it. For a further account of the subjects and mode of baptism, see Baptists, and Pantobaptists; also Ana-

BAPTISTS.

Baptism of the Dead, a custom which anciently pre-vailed
BAP

vailed among some people in Africa. The third council of Carthage speaks of it as a thing that ignorant Christians were fond of. Gregory Nazianzen also takes notice of the same superstitious opinion prevailing among some who delayed to be baptized. In his address to this kind of men, he asks, whether they flaid to be baptized after death? Philastrius also notes it as the general error of the Montanists or Cataphrygians, that they baptized men after death.

The practice seems to be grounded on a vain opinion, that when men had neglected to receive baptism in their life-time, some compensation might be made for this default by receiving it after death.

Baptism of the Dead was also a sort of vicarious baptism, formerly in use, where a person dying without baptism, another was baptized in his stead; a practice founded on 1 Cor. xv. 29. concerning the saine of which page all critics have been much divided. Several Catholics understand it of the baptism of tears, penance, and prayers, which the living undergo for the dead, and allege it as a proof of the belief of purgatory in the apostles' days. See Heinlius's Exerc. ad Nov. Tert. lib. vii. cap. 13.

Michaelis understands, with Grotius and Simon, by ertationen über, or baptism for the dead, a vicarious baptism for the dead. Whether this vicarious baptism was practised in the first century, and meant by the apostle, it is difficult at present to determine; and Dr. Teller, one of the most sensible expositors of the New Testament, candidly confesses, that he is unable to comprehend the meaning of the passage. It is, however, certain that the custom was not unknown in the fourth century, as appears from Chrysologon's 40th homily to the first epistle to the Corinthians; and in the same century it was not unusual to defer baptism till the approach of death, and if the patient died suddenly, to baptize even the deceased. Michaelis's Intro. by Marth, vol. i. p. 359.

Others have supposed that the superstitious custom of baptizing a living person as the representative of one who had died unbaptized, is more likely to have arisen from an erroneous interpretation of this passage than to have been so early prevalent. Some conceive that verum is here put for verum, and refers to those who were baptized into the religion of Jesus, who on the hypothesis of the adversaries against whom the apostle reasons, is still dead. Sir Richard Ellys, in his "Fortuita Saera," p. 137, interprets these words in the following manner: "what should they do who are baptized, in token of their embracing the Christian faith, in the room of the dead, who are just fallen in the cause of Christ, but are yet supported by a succession of new converts, who immediately offer themselves to fill up their place, as ranks of soldiers that advance to the combat in the room of their companions, who have just lain in their light." Dodd. in loc. Wakefield (Transl. vol. ii. p. 89.) renders the words: "Besides, what advantage above the other dead will they have, who are submitting constantly to baptism? Why indeed are they thus baptized, if the dead will certainly live no more? Why should we too expose ourselves to the danger of it every hour?" The apostle, says this critic, here begins a new argument of the resurrection, grounded on the practice of the apostles themselves, who had been eye-witnesses of their master's revival. What contributed not a little to obscure this passage, he adds, was the second verum über verum, a clause not acknowledged by the Coptic and Ethiopic versions. For this sense of baptism, the reader may consult Matt. xx. 22. Luke xii. 50. Ecce. Eccl. Hill. vi. 4. fin.; and for an illustration of the argument, Rev. xx. 4.

Baptism, Lay, seems to have been allowed in the rubric of the English liturgy, till the time of king James I. though there were great disputes among the bishops at the Hampton-court conference in 1603, whether the words of the liturgy imported such allowance or not. The bishop of Worcester allowed them to be doubtful; but that the contrary practice of the church, which confirmed women for conferring baptism, showed, that the compilers of the book did not intend them as a permission: they had indeed propounded them ambiguously, because otherwise, perhaps, the book would not have passed the parliament. The archbishop of Canterbury intimated, that the administration of private baptism by women and laymen was not allowed in the practice of the church, but, on the contrary, confined by the bishops in their visitations. He even added, that the words of the liturgy do not infer any such meaning. To which king James excepted; urging and preparing the words of the book, that they could not but intend a permission of women and private persons to baptize. Till this time it had been customary for bishops to license midwives to their office, and to allow their right to baptize in cafes of necessity, under an oath which was preferred to them.

At present, the English divines condemn it as invalid; and Barnet, bishop of Sarum, was severely handled by some of them, for asserting that faith in the Trinity gives every man a right to baptize. Collins's Disc. on Free Think. p. 73.

Baptism, Clinic. See Clinic.

Baptism is also applied abusively to certain ceremonies used in giving names to many inanimate things.

Baptism, in Sea Language, is a ceremony in long voyages aboard merchant-ships; practised both on persons and vessels which pass the tropic, or equinoctial line, for the first time.

That of vessels is simple, and confined only in the washing them throughout with sea-water; that of passengers is ludicrous; but neither the one nor the other is done without making the crew drunk; the seamen, on christening the ship, pretending to a right of cutting off the beak-head, unless redeemed by the master or captain.

Baptism of Bears. See Bell.

Baptismal Font. See Baptistry.

Baptismal Preface are in use in Germany, made by the sponsors to the infant, consisting of money, plate, or even sometimes fields of lands; which, by the laws of the country, are to be kept for the child till of age, the parents having only the truth, not the right of disposing of them.

An anonymous author has published a discourse express on this occasion, intitled, "De Pecunia Latinica."

Baptismal Vow, or Covenant, a profession of obedience to the laws of Christ, which persons, in the ancient church, made before baptism.

It was made by turning to the East, but for what mystical reasons is not well agreed.

Baptist, John, Monover, in Biography, an eminent painter of flowers and fruit, was born at Lille in 1635, and educated at Antwerp. The composition and colouring of this master are in a bolder style than those of Van Huydam, but his pictures are not so exquisitely finished. The disposition of his objects is so elegant and beautiful as to form a test by which his compositions may be distinguished from those of other masters. He was invited to England by the duke of Montagu, and employed in conjunction with La Feuille and Rouleau, to embellish Montague house, which is now the British Museum, and in which are preserved some of the finest performances of Baptist. A very celebrated work of this artist is a looking-glass preserved in the royal palace at Kensington, decorated with a garland
garland of flowers, for queen Mary II. who sat by him during the greatest part of the time whilst he was employed in painting it. He died in 1609. His son Anthony Baptist was also a painter of flowers in the style and manner of his father. Pilkington.

Baptist, John, Gasparis, a painter of history and portrait, was born at Antwerp, and was a disciple of Thomas Willeboorts Boefchaert. During the civil wars he came over to England, and after the restoration was employed by Sir Peter Lely, to paint the portraits and draperies of his portraits, and distinguished by the name of Lely’s Baptist. He made designs for tapestry, which were accounted good, and his drawings was generally correct. In the hall of St. Bartholomew’s hospital there is a portrait of king Charles II. painted by this master. He died in 1691. Pilkington.

BAPTISTRY, in Ecclesiastical Writers, a place or edifice where water is preferred for persons to be baptised in. Anciently, in the churches which baptised by immersion, the baptistery was a kind of pond where the catechumens were plunged; though in many places the next river served for a baptistery, which was the case in the time of Justin Martyr and of Tertullian.

About the middle of the third century, they began to build baptisteries; but there were none that accompanied to churches till the year 409, and then they flourished without the church, and of this kind the first was prepared for the baptism of Clovis king of France, who, with his father Audofledis, was dipped three times by immersion. But there were none within the churches till the fifth century; and it is remarkable, that though there were many churches in one city, yet, with few exceptions, there was but one baptistery. This simple circumstance became in time a title to dominion; and the congregation nearest the baptistery, and to whom in some places it belonged, and by whom it was lent to the other churches, pretended that all the others ought to consider themselves as dependent upon them. When the fashion of dedication was introduced, the church that owned the baptistery was generally dedicated to St. John the Baptist, and assumed the title of St. John in fonte, or St. John ad fontem, that is, the church near or at the baptistery. The noble and splendid cities of Florence, Pisa, Bologna, Parma, Milan, and many others in Italy, had but one baptistery in each; and these baptismal churches were usually built near rivers and waters, as was the case with respect to those of Milan, Naples, Ravenna, Verona, and many more. In later times, the bishop of the baptismal church, having obtained-peculiar power, granted licences for other churches to erect baptisteries; taking care at the same time to maintain his own dominion over the people.

By a baptistery, which must not be confounded with a modern font, is to be understood an octagon building, with a cupola roof, resembling the dome of a cathedral, adjacent to a church, but forming no part of it. The whole middle part of this edifice was one large hall capable of containing a great number of people; the sides were parted off, and divided into rooms; and in some, rooms were added on the outside in the fashion of cloisters. In the middle of the great hall was an octagon bath, which, strictly speaking, was the baptistery, and from which the whole building derived its appellation. Some of these were erected over natural rivulets; others were supplied by pipes, and the water was conveyed into one or more of the side-rooms. Some of the surrounding rooms were vestries, others school-rooms, both for transacting the affairs of the church, and for the instruction of youth. They were large and capacious; for as baptism was administered only twice a year, the candidates were numerous, and the spectators more numerous than they. In course of time there were baptisteries at most of the principal churches of Rome, as at those of St. Peter, St. Lawrence, St. Agnes, St. Pancras, and others. The most ancient is that at St. John Lateran. Baptisteries were also erected separately from the churches in all the principal cities of Italy, as Florence, Ravenna, Milan, Pisa, Parma, and the rest. The baptistery annexed to the spacious and splendid church of St. Sophia at Constantinople, reclamed the convocation room of a cathedral; it was very large; councils have been held in it; and it was called μεγάλη καθεδρία, the great illuminatory. In the middle was the bath, in which baptism was administered; and there were outer rooms for all concerned in the ceremony of immersion, the only baptism of the place. The Lateran baptistery, in Rome, belonging to the church of St. John Lateran, is an octagon edifice, the roof of which is supported by eight large polygonal pillars of porphyry; and under the cupola, in the centre of the floor, is the baptistery properly so called, lined with marble, with three steps for descent into it, and about five Roman palms, or 5-7 inches, deep. Ciampini apprehends, after much investigation of the opinion of antiquarians, that this baptistery was originally a bath in the precincts of the imperial palace; that it was begun to be converted into a baptistery by the emperor Constantine; that the buildings were carried on by pope Xyfixus III.; and that they were completed and ornamented by pope Hilary. Baptisteries were in fashion in Italy from the reign of Constantine to that of Charlemagne, during a period of about 500 years; and within this interval they were amply adorned and endowed. The first gifts of the faithful were milk, honey, and wine, for the refreshment of the catechumens and their attendants; the next were oils, ungents, and salts; along with these came cups, vales, plates, and utensils, marked with the initial letters of the name of John Baptist, I. B. or John the fore-runner, ἸΑΝ ΤΙΦΩΣ, which perhaps is the true origin of baptismal inscriptions; then came money for the poor, and for the support of those who spent their time in teaching and officiating; after these came habits, ornaments, pictures of John holding out his right hand, with a lamb lying in it, and with a symbol of his name, "Q T D G P," and these were followed by others more complex; the whole forming a large body of superstitious theology, glaring in practice, but cumbrousome to virtue.

In the baptistery of infants, it was unnecessary for the administrators to go into the water, and therefore they contrived cisterns, which they called fonts, in which the children were dipped. These were at first small baths, erected on a platform, into which those who performed the ceremony plunged children, without going into the water themselves. In modern practice, the font remains, but a bason of water set in the font serves the purpose, because it is not thought necessary either that the administrator should go into the water, or that the candidate should be immerged. This in England was customary, but not law; for in the time of queen Elizabeth, the governors of the episcopal church did in cleft expressly prohibit sprinkling, by forbidding the use of basins in public baptism. See "A book of certaine canons, concerning some part of the discipline of the church of England," in 1571, by John Daye, p. 19. Fonts in parish-churches for the purpose of baptising infants were introduced soon after the arrival of Aulbin the monk; and each parish was enjoined to provide fonts of wood and stone for this purpose. In the old church of St. Peter at Oxford, built by Grembald, who was brought over from Flanders into England by Alfred, in the year 885, there was at first a very ancient baptismal font, of a circular form, and elegant sculpture,
eleven feet in circumference, and of proportionable depth, with the twelve apostles represented in separate niches. After having kept its place about 500 years, it was ordered to be removed, and another much inferior put in its place. In the church of Bridekirk, near Cockermouth in Cumberland, there is a large open vault of greenish stone. Antiquaries pronounce it to be a Danish font. The chief characters on this baptismal font (see Gibson's Camden's Brit. vol. ii. p. 1097.) are Runic, but some are purely Saxon. This is supposed to be the oldest font yet remaining in this kingdom, being of the ninth century, when the Danes first received the Catholic religion. Whether the font be Danish or Saxon, the baptism which it exhibits is that of the Catholics opposed to that of the old Pelagian Britons.

There were several fonts and altars in each baptistery, because then they baptized at once, all of whom received the encaustic immediately after.

The right of having fonts was confined to parishes alone; and if any monasteries were found with baptismal fonts, it was because they had baptismal churches in another place: though the bishops sometimes granted them to monks, upon condition that they would have a secular priest along with them to take care of the people; but they afterwards found means to throw off the priest, and make themselves masters of the church, and attach it, with its baptismal fonts, to their own monastery. For a copious account of baptisteries and fonts, illustrated by figures, see Robertson's History of Baptism, p. 56—131.

Baptistery is also used for a baptismal or parochial church.

Baptistery is also used, by the Armenians, for the feast of Epiphany, when the anniversary of Christ's baptism is celebrated.

Baptistery is also used for a church-book, wherein the prayers and ceremonies of baptism were particularly described. Some take the baptisterium to have contained the order of all the sacraments, except the eucharist.

BAPTISTS, in Ecclesiastical History, from Epiph., I baptize, a denomination of Christians, distinguished from other Christians by their particular opinions respecting the mode and the subjects of baptism.

Instead of administering the ordinance by sprinkling or pouring water, they maintain that it ought to be administered only by immersion. Such, they infer, is the meaning of the word βαπτισμός; so that a command to baptize is a command to immerse. Thus it was understood by those who first administered it. John the Baptist, and the apostles of Christ, administered it in Jordan and other rivers and places where there was much water. Both the administers and the subjects are described as going down into, and coming up again out of the water. And the baptized are said to be buried in baptism, and to be raised again; which language could not, they say, be properly adopted on supposition of the ordinance's being administered in any other manner than by immersion. Thus also, they affirm, it was in general administered in the primitive church. Thus it is now administered in the Rulian and Greek church; and thus it is, at this day, directed to be administered in the church of England, to all who are thought capable of submitting to it in this manner. With regard to the subjects of baptism, the Baptist's say, that this ordinance ought not to be administered to children or infants at all, nor to grown up persons in general, but to adults only of a certain character and description. Our Saviour's commission to his apostles, by which Christian baptism was instituted, is to go and teach all nations, baptizing them; that is, lay they, not to baptize all they meet with; but first to instruct them—to teach all nations, or to preach the gospel to every creature—and whoever receives it, him to baptize in the name of the Father, and of the Son, and of the Holy Ghost. To such persons, and to such only, baptism appears to have been administered by the apostles, and the immediate disciples of Christ. They are described as repeating of their fias, as believing in Christ, and as having gladly received the word. Without these qualifications, Peter acquaints those who were converted by his sermon, that he could not have admitted them to baptism. Philip holds the same language in his discourse with the eunuch. And Paul treats Lydia, the jailor, and others, in the same manner. Without these qualifications, Christians in general think it wrong to admit persons to the Lord's supper, and, for the same reasons, without these qualifications, at least a profession of them, the Baptists think it wrong to admit any to baptism. Wherefore they withhold it, not only from the impenitently vicious and profane, and from infidels who have no faith, but also from infants and children, who have no knowledge, and who are incapable of every action civil and religious. They further infer, that all public inquisitions depend entirely upon the will and declaration of the inquirer; and that therefore reasoning by analogy from previous abrogated rites is to be rejected, and the express commands of Christ respecting the mode and subjects of baptism ought to be our only rule.

The Baptists in England form one of the three denominations of Protestant dissenters. They separate from the established church for the same reasons as their brethren of the other denominations do, with whom they are united; and from additional motives derived from their particular tenets respecting baptism. The constitution of their churches, and their modes of worship, are congregational or independent: in the exercises of which they are protected, in common with other dissenters, by the act of toleration. Before this act, they were liable to pains and penalties as non-conformists, and often for their peculiar sentiments as Baptists. A proclamation was issued out against them, and some of them were burnt in Smithfield in 1558. They bore a considerable share in the persecutions of the 17th and of the preceding centuries; and, as it should seem, in those of some centuries before; for there were several among the Lollards and the followers of Wickliff, who disapproved of infant baptism. There were many of this persuasion among the Protessants and reformers abroad. In Holland, Germany, and the North, they went by the names of Anabaptists and Mennonites; and in Piedmont and the South, they were found among the Albigenenses and Waldenses. See the Histories of the Reformation, and the above articles in this Dictionary.

The Baptists suffer under two denominations, viz. the Particular or Calvinistical, and the General or Armenian. The former is by far the most numerous. Some of both denominations allow of mixed communion, others disallow it; and some of them observe the seventh day of the week as the sabbath, apprehending the law that enjoined it not to have been repealed by Christ or his apostles. But a difference of opinion respecting these and other matters is not peculiar to the Baptists; it is common to all Christians, and to all bodies of men who think and judge for themselves. See Anabaptists, under which article an account will be given of the principal arguments in favour of infant baptism.

BAR, in architecture, a long slender piece of wood or iron, used to keep things close and fast together.

In this sense, we speak of bars of windows, of doors, and the like.
Bars of iron are made of the metal of the fows and pigs as they come from the furnaces.

These pass through two forges, called the finery and the shallown; where, undergoing five several heats, they are formed into bars. Phil. Trans. N° 158. p. 954. See Iron, and Forges.

Bar Shot, in Artillery. See Shot.

To Bar or strike a Vein, among Farriers, an operation performed on the veins of a horse’s legs, or other parts of his body, in order to stop the course, and lessen the quantity of malignant humours prevailing there. It is thus performed: the farrier opens the vein, after disengaging the vein, ties it above and below, and then divides between the two ligatures.

Bar of a Port, in Marine Fortification. See Boom.

Bar, in Geography, is used for a heap of sand or mud, or a chain of rocks, which block up the mouth of a river or port, so that there is no entrance except at high water. The bar of Siam is a remarkable bank of mud, gathered in the mouth of the river, which allows not above thirteen feet of water, when the tide is highest.

Bar, a town of Arabia, fifty-six miles south-east of El Catiff, near the Persian gulf.

Bar, a town of Hindostan, in the country of Bahar, fifteen miles north of Bahar, and thirty E. S. E. of Patna.

Bar, Le, a town of France, in the department of the Var, and chief place of a canton in the district of Graffe, four miles north-east of Graffe.

Bar for Aube, a town of France, and principal place of a district in the department of the Aube. N. lat. 48° 14’. E. long. 4° 36’.

Bar for Seine, a town of France, and principal place of a district in the department of the Aube, situate at the foot of a mountain, on the Seine; it has three gates, a college, and an hospital; 53 leagues S. E. of Troyes. N. lat. 48° 5’. E. long. 4° 16’.

Bar le Duc, a town of France, and principal town of a district in the department of the Meuse; and, before the revolution, the capital of the duchy of Bar. It is divided into the Upper and Lower town by a caille called the Bar, and was a kind of barrier between France and Lorraine. The walls and towers of this caille were demolished by Louis XIV. The river Osmin runs through the lower part of the town. It is seven leagues S. S. E. of St. Menchoul, and 92 leagues of Toul. N. lat. 48° 47’. E. long. 4° 14’.

Bar, Duchy of, was, before the revolution, the name of a country of France, situate to the west of Lorraine, thirty-two leagues long and sixteen wide; the face of the country is irregular, presenting hills and plains; and it abounds with wood, wine, corn, game, and fish. Its name was derived from the castle of Bar, and it was erected into a county by the emperor Otho, but the time when it was raised to a duchy is not ascertained.

Bar, a district of Switzerland, in the canton of Zug. See Zug.

Bar, is also the name of a fortres of Poland, in Podolii.

Bar, in Heraldry, denotes an ordinary nearly resembling the Fess: it consists of two lines drawn horizontally across the field, and contains a fifth part thereof. The bar hath two diminutives; viz. a closo, which is in breadth one-half; and a barret, which is in breadth one fourth of that of the bar. When the field is divided into four, the bar, eight, ten, or more equal parts, it is then blazoned, bartry; and the number of pieces are to be specified, e. gr. barry of so many pieces; but if it contains an odd number, the field must be first named, and the number of bars expressed; they are then called bars. See Plate of Heraldry.

Bars-Gemell, or Barri-Gemellis, are diminutives of the bar, and are placed in pairs, or two and two on a shield. They derive their name from the Latin gemelli, twins. See Plate of Heraldry.

Bar, in a Court of Justice, denotes an inclosure made with a strong partition of timber, three or four feet high, where the counsel are placed to plead causes; and where prisoners are brought to answer their indictions, &c.

This the French call barre d’audience, and in some places audiore. It answers to what, among the Romans, was denominated confesitum.

It is called bar, because inclosed with a barrier, called also in Latin writers cancelli and caules, by a metaphor taken from sheep-folds.

The denomination bar is also given to the benches where the lawyers or advocates are seated.—The apellation arose hence, that anciently there was a bar, or barrier, to separate the counsellors and pleaders from the attorneys and others.

Hence our lawyers who are called to the bar, or licensed to plead, in other countries called licentiati, are termed barristers. 24 Hen. VIII. c. 24.

Bar, or Barr, Barrak, in Common Law, denotes a peremptory exception against a demand or plaint.

The author of the "Terms of Law" defines bar, a plea brought by the defendant in an action, whereby the action of the plaintiff is destroyed for ever. And it is divided into bar to common intention, and bar special; the former is an ordinary or general bar, which is usually a bar to the declaration of the plaintiff; and the latter is that which occurs upon some special circumstance of the fact, as to the cafe in hand. Modern writers also divide bars into perpetual and temporary: bar perpetual, is that which overthrows the action for ever, and bar temporary, or bar pro tempore, is that which is allowed good for the present, but may fail, or be set aside hereafter. Plowd. 26. A plea in bar not giving a full answer to all the matter contained in the plaintiff's declaration, is not good. 1 Litt. Abr. 211. If one be barred by plea to the writ, or to the action of the writ, he may have the same writ again, or his right action again; but if the plea in bar be to the action itself, and the plaintiff be barred by judgment, &c. it is a bar for ever in personal actions. 6 Rep. 7. And a recovery in debt is a good bar to action on the cafe, for the same thing; and also a recovery on assumpsit in cafe is a good bar in debt, &c. Cro. Jac. 110. 4 Rep. 94. In all actions personal, as debt, account, &c. a bar is perpetual, and in such cafe the party hath no remedy but by writ of error or assize; but if a man is barred in a real action or judgment, yet he may have an action of as high a nature, because it concerns his inheritance; as e. g. if he is barred in a formulon in defendant, yet he may have a formulon in the remainder, &c. 6 Rep. 7. It has been resolved, that a bar in any action, real or personal, by judgment upon demurrer, verdict or confession, is a bar to that action, or any action of the like nature forever; but, according to Pemberton, chief justice, this is to be understood, when it doth appear that the evidence in one action would maintain the other; for otherwise the court shall intend that the party hath mitaken his action. Skin. 57. 58.

Bar to a common intent is good; and if an executer be sued for his tator’s debt, and he pleadeth that he had no goods in his hands at the day when the writ was taken out against him, this is a good bar to a common intention, till it is shown there are goods; but if the plaintiff can shew, by way of replication, that more goods have fallen into his hands since that time, then, except the defendant allege a better bar, he shall be condemned in the action. Plowd. 26.

Bar of Dower. See Dower.
BAR

BAR, Trial at. See Trial.

BAR, in the Manger, denotes the ridge or upper part of the gums, between the tults and grinders of a horse; the under and outward sides retaining the same gums.

The bars should be sharp-ridged and lean; for since all the subjection a horse suffers, proceeds from those parts, if they have not these qualities, they will be very little, or not at all sensible; so that the horse can never have a good mouth; for if the bars be flat, round, and insensible, the bit will not have its effect; and, consequently, such a horse can be no more governed by his bridle, than if one took hold of his tail. These ridges are always more prominent in young horses than in those that are old. See LAMPSAS.

BAR, in Mufet, denotes strokes drawn perpendicularly across the lines of a piece of music, including between each two, a certain quantity or measure of time, which is various as the time is triple or common.

The use of bars in music is a modern invention. They cannot be traced higher than the year 1754, and seem not to have been in general use till about the middle of the 17th century. It is not easy to imagine how music in many parts could be composed without bars, or how the maxims, or large, equal to eight semibreves, could be divided into bars of one or two semibreves in each. See Battuta, and TIME-TABLE. A double bar implies the end of a strain. When double bars are dotted on both sides, thus, ₋ ₋
the dots imply a repetition of each strain; but if dotted only on one side, that strain only which precedes or follows the dots, is to be repeated.

BAR, Mufet, in Mining, he who keeps the gage or dih, to measure all kinds of ore; he, or his servant, being always to be present when it is measured.

BAR, among Printers, denotes a piece of iron with a wooden handle, whereby the face of the press is turned in printing.

BARA, in Ancient Geography, an island of Italy, in the vicinity of Brundifum. Felius says, that the inhabitants of this island built the town of Barium.—Also, a port of Asiatic Sarmatia.

BARA, in Geography. See BARA.

BARABA, in Ancient Geography, the name of a metropolis city of Arabia Felix, according to some copies of Ptolemy and Ammianus Marcellinus.

BARABA, in Geography, a steppe or moor in the Russian empire, occupies the space between the Irtysz and the Ob, southward of the mountain, northward to the farther side of the Tana, and beyond the river Tuy. This extensive region, in length from north to south exceeding fix hundred versts, and full four hundred in breadth from west to east, is one continued flat, scarcely interrupted by a single hill, though containing many fresh water lakes, with some of bitter, and a few of common salt. This plain is for the most part of a good black foil, having the face of it enlivened by a number of pleasant forests of birch. All serving to flow, says Mr. Falk, that the Baraba must have formerly been one general bed of waters, and since more morrally and replete with lakes than it is at present. Even within the memory of man, according to the affirmation of the Barabines, the diminution of the lakes, and the exhaustion of the pools, reed-plants, and marshes, have been very observable, as well as the acquisitions thus made by the firm land. See Tooke's View of the Russian empire, vol. i. p. 149.

BARABALEMO, a river on the coast of Africa, fixes leagues east from the river of St. Barbara, east from cape Fermosa.

BARABENSIS, in Entomology, a species of Gryllus (Locusta) found about the pine-trees in the sandy deserts of Baraba. The wing-cases are pale and sprinkled with brown dots; wings transparent and pale yellow; veins and dots at the margin, and tip brown. Pallas. Size of gryllus tibialis.

BARABIACO, in Geography, a town of Italy, in the Province, situate on the Colona, 12 miles west of Milan.

BARABIELLO SAND, lies at the bottom of Bengal bay, within the river of Hughly.

BARABINIANs, a nation of the Russian empire. On entering the vast region of Siberia by the west, the first country we come to is that of the Barabinians. The large steppe, included between the Ob and the Irtysz, and reaching as far as the Altay mountains, is called Baraba; this appellation the Russians have corrupted into Baraba, and the people who occupy that desert they call Barabinitzi, or Barabinians. The Barabinians, at the time of the conquest of Siberia, had already suffered too much from the turbulence and ferocity of their neighbours, for being able to raise themselves to a numerous population; and remembering nothing but their misfortunes, they have forgotten whether they ever were governed by sovereigns of their own. At length, succcceedingly oppressed by the Kirghizes and the Soongares, they at present enjoy tranquillity under the protection of Russia, who, in consideration of an early tribute, takes charge of their defence. Alienation of their land is divisible among them. They have, in general, the Tartar physiognomy; but a flat face; the long eyes and little opened, and the hanging ears, are testimonies that some of them are of Mongolian race. The Soongares, their conquerors, at different times lived among, and probably are the progenitors of the Barabinians with Kalmucc countenances. The idiom of the Barabinians is a dialect of the Tartar language, and bears witness to their primeval origin. It is corrupted, but less than that of the Bashkirs. They live, however, in equal ignorance, and scarcely any of them know how to read. The humid vapours that arise in their steppe, and give a density to the atmosphere, render the inhabitants sallow and phlegmatie; their indifference and their apathy border on stupidity. In respect to them we might be tempted to adopt the expression of le Cat, and regard them, not so much as men animated by the heat of the blood, and the spirituous fluid of the nerves, but as hydraulic machines. This machinal state corresponds with their misery, and enables them to endure it without pain. Temperate alike in their amours and in their diet, with desires so feeble and so confined as to be cally gratified, they know nothing of robbery or theft; they are even ignorant of lying, having no use for it except for covering a flight fault, in order to gain time for repairing it. They have itinerant inhabitants for the winter; and sow a little barley or oats, sometimes a small matter of hemp; but their industry is always of scanty production; their steppe, poor in game, ill requires the fatigue of the hunter. They derive a slender profit from their flocks and herds, and a great number of fishermen owe their subsistence to the lakes. It is not uncommon in winter for the snow to envelop their huts in such manner that they could not get out were they to neglect to make a passage through the roof. Their summer dwellings are covered only with mats. Their herds, by no means numerous, though forming their principal wealth, consist of horses and horned cattle; the humidity of the soil hardly allows them to rear a few sheep. A great number of them possess not a single head of cattle; and a man passes for opulent who has from five to twenty horses, with still fewer horned cattle. It is not long since the richest man of the nation possessed seventy horses. It should seem that their droves would increase since they have no longer to dread the ravages.

BAR
When the army is in winter quarters, the soldiers usually build barracks; in the summer they are content with their tents.

**Barracks** is also more generally applied to buildings to lodge soldiers in fortified towns, or others. Thus we say the barracks of the Savoy, of Dublin, &c.

Baracks, when damp, are greatly prejudicial to the health of the soldiers lodged in them; occasioning dysenteries, intermitting fevers, coughs, rheumatic pains, &c. For which reason quarter-masters ought to be careful in examining every barrack offered by the magistrates of a place; rejecting all ground-floors in houses that have either been uninhabited, or have any signs of moisture.

**Barack-Alliance**, a special allowance of bread, beer, coals, &c, to the regiments stationed in barracks.

**Barack-Carrier**, the principal guard of a regiment in barracks; the officer of which is responsible for the regularity of the men, and for all prisoners duly committed to his charge while on that duty.

**Barack-Major-General**, a staff-officer at the head of the barracks department, who has a number of barracks-masters and deputies under him, that are stationed at the different barracks. He has an office and clerks for the dispatch of business, and to this office all reports, &c. respecting the barrack department are made.

**Baracoa**, in Geography, a sea-port town at the north-east end of the island of Cuba, having a good harbour for small vessels, but not for large ships; distant about seventeen leagues north-east from St. Jago. N. lat. 21° 4'. W. long. 76° 10'.

**Barcum**, in Ancient Geography, a town of the interior part of Africa, which Pline mentions among the conquests of Cornealus Balbus.

**Baracura**, a commercial town of India, on the other side of the Ganges. Ptolemy.

**Baracus**, a river of India, in the southern part of the island of Taprobana. Ptolemy.

**Barad**, a town of Palestine, in the southern part of the tribe of Judah, according to the book of Numbers.

**Baradileus**, or *Zanzalus, Jacobus*, in Biography, an obscure monk of the sixth century, who revived the sect of the Monophysites, when it was just expiring, to its former prosperity and influence. For this purpose, after having been ordained to the episcopal office by a few captive bishops, he travelled on foot through the whole east, established bishops and presbyters everywhere, revived the drooping spirits of the Monophysites, and produced such a astonishing change in their affairs by the power of his eloquence, and by his incredible diligence and activity, that when he died bishop of Edessa, A. D. 588, he left his feet in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. This poor monk had the wisdom to concert the means of success, as well as activity to put them in execution; for he almost totally extinguished all the animosities, and reconciled all the factions, that had divided the Monophysites; and when their churches became so numerous in the east, that they could not all be comprehended under the sole jurisdiction of the patriarch of Antioch, he appointed, as his assistant, the primates of the east, whose residence was at Tagris, on the borders of Armenia. The laborious efforts of Jacob were seconded in Egypt and the adjacent countries by Theodosius, bishop of Alexandria; and he became so famous, that all the Monophysites of the east considered him as their second parent and founder; and they are to this day called Jacobites, in honour of their new chief, Moishe Emel. Hist. vol. ii. p. 145. See Monophysites, and Jacobites.
BAR

BARADERES, in Geography, a small bay on the north coast of the peninsula at the west end of the island of St. Domingo, or Hispaniola. It is also land-locked, having a small island near the bottom in the south-east corner. N. lat. 18° 42', W. long. 75° 37'.

BARADY, BARADDA, or BARADA, a river of Syria, called by the ancients Clytorhoea, or the golden river; and by the Syrians, Parpar; which, rushing from Anti- libanus, descends to Damascus, and is there divided into endless streams, for the supply and decoration of that city; but uniting again at some distance from it, they lose themselves in a morass. The rivers Abana and Pharpar, the names of which are lost among the Arabian geographers, Maundrell supposes must have been branches of this river Barady, which issues out of the rock.

BARAE, in Ancient Geography, a people of India, placed by Ptolemy near the Ganges.

BARAFAT, BARAFAT, BARAFAT, a term in Logic, denoting the first indirect mode of the first figure of syllogisms.

A syllogism in baralp3on is when the two first propositions thereof are universal affirmatives, and the third a particular affirmative: the middle term being the subject of the first, and the attribute of the second. — For example:

BA Every evil ought to be feared:
RA Every violent passion is an evil:
LIP Therefore something that ought to be feared is a violent passion.

See letters A and I, and SYLLOGISM.

BARALLOT'S, BARALOTTI, the name of a sect at Bologna in Italy, who had all things in common, even their wives and children. They gave, it is said, in all manner of debauchery, and were also termed conflictori.

BARAMATIS, in Ancient Geography, a town of India, on this side of the Ganges. Ptolemy.

BARA-MAREKA, in Betany. See DOLEPHOS.

BARAN, in Geography, a river of Hindostan, in the province of Cabul, which is joined by the rivers Chugan-ferai, Ahlalfung, and Alikat, in the district of Kamel, and then runs eastward or south-eastward. But it is not absolutely certain whether these confluent rivers join the river of Cabul above Pashawur, or whether they form a separate river, and pass by Bjourie and Sewar.

Major Rennell thinks the former to be the most probable, and that the confluent river receives the name of Kamel, from the district in which the junction takes place, and then communicates it to the Cabul river, during the remainder of its course. Rennell's Mem. p. 156.

BARANCA, or ST. JACO, in Geography, a river belonging to Mexico, in North America, which directs its course to the west coast, and falls into the Pacific ocean about ten leagues west by north from Xatifico bay.

BARANCA del Malambro, a sea-port town in South America, in the country of New Castile or Terra Firma, on the east side of the Rio Grande, at the mouth of the river Magdelana, with a good harbour. This is a place of considerable commerce; as the merchandise of New Granada is brought down hither by boats, and conveyed to the bay about 40 miles below the town, or else directly to Santa Martha, by a branch of the great river; the chief article is salt, which is produced in the neighbourhood of the town. It is distant 25 miles north-east from Carthagena. N. lat. 11° 40'. W. long. 75° 30'.

BARANCAS, L. A., a town of North America, in the province of New Mexico, 45 miles S. S. E. of Santa Fé.

BARNETZ, a town or settlement in Siberia, on the Lena, 52 miles north-east of Vitimkoi. N. lat. 54° 50'. E. long. 113° 14'.

BARANGE, in Ancient Geography, a town of Asia, in Hryania. Ptolemy.

BARGHI, officers among the Greeks of the lower empire, whose husiefs it was to keep the keys of the city-gates where the emperor resided.

Codinus says, that the baranghi were those who stood guard at the door of the emperor's bed-chamber and dining-room.

Codinus and Cyporopatla observe, that the name is English, formed from bar, to flint; and that the barangi were Englishmen by country; Anglo-Danes, who, being driven out of England, were received into the service of the emperor of Constantinople, and made guards or protectors of his person. Whence they are called in Latin, by Cujaecus, protectores; by others, securigeri, as being armed with a battle-ax, securis. Codinus adds, that they still spoke the English tongue. Anna Comnena says, the barbari came from the island Thule, by which is doubtless meant our island. Yet Nicetas makes them Germans; a mistake may be at that distance, considering the relation the Anglo-Saxons bore to Germany. There were barangi as early as the emperor Michael Paphalagonius, in the year 1035, as appears from Cedrenus; but they were then only common-foldiers, not a life-guard.

Their commander was called regio, as importing a person who always followed the emperor.

BARANOW, a town of Poland, in the palatinat of Sandomir, sixteen miles south of Sandomir.

BARANOWKA, a town of Poland, in the palatinat of Volhynia; 40 miles N. N. E. of Conflantinow.

BAREZANO, Redemptus, in Biography, a Barnabite friar, was born in 1590, at Saraville, a town of Vercel, in Piedmont, and obtained eminence at the commencement of the seventeenth century, by daring to abandon the Aristotelian method of philosophy. That he coincided in his ideas with those of the illustrious lord Bacon, appears from a letter written to him on this subject, by this revoler of philosophy, in June 1622, and preferred in the third volume of "Nicenon's Memoirs." Having taught mathematics and philosophy at Anvers, he went to Paris, and formed an intimate friendship with La Mothe le Vayer, who speaks of him (Oeuvr. 12mo. tom. iv. p. 172.) as one of the first wits of the age. He adds, that this honest Barnabite had several times assur'd him, but always with submision to the good pleasure of God, that he would appear to him, if he should depart first out of this world. However his promise was not fulfilled, and he verified the sentence of a Latin poet, Catullus, Epigr. iii.

"Qui nunc it per iter tenebrosum
Fluit, unde negant redire quanquam."

"He passed the dark and dreary way
From whence there's no return to the bright genial day."

He died at Montargis in 1622. His works are "Uranocopia," or the universal doctrine of the heavens, printed in folio, in 1617; "Campus Philoplasticus," the first part of
his Summary of Philosophy, as taught at Anceci, printed at Lyons, in 1659; and "De Novis Opinionibus Phylos., printed at Lyons, in the same year. Gen. Dict.

BARAG, in Geography, a town of Spain, in Arragon, two leagues from Jaca.

BARA-PICKLET, bread made of fine flour kneaded with water which makes it very light and spongy, a kind of bread used in the Welch for bread made of flour.

BARAQUICMITO, in Geography, a town in Terra Firma, South America, in the province of Caracas, and in the head waters of Oroinoko river, about 80 miles south from Valencia, and 175 north-west from Calabaza. N. lat. 8° 55'. W. long. 60° 55'.

BARASA, in Ancient Geography, a town of Palestine, according to Josephus.

BARASZE, in Geography, a town of Poland, in the palatinat of Volhynia, 36 miles N.N.W. of Zytomiers.

BARTHIER, Bartholomew, in Biography, an Italian lawyer of the 15th century, was born in Placentia, and taught the Roman feudal law at Pavia and Ferrara, which he ranged anew, and then formed a text book for the school. The work was printed at Paris in 1611, under the title "De Feudis Liber Singularius;" and in 1695, by Schilper, under its true title "Libellus Feudorum reformatus." Moore.

BARATHRUM, from Barathrum, signifying the fame, among the Ancient Athenians, a deep pit belonging to the tribe Hippothoontis, into which condemned criminals were cast headlong. The barathrum was a dark woifome hole, having sharp spikes at the top, to prevent any escape, and others at the bottom to pierce and lacerate the offender.

From its depth and capaciousness, the name came to be used proverbially for a mire, or a gluton, always craving. In which sense, the word barathrum is used among the Latin poets. Thus Horace, Epift. I. ii. p. 691.

"Pernicies, et tempellas, barathrumque Macelli, Quicquid quaeferat, ventri donaret avaro;"

It is also used for a common prostitute, by Plautus (Dacchid. i. 2. 44.), thus:

"O barathrum, ubi nunc es? ut ego te usurprem libens!"

Barathrum is also used in Physiography, to denote certain baleful caverns, inacceffible on account of their fetid or poisonous fumes.

Thee amount to the fame with what others call fossa epharistos.

BARATIER, John Philip, in Biography, a learned German, was born in 1721, at Schwobach near Nuremberg. Under the instruction of his father he is said to have understood the Greek, Latin, German, and French languages, when he was five years old; and he acquired also the knowledge of the Hebrew in one year, so as to be able to read the historical books of the Bible; and at the age of nine years, he could not only translate the Hebrew text into Latin or French, but also re-translate these versions into Hebrew. At this age he could also repeat memorit the Hebrew psalms, in consequence of merely reading it with his father. Before he had completed his tenth year, he composed a Hebrew lexicon of rare and difficult words, with curious critical remarks. In 1731, he was matriculated in the university of Altdorf; and in this year he wrote a French "letter to M. le Maitre, minister of the French church at Schwobach, on a new edition of the Bible, Hebrew, Chaldaic, and Rabbinical," which letter is preferred in the twenty-sixth volume of the "Bibliotheque Germanique." In 1734, the margrave of Anspach granted him a pension of fifty florins a year, and allowed him the free use of books from the library at Anspach. As the fruits of his application to study, his translation from the Hebrew, with historical and critical notes and dissertations, of "The Rabbi Benjamin's Travels in Europe, Asia, and Africa, containing an account of the state of the Jews in the twelfth century," was published, in two volumes 8vo. at Amsterdam, in 1734; the author being at this time in his thirtieth year: and the whole work is said to have been printed in four months. Notwithstanding the extent of his philosophical pursuits, this00 stimuli youth applied to the study of mathematics and philosophy with such success, that he devised a method of finding the longitude at sea, which was laid before the Royal Academy of Sciences at Berlin, in a long letter, dated Jan. 21, 1735, the day in which he completed his fourteenth year. When this letter being well received, he determined to visit Berlin, with a view of enforcing his project; but in his way thither he passed through Hall, where Ludewig, the chancellor of the university, offered to confer upon him the honorary degree of master of arts. Flattered by this proposal, Baratier immediately, in the presence of many professors, drew up fourteen theses in philosophy, ecclesiastical history, and philosophy, which were printed the same night, and which he supported for three hours the next day with great applause; upon which he was admitted master of arts in philosophy. He then pursued his journey to Berlin; and, in the presence of the mathematical clafs, replied in French to some objections that were urged by M. de Vignoles, the rector, against his scheme; and he then proposed, in Latin, the plan of an astronomical instrument, which he offered to execute. M. Jablonski, the president; reported, that he had examined Baratier, in the king's presence, and that he had found him well acquainted with rabbinical learning, the oriental languages, and ecclesiastical history, and that he was then, with the usual form, admitted a member of the society. Upon his return to Hall with his father, he directed his attention to theology, and wrote an answer in Latin to Cresslius, who, under the assumed name of Artemonius, had published a Socinian interpretation of the introduction to the gospel of St. John. This was intitled "Anti-Artemonius, and published at Nuremberg, in 1690. in 1735. It was accompanied with a "Dissertation on the three dialogues, commonly attributed to Theodoret," intended to invalidate their authenticity. In 1737, he defended this piece against the criticisms of the journalists of Turcous, in another dissertation, which was printed in the forty-eighth volume of the "Bibliotheque Germanique." In the fortieth volume of the same journal, there was another dissertation of Baratier on "Two works attributed to Athanasius." Baratier being obliged to confess his ignorance of the public law, in reply to the inquiry propofed to him by the king of Prussia, was summoned by the king to go and study it, before he called himself a learned man. Such was his literary ambition, that he applied immediately to the study of it, and after fifteen months he supported a thesis on the subject with great credit. The uninterrupted exertion of his faculties soon impaired his constitution, which was naturally delicate and feeble; and after languishing for a decline for several months, Baratier died at the age of nineteen years eight months and seven days. His attainments were surprising; and yet it is said that, before he was ten years of age, he was accustomed to lie in bed twelve hours, and ten hours from that time to his death. The facts above adduced may seem truly astonishing; but they are founded upon unquestionable testimony. Some few examples of a similar kind have occurred; however they should by no means be contemplated as patterns of imitation.
Bar

Bar

As models of perfection. "The poplar, which soon becomes a lofty tree, will soon decay: the strong and sturdy oak, whose majestic trunk stands unimpaired through centuries, requires a century to bring it to maturity." Formey's Life of Baratier. Nouv. Dict. Hist.

BARATO, Caffe, in Geography, lies on the coast of Italy, on the north side of the peninsula of Piombi, and about S.S. from Leghorn. It has a small bay on the S.W. before which is anchorage.

BARATRUM, in Antiquity, denotes, according to Heychins, sacred games, celebrated at Thespatoria, in which the most rebuilt of the combatants was crowned.

BARATRY, BARETRY, or BARRETRY, in Law, signifies the moving and maintaining suits in disturbance of the peace; and the taking and detaining houses, lands, &c. by false inventions. 8 Rep. 37. 1 Hawk. P. C. 243. The word barattere, in French, signifies misdemeanour, fraud, deceit; it is derived from the old word barat, which signifies any imposition; whence also they said baratter, to impose on any one.

The punishment for this offence, in a common person, is by fine and imprisonment; but if the offender belongs to the profession of the law, a barrister who is thus able as well as willing to do mischief, ought also to be disabled from practising for the future. However it seems clear that no general indictment, charging the defendant without being a common oppressor and disturber of the peace, and flirrer up of strife among neighbours, is good without adding the words "Common Barrister," which is a term of art appropriated by law to this purpose. 1 Mod. 288. 1 Stad. 282. Cro. Jac. 526. 1 Hawk. P. C. 81. § 9.

No man can be a barrister in respect of one act only; and it hath been held, that a man shall not be adjudged a barrister for bringing any suits in his own right, though they are vexatious, especially if there be any colour for them; for if they prove false, he shall pay the defendant costs. 1 Rol. Abr. 355. 3 Mod. 98. A common solicitor who follicits suits, is a common barrister, and may be indicted thereof, because it is no profession in law. 1 Dan. Abr. 525.

It is enacted by statute 12 George I. c. 29, that if any one, who has been convicted of forgery, perjury, falsification of perjury, or common barretry, shall practice as an attorney, solicitor, or agent, in any suit, the court upon complaint, shall examine it in a summary way; and, if proved, shall direct the offender to be transported for seven years. To this head may also be referred another offence of equal malignity and audaciously; that of fusing another in the name of a fictitious plaintiff; either one not in being at all, or one who is ignorant of the suit. This offence, if committed in any of the king's superior courts, is left, as a high contempt, to be punished at their discretion. But in courts of a lower degree, where the crime is equally pernicious, but the authority of the judges not equally extensive, it is directed by statute 8 Eliz. c. 2. to be punished by six months imprisonment, and treble damages to the party injured. Blackit. Com. v. iv. p. 134.

Barratry, in a marine sense, is the matter of a ship, or the mariners, cheating the owners or insurers, whether it be done by running away with the ship, sinking her, deserting her, or embezzling the cargo.

Barratry of mariners is so epidemic on ship-board, that it is rare if the matter, be his industry ever so great, can prevent it, by reason of the encouragement one knavish sailor gives another; yet the law, in such cases, imputes the offences of the mariners to the negligence of the master, and from him the merchant is to seek for remedy for all goods or merchandise lost, embezzled, or otherwise dammified.

By the French ordonnances, insuffers are not obliged to make good the loss or damage accruing to a vessel, or its lading, by the fault of the master or crew, unless by the forms of the policy, they may be made accountable for the barratry of the patron. A master who, without necessity, takes up money on the body, provision, or tackling of a ship, or sells the effects on board, or, in his account of average, sets down fictitious expenses, shall pay the value, be declared unworthy of being master, and banished the port where he ordinarily resided. In some cases, he is also subject to corporal punishment, and even to death, where it appears he willingly threw away the ship.

Barratry is also used for bribery or corruption in a judge, giving a false sentence for money.

Barratry is also used in middle age Writers, for fraud or deceit in making of contracts, false, or the like.

BARATTA, or BARATTHA, in Ancient Geography, a town of Lycaonia, mentioned by Ptolemy.

BARAVEL, Str., in Geography, one of the Ladrone islands, lies south of the island of Guam, and was one of those discovered by Magellan, and debarked by Pigafetta. Besides this, there are also between 10° and 13° N. lat. the islands of Ban and Bota, and the bloss of Santa Rafa. N. lat. 12° 44'. E. long. 142° 28'. See Ladrone.

BARAWOE, a bay and village, on the north-east coast of the island of Shetland.

BARAWNAY, a town of Hindostan, in the country of Candeith, forty-miles N. E. of Barrampour, and seventy-four S.S.E. of Indore.

BARAZA, in Ancient Geography, a town of Armenia Major. Ptolemy.

BARB, St. in Geography. See St. Barbara.

Barr, in ornithology, is used for the Barbary pigen, the Columba Numidica of Moso.

BARBA, in Ancient Geography, a town of Spain, in Bética, placed in the Itin. of Antoninus, twenty miles from Ollippo, and twenty four miles from Antiquiarus.

Barba, in Geography, a town of North America, in the country of Mexico, and province of Cola Rica, twenty-two miles S.S.W. of Cartago.

Barba Aron, in Botany, a name given by some authors to the common great house-leek.

Barba Capre. See Spirea.

Barba Jovis. See Amorpha, Anthyllis, Cytisus, Eremus, and Psoralea.

BARBACAN, or Barbican, in the History of our Ancient Fortifications, was a fort of advanced work which frequently covered the drawbridge at the entrance of a castle.

In which sense, barbarian amounts to the fame with what is otherwise called, antemurale, promural, murus exterior, or outer wall. In towns and large fortresses the barbacans were large and strong, frequently having a ditch and drawbridge of their own. (See Grose's Hist. Eng. Army, II. 2.) The term is still preferred in the ruins of several of our castles; a small stone wall covering the gate of Bodiam castle in Sufsex, is still called the barbacan; and some work of a similar kind undoubtedly gave its name to one of the itreets at the north-west end of ancient London. Babacans are also mentioned in Framlingham and Canterbury castles. For the repairing of this work, a tax called barbacanaage was levied on certain lands. Grose Antiq. Pref. i. 5.

Barbacan is also used for a fort at the entrance of a bridge, or in the outlet of a city, having a double wall with towers. Such is that at one end of the wooden bridge at Rouen, which is still called by some Barbacana.

Barbacan is also used for an aperture in the walls of a city,
city, through which to fire with muskets on the enemy. See Embassure.

Barbacao, in Architecture, denotes a long narrow canal or passage left in the walls for water to come in and go out at, when edifices are raised in places liable to be overflowed; or to drain off the water from a terrace, or the like.

Barbace Point, in Geography, the eait point of St. Pedro's channel, at the south-east end of the island on which the city of Cadiz is situated.

Barbacos, a river on the coast of America, in the Pacific ocean, nearly east of the island of Gallo. Barbacoa point is situated ten leagues from the river Tellembier, in N. lat. 2° 45'. W. long. 33° 55'.

Barbadensis, in Conchology, a species of Voluta that inhabits the American ocean. The length of this shell is an inch and a half; shape tapering; colour reddish, with very fine transverse lines; aperture oblong-oval; spire obtuse. Figured only by Lilièr, t. 1819, p. 53. Gymeln.

Barbadensis, in Ornithology, a species of Psittacus, the afl-fronted parrot of Latham. This bird is about the size of a pigeon, and inhabits Barbadoes; the general colour is green; orbits and front cinnereous; crown, chin, cheeks, throat, and lesser wing-coverts yellow; greater ones blue; many of the primary quill-feathers violet on the outside, the red inside from the base, and the red blue. Gymelin. The legs are ash; claws black.

Barbadoes, in Geography, one of the most important of the Caribbee islands in the West Indies, standing somewhat detached from the rest, about thirty-five degrees from the African islands of Cape Verd. This island was probably first discovered by the Portuguese in their voyages from Brazil, and from them received its present name. It had then neither occupants nor claimants; the Carib or Caribbees having deserted it. The Portuguese thought it not of sufficient importance for a settlement; and having furnished it with a breed of swine for the use of future navigators, they left it as they found it. The English, in 1657, finding it without inhabitants, took possession of the country by fixing a cross on the spot where James-town was afterwards built, with this inscription: "James king of England and this island," but they formed no settlement. At this time it was overgrown with woods; but yet it furnished them with a supply of fresh provisions. They found here pigs, pigeons, and parrots; and the peco abounded with fish. Some years after this, a favourable report having been made of its beauty and fertility by the master and feamen of a ship of SirWilliam Courten, lord Ley, afterwards earl of Marlborough, obtained from king James I. a grant of the island to himself and his heirs in perpetuity. Accordingly Courten, probably under the patronage of Marlborough, projected the establishment of a colony, and sent about 50 letters to plant and fortify the island, who, in 1664, laid the foundation of James-town and this was the first English settlement on the island. About this time, James Hay, earl of Carlisle, established a colony in the island of St. Christopher, and obtained from Charles I. a grant of all the Caribbee islands, including Barbadoes. This grant was contested by earl Marlborough; but at length a compromise took place; and in the earl of Carlisle's undertaking to pay the annual sum of 500l. to the earl of Marlborough and his heirs for ever, the latter waived his claims; and in 1677, the patent of the former paffed the great seal, and he became the sole proprietor. However, the earl of Pembroke obtained a revocation of Carlisle's patent, and a grant to himself. In truth for Courten, who had projected the first settlement in the island. This grant was afterwards annulled, and the earl of Carlisle was restored to the possession and privileges of which he had been for a short time deprived. Accordingly he proceeded to distribute lands to such persons as chose to comply with his laws; and a society of London merchants accepted 10,000 acres, on conditions which promised great benefit to the proprietors. These men sought 164 men, each of whom was authorized to take up 100 acres of land; and thus, in 1628, they established a new colony, which soon overpowered the settlement, and annihilated the interest of Courten. In 1629, sir William Tudor was sent out by lord Carlisle as chief governor, and he distributed land, amounting to 15,872 acres, into 140 grants; and in 1630, he issued several laws; among which was one for dividing the island into six parishes. During the civil war, the emigrations from the mother country was so great, that in 1652 it was computed that there were 20,000 white men in Barbadoes, half of them able to bear arms, and furnishing a regiment of horse to the number of 1000. It seems that about this time: the existing governor granted lands to all who applied, on receiving a gratuity for himself; and the claim of the proprietor, whether disturbed in the island, or disfranchised amidst the confusion at home, was at length tacitly relinquished.

The colony, enjoying an unlimited freedom of trade, flourished in a singular manner by its own efforts. In 1646, the son and heir of the earl of Carlisle, the original patentee, revived his claims as hereditary proprietor, and by treaty with lord Willughby of Parham, conveyed to him all his rights by a lease of 21 years, on condition of receiving one-half of the profits. Lord Willughby obtained a commission as chief governor; and was received by the inhabitants, who were warmly attached to the king's interest, with respect and obedience. But soon after his arrival, the regal authority in England was abolished.

Barbadoes, in 1651, was reduced to the obedience of the new republic, who appointed another governor. Upon the restoration of Charles II., lord Willughby applied for leave to return to his government of Barbadoes; against which the inhabitants, now apprized of his connection and contract with the earl of Carlisle, and apprehending that they were regarded by these lords as mere tenants at will of their possessions, remonstrated. They pleaded that they were the king's subjects, and solicited his majesty's support and protection. They objected to the claims of the earl of Carlisle, and insisted that the charter granted to him was void in law. The several allegations and claims of the parties concerned were referred to a committee of the privy-council; and it was finally ordered, that lord Willughby should repair to his government, and demand the grant and establishment by the assembly of a permanent and irrecoverable revenue of 4% per cent. to be paid in specie, on all dead commodities, the growth of the island, shipped to any part of the world; and the money arising from this revenue was to be applied towards making provision for the earl of Kinnoul, the legal representative of lord Carlisle with respect to his rights in the West Indies, who had on this condition promised to surrender the Carlisle patent to the crown, towards paying the annuity to the earl of Marlborough, and towards the discharge of the creditors of both these noblemen. After the extinction of these incumbrances, it was stipulated, that the revenue, subject to the charge of 1200l. per annum to the governor, should be at the disposal of the crown. With these instructions lord Willughby returned to his government in 1663. The planters were dissatisfied, and preferred complaints, which, however, were unavailing. At length, finding resistance vain, the assembly passed an act for the purposes that were required, dated Sept. 12, 1663. Thus the proprietary
government was dissolved, and the legislation of the island vested in the crown.

The island of Barbadoes is about 21 miles in length and 14 in breadth, and contains 106,470 acres of land, most of which is under cultivation. The soil in the low lands is black, somewhat reddish in the shallow parts; on the hills of a chalky marl, and near the sea, generally sandy. Of this variety of soil, the black mould is best suited for the cultivation of the cane, and, with the aid of manure, has produced as great returns of sugar, in favourable seasons, as any in the West Indies, the prime lands of St. Kitt's excepted.

About the year 1670, we are assured that Barbadoes could boast of 50,000 whites, and upwards of 100,000 black inhabitants, whose labours are paid to have given employment to 60,000 tons of shipping. This account may probably have been exaggerated; but it is certain that the inhabitants of this island have decreased with a rapidity seldom known in any other country. It appears by authentic returns, that the number of its whites, in 1724, amounted to no more than 18,295, and that of its negroes in 1753 was no more than 69,870. In 1786, the numbers were 16,167 whites, 838 free people of colour, and 62,115 negroes. It appears also that the annual produce of this island, particularly of sugar, has decreased in much greater proportion than in any other of the West India colonies. Pothlethwayte states the crop of sugar in 1736, at 22,769 hogheads of 13 cwt. which is equal to 19,800 of 15 cwt.; and the author of the "European Settlements," published in 1761, calculates the average crop at 25,000 hogheads. If this statement be just, the island has fallen off nearly one-half in the annual growth of its principal staple. In an average of eight years, from 1740 to 1748, the exports were 15,048 hogheads of sugar of 15 cwt.: 12,884 puncheons of rum of 100 gallons; 60 hogheads of molasses; 4,667 bags of ginger; 600 bags of cotton; and 527 gourds of aloes. The exports on an average of 1764, 1765, and 1766, had fallen to 9,554 hogheads of sugar; 5,448 puncheons of rum; 6,320 bags of ginger; 8,331 bags of cotton; exclusively of some smaller articles, as aloes, sweetmeats, &c. of which the quantities are not ascertained. The dreadful succession of hurricanes, which had occurred within the half twelve years, has, without doubt, contributed to this great depression. The capital of this island was fearfully riven from the ashes to which it had been reduced by two dreadful fires, when it was torn from its foundations, and the whole country made a scene of desolation, by the form of the 14th of October, 1755, in which 4,226 of its inhabitants, blacks and whites, miserably perished, and the damage to the country estimated at 1,350,564l. 15s. sterling. In the year 1792, the produce of sugar was 11,073 hogheads, 125 trecs, 2,608 barrels; of molasses 188 hogheads; of rum 5,064 hogheads, 512 barrels; of ginger 3,046 bags and barrels; of aloes 515 gourds; and of cotton 974,178 pounds. From the great increase in the export of sugar in this year compared with several of the preceding years, and decrease in that of the minor staples, it seems probable that the advanced price of that article in Europe has encouraged the cultivation of it in plantations which had been formerly abandoned or appropriated to a different kind of culture. The average of the number of negro slaves in Barbadoes for seven years, from 1786 to 1792, was 63,271, of slaves imported 4363, and the average amount of taxes, during the same period, was 9,531l. 14s. 1d. The taxes consist of a capitation tax on negroes; a tax on sugar-mills, dwelling-houses, and carriages, together with an excise, &c. on wines imported. Besides which there is a peronchial tax on land, amounting on an average throughout the island to about two shillings per acre, and an assessment in labour for the repair of the highways. The whole is altogether exclusive of the heavy duty of 41 per cent. to the crown.

Barbadoes is divided into 5 districts and 11 parishes; and contains 4 towns viz. Bridgetown, Oistins or Charles-town, St. James's formerly called the 'Eole, and Speight's-town; Bridgenow is the capital, and the residence of the governor, whose annual salary is 2000l. per annum, paid out of the exchequer, and charged to the account of the 4 1/2 per cent. duty. The form of the government of this island resembles that of Jamaica, except that the council is composed of 12 members, and the assembly of 22. The most important variation respects the court of chancery, which in Barbadoes is constituted of the governor and council, whereas in Jamaica the governor is sole chancellor. On the other land, in Barbadoes, the governor sits in council, even when the latter are acting in a legislative capacity, which would be confedered, in Jamaica, as improper and unconstitutional. It may also be observed, that the courts of grand felions, common pleas, and exchequer, in Barbadoes, are distinct from each other; and not, as in Jamaica, united and blended in one supreme court of judicature. The heat of the climate is moderated by the trade-winds, and the air is pure. Its products, besides what we have already mentioned, are the palm, tamarind, figs, bananas, cedar, mallicb, cacao, papas, guava, and palmteers. Barbadoes is situated in N. lat. 13° 10'. W. long. 50°. See Edwards's History of the West Indies, vol. i. p. 321-350.

BARBADOS, Barbada, or Cape Barba, in Geography. See Cape Bara.

BARBALIS, in Entomology, a species of Phalena, that feeds on the trifolium pratense. The antennae pectinate, feelers shorter; anterior thighs with a projecting beard. Fabricius.

BARBALISSUS, in Ancient Geography, Beles, a considerable town of Asia, in Syria, near the Euphrates. E. S. E. of Hierapolis. This is the Barbaris of Ptolemy, according to M. D'Abbeville.

BARBANA, or Barbenna, a river of Illyrium, which flows from the Labatid Marsh, according to Livy.

BARBANA, in Geography, a town of Ilria, seven miles N.N.E. of Pola.

BARBANO, a small island in the northern part of the Adriatic, near the coast of Friuli. N. lat. 45° 45'; E. long. 13° 28'.

BARBANOLA, Cape, is the south of Smyrna gulf, on the coast of Asia, at the only extremity of the Mediterranean, and nine leagues S. by W. from Porto Nero.

BARBAR, a province of Abyffinia, separated from Abyssinia by the river Tacazzé; the capital of which is Gozo, which gives.

BARBARA, in Conchology, a species of Helix, with an oblong, coarse, imperforated shell, with eight wreaths, and a subrotund lactate aperture. This kind inhabits Algeria. Somewhat resembles helix papa, but is not above half the size, being usually about the bigness of a barley-corn. Cmcl. &c.

BARBARA, in Entomology, a species of Formica that inhabits Africa, and is as large as F. heredancana. It is black, with the head, antennae, and extremity of the legs ferruginous;
The word have contempt two Magellan. Cape Defolation lies to the S.E.; the entrance is open, and it will admit a large fleet of ships.

**Barbara, Bay of St.** in Geography, lies on the south-west coast of Terra del Fuego in South America, where at two leagues S. by E. from Cape Noir, are two rocky islets; but no haul is seen at E.N.E. from the cape, where is probably the channel of St. Barbara; which opens into the straits of Magellan. Cape Defolation lies to the S.E.; the entrance is open, and it will admit a large fleet of ships.

**Barbara, St. Channel of,** lies on the south shore of the straits of Magellan, between Bay de Choiseul and Cafedade bay. It is supposed to communicate with the bay of St. Barbara; its entrance on that side being opposite to James's Island. It has been thought of importance to explore this supposed channel from the strait; because it would afford, if found good, a quick and safe passage into the Southern Pacific Ocean.

**Barbara, St. Island,** the southernmost of two islands bearing north and south on the east side of the canal grande, or principal channel, from Cape Frio, on the coast of Brazil, to the bay of All Saints. It has two good roads; one on the south-west, and another on the north-east.

**Barbara, St. River,** lies on the coast of Africa, to the east from Cape Ferno, and six leagues west from Barabalo-

**Barbara, St. Canal of;** lies on the north-west of America, near the coast of New Albion; the north-west point of entrance into which is called Point Conception; in N. lat. 34° 32'. E. long. 239° 54'.

The wealdenmull, or first island, forming this canal, is called in one Spanish chart St. Miguel, in another St. Barnado; the next is called in one chart Santa Rosa, in the other St. Miguel; and nearer the island is a third island, upon which is a high hill called in the Spanish charts Santa Cruz. The canal continues in a easterly direction about 25 miles from point Conception to a point where it takes a southerly turn, when the country gradually rises to mountains of different heights. In the vicinity of the shores, which are compos'd of low cliffs or sandy beaches, are produced some flunted trees and groveling shrubs; and, notwithstanding the dreary appearance of the coast, it seems to be well inhabited, as several villages may be perceived at a great distance from one another, in the small bays or coves that form the coast. The inhabitants use causes of wood, decorated with shells; and traffic with their fish and ornaments for spoons, beads, and feffers. They deemed, 2lys Vancouver, to possess great fenibility and vivacity, and yet conducted themselves with the most perfect decorum. Their native dialect was unknown. The Spanish million of Santa Barbara, and also that of Buena Ventura, are situated at a small distance from the canal of Santa Barbara. The shores of the bay and headland of Santa Barbara are for the most part low, and terminate in sandy beaches, with the exception of the wefsen point, which is a steep cliff of moderate elevation, and which was denominat'd by Vancouver Point Eclipis. At Santa Barbara the latitude was 33° 24', the variation 10° 15' E. and the longitude 240° 43'. The tide regularly ebbed and flowed every six hours, its rise and fall being about three or four feet; and it is high water about eight hours after the moon passes the meridian. Vancouver's Voyage, vol. ii. p. 456.

**Barbara, in Logic,** the first mode of the first figure of syllogisms.

A syllogism in barbara is that whereof all the propositions are universal and affirmative; the middle term being the sub-

ject in the first proposition, and attribute or predicate in the second.—For example:

*BAR* Whoever suffers a man to starve, whom he ought to sustain, is a murderer.

*BA* Whoever is rich, and refuses to give alms, suffers thence to starve whom he ought to sustain.

*RA* Therefore, whoever is rich, and refuses to give alms, is a murderer.

**Barbarata island,** in Geography, are situated three leagues west from the river Turuno; the bay of Trifilo lies W.S.W. from them, on the Spanish main; and these islands are between the main and Venezuela, nearly west from the latter.

**Barbarasque,** in Zoology, the name given by Buffon to the Barberry squirrel; *Sesam gothia* of Schreber and Oken.

**Barbaria, in Ancient Geography,** the name given in the Periplus of the Erythraean sea to the kingdom of Abyssinia, now called Adel, the coast of which extends from the straits of Babelmandel to Cape Gardefan, about 450 geographical miles, and contains, according to the Periplus, four principal marts or anchorages, called by the general name of Tapera, the precise situation of which is not ascertained. Abilities was situated near the straits, Malao may be fixed at Delqua, and Mundus at Zyba; but the principal port was Moftilton, seated on a promontory, a whole degree north of Mundus; and this fails no other point on the coast but Barbara, a town on an island close to the shore, adjoining to a narrow cape of considerable extent.

**Barbarian, in Antiquity,** a name given by the ancient Greeks to all those who were not of their own country, or who did not speak the Greek language, or who did not speak it so well as themselves. In which sense the word signifies with them no more than foreigner, and did not carry that odium with it which it does now. Strabo derives the word *βαρβάρος* from *βαρβαρία*, because foreigners coming to Athens used to flatter, or speak coarsely; others derive it from *βαρβαρός*, a word that foreigners frequently stumbled on, which yet had no meaning.

The Greeks had such an high opinion of the pre-eminence to which they were raised by civilization and science, that they seem hardly to have acknowledged the rest of mankind to be of the same species with themselves. To every other people they gave the degrading appellation of Barbarians; and, in consequence of their own boastful superiority, they asserted a right of dominion over them, in the same manner, to use their own expression, as the soul has over the body, and men have over irrational animals. Extravagant as this pretension may now appear, it found admission, to the disgrace of ancient philosophy, into all the schools. Aristotle, full of this opinion, in support of which he employed arguments more subtle than solid (Polit. i. c. 24-7), advised Alexander to govern the Greeks like subjects, and the Barbarians as slaves; to consider the former as companions, and the latter as creatures of an inferior nature. But the sentiments of the pupil were more enlarged, than those of his master; and his experience in governing men taught the monarch what the speculativa science of the philosopher did not discover. See Plut. de Fortun. Alex. Orat. i. Strabo, lib. i. p. 116. A.

The Greeks gave the denomination of Barbarians in a peculiar manner, and with a contempt blended with animosity, to the Phrygians, on account of the enmity that had subsisted between them since the wars of Troy. This appears in the "Orestes" of Euripides, and in the echoa upon the "Ajax Malaligropus" of Sophocles. The Ro-
mans also, in imitation of the Greeks, called all other people, the Greeks excepted, barbarian; and the compliment was returned to them by the inhabitants of other nations.

Thus Ovid, who was considered at Rome as a polished courtier, was treated in his exile as a barbarian by the Getae, who did not understand his language, which was the idiom of Rome. Trist. l. v. ch. 15. v. 57.

"Barbuns hic ego sum; quia non intelligor uli:
Et silent flodi verba Latina Getae."

Under the lower empire, the appellation of barbarian became almost synonymous with that of stranger or foreigner. The Burgundians and Franks, who were established in Gaul, were there called barbarians; and in Italy this name was given to the Goths. The term was also applied by the 52d canon of the African church to the inhabitants of those provinces which had not submitted to the Roman empire; and the denomination is frequently extended by Gregory of Tours, and also by other writers, to Pagans as contradistinguished from Christians.

BARBARIAN, A. in Ancient Geography, a town of Spain, placed in the Anton. Mem. between Attahina and Graecius.

BARBARIAN PHILOSOPHY comprehends that of all ancient nations among whom the Greek language was not spoken. It has long been a subject of dispute, whether philosophy first appeared among the Barbarians or among the Greeks.

The inhabitants of Greece, who were at an early period remarkable for literary and philosophical vanity, and who soon acquired the use of an artificial method of philosophizing, were unwilling to allow that philosophy had any existence in other countries, except where it had been borrowed from them. They could not persuade themselves, that the mere communication of precepts of wisdom in the simple form of tradition, and in languages harsh and difficult compared with their own, could deserve to be called philosophizing. On the other hand, the barbaric nations in their turn treated the Greeks as barbarians, and looked upon them as children in philosophy. Plato, in his Timaeus, introduces a barbarian as instructing the wife Solon, and saying, "You Greeks are always children; there is not an old man among you; you have no finch thing as grey-headed wisdom." In this persuasion they were the more confirmed, when they understood that the most learned men, and most ancient philosophers among the Greeks, had either been Barbarians by birth, or instructed by Barbarians (see Clemen. Alex. Stromata. l. i. p. 302, 303; that Pythagoras, for example, was a Tuscan, Antithenes a Phrygian, Orpheus a Thracian, Thales a Phoenician; and that Thales, Pythagoras, Plato, and others, had derived their knowledge from Chaldaean and Egyptian priests.

Many of the Christian fathers contended, in this dispute, the cause of the Barbarians, and maintained, with great vehemence, and with all the learning they could command, that the Barbaric philosophy was the fountain of all the wisdom which had appeared among the Greeks, except so far as they had been indebted, in the way of tradition, to divine revelation. This dispute, however, was owing to the want of diffident ideas, and an accurate use of terms; and can in reality be considered as nothing more than a logomachy. For no one can assert that the barbaric nations were wholly inattentive to wisdom, or strangers to every kind of knowledge, human or divine: and, on the other side, it cannot be questioned, that they acquired their knowledge either by simple reflection than by scientific investigation, and that they transmitted it to posterity rather by tradition than by demonstration. Whereas the Greeks, as soon as they began to be civilized, discovered a general propensity to inquiry, and adopted scientific rules and methods of reasoning. Hence it is easy to perceive, that though the improvement of philosophy is to be ascribed to the Greeks, its origin is to be sought for among the Barbaric nations. Tatian, in Proem. Clem. Alex. Strom. l. i. p. 302. Gregor. Clemen. l. i. Eusebius. Hist. c. 3. Scaliger. Exerc. ii. contra Cardan. p. 138. Bus Animad. ad Script. c. 2. p. 12. Hume. Act. Phil. i. p. 204. Hymen. Ant. Phil. Barb. ed. Lugd. Bat. 1689.

The Barbaric philosophy, in the most extensive sense of the term, and in its reference to the state of philosophy, from the earliest times to the decline of the Roman republic, comprehends that of the eastern nations, including the Hebrews, Chaldeans, Persians, Indians, Arabsians, and Phricians; that of the southern nations, or Egyptians and Ethiopians; that of the western nations, to which we may refer the Celts, the Thracians, and the Romans; and that of the northern nations, including the northern Scythians, Thracians, Getae, &c. among whom Abaris, Anacharhis, Tosaix, and Zamolxis, obtained the praise of wisdom. See Brucker's Hist. of Philosophy by Erleb., vol. i. Introduction.

BARBARIKA, in Entomology, a species of Buprestis, found in Barbary. It is a small insect; colour above brassy, beneath coppery; wing-cases very entire and slightly flattened. Fabricius.

BARBARICA, a species of Chrysonela, of a brassy-green, with five red lines on the wing-cases; wings fangnous. Habits Barbary. Sulzer. Gmelin.

BARBARICII, in Antiquity, a kind of artificers, who, with threads of divers colours, expressed the figures of men, animals, and other things; or, as others describe them, those whose business was to gild and decorate shields and helmets with gold and silver.

The barbaric art was so called, because they learned this kind of painting from the Phrygians, who were particularly denominated barbarians, in regard of their opposition to the Greeks; though the name is sometimes also written branka-cari.

BARBARICII seem also to have been used for soldiers or officers, who wore marks and vizards thus adorned with gold and silver.

BARBARIUM, in Ancient Writers, is used for a military haunt, raised by the soldiers on point of engagement. This is called barbarium from the barbarians, in whose armies this method of shouting much obtained. The same appellation was given to a war or expedition undertaken against the barbarians. "Quoniam ad illam tempus quo barbaricum extortum est inter nos & vos."" Barbarium was also used for an armoury, or magazine, wherein the Greek emperors kept the spoils and do- naries taken from the barbarians in the time of war or peace.

BARBARICUM, in the Materia Medica, is also an appellation given by the modern Greeks to rubarb. It is thus called from the Stigma Barbaricius, by the way of which this root was first brought to them.

BARBARICUS, in Entomology, a species of Cinclus (Redwits), of a black colour; thorax and wing-cases obtuse ferruginous, and a little white line on the middle of the scutellum. A native of Barbary. Gmelin.

BARBARICUS, in Ornithology, a species of Rallus that inhabits Barbary. It is ferruginous, with a black bill; wings spotted with white; rump white, flecked with black; white below; legs obtuse brown. Gmelin. This is the Barbary rail of Latham.

BARBARICUS, a species of Turdus, of a green colour, with the breast spotted with white; rump and tip of the tail
BAR

tail yellow. Gmelin. This is the Barberry thryb of Latham, and grive buffette de Barbarie of Buffon. Inhabits Barberry; and is about the size of the mild thryb. BARBARISM. In Grammar, denotes an offence against the purity of style or language.

A barbarism differs, according to Lidore, from a barbarous term, as the former, for instance, is Latin, though corrupt or misused; whereas the latter, which this writer calls barbarologia, is a word merely foreign intruded into Latin speech.

In general, under barbarisms are comprehended things written, spoken, declined, or conjugated wrong; or used in a wrong quantity, or in an unusual sense; as when a word is used which is foreign to the language, and not received by the better and purer sort of writers therein. Such are liber for liber, fallaba for fallaba, patri for patris, text for legi, banus for proferiptio, &c.

Barbarism is often charged, with great justice, on modern writers in the learned languages. The Latin books of late ages are full of Anglicisms, Gallicisms, Germanicisms, &c. according to the country of the author. But what shall we say to Caip. Scipioni, who accuses Cicero himself of barbarisms in his own language?

There are great disputes among critics concerning barbarisms in the New Testament.

Divers pious person are startled at the apprehension of any thing like a barbarism in the inspired books, as supposing it an objection to the inspiration of them; yet this does not hinder but many of the Jews, after Abarbanel and others, fill maintain barbarisms in the Old Testament; in which they are seconded by M. Simon, Le Clerc, and others. The latter of these writings abound with Chaldaisms; and the books of Moses are not free from Egyptian words.

If we consider that among native Greeks a barbarous idiom could only mean such as was not conformable to the rules of their grammarians and rhetoricians, and to the practice of their writers of reputation, it may be conceded that the style of the New Testament is of this kind, without derogating from the character of the apostles and evangelists, without impeaching their inspiration, and without injuring the authenticity of their writings. This conception, the most learned and oratorical of the Greek fathers, as for instance Origen and Chrysostom, did not forbear to make; and, in such cases, it must be acknowledged that a native of common sense is a much better judge than any learned foreigner. Nevertheless many have contended that the Greek of the New Testament is as purely classical as that of the Attic writers, and they have even condemned as impious heretics those who have dared to diftind. It has been asserted, that the contrary implies an imperfection inconsistent with divine inspiration, and that men capable of such a doctrine were not only impious, but were guilty of the sin against the Holy Ghost. And yet this doctrine was maintained by Erasmus, Luther, Melancthon, Camerarius, Beza, Drusius, Caphthom, Chaldis, Cataker, Solanus, Olearius, and Vorhis; though it has been denied by Pichonius, Stolberg, Schmid, Georgi, and Blackwall. See Ernelli Instituti Interpretis N. T. p. 41. ed. 3tis. Lip#, 1775. But the advocates for this divine purity have not only betrayed their ignorance of the Greek language, but a high degree of pedantry in estimating the accuracy of language beyond its proper value. This late mistake has happened not only to the warm and partial friends, but likewise to the enemies of Christianitv, who, from the time of Celsius to the 18th century, have maintained, that a book written in such language is neither divinely inspired, nor deserving attention and respect.

Both parties have carried their zeal and their sentiments to too great a length; and they would hardly consider an absolute purity of style, and a total absence of foreign words, of such importance as to make the contrary a crime, if they would confound to quit the language of the schools for that of common life, or turn their attention from the language of the classics to those that are in common use. All foreign idioms, such as Hebrews in Greek, Grecisms in Hebrew, or Latinisms in either, may be comprehended within the definition of barbarism, and sometimes even of solecism; but these words, it should be recollected, have always something relative in their significations; that turn of expression being a barbarism or solecism in one language, which is strictly proper in another, and to one class of hearers which is not so to another. The apostle Paul does not hesitate, by implication, to call every tongue barbarous to those who do not understand it. 1 Cor. xiv. 11. Nor does it make any difference, as appears from the whole of the apostle's argument, even if what is spoken be spoken by the spirit. With equal reason we may say of those foreign idioms in any tongue, which render what is said unintelligible or even obscure to the natives, that in respect of them they are barbarisms. Nor will any judicious person deny, that there are some idiomatical expressions in the New Testament, which must have puzzled those who were absolute strangers to the language of holy writ. Such idioms the writers of the New Testament would naturally adopt. They occurred in the Septuagint, which they were in the habit of using; and these would co-operate towards infecting their style with the tendency, which, as natives of Palestine, they would derive from conversation, to intermix Hebraisms and Chaldaisms in their writings. If we would enter thoroughly into the idiom of the New Testament, we must familiarize ourselves with that of the LXX; and if we would enter thoroughly into the idiom of the LXX, we must accustom ourselves to the fluidty, not only of the original of the Old Testament, but of the dialect spoken in Palestine between the return of the Jews from the Babylonish captivity and the destruction of Jerusalem by the Romans; for this last, as well as the Hebrew, has affected the language both of the old Greek translation and of the New Testament.

Besides, it is proper to consider in relation to this subject, that vulgarisms and foreign idioms, which may obtain among strangers, and those of the lower ranks, have no more natural unfitness to convey the sense which they that use them intend to convey by them, than the terms and phrases which, in consequence of the preference given by their superiors, may be regarded as elegancies. It may be as reasonably objected against our religion, that the persons by whom it was propagated were chosen from a class which men in high life account the dregs of the people, as that the Holy Spirit should accommodate himself to the language of those who were actually chosen. Nay, language as well as dress being in fact no more than a species of mode, it may with as good reason be maintained that the ambassadors whom Christ deputed to promulgate his doctrine, should have been-habited like gentlemen and men of fashion, as that they should have spoken the dialect of such. Should it be asked, why did the Holy Spirit choose to deliver such important truths in such barbarous idiom of a few obscure Galileans, and not in the polite and more harmonious idiom of the Greek eloquence? The answer is obvious.—That it might appear beyond contradiction, that the excellency of the power was of God, and not of man. Moreover, the very expression and idiom, an intrinsic and irresistible evidence of their authenticity. They are such as, in respect of style, could not have been written but
Barbarism, Barbarities, is also used for that rudeness of mind, wherein the understanding is neither furnished with useful principles, nor the will with good inclinations.

Barbarissos, in Ancient Geography, a town of Asia, in Syria, in the Chalybionitide country. Ptolemy.

Barbarium Pronemotirium, a promontory of Lusitania, placed by Ptolemy south of the city of Oios-Hippon, or Olciscopus. Olcipo, or Libron, in 39° 45' N. latitude.

Barbaro, Francis, in Biography, a noble and learned Venetian, was born in 1508, and distinguished by his love of literature, and his talents for public business. Under the learned Grecian Chryfoloras, he acquired that profound knowledge both of the Greek and Latin languages, of which he gave specimens in his translations of Plautus's lives, of Ariosto, and Catulo, in his elegant moral work, written in Latin, intitled "De Re Uxoria," and first published without his name, in 460. At Paris, in 1515. This work furnishes useful instructions with regard to the choice of a wife, and the duties of wives and mothers. He was also the author of some orations and letters, which manifested good taste and an amiable temper. In all the public offices which Barbaro sustained, he displayed eminent virtues. Whim he was governor of Brescia, he had occasion for the exercise both of courage and discretion. The city was divided into two violent factions, which he prevailed upon to unite, and to act in concert for the public good; and though at the same time it was besieged by the Milanese forces under the great commander Piccinino, and suffered much by famine and disease, he at length, after a protracted siege of three years, obliged the enemy to retire. He died much regretted by his countrymen, in 1454, at the age of fifty-six years. His letters were collected and printed at Brescia in 1743. Gen. Dict.

Barbaro, Ermenlo, the elder, was the nephew of the preceding, and distinguished by his early acquaintance with the Greek language, insomuch that at twelve years of age he translated many of Aesop's fables into Latin. He was advanced, at the age of thirty years, by Pope Innocens, to the episcopal see of Trevigii; and ten years afterwards he was translated to that of Verona, where he died in 1479, aged sixty years. He left translations of Greek authors.

Barbaro, Ermenlo, or Hermelau Barbaro, the younger, was the grandson of Francis Barbaro, and born at Venice, in the year 1454. In very early life he was eminently distinguished by his genius, application, and proficiency; and at the age of fourteen years he received from the hand of the emperor Frederic the poetic crown. At sixteen, he undertook the translation of Themistius, which was published seven years afterwards. Having graduated in the school of Padua in jurisprudence and philosophy, he returned to Venice, and devoted himself entirely to affairs of state. However, after an interval of twelve years, he resumed his studies with fresh ardour; and, particularly attached to the Greek language, he read lectures, without gratuity, in his own house, upon Democritus, Theocritus, and Aristotle, which were very numerously attended. At the age of thirty-two years, he was sent ambassador to the emperor Frederic, who conferred upon him the honour of knighthood; and in consequence of a subsequent embassy to pope Innocent VIII. that pontiff created him patriarch of Aquilica. This office he accepted, though the laws of Venice had prohibited its ministers from accepting any dignity from any foreign prince, without the consent of the republic; and for his opposition to this order, the Venetians pronounced upon him a sentence of perpetual exile. For preventing its execution he wished to relinquish the patriarchate; but the pope refused to accept the renunciation. From this time, he resided at Rome; but upon the accession of the plague, he removed into the country, which, however, afforded him no asylum; for he was seized with this malady, and died in the year 1493.

Besides the translation of Themistius, Hermelau published versions of Diocorides, and of the rhetoric of Aristotle; an abridgment of the moral and physical doctrine of that philosopher; two large works upon Pliny, one intitled "Constitutions Plinian," the other "Constitutions Secundazi;" "Corrections of Pamphinius Mela;" and an "Explanation of the more difficult words in Pliny." He boasted that he had corrected 5000 errors in the text of Pliny, and 300 in that of Mela. Although he is charged with having been too free in his conjectural emendations, he exercised great ingenuity and industry in these labours. The illustrious Lorenzo de' Medici treated him with great respect, and when he was at Florence on an embassy from the republic of Venice, entertained him very liberally and offered him the use of his villa and library for the prosecution of his studies. Hermelau is certainly entitled to rank in the first class of learned men, at a period when classical learning was the first and almost the sole object of attention; nor is it any depreciation of his merit as a scholar, whatever it may be of his character as a philosopher,
phr, if the whimsical story be true, that, being exceedingly perplexed concerning the meaning of Aristo's ἀναγκαιότερον, a term which has perhaps never been understood, he endeavoured, or pretended to consult the devil upon the subject." Gefner in Bibliothec. Gen. Dict. 32.

BARBAROSSA, so called from the red colour of their beard, Arue or Horue, and Hayradin, were the sons of a potter of the island of Lefkos, or as some say, of a Sicilian renegade; who, prompted by a relish for enter- prising spirit, forsaken their father's trade, and joined a crew of pirates. They soon distinguished themselves by their valour and activity, and becoming masters of a small brigantine, carried on their infamous trade with such conduct and success, that they assembled a fleet of twelve galleys, besides many vessels of smaller force. Of this fleet, Horue, the elder brother, was admiral, and Hayradin second in command, but with almost equal authority. They called themselves the friends of the sea, and the enemies of all who fall upon it; and their names soon became terrible from the raids of the Dardanels to those of Gibraltar. Whilst they were acting as corsairs, they adopted the ideas and acquired the talents of conquerors. They often carried the prizes which they took on the coasts of Spain and Italy, to which they extended their depredations about the year 1504, into the ports of Barbary; and enriching the inhabitants by the sale of theirbooty, and the thoughtless prodigality of their crews, they were welcome guests in every place at which they touched. The convenient situation of these harbours, lying so near the greatest commercial states at that time in Christendom, made the brothers wish for an establishment in that country. An opportunity occurred for this purpose, which they eagerly seized and improved to their own advantage. Eutemi, king of Algiers, having made several unsuccessful attempts for taking a fort which the Spanish governors of Oran had built not far from his capital, sought the assistance of Horue, whose valour the Africans considered as irresistible. The active corsair gladly accepted the invitation, and leaving his brother Hayradin with the fleet, marched at the head of 5000 men to Algiers, where, in the year 1516, he was received as their deliverer. Such a force gave him the command of the town. The ambitious conqueror, having secretly murdered the monarch whom he came to affil, caused himself to be proclaimed king of Algiers in his stead. He then proceeded to establish the authority which he had usurped, by acts suited to the genius of the people whom he had to govern; by unbounded liberality to those who favoured his promotion; and by cruelty as unbounded towards all whom he had any reason to distrust. Having detected and defeated a conspiracy formed against him by the Arabs, and obliged the king of Tunis, who marched to their succour with a powerful army into the territory of Algiers, to seek refuge in the mountains; Barbarossa laid siege to Tunis, made himself master of it, and was acknowledged as sovereign. He then attacked the neighbouring king of Tremecen, vanquished him in battle, and added his dominions to those of Algiers. At the same time he continued his depredations on the coast of Spain and Italy; and the devastations which he committed obliged Charles V., at the beginning of his reign, to furnish the marquis de Comares, governor of Oran, with troops sufficient to attack him. That officer, afflled by the dethroned king of Tremecen, executed the commission with such spirit and success, that Barbarossa's troops being defeated in several encounters, he himself was shut up in the citadel of Tremecen. After defending it to the last extremity, he was reduced by the apprehension of famine to the necessity of attempting an escape by a subterraneous passage; and in order to delay the pursuit, he scattered his treasures upon the road. At length the Spaniards overtook him on the banks of the Hércules, eight leagues from Tremecen; and here Barbarossa with his Turkish followers fought for some time with an obstinate valour, but they were at last totally defeated, and the conqueror himself was slain, in the forty-fourth year of his age, A.D. 1518.

His brother Hayradin, known likewise by the name of Barbaroofa, assumed the sceptre of Algiers with the same ambition and abilities, but with better fortune. His reign being undisturbed by the Spaniards, who were fully employed in the wars among the European powers, he regulated with admirable prudence the interior police of his kingdom, carried on his naval operations with great vigour, and extended his conquests on the continent of Africa. For his greater security, he put his dominions under the protection of the Grand Signor, and received from him a body of Turkish soldiers sufficient for his defence against domestic as well as foreign enemies. Soliman at length A.D. 1533, offered him the command of the Turkish fleet, in opposition to Andrew Doria, who was the greatest sea-officer of that age. Barbaroofa, proud of this distinction, repaired to Constantinople, and with a wonderful versatility of mind, combined the offices of a courtier with the boldness of a corsair, and thus gained the entire confidence of the sultan and his vizier. To them he communicated a scheme which he had formed of making himself master of Tunis, the most flourishing kingdom, at that time, on the coast of Africa; and as they approved the scheme, they furnished him with every thing he demanded for carrying it into execution. Availing himself of the intellectual divisions of the kingdom, and making pernicious use of the name and interest of Abrahechid, an exiled prince, whom he deceived and imprisoned, he was supported by a powerful fleet and a numerous army. His fleet consisted of 250 vessels, with which he sailed towards Africa; and after ravaging the coasts of Italy, he appeared before Tunis. Having landed his men, he announced his intention of ascertaining the right of Abrahechid, whom he pretended to have left sick on board of the admiral galley, but who was in reality confined in the seraglio at Constantinople, and who was never heard of more. The fort of Goletta, which guards the bay, soon submitted, and the inhabitants of Tunis declared unanimously in favour of Abrahechid; so that the gates were opened to Barbaroofa, whom they considered as the refloer of their lawful sovereign. But as Abrahechid did not appear, they soon began to suspect the corsair's treachery; and with arms in their hands, surrounded the citadel into which Barbaroofa had led his troops. Their attack, however ardent and impetuous, was of no avail; and they were forced to acknowledge Soliman as their sovereign, and to submit to himself as his vicereign. Having put the kingdom into a proper posture of defence, he extended his depredations to the Christian states, so that complaints of his outrages were conveyed to the emperor Charles by his subjects both in Spain and Italy. The emperor concluded a treaty with Muley-Hafcen, the exiled king of Tunis, who implored his assistance; and made preparations for invading Tunis. His fleet consisted of nearly 500 vessels, and they had on board above 30,000 regular troops. The armament failed from Cagliari, and after a prosperous navigation, landed within sight of Tunis. Barbaroofa assembied at Tunis for opposing the imperial army,
army, a force composed of 20,000 horse, together with a vast body of foot. By the reduction of the Goletta, after an obstinate defence by 6000 Turkish soldiers under the command of Sinan, a renegade Jew, the bravest and most experienced of all Barbarossa's corsairs, the emperor became master of the fleet, consisting of eighty seven galleys and galleots, together with the arsenal, and 300 cannon nightly of brafs, that were planted on the ramparts. In these circumstances, however, Barbarossa neither lost his courage, nor abandoned the defence of Tunis. But as the walls were extremely weak as well as extensive, he determined to advance with his army, amounting to 50,000 men, towards the imperial camp, and to decide the fate of his kingdom by the issue of a battle. Having communicated his resolution to his principal officers, he proposed to provide against the danger of a mutiny among the Christian slaves, during the absence of the army, by massacring 10,000 of them before he began his march. The barbarity of the proposal filled his officers with horror; and Barbarossa, dreading their resentment, confined to spare the lives of the slaves. The emperor's army, which suffered immense loss in the battle, pursued their march over burning sands, soon came up with the Moors and Arabs under the command of Barbarossa, who were so completely routed, that, notwithstanding all his efforts to rally them, he was hurled along with them in their flight back to the city. This was found a scene of confusion; some of the inhabitants were flying with their families and effects; others were opening the gates to the conquerors; the Turkish soldiers were retreating; and the citadel was in possession of the Christian slaves. Barbarossa, disapponted and enraged, fled precipitately to Bona; and Tunis surrendered to the victorious army of the emperor. But the lustre of this victory was tarnished by the excesses of the soldiery, who sacrificed more than 30,000 of the innocent inhabitants, and carried away 10,000 of them as slaves. Barbarossa escaped first to Algiers, and then repaired to Constantinople, where he was received again into favour, and went with a fleet to ravage Calabria. Having persuaded Solyman to make war on the Venetians, he committed great devastations in the island of Corfu, and afterwards made an expedition to the coast of Arabia Felix, where he reduced all Yemen under the Turkish dominion. In a subsequent war, between the Turks and Venetians, he took many islands in the Archipelago. In 1538 he crossed over to Canea, and made an unsuccessful attempt on Candia. From thence he retired to the Ambracian gulf, where he was overtaken by the Christian fleet under the famous Andrea Doria. By his skilful manoeuvres he not only avoided the danger that threatened him, but gained some partial advantages, and caused Doria to make a hasty retreat to Corfu. In 1539 he recovered Caelo Nuovo from the confederates. In 1543, Barbarossa left Constantinople with a powerful fleet; and proceeding to the Faro of Messina, took Reggio, and sacked the coast of Italy. He then beleagured and took Nice; but when Doria approached with his fleet, Barbarossa avoided him; and remaining in those seas during winter, he next spring ravaged the coasts and islands of Italy, and then returned with many prisoners to Constantinople. During the remaining period of his life, he superintended the naval affairs of the grand signor, and pursued that voluptuous course to which he had been habituated, amidst a number of fair captives; and died at the age of eighty seven, in 1549, leaving his son Hassian in possession of the vice-royalty of Algiers, and heir to all his property. With the ferocity of a Turk and a corsair, Barbarossa polluted some generous sentiments, and obtained a character for honour and fidelity to his engagements. Mod. Un. Hist. vol. x. p. 66, &c. vol. xv. p. 14, &c. Robertson's Hist. of Charles V. vol. iii. p. 97, &c. Gen. Biog. See Algiers.

BARBAROSSA, in Entomology, a species of Scarabeus, described by Fabricius as a native of New Holland. The anterior part of the thorax is falciform; horns of the head recurved and short.

BARBARUS, in a general sense, denotes something that partakes of the quality of Barbariwm; and in this sense, the term is applied to a nation, age, writer, word, or the like, Barbarous Latin words are innumerable; the schoolmen abound with them; the chemists, physicians, and lawyers can scarcely write intelligibly without them. De-Cange has given two large volumes in folio of barbarous Latin words, and the modern or vulgar Greek is sometimes called barbarous Greek, "barbara-Greca," or "Greco-barbara lingua." Langius has published "Philologia Barbaro-Greca," "Grammatica Barbaro-Greca," or "Glossarium Barbaro-Grecom.

BARBARUS, in Entomology, a species of Papilio. (Pbld. Rar.) The wings are without tails, and bluish; beneath spotted all over with brown, and two spots behind.

Gmelin.

BARBARUS, a species of Tenorio, of a black colour, and very glossy; thorax orbiculated; anterior margin of the shield of the head elevated. This is about the middle size; wing-cases joined. Brander, &c.

BARBARUS, a species of Cryptoccephalus that inhabits Barbary. The antennae are serrated; body hairy, obscure, brassy. Found on composite flowers. Fabricius.

BARBARUS, in Ichthyology, a species of Syngnathus, found in European seas. It has neither caudal nor anal fin; body fixi-falcid. Gmelin. In the dorsal fin are about forty-three rays; and in the pectoral fin twelve rays; body olive with faint blueish transverse lines.

BARBARUS, a species of Vultur that inhabits Barbary, and some other parts of Africa. It is of a blackish brown; beneath white, inclining to brown; legs woolly; toes lead colour; claws brown. Gmelin. This is vultur barbatus, Brill. Orn. and bearded vulture of Edwards and Latham.

BARBARUS, a species of Falco, called by the English writers the Barbary falcon; the cere and legs are yellowish; body blueish, spotted with brown; breast immaculate; tail banded. Gmelin. The length of the bird is seventeen inches, and, as its name implies, it is a native of Barbary.

BARBARY, in Geography, the northern tract of Africa, is one of the three distinct parts of North Africa, according to the distribution of major Renell, and lying along the Mediterranean. See Africa.

As to the origin of the name of Barbary, we have a variety of conjectures. Some suppose, that the Romans, after they had conquered this large tract, gave it the name by way of contempt or dislike of the rude and barbarous manners of the natives. Marmol deduces it from the Arabic word "Barber," a name given by the Arabs to the ancient inhabitants, and which they retain to this day in many parts of this tract, especially along the ridge of the Great Atlas, where they are very numerous, and which was given to them by their new invaders on account of the barrenness of their country. Leo Africanus says that it was given to these people on account of their strange language, which appeared to them an inarticulate murmur, the Arabic word "barbar," signifying "a murmuring sound or noise." Others
Others derive it from “bar” twice repeated, which signifies a “defect,” which was its ancient state; accordingly, they say that the fugitive king Ifrik, from whom it is pretended the whole African continent derived its name, when closely pursued by his enemies in his flight out of Arabia Felix, and hefitating what course to pursue, was directed by some of his retinue by these words, “Bar, Bar,” that is “To the Defect, To the Defect.”

The history of the word “Barbar,” says Gibbon (Rom. Emp. vol. ix. p. 463.), may be clasped under four periods.

1. In the time of Homer, when the Greeks and Asiatics might probably use a common idiom, the imitative sound “of Bar-bar,” was applied to the wild tribes, whose pronunciation was most harsh, whose grammar was most defective. [Greek: ἑκατοστείους] (blind. ii. 867. with the Oxford Scholiast, Clarke’s Annotation, and Henry Stephens’s Greek Theaurus, tom. ii. p. 720.) 2. From the time, at least, of Herodotus, it was extended to all the nations who were strangers to the language and manners of the Greeks.

3. In the age of Plantus, the Romans submitted to the insult (Pompeius Felix, l. ii. p. 48. ed. Dacier), and freely gave themselves the name of Barbarians. They insensibly claimed an exemption for itself, and for its subject provinces, and at length removed the disgraceful appellation to the savage or hostile nations beyond the pale of the empire.

4. In every sense, it was due to the Moors; the familiar word was borrowed from the Latin provincials by the Arabians. The conquerors, and has judiciously settled as a local denomination (Barbary) along the northern coast of Africa.

Barbary is bounded on the north by the Mediterranean sea, which divides it from Europe, on the east by Egypt, on the south by Sahara, Zaara, or the Desert, and on the west by the Atlantic ocean. Its utmost extent from east to west, that is, from Cape Non, on the most western coast of Morocco, to the confines of Egypt, is almost 37 degrees, that is from 10° W. to 25° E. long., or about 2200 geographical miles. Its breadth from north to south is very unequal; in some parts it is not above 6 or 7 degrees; and where it is widest, as from Cape Non to Tangier, not above 10 degrees. Some geographers, however, have given it a much greater extent both in length and breadth, making the former 4000 miles, and the latter 1200, in order to which estimate they have included the creeks and windings, which are too precarious and unknown to be depended upon. Others have made the length from east to west to be only 1200 miles, and the breadth from north to south, which is very variable, 320 miles. It commences on the west at the famous island Atlas, called by the Arabs Ayducal, or Al Duacal, and includes the ancient kingdoms of Suez and Dela, now provinces of Morocco, and extends north-easterly along the Atlantic coast to the pillars of Hercules at Cape Finisterre, through the straits of Gibraltar, and so on by an eastern course, along the Mediterranean coast to the city of Alexandria, which is the southern boundary of Egypt, where it joins to this of Barbary. The principal kingdoms into which it is now divided, are those of Morocco, Fez, Algiers, Tunis, and Tripoli; the kingdom of Tlemcen or Trenucen having been incorporated with that of Algiers, and that of Daraa having been reduced to a dependence on that of Tripoli. (See each of these articles.) Both the coasts of Barbary, whether watered by the Atlantic ocean, or by the Mediterranean, are fertile in corn and pleasures; the former being watered by a multitude of small and large rivers which descend from the great Atlas, and empty themselves into the ocean; and the former extending along the declivity of a vast ridge of mountains, some of which are considerably high, and spread above 40 leagues into the inland, supplying a number of rivers, which after many windings through pleasant and fertile valleys, discharge themselves into the Mediterranean. Besides, the temperature of the climate contributes to its fertility. However, the coast and mountains along the Mediterranean from the straits of Gibraltar to Egypt, are rather cold than hot, and snow falls at certain times of the year; and the tops of some mountains are covered with it through the year. The winter in this country commences about the middle of October, and is often severe; the rains commonly begin about the end of the month, and continue to the end of January; in February the weather becomes milder; and in March the west and north winds begin to blow and to produce universal verdure. During the whole spring season, which begins about the latter end of February, the weather is generally serene and pleasant, except from the latter end of April to that of May, when refreshing flowers are abundant; which with the concurring heat of the sun, bring the productions of the earth to maturity; so that in the latter end of May, they begin to gather ripe figs and cherries in Tunis, Algiers, and some parts of Morocco; in the middle of July, the apples, pears, and plums are ripe, and grapes and other later fruits are completely gathered before the latter end of September. The former begins, according to their reckoning, on the 25th of May, and lasts till the 29th of August; during which the heats are excessive and dangerous; their autumn commences on the 27th of August, and ends on the 16th of November, when the heat abates; and their winter begins on the 17th of November, and ends on the 16th of February. The greatest cold begins on or about the 12th of December, and the greatest heat about the 12th of June. On mount Atlas, and the higher lands, they reckon but two seasons, namely, winter and summer; the former lasting from October to April, when great quantities of snow fall, and the latter from April to September, when the heat in the valleys is excessive.

The principal quadrupeds of the slates of Barbary are the horse, which has of late years very much degenerated, the ass and mule; the kumrah, produced between an ass and a cow, the camel, the black cattle, which are small and slender, the goat, and sheep, of which latter there are two species not known in Europe; the one the broad-tailed sheep, and the other the sheep of Sahara, as tall as our fallow-deer, and resembling them in shape. Each of these kinds of quadrupeds is very numerous and prolific. Several Arabian tribes, who can bring no more than three or 400 horses into the field, are possessed of more than so many thousand camels, and triple the number of sheep and black cattle. The Arabs seldom diminish their flocks by using them for food, but live chiefly upon bread, milk, butter, dates, or what they receive in exchange for their wool. Among the quadrupeds that are not naturally tame and domiciled, we may reckon the “bekker-el-wafi,” or wild cattle, which Dr. Shaw supposes to be the babylus of the ancients, or bos Africanus of Linnaeus; and deer, in fide between the red and fallow-deer; the fritiall or roe-deer, feeding in fere, sheep, and other circumstances, to be the tragelaphus of the ancients, or an animal befitting a goat and a deer; the gazell or antelope, of which there is a species called barass, supposed by Shaw to be the firemucos or chasses of the ancients. Among quadrupeds of a less tameable nature, we may enumerate the lion and panther; the fox or chassi of Pliny, the leifer panther, and the floucardi or spanish ginetta; the catsh or hyena; the deer or jacksil; the fiyah-gull or black-cared catt; the porcupine; the jird, and jerboa. Besides these animals, Barbary also produces the bear or dahl; the ape or shelddy; the
ichneumon or tezardes; the ferret or nimfe; and the weasel or sert-el-heile. The mole, likewise, the rabbit, the hare, and the wild boar, which is the chief prey and food of the lions, are everywhere numerous. Among the opossum quadrupeds, Dr. Shaw enumerates the land and water tortoife, the former being very palatable food, but the latter unwholesome; the warril or guardil; the dhab or daji; the zarn-noumeal; the skink or leicins; and the nelje-daimah or booka-shafr. Of the serpentine kind, besides the flow-worm and the flake, which are common, the most remarkable species are the thamboons, the zurrelke or jacubus, the lefah or dipus. These are the only species of the viper kind which Dr. Shaw discovered; and he adds, that the northern parts of Africa do not produce above five or six different species among the many that are described by Lucan and Niesnider. Among the birds, he enumerates, besides the eagle kind, the karabun, about the size of our buzzard, the red-legged crow or pihrelcorax; the cufcufy or ox bird; the boa-ook, one of the larger species of the horned-owl; the vartoun; the lappet; the houbara or houbarria; the blond or falsah; the kitawiah or African lapwing; the Barbary partridge or red-legged quail; the greater thrush; and the Lebiba-iraw. The insects of this part of Africa are more numerous than curious. The most curious species of the butterfly kind is the lappet butterfly, about four inches from one tip of the wing to the other, beautifully streaked with murrey and yellow, and having near the tail a spot of a carination colour. The rarest species of the libelle or adderbolts is one, 3/4 inches long, broad-tailed, of a rufly colour, with bright spotted wings. The least frequent of the beetle kind, is a species with one horn, of the colour and size of a chefun. In the hotter months of the summer, the cieade, i.e. the grasshopper, as we falsely translate it, is perpetually fluming the ears with its shrill and ungrateful noise, from mid-day to the middle of the afternoon. The locusts are very numerous, first appearing towards the latter end of March, and in the middle of April forming large swarms, which even darken the sun, and beginning gradually to disappear in May. Of the aecrab or scorpion there are several species. For other particulars relating to the productions, commerce, customs, &c. of the states of Barbary, see ALGIERS, MOROCCO, &c.

The coast of Barbary was probably first planted by the Egyptians. The Phcenicians afterwards sent colonies thither, and built Utica and Carthage. The Carthaginians soon became powerful and wealthy by trade; and finding the country divided into many little kingdoms and states, either subdued or made the princes on that coast their tributaries, who, being weary of their yoke, availed themselves of the opportunity of affiling the Romans in subduing Carthage. The Romans remained sovereign of the coast of Barbary, which indeed was along the whole of their possession, Egypt excepted, on the continent of Africa, until the Vandals in the fifth century reduced it under their dominion. The Roman, or rather the Grecian emperors, having some time after recovered the coast of Barbary from the Vandals, retained the dominion of it till the Saracen caliphs made an entire conquest of the north of Africa in the seventh century, and divided the country among their chiefs, of whom the sovereign of Morocco was the most considerable, possessing the north-west part of that country, which, in the Roman division, obtained the name of Mauritania Tingitana, from Tingis or Tangier the capital; and is now styled the empire of Morocco, comprehending the kingdoms or provinces of Fez and Morocco. In the eighth century, their ancestors made a conquest of the greatest part of Spain; but after the loss of Granada, about the year 1492, they were dispossessed of this country, and compelled by Ferdinand and Isabella to renounce their religion, or transport themselves to the coast of Africa. The exiles confederated with the Mahometan princes on the coast of Barbary, and fitted out little fleets of cruisers, which made depredations on Spain, brought away many of its inhabitants, and made slaves of them. The Spaniards assembled a fleet of men of war, invaded Barbary, took Oran and other places on the coast of Algiers, and were proceeding to make an entire conquest of the country. In this distress, the African princes besought the affiun of the famous Turkish rover, called Barbarossa (see the article BARBARISSA), against the Christians. When he had repulsed their enemies, he spared the government of Algiers, and treated the people who called him to their succours as slaves. His brother Hayradin pursued the same measures with regard to the people of Tunis; and a third by similar means obtained the government of Tripoli. In these usurpations they were supported by the grand signor, who claimed the sovereignty of the whole coast, and for some time they were considered as the subjects of Turkey, and governed by Turkish bailiffs and viceroy; but each of these states, or rather the military men, at length elected a sovereign out of their own body, and rendered themselves independent of the Turkish empire. The grand signor has not now so much as a bailiff or officer at Algiers; but the dey acts as an absolute prince, and is only liable to be deposed by the soldiers that advanced him.

At Tunis and Tripoli he has still bailiffs, who are some check upon the deys, and receive a small tribute. All of them, however, in case of emergency, claim the protection of the Ottoman court, and they still continue to pray upon the Spaniards, having never been at peace with them since the loss of Granada. They make prize also of all other Christian ships that have Spanish goods or passengers on board, and indeed of all others that are not at peace with them. The Turks of Algiers, Tunis, and Tripoli, are an abandoned race, confiding of pirates, banditti, and the refuge of Turkey, who have been forced to leave their several countries to avoid the punishment of their crimes. See ALGIRS, &c. and also AFRICA.

Barbary is chiefly inhabited by three sorts of people; namely, Moors, who are the original natives; the Arabs, who have overran this country; and the Turks, who have since made themselves masters of some of its seat provinces, and the several kingdoms of Tripoli, Tunis, and Algiers, though under a kind of tribute to, or dependence upon the Ottoman port. The Moors, or natives, are for the most part Mahometans; as there are few who have not been induced or compelled to embrace Mahometanism since their submission to the Turks. They are even more scrupulous observers of the Mahometan law than the Turks themselves; and as they are generally even more ignorant, they have adopted every absurdity of superstition. Among the corsairs of Barbary, no clamor, or magic spell, no expedient, though ever so wondrous, monstrous, and seemingly indiscoverable, can be invented, to which they will not have recourse, preferably to any of a more rational nature and efficacy, in fights, storms, or other emergencies attending their hazardous profession. Their condition is abject and miserable at the extreme, being crushed with a heavy load of taxes, and treated with the utmost cruelty by their inflicting masters, or exposed to the continual inroads of the plundering Arabs. Such is the state of those who live at large in the country upon their agriculture and cattle. As for those who inhabit the sea-ports along the coast, they are allowed to follow a variety of handcraft trades and manufactures, and even to carry on some commerce by land and sea. But they are no less oppressed with taxes and other exactions.
The Arabs of Barbary are like those of other parts of Africa; they follow the fame mode of living, are governed by their own despotic chieftains, and all of them, except those of the wandering kind, and such as live under the dominion of the emperors of Morocco and Fez, are in some form tributary to the Turks, ever since they have made themselves masters of the remainder of the Barbary coast. They are often obliged, by the oppression they suffer, to abandon their habitations, and to seek shelter among the most rocky and inaccessible mountains, whether the Turkish forces cannot pursue them. Such is the condition of those who live in the country, and along the ridge of mount Atlas; but there is another and more civilized class of them, who are, like the Moors, settled in some of the towns and villages, and apply themselves to agriculture, and especially to the breeding of that race of hordes to which is much esteemed, known to us by the name of barbs, for which their country has been famous all over Europe. The wild, or wandering Arabs, who range along the great Atlas and other parts of Barbary, are warlike, bold, and even desperate in all their plundering excursions; especially in their attempts on the large and rich caravans, which go from Morocco into Egypt. The Arabs of each class are addicted to the study of astronomy and astrology, to which they are disposed by their pastoral life, which affords much leisure, their clear sky, and natural superstition. The neither sow, reap, plant, travel, buy, or sell, nor undertake any expedition, without previously consulting the stars, or in other words, their almanacks, or some of the makers of them, whether they be Mahometans or idolaters.

The Turks are of all the inhabitants of Barbary the fewest in number, and in all respects the worst of all the three classes; being originally no better than a wretched crew of indigent, loose, idle, and thievish fellows, initiated in and about Constantinople, and sent from thence once in three years to recruit the garrison. They are wanton and savage in the exercise of their tyranny over both the Moors and Arabs. They make ostentatious professions of Mahometanism; but in practice they neglect and violate its precepts in the most licentious degree, and are fo notorious for the dilapidations of their manners, that they are abhorred by all true Mahometans.

The whole tract of Barbary from one end to the other is so excellently situated for navigation and commerce, so fertile of every necessary of life in its variety of soils and climates, so rich in its mines of gold, silver, and other metals and minerals, so healthy, and so populous, that it might defy the whole force of Europe or Afric to reduce it, were its inhabitants as indolent as they are ignorant and knavish, and were the several nations that inhabit it, or the several powers to which it is subjected, united in one common interest. Shaw's Travels, p. 265, &c. vol. xiv. p. 278, vol. xxxvii. p. 186, &c.

**BARBARY Point, the western point of the entrance into the river, &c. of Senegal, on the coast of Africa. N. lat. 15° 38'. W. long. 13° 30'.**

**BARBAS, Cape, lies on the coast of Africa, west from Cyprino river, and 26 leagues north from cape Blanco. N. lat. 22° 15° 30'. W. long. 16° 40'.**

**BARBASOTE, a fair port of Africa, in the kingdom of Fez, a little to the west of Ceuta.**

**BARBASTELLUS, Vespertilio, in Zoology, the tailed bat, with elevated hairy ears, and large ears, angulated on the lower part. (Linn. Syll. Nat. Gmelin, p. 48.)**

**Barbagielle of Buffon and Pennant. Its length is about two inches from nose to tail; extent about ten inches; upper part of the body dusky brown; under part ash coloured; forehead tuft; ears broad and long, lower parts of the inner sides touching each other, and thus concealing the face and head when viewed in front; nose short; cheeks full; end of the nose flattened; found in France. Shaw.**

**BARBATA, in Entomology, a species of Cantarhis that inhabits Germany. It is of a brown colour; antennae and feels pitchy. Olivier. The down on the body is changeable to a golden hue.**

**BARBATA, a species of Cicada (Dixina) of a brown colour, with greenish abdomen, and a snowy-white woolly tuft at the vent. Fabricius, Gmelin.**

**BARBATA, a species of Phalena that inhabits Barbary. The wings are greyish, with a brown spot in the middle, and an obtuse band behind. Fabricius, &c.**

**BARBATA, a species of Pimelia (Hyllops Fabr.), of a black colour; feelers advanced, and with the legs yellowish. Inhabits Saxony. Fabricius.**

**BARBATA, in Natural History, a species of Corallina, about three inches in length, that grows on the shores of Jamaica. Ellis, in his work on coralline, calls it the nodary or bead-coraline of Jamaica; it is the head-band lirring of Plunkett, and corallina major, nero cbrafian: fuchiformis tenebrifica brevisima nectente de Solano, (Brut. Jann.) This kind is specifically distinguished according to Dallas, Solander, and others, by being dichotomous, with cylindrical joints, the extreme ones bearded at the tips.**

**BARBATA, a species of Naias, about one third of an inch in length, that is found in wet places, in woods, and sometimes adhering to the helix planorbus and other fresh-water snails. The lateral bifilata are disposed in tufts, and it has no proboscis. (Mölker, Bonnet, &c.) The body is hairy beneath, and each segment furnished on both sides with divergent bifilata; eyes two, and of a Black colour; length four lines.**

**BARBATA, in Ornithology, a species of Fringilla that lives in the mountainous parts of Chili. This bird is about the size of a Canary-bird; of a pale yellow colour, with green wings, spotted with black and red; and has the chin bearded. It is said to fly delightfully, and to be capable of imitating the notes of other birds with the greatest facility. The bill is white at the base, and black at the tip; head black; chin in the young bird yellow, in a few months this changes black, and appears, when full grown, bearded; this is only in the male bird, for the female has no beard, and is of a cinnamon colour, with a few spots of yellow on the wing. Molin. Hist. Nat. Chili. Gmelin. &c.**

**BARBATA, a species of Muscicap, of an olive-brown colour above; beneath greenish yellow; crown yellow; rump yellow. A native of Cayenne; called by Buffon barbichon de Cayenne; and by Latham the whistler fly-catcher.**

The length of this bird is five inches; bill broad, de- prifed, and shorter than the whiskers. Female greenish black, yellowish beneath; breast brownish; on the crown an oblong yellow spot.**

**BARRATED LEAF, in Botany, is a leaf terminated by a bunch of small hairs.**

**BARRATELLI, Bernardo, called Pochetti, in Biography, a painter of history, fruit, animals, and flowers, was the disciple of Ridolfo Ghirlandaio at Florence; and from his school he went to Rome, where he applied with such affinity, and his mind was so engaged by the objects of his contemplation, that he neglected the necessary restraints of sleep and food. In painting the subjects, to which his attention was principally directed, he not only imitated but equalled nature. His touch was free, light, and delicate, and the colouring of his objects inexpressibly true; and besides his
his merit in his appropriate style of painting, his historical subjects, from sacred and profane authors, were much admired. He was born at Florence in 1542, and died in 1612.

Pilkington.

BARBATIA, in *Ancient Geography*, a town of Asia, towards the Tigris. It belonged to the Arabs, according to Pliny.

BARBATINA, or *Semen contro*, in the *Materia Medica*, a feed which is efficacious in extinguishing worms from the human body, to which children are chiefly subject; it comes from Persia, and the borders of Media. This feed, when good, is plump, of an agreeable scent, and very green. Special care must be taken that it be not dyed green, and that the feed of southern-wood be not sold instead of it.

BARBATISSUS, in *Ancient Geography*, a town of Asia, near the western bank of the Euphrates, on the small river Daradax, south-west of Nicephernus, about 35° 40' lat.

BARBAZO, in *Geography*, a river of Spain, which runs into the Atlantic, between Cadiz and the Straits of Gibraltar, about 9 leagues south of Cadiz.

BARBATO, or Puerto Barbato, a sea-port town of Spain, in Andalusia, on the coast of the Atlantic, near the mouth of the river Barbato.

BARBATULA, in *Ichthyology*, a species of Coelius with six cirri; head unarmed and compressed. (Linn.) This is the bearded loche of English writers; encheleopus, &c. Klein; cobicus fluvialis, Ray; fundulus, Marél. "The bearded loche is a native of Europe and Asia; and is most frequent in fresh-water streams and lakes in mountainous countries. From its habit of lurking at the bottom of the water, on the gravel, it has been called the groundling; but the latter name is given to the slippery loche, a fish distinguished from the present by having a forked spine under each eye; and is that species of cobicus which Gmelin calls tenia."

"This is a fertile creature; it spawns in the month of March and April, and grows to the length of three or four inches, but seldom larger. It feeds on aquatic insects; and, we are told by Mr. Pennant, is frequent in the stream near Almbridge in Wilthire, where the sportsmen, through frolic, swallow it down alive in a glass of wine."

"The loche is found in greater abundance in France, and other parts of Europe, than in England, and are in such high estimation for their exquisite delicacy and flavour, that they are often transported with considerable trouble from the rivers where they naturally inhabit, to waters more contiguous to the climates of the great. This is usually performed in winter, and it is necessary to keep the water in continual agitation the whole way, as the fish would otherwise die. Frederic I. king of Sweden, had them brought in this manner from Germany into his country, where they have been fine naturalized; a circumstance that leads us to conclude they were either scarce or not originally native of that country."

"In the dorsal fin of the specimen described, are nine rays, in the pectoral eleven; ventral eight; anal seven; and in the tail nineteen." — Donov. Brit. Fihes, vol. i. p. 22.

BARBATUS, in *Entomology*, a species of Cerambyx (*Prionus*), of a large size, that inhabits South America. The thorax is entire; jaws ferruginous, and very hairy; antennae of a moderate size. (Fabricius.) Antennae rough, extreme joint smooth and compressed; shell pitchy; abdomen villous white; legs black.

BARBATUS, a species of Scarabaeus; that is unarmed, smooth, and black; vent bearded. (Fabricius.) A native of India.

BARBATUS, in *Ichthyology*, a species of Goebius, with fan-shaped pectoral fins; twelve rays in the first dorsal fin, and thirteen in the second. Its native country is unknown. Gmelin.

BARBATUS, a species of Lophius, of a depressed form, with the lower jaw bearded. (Montin. adv. sect., 1779.) Inhabits the seas in the northern parts of Europe, is about three inches and a half in length, and is extremely rapacious. Perhaps not different from *Lophius Tryptolius*. Gmelin.

BARBATUS, in *Ornithology*, a species of Falclo, of a whitish red colour, with the back brown; and a black stripe above and beneath the eyes. Gmelin, &c. *Vultur barbatius Linn. Vulturne ang. Albin."

"Of this bird there is a variety of a russet colour, with the back black; and neck above russet white; quill and tail feathers brown. *Vultur anatus Buff.* *Vultur varius Ray. Golden vulture. Willughby and Latham. A third variety occurs, *Falco magnus* Gmel. It. in which the cere is bluish; legs and body beneath cinnamon, intermixed with white; tail cinereous."

The first kind inhabits the Alps; the latter the mountainous places of Persia. It is larger than the golden eagle, measuring rather more than four feet in length; is very daring, flies in flocks, and will attack men as well as animals.

BARBE, or BARE, in *Zoology* and *Commerce*, a kind of horse brought from Barbary, much esteemed for its beauty, vigour, and swiftness. Barbs have a long fine neck, not overcharged with hair, and well divided from the withers; the head is small and beautiful; the ears are handsome and properly placed; the shoulders are light and flat; the withers are thin and well raised; the back is straight and short; the flank and sides are round, and the belly not too large; the haunch bones are properly conjoined; the crupper is somewhat long, and the tail placed rather high; the thigh is well formed, and rarely flat; the limbs are fine, handsome, and not hairy; the tendon is prominent, and the foot well made; but the pattern is often long. They are of all colours, but generally greyish. In their movements they are apt to be careless, and require to be checked. They are swift, nervous, light, and make very fine hunters. These horses appear to be the most proper for improving the breed. The flavor, however, is not so large as could be wished. They are seldom above four feet eight inches, and never exceed four feet nine inches, or 14 hands. It is confirmed by repeated experience, that in France, England, &c. they produce foals which grow larger than their parents. Of the Barbary horses, those of the kingdom of Morocco are said to be the best, and next to these are the Barbs from the mountains. The horses of Mauritania are of an inferior quality, as well as those of Turkey, Persia, and Armenia. Buffon's Nat. Hift. vol. iii. p. 357. It is a maxim, that barbs grow ripe, but never grow old, because they retain their vigour to the last, which makes them prized for falcons: their mettle, according to the duke of Newcastle, never ceases but with their lives. It is said, they were anciently wild, and ran at large in the deserts of Arabia; and that it was in the time of the qibh Ithmael, that they first began to tame them. It is also affirmed, that there are barbs in Africa that will outrun ostriches; such have been ordinarily fold, according to Dapper, for 1000 ducats, or 100 camels. They are fed very sparingly, and, as Dapper says, with camel's milk. It is added, that in Barbary they preserve the genealogy of their Barbs with as much care as the Europeans do that of their noble families; and that in the
the tale of them, they always produce their titles of nobility. The race of horses is much degenerated in Numidia; the Arabs having been discouraged from maintaining it by the Turkish officers, who are sure to become masters of them. The Tingitanians and Egyptians have had the reputation of preferring the best breed both for size and beauty. Some of these are sixteen hands high, and all of them shap'd, according to their phrase, like the antelope. The good qualities of a Barbary horse, besides the suppos'd one of never lying down, and of standing firm when the rider drops his bridle, are to have a long walk, and to flop short, if required, in a full career. The Barb is very lazy and negligent in all his motions; he will stumble in walking upon the smoothest ground; his trot is like that of a cow, and his gallop very low and very easy to himself. This sort of horse, however, is for the most part snow-wary, nervous, and excellently winded; it is therefore good for a course, if not overweighted. The mountain barbs, which are the largest and strongest, are much esteemed; they belong to the Albarbes, who value themselves much upon them, and are as fond of them as other nations are, so that they are not easily procured. The common barbs have been usually bought in Provence and Languedoc in France, at a moderate price; and many of our people of fashion in England have them from thence. Barbs, amongst us, fall short of the swiftness attributed to them in their native country: this may be accounted for, partly from the smallness and lightness of their riders, and partly from their not being loaded with heavy saddles and bridles, as in Europe, nor even with shoes. An Arab saddle is only a cloth girt round with a pair of light stirrups, and a sort of hummel to fasten them.

Bagard-Barbs, those defending from the English mares, covered by barb Itallions, are, by experience, constantly found both better shaped and fitter for the saddle, and stronger for service than their fires. Phil. Trans. No. 105.

Barb, St. in Geography, a town of Mexico, in New Biscay, in the vicinity of which are very rich silver mines; distant 500 miles N. W. from the city of Mexico. N. lat. 26° 10'. W. long. 110° 5'.

Barb, St. Islands of; lie off the mouth of Green bay, and to the east of Cape Den, or the fourth point of White bay in the Harchigonis river; on the east coast of Newfoundland, and to the north of Cape Bonavista.

Barb or Barb, in the Military art.—To fire en Barb is to fire on the cannon over the parapet, instead of through the embrasures; in which case the parapet must not be more than three feet and a half high.

Barbe, or Barbe, is also an old term for the armament of the horses of the ancient knights and soldiers, who were accoutred at all points.

Della Croce says, the bars are an armament of iron or leather, wherever the neck, breast, and shoulders of the horse are covered.

Barbeau, in Geography, a river of Canada, which runs into the Ulwas. N. lat. 45° 15'. W. long. 76° 20'.

Barbed, in Heraldry. The five petals or leaves which appear on the outside of a full blown rose are called barbs, and are emblazoned thus: a rose gules barbed and seceded proper, the rose is red, the barbs green, and the feds yellow or grey.

Barbed Arrow, signifies an arrow whose head is pointed of an angular form, and jagged. See Plate of Heraldry.

Barbed Horse is a horse barbed at all points, that is, a war-horse completely armed, furnished, and accoutred.

Barbed and Crested, a term used in blazoning to express the comb and gills of a cock. The usual term in the English blazon is combed and wattled. Barbeau, or Barbed Cross, is by some called croc cranponnee and tourneste. See Plate of Heraldry.

Barbel, in Ichthyology. See Cyprinus Barbus.

Barbella, or Barbella, in Geography, a river of Africa, in Congo, which joins the Zaire near its mouth.

Barbelicote, in Ecclesiastical History, an ancient seat of Gnomes, ipoque of by Theodoret. The doctrine of the Barbelicote was, that one of the zones, possefl'd of immortality, had commerce with a virgin spirit named Barbelo, who demanded of him, first, precedence, then incorruptibility, and lastly external life, all which were granted to him, with the condition that being one day in a gayer humour than ordinary, the conceived, and afterwards brought forth light, which being perfected by the union of the spirit, was called Christ; the child Christ desired to have understanding, and obtained it; after which, understanding, reason, incorruptibility, and Christ, united together; and from their union arose autogenes, autogeny. To these fables they add divers others. They were also denominated Barbarians.

Barbella, Emanuel, of Naples. It would be unjust not to bellow a few words on this pleasing and peculiar player on the violin of the old school. The father of this singular but worthy and inoffensive character, was an eminent performer on the violin, and leader of the opera band at Naples in the beginning of the last century, during the life of Corelli, when his scholar Geminiani arrived in that city from Rome. (See Corelli, and Geminiani.) On the first hearing of the younger Barbella, he surprised no one who had heard Giardini and other famous violinists of the new schools. He was not young, indeed, when the parallel was drawn, and solo playing was disregarded at Naples, where vocal composition and singing were chiefly cultivated in the conservatories, and patronised by the public, to that teaching and orchestra playing were Barbella's chief employment and support; and for the latter he was ill-qualified by the softness of his tone, and the shortness of his bow. He performed, however, most admirably the famous Neapolitan air, which the common people constantly play at Christmas to the violin. Barbella executed it, with a drone kind of bagpipe balls, in a very humorous though delicate manner. But as a solo player, though his tone was very even and sweet, it was somewhat languid and inferior in force to that of Nevidini of the same school, and indeed to that of several others then in Italy; but he knew music well, had much fancy in his compositions, with a tunefulness of not disfigureable madness.

He was most remarkable for his sweet and inimitating manner of playing Cembali, Locke, and Neapolitan airs, and among the rest a humorous piece composed by himself, which he calls Tuna Nonsi; it is a nursery tune, or Lullaby, excellent in its way, and with his expression, was extremely captivating.

Barbella was the most obliging and best-natured of mortals; his temper has been said to be as soft and sweet as the tone of his violin.

In a correspondence with the author of this article, who had reques'ted of him an account of the Neapolitan school of music, and above all, of his own studies; as his answer concerning himself was short and characteristic, we shall here infect a translation of it.

"Emanuele Barbella had the violin placed in his hand when he was only six years and a half old, by his father Francesco Barbella. After his father's decease he took lessons of Angelo Zaga, till the arrival of Pasquillo Bini, a scholar
BARBERINO, Francis DA, an Italian poet, was born in 1266 at Barberino, a castle of Valdelsa, and educated for the profession of the civil and canon law at Padua and Bologna. Upon his removal to Florence in 1294, he served two bishops in the way of his profession, and made frequent journeys to the papal court at Avignon. He was honoured with the degree of doctor of laws by Clement V; and attended the general council at Vienna in 1311. Amidst his professional pursuits, he cultivated poetry, and published a work, intitled, "Documenti d'Amore," which treats of moral philosophy, and consists of twelve parts, each of which has for its subject some virtue and its rewards. His style is not distinguished by ease or elegance, but favours too much of Provençal poetry; and yet the author has been reckoned among the good writers and founders of the language. This poem was first printed at Rome in 1692, adorned with fine figures. Another work, in verse, on the Manners of Women, is preferred in MS. in the Vatican. Barberino died of the plague at Florence in the year 1348. Gen. Dict. Nov. Dict. Hillor.

BARBERINO, in Geography, a town of Italy, in the duchy of Tuscany, seated on a mountain, 16 miles south of Florence.

BARBERINO is also a town of Italy, in the duchy of Tuscany, situated at the foot of the Apennines, on the side of the river Sieve, four miles west of Scarperia. N. lat. 43° 40'. E. long. 12° 15'.

BARBEROLLA, or Blanc, Cape, lies on the coast of Asia, in N. lat. 58° 9', and E. long. 25° 27'.

BABBRI, in Botany and the Materia Medica. See Barberis.

BARBESIEX, in Geography, a town of France, and principal place of a district in the department of the Chaunain. It has a manufacture of linen cloth, and near it is a medical spring. N. lat. 45° 28'. W. long. 6° 15'.

BARBESOLA, or Barbela, in Ancient Geography, a river of Spain, in the country of the Baitoli. Ptolemy and Pliny.

BARBESOLA, Barbelsul, or Barbeulf, a town of Spain, in the country of the Balluli, situated on the strait between Cartia and Tranducta. Ptolemy, Pliny, and Mela.

BARDET, in Ornithology, the English name of a genus of birds in Latham's Synopse, corresponding with that of buco, Linn. See Bucco.

BARDETICUM JUGUM, in Ancient Geography, a promontory of Spain, in Baetica.

BARBETS, in Geography, the name of the inhabitants of several valleys in Piedmont, particularly those of Lucern, Angrona, Pernia, and St. Martin.

BARBEYRAC, Charles, in Biography, an eminent physician of France during the seventeenth century, was the son of a gentleman of Ceretel in Provence. He studied physic at Aix and Montpellier, and in 1649 took his doctor's degree in the University of the latter place, where he settled; and in 1658, became a candidate for the medical professorship, but on account of his being a protestant, he was ineligible. In the disputations on this occasion he acquired great reputation, and his advice was sought in difficult cases by persons both in his native country and also in foreign kingdoms. He declined the office of being physician to Madame dönem d'Ouroe, preferring liberty to the shackles of court; and at Montpellier, where he resided, he was attended in his visits by many students to whom he gave clinical instructions. His practice was distinguished by its simplicity,
simplicity and energy; and he introduced many valuable reforms into the state of medicine in that country. He was no less eminent for his benevolence and liberality than for his medical reputation, and he also visited the poor and the rich. The celebrated Mr. Locke was particularly acquainted with him at Montpellier, and testified to his honour, that he never knew two men more similar in their manners and opinions than Barbeyrac and his friend Sydenham. After an uninterrupted course of practice for 50 years, he died of a fever in 1699, in his 70th year, leaving a son of his own profession, and two daughters. The only works he published were " Traites nouveaux de Medicine, contenant les Maladies de la Peau et des Femmes, et quelque autres Maladies felon les nouvelles Opinions," 12mo. 1654; and " Questions Medice duodecim," 4to. 1658. A work, intitled, " Medicamentorum Constitution, &c." published in 1751, is ascribed to him upon uncertain authority, according to the editor M. Farjon. Halli. Bibl. Med. Prat. Gen. Biog.

Barbeyrac, John, the nephew of the preceding, was born in 1674 at Batz, whence he withdrew to Lau- sanne in 1695. His father designed him for the profession of theology, but his own inclination led him to the study of jurisprudence; and he became eminent in that particular branch of it which comprehends the law of nature and nations. After teaching the Belles Lettres in the French college at Berlin, he was appointed in 1710 to the new professorship of law and history founded at Lausanne by the magistrates of Berne, which he occupied seven years. In 1717 he was removed to the chair of law at Groningen, and this station he long occupied with great applause. His works are numerous and valuable. His French translation of Puffendorf’s " Law of Nature and Nations," and his treatises " On the Duties of a Man and a Citizen," and " Grotius on the Rights of War and Peace," were enriched with learned prefaces and notes, which enhanced the value of the originals. He also translated two discourses of Noudt, " On the Power of the Sovereign," and " On Liberty of Conscience," a treatise of Bykerhoek " On the civil and criminal Powers of Ambassadors; some of " Titlant's" Sermons;" and Cumberland's Latin treatise " On Natural Laws." Barbeyrac was also the author of several original works. But that which excited the greatest attention was his "Treatise on the Morality of the Fathers," 4to. 1728, in reply to the Benedicite Cellier’s " Apology for the Fathers," occasioned by Barbeyrac’s free critiques on them in his preface to the translation of Puffendorf. His " Treatise on Gaming," in two volumes, 8vo, was printed in 1709; his " Defence of the Rights of the Dutch East India Company against the Pretensions of the People of the Auroraum Netherlands," in 1725; and "The History of ancient Treaties differed in Greek and Latin authors to the time of Charlemagne," fol. in 1739. He also inflicted literary and critical remarks in different journals, and published some academical discourses. He closed a life of learned labour and moral worth about the year 1747. Nouv. Dict. Histo.

Barbi, in Natural History, a species of Echinornithus, of an ovate shape, yellow colour, faciated; neck long, white, cylindrical; and cyathiform (glass or pot- sherd) at the end, found in the intestina of the barbel. BARBICAN. See BARBACAN.

Barbican, in Ornithology, the name of the Gymelinian barco dubius, or doubtful barbel, in Buffon’s Hist. Birds. Barbica is also a name given by that writer to all the birds of the barco genus, which he describes.

BARBICANAGE, BARBICANAGIUM, in our Old Write-

 vet., money given for the maintenance of a barbicem, or watch-tower; or a tribute towards repairing or building a bulwark.

BARBICON (Barbicem de Cayenne), in Ornithology, the name of the Musiciapa barbata of Gmelin, in Buffon’s Hist. Birds.

BARCORNIS, in Entomology, a species of Brachyomma, which inhabits New Zealand. It is cylindrical, with the beak very long and bearded beneath; wing-cases elongated and variegated. Gmelin. This is Curculio barbicornis of Fabricius Spc. in 1777.

BARCORNIS, A species of Cerambyx, with the thorax spinous; four faint joints of the antennae bearded with black; body testaceous, variegated with black. Linn. A native of Asia.

BARCORNIS, a species of Cerice (Redivius) that inhabits Sierra Leone. This is of a Black colour, with the thorax and base of the abdomen olive. Fabricius. Obs. The thorax is sometimes, though rarely, black, and the antennae in one sex be barded.

BARCORNIS, a species of Tipula, of a black colour; antennae plumose, and simple at the tip. Inhabits Europe. This is a small species. Gmelin.

BARMER D’AUCOUR, John, in Biography, a coun-
tellor, and man of letters, was born of mean parentage, in 1641, at Langres, and educated at Dijon. On his removal to Paris, he was entered at the bar, and became a counsel-
tor of the parliament of Paris. He distinguished himself by the excellence of his "facultas" or written pleas; but being obliged, either through want of presence of mind or failure of memory, to flop at his first public pleading, he renounced the practice of his profession. In 1677 the minister Colbert appointed him preceptor to his eldest son, and in 1685, the latter was elected into the French Academy. Colbert conferred on him some lucrative employments: but, on his death, he was under a necessity of returning to the bar, and gained great reputation by the defence of Le Brun, the domine of a lady of Paris, who had been falsely accused of murder ing his mistress. He was soon after carried off by an inflammation of the lungs in 1694. His circumstances were so reduced, that when he was visited, in his last illness, by a deputation from the academy, which expressed concern at finding him so ill lodged, he replied, "It is my consolation, and a very great one it is, that I leave no heir to my wretchedness." When the abbe Choisi, who was one of them, said, "You leave a name that will never die;" "Ah! (replied D’Aucour) I do not flatter myself in that respect; if my works have any intrinsic value, I have been wrong in the choice of my subjects; I have employed myself in criterion, which has no long duration; for if the work that is criticized, should fall into contempt, the criticism falls with it, since it is immediately perceived to be useless: but if, in spite of the criticism, the book maintains its ground, the criticism is equally forgotten, because it is thought to be unjust." Barbier was in early life embroiled with the Jesuits, who by way of contempt called him "Sacer," in conformance of his having inadvertently used that word instead of "Sacer," in his reply to one of them. Referring this offence, he made the society and its writers the objects of his attacks; and he gained great credit as an ingenious writer by a work, intitled, "Sentimens de Claude fur les Entomologie," published d’Aucour par le Pere Bouhours, Jesu- ite, 12mo. vol. 2. 1674. This work has been often cited as a model of refined criticism, equally just and witty; and Bouhours could not support himself against it. Some other pieces of this author against the Jesuits, abounding with coarsc allay, did him no honour. In his 4 I two
two lalires, written in verse against Racine, he was unsuccessful. Besides his "acta mens" for Le Brun, he published some others. Nov. Dict. Hillor.

Barbier, Mary Anne, was a native of Orleans, and ranked among the dramatic writers of France. Her tragedies, and a comedy in verse, were reprinted at Paris, and printed in one volume, 12mo. The subjects are well chosen, but the characters, and those of the men especially, are without force, and the style is diffuse and profaic. Mad. Barbier was intimate with the abbé Pellegrini, who is said to have befrowned, at least, correction on her works. She died in an advanced age at Paris, about the year 1745. Nov. Dict. Hillor.

Barbier, Michel, first appeared as a new English singer, on the revival of the opera of Almahide in 1711, while questions were asked in Italian, and answered in English, and a contu. Her timidity on first appearing on the stage, gave birth to an admirable Speculator (No. 131), in which Mr. Addison apologizes for, and commends, diffidence and modestly with a sympathetic zeal and amiability. It is well known, that this excellent writer, with all his learning and abilities, was never able to perform his part in public as a speaker, when he was feeretly of fate; and in parliament, long after this paper was written: and here, by a kind of preconception, he estimates his fault before it was committed. With respect to Mrs. Barbier's diffidence on her first facing an audience on the stage, Mr. Addison has put it in the most amiable light possible: "this sudden defection of oneself," says he, "flames a diffidence, which is not displeasing; it implies at the same time the great-est respect to an audience that can be: it is a sort of mute eloquence, which pleads for their favour much better than words can do; and we find their generosity naturally moved to support those who are in so much perplexity to entertain them. I was extremely pleased," continues he, "with a late instance of this kind at the opera of Almahide, in the encouragement given to a young singer, whose more than ordinary concern on her first appearance, recommended her no less than her agreeable voice and just performance." This lady was a native of England, who continued to sing at the opera several years, and afterwards was a favourite concert and play-house singer, till the year 1729.

In the year 1717, it seems as if she had a little vanquished her bashfulness in private, however it may have incommended her in public; for she had much deficient courage sufficient to elope from her father's house with a person that was supposed to be of a different sex. During her absence, Mr. Hughes wrote the following pleasant verses:

"O yes!—hear all ye beaux and wits,
Musicians, poets, 'quiries, and cits!
All, who in town or country dwell,
Say, can you tarde or tidings tell
Of Tortorella's latory flight?
Why in new groves the lady delight;
And if in concert, or alone,
The cooing murmurer makes her moan?
Now learn the marks by which you may
Trace out and stop the lovely fray.
Some wit, more folly, and no care,
Thoughtless her conduct, free her air;
Gay, fearless, sober, indiscern,
In whom all contradictions meet.
Civil, affronting, levity, easy,
Form'd both to charm you and displease you;
Much want of judgment, none of pride,
Modest her charms, her hoop full wide;
Brown skin, her eyes of fable hue,
Angel when pleased, when vexed a thorn.

Genteel her motion when she walks,
Sweetly she sings, and loudly talks;
Knows all the world, and its affairs,
Who goes to court, to plays, to prayers,
Who keeps, who marries, fails, or thrives,
Lead honest or dishonest lives;
What money match'd each youth or maid,
And who was at each masquerade;
Of all fine things in this fine town,
She's only to herself unknown.

By this description, if you meet her,
With lowly bows and homage greet her,
If you bring the elegant beauty
Back to her mother and her duty,
Ask for reward a lover's bliss,
And, if she'll let you, take a kiss;
Or more, if you with and may
Try if at church the words she'll say,
Then make her, if you can—obey.

Barbieri, Giovanni Francesco, called Guercino Da Cento, an eminent historical painter, was born at Cento, a village near Bologna, in 1590; and was at first the disciple of Batistello Carracci, but afterwards studied for some time in the school of the Caracci. He preferred the style of Caravaggio to that of Guido or Albano, and conceived it impossible to imitate nature truly, without the assistance of strong lights and shadows; and on this principle, his light was admitted into his painting room from above. By this opposition of his strong lights and shadows he unquestionably gave such force to his pictures, that few, those of Caravaggio excepted, equal them in their effect. His principal attention was employed in acquiring perfection of colouring, from a persuasion that few persons are qualified to discern the elevation of thought which constitutes the excellence of a composition, or are perhaps capable of examining even the correctives of any part of a painting; whereas every eye, and even every imperfect judge of a picture, may be febly affected by the form and beauty of the colouring. His taste of design was natural, easy, and often grand, but without any extraordinary share of elevation, correctness, or elegance. The airs of his heads are often deficient of dignity, and his local colours of truth: nevertheless his colours possess great union and harmony, although his carnations are not very fresh; and in all his works there is a powerful and expressive imitation of life, which will for ever render them eligible. Towards the decline of life, observing that the clearer and brighter style of Guido and Albano had attracted the admiration of all Europe, he altered his manner even against his judgement. But he apologized for this conduct by declaring that he had formerly painted for fame, and with a view of pleasing the judicious; but he now painted to please the ignorant, and to enrich himself. The most capital performance of Guercino is the history of St. Petronilla, which is considered as one of the ornaments of St. Peter at Rome. He died in 1666. Pilkington.

Barbieri, Paolo Antonio, Da Cento, the father of the preceding artist, was born at Cento in 1596, and selected for his subjects fruits, flowers, insects, and animals, which he painted after nature with a lively tint of colours, with great tenderness of pencil, and a strong character of truth and life. Pilkington.

Baring is sometimes used in Ancient Statutes for shearing. Cloth is not to be exported till it be barbed, rowed, and thorn. 3 Hen. VII. c. 11.
BARBIROSTRIS, in Entomology, a species of Curculio, found in China and some other parts of Asia. It is black; snout bearded; anterior legs tridentated. Fabricius. Donov. Inf. China, &c.

BARBITANI MONTES, in Ancient Geography, mountains of India, on this side the Ganges, in which, according to Ammianus Marcellinus, are the springs of many rivers that flow into the Indies.

BARBITON, an ancient musical instrument, of which nothing is known but the name; and Roufeau has not even ventured to give us that. Complaints are frequently made of the darkness in which critics, commentators, and historians leave the subject of ancient music; which none have more cause to lament than those who have spent the most time and labour in its investigation. But as no record or memorial has been found, which ascertains the invention, form, or species of instrument called the barbiton, would more conjecture satisfy the complainants? Meffrs. Francky and Cadilhon, more courageous than the citizen of Geneva, have told us, in the new Encyclopaedia, all that is pretended to be known about it; though the former begins by telling us that it is an instrument about which nothing is known. The ancients and moderns have frequently confounded it with the lyre. Ducis conjectured that it was a strung instrument; and deriving its name from barytron, which implies thick strings of flaxen thread, he concludes that it was an instrument with thick strings. It is certain that flax was in use for strings to musical instruments, before the art was known of making them of the bowels of animals. Horace calls this instrument Lestian, Lestivum barbiton, ode i. lib. 1, and 32 of the same book, Lestivum primum modulare cives. "Thou, O barbarion, first touched by a citizen of Lesbos," meaning Alceus, to whom he ascribes the invention. But, says M. Caffilhon, we may conclude from what Mufonius affirms of this instrument, in his treatise "De Luxu Graecorum," that they made a kind of concert with the pella of the Lydians. (See Pectis.) He affirms that Terpander was the inventor of it. Julius Pollox also calls it barbiton barytron. Athenæus relates that they likewise called it barzis, and attributes the invention to Anacreon. We hope the grumblers will be perfectly enlightened by this clear, confident, and satisfactory account.

BARLE, or Barel, in Ichthyology. See Barbus.

Barbels, in the Manège, knots of superfluous flesh growing in the channels of a horse’s mouth; that is, in the intervals which separate the bars; and obstruct his eating. These are also called barbes; and obtain in black cattle as well as horses.

For the cure, they caft the beast, take out his tongue, and clip off the barbles with a pair of scissors, or cut them with a sharp knife; others chose to burn them off with a hot iron.

BARBONI, in Ichthyology, a name formerly given by many to the Mullus Barbatus; which see.

BARBONNE, in Geography, a town of France, in the department of the Marne, and chief place of a canton in the district of Sezanne, 1/4 league south from Sezanne.

BARBORA, an island of Africa, opposite to the kingdom of Adel, so called after a town of the same name upon the neighbouring continent. This island, which is almost contiguous to the Terra Firma, is very fertile, and produces plenty of corn, fruits, and cattle. The inhabitants are negroes clothed in the fashion of the natives of Adel, industrious in trade, and great breeders of cattle, for which the soil affords excellent pasturage. The produce of this island is exported into other countries. The city of Barbora lies at the bottom of a convenient bay; and was for a long time a kind of rival in commerce with Zela, and no less the place of resort for foreign merchants. It is situated near against the city of Adel, and made once a considerable figure, but was plundered and burnt by the Portuguese fleet in the year 1518; but the inhabitants, being previously apprized of their design, conveyed themselves and their most valuable effects away.

BARBOSA, ARIAS, or AVRES, in Biography, a native of Aveiro in Portugal, and one of the restorers of classical literature in his own country and in Spain. Having commenced his education at Salamanca under many disadvantages, he pursued his studies, particularly that of Greek, which he cultivated with great ardour, at Florence, under Angelo Politiano. After his return to Salamanca in 1494, he taught there for 20 years, in connection with Antony de Lebrix, who, with Andrew de Refanda, was also one of the principal promoters of useful learning in Spain. Barbosa directed special attention to poetry, and published a small volume of Latin poems, which were commended for the harmonious structure of the verses. He was afterwards employed for seven years as preceptor to the two princes of Portugal, Alphonso and Henry; and then retired to domestic life, in which he died at an advanced age in 1540. Besides the poems above mentioned, Barbosa published several works, which contributed at the time to the progress of literature; and are now forgotten; such as, "Commentaries on the poem of Arator," "Quoddamtes Quaestionum," "De Prophodia," &c. Moren. Nouv. Dic. Hif. Tor.

BARBOSA, Peter, a celebrated lawyer, was born at Viana, in Portugal, and became first professor in the university of Coimbra. Although he occupied several important situations, and was appointed by Philip II. of Spain, when he became master of Portugal, one of the four counsellors of the council of state, and afterwards chancellor of the kingdom, he prosecuted his professional studies; and, in 1595, he published an ample commentary on the article in the "Digests," on the recovery of dowry after the dissolution of marriage. In 1613, the works left by him in MS., which were commentaries on the "Digests," art. "On Judgments," were published by his nephew, and so well received, as to be reprinted at Frankfort in 1715. Other pedilous treatises were published at Lyons in 1652. Moreri. Nouv. Dic. Hif. Tor.

BARBOSA, Emanuel, an eminent Portuguese lawyer, was born at Guimarães, and was king’s counsellor for the province of Alentejo. In 1618, he published a treatise relative to contracts, law wills, and crimes, according to the Spanish and Portuguese law. In 1638, he published a work, "De Poteitate Episcopi," and in that year he died, aged near ninety years. Moreri. Nouv. Dic. Hif.

BARBOSA, Augustin, son of the preceding, studied civil and canon law under his father, and afterwards at Rome, with inceffant affility, searching libraries in the day, and composing in the night. It is related of him, that he received a serap of manuscript wrapping some fait fish, which he purchased, and that he refused the remainder from a similar life; and thus formed the work "De Officio Episcopi," which he corrected and published in his own name. A prejudice was thus conceived against him, and several of his treatises on the canon law were ascribed to his father. He was, however, a very judicious man; and on his return to Spain in 1652, he pursued the same kind of life which he had passed at Rome. His skull in ecclesiastical caufeas occasioned his promotion, in 1648, to the bishopric of Ugen-
BAR

to, in the territory of Otranto. Having been consecrated at Rome in the following year, he returned to Ugento with a view of performing the duties of his office, but died there within a few months. His works were numerous, and were printed at Lyons in 1716 and the following year, in 16 volumes folio. Moreri. Nouv. Dict. Hist.

BARBOSTHENEUS, in *Antiquitates*, a mountain of Greece in the Peloponnesus, 10 miles from Lacedaemon. Livy.

BARBOT, Penn.; BARBOTA, Rond.; in *Ichthyology*, synonymous names of the species of *Gadus* called *Lota* by Linnaeus.

BARBOTES Rocks, in *Geography*, are two rocks which are about half a league N.N.W. from the Calmardiers, and appear every tide.

BARBOUTINE, a feed otherwise called *femina fantonica*, and *femina contra vermes*, in English zoological.

BARBOUL POINT, lies within the south-west point of the bay of Cancale, to the east of St. Maloes, on the coast of France.

BARBOUR, or BARBER, John, in *Biography*, an eminent divine, historian, and poet, was born in the city of Aberdeen, as some say, about the year 1350, but according to others, in 1326. Having received a learned education, he entered into holy orders, and was promoted by king David II. to the archdeaconry of Aberdeen, A.D. 1356. Such was his love of learning, that he continued to prosecute his studies after his promotion; and with this view he prevailed on his own sovereign, David Bruce, with whom he was in great favour, to obtain permission from Edward III. to study at Oxford. The grant for this purpose was dated at Wettminister, Aug. 13th, A.D. 1357. He was also appointed by the bishop of Aberdeen, one of the commissioners for the ransom of David II. king of Scotland; and he obtained permission from Edward III. A.D. 1356, to travel through England to St. Dennis, near Paris, with six horsemen as his attendants. Barbou was not only famous for his extensive knowledge in the philosophy and divinity of those times, but still more admired on account of his admirable genius for English poetry; in which he composed, as he tells us, in 1775, a history of the life and glorious actions of Robert Bruce, king of Scotland, at the desire of king David Bruce, his son, who granted him a considerable pension for his encouragement, which he generously bestowed on an hospital at Aberdeen. This work is not only remarkable for a copious circumstantial detail of the exploits of that illustrious prince, and his brave companions in arms, Randolph earl of Moray, and the lord James Douglas, but also for the beauty of its style, which is not inferior to that of his contemporaneous Chaucer. This poem passed through about twenty editions in Scotland since the year 1616, in which the first edition, that can be discovered, was printed at Edinburgh, in 12 mo. But these editions were all modernized. An edition of this most ancient production of the Scottih muse extant, in the language and orthography of its author, from a MS. written in 1489, and preferred in the advocates' library at Edinburgh, was printed by Mr. Pinkerton, under the title of "The Bruce," with notes and a gl. title, in 1793, in 3 vols. 12 mo. The following verses, distinguished by their softness, afford a specimen of the author's talent at rural description, and also of the state of the English language in his time.

"This was in midst of month of May,
When birds did sing on alis sray;
Melland their notes, with femy found,
For softness of the sweet seazoun."
It extends in length from west to east from about the 30th degree of longitude to the 46th degree, and in breadth from north to south about 30 leagues, though its confines on the north side are very imperfectly ascertained. It is, in general, a dry and barren land, where the Arabs have called it "Sahara," or "Ceyrart Barka," that is the "Defert," or "Road of Whirlwinds and Hurricanes." Water is scarce and, except in the neighbourhood of its towns and villages, if they may be so called, where the ground produces some grain, such as corn, millet, and rice, it is quite denuded and uncultivated. The articles which the poor inhabitants produce they are obliged to exchange with their neighbours for dates, figs, and camels. This country forms part of the ancient Cyrenaica and Marmarica (see Cyrenaica, and Marmarica): in the most desert and dangerous district of it stood the temple of Jupiter Ammon (see Ammon). This spot, though in some respects pleasantly situated, is surrounded by quick and burning lands, which are very pernicious to travellers, and sometimes overwhelm whole caravans. Against this temple Cambyses and an army of 50,000 men, marched from Tybus in Upper Egypt; but their fate is uncertain, as they never returned either to Egypt or to their own country. (See Ammon.)

This country is indeed so defert, that there is no travelling through it without the aid of a compass, or the direction of the stars; and though it was once the thoroughfare for caravans from Barbary and Morocco to Mecca, yet it has been infested with wild Arabs to such a degree, that they are obliged to keep 50 leagues about to avoid being plundered. The French geographers divide the country of Barca into two parts; one called the kingdom, and the other the defert; the former hath, according to their statement, some considerable ports, towns, and villages, and is under the protection of the Porte, governed by a chief, who is the khaila of Cairo, and resides at Tripoli; but for this they have no sufficient authority. According to Sanfon and Baudrand, the other part, which extends along the eastern coast, called by them the eastern shore of Tripoli, reaches from the port of Solomon or Solymat, to the gulf of Syeda; but this coast is commonly distinguished by the name of Derna, one of the most considerable of its towns and ports; besides which it has several others, and the ruins of many more, which are now reduced to poor villages. The most remarkable is the cape Racalmone, called Portolone; and it is supposed that the island of Candia, which forms a peninsula, and the farther land towards Egypt is the town of Angela or Ouniula. (See Angela.) Between these two, are many others differently placed and named, as the Porto Tabarca, formerly Batraci, Batrach, and Patrach, cape de Lucou or Loco, anciently Promontorium Caryaionium, Porto Melusin, the haven of Salone or Salona, supposed by some to be the ancient Potos Pancronus, and Galium, and by others the Portus Catabathmus, which our latest geographers place on the most easterly verge of the Boccan coast, next to the confines of Egypt. To which may be added the large valley of Carto captive, the ancient Catabathmus, extending quite to Egypt, opposite to the spot where the temple of Jupiter Ammon stood. From these we proceed to Porto Albertene, or the Sultan's port; that of Cagnari, formerly Trifachi; the cape and haven of Raxa, anciently Parthomnum; and, lastly, the city of Barca or Barce, which gives name to the whole province, and lies farther inland, on the easterly coast of the gulf of Sydra. This was the capital of the Bocchi, and is mentioned by Strabo, Pliny, Scylax, and Ptolemy; and is said by the two former to have occupied the spot on which Ptolomais was afterwards built; but the latter are of a different opinion.
tion. It seems to have flood to the west of Cyrene, and had a port near the Greater Syrtis. As it was a maritime city, it is most probable that it flood by the port of the Barcæi, and not where Barcas flood; more especially as that capital was too fladia from the sea, according to Scylax. Herodotus says, that Barca was built by the brothers of Archedius II., king of Cyrene, more than a generation before the beginning of the reign of Cyrus; but it is more probable, that it was Phoenician, if not of Egyptian or Libyan extraction; for Barca was a Phoenician name, well known in those parts of Africa, as we learn from Silius Italicus, and others. Servius intimates, that its citizens came originally from Carthage, which would lead us to conclude, that Barca, Dido's brother, who attended her into Africa, with some of his countrymen, settled here. It sufficiently appears from Virgil and Silius, that the Barcæi spread themselves over several considerable parts of Libya; and, according to Servius, their metropolis made the greatest figure of any city in this region, except Cyrene. St. Jerome confirms these last authorities, when he affirms that this town was situated in a defert; and that its inhabitants, or at least their descendents, dispersed themselves over several districts, lying as far to the westward as Mauritania, and the eastward as India. The Barcæi learned (says Stephanus) the art of managing horses from Neptune, and of driving chariots from Minerva. The modern kingdom and defert of Barca undoubtedly derived their name from the Barcæi; and we may hence infer, that these people formerly held a considerable rank among the various nations of Libya.

What is the present condition of the towns of Barca, what is their commerce, and how they are governed, we have no authentic documents for ascertaining. The maritime towns are, probably, under the protection of the Porte; but it is not certain, whether they are under the government of the bæth of Egypt or Tripoli, or they have formed themselves into free states like those of Algiers and Tunis. This however is certain, that the inhabitants of the maritime towns are more civilized than those within land. The first profes Mahometanism, and have imbibed some notions of humanity and justice; but the latter, and especially those of the defert, who have neither religion nor any appearance of worship among them, are altogether brutish and savage, and live wholly upon theft and plunder, like all other wild Arabs. By them this tract, which was before a barren defert, was first inhabited. Deficient and indigent in the extreme, they are paid also to be the ugliest of all the Arabs; their bodies being meagre, their faces grim, and ascept fierce and ravenous; their garb, which is commonly stripped from the pouches and pilgrims, tattered with long wearing; whilst the poorest of them want rags to cover their nakedness. They are likewise reported to be reloutious and expert robbers and plunderers; but deriving a scanty supply from their own neighbourhood, they are compelled by necessity to extend their excursions as far as Numidia, Libya, and other southern parts, where they commit many atrocious acts of cruelty. So indigent and famished are these Barcæs, that they commonly let, pledge, and even sell their children, for procuring the necessaries of life, to the Sicilians, and other neighbouring Christians, from whom they have most of their corn, especially before they set out on any long expedition. The chief towns of Barca are Derna, the capital and residence of the fanatics, Tolometa or Tropoloma, and Grena or Caren. Anc. Un. Hlst. vol. xvi. p. 181. Mod. Un. Hlst. vol. xv. p. 196, &c.

Barca, a small port on the coast of Peru, about 5 lat. 11° 20', where ships may anchor, but obtain no supply.

Barcalao, a Spanish word, which the French pronounce bacula or baccala. By this last name the Bafques most commonly call the fish which we style cod; and those people call also the island which we call Newfoundland, the island of Bacala (Cod Island), because of the great plenty of cod caught there. There is, however, a league to the west of that large island, another small one, which is more particularly called Baccala.

Barcalon, an appellation given to the chief minister of the emperor of Siam, to whom belongs the care of trade both within the kingdom and out of it, the superintendency of the royal magazines, the receipt of the revenues, and the management of foreign affairs.

Barca Longa, a large Spanish fishing-boat, navigated with lug-sails, and having two or three masts. These are very common in the Mediterranean. See Barca.

Barcani, in Ancient Geography, a people of Asia, in the vicinity of Hyrcania. They are placed by M. D'Arville, on the east of the Caspian sea, near one of the mouths of the Ouxus.

Barcarolla, in Music, a kind of song in the Venetian language, sung at Venice by their gondoliers or watermen, in their boats or barks. These airs (says Roufeau) are composed for the common people, and often by the gondoliers themselves. They have so much melody, and such an agreeable accent, that there is not a musician in all Italy who does not imitate himself in knowing some of them. The being admitted gratis into a gallery appropriated to them in all the theatres, enables gondoliers to form their ear and taste, without trouble or expense, so that they compose and sing their airs, without altering their natural simplicity, in the style and expediency of persons not ignorant of the refinements of music. The words of these airs are commonly jocose, and more than natural, like the conversation of those that sing them; but such as the faithful picture of the manners of a people can please, and such as are likewise partial to the Venetian dialect, soon become passionately fond both of the words and music of these airs, chiefly known in England by the title of Venetian ballads, of which travellers into Italy make collections.

Barcarola, in Geography, a town of Spain, in Etramadura, 4 miles from Almedorelo.

Barce, in Ancient Geography. See Barca.

Barce, a town of India, built by Alexander, on the seacoast, in memory of his exploits, and where, according to Jullin, he erected altars.

Barcelona, in Geography, a rich and strong city and
and the capital of Catalonia, of which it is the capital, and the see of a bishop, suffragan of the archbishop of Tarragona. It was originally founded by Hamilcar Barca, the father of Hannibal, and from him called "Barcino," about 250 years before Christ. It was reduced by the Romans, and continued subject to them till the kingdom of Spain was over run by the Goths and Vandals, and afterwards by the Saracens and Moors. At the beginning of the ninth century it was po sessed by the Moors, under the government of Zade. This governor having abased the clemency of Charlemagne, and by his perfidious behaviour provoked his son, Lewis king of Aquitaine, Barcelona was invaded, and the generals who were intruded with the command of the siege had orders not to abandon it till Zade was delivered into the hands of Lewis. The Moor made an obstinate resistance; but finding that it was impossible to preserve the city any longer, after a defence of many months, he determined to throw himself upon the emperor's mercy, and was condemned to perpetual exile. At length, however, the city surrendered, and the king of Aquitaine appointed one Bera, count of Barcelona. The city continued subject to him, and his successors, who were distinguished by the title of "Counts of Barcelona," from the year 1131; when it was united to the crown of Aragon by the marriage of Don Raymond V. count of Barcelona, with Donna Petronilla the daughter of Don Ramiro the monk, and heirs of Arragon. In consequence of the revolt of the Catalonians, in 1465, Barcelona was besieged by Don Juan II. king of Aragon, in 1471. The siege was prosecuted for a considerable time with vigour, but without effect; however, in 1472, it capitulated on its own terms; and the king, upon his public entry into the city, confirmed all its privileges. In 1640, the Catalans, having shaken off the yoke of the Spaniards, called in the French to their succour; and they continued masters of the capital till 1652, when, after a siege of fifteen months, it surrendered to Don Juan of Austria. In 1697, it was again taken by the French under the command of the duke of Vendome, but restored the same year to the Spaniards by the peace of Ryswick. Although the inhabitants of Barcelona had taken the oath of fidelity to the king of Spain, Philip V. and received from him a confirmation of their privileges, they invited the English and Dutch, and the governor was obliged to surrender the town to the allies in 1705, when Charles, afterwards emperor, was received and proclaimed king. In the following year, Philip, afflicted by the French, assailed the city, and took the fortresses of Montjuic; but the fleet of the allies advancing in the relief of the besieged, he was compelled to abandon the enterprise and retire from the place, May 12th 1706. By the treaty of Utrecht, in 1713, the troops of the emperor evacuated Catalonia; but the inhabitants of Barcelona perished in their revolt, and would not acknowledge Philip for their king. Accordingly they suffered blockade for a year, which was followed by a terrible bombardment; and at length, after a siege of sixty-two days, from the opening of the trenches by the duke of Berwick, the town was taken by assault on the 11th of September 1714. By the moderation of the conqueror, the city was faved from pillage, but the inhabitants were deprived of their privileges; they have since, however, been re-established, and in 1715 a citadel was erected to keep them in awe.

Barcelona is now one of the largest and handsomest cities in Spain, and is reckoned the third most considerable city in the kingdom. It is situated on a plain by the sea-side, open to the south-east, but protected by hills on the north and west, so that it affords a healthy and delightful residence; however it is subject to a fog brought on by the salt wind. The city is surrounded by a good brick wall, round which is another, with fourteen bastions, hocused works, ramparts, and ditches. The ramparts are high and spacious, and a great number of carriages may be seen every evening driving upon them for pleasure. The city is divided into two parts; the old and the new, which are separated from each other by a wall and a large ditch. The streets are narrow and crooked, and the churches are rather rich than beautiful. Barcelona contains several considerable edifices: that called the Ter--fana, or the arsenal, is of large extent; and a prodigious gallery, containing twenty-eight forges, has been erected in it within a few years. The other most remarkable buildings are the cathedral, adorned with two high towers, the church of Notre Dame, the palace of the bishop, the exchange, the palace of the governor, that where the nobility of the country assemble, called "La Ca fa de la Deputacion," and that of the inquisition. The hofpicio contains about 1400 industrious poor; and in the house of correction are sometimes found women of rank, who have been guilty of drunkenness, or other low vices. The harbour is spacious, deep, and secure, and defended on one side from the winds by a mountain called Montfouj, which rises in the middle of the plain near the city, runs into the sea in the form of a promontory, is covered with vineyards, gardens, and groves of trees, and a strong fort for defending the city, and furnishes a quarry of fine hard freestone; and on the other side by a large mole; having a light-house with a small fort and garrison at the extremity. Into this harbour 1000 vessels are supped to enter during peace, and of these 500 are Spaniards, 120 French, 100 English, and 60 Danes. Barcelona is a place of great trade, on account of the convenience of its harbour; although none but small vessels can enter within the mole. Its chief manufactures are silk, cotton, and wool, and excellent fire-arms and cutlery: its chief imports are corn, flesh, and woollen goods; and its exports wine, brandy, cloth, and leather. Silks from Lyons, stockings from Nimes, several kinds of stuffs and cottons although they are prohibited, and particularly dried cod, an article for which Spain is paid to pay annually to the English three millions of piastras, pays into Catalonia through this port. About twenty years ago, a very large cannon foundry was established in this city, under the direction of M. Maritz, a Swiss; and it has several glass-houses. The inhabitants are industrious and active, and their number is said to exceed 100,000: they are hospitable to strangers; the women are as handsome as any in Spain, lively in their conversation, and less restrained in their conduct than in other parts of the country. Barcelona was erected into a county by Charlemagne, and became an independent sovereignty in the year 873 or 884. The king of Spain is called the count of Barcelona. The diocefe contains 213 parishes, besides 8 in the city. It is distant 13 leagues E. N. E. from Tarragona, and 92 E. N. E. from Madrid. N. lat. 44° 26'. E. long. 2° 13'.

Barcelona, or Caramyutto, a town of South America, in the country of Terra Firma, and principal place of a district in the province of Cumaná.

Barcelona, a town of France, in the department of the Gers, and chief place of a canton in the district of Nogaro, seated on the Adour, containing about 2000 inhabitants;
BAR

abitants; 3 leagues S.W. of Negaro, and 9f W.N.W. of Mirande.

BARCAREO, a sea-port town of the East Indies, on the coast of Malabar, between Goa and Mangalore, in a district ceded to the British by the treaty of 1759. It has a good harbour, and the Dutch had formerly a factory in this place, which carried on a considerable trade in pepper. N. lat. 13° 56'. E. long. 74° 45'.

BARCELLOS, a town of Portugal, with the title of a duchy, in the province of Entre Duero e Minho, not far from the sea, on the river Cavado, 8 miles W. of Braga. N. lat. 41° 20'. W. long. 7° 0'.

BARCES, or Barches, were formerly a kind of ship guns, not unlike fakors, only shorter, thicker in metal, and wider bored.

BARCHINO, in Geography, a town of Perú, in the province of Kornan, 120 miles S.E. of Sigrián.

BARCHOECHARAS, or Cazira, in Biography, a false Messiah of the Jews, who taking advantage of the animosity excited among his countrymen by the proclamations of the emperor Adrian, when he founded his new city of Ælia on the ruins of Jerusalem, about the year 134, assumed the name of Barchocharas, or child of the Star, in allusion to a prophecy of Balaam (Numb. xxiv. 17.) and pretended to be the long-expected deliverer of his nation. He chose for his preceptor the famous Akiba; and collecting together an army of 200,000 men from among the banditti who then infested Judaea, took possession of the strong town of Bithia, called by St. Jeron Betheron, between Cæarea and Diospolis, which he fortified as the place of his retreat and the capital of his newly-projected kingdom. Here he was anointed king, and caufed money to be coined in his own name, by which he proclaimed himself the Messiah and prince of the Jewish nation. However he deferred declaring war against the Romans, till Adrian had quitted Egypt, so that it did not break out till the 17th year of that emperor's reign. Adrian seems at first to have neglected this new revolt; but when he perceived that it was likely to become formidable, he sent Titianus Rufus with a strong reinforcement to quell it. This force being insufficient to restrain the depredations of these banditti, who massacred all the Romans and Christians that fell in their way, Julius Severus was recalled from Britain, and sent at the head of an army against the impostor. This general laid siege to Bithia, which was resolutely defended, till Barchocharas was slain. The town was then carried by storm, and this event, which, according to Eusebius, happened in the 18th year of Adrian, was followed by a most dreadful slaughter of the Jews. Crevier's Rom. Emp. vol. vii. p. 188, &c. Bahnage, Hist. des Juifs. l. vii. c. 13. Mod. Un. Hist. vol. x. p. 437. &c. See Akiba.

BARCHUL, in Geography, a town of Spain, in the country of Granada, five leagues from Guadix.

BARCHUSEN, or Barkhausen, John Conrad, in Biography, a learned physician and chemist, was born at Home in the county of Lippe, in 1666. After a liberal education, and a course of travelling through the principal cities of Germany; with a view to his improvement in pharmacy and chemistry, he became physician to the Venetian general in his expedition to the Morea in 1694; and on his return settled at Utrecht, where he obtained permission to teach chemistry, in which employment he continued till the time of his death in 1717. His character was distinguished by integrity and zeal for public good, as well as by indefatigable Industry in the pursuit of knowledge; without possessing any very extraordinary share of genius or facility of judgment. His works are, "Synopsis Pharmacutica," "Pyro sophia," Leyd. 1696, 3vo; "Acro maest ad Jatrochymiam & Physicam Speculantia," Utr. 1703, 8vo; "Historia Medicina," Amst. 1710, 8vo; published with enlargements under the title of "De Medicina ortu et progressu Diferuntiones," &c. Utr. 1723, 4to, in which work an account is given of all the facts and theories of medicine from the earliest times to the author's own age, but with less accuracy, especially in relation to the ancient writers, than those of Le Clerc and Friend; "Synopsis Pharmaceut," Leyd. 1712, 4to; "Compendium Ratiocinii Medicarum," Leyd. 1712, 4to; "Collecta Medicinae Prætiosa, Gentium," et Dialogus de optima Medicum feclit. Leyd. 1715, 8vo. Haller Ed. Med. Præf. 39

BARCINO, in Ancient Geography, a town of Hispania Tarraconensia, and capital of the Lactani; now Barcelona.

BARCLAY, Barclay, or Barklay, Alexander, in Biography, an elegant British writer of the 16th century, was a native either of England or Scotland, but probably of the latter country. About the year 1495, he came to Oriel college, Oxford, and having distinguished himself by his parts and learning, he travelled on the continent and acquired a competent knowledge of the languages spoken in Holland, Germany, Italy, and France. On his return to England, he became one of the priests of St. Mary Ottery in Devonshire, and afterwards a monk of the monastery of Ely. After the dissolution of this monastery in 1539, he was presented successively to several livings, the last of which were those of Baddow-Magna in Essex, and of Allhallows in London. He was honoured with the degree of doctor in divinity. He died at a very advanced age at Croydon in Surrey, in June 1552. Different accounts have been given of his character. Bale, the protestant, treats his memory with indignity, and charges him with being a scandalous adulterer, whilst he led a fingle life; but Pitts, the papist, affures us that he directed his studies to the service of religion, and employed his time in reading and writing the lives of the Saints. These accounts, however, are not altogether incompatible. As an imposer of English literature, his merits are acknowledged; and his industry in enrolling our language with many translations, written in a style more pure and fluent than that of his contemporaries, entitles him to grateful remembrance. Some of the principal of his works, of which there is no complete catalogue, are the "Miferere Curialeium," or "Miferes on the Miseries of Courtiers," compiled by Æneas Sylvius; the "Eclogues of Baptif Mauum," the "Callie of Labour," from the French; a treatise "Of Virtues," by Mancini; several "Lives of Saints," the "Jugurthine war" of Sallust; a "Treatise against Skelton," who was poet laureat, and a great enemy to priests; and the most popular of all his works, the "Navis Stultifera" or "Ship of Fools," which is a free translation, with considerable additions, from a work under the same title, by Sebastián Brantius; this is a satirical work, adorned with many pictures printed from wooden cuts; it passed through several editions, and was first printed at London by Richard Papnon, in 1509, in small folio, again in 1519, and in 4to. in 1570. Gen. Dict. Biog. Brit.

BARCLAY, William, a learned civilian, was born in Aberdeenshire in 1541, and descended from one of the best families in Scotland. After the captivity of Mary queen of Scots, by whom he was favoured, he retired to France about the year 1573, and then by close application became a proficient in the knowledge of the civil law, so that he obtained a professorship in that science in the university of Ponta-
Pontamoufflon, founded by the duke of Lorraine; he was also appointed by this duke counsellor of state, and master of

the chapters. In 1594, he married a lady of Lorraine, by whom he had a son, who was the cause of his contest with the Jesuits, by whose influence this work was reduced to the necessity of quitting Lorraine. He then came to England, and was offered a place in the council of James I., with a considerable pension, on condition of his embracing the established religion; but declining the offer, he returned to France, and accepted the professorship of civil law in the university of Angers, where he taught for some time with reputation. Here he died as some say in 1565, according to others in 1569, or 1611.

BARCLAY, John, the son of the preceding, was born at Pontamoufflon in 1592, and distinguished himself betimes as a proficient in police literature. The Jesuits wished him to enter into their society; but his father incurred their resentment by preventing it, and taking him to England, at the beginning of the reign of James I. He had already, viz. in 1601, published a commentary on the Thebais of Statius. He also prefixed to James, a Latin poem upon his coronation; and in 1603, published the first part of his "Satiricon Eurphormionis," which was dedicated to the king. He accompanied his father to Angers, with whom he continued till the death of the latter, and then removed to Paris. In 1606, he came over to England, where he obtained considerable employments under King James, and was made gentleman of the bed-chamber. He is said to have assisted this prince in a controvertial work, which occasioned some unfounded suspicions of his orthodoxy. Having finished his "Euphrönios," he published an apology for it in 1610. Upon his return to Paris, he printed in 1612, a work intitled "Pictœ," being a vindication of a performance of his father against the power arrogated by the popes over crowned heads, which had been attacked by Bellarmine. Nevertheless, he was invited to Rome by Paul IV., and resided there during the latter part of his life, cared for by Bellarmine, and possessing some lucrative employments, in return for which he wrote a work of controversy, intitled, "Praeœxis ad Sæctarios." Whilst he was employed in superintending the first edition of his principal work, intitled the "Argenis," he died at the house of Rome, in 1621. The disposition of Barclay was of a melancholy cast; his mornings were uninterruptedly employed in study, and the afternoons were devoted to his garden. His reputation, both as a scholar and a writer, was extremely high in his own times; but his works were not of a nature, calculated to command lasting attention. His Latin style was much admired by some, and very censured by others. Petronius was his model, but he formed what partakes of the florid afectation of Aurelius in his prose, and of the bombast of Lucian in his verse. His "Euphrönios," and "Argenis," were both works of instruction, passed through several editions in various languages. The latter is a kind of political allegory, exhibiting a picture of the vices and revolutions of courts, with real characters under fictitious names. It displays great ingenuity and learning, and abounds with lively imagery and elevated sentiments, but with too much parade. It was read with avidity whilst the subjects were recent; and a translation of it in English by a lady appeared in 1772, without attracting much notice. Gen. Dict. Biog. Brit.

BARCLAY, Robert, the famous apologist for the Quakers, was the descendant of an ancient family in Scotland, and the son of colonel David Barclay of Musters. He was born at Gordonston in the shire of Murray, in 1639, whether his father had retired, after quitting the army, and was sent for education to his uncle at Paris, who was at that time principal of the Scots college. Pains were taken to profligate him to the catholic religion; and he acknowledged that they were not altogether unsuccessful. He returned home, however, in his 17th year, and was distinguished by his accomplishments in literature, and particularly by his knowledge of the Latin and French languages. At home he extended his acquaintance, by diligent application, with the Greek and Hebrew; and being of a grave disposition, directed his inquiries towards theological subjects. His father, having in 1666 become a convert to quakerism, was soon followed by his son; whose zeal, though generally under the control of a sedate temper and sound judgment, was not altogether free from enthusiasm; for he conceived himself obliged by divine command to pass through the streets of Aberdeen clothed in sackcloth and ashes, and he actually yielded to this impulse. But he served the cause, to which he was attached from conviction, much more effectually by his powers of reasoning in its defence. His first publication to this purpose, intitled "Truth cleared of calumnies," &c. was a reply to a work of W. Mitchell, a preacher near Aberdeen, and dated at his father's house at Urie, in 1670. This was followed by an appendix and additional treatise, exhibiting a considerable portion of controversial acrimony, and had the effect of silencing his antagonist. In 1673 he published with a view of conciliating the good opinion of Protestants, a systematic exposition of the doctrines of his sect, under the title of "A Catechism and Confession of Faith, approved of and agreed to by the general assembly of the Patriarchs, Prophets, and Apostles, Christ himself chief Speaker in and among them," &c. The design of this work was to prove, that Quakerism was the perfection of the reformed religion, and that Protestants, as they receded from it, were so far inconsistent with themselves, and approached to Popery. His fundamental principle was, that the scriptures alone were to be regarded as the foundation of faith, and that Christians ought to receive no doctrines which were not capable of being proved by the express words of scripture. This work excited very general attention, and removed many prejudices that were entertained against the society. His next treatise, intitled "The Anarchy of the Ranters and other Libertines, the Hierarchy of the Romanists, and other pretended churches, equally refuted and refuted," &c. was intended to mark the dissension between the rationalists of his sect, and the enthusiasts; but some sentiments concerning church discipline, which it contained, involved him in disputes with some of his own brethren, and drew upon him attacks from some members of the university of Aberdeen, and from other quarters. He persisted, however, in his endeavours for forming a clear, methodical, and rational system of Quakerism; and in the year 1675, he was diligently employed in composing the most famous of all his writings, which is his "Apology for the true Christian divinity, as the same is held forth and preached by the people in scorn called Quakers." This was introduced by his "Theses Theologicæ," written in various languages, and addressed to the clergy of all denominations throughout Europe, requesting their examination.
tion and judgment. Two copies of the "Apology" were transmitted to each of the ministers plenipotentiary then assembled at the congress of Nimoguen. It was printed in 1676, at Amsterdam; and two years after, the author published an English translation of it. It was also translated into other languages, and excited very general attention. The "Apology" is a learned, scholastic, methodical performance; and it is regarded as the first authority for the principles of the fact. The society derived considerable reputation from it; and whilst it contributed to remove prejudices against this sect both at home and abroad, it gave them a respectable rank among the reformed churches. The dedication is no less remarkable than the apology itself. It is addressed to king Charles II.; and speaks to him in so plain and forcible a manner respecting the events of his own life, and pleads the cause of religion, and of the author's own society, with such a manly spirit, that it has ever been admired as a model in its kind. Let the following passage serve as a specimen: "Thou hast talked of prosperity and adversity; thou knowest what it is to be banished thy native country, to be over-ruled as well as to rule and sit upon the throne; and being oppressed, thou hast reason to know how hateful the oppressor is both to God and man." This address did not avail, as Voltaire afferts, to restrain the perfection which then raged against the Quakers; for Robert Barclay Limkild, after his return from Holland and Germany, which he visited in company with the famous William Penn, was, in 1677, imprisoned in Aberdeen, together with his father and many other Quakers, at the instigation of Sharp archbishop of St. Andrew's, with whom he renounced by an excellent letter on the occasion. By the interposition of Elizabeth the princesse patrine of Rhine, who rescued the Quakers and corresponded with both Penn and Barclay, he was soon liberated; and he even acquired the favour of the court, so that in 1679, he obtained a royal charter for erecting his lands at Urice into a free barony. In 1682, he was elected governor of East Jersey, in North America, by the proprietors of the province; but he declined accepting the appointment, and was satisfied with naming a deputy governor. Whilst he was in prison at Aberdeen, in 1677, he published a treatise on " Universal Love," intended to shew that this principle prevailed more in his church than in any other. In the same year he addressed a Latin letter to all "the ambassadors and deputies of the Christian princes and states, met at Nimoguen to consult the peace of Christendom," urging them to promote that good work, and pointing out the true causes of war, and its incompatibility with Christian principles. He had also written, in 1676, a Latin letter concerning "the Possibility and necessity of an inward and immediate Revelation," to Adrian Pacts, a person of distinction in Holland; and in 1689 this letter was translated into English and published. This was the last, and has by many members of the society, been reckoned among the most important of his performances. His time was very much occupied in journeys for the benefit of the society, with a view both of promulgating its doctrines, and protecting its members from oppression. Barclay and Penn were on terms of intimacy with James II.; who, sensible that he and his party needed toleration, affected to be the great patron of liberty of conscience. The non-refuting principles of the quakers in civil matters, might probably give him a predilection for their religious opinions above those of other Protestants. Barclay was engaged in a private conference with the king in the year 1688, just as the wind became fair for bringing over the prince of Orange, and on that occasion urged his majesty to make some concession for satisfying his people; but his advice was of no avail. Robert Barclay did not long survive the revolution. He died, after a short illness, in his house at Urice, in October 1690, in his forty-second year, leaving seven children, all of whom were living fifty years afterwards. The moral character of this eminent person corresponded to the great employment of his life, which was that of promoting what he conceived to be the cause of religious truth. He was amiable and respectable; nor did the gravity of his pursuits infuse any rigour or fowrds into his conversation and manners. He governed his house with great prudence and discretion, and preserved a serene mind under all the changes of his fortune. Biog. Brit. Gen. Biog.

BARCAY Fort, in Geography, is the well point of the entrance into English harbour, on the south side of the island of Antigua; the east point also has a battery, from which it is distant only about 300 yards.

BARCONE, in Navigation, a short broad vessel, of a middle size, used in the Mediterranean for the carriage of corn, wood, salt, and other provisions, from one place to another.

BARD, is used in the Culinary Art, for a broad slice of Bacon used to cover fowls before they are roasted, baked, or otherwise dressed.

BARD, or PARtha, in Geography, a town of Germany, in the circle of Upper Saxony and circle of Leuplick, 2 miles S.W. of Grimma.

BARDANA, in Botany. See ARCTIUM.

BARDANA, in the Materia Medica. See ARCTIUM Labba.

BARDANAE, in Entomology, a species of CURCULIO, of a cylindrical form, downy, greyish; anterior legs elongated. About the size of C. paraplecticus, and not unlike it in appearance. Inhabits Europe.

BARDARIOTAE, in Antiquity, were a kind of ancient guard attending the Greek emperors, armed with rods, wherewith they kept off the people from crowding too near the prince, when on horseback. Their captain, or commander, was denominated primuvergus. The word was probably formed from the barde or houlings on their horses.

BARDE. See BARBE.

BARDED, in Heraldry, is used in speaking of a horse that is caparisoned.

He bears fable, a cavaliier d'or, the horse baraded, argent.

BARDELLE, in the Mange, denotes a faddle made in form of a great faddle, but only of cloth stuffed with straw, and tied tight down with packthread, without either leather, wood, or iron. Barckiles are not used in France; but in Italy they trot their colts with such saddles; and those who ride them are called cavaliardours, or fonzons.

BARDESANISTS, in Ecclesiastical History, a left thus denominated from their leader, Bardeanus, a Syrian of Edessa in Melopotamia, in the second century. Bardanes was a man of acute genius and profound erudition, and wrote several works which procured him reputation. He was eloquent in the Syriac language, and well acquainted with the Greek. His thirst for knowledge induced him to travel into the call, in order to converse with the heathens and other philosophers of that country. He was held in high estimation by Abgarus, who reigned in Edessa from the year 152 to 187. A work written by him, "upon Delphini," against Abgarus the astrologer, was valued by the ancients; and a fragment of it is quoted by Eusebius, in his Prep. Evang.

Bardeanes adopted the oriental philosophy concerning the two principles; maintaining that the supreme God is free from all evil and imperfection, and that he created the world and its inhabitants pure and incorrupt; that in
proceeds of time the prince of darkness, who is the fountain of all evil and misery, enticed men to sin; in consequence of which, the supreme God permitted them to be defiled of those ethereal bodies with which he had endued them, and to fall into flagrant and gross bodies formed by the evil principle: and that Jesus descended from heaven, clothed not with a real but aerial body, in order to recover mankind from that body of corruption which they now carry about them; and that he will raise the obedient to mansions of felicity, clothed with aerial vehicles, or celestial bodies. It is said that Bardseans at length renounced the more chimerical part of his fytum. Eusebius denied that he ever returned to the Catholic faith. His facts subsided for a long time in Syria, to which his 150 hymns written in elegant Syriac very much contributed; as they also did to the propagation of his opinions. Momus's Exod. Hist. vol. i. p. 320. Lardner's Works, vol. ii. p. 299, &c.

BARDEWICK, in Geography, a town of Germany, in the circle of Lower Saxony, on the Ilmenau, supposed to be one of the most ancient towns in Germany. It was in a very prosperous state, and the seat of a bishop in 1180, when Henry the Lion, duke of Saxony and Brunswick, took and razed it to the ground, because the inhabitants would not acknowledge him after he had been proscribed by the emperor Frederick I. The bishoprick was then removed to Verden; and the city of Luneburgh received the advantages of trade and population; 4 miles N. of Luneburg.

BARDEWISCH, a town of Germany, in the circle of Westphalia, and county of Delmenhorst; 6 miles N. of Delmenhorst.

BARDI, a town of Italy, in the Parmesan, seated on a rock near the small river Ceno, and capital of a marquifate, to which it gives name; 26 miles W. of Parma.

BARDIN, a town of Persia, in the province of Segeltan, 30 miles W.S.W. of Zareng.

BARDIS, a town of Egypt, and residence of a sheik, whose authority extends a confiderable way along the Nile, 6 miles south of Girge.

BARDISTAN, CAPE, lies on the coast of Persia, in the Indian ocean. N. lat. 28° 0'. E. long. 52° 0'.

BARDO, a town of Piedmont, in the duchy of Aosta, seated on the Dora Baltea; 17 miles S.E. of Aosta.

BARDONACHE, a town of Piedmont, in a valley, to which it gives name; 10 miles north of Sezanne, and 6 W.N.W. of Exilles.

BARDOP, a river of England, which runs into the Read, 6 miles N.W. of Ellidon, in Northumberland.

BARDS, BARD, in Antiquity, ancient poets among the Gauls and Britons, who defcribed and sung in verse the brave actions of the great men of their nation; with design to incultate and recommend virtue, and even sometimes to put an end to the difference between armies at the point of engagement.

Bochart derives the word from parat, to sing. Camden agrees with Felius, that bardus originally signifies a finger: and adds, that the word is pure British. Others derive the word from Bardus, a druid, the son of Drys, and the fifth king of the Celts.

Amidst this uncertainty with regard to the etymology of the appellation bards or bard, we may add that some have derived it from bair, which signifies fury, and which bears, without doubt, some analogy to that poetical fury or enthusiasm with which the poets fancied themselves, or might feign to be inspired. Among the Welsh, we are told by others, bard is preferred as an indigenous term, having an abstract signification, and denoting one that makes conspicuous, or causes to be revealed. By another author we are informed that the word bard being a primitive noun, neither derived nor compounded, it can neither be traced to its root, nor resolved into its parts. It signified one who was a poet by his genius and profession, and who employed much of his time in composing and singing verses on various subjects and occasions.

The bards, it is said, differed from the Druids, in that the latter were priests and teachers of the nation, but the former only poets and writers.

Larrey, Bodin, and Paquier, indeed, will have the bards to have been priests, as well as philosophers: and Chuvies, orators too; but without much foundation in antiquity. Strabo divides the sects of philosophers among the Gauls and Britons into three, viz. the Druids, Bards, and Crates. The bards, adds he, are the singers and poets; the crates, the priests and natural philosophers; and the Druids, to natural philosophy add also the moral. Hornius however reduces them to two sects, viz. bard and Druids; others to one, and make a Druid a general name, comprehending all the others. Chuvies will have it, that there were bards also among the ancient Romans; because Tacitus makes mention of their songs and poems, which contained their history. Some have distributed the ancient Britons poets into two classes, the first class comprehending their sacred poets, who composèd and sung their religious hymns, and were called in Greek Evbatres, in Latin Pateres, and in their own language Faeds; the second comprehending all their secular poets, who sung of the battles of the heroes, or the heavenly breasts of love, according to the description of Ossian, and they called bards. The principal buildings of these bards was to celebrate the praises of the gods and departed heroes, in odes and verses, and to sing them to their harps, at their religious assemblies, public festivals, and private entertainments. These men were, in fact, the heralds, the chronologers, and the historians, as well as the poets of the land, for they kept up the memory of illustrious transactions, and, by their compositions, which tradition handed down to posterity, they transmitted from age to age the names and characters of patriots and warriors. It is remarkable that such a class of persons subsisted in almost all nations. They derive their origin from remote antiquity, and were ever held in high estimation. Mankind have been early led to poetical compositions. Agreeable sounds strike at first every ear, and poetry was necessary to give those sounds a lasting effect. Vergil has therefore been made use of to preserve the memory of remarkable events and great actions. The religious ceremonies of nations, their manners, and rural labours, were also recorded in numbers. Hence it was that Greece could boast of a Homer, a Hesiod, and of other poets, some ages before a historian had written in prose. Amongst the Gauls also, and other Celtic nations, there were poems composèd on various subjects from the earliest ages. Diodorus Siculus is the first author among the ancients, who mentions the bards as the composèrs of verses which they sung to the sound of an instrumenc: not unlike a lyre (l. v. § 31.). Annius Marcellinus informs us (l. xii. c. 9.), that the bards celebrated the brave actions of illustrious men in heroic poems, which they sung to the sweet sound of the lyre. This account of these Greek and Latin writers is confirmed by the general ftras; and by many particular passages of the poems of Ossian. "Beneath his own tree, at intervals, each bard sat down with his harp; they raised the song and touched the string, each to the chief he loved." But this union between poetry and music did not subsist very long, in its greatest splendours, perhaps, in any country. The musicians soon became very numerous, and those of them who had not a genius for com-
posing verses of their own, affiliated in singing the verses of others to the music of their harps. Many of those songsters, or parasites (as Athenaeus, 1. vi. c. 12, calls them), which the Celtic princes took with them when they went to war, were mere musicians, and the songs which they sung were composed by bards among them who had a poetical genius, and were called bards. Ollian, however, excelled as much both in vocal and instrumental music as he did in poetry, and he seems to have had no idea of playing on an instrument without singing at the same time. Whenever his bards touch the string, they always raise the song.

The bards constituted one of the most respected orders of men in the ancient British states; and many of the greatest kings, heroes, and nobles, esteemed it an honour to be enrolled in this order. They enjoyed, by law and custom, many honourable distinctions and valuable privileges. Kings and princes made choice of bards to be their bosom-friends and constant companions; indited them with the greatest familiarity, and gave them the most flattering titles. Their persons were held sacred and inviolable; and the most cruel and bloody tyrants dared not to offer them any injury. The bards, as well as the druids, were exempted from taxes and military services, even in times of the greatest danger; and when they attended their patrons in the field, to record and celebrate their great actions, they had a guard assigned them for their protection. At all festivals and public assemblies they were seated near the person of the king or chieftain, and sometimes even above the greatest nobility and chief officers of the court. Nor was the profession of the bard less lucrative than honourable. For, besides the valuable presents which they occasionally received from their patrons, when they gave them uncommon pleasure by their performances, they had estates in land allotted for their support. Nay, so great was the veneration which the princes of these times entertained for the persons of their poets, and so highly were they cherished and delighted with their tuneful strains, that they sometimes pardoned even their capital crimes for a song. It may be reasonably supposed that a profession, which was so honourable and advantageous, and to which were annexed so many flattering distinctions and definable immunities, would not be despised. Accordingly, the accounts we have of the numbers of the bards in some countries, particularly in Ireland, are hardly credible. In the poems of Ollian we often read of 100 bards belonging to one prince, singing and playing in concert for his entertainment. Every chief bard, who was called Alladh Redan, or doctor in poetry, was allowed to have 30 bards of inferior note constantly about his person; and every bard of the second rank was allowed a retinue of 15 poetical disciples. But it is probable that the bards of Britain and Ireland were not so numerous at an early period as they became afterwards; nor were they then guilty of these crimes by which they at length forfeited the public favour. In this most ancient period, the British bards seem to have been in general men of genius and virtue, who merited the honours which they enjoyed. Though the ancient Britons of the southern parts of this island had originally the same tale and genius for poetry with those in the north, yet notions of their poetical compositions have been preserved; and this may be safely accounted for. After the provincial Britons had submitted quietly to the Roman government, yielded up their arms, and had lost their free and martial spirit, they could take little pleasure in hearing or repeating the songs of their bards, in honour of the glorious achievements of their brave ancestors. The Romans too, if they did not prune the fame barbarous policy which was long after practised by Edward I. of putting the bards to death, would at least discourage them, and discontinue the repetition of their poems for very obvious reasons. Their sons of the song being thus peremptorily by their conquerors, and neglected by their countrymen, either abandoned their country or their profession; and their songs, being no longer heard, were soon forgotten. But so natural was a tale for poetry to the original inhabitants of this island, that it was not quite destroyed by their long subjection to the Romans, but appeared again in the poetical history of the provincial Britons, as soon as they recovered their martial spirit, and became a free, brave, and independent people. Nennius, who wrote in the ninth century, and in the reign of prince Mervyn, is the last of the British historians who mentions the bards. He says, that Talhiraun was famous for poetry; that Aneurn and Taliesin, Llywarch-hen and Chian, flourished in the 6th century. Of these bards, the works only of three are extant; those of Aneurn, Taliesin, and Llywarch-hen. Besides the bards already mentioned, there were others who flourished during this period; of whom the most eminent was Merddin Wylit, who composed a poem called Affallenau, or the orchard. From the sixth to the tenth century it is difficult to meet with any of the writings of the bards, owing probably to the devolutions of war, and to the civil divisions among the Welsh.

Such was the respect in which the bards were held, that by a law of Howel Dha, whoever struck any one of this order must compound for the offence by paying to the party aggrieved one-fourth more than was necessary to be paid to any other person of the same degree.

The election of the bards was made every year, in an assembly of the princes and chieftains of the country, in which they were alligned precedence and emolument suitable to their merit; but the bard most highly distinguished for his talents was solemnly chaired, and had likewise a badge given him of a silver chain. This congres of the bards was usually held at the royal residence of the prince of Wales; the sovereign himself presiding in that assembly. The bards, properly so called, were distinguished from the Druids and Eubates or Ovates, by the colour of their dreefs; they were clad in sky-blue garments, whilst the Druids wore white, and the Ovates green. Their discipies were arrayed in variegated garments of these three colours united. They held their meetings in circles of unwrought stones, astronomically placed as indexes of the feafons, in the open air, and when the sun was above the horizon, or as they expressed it, in the face of the sun, and in the eye of the light. They had four principal meetings in the course of the year. The first was on the winter solstice, called Alban Arthan, which was the beginning of their year; the second on the vernal equinox, or Alban Edair; the summer solstice, or Alban Henin, was the third; and the autumnal equinox, or Alban Elded, was the fourth solemn convention.

It appears, upon a close examination of its principles, that one of the primary intentions of bardism was, that it should be a regular system for preferring authenticated records and various kinds of knowledge in the national memory. as it were, by means of oral tradition. And, in order that nothing should have currency without due consideration, whatever was intended to be received into such a public record, whether the historical and aphoristic kind, or the didactic song, was always laid before the grand meetings. There it was discussed with the most scrutinizing severity; if then admitted, it was re-considered at the second meeting; if then approved of, it was referred to the third meeting; and being approved of by that, it was ratified or confirmed; otherwise it was re-
ferred to the triennial supreme convention for ultimate con-
defideration. At this national meeting, all that had been con-
formed at the provincial assemblies were also recited; and the
disciples, who there attended from every province, were en-
joined to learn them, in order that they might become as
widely diffused as possible. What was thus solemnly functioned
was to be recited for ever afterwards, annually at least, in addi-
tion to the former bardic traditions, in the secondary meet-
ings of districts, and also at one or other of the four grand
meetings. Such being the bardic establishment, by which tradi-
tion became formed into a well-combined science, we may rely on its triads for the best illustration of its prin-
ciples.

The three cultivators of song and imagination among the
nation of the Gymry were Grwyson Ganbelen, who was the first
in the world that composed poetry; Hu the mighty, who
first applied poetry to prefer memorials and composition; and
Tudno Taf Awun, or Tudno father of the year, who
first reduced poetry to an art, and established rules for com-
position. And from what these three persons executed, originat-
ed bardism and bardism, as conjoined with privilege and
custom by the three institutional bards, namely Penmyny-
der, Alun, and Grabon. They established the privileges and
customs which appertain to bards and bardism, and there-
fore they are called the three initiators. Nevertheless there
were bards and bardism before their time; but they were not
under the regulation of inviolable transit; and they had nei-
ther privileges nor customs, except what were obtained
through civility and courtesy, under the protection of the
country and nation, before the time of these three. Some
say that they were contemporary with Prydain, son of Arz
the Great; but according to others, they lived in the time of
Dywynwal Moel Mad, his son, who in some of the old
books is called Dywyrth, son of Prydain. For a further ac-
count of these institutional bards, and of the triads that
exhibit their character, office, and privileges, and that illus-
istrate their theology, we must refer the curious who wish
for further information on this subject. to William's Poems,
lyric and pastoral, in 2 vols. 8vo. London, 1794; and to
Owen's Heroic Elegies of Llywarch-tenn, in 1 vol. 8vo.
London, 1792. According to the latter of these writers,
the bards were divided into Bards Brani, who were the
civil magistrates or judges; and Bards Druig, who were
the priests of the community.

From the triads above referred to the reader may deduce
a correct outline of bardism; and as to the detail of its var-
ious parts, he may be surprised to be told that they are
still preferred in various memorials of the ancient Britons,
and in the memory of its initiated; though it is generally
supposed that this extraordinary system, known to the world
under the name of Druidism, has perished above fifteen hun-
dred years past, except the few hints given of it by Greek
and Roman writers. Loff it certainly would have been but
for its extraordinary means and precaution for self-prev-
ervation; especially in the middle ages, when it led to with-
fland the perfections of the popish church in the fulness of
its power. Here it may be worthy to remark that bardism
contains a great many things to induce a conviction of its
being the parent of true-masonry; and some of the prin-
ciples taught in both are the same in expression; and
indeed it is very remarkable, that artisan, or mason, is ex-
actly the meaning of ogy, or oate, the name of the third
class of bards; and in this character only could the bards
meet under cover. Free-masons do so now; but they pre-
serve a traditionary memorial of their meeting annually
on the tops of their highest hills, and in the bottoms of the
lowest vales, and when the sun was in its due meridian.

Thus bardism, whose principles were to be diffused in the
face of the sun and in the eye of the light, for the sake of
truth and self-preservation, had the means of becoming even
more secret than misfortunes veiled in the darkness of night.

There were three different classes of this order in Wales; the
first was called "Beidha," and they were the composers of
verses and odes in various measures; they were likewise the
recorders of the arms of the Welsh chieftains, and the re-
positories of the genealogies of families. This class was
accounted the most honorable, and was high in the public
estimation. The second class, called "Minhiers," were per-
formers upon instruments, chiefly the harp and the crwth.
The third were those who sung to musical instruments
in general, and were called "Datgymnshad."

The talents of the Welsh bards were not solely employed in
preferving the decrees of families, in the praise of heroes,
or in recording their illustrious actions; they sometimes in
plurality numbers mourned over the tomb of the fallen
warrior.

When tyranny erected her banner in Wales, by the cruel
policy of Edward in the massacre of the bards, that ancient
leaf of music and poetry was deftroyed by the mules, and conse-
quently was deprived of those fascinating arts which softened,
and at the same time that they invigorated, the genius of the
people. During the spirited resistance which ensued, and while the prosperous
injunction of Owen Glendower, the monks revisited their
native seats, encouraged by the munificence of that leader,
and animated by the transitory ray which had dawned upon
freedom. When the Welsh had made the last effort for their
expiring freedom, they sunk into a state of slavery the
most deep and severe. The bards were prohibited by law
from making their annual progress, and from holding pub-
lic assemblies, which privileges were called by the natives
"clera" and "cythortha." During this period, and the
contest between the house of York and Lancaster, the gen-
ius of poetry was nearly extinguished, or was only em-
ployed in soothing the miseries of the times, by obscure predic-
tions of more prosperous days. A brighter prospect opening
on this nation in the reign of Henry VII. a series of bards
arose from that time; and these bards, being supported in
the families of the Welsh chieftains, ascertained and preferred
their genealogies; and as the causes of reciting warlike
exploits had ceased, they celebrated the civil virtues of their
patrons, their magnanimity, their hospitable spirit, their tal-
ents, and the graces of their persons. They likewise,
amidst other duties, had the honourful office of composing
an elegy on the death of the chieftain in whose family they
receded, which was sung to the surviving relations in honour
of the dead, reciting the noble families from which the
deceased had sprung, and the great actions performed by him-
self or his ancestors.

Since the reign of Queen Elizabeth, there has not been
any regular assembly of the bards. The motives to emula-
tion having ceased, and the spirit of ancient freedom being
extinguished, the poetic fire, for which the Welsh nation
had been so renowned, gradually declined. But a spark of
that ancient fire still remains in the genius of the Welsh,
which, in the feasons of their felicity, breaks out into a sin-
gular kind of poetry, called "pennyll." Even at this day
some vein of the ancient minstrel survive among the
Welsh mountains. Numbers of persons assemble, and fit
round the harp, singing alternately "pennyll," or stanzas
of ancient or modern compositions. Often, like the mo-
dern improvisatore of Italy, they sing extempore verses;
and a peron conversant in this art readily produces a "pen-
nyll" apposite to the fact that was sung. Many have their
memories stored with several hundreds, perhaps thousands
of "pennyll," some of which they have always ready for
answers to every subject that can be propounded, or if their
recei-
recollected should fail them, their invention supplies them with something pertinent and proper for the occasion.

Bards have been found in many countries; and continued in Ireland and Scotland, as well as in Wales, to our own days. The genealogical somets of the Irish bards are filled the chief foundations of the ancient history of Ireland.

Spenfer, the poet, in his view of the state of Ireland in the reign of queen Elizabeth, observes that he caused several compositions of the bards to be translated; "and wisely," he adds, "they favoured of sweet wit and good invention, but skilled not of the gaudily ornament of poetry; yet were they sprinkled with some pretty flowers of their natural device, which gave good grace and comeliness unto them: which it is great pity to see so abused, to the gracing of wickedness and vice, which with good usage would serve to adorn and beautify virtue."

The songs of the Irish bards, says Warton in his "History of English Poetry" (diss. i. vol. i), are by some conceived to be strongly marked with the traces of Scaldic imagination; and the traces are believed still to survive among a species of poetical historians, whom they call "Tales Tellers," supposed to be the descendants of the original Irish bards. The Irish historians inform us that St. Patrick, when he converted Ireland to the Chrisitian faith, destroyed 300 volumes of the songs of the Irish bards. Such was their dignity in this country, that they were permitted to wear a robe of the same colour with that of the royal family. They were constantly summoned to a triennial festival; and the most approved songs delivered at this assembly were ordered to be preferred in the custody of the king's historian or antiquary. Many of these compositions are referred to by Keating, as the foundation of his history of Ireland. Ample effates were appropriated to them that they might live in a condition of independence and ease. The profession was hereditary; but when a bard died, his estate devolved not to his eldest son, but to such of his family as discovered the most distinguished talents for poetry and music. Every principal bard, as we have already observed, retained thirty of inferior note as his attendants; and a bard of the secondary class was followed by a retinue of fifteen. They seem to have been at their height in the year 558. None of their poems have been translated.

In the highlands of Scotland there are considerable remains of many of the compositions of their old bards (still preferred). But the most genuine, entire, and valuable remains of the works of the ancient bards, and perhaps the noblest specimen of uncultivated genius, are the poems of Ossian, the son of Fingal, a king of the Highlands of Scotland, who flourished in the second or third century, lately collected by Mr. Macpherson, and by him translated from the Erse or Gaelic language into English. Dr. Johnson, indeed, has suggested his doubts concerning the existence of such ancient MSS. as those from which the poems of Ossian have been translated. But this is not a place for discussing this subject of controversy. Admitting, however, their genuineness upon the whole, whatever additions may have been made to them, they afford an admirable specimen of what might be the conceptions of ancient bards. These poems, says Warton (ubi supra), notwithstanding the difference between the Gothic and the Celtic rituals, contain many visible vellages of Scandinavian interlusion. The allusions in the songs of Ossian to spirits who preside over the different parts, and direct the various operations of nature, who send storms over the deep, and rejoice in the shrieks of the shipwrecked mariner, who call down lightning to blast the forest or cleave the rock, and diffuse irresistible pestilence among the people, beautifully conducted and heightened under the skilful hand of a master bard, entirely correspone.
archbishop of Carleon, after his death he had reigned his see to St. David, and here is said to have died in 612. Bardsey Abbey, of which the remains are considerable, was founded in the year 516. A singular encloset belonging to it, consists of a long archd edifice, with an inflated stone altar near the east end. The island forms a remarkably fertile and well-cultivated plain of about two miles in compass. It contains a few inhabitants, and is rented from lord Newborough. It was granted by Edward VI. to his uncle sir Thomas Seymour, and after his death to the earl of Warwick. The late sir John Wynn purchased it from the late Rev. Dr. Willson of Newark. It is 10 leagues N.E. by N. of Caernarvon bar, and 12 leagues N. by W. of Holyhead in the isle of Anglesea. N. lat. 52° 58'. W. long. 5° 50'.

BARDSTOWN, a town of Kentucky, in the United States of North America, and chief place of the county of Nelson, on the Beech Fork river; about 25 miles from the Ohio. N. lat. 37° 48'. W. long. 86° 13' 30'.

BARDT, or BART, a poll-town of Germany, in the duchy of Pomerania, situated in a small bay on the Baltic, 6 leagues west from Stralsund. It belongs to Sweden. N. lat. 54° 20'. E. long. 13° 20'.

BARDUBITZ, or BERNBUDITZ, a town of Bohemia, in the circle of Chrudim, celebrated for its manufactories; seated on the Elbe 6 miles north of Chrudim.

BARE, in a general sense, signifies not covered. Hence we say, bare-headed, bare-footed, &c.

The Roman women, in times of public disfrets and mourning, went bare-headed, with their hair loose.

Among Greeks, Romans, and Barbarians, we find a feast called nudipedia, at which persons were to attend bare-footed.

The Abyssinians never enter their churches but bare-footed; nor on account of Moses, who was commanded to put off his shoes on mount Sinai, but in reverence of the place; as is also done by them in entering the palaces of kings and great men.

Sagittarius has a dissertation on those who went bare-footed among the ancients, "De Nudipedibus Veterum;" wherein he treats of such as went bare-footed in journeys or otherwise, either out of choice or necessity; also of bare-footed religious mourners and penitents, who went bare-footed; and, lastly, of the bare.

BARE, in respect of Manufacture. A cloth is said to be bare or naked when the nap is too short, as having been thrown too near, or not being sufficiently covered with wool by the teasel.

BARE is also used for a sort of bowing ground, not covered with green swarth.

Bare-footed Carmelites, and Augustines, are religious of the order of St. Carmel, and St. Augustin, who go without shoes like the Capuchins.

There are also bare-footed fathers of mercy. Formerly there were bare-footed Dominicans, and bare-foot mons of the order of St. Augustin.

Bare-footed Trinitarians. See Trinitarian.

Bare-footed under, in Sea Language, expresses the flate of a ship, when she has no sail set.

Bare-footed Pump. See Pump.

BARE, in Geography, an island in the Southern Pacific ocean, near the east coast of New Ireland. It is high land, not fertile, but inhabited; situated in S. lat. 59° 57'. and S. S. W. from cape Kidnappers.

Bare Haven, lies on the coast of Nova Scotia, in North America, about 3 leagues S. W. from cape Cano. It is sheltered by an island off the point called White point.

BAREA, in Ancient Geography, a town of Spain, upon the Iberian sea, in the country of the Bureis. Ptolemy.

BARET, in Geography, a province of Hindoostan, in the country of Lahore, between the rivers Ranaee, Beyah, and Setlodge.

BAREGE WATERS, in the Materia Medica, are celebrated for their hot springs, situated in and near the village of Barege, on the French side of the Pyrenees, at the foot of the lofty mountains. There are four principal hot springs in this place, which differ, however, very considerably in temperature, the highest being about 130° Fahr. and the lowest about 73°. This variety of heat gives every convenience for bathing, drinking, and topical application. Chemical analysis shows in this water a quantity of sulphur, in the form of sulphated hydrogen, united to a small portion of soda, a little common salt, and a kind of fliny bituminous matter. The sulphur and the soda, together with the heat, may be considered as the active ingredients, but the quantity of them is very small; as the water scarcely exceeds distilled water in specific gravity.

The waters of Burege are remarkable for a smooth foamy feel, and they give suppleness and smoothness even to dead skin that is immersed in them. They are used chiefly as a drenchent and detergent bath, in resolving indolent tumours and rigidity of the joints left by gouty or rheumatic affections. They are also of great advantage in cutaneous diseases. Internally taken, the water gives relief in disorders of the stomach, heartburn, indigitation, cholic, and also in several calaneous affections of the urinary organs. Sauners on Mineral Waters.

BARETH, BARTHE, or BATURE, in Geography, a town of Germany, in Franconia, in the margravate of Culmbach. It is the capital of the principality, and often called the principality of Bureath. Its palace, which was burnt down in the year 1773, was again rebuilt in a beautiful style. It has one Calvinist, and two Lutheran churches, a Roman Catholic chapel, a public school, a foundling hospital, and an academy, founded in 1722 by the margrave Frederic, besides the college. In 1430, this town was burnt down by the Hussites. It belonged to the prince of the house of Brandenburg, the last of whom dying in 1782, it descended to the king of Prussia. Near the Fichtelburg, Bureath produces a variety of beautiful marbles, and some curious minerals. The principality of Bureath is also known by the name of Culmbach; and, with Onolfsbach, forms the capital power in Franconia, now annexed to the sovereignty of Prussia. N. lat. 50° 0'. E. long. 11° 50'.

BARELLY, in the county of Hindoostan, in the province of Oude; 41 miles S. E. of Lucknow.

BAREN, a river of Germany, which runs into the Roer, near Schwert, in the county of Mark, and circle of Wellphalia.

BAREN, a town of Switzerland, in the Valais, 25 miles east of Sion.

BARENA, in Ancient Geography, a town of Asia, in Media, near Ecbatana. Steph. Byz.

BARENFLAS, in Geography, a town of Germany, in the circle of Upper Saxony; and county of Erzgeburg, 2 miles west of Altenberg.

BARENSTEIN, or BERNSTEIN, a town of Germany, in the circle of Upper Saxony, and margravate of Meissen, 17 miles south of Dresden.

BARENT, DITTERICK, in Biography, a painter of history and portrait, was born at Amsterdam in 1554; and having received early instruction from his father, travelled to Venice, where he was admitted into the school of Titian, and became the favourite disciple of that inimitable master. With
With Titian he continued several years, and painted a portrait of him, which gained him great reputation; and he was singularly successful in imitating the touch, the manner, and the style of colouring, peculiar to that excellent genius. Upon his return to his own country, he was very much employed in works that added to his honour; but the composition, which contributed more than any other to establish his fame, was the picture which represented the fall of Lucifer, containing a number of figures, naked, well contrasted, and excellently coloured. He died in 1752. Pitkington.

BARETTI, in Geography, a town of France in the department of the Lower Seine, 3 leagues N.W. of Rouen.

BARENTON, a town of France, in the department of the Channel, and chief place of a canton in the district of Mortain, seated at the source of the Ardèche, containing about 2000 inhabitants, and distant 7 leagues E.S.E. from Arras, and 14 S.E. of Mortain.

BARETSUND, a sea-port town of Sweden, in the province of East Gothland, between Norderkoping and Soderkoping.

BARETTI, Joseph, in Biography, was the son of an architect of reputation, and born at Turin about the year 1716. He received a good education, but squandered his patrimony in gaming. Being of a rambling and debauched disposition, he was frequently reduced, notwithstanding his talents and literary character, to circumstances of distress. In 1748, he was employed at Venice in teaching the Italian language to some English gentlemen; and in 1750, at the instigation of Lord Charlemont, he visited England, which was the place of his future residence. Possessing a wonderful facility in acquiring the knowledge of languages, as well as a critical acquaintance with his own, his talents were well adapted to the profession of a teacher of languages, in which he engaged. In 1753 he wrote a treatise in English, which was "A Defense of the Poetry of his native country against the censures of Voltaire." About this time an acquaintance commenced between Baretti and Dr. Johnson, which was kind and cordial on the part of the latter, and respectful in the highest degree on the part of the former. As he had acquired reputation by some works which he had published on the Italian language and literature, he availed himself of his friend's English dictionary to compile a dictionary of the Italian and English languages, which first appeared in 1760, and which maintains its superiority over all other works of the same kind. In this year he visited his native country, with some prospects of preferment, in which he was disappointed; but on his arrival, he published at Venice a periodical work, intitled "Frutti Letterari," under the character of an old complaining souldier who was returned to his country after long absence. His criticisms, however, in this work, which met with great success, were so severe, that he was obliged to leave the country; and after an absence of five years, he returned through Spain and Portugal to England. In 1763 he published "An Account of the Manners and Customs of Italy," intended chiefly as a reply to the severe strictures of Mr. S. Sharp, the surgeon, in his "Letters from Italy." By Dr. Johnson he was introduced into the family of Thrale, both as a teacher and a literary guest. In 1769, he visited Spain, probably intending to complete his account of a tour in that country. Soon after his return, an accident occurred, which was followed by very distressing consequences. Having engaged in an angry altercation with a woman of the town in the Hay-market, he was assaulted by three men, who insulted and jolted him. Alarmed for his life, Baretti took out of his pocket a French deft knife, and attacked one of the assailants; and unfortunately piercing the contest and repeating the blows, he inflicted wounds which proved fatal. He was arrested and tried for murder at the Old Bailey. In this trial the public were much interested; and a number of men of the first literary eminence appeared to bear testimony to Baretti's character; among whom were Johnson, Burke, Garrick, Goldsmith, Reynolds, and Smollett. The event was the acquittal of Baretti; but the charge very materially affected his reputation. In 1770 he published his "Journey from London to Genoa, through England, Portugal, Spain, and France," 4 vols 8vo. which was deservedly well received; and he continued publishing introductory works for the use of students in the Italian and some other modern languages. Although he had been domiciled in the family of Mr. Thrale, he left it in 1776, in disgust, and by this sudden act of whim or ill-humour, involved the latter part of his life in many inconveniences and difficulties. His attempt, in 1779, for introducing to the public a classical entertainment, which was the "Carmen Secundum" of Horace set to music, failed of success. Reduced to a state of precarious circumstances, he obtained under Lord North's administration a pension from government of 80l. 5s. to meet the urgent of public wants, this fell into arrear, and Baretti could scarcely preserve himself from absolute indigence. His last performance was published in 1786, and was intitled "Tollesdon: Speeches to John Burke about his edition of Don Quixote; together with some account of Spanish literature." Oppressed by anxiety and uncertainty of mind, and with a constitution impaired by fits of the gout, he died on May 6th, 1788. Baretti, although he had a rough and somewhat cynical appearance, was formed for society, and his conversation was instructive, particularly to young persons, with whom he had much intercourse. Having lived much in the world, and having had no opportunity in early life of acquiring fixed principles, he indulged a considerable laxness and freedom of opinion. However his integrity was unimpeached, his morals were pure, and his manners were correct. His charity had no bounds, and by the impiudence with which he exercised it, he was himself involved in difficulties. His literary talents, though not of the highest order, were useful and agreeable. "I know no man," said Dr. Johnson to Boswell, "who carries his head higher in conversation than Baretti; there are strong powers in his mind; he has not, indeed, many hooks, but with what hooks he has he grapples very forcibly." Boswell's Life of Johnson. Europ. Mag. for 1789. Gen. Biog.

BAREUX, in Geography, a town of France, in the department of the Lower Pyrenees, and chief place of a canton in the district of Mauleon, 5 miles south-east of Mauleon.

BAREX, in Law, a fee of 20 pence, which every person acquitted of felony pays the gaoler.

BAREX, in Geography, a sea-port town of France, in the department of the Channel. It had formerly a good harbour and a considerable trade; but in consequence of neglect, the harbour is choked with sand, and the trade decayed. Cape Barex is 6 leagues east from Cherbourg, in N. lat. 49° 40'. W. long. 1° 17'.

BARGA, a town of Italy, in the duchy of Tuscany, on the river Se chio, 2 leagues from Lucca.

BARGAIN, in a General Sale, a contract either for the sale, purchase, or exchange of a thing. The word is formed from the French bargaigner, to bargain or haggle. He that sells is the bargainer, and he that buys the bargained.

BARGAIN and Sale, in Law, is properly a contract made of
BAR

of manors, lands, and other things, transferring the property thereof from the bargainor to the bargainee, for a consideration in money: or, it is an instrument by which the property of lands and tenements is for valuable consideration granted and transferred from one person to another. It is called a real contract upon a valuable consideration, for parting of lands, tenements, and hereditaments, by deed indented and enrolled. 2 Inst. 672.

It is a good contract for land, and the fcc paffes, though it be not paid in the deed, to have and to hold to him and his heirs, and though there be no livery and seisin given by the vendor, so it be by deed indented, sealed, and enrolled, either in the county where the land lies, or in one of the king's courts of record at Westminster, within six months after the date of the deed.

This manner of conveying lands was created and established by the 27 Hen. VIII. c. 10. which executes all uses raised; and as this introduced a more secret way of conveying than was known to the policy of the common law, therefore the enrolment of the deed of bargain and sale was made necessary by the 16th chapter of that statute. The objects of this provision evidently were, first, to enforce the contracting parties to ascertain the terms of the conveyance by reducing it into writing; secondly, to make the proof of it easy, by requiring their seals to it, and consequently the presence of a witness; and lastly, to prevent the frauds of secret conveyances, by substituting the more effectual notoriety of enrolment, for the more ancient one of livery. But the latter part of this provision, which, if it had not been evaded, would have introduced almost an universal register of conveyances of the freehold, in case of corporeal hereditaments, was soon defeated by the invention of the conveyance by lease and release, which sprung from the omission to extend the statute to bargains and sales for terms of years: (See 8 Co. 93. 2 Ro. Abr. 204. 2 Inst. 671.) and the other parts of the statute were necessarily ineffectual in our courts of equity, because those were still left at liberty to compel the execution of trusts of the freehold, though created without deed or writing. The inconveniences arising from this insufficiency of the statute of enrolments are now in some measure prevented by the 29 Car. II. c. 3. which provides against conveying any lands or hereditaments for more than three years, or declaring trusts of them, otherwise than by writing. 1 Inst. 48 a. n. 3. See Blackett. Com. vol. ii. p. 338. Jacob's Law Dict. by Tomlins. Art. Bargain and Sale.

Bargains, in Commerce, are of divers kinds: verbal, those made only by word of mouth, and giving earnest; written, those where the terms are entered in form on paper, &c.

At Amsterdam they distinguish three kinds of bargains.

Bargains, Conditional, for goods which the seller has not yet in his possession; but which he knows have been bought for him by his correspondents abroad, and which he obliges himself to deliver to the buyer, on their arrival, at the price and the conditions agreed on.

Bargains, Firm, those wherein the seller obliges himself to deliver to the buyer a certain quantity of goods, at the price and in the time agreed on.

Bargains, Optional, those wherein a dealer obliges himself, in consideration of a premium received in hand, either to deliver or take a certain quantity of goods at a fixed price, and within a time limited; but with a liberty, nevertheless, of not delivering or not receiving them, if they think proper, upon forfeiture of their premium.

Bargains, Forbidding, are those, wherein goods are bought in order to be delivered at a certain time afterwards, some part of the price being advanced.

BARGASA, in Ancient Geography, a town of Afa, in Caria, seated at the bottom of the gulf called Ceramicus.

BARGAZAR POINT, in Geography, a cape on the coast of Iceland. N. lat. 66° 18'. W. long. 16° 38'.

BARGE, in Navigation, a kind of flat, or pleasure-boat, or large luggage-boat, used chiefly in the navigation of rivers which lead to great cities.

Barges are of various kinds, and acquire various names, according to the variety of their uses and structure: as,

A company's barge,  A Severn trough,
A row barge,  A Were barge,
A royal barge,  A light boreman,
A joint barge,  A Wye-country barge.

A barge differs from a bark, as being smaller, and used only on rivers; whereas the latter goes out to sea.

There are also barges, belonging to men of war, serving to carry generals, admirals, and chief commanders.

Sailing barges are vessels with one mast, and sometimes a bowsprit. Those that have boom-fails, are rigged like fishing-boats; but, having few hands on board, the boom and gaff are more easily hoisted or topped, the power being increased by the addition of blocks. Sailing lighter or barges, with a sprit-main-fall, rig with a sprit-yard at the head of the sail, hanging diagonally to the mast. Some large barges have vangs like a ship's mizen, and a down-hauler at the peak-end of the sprit-yard. Large barges have a fore-fall, jib, cross-jack-yard, and top-fall, similar to those.

Barge, or Barges, in Geography, a town of Piedmont, in the district of the 4 Vallies, 7½ miles south of Pine-rola.

Bargh-Bune, in Ornithology, Buffon's name of the duffey snipe;  folopex fusca, Gmelin.

Barge Blanche, is likewise a name assigned by Buffon to the white avocet, recurvishifa alba, Gmelin.

Barge le Chatel, in Geography, a town of France, in the department of the Ain, and chief place of a canton, in the district of Pont-de-Vaux, 4 leagues W.N.W. of Bourg-en-Bresse. N. lat. 46° 19'. E. long. 4° 49'.

Bargé-Couples, in Architecture, a beam mortised into another, to strengthen the building.

Barge-Charse is used by workmen, to signify a part of the tiling, which projects over the gable of a building, and is made up with mortar.

BARGEMON, in Geography, a town of France, in the department of the Var, and chief place of a canton in the district of Draguignan, 2 leagues N.N.E. of Draguignan.

BARGH, is used in some places of England for a deep horse-way up a hill.

It seems to come from the German bargh, a hill.

Bargh-Master, Barner, or Bar-Barger, in the Royal Mines, the steward or judge of the barghmote.

The word is formed of the German barg-mäster, q. d. master of the mines.

The bar-master is to keep two great courts of barome yearly, and every week a small one, as occasion requires.

BARGHMOITE, or Barmote, a court which takes cognizance of causes and disputes between miners.

Some suppose it thus called from a bar, at which the suitors appear; others, with more probability, derive the word from the German long, a mine.

By the custom of the mines, no person is to sue any miner for ore-debt, or for ore, or for any ground in variance, but only in the court of barghote, on penalty of forfeiting the debt, and paying the charge at law.
BAR

BARGIACIS, in Ancient Geography, a town of His-pania Tarraconensis, situated in the inner part of the country, and in the territory of the Vacceaeans. Ptolemy.

BARGIE, in Geography, the name of a barony in the southern part of the county of Wexford, province of Lein-ster, Ireland, which, with the adjoining one of Forth, was peopled by the followers of earl Strongbow. The language used there is said to be a broken Saxon, more like Flemish than English, and not one in a hundred knows any thing of Irish. "They are evidently," says Mr. Young, "a distinct people, and I could not but remark that their features and cast of countenance varied very much from the common native Irish. The girls and women are handsonse, hav- ing much better features and complexions. Their industry is superior to that of their neighbours; and their better living and habitations are also distinctions not to be forgotten. The poor have all barley bread and pork, herrings and potatoes. On the coast there is a considerable fishery of herrings. Both men and women wear straw hats, which give them a comic appearance. The inhabitants are reckoned more industrious and cleanly, and better farmers than in any other part of Ireland; but Mr. Young found their fylle very defective. The farms were in general from 20 to 80 acres at an average rent of a guinea per acre. The soil is light, and being extremely well tilled, produces large quantities of barley. Young's Tour, and Larouey's Ramble through Ireland.

BARGOSA, in Ancient Geography, a town of India, which was the country of the philosopher Zarmanochegas, who committed himself to the flames in the presence of Augustus, according to Strabo.

BARGOTA, in Geography, a town of Spain, in Na-varre, 6 leagues from Ezella.

BARGULIA, or BARGULUS, in Ancient Geography, a place of Illyria, in the neighbourhood of the people deno-minated Parthini, which Philip ceded to the Romans by a treaty, 204 years before the vulgar era.

BARGUS, a river of Illyria, both sides of which were inhabited by the Scordiæs; it discharges itself into the Ilfe, according to Strabo. Pliny says, that a river of this name flowed into the Hebrus.

BARGUSI, an ancient people of Spain, to whom envoys were sent from Rome to solicit the Spaniards to take part with the Romans rather than with the Carthaginians. They inhabited the interior of Spain, on the other side of the Ebro; and were subdued by Hannibal. Livy, i. xxi. c. 10. 23.

BARGUSIN, in Geography, a town of Siberia, in the province of Norththink, in the government of Irkutsk, formerly an olrog, now a circle-town, on the right bank of the river Bargusan, 20 versts above where it falls into the Bargusinian bay of the Baikal, 53° lat. 127° long. 524 versts north-east from Irkutsk. It is chiefly remarkable on account of the baths in its district. They were discovered in a wild region at the distance of eighty versts from any habitation. M. Grand, surgeon to a regiment quartered in those parts, having successively prescribed the use of these baths to se- veral patients, M. Von Klitha, the governor of Irkutsk, in 1779, caret some buildings to be erected there. They have proved of great benefit to persons afflicted with rheu-matism, fevers, phthisis, and other complaints of a like nature. The water is drank either pure, or, on account of its nauseous taste resembling that of rotten eggs, mixed with milk. It promotes perspiration, does not unquench thirst, and may be drank in large portions. When boiled, it is of a very agreeable taste, and is particularly good with tea.

BARGYLA, BARGYLLA, or BARGLEA, in Ancient Geography, a town of Ais Minor, in Caria, near Japh and Minus. It is mentioned by Pliny, Strabo, and Pto- lemy. It was situated near the Meander, south of Miletus. M. d'Anville places it north-east of Halicarnassus, on the gulf called Iaflus.

BARGYLIUS, a mountain of Phœnicia, on the confines of Syria, on the way towards Antiochene. It was situated north of mount Libanus.

BARI-NAGASH, in Geography. See Baharna- gash.

BARI, a sea-port town of Italy, in the kingdom of Naples, on the coast of the Adriatic; once the capital of a province of the same name, and seat of an archbishop. It is well-built, populous, and has a good trade. The harbour was almost destroyed by the Venetians. 120 miles E.N.E. of Naples. N. lat. 41° 31'. E. long. 17° 46'. It contains, says Swinburne, about 6,000 persons.

BARI, or Terra di Bari, a province of Naples, deriving its name from its capital. It is bounded on the north and north-east by the sea, on the east and south-east by the province of Otranto, on the south by the Baflolena, and on the west and north-west by the Captana. It is about 62 miles long, and its mean breadth is rather more than 20 miles. It produces corn, wine, oil, cotton, flax, and fucr; and the coast is guarded against the corsairs by sixteen towers. Its sea-ports are Barletta, Trani, Bari, and Molfetta; its mountains are Sanazzo, Femina Marta, Lapi-lo, Franco, and St. Agostino; and its rivers are Olanzo and Cane. The extent, according to Swinburne, is 869,097 moggies, 5 moggies being equal to 4 English acres; and he states the number of its inhabitants to be 281,048. The city of Bari is the ancient Barium; and coins struck by its principal magistrates still exist. The Lombards, Greeks, and Saracens disputed the possession of this city in the ninth century. In the tenth, it refle to diiission on becoming the residence of the Greek cattapan or vicerey, and of a metropolitain bishop. The book of constitutions, compiled for the judicial government of the province, and full in use, is a respectable voucher for the importance and policy of Bari during the middle ages. About the year 1000, Bari became the scene of conspiracies and revolutions. Melo confrated against the Greek emperor in this place; but it retained its subjection to the eastern emperor, and was one of the last and firmest supports of his dominion. In 1067, Robert Guiscard invaded it by sea and land, and enclosed it by a semicircle of ships joined together by chains and hovens, in order to prevent its obtaining succours. This blockade lasted four years. Earl Roger afterwards joined his brother with a strong fleet, defeated the Imperial squadron sent for the relief of the city, and made its admiral prisoner; upon which Bari opened its gates to the conquerors. A citadel was erected by king Roger for securing the allegiance of this town, but it was hardly finished when Lombaris razed it to the ground. At this time, Bari was a populous and strong place. It was afterwards treated with great severity by William the Bad, who levelled the dwellings of the inhabitants who joined in the grand rebellion against him to the ground. The city, however, must have risen feordly out of its ruins, as the emperor Frederic establisned an annual fair here in 1134. About 1138, he ordered the town to be destroyed, by way of punishing the inhabitants for treasourable practices. Bari frequently changed its proprietors, till it was settled by Alphonius the second upon the family of Sforza, in consideration of the marriage of his daughter Isabella with the duke of Milan. According to treaty, these states became the property of Bona, queen of Poland, at whose death this duchy returned.
to the crown, to which it has ever since remained annexed.

BARIANA, in Amanti Georaphy, a town of Asia, in Mesopotamia. Hill.

BARIARED, in Geography, a town of Peritas, in the province of Kerman, 19 leagues S. W. of Sirjan.

BARIEL, or Barnacle Point, is the south-eastern limit of Winthrop's bay on the north-east coast of Antigonus Island, and on the west side of the channel into Parham Harbour.

BARILLA, or Barilla, is the term by which the impure mineral alkali from the coasts of Spain and some other parts of the Levant is known in commerce. From Alicanta and the coasts of the province of Murcia is the most esteemed. It is brought over in the form of hard brown specked porous masses almost without smell, and tasting strongly alkaline. It is procured by burning to ashes several plants growing on the sea-shore of the species of Salina and Kali. For the particulars of this manufacture, see the article Soda. The term Brilho tortilla is also applied sometimes to Kelp, a much more impure sod, and sometimes, though improperly, to parsley, or the ashes of plants containing parsley, the vegetable alkali.

BARILLARIUS, an ancient officer in monasteries and great households, who had the care of the cauls and vessels of wine, &c. in the cellars.

BARILLOVITZ, in Geography, a town of Croatia, on the river Korana, 10 miles south of Carlsbad.

BARIN, a town of Asiatic Turkey, in the province of Natolia, 12 miles south of Amasiah.

BARING OF TREES, in Agriculture. See Ablaqueation.

BARJOLS, in Geography, a town of France, and principal place of a district in the department of the Var. The town is populous, and situated in a pleasant country; 9 leagues north of Toulon. Lat. 43° 35'. Long. 5° 23'.

BARIQUISOMETO, a river of North America, in the country of Terra Firma, which runs into the Oroonoke.

BARISSOGLEBSK, or Borissolegbe, a town newly created by Catharine II. in the province of Yaroslaf, is situated on the Volga, 57° 30' lat. 57° 9' long. has 4 brick, and 417 wooden houses, 2076 inhabitants, and a brick church. The trade of this town consists in the production of the fishery and several manufactures of hardware, chiefly pots and kettles. The home and foreign trade together amount nearly to 60,000 rubles. There is also a small town of the same name, situated 59° 50' lat. and 60° long. on the Khoper, in the governorship of Tambouf, consisting of 400 timber-houses, and 804 male inhabitants, several of whom are shop-keepers. It has two timber churches. The merchants a few years since invented themselves in the regitters as pellissiers of a capital of only 13,126 rubles. Here is a celebrated distillery.

BARITONO, in Muffs, a voice of low pitch, between a tenor and base. The term is formed of two Greek words κούς, grave, and ρως, tone. But those who are not partial to base voices, rather choose to derive the word from the Italian verb barrire, to bray.

BARK, in Vegetable Anatomy, is a term by which is commonly understood the external part of vegetable bodies; which is separable from the other parts of the plant without much difficulty, during the season of vegetation; but at other periods requires maceration in water, or boiling, and when detached by any of these means, the finer connexions which unite it to the wood are necessarily detached.

When bark is thus separated, and subjected to microscopic examination, it exhibits parts differing much in structure and use. These have been divided by anatomists into the epidermis or cuticle, the cellular envelope or parenchyma, and the cortical layers and liber.

The Epidermis is situated most externally, and gives a covering to every part of the vegetable body, except the authors and pistils of flowers. Its texture is varied not only according to the species of plant to which it belongs, but also by the different parts of the same plant; thus, it is strong, dry, and unyielding, upon the roots and trunks of trees; commonly smooth, gljdy, and flexible upon leaves and flowers; and sometimes it is villous, or covered with fine projecting procelles like hairs.

The most usual colour exhibited by the epidermis is that of brown upon the younger branches, and an ash colour upon these parts of the plants which are most aged; it is however white and shining in the birch, red and silvery in the cherry-tree, and brown upon the horse-chestnut and apple-tree &c. The epidermis is not withstanding, in all cases, a transparent membrane, and derives its colour from the substance which is placed immediately behind it, in the same manner as the colour of the skin of animals is produced by the existence of the mucous membrane.

In order to examine the epidermis of vegetables with success, it is necessary to detach it from the cellular tissue, upon which it is immediately applied. This is not difficult to perform, when the plant is full of sap, at which time the epidermis may be removed by a fine knife or lancet; but at other periods it must be submitted to a previous maceration in water before it will separate. When a portion of the vegetable cuticle is thus obtained, it should be inspected under water or spirits, and if viewed with a lens of moderate power, it exhibits the appearance of a plexus or reticulum, of which the meshes are not vacant, but filled by a fine pellicid membrane, as may be seen in Fig. 1 of Plate I. in Vegetable Anatomy; and the fibres composing the reticulation appear more condensed in some places than others, as represented by the letters a a. Hill describes the cuticle of plants as a triple membrane, or three plisuses laid the one upon the other. He observed, by employing high magnifying powers, that these plisuses were of regular forms; that what appeared as fibres in the perpendicular direction were longitudinal vessels, and that the spaces left between these vessels were oblong cells, close at their bottom, but opened at the top; and that the junction of the cells occasioned the appearance of transverse lines; and thus the reticulation was rendered complete. He even professed to have injected these vessels, by procuring an absorption of a solution of the corrosa acetata, or sugar of lead, and afterwards making it visible by adding a mixture of lime and operaum; and in other instances he filled the longitudinal vessels by the absorption of the texture of cochinille. The description, which has been given of the epidermis by Hill, does not appear, however, to deserve much attention, as it differs so much from that of other writers. It is indeed true, that Du Hamel and others have observed a second epidermis under the first, which appeared more green, fresher, and succulent; and that on these trees which frequently call the cuticle, as the birch, cherry-tree, &c. there is a succession of layers; but this does not prove that the epidermis is not a single membrane when first formed, and that where there are more layers than one, each is a perfect cuticle, proceeding in its turn to be exfoliated or call off. This mode of separation resembles what takes place in animals, especially in some reptiles, which have the new cuticle perfectly formed, before the old one is parted with. Upon the trunks of most trees which are dioecious, the successive layers of epidermis continue to adhere together; each of these cracks and gives way as the tree increases in thickness, and hence the deep efts which always appear in the bark of trees of any age. The several laminae, which
are in this manner left surrounded by the cracks, are larger or have more extent, the nearer they approach to the wood, in consequence of the most external epidermis having first yielded to the growth of the tree.

No subject has occasioned greater controversy amongst vegetable anatomists, than the mode in which the cuticle of plants is formed. It was the opinion of Malpighi and Grew, that the epidermis was produced by the last leaves of the cellular envelope, in consequence of their exposure to the air; but if the cuticle was formed by the dehydration of the cellular tissue, it would not admit of that extension which takes place in all circumstances to a certain degree, and which is so remarkable in the cuticle covering leaves, flowers, and fruits, and all parts of which the growth is rapid.

Several other circumstances might be mentioned to show that the epidermis can be produced by the drying of the cellular substance; thus when it is wounded or destroyed, and the part perfectly isolated from the action of the air, a new epidermis is soon formed without any exfoliation. The cuticle is in some instances formed, and in others continues to grow, under circumstances entirely beyond the agency of heat and evaporation, as may be observed in the fleshy plant, and its appendages, and the internal surfaces of buds, &c.; but although the epidermis does not appear to be the cellular tissue simply dried by exposure, it is sufficiently plain that it is the continuation of the same membrane which forms the cellular envelope.

According to the latest observations made on this subject by Mirbel, who is one of the most ingenious vegetable anatomists of the present time, the lines which give the reticulated appearance to the epidermis, correspond in figure with the cells of the parenchyma, and are really the termination of the septa of these cells in the cuticle. (See fig. 2. Plate I. Vegetable Anatomy.) The tubular tissue, which in some cases is perceived upon the superincumbent plants, enters also into the composition of the epidermis, as represented in fig. 3. Plate I. Vegetable Anatomy. These small tubes are however, upon close inspection, found to be composed of cells very much elongated, from whence it would appear, that the cellular substance is alone fitted for producing the epidermis of vegetables. The manner in which the cellular tissue is converted into cuticle, is probably beyond the reach of investigation; but that it is not the mere result of exposure to the air, is sufficiently plain from the facts already noticed. Like many other of the changes and operations of organic matter, we are unable to discover its immediate efficient cause, and in such cases, we must be content with observing the phenomenon, and slating it as the effect of a law of the system.

The growth of the cuticle is subject to considerable variety, according to the plant to which it may appertain, or the different parts of the same vegetable: thus, on leaves, flowers, fruits, &c. we do not meet with the successive layers of dead epidermis that exist upon trunks and branches. Some vegetables again have greater accumulations of dead cuticle than others; some get rid of these by repeated exfoliations; the plantain calls its cuticle every year; the epidermis of herbaceous plants and those which are perennials, is always most delicate in its structure.

The epidermis presents no peculiarities in the monocotyledons, or those plants with one seminal leaf. The uses of the external or cellular portion of the bark have been much controverted, although many of these are exceedingly obvious: it is evident that it serves as a defense to the whole surface of the vegetable; and accordingly we find its composition and strength dependent upon the functions which each part of the plant performs, and the injuries to which it is liable; on the roots it is tough and flexible; on the trunk rough, thick, and unyielding; on the leaves, flowers, and such parts as are only to possess temporary existence, and which at the same time exercise important functions, the cuticle is thin, delicate, and soft. The epidermis serves to guard the plant against the effects of weather; it likewise affords to moderate the operation of heat and cold, and thereby contributes to the maintenance of the equality and independence of vegetable temperature; it regulates the action of light upon the cellular tissue, and thus co-operates in the fixation of that subtle matter; but the most important, perhaps, of all its uses is the giving passage both to the fluids absorbed for the nutrition of the plant, and those expelled by transpiration, &c. Besides these known offices of the cuticle, others are ascribed to it. Many authors imagined that it restrained the growth of the whole tree; this however is disproved by the simple experiment of removing a portion of the cuticle, when it has been found that no bar or swelling took place; these trees also which are most distinguished for the cracks of the cuticle, are not observed to grow taller than others. For a further account of the functions of the cuticle of vegetables, see Epidermis, Leaves, Etiolation, Transpiration, Inhalation, and Pores.

The cellular envelope: This was the name given by Dr. Han nob to the cellular substance immediately under the cuticle, in consequence of its extending over every part of the plant; by Grew it was called parenchyma; and Mirbel, who has already noticed, has with propriety made a distinction between the cellular tissue immediately next the cuticle, and that which is continued into the cortical layers; the first he terms the herbaceous tissue, the other the parenchyma.

The herbaceous tissue is a composition of cells of an hexagonal figure, so applied to each other that each of the sides affords in forming the parietes of the adjoining cell, precisely like the construction of a honey-comb. The membranes composing these cells are extremely fine and transparent. See fig. 4. Plate I. of Vegetable Anatomy, in which the cellular structure is highly magnified, and also some foramina or pores, which establish a communication between the several apartments. These pores are not above the 500th part of a line in diameter. In some instances, the cells are elongated, especially in the parenchyma of the monocotyledons, which is exhibited in fig. 5. of Plate I.; and it is remarkable, that in proportion as the vessels become elongated the pores of communication are more frequent and regular. In some cases, where the cells are very much elongated, they are arranged in rows succeeding each other by intervals, which are perfectly regular. (See Glands, and Pores.) The cellular tissue has been described, by some writers, as composed of a number of fibres, interwoven like the texture of felt. Hill says it only differs from the epidermis in having its parts more distinct; and Malpighi believed the cellular substance to be made up of distinct vessels, collected together, which he called utricles, but, as we have already said, this is not the case; the whole being one continuous membrane, every part of which enters into the composition of two cells. Grew compared the cellular substance to the bubbles observed upon the surface of fermenting liquors, which is a very happy similitude, as it conveys a very perfect idea of its appearance when only examined with a single lens; but when the highest magnifying powers are employed, the hexagonal figure of the cells becomes evident. The herbaceous tissue is the immediate cause of the colour of the epidermis, and its own colour, again, depends upon that of the fluid contained in the cells, which is usually green, but is sometimes brown, red, yellow, &c. This juice is of a resinous nature, which circumstance would appear, as well as the colour, to be the effect of its continual exposure to the light.
light. It is probable that the sap is originally deposited in the cells, in the state in which it is absorbed, as it is, consisting of water and carbonic acid gas, and that there, by the agency of light, it undergoes a decomposition; the oxygen contained in both the water and fixed air being discharged by the pores of the cuticle, the carbon of the carbonic acid, and the hydrogen of the water producing the oils and the resin. A number of confluences arise from this operation, not only to plants themselves, but to the animal world, which make it the most important proceeds carried on in the vegetable system. See \textit{Respiration, Light, Oxygen, and Transpiration.}

\textbf{Parenchyma.} This part is composed of cells like those described in the herbaceous tissue; indeed, the only difference which exists between these two parts of the cellular substance, is in the colour of their contained fluid; the one being usually green, in consequence of its exposure to the light; whilst the other, not being situated so superficially, is generally found transparent. In other respects, they agree in structure, and appear to be formed of the continuation of the same membrane.

The parenchyma of Mirbel corresponds with the tissue cellular of Du Hamel, the syllepses of Maltzahn, and the parenchymatous syllepsis of Grew; whilst the herbaceous tissue is more strictly the envelope cellular of Du Hamel.

The parenchyma is not confined to the superficial tissues of vegetables; it paves between the fibres of the cortical and lignaceous layers, and forms the pith or medulla; the pulpiness of leaves and petals depends upon its existence; fruits, seeds, and the embro plant, are almost entirely composed of it; bulbous, and other succulent roots, owe their bulk to it; no other structure is observable in the fungi and fungi: in short, the cellular tissue is the first and simplest state of vegetable organization, and serves as the connecting medium between all the parts of the plant.

There is, strictly speaking, no circulation of the juices contained in the cellular tissue; fluids, however, being admitted into any of the cells, easily pass into the neighbouring ones, by means of the small pores of communication, already described.

The texture of the cellular substance is very quickly broken down by maceration, or boiling in water; which circumstance should be recollected in preparing the parts of plants for examination; otherwise the natural connections, which are produced by the cellular tissue, may escape observation.

\textbf{The Cortical Layers and Liber.} When the epidermis and the cellular envelope have been removed, the remainder of the bark appears to be made up of a number of reticulated fibres, containing cellular substance in their interstices; this appearance of the cortical fibres is plain to the naked eye, especially if the cellular tissue, which paves amongst them, be at all dissolved by maceration, or other means; but if examined by the microscope, these fibres become very distinct; their arrangement is then perceived to be regular, and difficult to describe. The fibres in their course, although longitudinal with respect to the plant, are not parallel with each other; each makes a short curve, and thus comes into contact with the one adjoining, with which it usually becomes incorporated or united, and thus produces a plexus or network, which was called by Du Hamel the cortical plexus; sometimes these fibres merely touch each other, and then go off again, to compose another mesh in the plexus, see fig. 6, Plate I. of \textit{Vegetable Anatomy}; and point out the reticulation produced by the fibres, and \textit{abb} the meshes, or spaces left between them. The meshes are not vacant in the recent vegetable, but filled with cellular tissue, which admits of the transverse motion of the fluids in plants. Du Hamel states, that upon examining these fibres by a high magnifying power, each appeared to be a fasciculus, the fibres of which could be again resolved into fibres, and these again might be divided into others, until they became too minute for observation; he, however, as well as other authors upon the subject, suppose the cortical fibres to be vessels. See Vessels.

The cortical layers, as the term implies, are not single, but consist of a number of concentric layers, placed upon each other in such a manner that the meshes of one plexus are situated opposite to those of another. Fig. 7, Plate I. exhibits this circumference as it has been represented by Du Hamel. The cellular tissue passes through all these meshes, and thus produces a kind of intertexture, which will be compared to cloth, calling the longitudinal fibres the warp, and the transverse the weft.

The meshes of the several net-work are smaller, the more internally they are situated; the gradation in this respect is regular from the external layer to the wood, as may be perceived in figs. 8, 9, 10, in Plate I. of \textit{Vegetable Anatomy}. In the more internal plexus, fig. 10, the longitudinal fasciculi are nearly parallel, and to close to each other that the interstices are almost obliterated.

The cortical layers, or net works, are found to increase in number according to the age of the part which sustains them. Thus Du Hamel reckoned only five or six plexuses upon the upper branch of the linden-tree, and seventeen at the base of the trunk of the same tree.

The same disposition of fibres does not exist in all plants; in the lagetto, or the larch bark tree, for instance, the cortical plexus exhibits a texture like gauze or lace. See fig. 11, Plate I. of \textit{Vegetable Anatomy}.

Much confusion may be observed in the descriptions which authors have given of that part of the bark called liber. The name would appear to have taken its origin from the likeness which the cortical plexuses, when partially separated, bear to the leaves of a book; and, conformably to this idea, Grew and others have considered all the cortical layers as belonging to the liber; whilst, on the other hand, Malpighi has given this name to the innermost layer only. The liber is, however, generally allowed to be the most important part of the bark, and is that substance from which the cortical layers are formed. When the bark is stripped off a tree in a state of full vegetation, in a very short time a gelatinous substance is observed to exude upon the surface of the wood; this substance acquires organization, and is converted into a new bark. It was termed \textit{carbium} by Du Hamel; the manner in which it is produced, and its composition, are both unknown, but its high utility in the vegetable economy is proved by some beautiful experiments. This formative or organizing substance is constantly renewed during the period of vegetation, and immediately produces the liber, which is indubitably converted into the layers of bark, and the alburnum, or white imperfect wood, which is next the bark; and hence the accretions of bulk in perennial vegetables, which are made every year, and indicate the age of the tree. That the liber is the immediate source of both the wood and the bark, or the central point or fountain of organization, is proved by two very elegant experiments made by Du Hamel. He separated a portion of the bark of a plum-tree, and made sure that it notified the inner cortical layers or liber; he then removed a similar portion of bark from a peach-tree, and replaced it with the piece taken from the plum-tree. The graft perfectly succeeded; and upon a future examination he found, that not only the grafted bark continued to grow, but that a corresponding portion of wood was produced, which was very distinguishable from the.
the rest of the tree, as it polished the red colour of the wood of the plan-tree, from which the bark had been removed. The other experiment is equally decisive; he passed several flatter wires through the bark of a tree, in the season of full vegetation, some of the wires only went through the parenchyma, whilst others were inserted into the liber; those which had only penetrated the cellular tissue, obeyed the excentric progress of the bark, and as the tree grew came nearer the surface; but the wires which had passed through the liber, were carried towards the centre, and after some years, were found covered with many layers of wood.

The conclusion which Du Hamel drew from these experiments was, that the bark produced the liber, the albummum, and the wood; but it is Mirbel's opinion, that the wood in giving origin to the cambium, produces the liber, which is finally converted into both the bark and wood. For the further discussion of this subject, see Cambium, Liber, and Wood.

It should be observed, that the period of vegetable existence depends upon the power of the plant to produce the cambium, and consequently the liber; accordingly, in herbs, most of which do not survive one or two years, the successive layers which characterize the wood of trees, are not to be seen.

Hitherto we have been describing the arrangement of the cortical layers, in the Dicotyledons; in those plants, however, which are called monocotyleans, or having one leafy leaf, the disposition of these parts is very different; only the cuticle and cellular substance are found on the surface of these vegetables; there are no concentric layers of either bark or wood; the interior of the plant is filled with parenchyma, in which are contained the woody fibres, scattered at irregular distances; the cambium is deposited round each fibre, and there produces the tubular and cellular tissue; the tubular tissue forms all the woody part or albummum, which contracts in thickness, elongates, and is ineffably converted into the perfect wood, and in contrasting is detached from the parenchyma and leaves a vacancy which is presently filled up by a new cambium; each of these fibres, therefore, might with propriety be considered as a distinct vegetable, insomuch as it has the means of an independent growth. See Cambium, Wood, Monocotylean, and Dicotylean. It has already been observed, that some of the more simply organized vegetables, such as the fungi and seculi, do not possess in any of their substance either cortical or woody fibres, but are altogether composed of the cellular tissue.

After the account which we have given of the different parts entering into the structure of the bark, it is unnecessary to insist upon its uses in the vegetable system; in it reside almost all the powers and energies of the plant; wounds only are healed by it; upon the exact contact of the fibres of two trees depends the whole of the success in engraving; and in the bark are prepared not only all the juices and secretions which are required for the fulness and increasement of the plant, but those peculiar substances which are applicable to so many of the purposes of common life and of medicine. See Vegetal, Succa Propria, and Secretion.

Bark, Peruvian, Cortex Peruvianus. The great importance in medicine of the peruvian bark has appropriated to it exclusively the term of the bark. We shall describe it under the botanical and now official name of Cinchona.

Bark, in Agriculture, a substance frequently employed by cultivators as a manure to particular kinds of land.

The bark of trees in general, and particularly that of the oak, becomes an useful manure after it has been employed by the tanner in the preparation of leather. One load of oak bark laid in a heap and rotted after having been thus used, it is said, will do more service to stiff cold land, and its effects will last longer, than two loads of the richest dung. Mr. Miller in his Dictionary observes, that it is much better for cold strong land than for light hot ground, if it be used alone as taken from the tan-yard; because it is of a warm nature, and it will loosen and separate the earth so effectually, that, by only employing it two or three times, a strong soil, not only to be wrought, may be rendered perfectly light and loose; but by mixing it with earth of a nature contrary to that which it is intended to correct, and in a proportion fitted to the nature of the soil on which it is to be laid, it will prove a good manure for almost any sort of land.

And Mottram has even asserted that it will alter and change the very nature of the soil, and turn it into a rich black mould. As it abounds with vegetable matter derived from the tree to which it belonged, and is strongly impregnated with mineral materials by the length of time which it has remained in the tan vats, in contact with the skins and hides of animals, it must necessarily prove beneficial as a manure where judiciously applied.

When laid on grazed land it has been recommended to be spread over it soon after Michaelmas, that the winter rains may wash it into the ground to the roots of the grasses, as when laid on in the spring, it is apt to burn the grass, and, instead of improving it, do considerable injury to that fecon. But when employed on arable land it should be applied and spread before the last ploughing in order that it may be turned down lightly into the soil, the fibres of the corn may easily reach it in the spring; when it lies too near the surface, it has however been supposed to hinder the growth of the crop at too early a period, and to be nearly consumed in the spring, when the nourishment is chiefly wanted for its support.

In his work on gardening and agriculture, Mr. Bradley says, he advised a gentleman to whom a considerable quantity of bark was left, upon the expiration of the leave of a tan yard, to lay some of it upon a piece of stubborn four land; which he did with such success, that his product was admired by all the gardeners and farmers in the neighbourhood. For such soils, he thinks it should be mixed with a sandy mould or earth; and that one third of bark to two thirds of such materials will be a sufficient proportion for clays in general, laying on about one hundred and fifty cart loads upon the acre.

Worlidge remarks, that the barks or rinds of other trees, though not of so high a value as that of the oak, which is the first principally used by tanners, much of necessity enrich either corn or pasture grounds, if broken into small pieces, and laid upon them.

It has been found from experience, that by mixing caustic lime with tanners bark, in the proportion of about two parts of the latter to one of the former, the conversion of the bark into vegetable mould may be greatly promoted, and that the composition when employed as a top dressing for either turnips or grazes proves an excellent manure, promoting the growth of the crops in a rapid manner.

Bark, in Gardening, comprehends the exterior parts or coverings of trees, plants, and vegetables, and also such substances in their dead state after being separated from them, and employed for different purposes.

The bark of trees, &c. is in itself a hard porous texture, and adheres loosely to the liber, or inner bark. It is flasted by Dr. Darwin, in his Philosophy of Gardening and Agriculture, that the barks of the trunks of trees are similar to those of their roots, and may be esteemed a part of them, as they confine an intertexture of the vessels which descend from the plume of each individual bud to the radius of it, and constitute its caulex. The bark of the root
is nevertheless, he says, furnished with lymphatics to absorb water and nutritious juices from the earth, and is covered with a moisened cuticle, while the bark of the item is furnished with lymphatics to absorb moisture from the air, and is covered with a drier cuticle; the latter resembling the external skin of animals and the lymphatics which open upon it; and the former, the mucous membrane of the stomach, and its lacelaxis.

The interior barks of some trees, like the alburnum or roots described above, contain, he thinks, much mucilaginous or nutritious matter; as the bark of elm (ulmus), and of holly (ilex), and probably of all those trees or shrubs which are armed with thorns or prickles, which are designed to prevent the depredations of animals on them, as the hawthorn, gooseberry, and gose, cerasus, ribes, graffallaria, ulex. The internal barks of these vegetables may, he thinks, be conceived to be their alburnum less diluted, and might probably all be used as food for ourselves or other animals in years of scarcity, or for the purposes of fermentation; as he doubts not but the inner bark of elm-trees, detached in the spring by being boiled in water, might be converted by the addition of yeast to small beer, as well as the alburnum of the maple and burch (acer and betula), all which are now suffered to be eaten by insects, when those trees are felled. For the sugar, which is extracted from the vernal sap-fauce of the maple and burch, as well as that found in the manna afs (frauxius ornus), feems, he observes, to refide during the winter months in the root or alburnum, rather than in the bark properly so called, and to become liquefied by the warmth of the spring, or dissolved by the moisture absorbed from the earth and conveyed to the opening buds; but resides solely in the roots of perennial herbaceous plants; and in the economy of grasse, and he fuppofes of the fugar-cane, it is deposited at the bottom of each joint, which is properly at the root of the item above it.

Of the above plants, continues he, the bark of the holly not only yields a nutritious moisened, and thus supplies much provender to the deer and cattle in Newfoord forest, by the branches cut off and dried upon the ground in fevere fATIONS of frost and snow, but contains a refinous material, which is obtained by boiling the bark and washing away the other parts of it. This refinous material pollifies a great adhesiveness to feathers and other dry porous bodies, and has hence obtained the name of bird-line, and much refelines the cerathecum or claffic fhin brought from South America, and also a foffil elastic bitumen found near Matlack in Derbyshire, both in its flaihiness and inflammability. Holles may, he therefore fuppofes, be worth cultivating for this material besides the urch of their wood; as the doctor was informed, that thirty years ago a person who purchased a wood in Yorkshire, feld to a Dutch merchant the bird-line, prepared from the bark of the nume-rous holles, for nearly the whole fum given for the wood; which, if it could be hardened, might probably, he fays, be fold for the claffic fhin above mentioned. Whether this reftemplates the nutritive refinous material found in wheat flour, when the moisened, and flarch are washed from it, might, he thinks, be also worth inquiry.

Other barks contain bitter, refinous, aromatic, or acid materials, which supply the fhips of medicine, as Peruivan bark, cafecharis, cinnamon, and were designed by nature, he fuppofes, to protect those vegetables from the depredations of quadrupeds or insects. Hence, he fays he, many trees, and even the wood of them, after it is dried and made into domestic furniture, is never devoured by worms, as the ma-

hogany, cedar, cypress; and hence many plants, as the fox-glove (digitalis), hounds-tongue (synophiion), heu-bane (ly-scyramus), and many trees, are not devoured by any animals, as their juices would be poisonous to them, or much disagree with their fisms, if their efquifit flavours to the nofe or palate did not prevent their eating them. The fame defence of the vegetable kingdom from human digestion, except those which have, in long periods of time, been fected and cultivated, appears, he remarks, from the relation of some unfortunate shipwrecked travellers, who have paffed some hundreds of miles along uninhabited countries almost without finding an efquifite vegetable production.

Other barks contain refringent or colouring particles, employed in the arts of dying and tanning, as that of the barberry, oak, and as (berberis, quercus, fraxinus). The art of tanning diflings in filling the pores of the animal mucous membrane with these refringent particles found in some vegetables, which are believed to perfec a quality of shortening animal fibres. Thus, when a long hair is immerfed for time in a folution of the bark of oak, or of the galls produced on its leaves by the punctures of insects, the hair is faied to be shortened. Whether this proceed occasioned by the chemical coagulation of the mucus, of which these fibres totally or in part confift, or by capillary attraction tending to diflend these fibres in breadth, and thus to shorten them, as a twisted string is shortened by moisture, has, he fays, not yet been well investigated. By this impregnating the pores of animal skins with vegetable particles they become less liable to putrefaction, as confilling of a mixture of animal and vegetable matter, as well as much better adapted to many domestic or mechanical purposes.

The art of dying diflings likewise in impregnating the pores of dry fibulances with a folution of the colouring matter extracted from vegetables by the capillary attraction of these pores to the coloured folution; and, secondly, by a chemical change of those colouring particles after they have been imbibed, and the water of the folution exhaled, by again steeping them in another folution, which may chemically affect the former. Thus, he fays he, as green diflings of a mixture of blue and yellow, it may be heat produced by boiling the material defigned to be dyed, in a folution of one of thofe colours, as of indigo, and then in that of another, as of the bark of barberry. And as a folution of iron becomes black when mixed with the cold of oak-galls, by being in part precipitated; it is probable that the particles of this combination, of a folution of iron with refringent matter, may be larger than either of thofe particles separately; and, therefore, that if a dry porous fubstance be immersed, in a folution of oak-galls, and, after being fuffed to dry, is thenimmerfed in a folution of iron, the black tinge will penetrate into minuter pores, and thus become more intense than if the fubstance had been immersed in the black dye already prepared.

Other barks are, he adds, used for apparel, paper, cordage, and for many mechanical purpofes, owing to the strength and tenacity of their fibres, or to the fineness of them; as hemp (canabis), flax (linum), for the purpofes of spinning and weaving. The bark or leaves of the papyrus, a flag of the Nile, was, he fays, fift used for paper; and the bark of the mulberry tree is fift made into cloth at Otheite, and other Sothern islands.

The art of separating the fibres of the bark of plants, as they conflit of the candeaces of buds, or the connceting veifes between the plumule and the radicules of them, is, he observes, performed by foaking them for weeks in stagnant water, till the mucous membranes, which connect the
BA R

these fibres, are destroyed by putrefaction; and afterwards by drying them, and beating off with hammers what may still adhere.

These fibrous parts of the barks of trees, as they contain no saccharine matter, like the alburnum, are, he observes, much less liable to decay than the sap-wood, or perhaps than any part of the timber. Maupertius, he adds, who went to Lapland to measure a degree of the meridian, lays, that among the numerous trees which lay upon the ground, destroyed by age, or blown down by the winds, many birch trees appeared whole, owing to the undecayed state of their bark, but crumbled into powder on being trod upon; and that the Swedes took the practice from this of covering their houfes with this unpiercable bark, on which they sometimes lay foil, and thus possesse aerial gardens.

To increase the quantity of bark, it must, the doctor remarks, be remembered, that the leaf-buds, or vitiparous offspring of trees, as they form new buds, acquire new candexes extending down into the ground, and thus increase the bark of the stem in thickness; but the flower-buds acquire no new candexes, but die as soon as they have ripened their seed, and consequently do not increase the thickness of the bark. Whence one method of increasing the quantity of the bark is to increase the number or vigour of the leaf-buds, in contradiction to the flower-buds, which may be done by pinching off the flowers as soon as they appear; and as the bark becomes gradually changed into wood, this may be one method, also, he thinks, of forwarding the growth of timber-trees.

It is added, that the method of preserving the bark of trees from moths consisls in rubbing off that parasite vegetable in wet weather, by means of a hardish brush; which is said to be used with advantage on the apple-trees in the cleyer countries; and may, at the same time, give motion to the vegetable circulation, or forward the acent of their juices aborded by the radical or cortical absorbents. In dry weather, the brush should be frequently dipped in water. Walking the barks of wall-trees by a water-engine, may also facilitate the protrusion of their buds in dry seasons; and might possibly prevent the canker, if applied to dwarfs or espalier apple-trees. Other parasite vegetables must be occasionally destroyed where they occur; as the lichens, fungi, millitoe, with the ivies and other climbers, as some kinds of lonicera, Clematis, and Fumaria, woodbine, virginsbower, and fumitory.

It is further remarked, that when a wound is made in the bark of a tree, it is, as it were, the alburnum to the air, the upper lip of the wound is liable to grow faller downwards than the lower one is to grow upwards, owing to the former being supplied directly with nutritive juices secreted from the vegetable blood after its vegetation, and consequent oxygenation in the leaves; whereas, the lower lip only receives those juices laterally by the inoeration of vessels. Over these wounds the cuticle is liable to project, and to supply a convenient hiding-place for insects, which either eat the new fibres of the growing bark, and perforate the alburnum; or by their moisture, their warmth, and their excrements, contribute to the decay of the alburnum, and prevent the healing of the wound. These dead edges of the projecting bark or cuticle should therefore, it is said, be nicely cut off, but not so as to wound the living bark.

It is remarked, that plasters of lime or tar with sublimate of mercury, have been recommended to preserve the wounded parts from the air, and from moisture, and from infects; but as all these materials are injurious to the fibres of the living bark, they should be used with caution, so as not to touch the edges of the wound, but only to cover the alburnum; for this purpose, white lead and boiled oil, mixed into a thick paint, or with the addition of sublimate of mercury, or of arsenic, or of spirit of turpentine, may probably answer the purpose; and may be of real utility on the wounds of those trees whose wood contains less acrimony, and is therefore more liable to be bored into and eaten by a large worm or maggot, almost as thick as a goose-quill; which is the doctor has seen happen to a pear-tree, fo as to consume the whole internal wood, till the tree was blown down.

In respect to the caution necessary to be observed in not touching the living edges of the wounded bark with such materials as may injure the tree by their absorption, he remembers seeing several young elm trees which died by their holes having been covered, as he was informed, by quicklime, mixed with cow-dung, to prevent their being injured by hares; and he has seen branches of peach and nectarine trees destroyed by sprinkling them, when in leaf, with a light solution of arsenic, and others with spirit of turpentine.

The composition recommended by Mr. Forfith, in his "Treatise on the Culture and Management of Fruit Trees," which is composed of cow-dung, fatte lime, wood-sashes, and river sand, seems however to have been made Use of in those cafes with much advantage, and without any inconveniency having been experienced in this way.

It is further stated, by the author of Phytophylia, that a more curious method of cure is said to have succeeded, where the bark of a tree has recently been torn off, even to great extent; and this is, by binding the fame piece of bark on again, or another piece from the fame tree, or from one of a similar nature, nicely adapting the edges of the bark to be applied to the edges of that which surrounds the wound of the tree, which, it is said, will coalesce, in the same manner as the vessels of the bark of the oak incrusted on; which is strictly analogous to the union of inflamed or wounded parts of animal bodies, as in the cure of the hare-lip, or the infection of the living tooth from one person into the jaw of another.

If the bark, over the cankered parts of apple-trees, adds the doctor, could be thus renewed by paring the edges of the mortified bark to the quick, and then nicely applying a piece of healthy bark, from an apple-tree of inferior value, and securitizing it with an elastic bandage, as a throb of plaster, it would be a very valuable discovery. Another method, where a branch of a valuable tree is in the progress of being destroyed by canker, might, he observes, be by inclining the cankered part, and some inches above it, in a garden pot of earth previously divided, and supported by stakes, and tied together round the branch, which might then strike roots in the earth of the garden-pot, and, after some months, be cut off, and planted on the ground, and might thus be preserved, and produce a new tree; which experiment (the doctor says) he has tried on two apple-trees, and believes it will succeed.

Bark, in its dead state, after having been employed in the vat of the tanner, is found to be a material of great utility for the purpose of constituting those hot-beds in floves and pits contructed for them, that are usually denominated bark-beds, and which from their being much more regular and durable in the temperature of their heat, than thoo formed from dung, become a great deal more convenient and useful for different purposes of the gardener; and are of course employed with much advantage in the growth and culture of various tender and curious exotic
exotics that require the aid of an uniform degree of artificial heat in this climate. See Bark-Bed, and Bark-Pit.

Barks of Trees, (Chemical Analysis of). Since the time that chemists have introduced a considerable degree of minuteness and comparative accuracy in the analysis of vegetable matter, many of the general classifications of medical chemistry have been found inconvenient and liable to error. This is particularly the case when vegetable substances designed for chemical examination, are claffed anatomically, or according to the use which they fulfill in the economy of the plant, rather than the properties which they exhibit under the hands of the chemist. Thus, in the infancy of the barks of trees, scarcely any common chemical character can be assigned to them, as their composition varies in almost every order of plants, and as they partake largely of the qualities of the common juice which circulates in the vegetable. If there is any principle common to all barks, it is (besides water, an invariable ingredient in vegetable matter), the ligneous fibre or infusible woody part, but even in this respect some very important differences occur in the several species which cannot be neglected by the chemist. The substances which render many barks peculiarly interlacing in the arts and in medicine are, Tannin, or the principle which causes several of them to be employed in the art of tanning; Extract, a substance varying considerably in properties, and much used in medicine; and the GaUic Acid, the basis of many of the black dyes and pigments when in conjunction with iron. These principles, however, are not peculiar to barks, but they are all found in other parts of vegetables. We have an example of an excellent analysis of the bark of the Cinchona, by M. FOURCROY, to which article we shall refer the reader who may wish to have a good specimen of the chemical analysis of vegetables.

Barks, general observations relating to. From the experiments of M. Baffo, it appears, that trees flipped of their bark through the whole length of their limbs, die in about three or four years. But it is remarkable, that trees flipped in the time of the sap, and suffered to die, afford timber heavier, more uniformly dense, stronger, and fitter for service, than if the tree had been cut down in its healthy state. Some of a like nature has been observed by Vitruvius and Evelyn. Mem. Acad. Scienc. 1758.

As animals are furnished with a paniculus adiposus, usually replete with fat, which invesls and covers all the fleshy parts, and fercens them from external colds, plants are encompassed with a bark replete with fatty juices, by means whereof the cold is kept out, and, in winter-time, the spicile of ice prevented from fixing and freezing the juices in the vessels: whence it is, that some fort of trees remain ever green the year round; because their barks contain more oil than can be fent and exhaled by the fun, etc. Ray's Wild. of God, &c., part i. p. 103.

The bark has its peculiar dififaces, and is infected with infects peculiar to it. Wounds of the bark often prove mortal. See Canker.

There are a great many kinds of barks in use in the several arts: some in medicine, as the quinquina, or jenait bark, macer, chacarilla, etc. others in dying, as the bark of the alder; others in spicery, as cinnamon, cihtra lignea, etc. the bark of oak in tanning; others on other occasions, as that of birch, of which a kind of birch is used by the Indians for canoes capable of holding twenty four persons.

Of the bark of willows and linden trees is ordinarily made a kind of ropes. The Siamese make their cordage of the bark of the cocoa tree, which is also the cafe in most of the Asiatic and African nations. In reality, flax and hemp, with all their toughnefs, are only the sap-veffels, or ligneous fibres of the bark of those plants.

The ancients wrote their books on barks, especially those of the afi, and tinta or lime-tree; not on the exterior or outer bark, but on the inner and finer, called phylla; which are of durable a texture, that there are manuscripts on it, still extant, a thousand years old.

In the East Indies they manufacture the barks of a certain tree into a kind of fluff or cloth. It is spun and dressed much after the manner of hemp. The long filaments separated from it, upon beating and steeping it in water compose a thread, of a middle kind between silk and common thread, neither so soft nor bright as silk, nor so hard or flat as hemp. See Neumain's Works, p. 426. note. Some of these fluffs are pure bark, and are called pinifiers, leaf-boners, etc. In others they mix flilk with the bark, and call them ginghams and nilas; the fountains too are part flilk, part bark, and are only distinguished by being flipped. The Japanese make their paper of a species of mulberry tree. (See Morus.) In the island of Otaletes, the natives make their cloth, which is of three different forts, from three different kinds of bark; that of the mulberry tree, that of the bread-fruit tree, and that of the cocoa tree. That made of the mulberry is the most white, and worn chiefly by the principal people. It is manufactured in the following manner. When the trees are of a proper size, they are drawn up and flipped of their branches; after which, the roots and tops are cut off; the bark of these rods being then flipped longitudinally is easily drawn off; and when a proper quantity has been procured, it is deposited in some running water to foot, and kept down by hard roncs; when it is fupposed to be sufficiently flipped, the women go down to the brook, and, flipping themselves, fitt down in the water to separate the inner bark from the green part on the out fide; for this purpose, they place the under fide upon a flat smooth board, and with a kind of hell scrape it very carefully, dipping it continually in the water, till nothing remains but the fine fibres of the inner coat. Being thus prepared in the afternoon, they are spread out upon plaitain leaves in the evening, and placed in lengths of about eleven or twelve yards, one by the fide of another, till they are about a foot abroad, and two or three layers are also laid one upon the other; care is taken that the cloth shall be in all parts of an equal thickness, so that if the bark happens to be thinner in a particular part of one layer than the rest, a piece that is somewhat thicker is flected to be laid over in the next. In this state it remains till the morning, when a great part of the water which it contained, when it was laid out, is either drained off or evaporated, and the several fibres adhere together, so that the whole may be railed from the ground in one piece. It is then taken away and laid upon the smooth fide of a long piece of wood, prepared for the purpose, and beaten by the women. The instrument used for this purpose is a square wooden club, having each of its four fides or faces marked, lengthwise, with small grooves or furrows of different degrees of lenuefs; those on one fide being of a width and depth sufficient to receive a small back thread, and the others finer in a regular gradation, so that the last are not more than equal to the thinner silk. They beat it first with the coarse fide of this mallet, keeping time like our smiths; it spreads fast under the strokes, chiefly, however, in the breadth, and the grooves in the mallet mark it with the appearance of threads; it is successively beaten with the other fides, and laid of all with the finest, and it is then fit for use. Of this cloth there are several sorts, of different degrees of finenes, in proportion as it is more or less beaten; and the other cloth
also differs in proportion as it is beaten, and the several cloths differ also from one another in consequence of the different materials of which they are made. The bark of the bread-fruit is not taken till the trees are considerably longer and thicker than those of the mahogany; the process afterwards is the same. Of the bark of a tree which they call "ponor," the "hibicus tiliaceus" of Linnaeus, they manufacture excellent matting; both a coarse fort on which they sleep, and a filler which they wear in wet weather. Of the same bark they also make ropes and lines, from the thickness of an inch to the size of a small packthread.

Bark Indian, Thuriis corte, a medical bark, brought from the East, rolled up like cinnamon, of a dirty color, a warm aromatic, bitter tafe, and pleasant smell; sometimes used in fumigation against fits of the mother.

Bark, Mill. See Mill.

Bark, Grafting in. See Engrafting.

Bark, in Navigation, denotes a little vessel for the sea, usually with pointed or triangular sails, in number two, or three at the mast. The term is usually appropriated by seamen to those small ships which carry three masts without a mizen top-sail. Our northern mariners in the coal-trade, apply the term to a broad-bermed ship, which carries no ornamental figure on the stern or prow. Bark is also a Mediterranean vessel, with three masts and no bow-sprit; the foremost rakes much forward and carries a latten sail; the main-mast is a pole-mast, and carries three square sails, like the palacare; the mizen-mast is small, and carries a mizen and a top-sail. Fishing-barks are small vessels with one mast, used for fihing, &c. by the Spaniards: on the mast they carry a square main-sail, with a jib upon the bow-sprit. Japanese barks are vessels similar to junks, 80 or 90 feet long on one deck, which have only one mast, that carries a square-sail, and forward one or two jibs made of cotton. They only use fihes, when the wind is large. Barks of Cacahoa and limits of Banda are vessels with flitch-decks, high fheer, and sharp forward. They have one mast, and the sail is similar to the Caracores, being long and narrow. These vessels are kept from upsetting by a fort of beams crossing the vessel and bending downwards at the ends, which fllen to a long round or flat piece of timber. Bombay-barks are called Dings. See Plates of Ships.

The word Bark is derived from the Latin Barca; by Fournier, from Barca, a city in Africa; and by Tolentus, from Barcelona.

Some authors use the word bark for any vessel that has no masts.

Bark, Armed, a kind of fire-ship filled with soldiers, used both for making fahies, and to attack galleries, and bar the passage over them.

Bark. Long, is a small vessel without deck, longer and lower than the common barks, being sharp before, and commonly going both with fahs and oars. It is built after the manner of a floop, and in many places is called a double floop.

Barks, Water, are little vessels used in Holland for the carriage of fresh-water to places where it is wanting, as well as for the fetching sea-water to make salt of. They have a deck, and are filled with water up to the deck.

Bark-Bed, in Gardening, that fort of hot-bed which is either wholly or principally constituted of tanner's bark. This fort of bed, from its preferring the most uniform and regular degrees of heat, is found by much the most useful in the propagation and culture of all kinds of tender exotic plants that are brought from warm climates, and which stand in need of the continued attendance of artificial heat in this part of the world. Beds of this nature, with a little trouble in the management of them, are found sometimes to support a pretty uniform and regular temperature for a considerable length of time.

These are the kind of hot-beds that are generally employed in hot-houses, being formed in pits or cavities constructed for the purpose in them, frequently the whole length of the house, fix or seven feet in width, and three in depth, being inclosed by means of brick work. See Bark-Pit.

In these beds, the pots of such tender exotics as have been mentioned, are plunged and supported; and they at the same time afford attendance in supplying such houses or flowers with those degrees of heat that may be proper for the growth and support of various other plants that do not require to be plunged into the beds, the heat of the surrounding air, produced in this way, being sufficient for their growth and preservation. Thus, by the aid of bark-heat, and that of fire during the severity of the winter season, the gardener is enabled to remove, within the hot-house, the temperature of distant climates, and not only to cultivate and bring to perfection the Bromelia Annans, or pine-apple, but also various other tender plants from different quarters of the globe, both of the herbaceous and woody kinds, and to exhibit them in their most healthy and beautiful states in this country.

Bark hot-beds are likewise occasionally formed in pits constructed for them, in the open ground, separately and detached from the hot-house. These are walled round with bricks chiefly above the surface of the ground, having a frame or coping of wood upon the top on which glafs lights are fixed so as to slide with facility. See Bark-Pit.

In these pits the bark-beds are made to the depth of three feet or more, in order to afford an uniform and lasting heat, for the purpose of raising and propagating different sorts of tender plants from seeds, suckers, layers, cuttings, &c. both of the flowe and green-housie kinds, as well as those of the natural ground. Such beds are of course of great utility where there are large collections of tender exotic plants, and as nursery-pits for young pine-apple plants to supply the flowe or pinery annually. See Stone.

Beds formed of bark are also employed with success in raising various sorts of early productions of other kinds, as early strawberrie, melons, peas, French beans, &c. which by the regular and moderate heat which they afford are mostly brought forward in the greatest perfection.

They are likewise made use of in forcing different sorts of curious flowers, both of the bulbuse, tuberofe, and fibrous rooted kinds, into early bloom; as lycopers, dwarf tulips, Narcissus, Jonquils, anemones, ranuncuieae, peans, &c. also many flowering plants of the small shrubie kind, as roses, hypernicus, &c.

Bark-beds are also employed with great advantage in forcing frames for the purpose of producing early fruit of the apricot, peach and grape kinds. See Forcing Frames, and Hot-Walls.

Hot-beds constituted of bark from the flowe and regular manner in which the heat is in common evolved, are not so liable, as those of dung, to injure the plants by their stearn; they are therefore to be preferred for all the more important purposes of forcing where the material can be obtained.

The heat of them may be perpetuated for a great length of time, by having recourse occasionally to the practice of forcing or turning them over, adding in such operations about a third part of new tan or bark. The beds are however
ever to be wholly, or in a great part, renovated every autumn or spring.

There are different sorts or sizes of bark made use of for the confection of these beds, as coarse, middling, and small. The first kind is the longest in taking on heat, and is apt to heat violently at the beginning, but is of the longest duration. The second sort heats sooner, is more regular, and is pretty durable in its effects. But the last kind heats the quickest, yet it is the weakest, and soon becomes earthy, consequently the least proper for the purpose. Where there is a choice of the material, the middling sort, or a mixture of it and the coarse, should constantly be preferred, admitting as little of the small as possible, and care should be taken that it be perfectly fresh from the vat of the tanner. When the bark is wet after being brought home, it is a good practice to throw it up into heaps or ridges for a few days, in order that it may be drained and rendered more dry, as without such precaution the process of fermentation may be too much retarded.

The periods of making beds of this nature must be regulated by circumstances; but where they are intended for pine-apple plants, they should be prepared about the latter end of September or beginning of October, in order that they may afford a good heat during the winter season; but when the raising of plants from beds, cuttings, &c., or the forcing of culinary vegetables, and fruits or flowers, are the principal objects, the spring may be the most favourable time, as in January or March. For particular uses they may, however, be made at any period.

In forming the beds, the tan or bark, prepared as above, is thrown into the pits that are constructed for it; and where there is old, the new bark well mixed and blended with it, by means of the tan-fork, quite to the bottom; then it is the practice to begin at one end and carry them on to the full breadth and depth, without treading upon them, as that would render the bark too solid for the process of fermentation. It is necessary to raise the surfaces of the beds about three or four inches higher than the tops or copings of the beds or pits, in order to allow for the settling that may take place. In the making of this sort of hot-beds for the purpose of raising pine-apples, the author of the "Scotch Forcing Gardener," in order to avoid the danger of too much bottom heat, never admits of the tan being fitted, or of more than one-eighth part of new tan being added, which is introduced by skimming off a portion of the old tan from the surface; by this means the new tan is not suffered to come within a foot of the surface of the bed, and of course the pots are entirely plunged in the old tan. It is his general practice to deposit half of the quantity of new tan that may be added, in the bottom of the trench, and blend the other half equally with the old, till within a foot of the top of the bed. And in trenched over the beds, it is his custom to throw the sides to the middle, and the middle to the sides, in order that the old tan may be incorporated in an equal manner with the new.

It is contended, that in this manner of preparing the beds, they will be "of a mild and equal temperature from the first, and continue much in the same state for three or four months;" and that after the first filling, they will be attended with but little expense for new tan. It is obvious that the filling the pits of new pineries, in the above intention, should either be performed some time before the plants are to be introduced, or the tan be well sweated down and reduced by frequent turning over in an open field or other convenient place; and in these cases it is even advised not to plunge the pots more than half their depths into the beds for the first two or three months after they have been filled.

The new bark or tan that is to be added should constantly be thrown up into heaps for eight or ten days before it is employed, in order that it may drain and cool; and as when used while wet from the tan pit, it is apt not only to take in the beds, but sometimes to heat violently.

It is necessary, as soon as the beds have been made, to thrum ficks into the bark in different parts, in order that they may be drawn up occasionally to ascertain the heat of them.

The beds, in the first method of making them, will, in general be of a proper temperature for the reception of plants in about ten days or a fortnight, as the examination of the sticks will show. If they be intended for pines or other plants that require pots, they must be plunged immediately into the bark, no earth being necessary as in other sorts of hot-beds; and in performing this business, it is of utility to have a board placed across the beds or pits to stand or kneel upon, and thereby prevent the bark from being trodden too close. The pots containing the plants must be placed to suitable depths, according to the differences in the degrees of heat of the beds, in order to be ultimately let down to their rims. When the heat of the beds is shown by the trying ficks to be on the decline, it will be proper to remove it by flitting up or turning over the bark, which, when of the large or middle sort, will seldom require any increase of new tan.

In accomplishing this business, it may be performed either in the manner directed above, or, after removing the pots, by beginning at one of the ends, and working up the whole of the bark to the bottom, afterwards breaking the humps and turning all the bark over, the pots with the plants being directly reformed. The same operation is to be repeated as often as the decline of heat may render it necessary, and such additions of fresh bark be made as may be required, but in common, not more than two or three turnings are requisite. The additions of fresh tan should modestly be made about the beginning of March or April, the crumblly earthy parts of the old bark being cleared away.

The making of new beds is mostly performed as it has been seen above in the autumn, about September or October, as after they have remained ten or twelve months, the bark is much exhausted both in heat and sub stance, and becomes useless. This earthy part is to be now separated by means of the fork, and new bark added, the whole being well blended together with the fork. When the whole of the old tan appears earthy, it is the best method to clear the pit out entirely, and make the bed up altogether of new bark. See Hot-House.

Bar-kound, a disease which has been supposed common to fruit and other trees, and to be capable of being cured by making a slit or opening through the bark, in a longitudinal direction, from the top of the tree or bough to the bottom, about February or March; and if the gaping be pretty considerable, to fill it up with cow-dung, or some other similar composition. This is probably not so frequently a disease as has been believed by gardeners, as the imperfect growth of trees often causes such appearances.

Bar-k-salling, is when trees are galled by thorns or by being bound to stakes, &c. It is cured by clay laid on the galled place, and bound on with hay ropes.

Bar-k-Pit, a pit or cavity of a long, square, or other form, a yard or more in depth, appertaining to a hot-house or stove, &c., and being turned internally, or detached externally, in which to make tan or bark hot-beds, commonly called bark-beds. The dimensions are four, five, or six feet in width, or more, having length in proportion to that of the hot-house, &c., and when in detached pits, such as may be required. See Bar.
both methods they are formed by a low surrounding brick wall, about a yard in height in the internal pits, and in the external ones three or four feet in front, by four or five in the back wall. These different sorts of pits are indispensably necessary, where the plants are placed in the beds in, as the short loose nature of the tan will not admit of being formed into compact regular beds, without the aid of such kinds of enclosed pits to confine it close together within the limits that are requisite in the formation of the beds.

For various purposes, bark-pits are necessary in all hot-houses or flowers, and occasionally in forcing-houses, &c. And detached bark-pits, distinct from the hot-house, are likewise very useful in all extensive gardens on many occasions, being of great service in the culture of many sorts of tender exotics, and in raising various kinds under different methods of propagation; as well as for raising and nursing those of similar kinds in their young and tender growth; also occasionally for feeding and raising early productions of several sorts of hardy plants in the most perfect manner.

The bark-pit of a hot-house, &c. is an essentially necessary interior compartment, and which, as before observed, is the internal cavity wherein the tan or bark hot bed is made, extending lengthways, and occupying almost the whole bottom space of the house, except about two feet on each side and ends, which is reserved for an alley or walk round, between the outward wall and that of the pit, which should be but very little fluke below the general surface of the floor of the surrounding walk, and formed by a thin wall of brick-work, generally railed, the greater part, three feet high above the surface, the bottom being paved with brick or stone, &c. and in which the bark-bed being made to the whole width, length and depth, leaves both to plunge the pots of the more tender exotics in, such as the pine-apple, &c. in order that they may receive the kindly moist heat thereof immediately about their roots; and, at the same time, to diffuse a peculiar beneficial warm vapour for heating the internal air, affixed by fire-heat in the flames in winter; but sufficient alone in summer and autumn; producing, from May till October, an effectual temperature of internal heat, for the preservation and growth of various tender exotic plants of the house kind, natives of different parts of the hot regions of South America, Asia, and Africa. See BARK-BED, HOT-HOUSE, and STOVE.

Hot-houses, or flowers of the common width, have in general only one pit, extending lengthways of them as described above; but if they are of considerable extent in length, the pit is sometimes divided in the middle by an intervening passage, to render it more convenient in performing the necessary culture of the plants.

Some hot-houses, however, of very great width, have two internal bark-pits ranging parallel lengthways with an alley or passage extending between them, which renders them more commodious in giving the requisite culture to the plants that are plunged in the beds, than if the whole was in one extremely wide pit, in which it would often be very inconvenient to come at the plants placed towards the middle of them; so that two parallel pits or four or five feet wide each, become more eligible than one of eight or ten feet, and by having an intervening passage, give a larger scope and afford a better current of air, for the growth of the plants in the beds, as well as admit of viewing them to greater advantage and effect.

Detached or external bark-pits are exterior erections, separate and distinct from the hot-house or stove, but in some manner connected with, or pertaining to them, being, on many occasions, employed for similar uses, as well as for various other purposes, where occasional artificial heat is wanted. They are, as has been observed, four, five, or six feet wide, having such length as may be required; formed by a surrounding wall of brick-work, three or four feet high in the front, by four, five, or six behind, where sometimes flues for winter fire-heat are fixed in the upper part; the whole being covered at top with moveable glass frames, sloping southward to the full sun, and in which, a bark-bed being made to the whole width, length, and depth, becomes an useful appendage to the stove; affording in the culture of various tender exotics of that repository, especially in the way of a nursery-pit, for raising and preserving them to some advanced state of growth; also occasionally in the propagation and protection of the more tender kinds of greenhouse plants, or any particular, curious, or tender exotic plant, of the full ground, as being always ready, and prepared with a continuing growing heat, wherein to plunge the pots, where artificial heat is required, or essentially necessary in raising such tender plants more effectually and expeditiously.

These kinds of bark-pits also prove exceedingly useful in raising many sorts of tender exotics from seed, cuttings, slips, &c. and in retaining and forwarding them in their growth for some time. Bark-pits of the same kind are likewise particularly useful and necessary in the culture of young ananas or pineapple plants, in rearing and nursing them till of a proper age and size, to be placed in the forcing-houses, fruiting-flour, or pinyeh. See BROMELIA ANANAS, and STOVE.

A similar kind of detached bark-pit is likewise occasionally used with advantage in the work of planting or transplanting, or raising tender or curious plants in pots, for plunging the pots which contain the same, as soon as re-planted, into which much expends their tender shoots, and brings them up at first into a free and vigorous growth.

Bark-pits, of the same kind, are also successfully employed in the work of forcing and raising early productions, such as melons, kidney-beans, peas, strawberries, &c. and for many sorts of flowers, both of the bulbous, rooted, and herbaceous kinds, as well as for small flowering shrubs. And if the dimensions of them were increased, especially in height, in the back parts they might have several sorts of dwarf-fruit trees in pots for the production of early fruit, placed in them. See FORCING-FRAME.

Detached bark-pits should always be erected in warm dry situations, in a sheltered aspect, and be constantly ranged lengthways in the direction of east and west, or nearly so, in order to have the whole front incline fully to the south sun, in a flopping manner, on which to place the gladii in the same position, being generally rational either contiguous to the hot-house or stove, but at a proper distance in front of it, at the situation and convenience of the place may admit. Or they may be erected at one or at both ends, extending in a line with it, but separated by a passage between them.

But detached bark-pits are sometimes formed with ridged tops, like the roofs of houses, the gladii flopping to both sides, being ranged lengthways north and south, in order to have the benefit of the sun equally on both sides, and used for the same purposes as the others; though the common south-fronting pits, extending east and west, are more generally adopted, being less expensive in glass-work, &c. and, in general, more convenient for different purposes of the forcing kind.

They should be constructed, as has been observed, with walls of brick work, forming the upright sides and ends nine inches thick; and were fire-flues are intended, the back wall should be of proper thickness from the bottom, to admit of having flues in the upper parts, a fire-place being contrived externally at the bottom at one end; or, in considerably
fiderably extended pits; a double fire-place may be formed in the middle, behind, or one at each end, either endways or in the back part, as may be thought the most convenient.

Some detached pits are formed of wood-work only, by means of post and planking, serving for particular occasions, where no fire heat is required, as flues for that purpose cannot be admitted in such kinds of pits; where additional heat is occasionally necessary, in such pits, it is effected by applying a strong lining of hot dung to the outside; by which a gool heat of hot dung may be supported. In these bark-pits, sometimes the younger pine-apple plants are deposed and nurfed for the first year; they are likewise occasionally used for the purposes of propagating, raising, and nurfing tender plants in spring and summer, &c.; also for forcing early elevator crops, flowers, &c.

The principal detached bark-pits should, however, be formed with brick-work walls; as being the most effectual for general use, and of the greatest duration.

At fig. 1. Plate l. in Gardening, is the representation of a bed or pit of the most common kind, which may be made of either with bark or dung.

Fig. 2. exhibs a view of a bark pit upon a larger scale.

Fig. 3. is the plan and section of two nurfing pits, as given by Mr. Nicol in the Scotch Forcing Gardener," adapted equally to the purpose of striking young pine plants, and the forcing of apleugs, cucumbers, melons, strawberies, French-beans, falds, flowers, &c. In the plan they appear considerably lower than the ground vel for the convenience of shifting. But in wet situations this should not be the case, but a bank of earth raised against them in a sloping direction all round, as by this contrivance the front flues may be useful in raising early falds, by having the front borders prepared. The furnaces are placed behind communicating furth with the front flues, but returning in the back lingly. The surface of the bark-bed is level with the bottom of the flues all round, to prevent the danger of burning; and at the distance of two feet from the wall of the pit. The inner wall of the flue is formed a brick on edge, and the outer one a brick in bed, for the purpose of strength. The divisions of the plan are only each thirty feet in length, but they may be extended to forty, and will be covered by the same furnaces.

One length of fah is sufficient, as they are worked in the manner of the common hot-bed, having fattenings at top to prevent their shifting down.

Fig. 4. is the plan and section of a single pitted pine flue, on an improved construction, as furnished by the same author, for a fruiting or succession house. It is wrought by two fires, having a feld behind it which may be converted to various uses.

The bottom of the bark-bed is level with the surface of the ground, but the surface much elevated, that the sun and light may be admitted more freely to the plants.

Trellis for vines may be placed against the brick-wall and upright fashes in front.

Two lengths of fashes are here necessary in the roof. The under ones should be made to move either up or down.

Fig. 5. is a bark-pit for succession pine-apple plants.

BARKARY denotes a tan-houfe, or place to keep bark in, especially for taners.

It is otherwise called "heath-leafe" in old writers.

BARKING OF TREES, in Rural Economy, the operation of stripping off the bark or rind, which, when taken from some kinds of trees, as the oak, elm, &c. is made use of by the taners, and of course becomes an article of profit to the proprietor.

It is the most useful in this climate to perform the operation in the month of May, as, at that season, the bark, by the rising of the sap in great quantity, is the most easily separated from the wood. This, however, renders it necessary to fell the trees in that month; by which the timber is of much less value than it would be if they were cut down after the falling of the leaf.

It is remarked by Dr. Darwin, in his "Phytology," that as the sap-juice rises in all deciduous trees during the vernal months to expand their foliage, though probably in greater quantity in some trees than in others; it must consist, not only of sugar and mucilage, as in the maple and birch, but of various other ingredients in different trees, which have not been attended to; as appears from the taste of their young leaves, as of oak or ash. And as some of these materials reside in the roots and sap-wood, or alburnum, so others of them may perhaps reside in the bark, where they have been deposited during the preceding summer, and become liquefied by the warmth of the spring, or dissolved by the moisture absorbed from the earth and air, and conveyed upwards to the opening buds; whence it is evident, he thinks, that the barks of trees should be taken off for use in winter, or in early spring, before their buds begin to expand; as then a part of these nutritious juices, or of the other materials which are required for medicines, or in the arts of dyeing and tanning, are in part expended on the young leaves, which generally pollishes the taste and qualities of the bark, though in a less degree. It may nevertheless be observed, he says, that all these allringent or other materials may reside in the alburnum of the trunk or roots of all perennial vegetables, as well as in their barks; because the young leaves, which pollute on decorated oaks, have the same bitter flavour as the leaves on those which have not been decorated; which may in part be derived from the bark of the root, which is still in the ground, and be carried up the vessels of the sap-wood to the new buds. Hence the bark of oak-trees should be taken off during the winter; but when the sap-juice, refilling or ascending in the vessels of the alburnum, becomes more liquefied by the warmth of the spring, or is mixed with moisture, and pushed up with great force by the absorbent vessels of the roots, it is carried off in some degree between the alburnum and the bark; and thus the bark becomes so much more readily separated from the sap-wood; whence this business, as has been already observed, is generally done early in the spring, and should always be performed as soon as this facility of detaching the bark appears; because this process of the germination of the buds continues to injure the bark, whether the tree be cut down or not; as the buds expand their foliage on new falled trees, as they lie on the ground.

It is observed by Mr. Marshall, in his "Rural Economy of Yorkshire," that the peeling of oak timber in that country is generally done by the day, the labourers being, he believes, invariably employed by the timber-merchant, not by the tanner; practices which are, he concedes, productive of a consideratie saving of bark. Men, says he, working by the ton or quarter, or tanners paying by weight or measure, will not induce them to peel the boughs sufficiently near; as it is against their interest to do it. But it is the interest of the timber-merchant, or of the tanner, if he purchases by the groth, or by the ton of timber, to peel it for as long as the bark will pay for the labour. The, he thinks, accounts for the faults of the trunks which are peeled in that country; if the bark ran freely, twigs not much thicker than the finger are frequently stripped of their bark.

The tool commonly made use of for this purpose is made by
BAR

countries is made either of bone or iron. If of the former, the thigh or shin-bone of an ais is preferred, which is formed into a two-handed instrument for the fihn and larger boughs, with a handle of wood fixed at the end. The edge once given by the grinding-iron, or rasp, keeps itself sharp by the wear that afterwards takes place in the operation.

The manner of drying bark in the above country is generally the common one of letting it in a kaming posture against poles lying horizontally on forked flakes. But in a wet leaft, or when the ground is naturally moist, it is laid across a line of top-wood, formed into a kind of banklet, raising the bark about a foot from the ground. By this practice no part of the leaves is allowed to touch the earth, and it is perhaps, upon the whole, the best practice in all seasons and situations. The bark is then put into stacks or houses, and generally shaven or chopped ready for the tan-pit, and afterwards folded to the Tanner at so much the quarter. This custom, however, appears to be founded on a false basis; the Tanner is the best judge of the mode of preparation, and the operation ought, therefore, to pass under his immediate inspection.

The practice of grinding bark does not seem to have yet got sufficient footing in the district mentioned above; when ever it does, Mr. Marshall observes, it will of course bring the preparation of it into its proper channel.

The price of chopped bark varies considerably, according to the quality and the circumstances under which it is placed.

Maliciously barking of apple-trees, or other fruit trees, is made felony by 37 Hen. VIII. c. 6.

By the French laws, all dealers are forbid to bark their wood while growing, on the penalty of 300 livres. This law was the result of ignorance; it being now found, that barking of trees, and letting them die, increases the force of timber.

Barking is also a name given to the cry of dogs and foxes.

The term is also applied to certain quaint noises, made by sick persons in some diseases.

In convulsive spasms, and epileptic fits, the patient sometimes snarls, howls, and barks, with all the notes of a dog. But it is in the hydrophobia that barking has been oftentimes observed; persons feized with this, are apt to rave, bite, foam, and make a harsh noise in their throats, which is called barking.—Vide Phil. Trans. No. 280. No. 323. No. 207. and No. 242.

Barking, in Geography, a market town in the county of Essex, seven miles from London, is so called from a creek on which it is situated. The town is of considerable extent, and chiefly inhabited by fishermen, from whom the fish-markets of London are frequently supplied. The parish is divided into the four wards of Barking, Great Ilford, Chadwell, and Ripplewood, abounding with fertile lands and beautiful prospects. It was to this place that William the Conqueror retired, shortly after his coronation, till he had erected much castles in London as might awe the people whom he governed; and here the great barons Edwin and Morcar came and swore fealty. Very lately the remains of an intrenchment were visible at this place; but the plough has nearly obliterated the whole. Much land in the parish has been recovered from the rivers Thames and Roding. The second minster of the Saxons was founded at Barking by Ethelwald, fourth bishop of London, in 665, for Benefices; the bishop placing his fitter Ethelburga (afterwards canonized) as the first abbess. She was constituted lady paramount in all the monasteries within the half hundred of Becontice, and held of the king an entire barony, a privilege granted to only three other religious foundations in England, hoke of Wilton, Shaftesbury, and Winchester. At the dissolution, the revenues of Barking abbey were estimated at 80l. 12s. 5d. A gateway and a great part of the wall of this magnificent structure still remain adjoining the church-yard. In the township of Great Ilford is an ancient hospital for lepers. The parish church is a large handsome structure, which formerly belonged to the abbey, but is now in the gift of the warden and fellows of All Souls college, Oxford.

The market is held on Saturday, and a fair on October 2nd for horses; another fair is held yearly on the second of October, concerning which the following summary may be acceptable. Many years since, Mr. John Day, a worthy but whimsical character in Wapping, used annually to dine with his friends on beans and bacon under the shade of this famous oak; hence arose the fair. Fairlop oak has sustained its dignity in the forest of Hatfield for many centuries, and though it has been materially suffered, still maintains a majestic appearance peculiar to itself. About a yard from the ground, where its rough fluted stem is thirty-five feet in circumference, it divides into eleven vast arms, not in the horizontal manner of the oak, but rather in that of the beech. The fair held beneath its shade, which overtops an area of 300 feet in circuit, has been injurious to the parent stem, by means of fires which the visitors have occasionally kindled in the cavities formed by the decayed roots of the tree. Mr. Forsyth's composition, however, has in some degree remedied the decay; and a clove fence five feet high, with a board on which is painted, "All good foresters are requested not to hurt this old tree, a plank having been lately applied to his wounds," will, it is hoped, preserve Fairlop oak from further destruction.

BARLOW, a town of Poland, in the palatinate of Breslaw; 43 miles W. N. W. from Drachaw.

BARLOU, a village of Africa, in the county of Agonna, where the Dutch have a fort. See AGONNA. Little Barka lies about a league and a half from the former.

BARKWAY, a populous and flourishing village of Hertfordshire, in England, is situated in the hundred of Edwinea, 3 miles from Royton, 19 from Cambridge, and 24 south from London. This is a considerable thoroughfare in the road to Lynn, and has several good inns. At the time of the conquest, the lands here were divided between four great lords into as many manors.

Barkway was anciently a market town, privileged by Edw. I. to keep a market on Tuesday, and an annual fair for six days. The market was altered in the reign of Elizabeth to Friday, and at last discontinued on account of its proximity to Royton. The church is a handsome spacious building, and the vicarage is in the gift of the Chetlen family; within the building are several fine monuments and some curious painted glafs. This village was greatly damaged by fire in 1748. Its houses amount to 147, and its inhabitants to 660.

BARLAAM, in Biography, a learned monk of St. Bafl, flourished in the fourteenth century, and was born at Seminara in Calabria. Having in his youth visited Greece for the purpose of learning the Greek language, he settled at Constantinople in 1327, where he obtained by his extensive erudition the favour of the emperor Andronicus the younger, and also that of his confidential domestic John Cantacuzene, in whose house he resided. He was employed in teaching the languages and belles lettres; and in 1331, was made abbe of the monastery of the Holy Ghoft. Barlaam is described by Petrarch and Boccaccio as a man of a diminutive stature, though eminent for his learning and genius; of a piercing discernment, though of a flow and painful elocution.
elocution. Having visited the monks of mount Athos, he engaged with them in a controversy concerning the place of the soul and the essence of God. These fanatical atavistic, in their mental relations, pretended to see the light of Mount Athos, which had been manifestly to the disciples in the transfiguration of Christ, on the region of the navel, conceived by them to be the seat of the soul; and this light was adored by them as the pure and perfect essence of God himself. Fier were their simian futilities inquisitive, how the divine essence could be a material substance, or how a material substance could be perceived by the eyes of the body. Barland replied that monks, and accused them of heresy and blasphemy. He attacked the doctrine of the monks to recant or dissemble the simple devotion of their brethren; and Gregory Palamas, who took a lead in this dispute on the part of the monks, introduced a scholastic distinction between the essence and operation of God. This direction, however, did not escape the reproach of polytheism; and Barland charged the adherents of Palamas with holding two eternal substances, a visible and an invisible God. The dispute was violent, and Barland's life was in danger. However, he secured himself by a timely retreat; and Andronicus, who, with a view of obtaining the aid of the western princes against the Turks, wished to reconcile the Greek church with the see of Rome, sent Barlaam in 1339 to conduct the negotiations at the court of pope Benedict XII. at Avignon. Here he formed an intimate connection with Petrarach, whom he instructed in the Greek language, and Barlaam said to have been the first who revived, beyond the Alps, the memory, or at least the writings of Homer. Being compelled, however, to relinquish a fruitsless embassy, he returned to Constantinople, and his dispute with the monks of Athos was renewed; and the council of a council, held in 1344, obliged him to quit the east. After a separation of three years, he renewed his acquaintance with Petrarach in the court of Naples; and by his recommendation Barlaam was finally settled in a small bishopric of his native Calabria at Hieracium, now Gerace, where he died about the year 1348. He defervingly incurred the charge of inconsistency in religion; because, when he was a Greek monk, he wrote against the Latin communion, which he vindicated after having been made a Latin bishop. Having adopted the sentiments and precepts of the Greeks with respect to the obligations of morality and the duties of life, he digested them into a work entitled "Ethica ex Stoicis." He also wrote a work on arithmetic, and some letters and orations. Moretti. Gibbon's Hist. vol. xi. p. 388. vol. xii. p. 66. 120. Mollard's Eccl. Hist. vol. iii. p. 305. 368.

BARLAAMITES, in Church History, the followers of the Calabrian monk mentioned in the preceding article. They are the same with those otherwise denominated Aenitemus.

BARLEUS, Gaspar, in Biography, an eminent Latin poet of the 16th century, was born at Antwerp in 1524, and educated for the ministry at Leyden, where he afterwards settled in the exercise of his profission, and also as a sub-principal and professor of logic. But in consequence of having joined the Arminian party, he was deprived of all his employments, and devoted himself to the study of medicine, for which purpose he took a doctor's degree at Caen. In the practice of physic he made no great progress; but reforming the office of a teacher, delivered lectures in philosophy and the belles lettres in English and Latin. From that time hence he was invited in 1651 to be professor of philosophy in the public school founded at Amsterdam, where, on account of his attachment to Arminian principles, he was the object of jealousy to the orthodox, by whom he was unkindly treated, and unjustly charged with Socinianism. At length he fell into the hypochondriac maladies incident to literary men, and died in 1654. Barleus was a man of erudition as well as genius; and he principally distinguished himself by his Latin poetry, in which he has been thought to rival the ancients, and at least to be upon a par with Claudian. His "Poems," printed at Leyden in 1628 and 1631, contain three books of heroic pieces, two of elegies, and one of miscellaneous, confounding of fables, epigrams, &c.

BARLEUS, Lambert, the brother of the preceding, was born at Berne in Guelphland in 1505, and became professor of Greek in the university of Leyden. His inaugural oration "De Graeco-Latinis Practicis aetatis Utilitate" was pronounced in 1614. In 1621, he published the "Timon of Lucian," with notes; and after his death, which happened in 1655, his "Commentary upon the Theogony of Hesiod" was printed in 1658. Gen. Dict.

BARLAMONT, or BARLEMON, in Geography, a town of the Netherlands in the county of Hainaut; 4 leagues south-east of Le Quefnoy.

BARLAND, Adrian, in Biography, a writer of the sixteenth century, was born about the year 1468 at Barland, a village of Zeeland, whence he took his name. Having studied at Ghent and Louvain, he became first a private teacher at the latter place, and afterwards professor of eloquence in the university; in which station he continued till his death in 1642. His works, which were all written in Latin, were numerous. Some of the principal are "Notes on Terence, Virgil, Menander, and Pliny the younger;" "An Abridgment of Universal History, from the birth of Christ to 1532;" "On the Doxes of Venice;" "Chronicle of the Dukes of Brabant;" "History of the Counts of Holland;" "Life of Charles, Duke of Burgundy;" "Catalogue of the Chief Towns of Lower Germany;" "De literariis Urbis Romae Principibus." Several of his historical works were published together at Cologne, in 1603, 8vo. Morevii.

BARLENGA, in Geography, a small island, is the principal of a cluster in the Atlantic ocean, about 3 leagues from the west coast of Portugal, with a fortress. These islands are called "Boringa" by the English seamen, and most of them are merely rocks. N. lat. 39° 28'. W. long. 8° 41'.

Species,
Species, 1. B. longifolia. Annuata. Pluk. Alm. 30. t. 133. f. 4. Morr. 3. t. 11. t. 27. f. 5. "Spines of the whorls sixfold; leaves entire, very long, feathery." The stems are erect, rough, obtusely quadrangular; leaves opposite, lanceolate-sword-shaped, entire, twice the length of the internodes; flowers in whorls, axillary; three spines on each side of the stem of the length of the whorls. A native of the East Indies. Introduced here by Sir J. Banks in 1781. 2. B. foliosa. Plum. g. 31. 43. f. 2. "Spines axillary; leaves lanceolate, tooth-knotted." Stems erect, square, three feet high, with two oblong entire leaves at every joint, above which the flowers stand in whorls, surrounding the stalks, and under each whorl are six thorn spines as long as the calyx; the flowers are blue, and more completely lobated than the other species of the genus. 3. B. hystrix, hylirix frutex. Rumphi. 7. 22. 13. "Spines axillary, thin, simple; leaves entire, lanceolate-ovate." Stem wand-like, not firm; branches scarcely angular; leaves smooth on both sides; axillary spines thin, filiform, horizontal. A native of the East Indies. 4. B. Proridii. Coelota-Vecta. Rheed. Mal. 9. 77. 41. "Spines axillary, pedate, fourfold; leaves entire, lanceolate-ovate." Stems herbaceous, round, thin; leaves opposite, running down the petioles, pubescent underneath, between the branch and leaf a spine, with four thorn rays from the centre; calyxes acuminate-filipn. A native of the East Indies. 5. B. buxifolia. Carachallii. Rheed. Mal. 2. 91. 47. "Spines axillary, opposite, solitary; leaves roundish, entire." Stalks bristly, five or six feet high, with strong spines under the leaves; flowers in whorls towards the upper part of the stalk; seed-vessels short, containing three or four flat seeds. A native of Jamaica and the East Indies. 6. B. molliflora. "Spines axillary, branching; leaves lanceolate, entire, cuspidated; bracteae ovate, farrifo; tube elongated." Flowers blue, resembling those of B. buxifolia, but longer, and expanding during the night; bracteae smooth. Observed near Tanjour by Koenig. 7. B. crista. Melampyo cognata, &c. Morr. Hill. 3. 429. f. 11. t. 23. f. 7. "Leaves oblong, entire; two leaflets of the calyx broader, exalted, and two linear, acute." Stem round; leaves oblong-obovate, sharp at both ends; flowers axillary, fuscous; two leaflets of the calyx ovate, acuminate, farrifo-filipn; two alternate, shorter, linear, acute, entire, spreading; corolla blue, with ovate lobes. 8. B. cocinea. Plum. g. 31. 43. f. 1. "Unarmed; leaves ovate, tooth-knotted, petiolate." Stems smooth, four feet high; flowers scarlet, in whorls at the joints, and appearing from July till September. A native of South America. 9. B. pungens. "Unarmed; leaves ovate, acute, pungent; bracteae ciliated." Found at the cape of Good Hope by Thunberg. 10. B. longiflora. Gazz. Furt. 253. "Unarmed; leaves ovate, fuscous, bracteae cordate, scarios; corollae very long." An underbrub, with opposite filicy branches; leaves opposite, entire, on stalks; flowers terminal; bracteae two or five, fuscous, nearly as large as the leaves, and below the four other bracteae disposed cross-wise, linear, spreading, fuscous, as long as the leaves; capsule pointed at each end, quadrangular; seeds much flattened, covered with woven bundles of appressed hairs. Found on the mountain of St. Thomas in Malabar by Koenig. 11. B. procumbens. Lom. Cochinch. 373. "Unarmed; leaves lanceolate, crenate, bifid, head terminal." This is a procumbent twined rough underbrub; leaves opposite, broad-lanceolate; flowers yellow; bracteae acuminate, ciliated; segments of the calyx filiculate, hairy; capsule oblong, angular, with orbicular seeds. A native of China, near Canton.

Propagation and Culture. All the species of this genus require the protection of aark-floes. The second, fourth, sixth, and eighth were cultivated by Miller, but the others have not yet been introduced here. The second is to be propagated by seeds, which will flow themselves in the pots which are near them in the flower, when the plants are once obtained; but where the seeds are received from abroad, they must be sown on a hot-bed in the spring; and when the plants are fit to remove, they must be each planted in a separate pot, plunged into a hot-bed of tanners' bark, where they must continue to remain, and be managed in the same manner as other tender exotics from the same countries, giving them water frequently in summer, and allowing them fresh air even in winter. They flower from June till November. The fourth has flexible perennial stalks, which, if cut off during the summer months and made into lengths of six or eight inches, and planted in pots, plunging them into hot-beds, and duly watered and shaded from the sun, will soon put forth roots, when they may be each planted in a small pot and plunged into the hot-bed in the flower, where they are found to grow better than in the dry flower. This species rarely produces flowers in England. The fifth and eighth will produce seeds which are to be treated in the same manner as the former. See Martin's Miller's Dict. of Gardening.

BARLETTA, in Geography, a sea-port town of Italy, in the kingdom of Naples and county of Bari, on the Adriatic, 4 miles west of Trani. The inside of this city is magnificently built, though it has not from a ruinous aspect, and is thinly peopled. Frequent changes of masters, bad administration, and decay of commerce, have blunted its prosperity. Its streets are wide and well paved, and its houses large and lofty. The style of building fixes their date at the first emergence of the arts out of the chaos of barbarism; many of the houses still retaining pointed arches, short twisted columns, and other remains of Saracenic taste; while others are decorated with pillars, entablatures, and members characteristic of the ancient Grecian architecture. The city owes its embellishments to the policy of the Aragonian Kings, who resided here to secure the allegiance of the Pugilists. In the cathedral, which is remarkable for its antique granite columns, Ferdinand I. was crowned. In the market-place stands a colossal bronze statue, seventeen feet three inches high, representing, as it is supposed, the emperor Heraclius, who began his reign in 610. The citadel is spacious, and commands the port, consisting of several irregular piers, but without any shelter from the north wind, which sweeps the whole bay. The exports from this place are salt, corn, almonds, and liquorice, which latter grows spontaneously in the swamps. During the hot months the air is accounted unwholesome. Barletta is said to have derived its name from a tower, or drinking-house, situated on the road to Canne, having for its sign a barrel, called bigillets; and when the cities of Canne and Carofo fell to decay, and the advantages of trade drew people to the coast, a numerous colony gathered round this tower, and in 684, pope Gelasius consecrated a church for the settlers, which became the cathedral of the united fests of Nazareth, Canne, and Monteverde. The emperor Frederick added greatly to Barletta, and has been by some called its founder. Others suppose it to have been the Bardili of the Itineraries. In the fifteenth century, Barletta was esteemed one of the four strongest fortresses in Italy; the other three being Fabriano in the March, Prato in Tuscany, and Crena in Lombardy. Swimb. Trav. vol. i. p. 275. N. lat. 30° 30'. E. long. 10° 32'.

BARLEY, in Botany, a graminious, frumentaceous herb, whose seeds are of the larger fort, being covered with a hull, growing in a spike, and the grains bearded. See Hordeum.
Pearl Barley, and French Barley, are barley fed from the husk, and rounded by a mill; the distinction between the two being, that the pearl barley is reduced to the size of small shot, all but the very heart of the grain being ground away. In mills appropriate to this purpose, the mill-stone is rough-hewn round its circumference; and instead of an under stone, has below it a wooden cafe, in which it revolves, and which, on the inside, is lined with a plate of iron pierced like a grater, with holes having their sharp edges turned upwards. The barley is thrown upon the stone, which, as it runs round, draws it in, frees it from the husk, and rounds it; after which, it is put into sieves, and sifted. The first kind of barley-mills is a German invention. In Holland, the first was erected at Staddam, not earlier than the year 1680. This mill, which was at first called the Pellikan, yearly produced in several years profit sufficient to maintain a family; but in the beginning of the last century, there were at Staddam fifty barley-mills, which brought considerable profit to their proprietors.

Barley, in Agriculture, is a well-known kind of grain from which malt is made. Miller enumerates four different sorts of this useful grain: spring barley, long-cared barley, short-barley, and winter barley.

The spring barley has a double row of beards or awns standing erect. This is the sort principally cultivated in the southern and eastern districts of both England and Scotland, and which the farmers distinguish into two different kinds, the common and the rathripe barley: but the two sorts are in reality the same, as the rathripe is only an alteration of the common barley, occasioned by being long cultivated upon warm gravelly soils. The feed of this, when sown on cold or strong land, will, the first year, ripen nearly a fortnight earlier than that taken from strong land, and therefore the farmers in the low districts generally purchase their feed barley from the warm or gravelly lands; for when cultivated in the vales two or three years, it becomes as late in ripening as the common barley of their own produce: on the other hand, the farmers on warm gravelly lands are obliged to procure their feed barley from the strong lands, otherwise their grain would degenerate in bulk or fulness, which by this change is prevented. This sort of barley is easily distinguished as above, and besides the rind is much thinner, and of course it is esteemed better for making malt.

The long-cared barley is likewise cultivated in many parts of England, and is a good sort; but some cultivators object to it, because from the ears being long and heavy they think it more apt to lodge. In this sort of barley, the grains are generally ranged in a double row, lying over each other, like the tiles of a house, or the scales of fish. It has no beards or awns; and its rind is very thin, and therefore it is esteemed for making malt.

The short-barley, which is sometimes also called Battledore, Fulham, and Putney barley, from great quantities being cultivated in the neighbourhood of those places, has shorter and broader ears than either of the former sorts; the awns or beards are longer, which tend greatly to prevent it from the birds, and the grains are placed together. It seldom, however, grows so tall as the other kinds; the straw is generally coarser, and therefore not so good as fodder for cattle.

The winter barley, which is called also square barley, bear barley, and big, is seldom cultivated in the southern parts of England; but in the northern counties, and in Scotland, it is the sort generally sown, as being much harder than the others. There are two kinds of this barley, the one with four rows of grains, and the other with six, the latter of which is commonly distinguished by the name of barley big. The grain is large and plump; but the rind and chaff of it being thicker than that of either of the preceding sorts, it is less esteemed for making malt.

Barley, from its being that sort of grain which is considered next in value to wheat, is very generally cultivated. On dry, light, mellow soils, the thinned-rinded and large-bodied barley, which is always esteemed the best in quality, is produced. Even light poor soils, when dry, and from nature and situation warm, yield barley which is superior in quality to that which is commonly reaped from the strongest land when cold or of a moist nature.

In the corrected report of Middlesex it is observed, that the tender nature of this plant, in its infant state, unfitls it for cold and compact soils. It thrives best in a soil that is moderately dry and light, as a leeny land, and is esteemed rather a clean crop. As, for this crop, the soil is generally well tilled late in the spring, it reduces the weeds very much; and from its occupying the ground only four months, they have not time to recover themselves and perfect their head. This grain may and frequently is, the winter sown, after every kind of crop, but always succeeds but after turnips, pease, beans, or others of an ameliorating quality.

In the preparation for this grain, the soil should invariably be well pulverized and rendered light first by the ploughing and then by harrowing, which should be followed up at a great distance as the seafon will admit by a more dense cross ploughing, harrowing, and rolling. The feed should then be ploughed in with a very small furrow, and immediately afterwards covered over with harrowed in with short-tined harrows, which leaves the land as light as possible. The next thing to be done is, with one horse to draw a very light roll over the land, in order to press the mould gently on the seeds. These operations promote a more certain, speedy and equal vegetation than can be procured by harrowing in the feed. Harrowing in the feed is, however, the more usual method, and is, he thinks, the cause of much grain being lost, and also of the crop being often of two or three growths. Many farmers postpone the last rolling until the first leaves of the feeds are up, but, it is believed, more from the hurry of the seafon than from choice. This perfect tillage seldom fails to secure a good crop of barley, and a plant of clover.

In the event of land-springs, or excessive rains, it may be advisable not to plough the land flat, but to ridge its parts of about eighteen inches wide. These will drain themselves dry in any weather, at least so much so, that two or three dry days will prepare the soil for harrowing previous to the second ploughing; and if the seafon should still continue favourable, the land on such second ploughing might be laid up in a similar manner till sowing-time; when two or three days more of fair weather would render it fit to be harrowed or scuffed down, and for ploughing in the feed; otherwise a third ploughing may be given, and the feed be harrowed in; which last is considered the better practice, where the soil is not quite so dry as could be wished. Scuffling the land, instead of the second ploughing, would in fine seafons dispatch the work, and be a saving of expense. In the cleanest soil it would be equal to cross ploughing, and in soils not quite free from root-weeds it would be much more useful by bringing them within reach of the harrows. It will perform more than double the quantity of work with the same number of men and horses, and leave the land equally ready for the harrow and roller before sowing the feed.

The author of the Synopsis of Husbandry observes, how-
ever, that it is improper to sow clover among barley on rich land, because the natural fertility of the soil happens on the vegetation of the grass, which will before harvest have advanced to a considerable height among the corn, and will occasion a longer time to be necessary for drying the swath; and thus, by lying abroad longer than would otherwise have been required, a total destruction of the crop may ensue; but in those lands, where there is not the danger of so luxuriant an increase, clover, trefoil, and other grass-feeds may, he thinks, often be sown among barley; and if a favourable time can be procured for harrowing it, the straw may be greatly improved by the mixture of the clover or other grasses, and become then a valuable fodder in the winter; but barley-straw simply is, he says, the most ordinary cattle-food of any.

Where barley succeeds turnips, the land is sometimes only once ploughed; but the author of modern agriculture says that it is a much better method to plough it twice, first early in the spring, and again before sowing the feed. This half is the practice in Norfolk, where that species of grain is cultivated in a more perfect manner and to a greater extent after turnips, than perhaps in any other district. But when barley is sown after peas, beans, or oats, the land is commonly first ploughed in autumn; and the attentive farmer always takes care on this occasion to plough in such a manner as to expose as great an extent of surface to the influence of the air and soil as possible, and at the same time to form the ridges in such a way as to prevent the field from receiving any damage from excessive rains during winter. The second ploughing is given immediately after the out-feeding is finished. This ploughing is intended to answer two purposes; in the first place, to loosen the couch-grain and other root-weeds where they abound, so that they may be easily taken out by the harrows, which are immediately afterwards applied; and in the second place, to reduce the soil to a finer tilth, whereby the feed-weeds are encouraged to vegetate, and which the subsequent ploughing and harrowing at feed-time effectually destroy.

This sort of grain is also frequently sown after wheat, when the fame mode of culture as just mentioned is adopted. But however common this rotation of cropping may be in some districts, there is no good reason, he says, why it should be recommended to the general notice of farmers. For two white corn crops succeeding each other is undoubtedly an erroneous method, both for profit and improvement. Besides, it mostly happens, that where barley succeeds wheat, the crop is in some measure blighted, many of the stalks becoming white about the middle of July; and where there are any grains in the ears, they are shrivelled and never come to maturity, though the soil may be well suited to the production of this sort of grain.

The author of the Survey of Middlesex indeed thinks, from the nature of corn crops, that barley ought not on any account to be sown after either wheat, rye, or oats; a much better practice being to sow it after turnips, potatoes, carrots, tares, &c. and in some cafes, after hemp, flax, and rape. The land should not receive any further manure than what was laid on for the preceding crop, together with the dung and urine deposited by cattle during the time they are eating the green crops off the lands.

The feed season for barley begins, in most of the southern counties, about the first week of March, and terminates in the more northern ones, towards the middle of June. But from the middle of March to the end of April may be reckoned the chief barley feed season, as within these periods by much the greatest proportion of that species of grain is put into the ground.

The writer just mentioned observes, that barley, though usually sown during the months of March, April, and May, has succeeded when put in the first week in June; but it ought to be sown as early as the soil is sufficiently dry and in condition to receive it, and the prior attention which is due to the oat, taro, and other crops will permit. Let it always be kept in mind, says he, that barley will bear late sowing much better than those crops. Both the four and six-rowed kinds of barley are frequently sown in the autumn nearly at the same time with wheat, not only in temperate climates, but also in very cold countries; their hardiness being such as to bear the severity of the winter season even in the mountainous parts of the northern countries. In hot countries they are mostly sown in January, February, and March.

All the other sorts are sown in the spring of the year in a dry time, as has been already seen; when this sort of grain is sown late on strong clayey soils, if the season does not prove very favourable, it is very late in autumn before it is fit to reap or mow, unless it be the early or rath-ripe sort, which is often ripe in nine weeks from the time of sowing.

In the seventh volume of the Annals of Agriculture, Mr. Young gives the following experiments by Mr. Macro, on early and late sowing of barley; on Nov. 16, 1795, he began his experiments by sowing two bushels of barley, which he harrowed in on clover land that had been folded the same as for wheat; this first sowing, therefore, had only one earth. The barley came up about a week sooner than the wheat by the side of it, which was sown the same day, and was exceedingly flourishing till the first sharp frost let in, which damaged the blade, but did not seem to affect the root. As near the middle of December as the weather would permit, he sowed two bushels more, on exactly the same quantity of ground, and some about the middle of every month, till the month of May 1786. This and every sowing after, it had two earths; one cast, or half the feed, was ploughed in, and the other half harrowed in; all the land was folded alike in the month of November. The second sharp frost killed some of this sowing, and a good deal of that sown in November; but they both, with that sown in January, seemed to suffer still more by the sharp cutting winds in the month of March, when there was no snow to cover the blade, and it was injured by the frost. The sowings in February and March left few, if any, of their plants, and, what was somewhat remarkable, were both forward enough to be harvelled on the same day with the three preceding sowings. That sown in April was full a fortnight later; and that sown in May, there not being any so late sown in the neighbourhood, was entirely destroyed by vermin.

As he some years before intended trying the fame experiment, but was disappointed of knowing the event by the rapidity of his workmen, he determined this time to prevent any mistakes by mixing the different parcels in the barn, to thrust enough of the different sowings in the field to satisfy himself which was the most profitable crop, and accordingly attended the theresher the whole day himself. As it was not at all necessary for the experiment to thrust the whole crop, he took three swathes of each sowing twelve yards in length, on the lowest part of the land, where he thought the soil was the most equal for the purpose of the experiment, which, he should have observed before, were by the side of each other on the same acre of land. He had every parcel drenched and put into a sack by itself as soon as thrashed, and the account thereof thus:

From
The last fowling, as observed above, was entirely destroyed by the rooks; he believes it had not been sown more than three days before they began to scrape and pick it up, and completely devoured it. It was the same with the very early fowings, but that he expected, and was surprised against it. It may however serve he thinks, as a lesson to young farmers, that although early fowling may in most cases be profitable, yet it will not answer in large open fields, where the lands are intermixed, unless neighbours fow at the same time; for, if only one farmer fowls early, he must have as many keepers as he has pieces of land. The barley of all the fowings was of the Zealand stock. On the same piece of land on which he tried the above experiments, which was a deep land, value about six or seven shillings per acre, he tried two others, one about ten years since, with chalk from different pits, some of which was a dry chalk, and others grey; he carried only one load of each sort, and laid it about the thicknesses of seventy loads to an acre. Neither of them did the least good, for he could not tell by any of the crops fine, without looking at the soil, for which they were laid. The other was by deep ploughing, in the autumn of 1785, when he fowed part of the piece with wheat, by going with a second plough after the first for one stretch only, and raking about three or four inches of soil that had never been turned up before; on viewing it about midsummer he could not find where it was by any apparent difference in the crop; nor could he see that the barley in January was the best crop. By the same rule, when he began to try the experiment before, that fown in February was the best, and it appeared so on view, he remembers, all the summer.

The quantity of feed barley allowed to the acre varies very much; and depends not only on the quality of the land and the season, but on what was the preceding crop, and also on the condition of the land for receiving the feed. When barley succumbs turnips, the land being then in the best state for the feed, a less quantity is necessary than if it were to be fown after two or three successive white corn crops. The usual allowance to the acre is from three bushels and a half to five; but four bushels and a peck may be considered as the general average, so large a quantity as five bushels being never fown but on lands exhausted and worn out by improper cropping.

Mr. Middleton remarks (in his Survey of Middlesex) that early fowling requires less feed than late; but on a medium soil in proper condition, fown broad-cast, in March three and a half, in April four, and in May four and a half bushels per acre are sufficient. A rich soil makes such a great difference, that it can hardly be fown too thin; even one bushel and a half early fown, has produced as much as could stand; whereas had three or four bushels been fown, the crop would have been lodged, and of a very reduced value.

It is observed by Mr. Donaldson, that if a flatment of the average returns of barley by the acre was confined to England and the south of Scotland, it might be rated at thirty-two bushels; but when Wales and the north of Scotland are included, where, owing to the imperfect modes of culture still practised, the crops are very indifferent, the general average over the whole will not probably exceed twenty-eight bushels the acre. The author of the Agricultural Report of Middlesex states it as varying in England from fifteen to seventy-five bushels per acre. The average produce of the county of Middlesex, he says, is about four quarters of corn and two loads of straw per acre. The straw usually falls at about a guinea a load delivered in which, with chaff and thin grain, is equal to one shilling and sixpence per bushel on the corn; and as the corn had averaged three fellings, together they produce four fulllings and sixpence per bushel, or seven pounds four shillings per acre.

The ultimate destination of barley to be converted into beer and spirits, he says, raises the value of this crop to more than thirty pounds per acre. He understands that porter is brewed in the ratio of 162 gallons from one quarter of malt; and is sold by the retailer after the rate of one shilling and twopenny per gallon, which produces nine pounds nine shillings; deduct the value of the hops, and there remains upwards of a guinea a bushel for the malt, or 40 shillings per acre. In the article of spirits, he thinks, it must necessarily yield much more. According to Mr. Donaldson, barley is applied to various uses. In Wales, Wellesmore, Cumberland, and in the north, as well as in several parts of the west of Scotland, the bread used by the great body of the inhabitants is made chiefly from barley. Large quantities of the barley cultivated in England are converted into beer, ale, porter, and what is called British spirits, as English gin, English brandy, &c. The remainder, beyond what is necessary for feed, is made into meal, and partly consumed in bread by the inhabitants of the above districts, and partly employed for the purposes of fattening black-cattle, hogs, and poultry. There is a much greater share of the Scotch barley consumed in distillation in proportion to the quantity cultivated, than there is in England. Exclusive of what is used for feed, the Scotch barley has a tendency both to beer and ale; and what is made into pot barley, or into meal, for the use of the inhabitants of the more remote and less cultivated parts of the kingdom; or, lastly, into whisky.

In the Report of Middlesex it is also stated, that much of the most ordinary barley is given to poultry; the rest is sold to the maltsters, except for much as is reserved for feed.

In respect to pearl barley it is observed, that a mill to manufacture it costs about twenty pounds. A ton, or 160 stone, of pearl barley sells for twenty-three pounds, which is rather under three shillings a stone, or thirteen shillings and fourpence a bushel. Twenty-three stone and half a bushel of common barley produces five stone and a half of pearl barley by the ordinary method of manufacturing it; but by an addition to the mill, which would cost in a year a pound, the barley corn would be split, and then the same quantity would yield nine stone of pearl barley. This is stated on
the authority of evidence before a committee of the London Society of Arts.

With regard to the choice of feed barley, it is necessary to observe that the best grain for fowing is that which is free from blackness at the tail, and is of a pale lively yellow colour, intermixed with a bright whitish red; and if the grain be a little shrivelled, it is so much the better, as it shows that it has fected in the mow, and is a sure indication that its coat is thin. The hull of thick-rinded barley being too stiff to shrink, will lie smooth and hollow even when the inside flour has shrunk from it.

The necessity of a change of feed from time to time, by fowing that of the growth of a different foil, as has been observed, is in no instance more evident than in the culture of this grain, which otherwise becomes coarser and coarser every year. But in this, as well as in all other grain, the utmost care should be taken that the feed be fully boiled.

It is easy to Suppose that barley, like wheat, may be benefited by being f eed before it is fown. For as rain cannot always be depended upon foon after the fowing of spring corn, there is at any rate equal reason for extending the practice to these sorts of grain as well as thofe which are fown in autumn. Liming indeed may hurt barley in fo me places, but a little sprinkling of foot bids fair for improving it, at least it may prevent infects from preying upon the feed.

Mr. Middleton indeed remarks, that the feed is never fteeped, and yet the farmers are constantly complaining of its coming up at different periods, thus producing two crops which do not become ripe at the fame time, and are injurious to the faple. Steeping the feed a proper number of hours, which might be ascertained by experiment, fays (he fays) to be as well calculated to secure an uniform vegetation and prevent this complaint, as poisoning the feed appears to be to keep it from vermin.

According to Miller, the common method is to fow the barley-feed with a broad-call at two fowings; the feed being harrowed, after each, and then not until the feed is buried. The common allowance of feed is four buifhefs to an acre; but (fays he) if the farmers could be prevailed upon to alter this practice, they would foon find their account in it; for if a third part of that quantity be fown, there will be a much greater produce, and the corn will be much less liable to lodge, as he has many times experienced; and when corn or any other vegetable flands very clofe, the falks are drawn up weak, and thence incapable of refifting the force of the winds, or fupporting themselves under heavy rains; but when they are at a proper distance, their falks will be more than twice the fize of the other, and therefore are feldom laid. He fays he has frequently observed in places where there has been a foot-path through their middle, that the corn which has ftood thin on each fide of the path has ftood upright, when all the rest on both fides has been laid flat on the ground; and whoever will give himfelf the trouble to examine thofe roots near the path, will find them tender, that is, have a greater number of falks, to more than four times the quantity of the other parts of the ffield. He has been experiments made by fowing barley in rows across direct parts of the fame field, and the grains ftood thin in the rows, fo that the roots were three or four inches afother in the rows, and the rows a foot distant; the intermediate spaces of the fame field were at the fame time fown broad-call in the usnal way. The fucces was this: the roots which ftood thin in the rows, tillered out from ten or twelve to upwards of thirty falks on each root; the falks were longer, the ears longer, and the grains larger, than any of thofe fown in the common way; and when thofe parts of the field where the corn was fown in the usual way have been lodged, thofe parts fown thin have supported their upright position against wind and rain, though the rows have been made not only lengthways but across the lands in fveral different parts, fo that there could be no alteration in regard to the goodness of the land, or the situation of the corn. Where therefore fuch experiments have been made, and always attended with equal fucces, there can be no room to doubt which of the two methods is moft eligible, since, if the crops were only fuppofed to be equal: first, the fowing two thirds of the corn fown is a very great advantage, and deferves a national consideration, as fuch a faving in fcarce times might be of very great benefic to the public. This faving of feed-corn (fays he) must be understood to regard fuch as is fown broad-call; for if it be fown in drills, an eighth part of the feed usually fown will be fufficient for an acre of land, and the produce be greater; for al farts of corn are naturally inclined to fend out fveral falks from each root, which they rarely fail to do where the roots are at a proper distance and have room; nor do the falks grow in this cafe near to falk, but are much ftronger than when they are near together, when they rarely have more than three or fite falks, whereas thofe plants which have proper room feldom have faks from ten or twelve. He has had eighty falks upon one root of barley, which were ftrong, produced long ears, and the grain was better filled than any he ever faw grow in the common method of husbandry, and the land on which this grew was not very rich; but he has frequently obferved on the fides of hot-beds in the kitchen gardens, where barley flour has been used for covering the buds, that fome of the grains left in the ears have dropped out and grown, the roots have produced from thirty to fifty falks each, and thofe have been from the as larger in fize than the falks ever arri ved at in the common way. But to this, he knows, it may be objected, that although upon rich ground in a garden the roots of corn may probably have fome falks, yet in poor land they will not have fuch produce; therefore, unless a greater quantity of feeds he fown, the crop will not be worth fanding; which is (he fays) one of the greatest fallacies that can be imagined; for to Suppose that poor land can nourifh more than twice the number of roots in the fame fpace as rich land, is fuch an absurdity as one could hardly Suppofe any perfon of common understanding guilty of: and yet fo it is; for the general practice is to allow a greater quantity of feed to poor land than for richer ground; not confidering that where the roots ftood clofe, they will deprive each other of their nourifhment, and consequently flare themfelves, as is always the cafe when the roots ftood clofe, which any perfon may at first sight obferve in any part of the fields where the corn happens to scatter when they are fowing it; or in places where by harrowing the feed is drawn in heaps, thofe patches will flare, and never grow to a third part of the fize as the other parts of the fame fpace; and yet, confidering this, it is little noticed by farmers, either (fays he) they fhrly would not continue their old custom of fowing. He has made many experiments for feveral years in the pooreft land, and has always found that all crops which were fown or planted at a greater distance than ufual, have fucceeded better upon fuch land; and he is convinced, if farmers would be prevailed upon to quit their prejudices and make trial of the method of fowing their corn thin, they would soon fee the advantage of this hufbandry.

The experiments of Mr. Young, however, lead us to a different conclusion. On April 25th, 1791, upon a land of moift loam on a wet marl bottom, worth about sixteen flailings an acre, he marked four beds, each eight feet long.
long by three feet broad, and dibbled them with four-rowed barley.

No. 1, 91 holes, and four seeds in each hole.
2, 198 ditto, three seeds in each.
3, 198 ditto, one seed in each.
4, 198 ditto, two seeds in each.

No hooks given; but before they ripened a net was suspended over the whole, to guard the barley from the ravages of birds.

On Sept. 9th he reaped them, and clipping off the ears, weighed them.

No. 1, 2 74 ounces.
2, 27.
3, 204.
4, 24.

In No. 1, 13 grains of seed give one ounce produce.
2, 19 grains of seed, one ounce produce.
3, 9 grains, ditto.
4, 16 grains, ditto.

In No. 1, 15 grains of seed per square foot.
2, 24 ditto.
3, 8 ditto.
4, 16 ditto.

It seems (says he) remarkable, that comparing No. 1 and 4, the feed are nearly the same, yet the crop is different, and very considerably in favour of the feed being crowded together in clusters, rather than spread much more equally over the ground. This (continues he) is a most singular circumstance; it coincides very much with the modern practice of dibbing wheat, which has been changed gradually from one grain in a hole, to two, three, and even four, and this cluster-fowling has been found to answer best. But upon what principles? and owing to what cause? Theory would seem to tell us, that plants flanging single would have regular spaces for the roots to feed in, without struggling with each other for nourishment; but there must be some other circumstance which more than balances this advantage. The farmers say that the plants affix each other: but how? Is it by shelter? is it by an accelerated fermentative motion from additional warmth? Very obscure all this; but highly deserving further repeated and varied experiments. More quantity of feed appears to have much effect; No. 2, the mild feed, has of all the greatest crop.

It is a common practice in some parts, to scatter the dung of pigeons, poultry, &c. over barley and other grain after they are fowen; but if this method be purged, care should be taken to scatter such dung on immediately, because then the float will easily make its way through; but when laid on later, it is apt to burn up and destroy the blades of the young plants.

It often happens, on the more stiff soils, from unfavourable weather and an extremely dry spring, that it is impracticable, by the common method, to break the clods and prepare the ground sufficiently for sowing barley; in which case it has been the usual method to break the clods with a large beetle, called from its use a clodding-beetle: but this being a very expensive and tedious method of preparing land, induced the ingenious Mr. Randall of York to construct an instrument, which he called a Digit roller, by the assistance of which a large quantity of land may, in such a dry season, be loosen reduced to an exceeding fine tilth, with very little trouble. See Spike Roller.

After the barley is sown and harrowed in, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth, which will render it easier to mow the crop, and also cause the earth to lie closer to the roots of the corn, which may be of great service to it in dry weather; and also when the barley has been up three weeks or a month, it may be a good method sometimes to roll it over with a weighty roller, which will again press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground in dry seasons; and this rolling of it before it falls, may likewise cause it to fill out into a greater number of stalks; so that if the plants should be thin, it may cause them to spread out as to fill the ground, and likewise strengthen the stem.

If the corn should grow too rank, as is sometimes the case in a wet spring, mowing is then much better than feeding it, because the leavethe takes off only the rank tops, but the deep feed upon all indifferently; nor should they ever in any case be left upon it too long, because, being particularly fond of the sweet end of the stalk next the root, they bite so closely as to injure the future growth of the plant.

Barley is ripe when the red room, as the farmers term it (a reddish colour on the ear), is gone off, or when the ears drop and fall as it were double against the straw, and the stalks have lost their verdure. If it be full of weeds, it must lie in the swath till they are dry. It is not apt to rot, but in wet weather it will be apt to sprout or grow mouldy; and, therefore, every fair day after rain it should be hanked up and turned; and when it is tolerably dry, let it be made up into shocks: but be careful never to house it till thoroughly dry, lest it row-hurn, which will make it malt worse than if it had spered in the field.

Barley and Columbia Indian. See Verbascum Scandii.

Barley Water. (Decoctum Hordei P. Lond. &c.) It is of some consequence that the preparations which generally fall under the care of the nurce, should be made with as much attention as those of the apothecary. Barley water, either by itself or with a variety of additions, forms an agreeable and valuable drink for the sick room. When prepared in the following manner, it is smooth, uniform, and palatable. Take of pearl-barley two ounces, water five pounds: first wash the barley from the mealy matter that adheres to it, with some cold water; then boil it a little with about half a pound of sugar to extract the colouring matter; throw this away, and put the barley thus purified into five pounds of boiling water, which is to be boiled down to one half, and strained.

Barley Water Compound. (Decocum Hordei Compagnum P. Lond.) Take of the preceding barley water two pints; sliced fig two ounces; liquorice root, sliced and bruised, half an ounce; raisins, floured, two ounces; water one pint; boil to two pints, and strain. This decoction is more telling than the former, and is very palatable; it forms a good aliment liquor in fore throats of every kind, and is very considerably nourishing. It is apt, however, to cloy the stomach if taken in large quantity; lemon juice, or any other acid, may be added to it with advantage.

Barley-bird, in Ornithology, a name given in Suffolk to the Sifin.

Barley-corn is used to denote a long measure, containing in length the third part of an inch, and in breadth the eighth.

The French carpenters also use barley-corn, grain d'orge, as equivalent to the line or the twelfth part of an inch.

Barley-corn, grain d'orge, is also used, in Buildings, for a little cavity between the mouldings of joiners' work, serving to separate or keep them alander; thus called because made with a kind of plane of the same name.

Barley-sugar. See Sugar.

Barley-cows, in Geography, a creek on the south-west coast
craft of Ireland, between Mizen-head, the Notium of Pro-
leny, and Brougham in the county of Cork. N. lat. 51°
24', W. long. 9° 40'.
BARLOWE, WILLIAM, in Biography, was a defen-
dant at the ancient family of the Barlows in Wales, and born
in the county of Essex. He was at first a monk in the
Augustine monastery of St. Othf in Essex; and having
commenced his education in this place he finished it at Ox-
ford, where he obtained the degree of doctor in divinity.
He afterwards became prior of the canons of his order at
Bilham in Berkshire, and at the dissolution of the monas-
teries he resigned his house, and prevailed on many abbots and
priors to follow his example. In 1535 he was appointed
bishop of St. Asaph, and in 1536 translated to St. Da-
vid's, where he formed the unsuccessful project of removing
the episcopal see to Caermarthcn, as being situated more in
the centre of the diocese. He was a favourite of king Henry
VIII., and was employed by him in the matter of his di-
 vorce; and he was also much esteemed by lady Ann Boleyn.
In 1547, he was translated to Bath and Wells; but as he
was attached to the protestant religion, he was deprived of
his bishopric in 1553, upon queen Mary's accension, on
pretext of his being married, and committed to the Fleet
prison. Having made his escape from confinement, he re-
tired with many others to Germany, where he remained in
a poor and difflcult condition till the happy inauguration
of our present queen Elizabeth. On this occasion he returned to
his native country, and in 1559 was promoted to the see of Chil-
chester, where he died in 1568. He was reckoned a learned
prelate; but appears, notwithstanding his profession of the
protestant religion, not to have possessed the spirit of a mar-
ty. Besides other pieces which he wrote, he was concern-
ed in the composition of the treatise entitled "The Godly and
Pious Institution of a Christian Man," commonly called the
"Bishop's Book," printed at London in 1537; and in the
reign of Edward VI. he is said to have translated into Eng-
lish the "Apocrypha" as far as the book of Wifdom.
He had five daughters, all of whom were married to bishops.
Biog. Brit.

BARLOWE, WILLIAM, son of the former, was born in
Pembrokehire, and in 1560 entered at Balliol college. He
afterwards travelled, and became skilful in navigation. On
his return he took orders in 1573, and obtained several pre-
ferments in the church, the last of which was that of the
archdeaconry of Salisbury, to which he was promoted in
1614. He died at Eaton near Winchelsea in 1625. In
his acquaintance with the nature and properties of the load-
dstone, he seems to have preceded Dr. William Gilbert, and
wrote upon this subject twenty years before Gilbert's book
was published. He was the first that made the inclinatory
instrument transparent, and to be used hanging with a glass
on both sides and a ring at the top; and he also contrived to
hang it in a compass box, and to adapt it for use at
sea. He was also the first person that discovered the
difference between iron and steel, and their respective tem-
peratures, for magnetical purposes. He also shewed the right
method of touching magnetic needles, and showed how to
piece and cement load-stones. Moreover he explained the
reason why a load-stone being double capped, takes
up so great a weight. On these subjects he wrote the
Lond. 1597; "Magnetical Advertisements, &c." 4to.
Lond. 1616; and "An Answer to Dr. Ridley's Animal
versions on this work." Biog. Brit.

BARLOW, THOMAS, a learned English bishop of
the 17th century, was born at Langhill in the parish of
Orton in Wiltshireland in 1607, and educated at Queen's
college in Oxford. In 1635, he was appointed reader of
metaphysics in the university, and his lectures were pub-
lished. On the surrender of Oxford to the parliament in
1646, he retained his fellowship, and in 1652 was appointed
keeper of the Bodleian library. In 1657, he was chosen
provost of his college. Upon the restoration he contrived
to be chosen one of the commissioners for rectoring the
members that had been wrongfully ejected in 1648, and
in 1660 was created doctor of divinity and Margaret pro-
fessor in that department. In this year he wrote "The
Cafe of a Toleration in Matters of Religion," which he
extended farther than any divines of that age. As he
was distinguished for his skill in the civil and canon law,
he was often applied to as a lawyer; and in 1671, he wrote
Mr. "Cottington's Cafe of Divorce." In 1675, he was
promoted, notwithstanding the opposition of archbishop
Sheldon, to the bishoprick of Lincoln; and after his ad-
vancement wrote several pieces particularly against popery,
which served to found the alarm with respect to the dan-
ger of a papish faction. However on the accession of James
II., he was one of the most forward in procuring thanks to
the king for his declaration in favour of liberty of con-
science, and he vindicated the royal power of dispensing
with penal laws; which conduct some have entdured as ma-
ning a compelable accommodation to the times, and others
have ascribed to his love of toleration. With the re-
olution he adopted its principles, and avowed his allegiance
to the successors of James. As to his sentiments, he was in
theology a rigid Calvinist; and in philosophy a strict Aris-
totelian, and an enemy to the new mode of experiment en-
couraged by the Royal Society. As a bishop he neglected
his duties in his cathedral and diocese, and refuted constant-
y at his manor seat at Bagden; nevertheless his tolerating
spirit and opposition to popery seem to have produced in
the author of the "Confessional" a singular predilection in
his favour. He died at Bagden in 1691, in the 85th year of
his age; and he was eminently distinguished by his learn-
ing and liberality. The works of this bishop, printed after
his death, were a volume of "Cafes of Confidence," re-
solved by him, 8vo. 1692; and his "Genuine Remains,"

BARLOW, FRANCIS, a painter of birds, beasts, and fish,
was born in Lincolnshire, and excelled in drawing every spe-
cies of animals with great correctness; but his knowledge of
colouring was very imperfect. This artist died in 1702.
Pilkington.

BARM, otherwise called ycait; the head or workings
producing by the fermentation of ale or beer. It is the
froth that forms on the surface of beer or wine of grains
during their fermentation; which, mixing with dough,
rises more quickly and better than leaven, and makes the
tipped bread. See LEAVEN, and YEAST.

BARMACH, in Geography, a lofty mountain of Per
da, in the province of Schönvan near the Carpathian
sea.

BARMANCOTTY, a town of Ayr, in the country of
Thibet; five miles south of Sinagur, and thirteen north of
Deprag.

BARMENA, Harva, is a large bay, situated about four
miles S.W. by W. from Cape Machiracca, two leagues N.E.
by N. from Placentia, and four from Bilboa.

BARMEN, a town of Germany, in the circle of Weif-
phalia and duchy of Berg, situate in a fertile valley to
which it gives name, five miles north of Lannep.

BARMINE denotes such mine or ore as is adjudged at
a court of bargemote.

BARMOUTH, in Geography, a small watering place in
the parish of Llanaber, Merionethshire, North Wales. The
houses
houses are singularly placed at the bottom and on the side of a steep hill which overlooks a narrow winding valley to the south, and the bay with St. George’s channel on the west. The situation of the houses affords matter of astonishment to most travellers; none being placed on the sands close to the beach, and others at such varied heights on the rocks, that in some of the winning paths a person may look down into the door of one house on his right hand, and down the chimney of another on his left. This place is at the mouth of the river Mawddach, which, at high tide forms a bay of about one mile over; but the entrance is rather unsafe on account of the sand banks. The Welsh call it Aber maw, i.e. the mouth or confluence of the river Maw. Darmouth is much frequented as a convenient bathing place during the summer by many gentile families. Here are a few bathing machines for the use of ladies, but the gentlemen commonly bathe from the coast. This place is the port of Mawddach, and great quantities of flannels and hose are annually exported hence. Mr. Pennant states that forty thousand pounds’ worth of the former and ten thousand pounds’ worth of the latter have been shipped from this port in one year. About one hundred vessels belong to this place, some of which fail up the river nearly to Dolgelly.

Not far from Darmouth, the river Mawddach divides into two arms, and forms a small island called Ynys y Brawd, or the friar’s island. The number of houses in this parish is 317, and its inhabitants amount to 1463. Bingley’s Tour round North Wales.

BARN, in Rural Economy, a covered building constructed for the purpose of laying up and preserving all sorts of grain, hay, straw, &c. Arable as well as hay farms should in general be provided with barns proportioned to the quantity of grain or hay they produce; though since the practice of flacking hay and grain and of threshing by mills has become more general, there seems to be much less need of large barns.

Buildings of this sort should have a dry, rather elevated situation, and be placed on the north or north-east side of the farm yard, but not by any means contiguous to the house or offices as are connected with it.

Barns may either be constructed on wooden frames and covered over the outides with weather boarding, or built of brick or stone, which over the country affords in the greatest plenty; but in either case, there should be such vent-holes or openings in their sides or walls as may be sufficient to afford free admission to the air, in order to prevent the moulds that would otherwise from the heat damp lodge in the grain. The gable ends of such buildings are probably always best framed of brick or stone, on account of their greater solidity; the whole may be roofed with either thatch or tiles as can be most conveniently procured. They should have two large folding doors facing each other, one on each side of the building, for the convenience of carrying in or out a cart or waggon load of corn in sheaves or any other sort of bulky produce; and these doors should be of the same breadth with the threshing floor, to afford the more light and air; the former for the thresher, and the latter for the purpose of winnowing the grain. Over the threshing floor, and a little above the reach of the flail, poles are often laid across from one beam to another, to form a kind of upper floor, upon which the thrasher may throw the straw or chaff, to make an immediate clearing till he has time to flow it properly elsewhere; and on the outside over the great doors, it is sometimes convenient to have a large pent house, made to project sufficiently to cover a load of corn or hay, in case a sudden storm should come on before it can be houfed, and also to shelter the poultry in the barn yard from too great heat or bad weather of any kind.

It was formerly much the custom in countries that abounded in corn to have separate barns for wheat, for spring-corn, such as barley and oats, and for peas, tares, clover, faintoins, &c., but where the grain, hay, and other similar produce can be flacked, the heavy expense of so many buildings of this kind may be avoided, and at the same time the different articles be preserved with equal safety and convenience. In the corn barns it was formerly also much the custom to have bays or large separate chambers formed in their sides or ends for the purpose of containing the grain when threshed out, straw, and other articles; but these at present are not so much in use. The hay barns should commonly be constructed of wood and not made too close. They are sometimes formed in such a manner as to be capable of being moved to different places by having low wheels or rollers fixed on the bottom frame. In grazing farms that do not afford a supply of straw for flacking the flacks with, movable roofs erected on strong uprights of wood, on which and sometimes termed Dutch barns, may be useful; as they may be raised or lowered at pleasure by screws or levers so as to accommodate themselves to the quantity of hay, either in proportion to the crop or its consumptions; while at the same time they are cheaper, more airy, and less troublesome in case of heating, than close barns.

It is observed in the sixteenth volume of the Annals of Agriculture, in speaking of the construction of barns, that the underpinning should be of brick or stone, two feet high above ground, and the sides boarded; the roof of the barn is best covered with red or straw, and those of the flables on its sides with slate or glazed tile; because they must be more flat, and the water which runs from the roof of the barn would injure most other coverings. At each end of the barn, and over the back door, small doors four feet square should be fixed at the height of twelve feet from the ground; the two former for putting corn in at the ends, and the latter for filling the middle of the barn after the bays are full. All the bays should have a floor of clay or mud, and the threshing floor be made with hard bricks, which will be sufficient for all sorts of grain except wheat and rye; and for threshing them it will be good economy to have planks of oak or red deal well fitted together and numbered, to be laid down occasionally and confined by a frame at their ends. A barn built on such a plan would hold a great deal of corn and be filled more conveniently; and if the flacks of corn were built at each end, they might be taken in without any carting. If more buildings are requisite, two may be added on the back side like the flables in front; otherwise if doors are made under the eaves on the back side, as directed at the ends, and flacks be placed opposite to them just far enough to avoid the coves’ dropping, by placing a waggon between them and the barn by way of a ladder, these flacks may be taken in without carting; which method spares a great waste of corn and much trouble. The spars of the roofs of the flables rest upon the upper eills of the sides of the barn, and the outside wall of the flables is eight feet high; the barn supplying the highest eills and one end of each flable, and the flables in return are buttresses to the barn and strengthen it greatly.

It is remarked by the author of the Agricultural Survey of the county of Somerset, that the practice lately introduced of placing barns on a declivity cannot be too much recommended; as a warm commodious range of flails for cattle, covered by the same roof, is by that means obtained.
And besides, the barn-floor, by being thus elevated, is rendered more durable, and less subject to vermin; the grain is kept more dry and sweet than on a ground floor, and cannot slip through it without discovery. The plan is indeed, in his opinion, almost unexceptionable. Barns, when built in this way, should have a southern aspect, the arches of the cattle-halls facing that way. Mr. Marshall, in the "Rural Economy of Yorkshire," also speaks highly of the advantages of barns formed in this manner.

In respect to the size of barns, the same writer has observed, that in Gloucestershire fifty-two by twenty feet is the clear, and from sixteen to twenty feet in height to the plate, is considered a good barn; these dimensions admitting of four bays of ten feet each, with a floor in the middle.

The advantage of having buildings of this sort conveniently situated, is extremely great both in regard to the feeding of cattle, sheep, and hogs, and likewise in the economy of labour, and the preventing of waste in different kinds of fodder.

The invention of threshing machines has, in some measure, varied the construction of barns, as where they are made use of they should be contrived chiefly with a view to the distribution of the straw; the machines being built in the centre, with the grain flacks adjoining them, in such a manner as that they may be supplied without the affluence of carts or horses. The barns in these cases need not be so large, but they should have granaries provided in them, which may probably be most conveniently placed over the floors. In most old barns, threshing machines may be erected without much inconvenience or trouble.

But notwithstanding the superiority of flacking grain in the open air has been fully shewn by different writers, and of course the necessity of large barns in a great measure obviated, there are still many agricultors attached to the method of housing corn in the straw; it may therefore be proper to give a few plans and descriptions of such as appear to be the most calculated for that purpose.

At fig. 1, Plate I. of Agriculture, are given the elevation and ground plan of a small common barn used in most parts of the kingdom, for the smaller kinds of farms. The threshing-floor is in the middle; on one side of which a croft wall is sometimes raised to the height of about three feet, in order to keep the threshed corn from being mixed with that which is unthreshed; 

2 is a place for containing the threshed grain till it is to be cleaned, or a large quantity be accumulated for that purpose. It is about three feet in height, being covered over with boards, and open only on the side next the threshing-floor of the barn.

At fig. 2, the elevation and ground plan of a double barn with two threshing floors are seen. In this sort of barn a wall is sometimes raised across in the middle. These barns are often built of large dimensions, but possess few conveniences, except for piling up the grain while in the straw.

At fig. 3, the elevation and ground plan of an improved barn are given, in the middle of which is the threshing floor, and on one side of the same wall where the Henes are placed near the end a place for depositing the threshed corn, with stairs up to a small granary, below which is a place for putting potatoes, 

and on the other a division that may be made use of for different purposes, such as the rearing of calves, preserving implements, &c.

And at fig. 4, the elevation and ground plan of an open improved barn are shown, the threshing floor of which is placed towards one end. And on each side of it below are divisions for a great variety of different purposes; the corn being kept above in the straw till threshed out. In this barn much expense is saved in masonry by the great number and largeness of the openings in the upper part, and at the same time the air is admitted more freely.

Fig. 5 is the representation of a Dutch moveable barn which has many conveniences, and at the same time is capable of being made to cover the parts of such hay stacks as are cutting. It moves on five wheels each two feet in diameter, and costs, when complete, about sixty pounds.

Some degree of art, which must be the result of practice, is necessary in placing and piling up the straws in barns; and it may not be useless to observe, that it is always necessary to press them as close to the walls of the barn as possible, so as not to afford the least room for rats or other vermin to creep in between them, for if they once get admittance, they will soon penetrate farther, lodge themselves in the mow, and do prodigious damage to the grain. Where this misfortune happens, the only remedy is to take down the mow, destroy the vermin, and pile it up anew in a more careful manner.

As the introduction of threshing machines has made considerable alteration in the construction of barns, it may not be improper to give a few plans or representations by which the manner of their attachment to them may be rendered more clear and comprehensible. These machines may be wrought by different powers, as water, wind, or animals; but the threshing machines used in this country are, by far the most convenient, and most regularly worked.

At fig. 1, Plate II. of Agriculture, are given a front and end elevation, with the plan, of a small barn adapted for a two-horse threshing machine. The barn is only fifty feet in length within the walls, and sixty feet in width. The walls are ten feet in height, which admits of a granary or room thirty feet long above the machine, as is shown by the dotted line in the elevation, which denotes the extent of the granary as well as the height of the floor from the ground. The floor is not continued the whole length, in order that there may be more room left in the other end for containing the unthreshed grain, which is introduced at a, figs. 2 and 3. At b, fig. 2, is seen the space occupied by the machine within the barn, which is only ten feet by seven, including the distance from the wall; c, d, figs. 2, and 3, shew the horse beam or lever; which is twenty four feet in length, and which gives motion by a laying shaft through the wall, to the machine within. In this there is no shed or cover over the horse path and parts on the outside of the barn, as is usual, except g, b, fig. 2, which is closely boarded to protect the wheels of the first movement from the effects of weather, a part of one side being fixed with hinges for the purpose of opening to apply grease. The expense of a machine on this plan will be from thirty to forty pounds, according to the strength and manner of its being put together.

And at fig. 4, are seen the front and end elevations, with the plan of a barn and horse threshing machine upon a much larger scale, being intended for three or four horses or other sorts of cattle; and designed to winnow or clear the grain at the same time that it is threshed out. It may likewise be so contrived as to hoist it up to the granary above, to split beans, cut straw, and perform several other operations, such as churning, pumping, grinding, &c. Such a barn and machine will suit a farm of almost any extent. The shed over the horse-path and first movements is mostly made with a conical roof merely for the purpose of covering them; but as the expense is consider able, it is here made to answer the double purposes. It is shown, as shewn at fig. 5, by a, b, c, d; the dotted circle is the horse path, in the corner of which stands the upright axe e, fig. 6. Above this, by raising the pillars to a proper height, may be obtained a convenient place
place either for putting corn in the thrashing-floor, or for keeping straw or hay, or as a granary. But in either case the floor must be so constructed as to support the weight upon it without sinking in the middle. A communication with the barn may be made near the thrashing machine at $f$, fig. 5, which will afford an easy access to the machine in case grain be deposited there to be thrashed. In this barn, the machine is erected on a floor raised seven or eight feet above the ground-floor, in order that there may be sufficient room for the faners or winnowing machine below. This floor may be extended the whole breadth of the barn and fifteen feet or more towards $i$, from the back part of the machine at $j$, by which, and being properly partitioned below, a very necessary and useful division will be obtained for containing the grain till hoisted up to the grana. The doors of this place may be locked by the farmer, if thought necessary, during the time of thrashing. The space $k$ will contain the chaff blown by the faners. There is a door through $g$ to render the communication more easy and expeditious from the part $i$, where the unthreshed grain is deposited; as it may be proper to look often below while the machine is at work; there might likewise be a door in the partition at $l$, but this is not so very necessary, as the farmer can easily see what his servants are about at $m$ where the straw goes, by standing on the thrashing floor, to which there should be steps up at $n$. This machine may also be so constructed as to rake away the straw, and throw it down to $o$; which saves the labour of a person in raking from the machine.

The expense of a machine on this plan, when made to clean the grain and rake away the straw only, will amount to about fifty pounds exclusive of flooring, &c.; and when made so as to hoist up the grain, split peas or beans, and cut straw, from six to ten pounds in addition for each.

Other more powerful machines of this kind will be described under the article Threshing Machine.

Barn Floors, in Rural Economy, the space or floor on which the grain is threshed out by the flail. It is for the most part made in the middle of the barn, and should be so formed as to be perfectly close, firm, and strong. It is sometimes termed threshing-floor. In constructing these floors, various sorts of materials are employed; such as compositions of earthy kinds, tiles, bricks, and wood. The last, when properly laid and put together, is probably the best and most secure from such causes as are liable to injure grain. The floors of barns, when made of wood, are sometimes so contrived as to be moveable at pleasure, which is a great convenience in many cafes. Barn floors are made of different dimensions, but from twelve to fourteen by eighteen or twenty feet may be considered as good sizes.

As the floor, or threshing-place, is the principal part of every barn, the greatest care ought to be taken in making it. In order to this, in some places the surface of the intended threshing-place is dug away to the depth of about six inches; and the earth thus taken out, when of a proper kind, after being well cleared of stones, is mixed with the strongest clay that can be procured, and with the dung of cattle. This mixture is then worked together with water till it is of the consistence of stiff mortar, and the compost thus made is spread as broad as and even as possible with a trowel upon the spot from whence the earth was taken. As it cracks in drying, it must frequently be beaten down with great force, or rolled with a heavy roller, until all the crevices are filled up; and this must be continued till it is quite solid, hard, and firm. Earthen floors are not however to be recommended, except where the materials are extremely good, and the method of forming them well understood, which is but seldom the case.

The best barn floor, both for threshing upon, and for keeping corn, is that which is the driest, smoothest, most completely solid, and consequently the moist free from cracks and holes in which insects and vermin may shelter themselves and breed. The ancients were remarkably careful in this last respect, as is evident from the writings of Cato, Varro, and Columella. The laft of these relates particularly the great pains they took, first to dig up the ground to some depth, in order to moisten it with fresh lees of oil, but not with any that had fallen in matters in them; then to mix it thoroughly with chaff, and run it down as close as possible; afterwards, as it dried, to stop all the cracks and crevices that appeared; to continue beating it down with great force to render it quite level; and, lastly, to throw it again with chaff, which they trod in, and then left it to be completely dried by the sun. All of them agree, that the lees of oil thus used prevent the growth of weeds in the floors, and contribute to preserve the corn from being plundered by the mice and ants. In this they were, however, probably mistaken. Their barns were always kept high, and as dry as possible. A floor made in the above manner, though not good, was probably preferable to either stone or the earthen floors formerly common in many parts of this country, from which such damps has been communicated to the corn, as has rendered wheat, for example, fpence or a shilling a bushel worse either for keeping or exportation. Bricks, when hard and well laid, may form a tolerable floor for many purposes; but, from their attracting moisture, are not by any means to be recommended where grain is to remain much upon them. And most forts of stone are liable to the fame objection.

Wood is by much the best for this use. Boarded threshing floors, made of sound, thick, well-leaved planks of oak, are excellent for threshing upon, will last a long time, and may be converted into good floors for rooms, by planing them down after they are become too uneven for the purpose originally intended.

There are various ways of laying and constructing barn floors, when made of wood. The most common method is that of nailing the planks, after their edges have been shot true and well joined, down to wooden sleepers firmly placed on the ground. But in the midland counties another method is followed, which, Mr. Marshall says, is that of first having the floors laid with bricks, and then covering them over with the planks, without any other confinement than that of their being dowelled together, or ploughed and tongued, and their ends let into fills or walls placed in the usual manner on each side of the floors. The advantages of this method of making the floors are, that when the brick work is well executed and made perfectly level, vermin cannot be concealed underneath them, nor damp air be communicated; besides, floors formed in this way are found to wear better than those laid simply upon sleepers. The planks employed in this way should, however, always be well seasoned. It is evident, notwithstanding, that where barn floors can be made hollow, they must be much better for the purpose of threshing upon than such as are either laid on brick work or the ground, from their greater elactity; the grain is of course threshed out with more ease and certainty. But in whatever manner these floors are constructed, they become expensive, and do not last any great length of time. Such as are laid on the common ground, upon three fills, with two-inch oak planks, will in general cell from eighteen to twenty pounds, and only last fifteen or twenty years; and such as are made hollow, and placed wholly on brick work,
B A R

Besides, the barn-floor, by being thus elevated, is rendered more durable, and left subject to vermin; the grain is kept more dry and sweet than on a ground floor, and cannot slip through it without discovery. The plan is indeed, in his opinion, almost unquestionable. Barns, when built in this way, should have a southern aspect, the arches of the cattle-stalls facing that way. Mr. Marshall, in the "Rural Economy of Yorkshire," also speaks highly of the advantages of barns formed in this manner.

In respect to the size of barns, the same writer has observed, that in Gloucestershire fifty-two by twenty feet in the clear, and from sixteen to twenty feet in height to the plate, is considered a good barn: these dimensions admitting of four bays of ten feet each, with a floor in the middle.

The advantage of having buildings of this fort conveniently situated, is extremely great both in regard to the feeding of cattle, sheep, and hogs, and likewise in the economy of labour, and the preventing of waste in different kinds of fodder.

The invention of threshing machines has, in some measure, varied the construction of barns, as where they are made use of they should be contrived chiefly with a view to the distribution of the straw; the machines being built in the centre, with the grain stacks adjoining them, in such a manner as that they may be supplied without the affilence of carts or horses. The barns in these cases need not be so large, but they should have granaries provided in them, which may probably be most conveniently placed over the floors. In most old barns, threshing machines may be erected without much inconvenience or trouble.

But, notwithstanding the superiority of staking grain in the open air has been fully shown by different writers, and of course the necessity of large barns in a great measure obviated, there are still many agriculturists attached to the method of housing grain in the straw; it may therefore be proper to give a few plans and descriptions of such as appear to be the best calculated for that purpose.

At fig. 1, Plate II. of Agriculture, are given the elevation and ground plan of a small barn adapted for a two-horse threshing machine. The barn is only fifty feet in length within the walls, and fifteen in width. The walls are ten feet in height, which admits of a granary or room thirty feet long above the machine, as shown by the dotted line in the elevation, which denotes the extent of the granary as well as the height of the floor from the ground. The floor is not continued the whole length, in order that there may be more room left in the other end for containing the unthreshed grain, which is introduced at a, figs. 2 and 3. At b, fig. 2, is seen the space occupied by the machine within the barn, which is only ten feet by seven, including the distance from the wall; c, d, fig. 2, and 3, is the horse beam or lever; e is twenty four feet in length, and which gives motion by a laying shaft through the wall, to the machine within. In this there is no shed or cover over the horse path and parts on the outside of the barn, as is usual, except g, b, fig. 2, which is closely boarded to protect the wheels of the first movement from the effects of weather, a part of one side being fixed with hinges for the purpose of opening to apply grass. The expense of a machine on this plan will be from thirty to forty pounds, according to the strength and manner of its being put together.

And at fig. 4, are seen the front and end elevations, with the plan, of a barn and horse threshing machine upon a much larger scale, being intended for three or four horses or other forts of cattle; and designed to winnow or clear the grain at the same time that it is threshed out. It may likewise be so contrived as to hoist it up to the granary above, to split beans, cut straw, and perform several other operations, such as churning, pumping, grining, &c. Such a barn and machine will suit a farm of almost any extent. The shed over the horse path and first movements is softly made with a conical roof merely for the purpose of covering them; but as the expense is considerable, it is here made to answer other uses. It is square, as shown at fig. 5, by a, b, c, d; the dotted circle is the horse-path, in the corner of which stands the upright axle e, fig. 6. Above this, by raising the pillars to a proper height, may be obtained a convenient place.
place either for putting corn in the straw till threshed out, or for keeping straw or hay, or as a granary. But in either case the floor must be so constructed as to support the weight upon it without sinking in the middle. A communication with the barn may be made near the threshing machine at $f$, fig. 5, which will afford an easy access to the machine in case grain be deposited there to be threshed. In this barn, the machine is erected on a floor raised seven or eight feet above the ground-floor, in order that there may be sufficient room for the fan or winnowing machine below. This floor may be extended the whole breadth of the barn and fifteen feet or more towards $i$, from the back part of the machine at $f$, by which, and being properly partitioned below, a very necessary and useful division $f^{2} b h$, will be obtained for containing the grain till hoisted up to the granary. The doors of this place may be locked by the farmer, if thought necessary, during the time of threshing. The space $k$ will contain the chaff blown by the faners. There is a door through $g$ to render the communication more easy and expeditions from the part $i$, where the unthreshed grain is deposited; as it may be proper to look often below while the machine is at work; there might likewise be a door in the partition at $h$; but this is not so very necessary, as the farmer can easily see what his servants are about at $m$, where the straw goes, by standing on the threshing floor, to which there should be steps up at $n$. This machine may also be so constructed as to rake away the straw, and throw it down to $m$; which saves the labour of a person in raking from the machine.

The expense of a machine on this plan, when made to clean the grain and rake away the straw only, will amount to about fifty pounds exclusive of flooring, &c.; and when made for as to hoist up the grain, split peas or beans, and cut straw, from six to ten pounds in addition for each.

Other more powerful machines of this kind will be described under the article Threshing Machine.

Barn, in Rural Economy, the space or floor on which the grain is threshed out by the flail. It is for the most part made in the middle of the barn, and should be so formed as to be perfectly close, firm, and strong. It is sometimes termed threshing-floor. In constructing these floors, various sorts of materials are employed; such as compositions of earthy kinds, flones, bricks, and wood. The last, when properly laid and put together, is probably the best and most sure from such causes as are liable to injure grain. The floors of barns, when made of wood, are sometimes so contrived as to be movable at pleasure, which is a great convenience in many cases. Barn floors are made of different dimensions, but from twelve to fourteen by eighteen or twenty feet may be considered as good sizes.

As the floor, or threshing-place, is the principal part of every barn, the greatest care ought to be taken in making it. In order to this, in some places the surface of the intended threshing-place is dug away to the depth of about six inches; and the earth thus taken out, when of a proper kind, after being well cleared of flones, is mixed with thestrongest clay that can be procured, and with the dung of cattle. This mixture is then worked together with water till it is of the consistence of stiff mortar, and the compot thus made is spread as smooth and even as possible with a trowel upon the spot from whence the earth was taken. As it cracks in drying, it must frequently be beaten down with great force, or rolled with a heavy roller, until all the crevices are filled up; and this must he continued till it is quite solid, hard, and firm. Earthen floors are not however to be recommended, except where the materials are extremely good, and the method of forming them well understood, which is but seldom the case.

The best barn floor, both for threshing upon and for keeping corn, is that which is the driest, smoothest, most completely solid, and consequently the most free from cracks and holes in which insects and vermin may shelter themselves and breed. The ancients were remarkably careful in this last respect, as is evident from the writings of Cato, Varro, and Columella. The left of these relates particularly the great pains they took, first to dig up the ground to some depth, in order to moisten it with fresh lees of oil, but not with any that had saline matters in them; then to mix it thoroughly with chaff, and ram it down as close as possible; afterwards, as it dried, to fill all the cracks and crevices that appeared; to continue beating it down with great force to render it quite level; and, lastly, to throw it up again with chaff, which they trod in; and then left it to be completely dried by the sun. All of them agree, that the lees of oil thus used prevents the growth of weeds in the floors, and contribute to preserve the corn from being plundered by the mice and ants. This they were, however, probably mistaken. Their barns were always very high, and dry as possible. A floor made in the above manner, though not good, was probably preferable to either stone or the earthen floors, formerly common in many parts of this country, from which such dampness has been communicated to the corn, as has rendered wheat, for example, unserviceable. Bricks, when hard and well laid, may form a tolerable floor for many purposes; but, from their attracting moisture, are not by any means to be recommended where grain is to remain much upon them. And most floors of stone are liable to the same objection.

Wood is by much the best for this use. Boarded threshing floors, made of round, thick, well-seasoned planks of oak, are excellent for threshing upon, will last a long time, and may be converted into good floors for rooms, by planing them down after they are become too uneven for the purpose originally intended.

There are various ways of laying and constructing barn floors, when made of wood. The most common method is of nailing the planks, after their edges have been shot true and well joined, down to wooden fleapers firmly placed on the ground. But in the midland counties another method is followed, which, Mr. Marshall says, is that of first having the floors laid with bricks, and then covering them over with the planks, without any other confinement than that of their being dowelled together, or ploughed and tongued, and their ends let into hills or walls placed in the usual manner on each side of the floors. The advantages of this method of making the floors are, that when the brick work is well executed and made perfectly level, vermin cannot be concealed underneath them; for damp air cannot be communicated; besides, floors formed in this way are found to wear better than those laid simply upon fleapers. The planks employed in this way should, however, always be well boxen. It is evident, notwithstanding, that where barn floors can be made hollow, they must be much better for the purpose of threshing upon than such as are either placed on brick work or the ground, from their greater elasticity; the grain is of course threshed out with more ease and certainty. But in whatever manner these floors are constructed, they become expensive, and do not last any great length of time. Such as are laid on the common ground, upon three hills, with two-inch oak planks, will in general cell from eighteen to twenty pounds, and only last fifteen or twenty years; and such as are made hollow, and placed wholly on brick work.
or only on brick quins, with two-inch and half oak planks, are still considerably higher, being often from twenty-five to thirty-five pounds or more, and not much more durable. Beech floors, which were lately introduced instead of oak, have been found not to last more than seven or eight years; consequently to be by no means advantageous.

In order therefore to obviate the continued heavy expenses of these floors, as well as the great consumption of timber in the construction of them, and also to guard against the great waste of grain in threshing upon them after they begin to decay, another kind of barn floor has been invented by Mr. Upton of Petworth in Sussex, which has been found on trial to prevent these inconveniences in a great measure, and at the same time to afford other great advantages, such as those of being more easily drawn upon by loaded waggons or carts; providing, when down, comfortable shelter for hogs; and, when turned up, being capable of being employed as a stable, ox-stall, hovel, or cart-house. This is the movable barn floor, which, it is said, can be placed or displaced in a few minutes by two persons. This new-constructed hollow floor is composed of oak planks five feet eight inches in length, and one inch and a half in thickness, and costs from twenty-three to twenty-four pounds. By these dimensions being considerably less than those used in common barn floors, much advantage is gained in respect to timber; besides, planks of deal, beech, or elm, may be made use of, as they will not be liable to decay, from there being little or no dampness, and in this way the expense be lessened; and when timber from the stave is employed, it may be still farther diminished, as these floors may be composed of fluff of small kindlings, which may be had from short timbers of but little value in comparison to those made use of in other kinds of barn floors. It is supposed that floors constructed in this method will last an hundred years, or as long as the barns; as they are perfectly free from damp, from their being so much raised from the ground when down; also from their being movable, when there are more barns than one in the same yard, they may be conveyed from one to another, and by that means save the expense of having different floors.

At fig. 7. Plate II of Agriculture, may be seen the representation of a barn floor of this kind; one part of which affords a view of the floor as laid down for threshing upon, and the other part is raised up, with racks for feeding cattle, &c.: a rack boards, b slip boards for admitting air, c wooden floor fills for the slip boards & to rest upon, d movable floors, to one part of which are wooden legs serving to support it when it is necessary to put the displaced timbers into the recess e: a recess for receiving the threshed grain before it is winnowed, or for containing the movable timbers; f an iron hook to lift the floor up with when not used for threshing upon; there are two of these hooks employed in the barn; g the movable timbers that support the floor, having grooves along their surfaces to prevent the loss of grain; two of these timbers are represented larger at g; one being the crofs piece with a leg and tenon for fixing in the flore mortises, the other intended to lie lengthwise, and level with the floor of the barn; in the ground are fixed riones with mortises in them to receive the tenons of the timbers described above: h the ground, which should be made of materials sufficiently hard to prevent the hordes, carts, or waggons from making depressions in it; ii poits with iron haps, to support the floors when out of use; k racks for feeding cattle at, when the barn is applied to other purposes than threshing upon. When the floor is not wanted for threshing upon, the floors may be first turned up and fixed with the iron pins, bolts, and haps; then the middle tim-

Barn, or White Owal, in Ornithology, is in England the common name of that species of Syrinx, which is found about barns and out-houses, and which is specifically called Flamma by Gmelin, and some other naturalists.

BARNABAS, S. in BGGAR, a teacher of Christianity contemporary with the apostles, was a Levite of the country of Cyprus. His original name seems to have been "Joseph"; and the appellation of "Barnabas," signifying "Son of Conolation or of Exhortation," was conferred upon him by the apostles. He was one of those Christians who, soon after the resurrection of Christ, sold their property and laid the money at the apostles' feet. Acts, iv. 36, 37. By him St. Paul was prefected to the other apostles three years after his conversion, or about the year 37 of the vulgar era; and he was appointed a missionary to Antioch, in order to confirm the disciples. From thence he went to meet Paul at Tarsum, and they refided together a year at Antioch; and were afterwards entrusted with the conveyance of alms to the Christian brethren at Jerusalem. A.D. 44. Here he was declared joint apostle of the Gentiles with Paul, whom he accompanied to various places and with whom he co-operated in preaching the gospel. At length a diffusion occurring between them with respect to Mark, whom Paul refused to accept as a companion, they separated, probably in friendship and mutual good will, and Barnabas with Mark as his associate went to Cyprus. St. Luke bears this honourable testimony to Barnabas, that he "was a good man, and full of the Holy Ghost, and of faith." Such is the substantia of the account given of him in the New Testament. Some of the ancients, however, have supposed that he was one of Christ's seventy disciples, whom he employed during his ministry as a preacher in the land of Judaea. It has been said that he suffered martyrdom, being stoned to death by the Jews of Cyprus at Salamis; that he was buried by Mark in a cave near that city, and that his body was discovered in this island in the reign of the emperor Zenus about A. D. 438, with the epistle of St. Matthew written in Greek with his own hand, upon his breast. Lardner's works, vol. ii. p. 11, &c.

Barnabas, Epistle of, in Ecclesiastical History, an epistle still extant, addressed to St. Barnabas. It consists of two parts; the first being an exhortation to constancy in the belief and profession of the Christian doctrine, particularly as to its simplicity without the rites of the Jewish law, and the second part containing moral instructions. Learned men have differed with regard to the genuineness of this epistle. It is cited by St. Clement of Alexandria and by Origen. Eusebians reckon it among those books that are spurious, meaning probably by the term, contradicted. St. Jerome says, that it was read for edification among the apocryphal scriptures. Amongst the moderns, Pearson, Cave, Du Pin, Wake, Dr. Clarke, and many other learned men, suppose it to be a genuine epistle of Barnabas the companion of Paul. Some are doubtful, as Cotelerius, who inclines to think that it was not written by Barnabas. The objections against the genuineness of it are strongly urged by Bagnall,
Rasaage, and also by Mr. Jeremiah Jones. To this purpose he alleges that it is not in any of the ancient catalogues of sacred books; that it is not cited in scripture by any of the fathers; that it was not read in the assemblies of the primitive Christians; that it contains contradictions, notorious falsehoods, and gross mistakes; and also many things that are trifling and silly.

Mossheim says that it was the production of some superstitious Jew whose attachment to Jewish fables, as well as mean abilities, shew that, notwithstanding the uprightness of his intentions, he must have been a very different person from the true Barnabas who was St. Paul's companion. Mr. Jones supposes that it was written by a person who had been originally a Gentile or Pagan.

Dr. Lardner thinks it most probable, that it was written by Barnabas, soon after the destruction of Jerusalem by Titus, in the year of our Lord 71 or 72; and that it was addressed not to Jews, as archbishop Wake supposes, but to Gentiles, or perhaps rather to Christians in general, and intended to abate their respect for the peculiar rites and institutions of the Jews and to shew that they were not binding upon Christians. It was written in Greek; but the four first chapters or sections, and a part of the fifth, are wanting in the Greek copies. It is however entire in an ancient Latin version. This epistle has no inscription, as it is not directed to the Christians of any particular place; and on this account it has been sometimes called a Catholic epistle. Lardner's works, vol. ii. 12, &c. Jones's New and Full Method of settling the Canonical Authority of the New Testament, vol. ii. p. 503, &c. Mossheim's Eccl. Hist. vol. i. p. 113.

Barnabas, St., Gospel of, a spurious gospel mentioned by pope Gelasius, in his decrees against apocryphal books. The Turks have a gospel under this name, in which there are many things injurious to Christ and honourable to Mahomet. It was composed in Arabic, as M. de la Crole thinks, under the emperor Frederic II., A. D. 1211 to 1250, and was translated into Italian about the middle of the 15th century. Professor White has given extracts from this gospel at the end of his "Sermons at the Bampton Lectures."

Barnabas', St., Day, in the Calendar, a Christian festival celebrated on the 11th of June.

Barnabas, Cape, in Geography, lies in the north-west of America, in N. lat. 57° 15', between Trinity Island and Cape Breiville.

Barnabe, St., Island, is situated at the mouth of a small river of this name which falls into the river St. Lawrence, and most remote to the north-east on the southern or Barbard shore in coming down from Quebec.

Barnabites, in Ecclesiastical History, an order of religious thus called from the church of St. Barnabas at Milan, where they were first established, and which was bestowed upon them in the year 1545; and not as some have imagined because St. Barnabas was their patron: in reality, St. Paul is the patron of the Barnabites.

The Barnabites are regular priests of the congregation of St. Paul. Their habit is black, and the same with what they wore when first established, in 1545, by the express bull of pope Clement VII. and afterwards confirmed by Paul III. Their office is to instruct, catechize, and live in monition.

Barnach, in Geography, a small island near the west coast of Ireland, situate in Black Sed bay.

Barnacin, in Ancient Geography, a town of Hispania Tarraconensis, in the territory of the Carpetani. Ptolemy.

Barnacle, or Barnacle, in Conchology, is the common name of the species of Lepas called Anatifera: and is applied also in a general manner to all the shells which belong to the Lepas genus.

Barnacle-Goose, or Barnacle-Goose, in Ornithology, the common English name of that kind of goose which was deemed the offspring of the Lepas Anatifera in the sixteenth century. See Anatifera, and Anas Erythropus, the latter being the Latin name of the Barnacle goose.

Barnaidesia, in Botany, a shrub so named by Mitis, from Michael Barnades, a Spanish botanist. Lin. g. Schrdb. Supp. 55. 1778. Clafs, fyngepis polv- gamin equallis. Nat. Ord. Compoite dés-Corymbifer Juif. Gen. Char. Cal. common, somewhat ventricose, spreading at the tip, imbricate; scales numerous, gradually longer from the base to the tip; the inferior or exterior, ovate, closely imbricate, sharp, pungent; the superior or interior, subulate, flat, spreading, pungent. Cor. compound, rayed; corollas hermaphrodite, tubular, very few (three or four), remote, in the disk ligulate, in a simple series, in the ray. Proper to the former, funnel-form; tube very short; borders hairy, five-parted; parts converging. Proper to the latter, ligulate, lanceolate, spreading at the base, incurved at the tip, and split, outwardly very hairy; tube longer than the calyx. Stam. filaments five; anthers cylindrical, tubular. Pet. gern ovate; style filiform, longer than the stamens; stigma blind; clefts spreading, ovate-rounded. Fr. none; calyx converging; seeds very many, ovate, hairy; hairs revered. Down of the flowers of the disk bristly; rays subulate, flat, broken backwards, naked or covered with minute hairs; of the radial flowers long, erect, spreading, many-rayed, feathery, soft. Recept. flat, villose, without chaff.

Eff. Gen. Char. Cal. naked, imbricate, pungent. Cor. radiate; down of the ray feathered, of the disk bristly, broken backwards.

Species. Barnaclesia fusca is a shrub with very smooth branches, set with a pair of thorns at their origin, which at first were filipules; they are petalous, brown, smooth; leaves alternate, simple, ovate, entire, sharp, flat, veined, somewhat hairy on both sides, whitish underneath; petals very short; filipules in pairs, small, subulate; flowers in panicles, terminating; calyx pubescent. The flower is singular in having two sorts of down. This, which is the only species of this genus, is a native of South America, where it was discovered by Mitis.

Barnard, of Bernard, John, in Biography, was born at Calfor in Lincolnshire, and educated at Queen's college in the university of Cambridge. In 1643, he was admitted, by order of the visitors appointed by parliament, fellow of Lincoln college at Oxford. After the restoration, he conformed, and was promoted to be prebendary in the church of Lincoln. He died at Newark, on a journey to the Spa, in 1683. He was in good repute for his learning and orthodox principles, and was author of the following books: viz. "Cenfus Clerlor, against Roundhouse Ministers, &c." 4to. 1660; "Theologo-Historius, or the Life of Dr. Heylyn," whose daughter he married, 8vo. 1683; "An Answer to Baxter's false accestation of Heylyn;" and "A Catechism" for the use of his parish. Biog. Brit.

Barnard, Sir John, a patriotic citizen and distinguished magistrates of London, was born at Reading, in Berkshire, in 1679, of parents who were Quakers, and educated at a school belonging to persons of this persuasion at Wandsworth in Surry. In early life he was distinguished by the integrity and candour of his mind, so that all differences among his school-fellows were submitted to his decision. In the fifteenth year of his age, his father, who was now settled in
London in the wine-trade, introduced him into his own business; and his conduct was such as fully to justify the confidence that was reposed in him. Amidst other avocations that occupied his thoughts and time, he directed his particular attention to religion; and without doubt from conviction, renounced the profecution of his parents, and became a profyte to the established church. Accordingly he was baptized by Dr. Compton, bishop of London, after several previous conferences, at his chapel in Fulham, in 1703. It was the uniform practice of Mr. Barnard, from his earliest youth, to associate with persons of riper age than his own, and with such as were distinguished by their talents, learning, and religion; and his improvement in knowledge and virtue corresponded to the selection he made of his companions and friends. In this course of judicious application to mental culture as well as to secular employment, Mr. Barnard persevered till he had attained the thirty-sixth year of his age; and he was only known in private life by the excellencies of his character. About this time a bill that materially affected the wine-trade had passed the commons, and was depending in the upper house. The merchants that were likely to be injured by the operation of this bill, appointed Mr. Barnard to state their objections before the lords; and such were the abilities which he manifested on this occasion, and such was the success that attended his exertions, that in 1721 he was proposed, without his knowledge, as a candidate to represent the city of London at the next election, which took place in the following year. The contest was as warm as any that had ever been known in the city; but Mr. Barnard, though he declined all personal solicitation, succeeded by the zeal and activity of his friends. His parliamentary conduct, during a period of forty years, was in the highest degree independent and respectable; and he derived from his character as well as talents singular influence. He distinguished himself by his opposition to the measures of administration, then conducted by Sir Robert Walpole, and particularly to the extension of the excise, which he condemned both in a commercial and political light, and which, by his vigorous and affidious efforts, he induced the minister at length to abandon. Needles of popularity in measures which in his judgment concerned the good of his country, he attempted to reduce the interest of the national debt from four to three per cent.; and by his endeavour incurred a temporary odium. In 1732 he had obtained the honour of knighthood, on occasion of presenting a congratulatory address to king George II.; and in 1737 he was raised to the dignity of the chief magistrate of the city of London; an office which he executed with singular reputation to himself and advantage to the public. So attentive was he to the duties of this office, that he would not keep a single night in his house at Clapham, lest any person should be suspected of temporary absence. No magistrate ever more vigilantly in his attention to the internal police of the city over which he presided; and blended lenity with severity in the administration of it with so much discretion. He would never suffer any person to be committed to prison for a single night, till the accusation against him had been fairly heard; for he well knew the danger to which unguarded youth would be exposed even by a short abode in these receptacles of infancy. The state of our gaols had been the object of his particular investigation, and he was fully apprized of those abuses that needed correction and restraint. In 1745 Sir John Barnard took the lead in signing an agreement to take bank notes in lieu of cash, and in thus supporting public credit at a period of peculiar danger. In 1749, he became the father of the city; and the London merchants had previously, viz. in 1747 testified their veneration of him by erecting his statue in the Royal Exchange. This token of respect, however, he disapproved; as he thought that no character was entitled to it, till its perseverance in integrity had been sealed by death: and such was his modesty, that he never after transacted business within this edifice. In 1754 he was for the last time, without solicitation and in opposition to his own wishes, elected a representative of the city; but his infirmities increasing, he thought proper, in 1758, to resign his alderman's gown. After some years of honourable retirement, he died at Clapham in 1764, leaving one son (distinguished by his taste in the polite arts, and by his admirable collection of pictures) and two daughters. Few persons ever sustained a character so uniformly respectable as Sir John Barnard. He was not only blameless, but eminently exemplary in the various relations and offices of life. To the faithful and active discharge of the personal and social duties, he added a most devout sense of religion. The first hour, at least, of every day was employed in the exercise of devotion and the study of the scriptures. He attended public worship twice on a Sunday, and was constant in receiving the communion. He had such a high reverence for the bible, that he always expressed a great dislike of any attacks which were made upon its sacred original and authority. Although he relinquished the profecution of his youth, he retained, in a considerable degree, that simplicity of manners and plainness of drefs which distinguished the respectable body to which his family belonged. But though he was modest in his deportment, he was firm and fearless in the discharge of his duty. His language was clear, concise, and unaffected; and his wisdom and knowledge were recognized by persons of the first character in his time; infomuch that he was urged in 1746, by king George the second, to accept the office of chancellor of the Exchequer, which he refused. Lord Granville and Mr. Pulteney frequently consulted him on affairs of moment; and lord Clavitham, when Mr. Pitt, has been known to flile him the great commoner. The mule of Pope, by exhibiting him in contrast to worthies wealth and title, has immortalized his name.

"Barnard in spirit, sense, and truth abound; Pray then what was he? Fourscore thousand pounds." Biog. Brit.

BARNARD, in Geography, a township of America, in Windfor county and slate of Vermont, containing 673 inhabitants. It gives rise to the northern branch of Water-queue river, and is distant 65 miles N. E. from Bennington.

BARNARD CASTLE, or CASTLE BERNARD, a town of Durham, in England, 246 miles N. W. from London, and 26 from Durham. The town is about a mile in length, and consists of several streets; the principal of which is upwards of forty yards in width, and is mostly filled with handsome modern buildings. The air of this part of the country is remarkably salubrious, the market is abundantly supplied, and the situation provides every advantage to render it pleasant. The woollen manufactories have declined of late from the great use of cotton goods; much business is done by the tanners; and the flocking trade is particular flourishing. This town is mentioned as existing soon after the conquest; though it was then probably but an insignificant place, as it derived its chief consequence as well as its name from the magnificent castle founded here by Bernard Baliol about the year 1178. This fortress is situated on the summit of a high rock to the westward of the town, and was anciently of much importance; maintaining a number of officers, and being vested with high privileges
legs by its different possessors. We find the names of John Balliol, father to the king of Scotland, the celebrated Guy Beauchamp earl of Warwick, and Richard duke of Gloucester afterwards Richard III., occur among the proprietors of the castle. The latter founded a college for a dean, 12 secular priests, 10 clerks, and 6 choristers; but it is presumed that his intentions were in part frustrated by the subsequent troubles of his reign, as no traces of this foundation are now discernible. In the reign of Charles I., this castle, after being several years in the possession of the crown, was purchased by an ancestor of the present earl of Darlington, and gives a title to his lordship's eldest son. In the year 1699 it was created a barony by king William III. The present remains cover about six acres of ground. The parts of chief strength stand on the brink of a steep rock about eighty perpendicular feet above the river Tees, and every way command a most beautiful prospect. Many fragments of the ruins have the arms of Richard the third, who is supposed to have considerably contributed to this building. Though we can readily ascertain from the above that this fortress must have been of a place of great strength and extent, yet it is not possible to form any competent idea what it was in its original and perfect state. Leland in particular mentions parts of which there are not the least remains. The environs of the town are remarkably beautiful; the vale of the Tees abounding with a great variety of picturesque, pastoral, and august scenery. From the castle cliffs northward, the river is bordered by a hanging forest of oaks on one hand, and on the other by fine meadow land. The extended battlements, the circular tower and the most flately parts mantled with ivy, the brown rocks fringed with broad wood, the brighter yellow towers, and the dark and shaded battlements, are controllable by the azure lake on whose surface they are reflected. Near the path on the margin of the river is a fine new bridge of one arch, lately erected by Saurey Moritt Esq. of Rokeby Park. The number of houses in the town is 312, and its inhabitants 2556. Hutchinson's History of Durham, vol. iii. 146.

BARNARD'S ISLANDS, are five islands on the north coast of South America, laid down in modern charts off the north point of the entrance into Moroquillo bay. They lie S.S.W. from the harbour of Carthagena, in the direction of the coast. To the west of four from them is the opening into the gulf of Darien, which is the limit between North and South America. These islands form a large bay and harbour in N. lat. 5° 35', and W. long. 77° 20'. The easternmost island is called St. George's, the innermost is St. Gibraltak, and Goerace island lies between them. The river Chen is to the west of these islands.

BARNASNE, mountains of Ireland, in the county of Kerry, 8 miles S.W. of Killarney.

BARNUAL, a town of Siberia, on the west side of the Ob, 100 miles S.S.E. of Kolyma. It is situated on the Obi, in the government of Kolyma, famous for its silver and copper mines, which also produce gold. These mines are much more productive than those of Nerchinsk; for the pits hitherto opened in the latter have no continued or ready veins, are never powerful, and seldom terminate in large nsects, are always poorer as they proceed in depth, and change their contents at every fathom. The mines of Barmual belong to the crown. About 48,000 bours earn their capititation tax in working at them, over and above the miners and other workmen properly belonging to them. The quantity of gold produced at Barmual and the Shlangenberg from 1745 to 1780, amounted to 686 pounds, 16 pounds, 49 lobotniks of pure gold.

BARNEGAT INLET, called in some maps New Inlet, is the passage from the sea into Flat-bay found, on the south-eastern coast of New Jersey, 64 miles N. E. from Cape May. N. lat. 39° 37', 50'. W. long. 74° 13'.

BARNER, James, in Geography, born at Elbing, in Prussia, in 1644, applied himself early to the study of chemistry, in which he made such progress, that in 1670 he was engaged to give lectures in that art at Padua. After residing some years in that university he went to Leipzig, where he practiced medicine with success. Retiring at length to Elbing his native country, he died there in 1686. Barner left several works on the subject of chemistry, but that by which he is principally known is his "Chymia Philo-lopica, cum doctrina alchimica medicamentis fine igne culinari parabilibus;" published at Nuremberg 1689, three years after his death, a work rather curious than useful. Haller Bib. Med. Eloy Dict. Histon.

BARNERA, in Geography, a small island of Scotland, near the west coast of Lewis, separated from the main land by a strait, called Loch Barnera, about a mile wide. N. lat. 58° 25'. W. long. 7° 3'.

BARNES, Joshua, in Biography, an English divine and classical scholar, was born in London in 1614, and educated in grammar-learning at Chrift's hospital, where he was distinguished by his proficiency in Greek, and by some Latin and English poems. In 1671, he was admitted a servitor of Emanuel college in Cambridge; and in 1678, he was elected a fellow of the same college. In his numerous writings, which were critical, poetical, and historical, he displayed more industry and fancy than taste and judgment. His memory was singularly retentive, so that he could both converse in the Greek tongue with great readiness; though Dr. Bentley facetiously remarked of him, that he understood as much Greek as a Greek cobbler. But if he excelled in tenaciousness of memory, he was notoriously deficient in solidity of judgment; and therefore some person recommended this pun to be inscribed upon his monument:

"Joshua Barnes,
"Felicis memoriae, Judicium expectans."

The enthusiasm of his temper was manifested in various singularities of opinion and conduct. Believing that charity never fails in this life of obtaining due recompense, he has given his only coat to a common beggar; and he used to recite strange stories of some unexpected remuneration which he had derived from charities of this kind. Of his talents and learning, and particularly of his acquaintance with the Greek language, he was vain and boastful; and at the same time he was prone to depreciate and abuse others. Of his works the most respectable were his editions of the Greek classics; and these he dedicated, without much appropriate felection, to persons of high rank. In 1695, he was elected Greek professor of the university of Cambridge. In 1700, he married a widow with a handsome jointure, who is said to have made the first advances; and, with a view to her amulence, and in order to induce her to supply him with money towards defraying the expense of his edition of Homer, he wrote a copy of English verses, designed to prove that Solomon was the author of the poems under Homer's name. He died in 1712, and was buried at Hemingford in Huntingdonshire, where a curious monument was erected to him by his widow, with an inscription partly in Latin and partly in Greek Anacreontics. The following memorandum is annexed: "Mr. Barnes read a small English bible, that he usually carried about him, one hundred and twenty-one times over at leisure hours." Of his numerous publications, the principal are the following: "A Poetical Paraphrase on the History of Either," intituled, "Adagiosis vera," or "The Courtier's Looking-glass, &c." The story is paraphrased in Greek.
B A R

Greek verse, with a Latin translation in the opposite page and Greek scholia; to which is added, "An Homeric Parody on the same Story." "The History of that most victorious monarch Edward III. &c." Camb. fol. 1688.

This historical work, for which the author's talents seem to have been very ill adapted, abound in false inferences and tedious digressions; and in long and elaborate speeches, after the manner of Thucydides and other ancient historians, which seem to be the result of his own imagination; the whole disapproving neither the judgment of a politician, nor the tale of a good writer. "Europes que extant omnis, &c." Camb. fol. 1694.

In this edition, the poems of Anacreon are corrected, and much enlarged by the addition of several whole pieces and fragments. The life of Anacreon is annexed; and in the Prolegomena, the author treats of the antiquity and invention of lyric poetry, and the peculiar character and metre of that poet. The dedication to the duke of Marlborough is followed by a Greek Anacreontic ode upon the victory at Blenheim. The editor has also subjoined the epigrams of the ancients and moderns upon Anacreon, and some odes of his own composition under the title of "Anacreon Christianus." "Homer Illis et Odysseis, &c." 2 vols. 4to. Camb. 1710.

This edition is furnished with an exact Latin translation, with the ancient Greek scholia, many notes upon the text and scholia, and various readings; to which are subjoined the "Patrochomomyachia," the "Hyms and Epigrams," and "Fragments," and "Two Indexes." This edition of Homer has been generally esteemed as correct and complete; though in the Acta Eruditorum for Jan. 1711, there are some objections against it, which have been answered by Dr. Bentley. Barneveldt's editions of the Greek classics have of late years been linking into disputation; and modern critics place little confidence in his judgment or fagacity. He has been charged, in some of his various readings, by the learned Dr. Clarke, with audacity and unkindness.

As for his other works, both in prose and verse, it would be tedious to enumerate even their titles; and this is the least necessary, as they are now confined to total oblivion. Biog. Brit.

B A R

BARNET, a township of America, in Caledonia county, and state of Vermont, containing 477 inhabitants, and distant 112 miles N. E. from Bennington.

BARNEVELD, a family distinguished in Biography, a minister of Holland, eminently distinguished by his abilities and patriotism, was born in 1547. In his early negotiations on behalf of the states general with France, England, and the neighbouring powers, he gave great satisfaction to those who employed him, and gained equal credit and esteem in the judgment of Henry IV. and queen Elizabeth. As grand pensionary of the states of Holland, he obtained extensive influence; and firmly attached to the liberty of his country, he observed the growing power of the house of Orange, directed by the warlike and aspiring prince Maurice, with jealousy and apprehension. Amidst the collision of different parties, he was regarded as the leader of the opposition to the measures of that prince. The authority of Maurice depended, in a great measure, on the continuance of the war with Spain, and Barneveldt was very zealous of terminating it. By his zealous endeavours to effect this purpose under the mediation of the king of France, he incurred the violent odium of the adverse party. At length, however, he succeeded by obtaining, in 1669, a truce for 12 years; the first article of which recognized the independency of the united states. Soon after this event, the disputes between the Arminians and Calvinists, or Remonstrants and Contra-remonstrants, furiously agitated the Dutch provinces. Barneveldt, inclining to the former, and the advocate of toleration, exerted himself in procuring for the Arminians or Remonstrants that liberty of conscience to which they had an equitable claim. Prince Maurice placed himself at the head of the other party, which was the most numerous; and probably took pleasure in the opposition and calumny encountered by Barneveldt in his endeavours to promote the cause of religious freedom and moderation. At this time, notwithstanding the suspicions excited against Barneveldt, as if he wished to subject his country again to the yoke of Spain, he was essentially carrying this by negotiating with James I. for the reformation of the towns of Fluizing, Rammekeen, and the Brille, which had been put into the hands of Elizabeth as security for the money which she had lent to the states. Barneveldt's success in this negotiation added James to the number of his enemies.

The religious disputes, which had been appealed in the province of Holland by the influence of Barneveldt, prevailed so much in the other provinces, that a national synod was assembled at Dortrecht in 16018 in order to bring them to a termination. To this synod the kings of England and France, and most of the Protestant states of Europe, sent deputies; and the Arminians, who did not comply with the citation to appear before this assembly, incurred a formal condemnation. On this occasion, Barneveldt, Grotius, and other Remonstrant chiefs of the anti-Orange party, were arrested and imprisoned in the castle of Louvain. Barneveldt, however, was the devoted victim. Many accusations were alleged against him, as the fomentor of the disturbances that had occurred at Utrecht, and as an enemy to the public liberty; and being tried by a court, composed chiefly of his enemies, and admitting inadequate proofs, he was capitaly condemned. Prince Maurice, to whom application was made from various quarters in his favour, remained inexorable; and he would only promise a pardon upon condition of his being solicited by the family of Barneveldt but they refused to do an act, which would imply the guilt of their
their venerable chief. Barneveldt prepared for death, and
without alluding any favour for himself, merely solicited the
protection of his children. The morning of execution, Barneveldt proceeded to the scaffold with a serene counte-
nance; but being somewhat disturbed on his arrival, he ex-
claimed with uplifted eyes to heaven, "O God! what is
man!" Having prayed with the minister who attended
him, he rose from his knees with composure, declared
his innocence to the executioners, and directed the executioner
to perform his office. His head was struck off at a blow,
in his 72d year, May 13th 1619. The popular hatred soon
subsided; his memory was revered as that of the purest
of patriots and most respectable of men, and his death left a
stain on the character of prince Maurice which all his great
qualities and services were not sufficient to efface. The
states of Holland, in the register of his death, added these
words, which may serve as a testimony to his character;
"He was a man of great coddent, industry, memory, and
prudence; yes, singular in all. Let him who flanders, take
heed of his fall. God be merciful to his soul! Amen."
"Never (says the French ambassador De Maurier) was there
so wise a wife and virtuous man as M. de Barneveldt. He
had a masterly preference, and said much in few words, with a
grave and succinct eloquence." Barneveldt left two sons in con-
siderable employments; who being deprived of them by
prince Maurice, engaged in a conspiracy against his life.
One was beheaded, and the other made his escape. When
the mother of him who was taken and condemned, fell at
the feet of Maurice supplicating his life, the prince ex-
pressed his surprize that she who had refused to ask her hus-
tand's pardon, should condescend to intercede on behalf of
her son. "I did not ask pardon for my husband," said the
mother with a noble spirit, "because he was innocent. I
ask it for my son, because he is guilty." Mod. Un. Hist.

Barneveldt's Islands, in Geography, are two small flat
islands, close to each other, on the west side of Terra del
Fuego, partly surrounded by rocks, and 24 leagues distant
from the straits of Le Maire. S. lat. 55° 45'. W. long.
66° 58'.

Barnevilles, a town of France, in the department
of the Channel, and chief place of a canton in the district
of Valognes. 54 leagues S.S.W. of Cherbourg.

Barnifianti, in Ornithology, is an aquatic bird, of
which Oviedo speaks in his "Hill. des Indes," book 14,
c. 23; but which it is impossible to ascertain from what that
author has said of it.

Barnsley, in Geography, a small market town of Eng-
land, in the west riding of Yorkshire, 15 miles from Doncaster,
and 176 north-west from London. It is situated on the side
of a hill, and about 5 furlongs in extent. The town, though
well built of stone, is called Black Barnsley; probably from its
smoking furnaces, or rather from the smoke of the coals with
which it is surrounded. The land is very prolific in wheat and other grain, and coal is also exceedingly plentiful.
The abundance of flax, timber, iron-stone, &c. and the
cheap living necessary for population, render this place very
appropriate for any kind of trade. At present its wire
works are supposed the best in the kingdom; and the wire is
of two sorts; the hard, made into teeth for cotton and wool
cards, the soft for flocking-frame needles. Processes of a
leifer kind are weaving of linen, in which 500 looms are
employed, and a glass manufactory of black bottles. Barnsley
has a well built church, which is a chapelry under Silkeston,
a free grammar school, a market on Wednesday, and three
fairs; the population of this township consists of 722
houses, inhabited by 3060 persons.

Barnstable, a very ancient corporate town and
seaport in the county of Devon, is situated in a broad
and fertile vale on the eastern bank of the river Taw,
and bounded by a semicircular range of hills. It is one of
the nearest and most reputable towns in the north of the county;
the streets being spacious and regular, and the buildings re-
spectable. Before the conquest, Barnstable was a royal de-
meifie; and king Athelstan is reported to have constituted
it a borough, and to have erected a castle near the confluence
of the rivers North Yeo and Taw; but remains, however, of
this fortress continue, except a high artificial mound. In
Domeday book it is noticed as containing "forty bur-
gesses within the borough, and nine without;" and the in-
habitants were exempted from serving on any expedition
or being otherwise taxed, but in equal proportion with Exeter
and Totnes. The town was re-incorporated by Henry I.
but till retaining some of its ancient feudal privileges, which
250 of the common burgesses at this day possess; namely,
a right to vote with the corporation for two members of
parliament.

The corporation is composed of a mayor, high steward
(at present earl Fortescue), two bailiffs, two eldersmen, a re-
corder, twenty-two common-council men, and other officers.
King James I. ratified and confirmed the privileges of
the town by a charter in the eighth year of his reign;
and we find by authentic documents, that the first
return for members to parliament was made in the 23rd of
Edward I.

Respecting the trade of Barnstable, its harbour is so fa-
shon that vessels of more than 200 tons cannot enter; yet
the baize, silk-flocking, and woollen manufactories still
give life to the place, and in a great degree compensate
the loss of its former woollen trade; added to this, the beautiful
scenery and pleasantries of the neighbourhood, and the
cheapness of living, have induced many independent families
to make it their sole residence.

A noble quay along the river is terminated by a handloome
piercote, over the centre of which is placed a statue of queen
Anne. Over the river is a stone bridge of sixteen arches.
The church is a lofty building, with a handloome spire and
a good organ; formerly it contained several chantries.
We find also that in the town Judhall de Totnes founded
a priory for Chiaic monks, which, at the dissolution, was
valued at £39 6s. 7d. per annum.

The grammar school is famous for having upon its foun-
dation several eminent characters; bishop Jewel and his oppo-
site professor Harding, the poet Gay, Dr. Maturine, &c.
For the useful education of the lower clays of inhabitants,
a charity school is erected over the north gate; near which
is a pleasant walk, denominated Northern Hay, from the
fine prospects it commands, as well as an agreeable prom-
enade.

The number of houses in the whole parish is estimated at
633, and the inhabitants at 3748. N. lat. 51° 15'. W. long.
4° 5'.

Barnstable Bay, is an opening in the Bristol channeled
by the union of the rivers Taw and Tonebridge. This is
the common bay or road to the towns of Barnstable
and Biddeford, on their respective rivers.

Barnstable, a county of America, lying upon the
peninsula, the point of which is cape Cod, the south-eastern
point of Massachusetts's bay, opposite cape Ann. This
county is about 65 miles long, and in various parts from 3
to 6 and 9 miles broad. It contains 11 townships, and the
plantation of Marshpee, having 2543 houses, and 17554
inhabitants. Barnstable was made a shire in 1667. See
Cape Cod.
BARNSTAPLE, the Mattacheese or Mattakeeset of the ancient Indians, is a port of entry and poll town, and the shire town of Barnstaple county in North America. It extends across the peninsula, and is washed by the sea on the north and south, having Sandwich and the district called Martha-pec or Marthapec on the west; and is about 5 miles broad and 9 long; 67 miles S. E. from Boston. Sandy-neck on the north shore, running east almost the whole length of the town, forms the harbour, and embosoms a large body of salt-marsh. The harbour is about a mile wide and four long; and the tide rises in it from 8 to 14 feet. Its bar, running off N. E. from the neck several miles, prevents the entrance of large ships; but small vessels may pass any part of it at high water. There is another harbour on the south, called Lewis's bay. Its entrance is within Barnstaple, and extends almost 2 miles into Yarmouth. This harbour is commodious and safe, and is completely land-locked. In Barnstable there are about 20 or 30 ponds. The land here produces about 25 buhuds of Indian corn to an acre, and ryce and other grain in proportion. Wheat and flax are cultivated; the latter with success. From 12 to 18,000 bushels of onions are raised for the supply of the neighbouring towns. The fishery, which is annually increasing, employs about 100 men. The people, who are in number about 2610, are generally healthy; and many instances of longevity occur. Many of the farmers are occasionally leaumcn, and many mariners and mallers of vessels, who fall from other ports, are furnished by this town. N. lat. 41° 43'.

BARNSTEAD, a township of America, in Strafford county, New Hampshire, containing 897 inhabitants; 32 miles N. W. of Portsmouth, and 16 E. by S. from Canterbury on Connecticut river.

BARNSTORF, or BERNSTORF, a town of Germany, in the circle of Weftphalia, and county of Diepholz, 8 miles north of Diepholz.

BARNTRUP, a town of Germany, in the circle of Weftphalia, and county of Lippa, 4 miles N. E. of Blumberg.

BARNWELL, a village situated about half a mile north-east of Cambridge, in England, was formerly of great consequence from its ancient priory, which, at the dissolution, was valued at 351 L. 15s. 4d. The village has suffered very much by fire. Barnwell has a fair kept in its neighbourhood, commencing annually on Midsummer-day, and continuing a fortnight. This fair derives its origin from a custom of the children in the neighbourhood assembling on Midsummer-eve at Barn's-well. A number of pedlars resorted to the spot, and exposed their merchandise for sale, so early as the reign of Henry I.; the articles brought being mostly pottery, the festival obtained the appellation of Pet Fair. It appears, however, to have assumed its legal form in the reign of Henry III. by whom it is said to have been chartered and granted to the priory. The fair is still proclaimed on Midsummer-eve, and the field in which it is held is called Midsummer Green. But Barnwell is most famous for the great assemblage of merchandise annually held in a large meadow, called Sturbridge Fair; the origin of which Dr. Stubley was induced to ascribe to his hero Carausius: it is however evident that king John granted the whole for the use and maintenance of an hospital for lepers who had an ancient chapel here; and the chaplain claimed the dues, till Hen. VIII. In consideration of 1000 marks paid by the corporation of Cambridge, gave them the grant of the fair, which was confirmed by Elizabeth. The field in which it is held is about half a mile square, having the rivers Cam and Sture on its northern and eastern sides. The booths are built in regular order, each row being particularly named, as Ironmonger's row, Bookfeller's row, &c.; the centre is called the Dadderly, and chiefly occupied by drapers, mercers, and wholesale dealers in cloths. Sturbridge fair is solemnly proclaimed on the 8th of September, by the vice-chancellor, proctors, and other officers of the university; and afterwards by the mayor and aldermen. The listed time for its continuance is fourteen days. Dramatic exhibitions are forbidden within nine miles of the university, except during this fair and the week preceding. This was formerly the greatest mart in England; but its businesse declining, owing to the circulation of commerce throughout the country, its consequence is very much diminished. Beauties of England and Wales, vol. ii.

BARO, or BARN, PETER, in Biography, a professor of divinity in the University of Cambridge, was born at Elampes in France, and educated for the law at Bourges; but driven from his country to England by the persecution of the Protestants in the reign of queen Elizabeth. By the recommendation of Lord Burleigh, he was elected professor at Cambridge in the year 1574. He was attacked by the rigid Calvinists on account of the reputed laxness of his sentiments concerning the doctrines of predestination and justification; and a complaint was preferred against him as an encourager of the spread of Pelagianism in the university, to archibishop Whitgift in 1595, which produced the Lambeth Articles, that were made use of to silence him. But as he continued to preach his former doctrines, he was cited before the vice-chancellor, and several articles were exhibited against him. The proceedings against him, however, were prevented by the interference of the chancellor Lord Burleigh, and he was recommended by his learning and character to the protection of the archibishop Whitgift. At length wearied by the persecution of his enemies, he retired from the university to London, where he died three or four years afterwards. A collection of his theological works in Latin was published at London in 1579, fol.; as were also some detached pieces in that language, and some sermons, &c. in English. Biog. Brit.

BAROACH, BROACH, or BARIJUH, the ancient Baryga, in Geography, a town of Hindostan, in the country of Guzerat, lying in the route from Surat to Ambedab, and seated on the great river Nerbuddah, about 25 miles from its mouth. Baroach has been, in different ages, a port common both to Nehrwalch, the capital of Guzerat, and Tagara, supposed to be the modern Dowlatabad. The former was eight journyes, the latter ten, from Baroach. It is situated about 217 British miles north from the Plithana of Arrian, or the modern Pultanah; and all kinds of mercantile goods throughout the Deccan were anciently brought to Tagara, and from thence conveyed on carts to Baroach or Baryga across the Balga-Gaut mountains. Baroach is famous for its manufacture of very fine bafts and other cottons; and the water of the river Nerbuddah is said to have a peculiar property for bleaching of cloth to a perfect whiteness. Agates are likewise an article of trade in this place; which are brought from the mountains near Brampour, and are mostly disposed of at Cambaya. The fortresses of Baroach is large and square, standing upon a hill, which is the only eminence for many miles, and might be made very strong. The Dutch factory was established here in 1617, but is in a low state. N. lat. 21° 45'. E. long. 72° 58'.

BAROCCIO, FREDERICK, in Biography, an eminent painter of history and portrait, was born at Urbino in 1538, and instructed in the principles of painting by Battila Venetiano, and in those of perspective by his uncle Bartolomeo Genga. Having availed himself of these instructions till his
20th year, he removed to Rome, and pursued his studies with such affinity and success, that he became one of the most graceful painters of his time. At Rome he was particularly encouraged by the protection of cardinal della Rovere, and by the commendation of Michael Angelo. On his return to Urbino he gained great applause by several pictures, and more especially by that of a St. Margaret, which induced pope Pius IV. to invite him to Rome, and to employ him, in conjunction with Federigo Zuccerbo, in the decorations of his palace of Belvedere. It has been said, that his superior merit excited the jealousy of his brother artists to such a degree, that they gave him poison at an entertainment. Whether this be true or not, his health declined; and for the recovery of it, he was under a necessity of recurring to his native air, and of interrupting his labours. However, by due attention, his life was prolonged to the advanced age of 84 years. His genius principally inclined him to the painting of religious subjects; and his works evince that it was his chief ambition to imitate Correggio in his colouring, and Raphael in his manner of designing. It is easy to observe, that he endeavoured to reanimate the former illustrious artist in the sweetness of his tints, in the harmony of his colouring, in the graceful air of the heads, in the disposition of his draperies, and the forms of his Bambinos, though he sometimes expressed the mufcular parts of the human body too strongly. He seldom painted any historical figure without having either modelled it in wax, or placed some of his disciples in such attitudes as he wished to represent; his fitter was the model for the Madonnas, and her child for his Bambinos. He is said to have employed seven years in painting at Assife, the birth-place of St. Francis, a picture called the "Pardon," in which the figure of the faint kneeling, by the force of shade, seems to rile from the canvas. The works of this master are numerous; the principal of which are at Rome, in the Belvedere, and several churches; at Urbino, Assife, Cortona, Arezzo, and other towns in Italy; in the gallery of Florence; the Efeurial; and the duke of Orleans’s collection. Barocci engraved four of his own pieces with peculiar spirited, and more than thirty more have been published by different engravers. Pilkington and Strutt.

BAROCHE, L.A, in Geography, a town of France, in the department of the Orne, and chief place of a canton in the district of Domfront; 4 miles S.S.E. of Domfront. BAROCO. in Logic, denotes the fourth mode of the second figure of the syllogism.

A syllogism in baroco has the first proposition univcrsal and affirmative, but the second and third particular and negative; and the middle term, the attribute or predicate in the two first.—For example:

"BA Every virtue is attended with derivation.
RO Some kinds of zeal are not attended with derivation.
CO Therefore some kinds of zeal are not virtues."

"BAR Nullus homo non est bipes.
OC Non omne animal est bipes.
O Non omne animal est homo."

BAROLITE, in Mineralogy. See WITHERITE.

BAROMETER, compounded of βαρος, weight, and μέτρον, measure, is an instrument for measuring the weight of the atmosphere and its variations, in order chiefly to determine the changes of weather, and the heights of mountains, &c.

The barometer is frequently confounded with the βαροσφαῖρα, though somewhat improperly; the latter, in fête fnefs, being an instrument that barely flew an alteration in the weight of the atmosphere: but it is one thing to know that the air is heavier at one time than another, and another to

measure how much that difference is; which is the business of the barometer.

The barometer is founded on the Torricellian experiment, as it is called from its inventor Torricelli, who, in conformity of the previous suggelion of Galileo, with regard to the acent of water in a pump, upon drawing up the piston, proceeded, in 1643, to fill with mercury a glass tube, hermetically sealed or cleft at one end, the other end being open and immered in a bafon of magnific mercury. Judging that, in the former case, the water was fnultained in the pump by the pressure of the air on the water in the vefsel, in which its open end was immered, and that it was the measure of this pressure, he hence concluded that mercury would in like manner be supported by it in the tube, and at a height which was also the measure of the air's pressure, or above 15 times less than water. His experiment was completely verified; for he observed that the mercury defended in the tube, and finally settled at the perpendicular height of 29.4 Roman inches, whether the tube was vertical or inclined, according to the known laws of hydrostatical pressure. This famous experiment was repeated and diversified in various forms, with tubes filled with other fluids, such as water, wine, oil, &c.; and the refult being the fame, the weight and pressure of the air were established beyond contradiction or doubt. Those who had any remaining doubts were completely satisfied by a beautiful experiment exhibited by M. Auzout. He provided a small box or phial EFGH (Plate IX. Pneumatics, fig. 74.) into which he inserted two glass tubes, AB, CD, each three feet long, in such a manner that they were firmly fixed at one end, and reached nearly to the other end. The tube AB was open at both ends, and CD was closed at D. This apparatus being completely filled with mercury, by unfcrewing the tube AB, and filling the box and the tube CD, and then screwing in the tube AB and also filling it, was inverted, whilst a finger was held on the orifice A, and set upright in the manner exhibited in Fig. 75, immersing the orifice A of Fig. 74, or A of Fig. 75, in a small vessel of quickfiver. Upon this, the mercury ran out at the orifice A, till its surface mn within the phial defended to the top of the tube ba. The mercury began also to descend in the tube de (Fig. 75.) corresponding to DC in Fig. 74, and flowing over into the tube ba, ceased at a, till that in de was very nearly on a level with mn. In ba, the mercury flowed at k, 29.4 inches above the surface op of the mercury in the cijern, as in the Torricellian tube. Indeed, this whole apparatus may be first con sidered as a Torricellian tube of an uncommon form, from which the mercury would flow out at a. But when any of it escaped, a vacant space would be left above mn, and the mercury in the tube de would also descend, and running over into ba, supply its vacant, till de became almost empty, and could no longer supply ba. The inner surface being therefore deprefed as much as possible, till it became level with b, no more mercury could enter into b, and yet its column being too heavy to be supported by the pressure of the air on the mercury in the ciferin. Indeed, this whole apparatus may be more closely con sidered as a Torricellian tube of an uncommon form, from which the mercury would flow out at a. But when any of it escaped, a vacant space would be left above mn, and the mercury in the tube de would also descend, and running over into ba, supply its vacan t, till de became almost empty, and could no longer supply ba. The inner surface being therefore deprefed as much as possible, till it became level with b, no more mercury could enter into b, and yet its column being too heavy to be supported by the pressure of the air on the mercury in the ciferin.

This state if a small hole g were made in the upper cover of the box, the external air would rush in by its weight, and press on the mercury in the box. This pressure would immediately cause the mercury to rise in the tube de to k, 29.4 inches above mn. It likewise presses on the mercury at k in the tube ba, balancing the pressure of the air on the mercury in the ciferin. The mercury in the tube, therefore, must defend to the bottom by its own weight. By this experiment the doctrine of the gravity and pressure of
of the air is decisively established. See Air, Weight of, and 

Experiments with the Air-Pump.

Notwithstanding the satisfactory demonstration of the air's preface, afforded by the Torricellian experiment, some attempts were made by the advocates of a plenum for evading it, and for explaining the phenomena of this experiment by some other hypothesis. Accordingly Linus contended, that in the upper part of the tube there is a film, or "rope of mercury," whence his hypothesis was called "the funicular hypothesis," which extended through the feeling vacancy; and that, by means of this rope, the rest of the mercury was suspended, and kept from descending into the basin. In proof of this absurd and ridiculous hypothesis he alleged the following experiment. Take, says he, a small tube, about 20 inches long, open at both ends; fill it with mercury, and stop the lower orifice with your thumb. Then closing the upper end with your finger, immerse the lower end in stagnant mercury; and upon the removal of your thumb, there will be a sensible suction of the finger into the tube; and both the tube and mercury will adhere to it so firmly, that they may thus be carried about the room. Hence he concludes, that the internal cylinder of mercury in the tube is not sustained by the pressure of the external air; for this, he argues, would not account for the strong suction, and the adhesion of the tube to the finger. If the tube be not quite filled with mercury, but a small interval of air left at the top, after the tube is immersed in stagnant mercury, a considerable suction will be perceived. From these experiments, which actually furnish evidence of the air's preface, the funicular hypothesis of Linus derived support for some time; but it has been long since exploded. When it was perceived that the mercury on the top of a high mountain subfided, and flooded at a lower height than on a plain, and that in the vacuum of an air pump it descended to the bottom of the tube, this hypothesis could have no advocates. However, an experiment mentioned by Mr. Huygens, in which mercury well purged of its air remained suspended in a tube at the height of 7½ inches, suggested a more considerable difficulty, which has been variously solved. See an account of it, under the article Torricellian. For an explication of the phenomenon of a pipkin, which discharges water under the exhausted receiver of an air-pump, see Siphon.

Barometer, Common, the Construction of it.—A glass tube (AB, Plate IX. Pneumatics, fig. 76.) open at one end, and hermetically sealed at the other A, having its diameter about one third or one fourth of an inch, and its length thirty-three or thirty-four inches, is filled with mercury to such an extent as not to have any air over it, nor any bubbles adhering to the sides of the tube; which is best done by means of a small paper or glass funnel, with a capillary tube. If a small bubble of air be moved backwards and forwards in the tube, it will help to clear the mercury; which will appear, when pure, like a polished rod of steel. The orifice of the tube, filled after this manner, so as to overflow, is then closely pressed by the finger, so as to exclude any air between it and the mercury, and thus immersed in a vessel of a convenient diameter, so however as not to touch the bottom; at the distance of twenty-eight inches from the surface of the mercury are fixed two plates, CE and DF, divided into three inches, called "the scale of variation," and these again subdivided into any number of small parts. Lastly the tube is enclosed in a wooden frame, to prevent its being broken; the bafon, though open to the air, secured from dust; and the barometer is complete. As the lowest station of the mercury in this country is about 28 inches, and the highest about 31 inches above the surface of the mercury in the baron, the former point is the lowest in the scale of variation, and in the common barometers, called "weather-glasses," it is marked frozen; and the latter is marked on one side very dry for the summer, and on the other very hard frost for the winter. To the next half-inch below this highest point are annexed hot fair on the one side, and frost fair on the other. At the height of 30 inches, the word fair is marked on one side, and frost on the other; at 29½ is marked the term changeable both for summer and winter; at 29 are inscribed on the one side rain, and on the other snow; and at 28½ inches are the words much rain on one side, and much snow on the other. Each of these larger divisions is usually subdivided into ten parts, and by means of a sliding index adapted to the instrument, the ascendent or descent of the mercury may be ascertained for any number of divisions. Each of these tenths is again sometimes divided into ten more, or hundredths of an inch, by means of a sliding piece of brass, with a scale called Nominus and Vermin; for the use of which see these terms, and the follow of this article.

The common barometer is the best, and most to be depended upon in accurate observations, it may be proper to add some directions for preparing it: they are collected chiefly from the publications of Mitchelhbrook, Desaguliers, and de Luce on this subject. It appears from many experiments, that the mercury floats higher in tubes of a larger, than in the of a narrower bore; and therefore when observations are made with different barometers, some regard should be paid to the difference of their diameters, and it would be desirable to have them constructed of tubes of the same diameter. The bore of the tube should be large, in order to prevent the effects of the attraction of cohesion; not less than one fourth of an inch; but if they are one third of an inch diameter, they are better. If a cilind be used as a reservoir for the stagnant mercury, it should be large in proportion to the diameter of the tube, at least ten times greater; that the addition or subtraction of the mercury, contained between the greatest and least altitudes, may not sensibly affect its depth; for the numbers marked on the scale annexed to the tube, shew their distance from a fixed point, and cannot truly indicate the height of the column above the mercury in the cilen, unless its surface coincide with this point, and be immovably. In order more effectually to preserve the lower surface at the same height, from divisions on the scale fixed to the instrument, the father of the late Mr. George Adams first applied to the barometer a floating gage, by means of which the same cireul which renders the barometer portable, regulates the surface of the mercury in the cilen, so that it is always at the place from whence the divisions on the scale commence. See Portable Barometer.

The tube should be preserved free from dust till it is used; and for this purpose it may be hermetically sealed at both ends, and one end may be opened with a file, when it is filled. If this precaution has not been observed, the inside should be well cleaned, by waving it with alcohol highly rectified, and rubbing it with a little piece of hamp- my leather fastened to a wire. The mercury should be pure; and may be purged of its air, by previously boiling it in a glazed earthen pipkin covered close; and when the tube has been uniformly heated and rendered electrical by rubbing it, the hot mercury should be poured into it in a regular current, through a glass funnel with a long capillary tube, so that the air may not have room to pass between the parts of the quicksilver. M. de Luce directs, as Mr. Orme had practiced many years ago in the construction of his improved diagonal barometers, that the mercury should be boiled in the tube,
tube, as the most effectual method of purging it of its air and moisture. The process is briefly this: he chuses a tube of 24 lines or 3 lines bore, and not exceeding half a line in thickness; he fills it with mercury within two inches of the top, and holds it with the sealed end lowest in an inclined position over a coining dish of burning charcoal, presenting first the sealed end to the fire, and moving it obliquely over the coining-dish. As the mercury is heated, the air bubbles appear like so many fluids on the inner surface of the tube, and gradually running into one another, ascend towards the higher parts of the tube, which are not heated; here they are condensed and almost disappear; and after successive evaporation, they acquire a bulk by their union, which enables them at length to escape. When the mercury boils, its parts strike against each other, and against the sides of the tube, with such violence, that a person unaccustomed to this operation is ready to apprehend their force to be sufficient to break the tube. The mercury is thus freed from all the heterogeneous particles contained in it, together with their surrounding atmospheres, and the air which lines the inside of the tube, which cannot be easily expelled in any other way, is discharged; when this last-mentioned fintum of air is thus expelled, the tube may be afterwards emptied, and filled even with cold mercury, and will be found nearly as free from air as before. The mercury in the tubes thus prepared by a determinate quantity of heat, will rise higher than in those of the common form, and the barometers will more nearly correspond with each other; whereas there will be a difference of six or eight lines in the ascent of the mercury in common barometers.

When this operation is completed, the mercury generally remains suspended at the top, and will not descend to its proper level without shaking the tube to bring it down. The tubes, which should be chosen not less than three feet long, may now be filled to their proper length.

Barometers of this kind rise uniformly in a heated room; whilst the mercury in those that had been prepared in the common way descended, and in different proportions. When the room cooled, the former descended uniformly, and corresponded with each other; the latter rose with the same irregularity with which they had before descended, nor were they found, at the close of the experiment, to stand at the same relative heights as they did at the beginning of it. The reason of which is obvious, from the effects of heat on the air remaining in unequal quantities in the tubes in the one cafe, and on the purer mercury in the other.

Another circumstance that requires attention in the construction and use of barometers is the temperature of the air; for unless this remains the same, the dimensions of a given quantity of mercury will be variable; and the altitude of the mercury will be an uncertain measure of the weight of the atmosphere, because it is diluted by heat, and contracted by cold, when probably its weight and pressure are unchanged.

M. De Luc attended particularly to this circumstance, and contrived to estimate the effects of heat on the quicksilver in the barometer, when it is used for accurate observations, by means of a thermometer; the scale of which is divided in such a manner as to indicate, with little labour of calculation, the correction to be made on account of heat. As an increase of heat that is sufficient to raise the mercury in the thermometer from the point of melting ice to that of boiling water, will lengthen the column of mercury in the barometer six lines, he divides each line in the scale of the barometer into four parts, each of which may be easily subdivided into four finer parts, or sixteenths of a line. The scale of the thermometer marking the interval between the freezing and boiling points, and answering to the six lines of the barometer, is divided into ninety-six equal parts; each of which will correspond to the four hundredth of a line in the motion of the mercury in the barometer diluted by heat, which must be added to or subtracted from the height of the mercury in the barometer, for every degree of the variation of the thermometer.

A scale of this kind, continued above boiling or below freezing water, is annexed to his Portable Barometer and Thermometer. M. de Luc prepared two barometers with their respective thermometers graduated in the manner above explained; he placed one pair in the cellar of one house, and the other pair in the upper room of another house in a lower situation, so as to be exactly on a level with the cellar; he found that the thermometer in the room rose nine degrees, and the barometer $\frac{1}{9}$ of a line higher than those in the cellar; whence he drew that, without allowing for the effect of heat, the difference in the heights of these two barometers would have indicated a difference of about forty-five feet in the heights of these two places, though they were exactly on the same level.

M. Prins, an artist in Holland, has made an improvement in the refervoir of the simple barometer, by means of which the mercury contained in it is constantly kept at the same level; but the construction is difficult, and therefore it has not been generally adopted. De Luc's Recherches, &c. vol. i. p. 35.

The common barometer is a kind of chamber barometer, and serves for observing in a fixed place the changes of the atmosphere; but is not adapted for removal from one place to another, and in this respect differs from the portable barometer. It is sometimes combined with a thermometer, and sometimes sold with a hygrometer, and in this form prepared by the mathematical instrument makers. An instrument of this kind constructed by Meffrs. Jones, opticians in London, is exhibited in fig. 84, and consists of a barometer, thermometer, and hygrometer, all in one mahogany frame. The thermometer or hygrometer of this apparatus may be conveniently separated from the frame, and occasionally used apart, if it be necessary. The thermometer is separated by means of two screws on a; and the hygrometer, by unloosening a brass pin at the back of the frame. The index of the hygrometer is set at any time, merely by moving with the fingers the brass wheel seen at c; and the two sliding indexes of the barometer and thermometer are moved by rack-work, set in action by the key g placed in the holes b and i. The divisions of the barometer plate a are in tenths of an inch, from 28 to 31 inches; and these are subdivided into hundredths, by the Monius or Vernier scale, placed on a sliding flip of brass, similar to that of the common barometers. This Vernier (fig. 85) is divided into ten equal parts, all of which are equal to eleven of those on the scale of inches, or to eleven tenths. By this artifice, the height of the mercury at E is evident merely by inspection to the hundredth part of an inch. For understanding this, it should be considered that the tenth of a hundredth part of an inch is the eight hundredth part of an inch. But every tenth of an inch in the scale B is divided into ten equal parts by the flip or Vernier A; for since ten divisions on that exceed ten on the scale by one division, that is, by one tenth of an inch, one division on the Vernier will exceed one division on the scale by one tenths part, and two divisions on the Vernier will exceed two on the scale. By two tenths, and so on; therefore every division on the Vernier will exceed the same number of divisions on the scale by so many tenths of a tenth, or by so many hundredths parts of an inch. Consequently the ten equal divisions of an inch on the scale B must be considered as fo
many ten hundredth parts of an inch, and numbered accordingly, 10, 20, 30, 40, &c. parts of an inch; then the Vernier gives the unit to each ten, thus: let the index very accurately to the top of the surface of the mercury E; and if at the same time, the beginning of the divisions at C coincide with a line of division in the scale B, then it shews the altitude of the mercury in inches and tenths of an inch exactly. But if the index line C of the Vernier fall between two divisions or tenths on the scale B, then there will be a coincidence of lines in both at that number of the Vernier, which shews how many tenth parts of that tenth the index of the scale has passed the last decimal division of the scale. E. G. Suppose the index of the Vernier were to point somewhere between the six and seventh tenth above 30 on the scale; then, if by looking down the Vernier, you observe the coincidence at number 8, this shews that the altitude of the mercury is 30 inches, and .68 parts of a hundredth of another inch, or simply thus, 30.68 inches. See Vernier. The screw $f$, in fig. 84, serves to press the mercury up into the tube, when the instrument is to be moved, and thus to render the instrument a portable barometer.

The barometer belonging to the house of the Royal Society is of the cijerica kind; and the Hon. Mr. Cavendish prefers this form to that of the syphon kind, because both the danger of observing and the error of observation are less, as in the latter we are liable to an error in observing both legs. Moreover he remarks, that the quicksilver can hardly fail of settling more exactly in the former than in the latter; for the error in the settling of the quicksilver can proceed only from the adhesion of its edge to the sides of the tube. In the latter the adhesion may take place in two legs, but in the former only in one; and besides, as the air has necessarily access to the lower leg of the syphon barometer, the adhesion of the quicksilver in it to the tube will most probably be different according to the degree of dryness or cleanliness of the glass. It is true, as M. De Luce observes, that the cijerica barometer does not give the true pressure of the atmosphere; the quicksilver in it being a little depressed on the same principle as in capillary tubes. But it appears by calculation, that in the barometer of the society, the error arising from the alteration of the height of the quicksilver in the cijerica can scarcely ever amount to so much as $\frac{1}{10}$th of an inch. In this barometer, the height of the quicksilver is estimated by the top of its convex surface, and not by the edge where it touches the glass; the index being properly adapted for that purpose; and this manner of observing is more accurate than the other. Phil. Trans. vol. lxvi. p. 381.

As soon as it was discovered that the different heights of the mercury indicated by the barometer were in some degree connected with the state of the weather, and that it might be applied to the purpose of a "weather-glass," many attempts were made to render the changes in it more sensible, and so to measure the variations of the weight of the atmosphere more accurately; and these attempts have given rise to a great number of barometers of different structures, deviating from the simplicity of the common barometer, and at the same time less accurate. Hence the wheel barometer, diagonal barometer, horizontal barometer, pendulum barometer, &c.

Des Cartes suggested the first method of increasing the apparent sensibility, or enlarging the scale of variation, of the barometer, though he did not live to execute it. He proposed a tube AB (Plate IX. Pneumatics, fig. 77.) about twenty-seven inches long; terminating in a cylindrical vessel CD; one half of which vessel, connected above with a long tube of a very small bore, fixed at top, and exhausted of its air, was to be filled with water extending up into the small tube; the other part of the vessel, and the lower part of the tube, were to be filled with mercury. Whenever the mercury rose in the cylinder, it would force up a proportional quantity of water into the narrow tube, where it would have a considerably larger range than that of the mercury in the cylinder; neglecting the weight or pressure of the water, the motion of the water and of the mercury would be in the inverse ratio of the squares of the diameters of the vessels containing them. But the water presses on the mercury according to its height; and therefore if the whole range of the mercury in the cylinder, or in a common barometer, were supposed to be two inches, the specific gravity of water is that of mercury as 5 to 1; the difference between the diameters of the cylinder and tube a maximum or infinite, then the entire scale of variation in this instrument would be twenty-eight inches; or the extent of this scale would be to that of the common barometer in the inverse ratio of the specific gravity of water to that of mercury. It is evident that in practice it would be somewhat less than twenty-eight inches. Huygens constructed a barometer of this kind; but here, though the column suspended was larger, and consequently the variation greater, yet the air imprisoned in the water getting loose by degrees, filled the void space in the top, and so ruined the machine.

Huygens then thought of changing the construction of the barometer, and of placing the mercury at top, and the water at bottom, in the following manner: ADG (fig. 78.) is a bent tube hermetically sealed in A, and open in G; the cylindrical vessels BC and FE are equal, and about twenty-nine inches apart; the diameter of the tube is about a line, that of each vessel fifteen lines, and the depth of the vessels is about ten; the tube is filled with mercury (the common barometer standing about twenty-nine inches) which will be suspended between the middle of the vessel FE, and that of the vessel BC; the remaining space to A being void both of mercury and air; lastly, common water, tinged with a fifth part of aqua regis to prevent its freezing, is poured into the tube FG till it rises a foot above the mercury in DF.

When the mercury rising above the level of that contained in FE, through the tube AD, becomes a balance to the weight of the atmosphere; as the atmosphere increases, the column of mercury will increase, consequently the water will descend; as the atmosphere again grows lighter, the column of mercury will descend, and the water ascend. This double barometer, as it was called, which is nearly the same with that of Dr. Hooke, will therefore discover much minute alterations in the air than the common one; for, instead of two inches, the fluid will here vary two feet; and by enlarging the diameters of the cylinders, that variation may be still increased; but it has this inconvenience, besides others, that the water will evaporate, and so render the alterations precarious; though the evaporation be in some measure prevented by a drop of oil of sweet almonds swimming at top; the column of water will likewise be sensibly affected by heat and cold.

The double barometer of Dr. Hooke was invented in the year 1668, and is deferred in the Phil. Trans. N. 54. 185. The invention was claimed by Huygens and De la Hire; but it sufficiently appears, that Hooke was the original inventor. (See De Luce's Recherches, vol. i. p. 18.) This consists of a compound tube ABCDEFG (fig. 79.), of which the parts AB and DE are equally wide, and EFG as much narrower as it is proposed to enlarge the scale. The parts AB and EG are made as cylindrical as possible. The
The part HBCDI is filled with mercury, having a vacuum above in AB. IF is filled with a light fluid, and FG with another light fluid, which will not mix with that in IF. The cistern G is of the same diameter with AB. It is plain that in this instrument the range of the separating surface at F must be as much greater than that of the surface I, as the area of I is greater than that of F; and this ratio may be selected at pleasure. This barometer is the bell of those with an enlarged scale; it is most delicately moveable, and is the bell adapted to a chamber for the purpose of amusements, by observations on the changes of the atmospheric pressure. It rises or falls by the slightest breeze, and is continually in motion. The most accurate method for graduating such a barometer would be to make a mixture of vitriolic acid and water, which should have the density of mercury. Then, let a long tube stand vertical in this fluid, and connect its upper end with the open end of the barometer by a pipe with a branch to which the mouth may be applied. By sucking through this pipe, the fluid will rise both in the barometer and the other tube; and the rise of ten inches in this tube will correspond to adefect of one inch in the common barometer. Thus every point of the scale may be adjusted in due proportion to the rest. But nothing except actual comparison can determine what particular point of the scale corresponds to some determined inch of the common barometer. When this is done, the whole becomes equally accurate. It is liable, however, to several inconveniences. Although the heights of the contained fluids are always the same in a constant temperature, nevertheless their weight or pressure on the base is not always the same on account of the difference of their specific gravity; and though there be no sensible difference in the action of these fluids against the sides of the tube, yet there is a continual action, and therefore the movements of this barometer cannot be so free as those of the simple barometer. These differently coloured liquors mingle with one another, and form a deposit on the sides of the tube, so that their respective boundaries cannot always be ascertained with precision. The fluid of this barometer is also subject to evaporation; and heat acts upon the fluids which it contains. On account of these and such defects, others have had recourse to an

Horizontal or rectangular barometer ABCD (fig. 80), the tube whereof is bent in form of a square BCD: at the top of its perpendicular leg it is joined to a vessel or cistern AB; and its variations accounted on the horizontal leg CD. Now in the interval, and space of variation, may be made of any extent at pleasure, and so the minute change in the air become sensible. For the diameter of the tube CD being given, it is easy to find the diameter of the vessel AB, so as that the scale of defect in the tube DC shall have any given proportion to the scale of ascent in the vessel AB; the rule being that the diameter of the vessel is to that of the tube in a subduplicate reciprocal ratio of their scales.

The diameters then of CD and AB being given, together with the scale of ascent of the mercury in the vessel, the scale of mercury in the tube is found thus: as the square of the diameter of the tube is to the square of the diameter of the vessel, fo reciprocally, is the scale of mercury in the vessel, to the scale of mercury in the tube.

Caffini was the first inventor of this kind of barometer, though the same construction had been thought of, and first published by M. J. Bernoulli, in the year 1710.

This and the preceding contrivance of Huyghens are founded on a theorem in hydromatics; viz. that fluids, having the same base, gravitate according to their perpendicular altitude, not according to the quantity of their matter; whence the same weight of the atmosphere supports the quicksilver that fills the tube A C D, and the cistern B, as would support the mercury in the tube alone.

This last, however, with its excellencies, has great defects: for, by reason of the attraction between the parts of the glass and of the mercury (which Dr. Junius has shown to be considerable), with the length of the scale (consequently the quantity of motion), and the attrition against its sides, especially in sudden rises and descents, the mercury breaks, and parts of it are left behind, and the equality of its rise and fall ruined. Some therefore prefer the

Inclined barometer, or diagonal, of Sir Samuel Moreland, where the space of variation is considerably larger than in the common one, and yet the rise and fall more regular than in the other. — Its foundation is this; that in a Torricellian tube BC (fig. 81) inclined at any angle to the horizon, the cylinder of mercury equivalent to the weight of the atmosphere, is to a cylinder of mercury equivalent to the same in a vertical tube, as the length of the tube BC to the perpendicular height DC.

Hence, if the height DC be subtriple, subquadriple, &c. of the length of the tube, the changes in the diagonal barometer will be triple or quadrupole, &c. of the changes in the common barometer. This barometer will scarce allow its tube to be inclined to the horizon at less angle than 45°, without undergoing the inconvenience of the horizontal one.

Mr. Orme, in order to obviate some of the objections to which the diagonal construction of the barometer is liable, purified the quicksilver from its dross and earthy particles by distillation; and when the tube was filled with a certain quantity of mercury, discharged the remaining air by an intense heat sufficient to make the mercury boil; and he continued this operation for four hours. In the process, an innumerable quantity of small particles were emitted, and when no more bubbles rise in the tube, the mercury appeared extremely bright, but sunk lower in the tube than when it was first put in, by two inches. Phil. Trans. Abr. vol. viii. p. 455.

The subed barometer was a contrivance of Dr. Hooke, in 1668, to make the alterations in the air more sensible: the foundation of this is the common vertical barometer, with a large ball above, and turned up at the other end, with the addition of a couple of weights A and B (fig. 82) hanging on a pulley, the one of them playing at liberty in the air, the other resting on the surface of the mercury in the inverted tube, and rising and falling with it.

Thus is the motion of the mercury communicated, by means of the pulley, to an index which turns round a graduated circle; and thus the three inches of vertical ascent are here improved to five, six, or more, at pleasure.

But the friction of the axis of this index, and more especially when it has contracted some rust, generally renders this sort of barometer useless; and, at best, the graduation of inches on the circle can only be considered as a scale of motions of the mercury in its tube; for the great variation of the height of the surfaces of the mercury in the tube below will perpetually falsify the inches and tenths upon the plate above. In a just or standard barometer, the inferior surface of the mercury in the cistern or tube below should either be invariable, or reducible by a pressing screw to a fixed or determinate gauge point.

The wheel barometer has lately been obstructed upon the public by the ittolling Italian hawkers in our streets; but the imperfect manner in which these barometers are constructed,
An instrument of this kind, with considerable improvements, has been constructed by Mr. Fitzgerald, F.R.S. It is furnished with two pulleys that move on friction-wheels, each of which turns an index on the centre of a graduated circle. The smaller circle is four inches in diameter, and divided into three equal parts, each of which is again subdivided decimally; and the changes corresponding to the rise or fall of the mercury from 28 to 31 inches, are marked on the margin of it, as they are on the scales of common barometers. The larger circle is divided into 300 equal parts; and being about 30 inches in circumference, the index belonging to it will mark distinctly the 600th part of an inch in the rise or fall of the mercury. On the centre of this circle two registers are fixed, which are placed along the index when the instrument is adjusted; one of them is carried round with the index, and left behind on its return; so that their distance will determine the limits of the variation from one observation to another. Phil. Trans. vol. liii. part i. N. 29. Ibid. vol. lx. No. 10.

The pendulent barometer, invented by M. Amontons, in 1689, is a machine rather pretty and curious than useful (fg. 83). It consists of a conical tube, placed vertically, its upper and smaller extremity hermetically sealed; it has no vessel or cistern, its conical figure supplying that defect: for when filled, like the rest, there will be as much mercury sustained as is equivalent to the weight of the atmosphere; and as that varies, the same mercury takes up a different part of the tube, and so becomes of a different weight.

Thus, when the weight of the atmosphere is increased, the mercury is driven up into a narrower part of the tube; by which means its column is lengthened, and, for the reason just given, its weight increased. Again, the atmosphere decreasing, the mercury sinks into a wider part of the tube; by which means its column is again shortened, and its pressure accordingly weakened. Thus, the same mercury is still a balance to the atmosphere under all its variations. The inconvenience in this barometer is, that to prevent the mercury and air from changing places, the bore of the tube must be very small; which smallness of the bore renders the friction so sensible as to impede its playing.

The marine barometer is a contrivance of Dr. Hooke, in 1700, to be used at sea, where the motion of the waves renders the others impracticable; it refines that of Amontons in 1689. This is nothing more than a double thermometer, or a couple of tubes half filled with spirit of wine; the one hermetically sealed at both ends, with a quantity of common air inclosed; the other sealed at one end, and open at the other.

Now the air, we know, is able to act on the spirit of wine, and raise it, two ways; partly by its gravity, as in the Torricellian tube; and partly by its heat, as in the thermometer. If then the two tubes be graduated, so as to agree with each other at the time when the air is inclosed, it will easily follow, that, wherever the two agree afterwards, the pressure of the atmosphere is the same as at the time when the air was inclosed. If in the thermometer open to the air the liquor shall higher, considering at the same time how much the other is risen or fallen from the other cause of heat or cold, the air is heavier; on the contrary, when it is lower, compared with the other, the air is lighter than at the time when the instrument was graduated. Here the spaces answering to an inch of mercury will be greater or less, according to the quantity of the air inclosed, and the smallness of the tubes; and they may be increased almost in any proportion. But it must be remembered, that the density and rarity of the air, on which this machine is founded, do not only depend on the weight of the atmosphere, but also on the action of heat and cold. This, therefore, can never be a jut barometer; but may properly enough be called a manoscope, or instrument to shew the density of the air. See MANOMETER.

Nevertheless, the instrument is said to be of good use in giving notice of all bad weather at sea, as also of variable winds, and of the neighbourhood of ice. Phil. Trans. N. 429. p. 133.

Improved marine barometers. In the bell of these barometers, Meffrs. W. and S. Jones apply a small ivory floating gage, or index, to an aperture in the cistern of mercury below; the index floats on the mercury; a mark is cut on its stem, and another on the socket in which it moves; these two marks are brought to a coincidence by turning the screw below; and thus the surface of the mercury in the cistern is made to be jut to the divisions of the plate above.

Mr. Nairne, an ingenious artificer in London, constructed a marine barometer for captain Phipps, in his voyage to the north pole; the upper part of which was a glass tube, about three tenths of an inch in diameter, and four inches long, to which another glass tube was joined with a bore about $\frac{1}{4}$th of an inch diameter. These two glass tubes formed the tube of this barometer, which was filled with mercury, and inverted into a cistern of the same. The instrument was fixed in gimbal, and kept in a perpendicular position by a weight fastened to the bottom of it, and was not liable to the inconvenience attending the common barometer at sea. Voyage to the North Pole, p. 123.

The marine barometer, as it is commonly constructed, differs from the common one merely in having the bore of the tube small for about two feet in its lower part; but above that height it is enlarged to the common size. Through the small part of the instrument the mercury is prevented from ascending too hastily by the motion of the ship, and the motion of the mercury in the upper wide part is consequently lefited. Much depends upon the proper suspension of this instrument; and Mr. Nairne has found by experiment the point from which it may be suspended so as not to be affected by the motion of the ship.

We shall here subjoin the description of two kinds of marine barometers, which are constructed by Meffrs. W. and S. Jones of London, and which seem to be well adapted to marine purposes. In Plate X. fig. 86, one of these barometers is represented as supported on its fland in the cabin of a ship, ready for observation: $a$ & $c$ are the folding mahogany legs, about three feet each in length; $A$ is a circular brass plate, with two hollow brass tubes fixed perpendicularly upon it; the gimbal filings ring with its axis is made to turn between these tubes; and on two or three springs placed in the tubes, the axis of the gimbal ring acts. The barometer frame $B$ is attached inward to this ring by an axis and two screws, in a position at right angles to the axis in the uppright, yet left free to move; the three legs are screwed down to the floor of the cabin. Whatever heave or motion the ship may receive, the barometer, by its action on the gimbal, on the springs in the tubes, and on its axis, will always tend to keep its vertical position, and as speedily as possible attain to a state of quiescence; $d$ is a screw that serves to move the folding Nonius scale upon the plate above; $e$ is a small mahogany door that is slant over the tube and plate, to defend them when this instrument is not in use. On the top of the frame there is a pendent brass ring $g$, by which the barometer,
rometer, without the fland, may be hung on a neck against the wall of a room or side of a cabin; the screw \( f \) at the bottom of the frame serves to compress the mercury in the cylinder, in order to force it up to the top of the tube, as in the common barometers. By the barometer's being moveable from its stand, and the stand folding up into a small extent, the whole apparatus may be packed up in a convenient narrow deal case for carriage.

The principal inconvenience, which has been found to attend this barometer, has been the ground occupied by the feet in the cabin when the instrument is in use; this being sometimes more than a mariner can spare; and besides, it is liable to be flung against by a heedles by-flounder. To obviate this inconvenience, another principle of mounting has been adopted (see fig. 87). The barometer in this figure is in every respect the same as the preceding, but its mode of suspension is as follows: on the sides of the frame, at its centre of gravity, are fixed two iron centres; as an axis to thefe there is fixed a brass frame \( a \), and brass pillar; one end of this pillar is framed on a vertical joint, having only one motion upwards, and checked by a brass socket fitted below, to keep the pillar and arm in an horizontal position; thus, causing the barometer to be suspended in a vertical direction. The length of the pillar and arm together is about 14 inches; the joint socket at the end of the pillar is attached to a strong round brass plate \( b \), about 2 inches diameter, with four counterfunk holes for receiving screws, by which the whole instrument may be screwed securely to the side of a cabin, in any convenient or safe situation. When the instrument is in a state of suspension for observation, it will be about 15 inches from the side of the cabin, and being also free to act on its axis of suspension at \( a \), it is evident that notwithstanding any common motion or reel of the ship, the barometer will tend to keep a vertical position, or to recover it after having been agitated. The only circumstance to apprehend is the possibility that, by a violent motion, the bottom of the barometer should strike against the side of the cabin, and endanger the glass tube; but this is easily avoided by fixing a temporary leather cushion against that part of the cabin against which alone it could strike. When the instrument is not wanted for any observation, while the ship is in motion, it may be moved upwards upon the joint, and it will close to the side of the cabin or wall, and may be bucked fast by a leather strap and buckle \( e \) attached for that purpose (see fig. 86.), and thus be out of any danger from any person suddenly or unguardedly coming to it; and it will answer the purpose of the common chamber barometer.

M. Paiffement, an ingenious artist at Paris, accommodates the barometer to nautical ues, by twitting the middle part of the common barometer into a spiral, consisting of two revolutions: by this contrivance, the impulfs which the mercury receives from the motions of the ship, are defivated by being transmitted in contrary directions. De Luce's Recherches, &c. vol. i. p. 34.

The flattened barometer, or barefoot, used by Mr. Boyle, Otto de Gueric, &c. consisted of a large glass bubble, about the size of a large orange, and blown so thin as to weigh only 70 grains. This being balanced by a brass weight, in a nice pair of scales, that would turn with the 30th part of a grain, was found to act as a barometer; for this obvious reason, that the surface of the bubble was opposed to a much larger portion of air than that of the brass weight, and consequently was liable to be affected by the varying specific gravity of the atmosphere; so that when the air became specifically light, the bubble defended, and vice versa. Thus (says Mr. Boyle) he could perceive variations of the atmosphere no greater than such as would have been sufficient to raise or depress the mercury in the common barometer an 8th part of an inch. Nevertheless, the two bodies being of equal gravity, but unequal bulk, if the medium in which they equilibrate be changed, there will follow a change of their weight; so that if the air grows heavier, the greater body, being lighter in specie, will lose more of its weight than the lighter and more compact; but if the medium grow lighter, then the bigger body will outweigh the less.

The barometer of Mr. Cavell, described in the Philosophical Transactions, has been much commended for its accuracy; the structure of it is as follows: suppose \( A B C D \) (fig. 88.) a bucket of water, wherein is the barometer \( x y z o m \), consisting of a body \( x r s m \), and a tube \( e z y o \). The body and tube are both concave cylinders, communicating with each other, and made of tin, or rather glass. The bottom of the tube \( e y \) has a lead weight to link it, so that the top of the body may just swim even with the surface of the water, by the addition of some grains weights on the top. The water, when the instrument is forced with its mouth downwards, gets up into the tube to the height \( y o \). There is added on the top a small concave cylinder, which we call the pipe, to distinguish it from the other at bottom which we call the tube; this pipe is to sustain the instrument from sinking to the bottom; \( m d \) is a wire, \( m s \) and \( d e \) two threads oblique to the surface of the water, performing the office of diagonals. Now, while the instrument sinks more or less by the alteration of the gravity of the air, there where the surface of the water cuts the thread is formed a small bubble, which ascends up the thread as the mercury of the common barometer ascends, and vice versa.

This instrument, as appears from a calculation which the author gives, shews the alterations in the air more accurately than the common barometer, by no less than 1200 times. He observes, that the bubble is seldom known to stand still a minute; a small blast of wind that cannot be heard in a chamber will make it sink sensibly, and that a cloud always makes it defend, &c.

Mr. Rowing (Phil. Trans. N. 427, and Syllom of Philosophy, part ii. diff. 4.) has described a barometer, in which the scale of variation may be infinitely extended. \( A B C D \) (fig. 89.) is a cylindrical vessel, filled with a fluid to the height \( H \); in which is immerged the barometer \( S P \), consisting of the following parts: the principal one is the glass tube \( T P \) (represented separately at \( p \)), whose upper end \( T \) is hermetically sealed; this end does not appear to the eye, being received into the lower end of a tin pipe \( G H \), which in its other end \( G \) receives a cylindrical rod or tube \( S T \), and thus fixes it to the tube \( T P \). This rod \( ST \) may be taken off, in order to put in its stead a larger or a letter as occasion requires. \( S \) is a bar at the top of the rod \( S T \); and serves as an index by pointing to the graduated scale \( L A \), which is fixed to the cover of the vessel \( A B C D \). \( M N \) is a large cylindrical tube made of tin (represented separately at \( m n \)), which receives in its cavity the smaller part of the tube \( T P \), and is well cemented to it at both ends, that none of the fluid may get in. The tube \( T P \), with this apparatus, being filled with mercury, and plunged into the basin \( M P \), which hangs by two or more wires upon the lower end of the tube \( M N \), must be so poised as to float in the liquor contained in the vessel \( A B C D \); and then the whole machine rifes when the atmosphere becomes lighter, and vice versa. Let it now be supposed that the fluid made use of is water; that the given variation in the weight of the atmosphere is such, that by pressing upon the surface of the water at \( H \), the
the surface of the mercury at \( X \) may be raised an inch higher (measuring from its surface at \( P \)) than before; and that the breadth of the cavity of the tube at \( X \) and of the bafon at \( P \) are such, that by this ascent of the mercury there may be a cubic inch of it in the cavity. \( X \) more than before, and consequently in the bafon a cubic inch less. Now, upon this supposition, there will be a cubic inch of water in the bafon more than there was before, because the water will succeed the mercury to fill up its place. Upon this account the whole machine will be rendered heavier than before by the weight of a cubic inch of water; and therefore will sink, according to the laws of hydrostatics, till a cubic inch of that part of the rod \( WS \), which was above the surface of the water at \( W' \), comes under it. Then if we suppose this rod so small that a cubic inch of it shall be 14 inches in length, the whole machine will sink 14 inches lower into the fluid than before; and, consequently, the surface of the mercury in the bafon will be prefixed more than it was before, by a column of water 14 inches high. But the preffure of 14 inches of water is equivalent to one of mercury; this additional preffure will make the mercury ascend at \( X \) as much as the supposed variation in the weight of the air did at first. This ascent will give room for a second cubic inch of water to enter the bafon; the machine will therefore be again rendered so much heavier, and will subfide 14 inches farther, and so on in infinitum. If the rod was so small that more than 14 inches of it were required to make a cubic inch, the variation of this machine would be negative with respect to the common bafonometer, and instead of coming nearer to an equilibrium with the air by its ascent or descent, it would continually recede farther from it: but if less than 14 inches of rod were required to make a cubic inch, the scale of variation would be finite, and might be made in any proportion to the common one.

The fame author has also contrived a compound bafonometer, in which the scale of variation shall bear any proportion to that of the common one. \( ABC \) (fig. 90.) is a compound tube hermetically sealed at \( A \), and open at \( C \); empty from \( A \) to \( D \), filled with mercury from thence to \( B \), and from thence to \( E \) with water. It appears from the nature of a fiphon, that if \( H, B, G \), be in the fame horizontal line, and the column of mercury \( DH \) will be in equilibrio with the column of water \( GE \), and a column of air of the fame bafe, and will therefore vary with the sum of the variations of thefe. He has subjoined a calculation, whence it appears, that if the tubes \( AF \) and \( FC \) are of an equal bore, the variation in this is lefs than that of the common bafonometer, in the proportion of 7 to 13; but if the diameter of \( AF \) be to that of \( FC \) as 5 to 1, the variations will be to those in the common bafonometer, as 175 to 1; but if the proportion of the diameters be greater, the variations will be infinite in refepect to those of the common bafonometer. Of the practical utility of this construction the author had no experience. Kowning's Nat. Phil. part ii. dift. 4.

Another contrivance for enlarging the scale of the bafonometer is exhibited in fig. 91. \( AB \) is the tube of a common bafonometer, open at \( E \), and sealed at \( A \), fupended at the end of a lever which moves on the fulcrum \( E \). \( D \) is a glass tube fixed, and ferving for a cilinr, which is wide enough to admit the free motion of the barometrical tube \( AB \). \( AB \), when filled with mercury, is nearly counterbalanced by the long end of the lever. When the atmosphere becomes lighter, the mercury descends in the long tube, and the surface of the mercury rising in the cilinr, pushes up the tube \( AB \), which carries the lever to the other side, and to point out by its index moving along a circular arc, the most minute variations. This apparatus, however, is liable to the inconvenience of the friction as well as weight of the lever, when put in motion by the rise or fall of the tube \( AB \).

While some have endeavored to enlarge the variations of the bafonometer, others have endeavored to make it more convenient, by reducing the length of the tube. M. Amontons, in 1698, first proposed this alteration in the structure of bafonometers, by joining several tubes to one another, alternately filled with mercury and with air, or some other fluid; and the number of these tubes may be increased at pleasure: but the contrivance is more ingenious than useful.

M. Mairin's reduced bafonometer, which is only three inches long, serves the purpose of a manometer in discovering the dilatations of the air in the receiver of an air-jump; and instruments of this kind are now generally applied to this use. See Air-Pump, and CAGE.

The bafonometer lately invented by Alexander Keith, Eqq. F. R. S. and F. A. S. Edinb. marks the rise and fall of the mercury from two different times of observation. This instrument consists of a glass tube \( ABCD \) (fig. 92.) bent in the manner represented in the figure, open at \( D \), and hermetically sealed at \( A \). The length from \( A \) to \( B \) is 8 inches, and its calibre about \( \frac{1}{4} \) of an inch; from \( B \) to \( C \) it is \( \frac{1}{4} \) inches long, and about \( \frac{1}{4} \) inch calibre; and from \( C \) to \( D \) \( \frac{1}{2} \) long, and \( \frac{1}{2} \) inch calibre. The tube is filled with mercury, the length from \( A \) to \( B \) being \( 2^{9}\frac{1}{2} \) inches. When the tube is hung perpendicularly, the mercury will fall from \( B \) towards \( E \), leaving a vacuum from \( A \) to \( B \). When the atmosphere becomes heavier, the mercury falls in the tube \( DC \); and when lighter, it rises. The range of the scale is about 3 inches, being equal to that of a common bafonometer of the bell construction, which has a bafon with a very broad funnel. This instrument moves in a direction contrary to that of the common bafonometer, the one rising while the other falls. The tube \( DC \) is represented on a larger scale in fig. 93.; \( F \) is the float, having the float-direct fixed to it, terminating in a knife at a right angle between the indexes \( LL \), where it embraces a very small wire stretched along the scale, and thereby raises or lowers them as the mercury rises or falls in the tube \( DC \). The bafonometer is prepared for observation, by bringing down the one and raising the other index, till both touch the knee of the float-direct. When next observed, the upper index will point out the greatest depression of the mercury, or lightness of the atmosphere; and the lower the greatest rise of the mercury, or weight of the atmosphere since the scale was prepared. By these means, the variations of the atmosphere are more truly pointed out than by the common bafonometer; for it often happens that during tempestuous weather, or before it, the mercury both rises and falls within a few hours, or during the night time; which variations cannot be noticed by any of the bafonometers now in use. The sudden fall and rise, or even the rise and fall of the mercury, always denote an extraordinary agitation in the atmosphere. In a common bafonometer, the mercury may be at the same height in the morning that it was the night before; which leads to a conclusion that as there has been no agitation of the mercury, there will be calm or settled weather; but this new bafonometer will often show in such cases, that the one float has been raised \( \frac{1}{2} \), and the other depressed as much; which instead of indicating calm weather denotes that tempestuous weather may be expected.

The weight of the atmosphere at great heights might be discovered by suspending this instrument to an air-balloon. Edinb. Trans. vol. iv. 1798.
The portable barometer is so contrived, that it may be carried from one place to another without being disordered; and since it has been applied to the menuration of altitudes, it has undergone many improvements in its construction and appendages. The most common instrument of this kind consists of a tube of a proper length accurately filled with mercury; the lower end of the tube is glued to a wooden reversion, the bottom of which is formed of leather; the superfluous mercury descends into this reversion, and the air, by pressing upon the flexible leather, keeps the mercury suspended at its proper height. This reversion is concealed from the eye by a neat mahogany cover or box; through the bottom of which passes a screw, having upon its end a round plate, which presses upon the leather bag and forces the mercury to the top of the tube, so that it is prevented from shaking or breaking the tube by damping against the top of it when the instrument is removed from one station to another. This apparatus is placed in a frame, having on its upper part a silvered brass plate with a scale of inches and tenths reckoned from the surface of the mercury in the cylinder; and close to the line of inches is a slit or groove for finding the nonius scale up and down. On the left hand side of the plate are engraved the words "air, changeable, and rain." When this barometer is used, the screw at the bottom of the frame is to be so turned that the mercury may fall to its proper height, and indicate the corresponding changes in the weight of the air. The upper edge of the index is adjusted so as to coincide with the surface of the mercury in the tube, and then the nonius scale will shew the height of the column. Before every observation, the frame should be gently struck with the knuckles in order to disengage the quicksilver from the tube. This barometer does not admit of being adjusted in such a manner, that the divisions on the scale may be at that height from the mercury in the cylinder, which is expressed by the numbers affixed to them; because the mercury as it falls in the tube rises in the reversion, and when it rises in the tube it flanks in the reversion; and thus its distance is perpetually varying from the divisions on the scale. Besides the tension of the leather occasions a considerable resistance to the pressure of the atmosphere. The portable barometer has of late received a variety of improvements, the principal of which are here recited.

The portable barometer of Mr. Ramden is constructed with his usual accuracy. The principal parts of this instrument are a simple straight tube, fixed into a wooden cylinder, which for the convenience of carrying is flushed with an ivory screw; and that being removed, it is open when in use. Through this aperture is distinctly seen the coincidence of the gage-mark with a line on the rod of an ivory float, swimming on the surface of the quicksilver, which is raised or depressed by a brass screw at the bottom of the cylinder. From this, as a fixed point, the height of the column is readily measured on the scale attached to the frame, always to one-thousandth part of an inch, by means of a nonius moved with rack work. A thermometer is placed near the cylinder, whose ball was usually enclosed within the wood work; but that defect has been since remedied. The three-legged stand, supporting the instrument when in use, serves as a caze for it when inverted and carried from place to place. Two of these barometers after the quicksilver in them hath been carefully boiled, being suffered to remain long enough in the same situation, so as to acquire the same temperature, usually agree in height, or rarely differ from each other more than a few thousandth parts of an inch, which are to be allowed for in calculating altitudes, as well as in estimating the rate of expansion.

The next instrument of this kind which we shall mention and minutely describe, is that of M. de Luc. This portable barometer consists of a tube composed of two pieces, or of two tubes (see fig. 94): one of these tubes is thirty-four French inches in length, and straight from the top but bent at the bottom in form of a hiphon; the other tube is eight inches long, open at both ends, of the same diameter with the former, and communicating with its open end by means of a cock. When this barometer is carried from one place to another, it is inverted very slowly to prevent the intrusion of any air; the quicksilver retires into the long tube on which the key of the cock is turned; and to prevent the cock from being too much pressed by the mercury, the barometer is conveyed in this inverted posture. When an observation is to be made, the cock is first opened; the tube is then turned upright very slowly, to prevent, as much as possible, such vibration of the mercury as would disturb the observation; and according to the weight of the atmosphere, the mercury will fall in the larger branch, and rise up through the open cock into the shorter. The cock is wholly made of ivory, except the key; and is composed of two small ivory cylinders a and b, open through their whole length and admitting the free passage of the tube, and of a square piece of ivory c, thirteen lines long, as many broad, and nine lines thick, having two holes, one for receiving the key f d e, and the other in a vertical direction with two short tubes, b, i, at its extremity, adapted to the holes in the small ivory cylinders above mentioned. The most essential part of the cock is the key, which serves to open and close the communication between the two glass tubes. The part of the key that turns within the cock and passes through the opening in c to f, is formed of cork, and the outward part or handle d e, is made of ivory. The cork is firmly fastened to the ivory by means of a broad thin plate of fletch, which cuts both the ivory and cork, lengthwise, through the centre, and reaches within to the hole of the key. This plate serves to counteract the flexibility of the cork, and to make it yield to the motion of the handle, although it is compressed in a very considerable degree by the ivory, in order to preserve it tight. But that this compression may not contract the diameter of the hole of the key, it is lined with a thin hollow ivory cylinder of the same diameter with the tubes. The extremities of the tubes are wrapped round with a membrane employed by gold-beaters with fish-gill in order to fix them tight, the one in the lower, and the other in the upper end of the vertical canal of the cock. On the upper end of the shorter tube is fixed, during the intervals of observation, a kind of funnel, with a small hole in it which is flush with an ivory flopple. This is intended for keeping the tube clean, for replacing the mercury that may have escaped through the cock in consequence of any dilatation; and also for replacing the mercury taken out of the shorter tube, after flushing the cock, when any observation is completed; because when the mercury is left exposed to the air, it contracts on its surface a dark pellicle that suffices both itself and the tube. The shorter tube should be cleaned occasionally, by a little brush of sponge fixed to the end of a wire adapted to the purpose.

The barometer thus constructed, and described more in detail by the author (Recherches, vol. ii. p. 6, &c.) is placed in a long box of fir, the two ends of which are lined within with cushions of cotton covered with leather. This box may be carried on a man's back like a quiver in its natural position, though the inverted position is to be preferred, either walking or riding; and

Vol. III.
should be defended from the rain by a cover of wax-cloth. In order to prevent its being unduly affected by heat, it should be kept at a distance from the body of the man who carries it, and be protected from the sun by an umbrella, when it is near the place of observation. To the apparatus a plummet should be annexed, in order to ascertain its vertical position, and a three-legged frame or tripod will serve to keep it firm in that position at the time of observation. The scale of this barometer is annexed to the long tube; it commences at a point on a level with the upper end of the short one, and rises in the natural order of the numbers to 21 inches. Below the above point, the scale is transferred to the short tube; and depends upon the being a natural progression of the number 17. The interval of 27 inches, comprehended between the point marked 20 in the upper tube, and that which corresponds to 7 in the lower, is divided into 27 parts, which are inches. These inches are again divided into lines, fourths, sixteenths, and even thirty-second parts of lines. The adhesion and friction of the mercury in the tubes will not allow of a more minute subdivision. As the mercury falls in the one tube, it will rise in the other; and therefore the total altitude will be found by adding that part of the scale which the mercury occupies in the long tube, to that part of it which the mercury does not occupy in the short one. In eliminating, however, the total fall or rise in the long tube, every space must be reckoned twice; because in barometers of this kind, half the real variation only appears in one of the branches.

One of the thermometers, exhibited in fig. 95, is designed for ascertaining the corrections that are to be made in the height of the mercury on account of any variation in the temperature of the air by heat and cold. For this purpose it is placed near the middle of the longer tube, that it may partake as much as possible of its mean heat. The ball is nearly of the same diameter with that of the tube of the barometer, that the dilatations or condensations of the fluids contained in them may more exactly correspond; and this ball should also be enclosed in wood that it may participate, as well as the barometer, of the heat of the bottom of the box. The scale of the thermometer is divided into 96 parts, between the points of boiling water and melting ice. M. de Luc, having found that an increase of heat, sufficient to raise the thermometer through this interval, augmented the height of the mercury in the barometer, when it was at 27 French inches, precisely 6 lines, was led to divide it into 96 equal parts; so that one of these parts corresponded to 1/4th of a line in the height of the barometer: and this quantity therefore must be added to or subtracted from the said height, for every degree of variation of the thermometer thus graduated. He placed the term o, one eighth part of the above interval above the lower point; so that there are 12 degrees below and 84 above it; because as 27 French inches expresses the mean height of the barometer, so the 12th degree above freezing is nearly the mean altitude of the thermometer. Hence by taking these two points, the one for the mean altitude, and the other for the mean heat, there will be fewer corrections necessary for reducing all observations to the same flat, than if any higher or lower points had been taken. The divisions above o or zero, are considered as positive and denoted by +, and those below as negative and expressed by -. If the barometer remains at 27 French inches, and the thermometer at o, according to the above explained graduation, no corrections are necessary. But if, while the barometer continues at 27 inches, the thermometer should rise any number of degrees above 0, so many sixteenths of a line must be subtracted from the 27 inches, in order to obtain the true height of the barometer produced by the weight of the atmosphere, and to reduce this observation to the state of the common temperature. On the other hand, if the thermometer should fall any number of degrees below o, while the barometer remains at 27 inches, so many sixteenths must be added to that height in order to obtain the true altitude. These corrections are very simple and easy when the height of the barometer is at or near 27 inches. But if it fall several inches below this point, as the portable barometer frequently must, according to the tables in which it is placed for the purpose of measuring altitudes, the dilations will no longer correspond with the degrees of heat, after the rate of 1/12th of a line for every degree of the thermometer; because the columns of mercury being shortened, the quantity of fluid to be diluted must be diminished; and, according to a general statement, the quantity of dilution for the same degree of heat will be as much diminished as the column is shortened. If, then, it should be still found convenient to reckon the dilations by sixteenths of a line, these sixteenths must be counted on a scale, of which the degrees should be as much longer than the degrees of the first scale, as the shortened column of mercury is less than 27 inches, the height to which the length of the degrees of the first scale was adapted. E. G. Let the mercury descend, in consequence of the elevation of the barometer, to 1 1/2 inches, or half the mean column, and let the thermometer ascend ten degrees above the mean heat; then according to the rule 2/3ths should be deducted from the mean column for this temperature; but ten half-sixteenths only or 9/32ths must be subtracted from the column of 13 1/2 inches, because the sum of its dilations will be half that of the former; the quantities of fluid being to one another in that proportion. As it would occasion considerable embarrasment to subdivide the sixteenths of correction into smaller fractions proportional to every half inch of defect in the barometer, the same end may be obtained in a much more easy manner by reckoning the corrections on different scales of the fame length, with the degrees longer as the columns of the barometer are shorter. E. G. The degrees of correction on a scale applicable to the column of 13 1/2 inches will be double in length to those of the same degrees adapted to the column of 27 inches, and consequently the number of corrections will be reduced to likewise one half. M. de Luc conftructed, in the manner which he has minutely described (Recherches, vol. ii. p. 26, &c.), on a piece of vellum, scales with these properties for no less than 23 columns of mercury, being all those between 28 inches and 29 inclusive, reckoning from half inch to half inch, within which extremes every practical case will be comprehended. This vellum he wrapped on a small hollow cylinder, including a spring, like a spring curtain, and he fixed it on the right side of the thermometer. The vellum was made to pass from right to left, behind the tube of the thermometer, and to move along its surface. The observer, in eliminating the necessary corrections, draws out the vellum till the scale corresponding to the observed altitude of the barometer, touches the thermometer, and he counts them on that scale. The vellum is then let go, and it is gently furled up by the serew.

M. De Luc, having provided the necessary apparatus for the accurate mensuration of heights, proceeded to establish by experiment the altitudes corresponding to the different deferts of the mercury; and he made choice of Salève, a mountain near Geneva, about 3000 French feet high, for the scene of his operations. The height of this mountain was twice measured by levelling, and the result of the mensurations, at the interval of six months, gave a difference of only 10 1/2 inches. On this mountain he selected no less than 15 different stations, riling on the side of nearly 200 feet one above another; and here he proposed to make such number of observations as
would serve either to establish a new rule of proportion between the heights of places and the defects of the mercury, or to justify the preference of some one of those that had been formerly discovered.

Soon after he had commenced his observations, an unexpected phenomenon occurred. Having observed the barometer, at one of the stations (Recherches, vol. ii. p. 49, &c.) twice in one day, he found the mercury higher in the second observation than in the first; and this variation he naturally attributed to a change in the weight of the atmosphere, which must have affected his other baromterial stations on the plain in the same manner. But he was not a little surprized when, on examining the state of the latter barometer, he found that it had pursued a contrary course, and that it had fallen while the other rose. As this difference could not proceed from any inaccuracy in the observations, it was so considerable as to discourage his progress, and to disappoint his hope of success, unless he should be able to explain its cause, and to make due allowance for its effects. The experiment was carefully repeated at different periods. An observer on the mountain, and another on the plain, took respective stations at the rising of the sun, and continued to make their respective observations, both of the barometer and thermometer, every quarter of an hour till the sun set. It was found, that the lower barometer gradually descended for the first three quarters of the day; after which it re-ascented, till in the evening it fell at nearly the same height as in the morning. But the higher barometer ascended for the first three quarters of the day, and then descended, so as to regain likewise about fun-set the altitude of the morning. The following theory seems to afford a satisfactory solution of this phenomenon. When the sun rises above the horizon of any place, his beams penetrate the whole atmosphere of that horizon, which is the base; but falling very obliquely on the greater part of it, they communicate little heat, and consequently produce little dilatation of its air. As the sun advances, his rays become more direct, and the heat and rarefaction of course increase. However, the greatest heat of the day is not felt when the sun is in the meridian and his rays are most direct, but it increases after mid-day while the place receives more heat than it loses; just as the tide attains not its highest altitude till the moon has proceeded a considerable way to the west of the meridian. Besides, the heat of the atmosphere is greatest at the surface of the earth, and seems not to ascend to any great distance above it; and therefore the dilatations of the air occasioned by the sun will be found principally, if not solely, near the earth. A motion of the adjacent air, in all directions, must take place in order to allow the heated air to expand itself. The heated columns, extending themselves vertically, will become longer, and also specifically lighter in consequence of the rarefaction of their inferior parts. As the motion of air, till it rises into wind, is not rapid, these lengthened columns will take some time to dissipate their summit among the adjacent less rarefied columns that are not so high; at least they will not do this as speedily as their length is increased by the rarefaction of their bases.

In order to apply this theory to the solution of the phenomenon above mentioned, it should be considered, that the barometer on the plain begins to fall a little after morning, because the column of air that supports it becomes specifically lighter on account of the rarefaction occasioned by the heat of the sun. It continues to fall during the three first quarters of the day, because the heat and consequent rarefaction are continually increasing. After this period it rifes again, because the cold and condensation coming on, the specific gravity is augmented by the rising in of the adjacent air. Thus the equilibrium is restored, and the mercury returns to the altitude of the morning.

The barometer on the eminence rifes after morning, and continues so to do for three fourths of the day, for two reasons. The density of the columns of air is greatest near the earth, and decreases as the distance from it increases. The higher therefore we ascend in the atmosphere, we find air specifically lighter. But by the rarefaction of the base of the column that supports the mercury of the barometer on the eminence, the denser parts of that column are raised higher than they would naturally be if left to the operation of their own gravity. On this account, the higher barometer is prefifted with a weight nearly as great as it would sustain, if it were brought down in the atmosphere to the natural place of that denser air now raised above it by the prolongation of the base of the column. The other reason is, that as the rarefaction does not take place at any great distance from the earth, little change is produced in the specific gravity of the portion of the column that preffes on the higher barometer, and the summit of that column dissipates itself more slowly than it increases. This we see how this barometer must ascend during the first three fourths of the day, and pursue a contrary course of that on the plain. The condensations returning after this time, the denser air subsides, the equilibrium takes place, and the mercury descends to its first position.

This phenomenon suggested to M. De Luc (Recherches, vol. ii. p. 54, &c.) the idea of a second pair of thermometers, in order to measure the mean heat of the column of air intercepted between the barometers. These thermometers are extremely delicate and sensitive, their tubes being the finest capillary, the glafs very thin, and the diameters of the balls only three lines; the balls are infalted or detached from the feales, which are fixed to the tubes only by ligatures of fine brahs wire covered with filks: by this contrivance the air has free access to the balls on all sides; and if the direct rays of the sun be intercepted at some distance by a carrier of paper or by the leaf of a tree, the thermometers will quickly mark the true temperature of the air. For the necessity and utility of these appendages to the author's apparatus, see the sequel of this article.

A new kind of portable barometer for measuring heights has been invented by Dr. J. A. Hamilton, and described in the Transactions of the Royal Irish Academy (vol. v. p. 95.). Instead of the leathern bag which confines the mercury in the common portable barometer, Dr. Hamilton substitutes a cylindrical cylinder of ivory, about two inches long and upwards of one inch in diameter, with a screw'd to its open top, somewhat contracted into a shoulder that receives internally a sound, clean and porous cork, about 2/ of an inch in length, and one in diameter, through which the glass tube is nicely infalted and pushed down midway. The construction depends upon this principle, that spongy cork affords a ready passage through its pores to the particles of air, but prevents the escape of quicksilver, unless a very powerful pressure be applied. Nevertheless, as it is not through the pores of that substance, but through the minute interstices between the cork and the inside of the ivory cylinder, that the air insinuates itself, some caution and experience are requisite to prevent the flopper from being fitted too tight; nor can the observer be always assured, that the confinement of the cork will occasion no inaccuracy in the result; for it will evidently require a considerable time, through the extremely slender communications, to refill the balance between the external and internal air, if ever that balance can rigorously obtain.
Hamilton gives very copious and circumstantial directions, together with an annexed engraving, for the construction, adjustment, and application of this instrument. AB (fig. 96.) represents a section of the barometer longitudinally, when put together and ready for use. F the ivory cylinder, CD the scale, with a vernier that slides so as to cover the aperture when the instrument is put by, E the attached thermometer in its case, and GG the brass caps that secure the ends. AB (fig. 97.) represents a section of the ivory cylinder with its cork C, and its tube T; SS is the surface of the mercury; M its masts; EE the shoulders that keep the cork C in its place; and FF is the bottom that ferrees in tight. Dr. Hamilton remarks, that mercury is best cleaned by flaking it repeatedly in a phial with fresh portions of water; and the remark deserves attention. For correcting the errors of altitude caused by the fluctuation of the surface of the mercury in the bafon, he recommends the computation of tables from which the aperture of the tube bears to that of the cylinder. His paper contains practical precepts for calculating heights from observations of the barometer, and for making ivory or cork, and he proposes to delineate vertical sections of a country, by means of a series of such observations, made during settled weather. In the same volume (p. 117, &c.) we have remarks and hints for the further improvement of barometers, by Dr. H. Hamilton, dean of Armagh, occasioned by the preceding communication. He observes, that the pores of cork may in time become choked with dust or moisture; and he therefore proposes, that instead of cork the box should have a top of ivory with a hole to drop in a floating gage, which might be occasionally dopped with a peg or screw, to render the instrument safely portable: or, which would be better, to have a cover ferewed over the top of the box, and a hole in it corresponding with that in the box. When these two holes are connected, the box is open; and it is shut, when the holes are removed from each other by turning the cover and ferewing it tight to the top of the box; and if there be a plate of soft leather between them, it will be sufficient to keep in the mercury when the instrument is agitated by carriage. The dean had a barometer made in this form, and found it to answer all the purposes of an open and of a portable one. Instead of making tables for correcting the error occasioned by the variation of the level of the mercury in the bafon, he thinks it would be more convenient to contract proportionally the divisions of the scale. This obvious plan is illustrated at length. It is suggested, that these clove barometers would serve just as well as sea as on land; and the hint merits attention, as a marine barometer is still an important desideratum.

Various improvements in the construction and use of the portable barometer, with its annexed apparatus, have been suggested by Sir George Shuckburgh and Gen. Roy; and they have been adopted by several instrument makers in London. An instrument of this kind, polishing all the advantages of those by Mr. Ramfden and M. de Luc, and from its principle (free from some inconveniences and errors, to which theirs is liable), is constructed by Mr. William Jones, an ingenious artist in Holborn. It is represented in (PLXII, fig. 100.), as included in his mahogany case by means of three metallic rings, a, b, b. This cafe is in the form of a hollow cone divided into three arms or legs from a to c, and so carved in the inside as to contain readily the body of the barometer; and the arms, when separated, form three firm legs or supports for the barometer, when it is used for making observations. (See fig. 101.) The instrument is suspended at the part g of the cafe, by a kind of improved gimlets, and thus, by its own weight, it will be sufficiently ready when exposed to the weather. In that part of the frame where the barometer tube is visible, a, there is a long slit or opening, so that the altitude of the mercury may be seen against the light, and the vernier piece a brought down to coincide with the edge of the mercury to the greatest possible exactness. When the instrument is placed on its support, the screw f is to be let down, that the mercury may subside to its proper height; and also a peg at p must be loosened, to give admission to the action of the external air upon the mercury contained in the box b. The adjustment, or mode of observing what is called the zero, or c, division of the column of mercury, is by means of a small floating ivory index or item that rises up through the brass box from the eilern below in a hole made for that purpose. This will rise and float itself directly under a small plate and screw fixed over as a cover, and is unfreewed to move upwards. With one eye even with the upper surface of the box, the hand at the regulating screw at the bottom of the frame must turn the screw till the top of the index is very exactly even with the surface; thus will the adjustment for reading off be made after the flattened vernier piece at a that determines the altitude of the column of mercury is to be brought down by the hand to a near contact, and then accurately adjusted by a small adjusting screw attached to the top of this vernier scale. This barometer has usually two different sorts of scales inserted on it: that on the right at a is a scale of French inches from 19 to 31, measured from the surface or zero of the mercury in the box b below, divided into twelve parts or lines, and each line subdivided by the vernier into ten parts, so that the height of the column of mercury may be ascertained to the 10th part of a French inch. The scale which is on the other side, or the left of observation, is of the same length; but divided into English inches, each of which is subdivided into 20ths of an inch, and the vernier subdivides each 20th into 25 parts; so that the height of the mercury is thus ascertained to the 500th part of an English inch (viz. 20 x 25 = 500). But this vernier is figured double for the convenience of calculation: the first 5 divisions are marked 10, the 20 marked 40, and the 25 marked 50: then each exact division is reckoned as the two thousandths of an inch, which amounts to the fame in value as \( \frac{1}{250} \) of an inch. A thermometer is always attached to the barometer, and indeed it is indispensably necessary: it is fastened to the body at e, counterfunk beneath the surface of the frame, which makes it less liable to be broken; the degrees of the thermometer are marked on two scales, one on each side; viz. that of Fahrenheit and Reaumur, scales generally known; the freezing point of the former being at 32, and the latter at 0. On the right hand side of these scales there is a third, called a scale of correction: it is placed opposite to that of Fahrenheit, with the words add and subtract; and it serves as a necessary correction to the observed altitude of the mercury at any given temperature of the air blown by the thermometer. There are several other valuable appendages to this instrument which cannot be distinctly represented in the figure: but its nature and use may be apprehended from the above statement. In complete observations, such as those to which we now refer, the observer should be provided with two barometers, or rather three, for fear of danger, and two or three separate thermometers. See the sequel of this article.

By very small additional contrivances this instrument may be rendered equally useful for making observations at sea with any marine barometer that has hitherto been invented.

The editor has been furnished with the following description.
tion of the cifer, &c. of the portable barometer, according to the construction of Mr. Hawes, lately an eminent instrument-maker in London. A fection of the cifer is represented in Plate XII. of "Pneumatics," fig. 102. \( \text{AAAABB} \) is the cifer: the part \( \text{AAAA} \), which contains the quicksilver, is made of wood, with a bottom of leather \( C \), glued on the wooden ring \( DD \), and preffed close against the wooden cylinder by means of the cifer at \( EE \), which cifers on the brass cover or collar \( FF \) that covers the cylindrical cifer \( AA \). This collar has a bevel at the top, as seen at \( G \), to prevent its flippmg, while it preffes the ring \( DD \) against the wooden cylinder \( AA \). When cifered tight, the quicksilver \( HH \) is prevented from escaping. It is part of the tube of the barometer, drawn nearly to a point, and covered with an ivory cap \( KK \) for defending it against injury. \( LL \) is a cifer, with a glass circular top \( Q \), by means of which the thread \( C \) forces up the quicksilver so as to fill the tube, when the instrument is carried from one place to another. In order to prevent the oscillations of the quicksilver from breaking the tube by sudden jerks, a pin \( a \) with a head \( b \) passes through the cifer \( LL \); this pin has on the under side of the head a spiral spring to counteract the violence of a sudden motion. The two nuts \( M \), \( N \), are used to raise or depress the cifer \( LL \), and consequently the quicksilver; the proper height of which is indicated by the floating gage \( OO \), the top of which \( P \) corresponds to the top and outside of the cifer. When the barometer is not in use, the gage and aperture are covered by the plate \( \epsilon \), which effectually confines the quicksilver, the under side of \( \epsilon \) being covered with leather. The lower end of the cifer \( LL \) is fit up as high as \( \epsilon \), and carries a crofs pin \( d \) passing through the bottom of the pin \( b \) to prevent it from rising too high.

*Fig. 103.* represents a square frame to be cifered on the part \( BB \) (fig. 102), and connected by wires from the angles to the legs as seen in the perspective view in *fig. 101.* This is used to prevent the barometer from vibrating.

The nonis is exhibited at large in *fig. 104.* \( A \) is a cifer with a milled head tapped into the piece \( B \), and also let into and moveable in the piece \( C \) in the manner represented at \( D \) in *fig. 105.*, which is a side view.

\( B \) and \( C \) in *fig. 106.* are horizontal sections of \( B \) and \( C \), *fig. 104.* The spring \( a \) of the piece \( B \) is considerably stronger than that of \( C \); so that it requires much greater force to make it flde up and down, whilst \( C \), which slides very easily, is moved by turning the milled head \( E \); and thus the lower surface of \( C \) is made to coincide with the upper surface of the mercury at \( F \); and, besides, both the piece \( B \) and the nonis \( C \) may be deprefsed or raised at pleasure, as occasion requires, for a due adjustment of the nonis. Behind the plate \( a b \), in the perspective view *fig. 101.*, hangs a pendulum supported at the point \( a \) which serves for setting the instrument vertical; and when it is brought into this position, a mark on the bob coincides with another on the plate, as seen at \( b \). When the instrument is not in use, a fork connected with the cifer \( \epsilon \) is pulled up, and prevents the pendulum from flaking.

In order to adapt the portable barometer more completely to the purpose of measuring heights, in which use of it peculiar accuracy of observation is necessary, it should be furnished with two microscopes or magnifying glasses, one of which should be placed at the beginning of the scale; and either this should be moveable, so that it may always be brought to the surface of the mercury in the cifer, or the cifer should be so contrived that its surface may always be brought to the beginning of the scale. By this means the coincidence may be accurately perceived. The other microscope must be moveable, so as to be set opposite to the surface of the mercury in the tube; and the scale should be furnished with a vernier, which divides an inch into 1000 parts, and constructed of materials, the expansion of which is precisely ascertained. For an account of many ingenious contrivances to make the barometer accurate, portable, and commodious, the reader may consult Magellani's "Diff. de Diferitos Instr. de Phys." Phil. Trans. vol. lxxv. vol. lxxvi. Journ. de Phys. xvi. 592. xvii. 391. xix. 328. xxi. 436. xxii. 390. Sulzer, Act. Helvet. iii. 359. De Luca, Recherches, &c. ubi supra. Cardia de Luynes, Mem. Par. 1768. Van Swinden's Ptolemes Phys. Com. Acad. Petrop. i. id. Nov. ii. 200. viii.

Mr. Magellani, in his edition of "Cronte's Philosophy," has shewn that great errors may arise in barometric measurements for want of due attention to the specific gravity of the mercury with which barometers are filled. If two barometers, each 30 inches high, and in every other respect similarly circumstanced, be filled with mercury of different specific gravity, that of the one being 13.62, and that of the other 13.45, the error in the result would be no less than 327 feet; because the heights of the mercureial columns in each barometer must be in the inverse ratio of their specific gravities; viz. \( \frac{13.45}{13.62} = 0.9845 \), and that of 327.745 inches, neglecting the indices, and their differerce is 54.172, which shows that there is a difference of 54.172 feet or 327 feet in the altitudes of the two places, where the barometers should have been stationed, though in reality they were on the same level. But if the specific gravity of the mercury in the two barometers were according to the different statements of Bergman and Fourety, the one 14.110 and the other 13.000, (and this may happen to be the case, as the heaviest is commonly reputed to be the purest mercury,) the error must have amounted to 355.76 toises, or 2134 feet, because 13000 : 14110 :: 30 : 23561.

But the logarithm of 30 is 1.477121, and that of 325.610 is 1.526975, and the difference, or 555.76, shows that the error should amount to some fathoms, or 2134 feet. See the sequel of this article.

**Barometer, Phenomena of.** Thce are the variations of height in its mercureial column, for ascertaining which many contrivances in the structure of the barometer have been proposed; the principal of which have been detailed in the preceding articles; and the subject will be further purified in the sequel. The uses to which these phenomena have been subervient, are the prediction of the weather from the variable weight of the atmosphere, indicated by the rise and fall of the mercury in the barometer, and the measurement of altitudes, to which they have been lately applied with singular facility and success.

The phenomena of the barometer, considered as a "weather glass," have been very differently stated and explained by various writers; and the care to predict from them the changes of weather is extremely difficult to form any fixed and general rules concerning them. Although we have reason to believe, that the barometer never fails to indicate a storm, or any very great change of weather, for some hours before it occurs; yet its variations afford no indications or prognostics that are absolutely certain, with respect to those least considerable changes to which the weather is subject in our variable climate. With certain restrictions, they afford some ground for probable conjecture; and these restrictions are to be determined merely by the sagacity of long-continued observation and experience. Strictly speaking, the height of the mercury in the barometer hath no immediate and necessary connection either with rain or fair weather. That its variable height is the immediate consequence of the variable
The variable preface of the atmosphere, is a fact that admits of no doubt; but the causes of this variable preface have not yet been fully and satisfactorily ascertained; and how far the state of the weather, in all its minute and sudden changes, depends upon it, is a question that still remains to be determined. M. Pafcal was one of the first persons who particularly observed the variations of the barometer, and referred them to corresponding changes in the weight of the air; but he acknowledges, that it is very difficult to explain both the one and the other, as well as the connection that subsists between them. He observes, in general, that the mercury is commonly highest in winter and lowest in summer; that it is least variable at the solstices, and most variable at the equinoxes: and he adds, in direct contradiction to later experience, that the mercury usually falls in fine weather, and that it rises when the weather becomes cold or the air is loaded with vapours. M. Pafcal was followed by Perrier, Beal, Wallis, Garin, Garden, Lisher, Halley, Gersten, De la Hire, Mariotte, Le Cat, Woodward, Leibnitz, De Mairan, Bernouilli, Mafchenbroek, &c.; all of whom have given different solutions of the phenomena of the barometer.

The principal observations, that have been made on the variations of this instrument, are summed up by Mr. Kirwan (Irish Trans. vol. ii. p. 46, &c.) in the following particulars.

I. The more considerable elevations and depressions of the mercury in the barometer happen at a very short interval of time in places very remote from each other. This correspondence was observed by Mr. Derham in 1699 between the heights of the mercury at Upminister in Essex and Townaley in Lancashire; and afterwards by Mr. Murray between the variations at Paris and Genoa, at the distance of nearly four degrees of latitude, who adds, during these variations different winds prevailed at those places. But Mr. Kirwan observes, that where there is a considerable difference of longitude, the like agreement is not found.

II. The deviations of the mercury from its mean annual altitude are far more frequent and extensive in the neighbourhood of the poles than in that of the equator. At Peterburgh, in 1775, the mercury once fell at the stupendous height of 31,59 inches, if we may credit Mr. Comfett; and yet it has been seen so low as 28,14 inches. In the northern parts of France the variations are greater than in the southern: at Naples they fearfully exceed one inch. In Peru, under the equator, and at the level of the sea, they amount only to two or three tenths of an inch; but in other parts, within a few degrees of the line, on the approach of the rainy season or of hurricanes, the barometer falls an inch or more.

III. The variations without the tropics are greater and more frequent in the winter than in the summer months.

IV. The variations are considerably smaller in very elevated situations than on the level of the sea. Thus M. Bouguer observed, that on the coasts of Peru the variations extended to 3 inches; at Quito, elevated 3747 feet above the sea, they comprehended only 0.083 of an inch. M. Saunfrie made similar observations in Savoy, as did Mr. Lambert in Switzerland.

V. The mean height of the barometer on the level of the sea in most parts of the globe hitherto examined, is about 29.968 inches. M. Bouguer, under the line, observed it at 29.698 inches; but as his barometer was not purged of air by fire, it stood lower than it should have done. Sir George Shuckburgh (Phil. Trans. vol. Ixxvii. p. 586.), on a mean of several observations on the coasts of Italy and England, found it at 30.04, when the temperature of the mercury was 55°, and that of the air 62°. The mean height of the barometer in London, upon an average of two observations in every day of the year, kept at the house of the Royal Society, for many years past, is 29.88; the mean temperature or height of the thermometer, according to the same, being 58°. The greatest height observed by Sir G. Shuckburgh, Dec. 26, 1778, in London, was 30.048 inches, the thermometer being at 47°; and reduced to the heat of 50°, it was 30.357; and this, he says (Phil. Trans. vol. lxix. p. 270.), is the greatest height, which, as far as he has been able to collect, it has ever been seen to stand at any country, where observations have been made and recorded, since the first invention of this instrument. In the proximity of the poles, says Mr. Kirwan, the annual mean heights of the barometer differ much more from the above standard than in the more southern parts of our hemisphere.

In estimating the connection of the variations of the barometer with the weather, Dr. Halley has proposed the following rules:

1. In calm weather, when the air is inclined to rain, the mercury is commonly low.

2. In serene and settled weather, and also in calm and frothy weather, the mercury is generally high.

3. Upon very high winds, though not accompanied with rain, the mercury falls lowest, according to the point of the compass from which the wind blows.

4. The great heights of the mercury are found upon easterly and north-easterly winds, other circumstances being alike; to which it may be added, that under a southerly wind it is commonly low. The above four observations, made by Dr. Halley in England, seem to be most universal, as they were found by Mr. Mclander (Schwed. Abhandl. 1778. S. 255.) to apply to lat. 39°, and by M. de Luc to lat. 34°.

5. After very great storms of wind, when the mercury has been very low, it generally rises again very fast.

6. The more northerly places have greater alternations of the barometer than the more southerly.

7. Within the tropics, and near them, there is little or no variation of the mercury in all weather. At St. Helena it is little or nothing; at Jamaica 5ths of an inch; whereas in England it amounts to 24 inches, and at Peterburgh to 35 nearly.

Dr. Beal, who adopted the opinion of M. Pafcal, observes, that, ceteris paribus, the mercury is higher in cold weather than in warm; and usually in the morning and evening higher than at mid-day: that, in settled and fair weather, it is higher than either a little before or after in the rain; and that it generally descends lower after rain than it was before it.

And he ascribes these effects to the vapours with which the air is charged in the former case, and which are dispersed by the falling rain in the latter. If it chance to rise higher after rain, it is generally followed by a settled fertility. He adds, that there are frequently great changes in the air, without any settled alteration in the barometer.

An ingenious author observes, in relation to this use of barometers, that, by their means, we may regain the knowledge, which still resides in brutes, and which we have forfeited by not continuing in the open air as they generally do, and by our intemperance corrupting the crails of our organs of sense.

Mr. Patrick's rules for judging of the weather by the rise and fall of the mercury in the barometer, have been much approved, and are to be accounted for on the same principles with those of Mr. Halley. They are as follow:—1. The rising of the mercury signifies, in general, fair weather; and...
BAR

and its falling, foul weather; as rain, snow, high winds, and fl orms.

2. In very hot weather, the fall of the mercury indicates thunder.

3. In winter, the rising prefigures frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw: but in continued frost, if the mercury rises, it will certainly snow.

4. When foul weather happens soon after the falling of the mercury, expect but little of it: and, on the contrary, expect but little fair weather when it proves fair shortly after the mercury has risen.

5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes, then expect a great deal of wet, and probably high winds.

7. The unsettled motion of the mercury, denotes uncertain and changeable weather.

Then you're not so strictly to observe the words engraved on the plates (though for the most part it will agree with them), as the mercury's rising and falling; for if it stands at much rain, and then rises up to changeable, it prefigures fair weather, although not to continue so long as it would have done, if the mercury were higher: and so, on the contrary, if the mercury flood at fair, and falls to changeable, it prefigures foul weather, though not so much of it, as if it had sunk down lower.

From these observations it appears, says Mr. Rowning (Nat. Philos. part ii. diff. 4.), that it is not so much the height of the mercury in the tube that indicates the weather, as the motion of it up and down: wherefore, in order to pass a right judgment of what weather is to be expected, we ought to know whether the mercury is exactly rising or falling, to which end the following rules are of use:

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is generally a sign that the mercury is then rising.

2. If the surface of the mercury is concave, or hollow in the middle, it is sinking. And,

3. If it is plain or level, or rather if it is a little convex, the mercury is stationary; for mercury being put into a glas tube, especially a small one, will naturally have its surface a little convex; because the particles of mercury attract each other more forcibly than they are attracted by glas. Farther,

4. If the glas be small, shake the tube; and if the air be growing heavier, the mercury will rise above half the tenth of an inch higher than it flood before: if it is growing lighter, it will sink so much. This proceeds from the mercury flocking to the sides of the tube, which prevents the free motion of it, until it is difengaged by the shock. Therefore, when an observation is to be made by such a tube, it ought always to be shaken first; for sometimes the mercury will not vary of its own accord, until the weather it ought to have indicated be present.

To the preceding rules we may subjoin the following, deduced from later and more accurate observation of the motions of the barometer, and the consequent changes in the air of this country:

1. In winter, spring, and autumn, the sudden falling of the mercury, through a large interval, denotes high winds and fl orms; but in summer it denotes heavy showers, and often thunder; and it always sinks lowest of all for great winds, though not accompanied with rain; though, however, it falls more for wind and rain together, than for either of them alone. Also, if, after rain, the wind change into any part of the north, with a clear and dry sky, and the mercury rises, it is a certain sign of fair weather.

2. After very great fl orms of wind, when the mercury has been low, it commonly rises again very fast. In settled fair and dry weather, except the barometer sink much, expect but little rain; for its small sinking then is only for a little wind, or a few drops of rain; and the mercury soon rises again to its former station. In a wet season, suppose in hay-time and harvest, the smallest sinking of the mercury must be regarded; for when the conflation of the air is much inclined to showers, a little sinking in the barometer then denotes more rain, as it never at this time stands very high. And if, in such a season, it rise suddenly, very fast, and high, expect not fair weather more than a day or two, but rather that the mercury will fall again very soon, and rain immediately follow. The slow gradual rising, and keeping on to do so for two or three days, are most to be depended upon for a week's fair weather; and the unsettled state of the quicksilver always denotes uncertain and changeable weather, especially when the mercury stands any where about the word changeable on the scale.

3. The greatest heights of the mercury, in this country, are found upon calmer and north-calmer winds; and it may often rain or snow, the wind being in these points, and the barometer may sink but little or not at all, or it may even be in a rising state, the effect of these winds counteracting. But the mercury sinks for wind, as well as for rain, in all the other points of the compas; but rises as the wind shifts about to the north or east, or between those points: but if the barometer should sink with the wind in that quarter, expect it soon to change from thence; or else, if the fall of the mercury should be considerable, a heavy rain is likely to ensue, as it sometimes happens.

BAROMETER, Cause of the Phenomena of the. Those which have been enumerated, are the chief phenomena of the barometer; to account for which, the hypotheses that have been framed are almost innumerable. It would far exceed our limits to detail them all; we must content ourselves with briefly reciting some of the principal, and refer the reader who is desirous of farther information to De Luc's "Recherches," vol. 1. ch. iii.

Some, as Pafcal, Deal, Wallis, and Garcin, have accounted for the change in the weight of the air by the augmentation of the atmosphere in consequence of the introduction of vapours, and its diminution by their fall; others, as Perrier, Garden, Le Cat, and De Mairan, have ascribed it to the variations of heat; and others, as Garden, to the alterations of the specific gravity of the air; and Dr. Halley refers it to the accumulation or dispersion of the air by contrary winds. Wallis, Halley, and De Mairan have supposed that there is a difference in the vertical prelude of the air, when in motion and at rest. Wallis, and some other philosophers, have conceived that the height of the barometer depends upon the variations that occur in the elasticity of the air, and that it is directly proportional to these variations. Some have also had recourse to the contractions and dilatations of the mercury itself, as Wallis and Lifter; others, as Gerden, suppose vibrations produced in the particles of air by these winds. De la Hire and De Mairan imagine that air is removed from the south to the north, and from the north to the south: Mariotte supposes that the inclination of the winds to the surface of the earth is sometimes greater and sometimes less. Woodward and Hambarger conceive that there is a shock of vapours against the air, when they rise, and that this ceases when they are at rest. Leibnitz supposes...
poses that there is a diminution in the weight of the air when rain falls; and De Moiran apprehends, that an agitation of the air is occasioned by vapours; and Bernouilli is of opinion, that an augmentation of the atmosphere is produced by a dilatation and discharge of the air included within the bowels of the earth, and that there is a diminution of it when the contrary happens. To these several causes acting separately or conjointly, and to several circumstances attending their different operation, the variations of the barometer have been attributed. But these causes may all be reduced to three general classes: viz. variations of temperature; the velocity and other qualities of different winds; and the agency of vapour.

Dr. Lister accounts for the changes in the barometer from the alterations of heat and cold. This, he says, he has often observed, that in storms, &c. when the mercury is at the lowest, it breaks, and emits small particles, which he calls a kind of fretting; and argues, that in all times of its descent, it is more or less on the fret. In this disorder, he thinks, its parts are contracted, and brought closer together; and, for that reason, defend: besides, in the fretting they set go little particles of air, before inclosed in them, and these rising into the top of the tube, the mercury must sink, both from the column's being shortened by their escape, and by their lying upon it. Mercury therefore, he adds, rises either in very hot or very cold weather, between the tropics, &c. as being then in its natural state; and again, in the intermediate degrees of heat and cold it falls, as being contracted, and as it was convoluted, and drawn together. Phil. Trans. No 165. But his account, however ingenious, yet comes far short of accounting for the phenomena; may, in some respects it contradicts them.

The changes in the weight of the atmosphere, therefore, must be laid down as the cause of these in the barometer; but then, the cause of that cause, or whence those alterations arise in the atmosphere, it will be no easy matter to determine; there being, perhaps, no one principle in nature that will account for such a variety of appearances, and those too so irregular. It is probable the winds, as driven this or that way, have a great share in them: some share too, vapours and exhalations, rising from the earth, may have; some, the changes in the air of the neighbouring regions; and some, the flux and reflux occasioned in the air by the moon; and also some chemical causes operating between the different particles of matter.

Dr. Halley thinks the winds and exhalations sufficient; and, on this ground, gives us a rationale of the barometer. The sufficiency of what may be laid on that head, is as follows:

1st, then, The winds must necessarily alter the weight of the air in any particular country; and that, either by bringing together and accumulating a greater quantity of air, and so loading the atmosphere of any place; which will be the case, as often as two winds blow at the same time, from opposite points towards the same point; or by sweeping away a part of the air, and removing some of the load, and thus giving room for the atmosphere to expand itself; which will be the case when two winds blow at the same time, and from the same point, opposite ways; or laffly, by cutting off the perpendicular prefire of the atmosphere; which happens as often as any single wind blows briskly any way; it being found, by experiment, that a strong blast of wind, even made by art, will render the atmosphere lighter; and accordingly, the mercury, in a tube which it pafles, as well as in another at a distance from it, will subside considerably. See Phil. Trans. No 292.

2dly, The cold nitrous particles, and even air itself con
denfed in the northern parts, and driven elsewhere, must load the atmosphere, and increase its prefire.

3dly, Heavy dry exhalations from the earth must increase the weight of the atmosphere, and heighten its elastic force, as we find the specific gravity of monoliths increased by dissolved fluids and metals.

4thly, The air being rendered heavier from these and the like causes, is thereby the more able to support the vapours; which being likewise intimately mixed with it, and swimming every where equally through it, make the weather serene and fair: again, the air being made lighter, from the contrary causes, it becomes unable to support the vapours where with it is replete; these, therefore, precipitating, are gathered into clouds; and those, in their progress, coalesce into drops of rain.

These things observed, it appears pretty evident, that the same causes which increase the weight of the air, and make it more able to support the mercury in the barometer, do likewise occasion a serene sky, and a dry season; and the same causes which render the air lighter, and less able to support the mercury, do likewise generate clouds and rain.

Hence, 1st, When the air is lighter, and the mercury in the barometer is lowest, the clouds are very low, and move swiftly; and when, after rain, the clouds break, and a calm sky again ensues forth, being purged of the vapours, it appears exceedingly bright and transparent, and affords an early prospect of remote objects.

2dly, When the air is heavier, and the mercury stands higher in the tube, the weather is calm, though somewhat less clear, because the vapours are diffused every where equally; if any clouds now appear, they are very high, and move slowly; and when the air is heaviest of all, the earth is frequently found enveloped in pretty thick clouds, which appear to be formed out of the grofer exhalations, and which the air is then able to sustain, though a lighter atmosphere could not.

3dly, Hence it is, that with us the mercury stands highest in the coldest seasons, and when the wind blows from the north or north-call corner: for, in that case, there are two winds blowing towards us at the same time, and from opposite corners; there being a conflant well wind found in the Atlantic ocean, at the latitude corresponding to our's. To which we may add, that in a north wind, the cold condensed air of the northern parts is brought hither.

4thly, Hence, in the northern regions, the variation of the mercury is more sensible than in the southern ones; the winds being found more strong, more frequent, more various, and more opposite to each other in the former, than in the latter.

Laxly, Hence it is, that between the tropics, the variation of the mercury is scarcely sensible; the winds there being extremely gentle, and unifally blowing the same way.

But this account, however well adapted to many of the particular cases of the barometer, seems to come short of some of the principal and most obvious ones: and is, besides, liable to several objections.

For, 1st, If the wind were the sole agent in effecting these alterations, we should have no alterations without a sensible wind, nor any wind without some alteration of the mercury; both which are contrary to experience.

2dly, If two winds be supposed blowing from the same place, viz. London, opposite ways, viz. N.E. and S.W. there will be two others, blowing from opposite points, viz. N.W. and S.E. to the same place; which two will balance the first, and bring as much air towards the point, as the others swept from it. Or thus, in proportion as the air is
BAR

is carried off N.E. and S.W. the adjacent air will crowd in from the other points, and form a couple of new currents in the direction N.W. and S.E. to fill up the vacancy, and restore the equilibrium. This is a necessary consequence from the laws of fluids.

3dly, If the wind were the sole agent, the alterations in the height of the mercury would only be relative, or topical; there would be still the same quantity supported at several places taken collectively: thus, what a tube at London loft, another at Paris, or at Pisa, or at Zurich, &c. would at the same time gain. But we find the very contrary true in fact; for from all the observations hitherto made, the barometers in several parts of the globe rise and fall together; so that it must be some alteration in the absolute weight of the atmosphere that accounts for the rise and fall of the mercury.

Lastly, Setting aside all objections, these popular phenomena, the mercury’s fall before, and rise after rain, seem to be inexplicable on the ground of this hypothesis: for suppose two contrary winds sweeping the air from over London, we know that few, if any, of the winds reach above a mile high; all, therefore, they can do, will be to cut off a certain part of the column of air over London: if the consequence of this be the fall of the mercury, yet there is no apparent reason for the rain’s following it. The vapours indeed may be let lower, but it will only be till they come into an air of the same specific gravity with themselves; and there they will be suspended as before.

M. Leibnitz, about the year 1710, in a letter written to the abbe Baguron, endeavoured to supply the defects of this hypothesis with a new one of his own. The new principle, upon which Leibnitz’s hypothesis is founded, was illustrated by M. Fontenelle in the Histoire of the Royal Academy of Sciences at Paris for the year 1711. He affects, that a body immersed in a fluid only weighs with that fluid while it is surrounded by it; so that when it ceases to be surrounded, i.e. when let fall, its weight ceases to make a part of that of the fluid, which by this means becomes lighter. Thus, adds he, the watery vapours, while surrounded in the air, increase its weight; but when let fall, they cease to weigh along with it. Thus the weight of the air is diminished; and thus the mercury falls, and rain ensues.

But M. Leibnitz’s principle, notwithstanding the experiment he brings to confirm it, is false, as has been evidently made appear by a counter experiment of Dr. Desaguliers. (See his Course of Exp. Philos. vol. i. p. 282, &c.) For a body, whether specifically equal or lighter or heavier than a fluid, while it is immersed in it, whether it be at rest, or in motion, adds to the fluid a weight equal to that of an equal bulk of the fluid; as follows from that law in hydrostatics, that fluids gravitate according to their perpendicular altitudes. However, were M. Leibnitz’s principle true, yet it is defective; and that in the same respect with Dr. Halley’s; nor would it account for the phenomena more than the other. For, supposing the vapours by being condensed, to be put in a motion downwards; and so causing to gravitate with the atmosphere; they will therefore fall, till they reach a part of the atmosphere of the same specific gravity with themselves; and there they will hang as before. If the mercury fall, it will only be during the time of that descent; for these once fixed, the former gravity is retrieved; or, were it not retrieved, yet no rain would succeed the fall of the mercury.

The hypothesis, proposed by Mr. Chambers, is somewhat similar to that of Leibnitz, and liable to the same objection. It is as follows: suppose any number of watery vessels floating in any part of the atmosphere, over any determinate portion of the globe; if the upper vessels be condensed by the cold of the superior regions, their specific gravity will be increased, and they will descend; where meeting with other vessels not yet precipitated, they will coalesce, or run into larger vessels, by the known laws of attraction. Or, if we rather choose to have the wind act, let it drive either horizontally or obliquely; some vessels will be driven against others; by which means likewise will the particles coalesce, and form new wad larger vessels as before; so that their number, which before was, suppose a million, will now be reduced, v. gr. to a hundred thousand.

But by the same coalition whereby their number is diminished, their specific gravity, if we may so call it, is increased, i.e. they come to have more matter in the same space, or under an equal surface; as may be easily proved from principles of geometry: for in augmenting the mass of any homogeneous body, the increase of surface does not keep pace with that of the solidity; but that of the former is as the square of the diameter, and that of the latter as the cube of the same.

But since the same quantity of matter is now in a less space or under less dimensions, it will lose less of its weight by the resistance of the medium. This is evident; for a body immersed in a fluid loses nothing of its weight but by the friction of its parts against those of the fluid; but the friction is evidently as the surface; therefore, when the surface is increased, the resistance must be so too. Consequently, the vessels, whose gravity before the coalition was equal to the resistance of the medium, now that resistance is diminished, will descend; and that with a velocity in the ratio of the increase of the mass to the increase of the surface.

In air deficient, as they arrive at denser parts of the atmosphere, their mass and surface again will be increased by new coalitions; and thus, by constant fresh accensions, more than equal to the constant resistances, they will be enabled to pursue their journey through all the flags of the air, till they reach the earth; their masses exceedingly magnified, and in the form of rain.

Now that the vapours have got down, let us consider how the barometer must have been affected during their passage.

Before any of the vessels began to subside, either from the action of the cold, or of the wind, they all floated in a certain portion of the atmosphere, and all gravitated towards the centre. Here now, each respectively relying in a part of the medium of the same specific gravity with itself, will lose as much of its weight as is equal to that of a part of the medium of the same bulk with itself, i.e. each will lose all its weight. But then, whatever weight each looses, it communicates to the medium, which now press on the surface of the earth with its own weight and that of the vessels conjointly. Supposing then this united pressure keeps up the mercury in the barometer at thirty inches: by the coalition of the vessels from the clouds aforesaid, their surfaces, and consequently their friction, are lessened; therefore, they will communicate less of their weight to the air, i.e. less than the whole; and consequently they will descend with the excess. i.e. with a velocity equal to the remainder, as before observed. Now, as the vessels can act no otherwise on the surface of the earth but by the mediation of the interjacent air, in proportion as their action on the medium is less, their action on the earth will be less. It is also evident, that the surface of the earth must be now less pressed than before; and that in proportion as the velocity of the falling vessels; which is
again in proportion to their bulks. Thus, as the vehicles
defend, the bulks continually increasing, the friction, and
therefore the preffure on the earth, and laftly the height
of the mercury, will continually decraee, during the whole
time of the fall.—Hence we fce, both why the vehicles,
when once beginning to fall, perferve; why the mercury
begins to fall at the fame time; and why it continues and
coalesces to fall together with them; which were the great de-
fiderata in the philosophy of the barometer.

There is one objection that evidently lies againſt this the-
ory, viz. that the vehicles being put in motion, and striking
against the particles of the medium and one another with
fome moment, will meet with a confiderable refiffance from
the vis inerite thereof; by which means their defcent will be
 retarded, and the preffure of the atmosphere retrieved;
the impetus of the moving vehicles being fuppofed to com-
penfate for their lofs of surface. Thus a heavy body suftained
in a fluid by a hair, and moved up and down therein,
prefles more on the bottom than when held at reft; which
additional preffure will be the greater as the velocity of the
falling vehicles is greater; a greater impetus being required to
break through the vis inerite of the contiguous particles
in a left time than in a larger.

But it is alleged, that we have both refon and experimen-
tment againſt this objeétion; for the velocity of the vehicles,
in thefe circumftances, must necelfarily be very fmall, and
their impetus inconfiderable; besides, the vis inerite of the
air muft be exceedingly weak, by reafon of its extreme sub-
tility; and it muft be a very improper vehicle to convey an
impetus to a distance by reafon of its elalicty; we all find
that a piece of lead, which is a ponderous body, falling
with great moment, gravitates confiderably left, in its de-
ffent through water, which is a grofs unelallic medium,
when than falinated at reft therein; in which the feveral ex-
periments of Reaumur, Ramazzini, and Defaguliers, all agree.

M. de Luc (Recherches, &c. vol. i. p. 139.) fuppo fes that
the changes observed in the weight of the atmosphere are
principally produced by the presence or abfence of vapours
floting in it. Others have attributed the effect to vapours,
but have given a different explication of it. It is his opinion,
that vapours diminish the specific gravity, and confequently
the absolute weight of those columns of the atmosphere into
which they are received, which, notwithstanding this ad-
miixture, remain of an equal height with the adjoining col-
unns of pure, or dry air. He afterwards more
largely explains and vindicates this theory, and applies it to
the folution of the principal phenomena of the barometer,
connected with or produced by the varying density and
weight of the atmosphere.

Dr. James Hutton, in his "Theory of Rain" (Ice Rain),
printed in the Edinburgh Transactions, vol. i. p. 41, &c.
fuggests feveral plausible reafons in favour of his opinion,
that the diminution of the weight of the atmosphere by the
fall of rain is not the caufe of the fall of the barometer;
but that the principal, if not the only caufe, is to be fought
for in the cautions of the atmosphere that are chiefly
produced by fudden changes of heat and cold in the air.

"The barometer," he fays (p. 78.), "is an instrument ne-
cifarily connected with motions in the air; but it
is not equally affected with every motion in that fluid body.
The barometer is chiefly affected by fuch motions by which
there are produced accumulations and abtractions of this
fluid, in places or regions of fufficient extent to affect the
preffure of the atmosphere upon the surface of the earth.
But as every caution in the air is, under
proper conditions, a caufe for rain, and as the want of
caution in the atmosphere is naturally a caufe of fair
weather, this instrument may be made of great imporfance
for the purpofe of meteorological obfervations, although
not in the caurin and more fimple manner in which it has
been, with the increafe of science, fo successfully applied
to the measuring of heights."

In the "Encyclopaedia Britannica," art. Barometer,
we have another theory of changes in the barometer, as de-
pending on the heat in the atmosphere, not as producing
commonations in it, but as altering the specific gravity of the
air by the variations of heat and cold. The preliminaries to
this hypothesis are: 1. That vapour is formed by an
imize union between the elements of fire and water, in con-
quence of which the fire or heat is fo totally enveloped,
and its action fo entirely suspended by the watery particles,
that it not only lofes its properties of burning and of giving
light, but becomes incapable of affecting the most fensible
barometer, in which cafe, it is faid by Dr. Black, the au-
thor of this theory, to be in a latent state. 2dly. If the
atmophere be affected by any unusual degree of heat, it
thence becomes incapable of supporting fo long a column of
mercury as before, for which reason the barometer finks.

From these prineiples or axioms it is inferred,
that as vapour is formed by a union of fire with water,
whether by an elective attraction or a folution of the water
in the fire, the vapour cannot be condenfed till this union,
attraction, or folution be at an end. Hence it follows that
the commencement of the condenfation of the vapour, or
the firft figns of approaching rain, must be the feparation
of the fire which is latent in the vapour. This may at firft be
flow and partial, or it may be fudden and violent; in this cafe
the rain will come on flowly, and after a confiderable in-
erval; in the other it will come on very quickly and in a great
quantity. But Dr. Black has proved, that when fire quits
its latent state, however long it may have lain dormant and
infeinfible, it always re-affumes its proper qualities, and af-
fects the thermometer as if it had never been abforbed. The
confequence of this must be, that in proportion as the la-
tent heat is difcharged from the vapour, thofe parts of
the atmosphere into which it is difcharged, will be fefiblely af-
fected by it; and in proportion to the heat communicated
to thofe parts, they will become fpecifically lighter, and of
courfe the mercury will fink. When the feparation between
the fire and water is gradual and flow, the barometer may
indicate rain for a confiderable time before it happens; or
if the fefible heat fhould be abforbed by the colder parts
of the atmosphere, or by any means be prevented from af-
secting the fpecific gravity of the air, the barometer will
not be affected; and yet the water, deprived of the heat
that is neceufary for perifhing it, must defend in rain; and
hence it happens, that the indications of the barometer are
not always juft. Hence it also appears, that though the
fpecific gravity of the air is diminished, unless this diminu-
imtion proceeds from a discharge of the latent heat containing
in the vapours, no rain will follow; and thus the finking
of the barometer may progoflicate wind as well as rain,
or fometimes no change at all. The great defcent of the
mercury in the barometer between the tropics in the time of
hurricanes, noticed by Dr. Halley, is ascribed, as to its
probable caufe, to a great commotion in the electric fluid,
by which the air is internally agitated, and its gravitation in
part fupended.

In the fourth volume of the "Memoirs of the Literary
Society of Manchester," we have a curious paper on this
subject, viz. "Meteorological Obfervations made on dif-
fent parts of the Western Coast of Great Britain," ar-
anged by T. Garnett, M. D. The materials of this pa-
per were furnished by feveral obervers; but thofe of Mr.
Copland,
Copland, surgeon at Dumfries, are of peculiar importance. This gentleman is of opinion that the changes of the barometer indicate approaching cold and hot weather, with much greater certainty than dry and wet. "Every remarkable elevation of the barometer, he says, when it is of any duration, is followed by very warm or dry weather, and moderate to cold wind; by all of them; but he thinks to have more influence and connection; and when it is deficient, the continuance of the other two will be longer and more remarkable; therefore the calculation must be in a compound ratio of the excess and deficiency of the heat, and of the dryness of the weather in comparison of the medium of the season; and with regard to the want of strong wind, it appears to be intimately connected with the last, as they show that no precipitation is going on in any of the neighbouring regions."

In his 14th and 15th remarks, he had said, "14th. That the barometer being lower, and continuing so longer than what can be accounted for by immediate falls, or stormy weather, indicates the approach of very cold weather for the season; and also, cold weather, though dry, is always accompanied by a low barometer, till near its termination."

"15th. That warm weather is always preceded and mostly accompanied by a high barometer; and the rising of the barometer in the time of broken or cold weather, is a sign of the approach of warmer weather; and also if the wind is in any of the cold points, a sudden rise of the barometer indicates the approach of a more southly weather, which in winter generally brings rain with it."

In the two following remarks, Mr. Copland had explained certain phenomena from a principle similar to that on which Dr. Darwin has so much insisted. (Botanic Garden, i. notes p. 79, &c.)

"That the falling of the barometer may proceed from a decomposition of the atmosphere occurring around or near that point of the globe where we are placed, which will occasion the electricity of the atmosphere to be repelled upwards in fine lambent portions; or driven downwards or upwards in more compacted balls of fire; or lastly, to be carried along with the rain, &c. in an imperceptible manner to the surface of the earth; the precipitation of the wetter parts generally very soon takes place, which diminishes the real gravity of the atmosphere, and also by the decomposition of some of the more active parts, the air loses part of that elastic and repulsive power which it then eminently possesses, and will therefore press with less force on the mercury of the barometer than before, by which means a fall ensues.

"That the cause of the currents of air or winds, may also be this way accounted for: and in very severe storms, where great decompositions of the atmosphere take place, this is particularly evident, such as generally occur in one or more of the West India islands at one time, a great loss of real gravity, together with a considerable diminution of the spring of the air immediately ensues; hence a current commences, first in that direction whence the air has most gravity, or is most disposed to undergo such a change; but it being soon relieved of its superior weight or spring on that side, by the decomposition going on as fast as the wind arrives in the island, it immediately veers to another point, which then rushes in more swiftly with an increase of force; thus it goes on till it has blown more than half way round the points of the compass during the continuation of the hurricane. For in this manner the West India phenomena, as well as the alteration of the wind during heavy rains in this country, can only be properly accounted for." See remark No. 4.

Mr. C's 4th aphorism is, 'That the heaviest rains, when of long continuance, generally begin with the wind blowing Cellularly, when it gradually veers round to the south; and that the rain does not then begin to cease till the wind has got to the west, or rather a little to the northward of it, when it may be added, it commonly blows with some violence.'

Mr. Kirwan, in an elaborate paper on this subject (see Irish Transactions, vol. ii. p. 49, &c.) examines the different causes to which the phenomena of the barometer have been ascribed. He begins with the influence of different temperatures. It appears, he says, by observation, that a variation of the mass of the atmosphere is not a necessary consequence of an alteration of the temperature; for the mercury is often at the same height at different seasons, and at different places in the same season; and even when the height of the mercury changes simultaneously with the temperature, the change is often directly contrary to that which the change of temperature would lead one to expect. Besides, great changes of temperature take place only in the lower atmosphere; but in the higher regions they are inconsiderable. Any increment or decrement of the mass of the lower atmosphere which can be ascribed to a change of temperature, is too small to produce any considerable alteration in the height of the barometer; for in winter the height to which any considerable variation of temperature may be supposed to extend, scarcely exceeds 5000 feet, as we learn from the testimony of aeronauts and the height of the clouds; and indeed the winds that prevail on the surface of the earth, and which are the primary agents in producing a change of temperature, seldom reach higher, and in the more northern regions not so high. This cause, the effect of which is estimated by calculation, and compared with the actual variation, though not absolutely inefficient, on the supposition that the whole mass of the superincumbent atmosphere is increased by the accession of new air in proportion to the condensation, is nevertheless inadequate to the effect produced.

Mr. Kirwan next examines the efficacy of winds in producing the variations of the barometer; and these are such as reign in the lower regions of the atmosphere. If, according to Dr. Halley's theory, the rise of the barometer above its mean altitude was owing to the accumulation of air over the place of observation, occasioned by two contrary winds blowing towards that place, we should always have a calm when the mercury stands highest; but it is notorious, that the greatest mercurial heights are accompanied by an easterly or northerly wind, as Halley himself has observed. Nor can that equality of barometrical heights, which takes place in very distant countries, where very different winds prevail, be explained by this hypothesis. This hypothesis ascribes the defect of the mercury below its mean altitude to the rarefaction of the atmosphere over the place of observation, which rarefaction is owing to its exhaustion by two contrary currents; for instance, over England, if it should blow a westerly wind on the German, and an easterly wind on the Irish sea. But Mr. Kirwan thinks, that a rarefaction in such circumstances from such a cause is impossible; for if such currents took place, the northern or southern air would flow in to maintain the equilibrium in the same proportion; or if this did not happen, and that four contrary currents took place, the higher air should descend, and cause a sensible cold, which yet is seldom observed in England, when the mercury is low; on the contrary, a warm south wind commonly prevails, to whose temperature nevertheless the rarefaction cannot be ascribed. Dr. Halley's explication of the defect of the mercury on high winds is
flrorn appears to Mr. Kirwan to be unsatisfactory. "The
region of the earth," says Halley, "wherein those winds rage, not extending round the globe, the stagnant air left behind and that on the sides cannot rush in fast enough to
restore the evaporation made by fo swift a current, fo that the
air must be attenuated where the fast winds continue to blow."—4 Add that the horizontal motion being so quick may take off some part of the perpendicular prencipal.
This half reason seemed to acquire some confirmation from an
experiment made by Mr. Hawkebee; for having passed a
stream of air through a box in which the lower flank of a
barometer was inferted, he observed the mercury to fall
while the current passed through the box; as also in ano-
other barometer which communicated with the box, over
which the current of air did not flow. Allowing this, the
phenomenon is not sufficiently explained; for Mr. Kirwan
observes, that not only during the storm, but several hours,
if not days, before it, the mercury descends considerably, as
Halley himself, and all who recommend the marine baro-
meter, attest; otherwise this instrument would be useless.
Mr. Caswell observes (Phil. Trans. A. vol. viii. p. 458.),
that two days before the great storm of January 1753-54,
the mercury fell $\frac{1}{2}$ of an inch below 28 inches. But if
the fall were concomitant with the storm, Dr. Halley’s rea-
sons would not prove their connection. In order to a bo-
dy’s moving through air with such a velocity as to leave a
vacuum behind it, there is a necessity that it should move
at the rate of 11 or 1200 feet per second, as appears by the
observations of Mr. Brice and many others. (See Phil.
Trans. for 1766, p. 266.) The insufficiency of the second
reason alleged by Dr. Halley has been clearly shown by M.
de Luc; nor is the experiment of Mr. Hawkebee conclusive,
as it appears that part of the air already confined in the
boxes was forced out by the blast of air; and besides, Mr. Derham observed that during the greatest vehement
of storm, the mercury rises instead of falling lower. (Phil.
Trans. A. vol. iv. pt. 2. p. 77.) Mr. Kirwan made the
same observation on the 26th of February 1785, in Lon-
don.
The third hypothesis is that of those who acribe the va-
riations of the barometer to the presence or absence of va-
pours in the atmosphere; but Mr. Kirwan infers, from a
view of the nature of vapours, and the change they pro-
duce in the weight and elasticity of the atmosphere, that
this theory does not fully account for the phenomena.
If we suppose, says he, the atmosphere perfectly dry, the
barometer at 30 inches, and the thermometer at 65°, and
then a column of it to be satured with moisture, its elas-
ticity being increas’d $\frac{1}{2}$, which, according to his com-
putation, would be the case, it will contain $\frac{1}{2}$ of its volume
less air than before saturetace, since the increas of its elas-
ticity ariseth from the introduction of a new elastic fluid
amounting to $\frac{1}{2}$ of its bulk; and since the weight of
the whole volume was at first equal to that of 30 inches of
mercury, its weight will now be lessef by $\frac{1}{2}$ of 30 inches,
that is nearly 0.59 of an inch. But on the other hand, it
gained $\frac{1}{2}$ of its volume of vapour, and therefore its real
los of weight will be the difference of the weight of $\frac{1}{2}$ of
air, and $\frac{1}{2}$ of vapour; but the weight of air is to that of
vapour as 12 to 10, therefore the gain here is 0.49 of an
inch, which deductid from 0.59 the los, leaves the los
$\frac{1}{2}$ of an inch. Accordingly, this is the variation which
the barometer should undergo by the passage of a column
of air from absolute dryness to complete saturetation; a cir-
cumstance which never takes place, as the atmosphere is
never absolutely dry; and yet previously to heavy rains, we
often observe the barometer to fall 3, 4, or 5 tenths of an
inch; a fall which, from the above calculation, cannot ori-
inate from the saturetation of the atmosphere with vapour.
Nor is there any proportion between the affect of magnets
after heavy rains, and the weight of vapour condensed; for
in such cases, the mercury sometimes rises 3 or 4 tenths of
an inch; and yet the heaviest rain seldom produces one
inch of water, and the weight of a cubic inch of water is not
equal to that of of even one tenth of a cubic inch of
mercury.
Mr. Kirwan, having examined the causes to which the
variable weight of the atmosphere and height of the baro-
meter have been usually referred, and controverted their
sufficiently, proceeds to explain that which alone seems
to him adequate to the effects produced. This, in his opinion,
is the accumulation of air over those parts of the globe in
which the mercury exceeds its mean height; that is, the
height suited to its situation; and the diminution or sub-
traction of the natural quantity of air over those regions in
which the mercury falls beneath its mean height. In order
to trace the origin of this accumulation and diminution, this
ingenious author considers what may be called the natural
state of the atmosphere, and how that state may be disturbed.
The natural state of the atmosphere is that in which the
barometer on the level of the sea would stand at 30 inches
in serene weather, conformably to the fifth observation above
mentioned. For producing this state, the weight of the
atmosphere must be every where equal at the surface of
the sea; and as its weight proceeds from its density and height,
in order to obtain this equality of weight, it should be
lowest where its density is greatest, and highest where its
density is least; and these extremes of density take place in
the equatorial and polar regions. Hence it follows, that if
the height of the mercury be 30 inches under the equator
and under the poles, the atmosphere must be highest under
the equator and lowest under the poles, with several interme-
tiate gradations. (See Figure of the Atmosphere.) But
though the equatorial air be less dense to a certain height
than the polar, yet at certain greater heights it must be
more dense; for the mercurial heights at the level of
the sea being equal, the masses of the corresponding atmospheric
columns must be equal. The same observation applies to
the extratropical columns with respect to each other, where
great differences of heat prevail. Hence it follows, that in
the higher regions of the atmosphere, the denser equatorial
air, not being supported by the collateral extratropical
columns, gradually flows to the north and south. If the
affluence of the northern and southern air to the equator
by the trade winds kept pace with the affluence of the supe-
rrior air, some degree of equilibrium might still be mainta-
ned. But the trade winds move only at the rate of about 8 miles
an hour; whereas without the tropics, or at least beyond
latitude 30°, the currents of the upper atmosphere are incom-
parably more rapid. The mean heat of the whole space
between latitude 0° and latitude 30° being only seven de-
grees less than the mean heat under the equator, the dif-
cence of density is not so great as to cause any rapid col-
lapse of the inferior columns within that space; but from
latitude 30° to latitude 60°, a much smaller space, the mean
annual heat over the ocean differs from that of latitude 30°
by nearly fourteen degrees; and, therefore, the rapidity of the
upper current towards the polar regions is much greater, and
will occasion frequent interruptions, during which the weight
of the air will be diminished. Hence, notwithstanding
the high winds that frequently prevail between the tropics,
the barometer incomconsiderably and but seldom varies; whereas,
without them, the variations are frequent and considerable,
nealy in proportion to the distance from the equator: and thus
thus the second observation is sufficiently explained. During the summer of the northern hemisphere, when it is winter in the southern, the density of the equatorial air becomes superior to that of the southern air at a much lower height than that at which it becomes superior to the northern, which is expanded by the prevalence of the sun in the northern tropic; the exuberance will therefore be poured on the southern regions, and a smaller quantity will flow over the northern; consequently the variations of the barometer are smaller with us in the summer season. In winter, on the contrary, the superior current is chiefly directed to the northern hemisphere, and hence the greatest mercurial heights are found in this season; and thus the third observation is illustrated and confirmed. This accumulation takes place where the columns of the inferior air are colder and shorter, as over that part of Asia beyond latitude 35°, and east of the Caipian sea to the Frozen ocean, and over the continent of North America; and hence the barometer usually stands higher in North America, and varies less than with us even in Hudson’s Bay, latitude 59°. Accumulations are also found in the southern parts of the old continent; and when the rarefaction in the northern parts of Europe is frequent and considerable, the southern air flows from these tracts to restore the equilibrium, and while this current fails, the barometer muff fall in the intermediate regions; so that the deficit of the mercury is never the effect of a southerly wind, but both it and this wind are the concomitant effects of a rarefaction in the northern parts. On the other hand, the mercury generally rises under a northerly or colder wind, because the superior atmosphere is accumulated chiefly in those parts of our hemisphere from whence these winds issue, and this accumulated air palls with them to the southern regions. In the same manner, when the mercury falls before a storm, both the storm and this fall proceed from a great rarefaction of the air in the quarter towards which the storm blows, and this rarefaction is occasioned by the diminution or destruction of the superior atmosphere. As the superior accumulation is derived to us chiefly from North America, hence it is that the variations of the barometer generally begin to the westward with us in Europe, and are thence gradually propagated eastwards. In spring the current of superior air begins to flow to the south, and in autumn to return from it; hence the equinoctial forms and frequent variations of the barometer in those feasons. The quantity of equatorial air devolved on our hemisphere in different years is variable, and so is the quantity consumed in the northern regions; and hence the mean barometrical height is different in different years. In some years, the accumulation relling on the mountainous countries of the south of Asia and Europe, and the northern part of Africa, is greater than in other years; owing perhaps to a greater or earlier fall of snow; when this is the case, the northern air is lighter, and the southern colder, than usual, and south winds principally prevail, which in the northern parts must seem to be comparatively warm; and hence, when the winter is remarkably severe in the south of Europe and Asia, it is often as remarkably mild in the northern parts, and the barometer low. Although clouds and a disposition to rain frequently follow the descent of the mercury, this descent is not the immediate confluence of either cious or rain on the contrary, the mercury frequently rises during rain. But the rarefaction of the atmosphere, which produces the descent of the mercury, and which arises from the removal of the superior accumulation, is favourable to the production of clouds; as a heavy atmosphere, though it supports vapours once formed, obstructs evaporation, when therefore its weight is diminished, and evaporation increased, it soon becomes saturated in the higher regions, and clouds are formed.

But rain seems to arise from a subtraction of the electrical fluid, which, when the air abounds with vapours, is easily conducted to the earth. In serene and settled weather the mercury is generally high, because the greatest disturbances of the atmosphere are connected with its rarified state, which is commonly pretty distant when the superior accumulation is considerable.

That the variations of the mercurial heights should be greater at the level of the sea than at great elevations above that level, is very natural. For supposing the mercury at the level of the sea to stand at 30 inches, and at a certain elevation above that level at 25 inches, then, if the weight of the atmosphere be diminished one hundredth part, the mercury at the level of the sea should fall one hundredth part of 30 inches = 0.3 of an inch; but that on the elevation should fall one hundredth of 25 inches, = 0.25 of an inch. But it has been observed, that the variation on high mountains is beyond all proportion smaller than on the level of the sea; and this proceeds from a property which they seem to possess of condensing and accumulating the air incumbent upon them in a greater degree than the air incumbent over plains is condensed at equal heights; and hence, when the barometer on the plains falls, and that on the mountain also, it will be found, after allowing for the difference of temperature, that the fall is proportionally greater in the inferior than in the superior barometer; and, on the contrary, if the mercury ascends in both barometers, the ascent will be proportionally greater in the inferior than in the superior.

To this purpose General Roy found, on the 7th of August 1775, at 9 o’clock, the correct height of a barometer on Cænaron quay 30.375, and on the peak of Snowdon 26.418 inches; at 2 o’clock, that on the quay fell to 30.043, and that on the peak to 26.405; the fall of the mercury on the quay was therefore *3/87* of the whole, and the fall on the mountain was only *1/13* of its original height. On the other hand, at 2 o’clock, the barometer on the quay rose to 30.045, while that on the peak rose to 26.415 inches correct height; therefore that on the quay ascended only *25/143* of the whole, and that on the peak ascended *22/143* part of its height. Yet as the descents of the mercury beneath its most useful mean height are much more frequent and considerable than its ascents above it, the variations on mountains are upon the whole proportionally smaller than at the surface of the sea. For a more particular illustration of the theory of Mr. Kirwan, and the collateral observations which he deduces from it, we must refer to his paper, ubi supra. See Atmosphere, and Aurora borealis. For other particulars of the weather, besides the variations of the barometer, see Weather.

Another important purpose to which the variations of the barometer have been applied, is the "measurement of altitudes." Whilst M. Pâcel and M. Perrier were prosecutions experiments for ascertaining the weight of the air by means of the barometer, as early as the year 1648, they found that the mercurial heights varied according to the situations, either more elevated or more depressed, in which the barometer was placed; and hence they concluded, that this instrument might serve to determine how much one place was higher than another. M. Pâcel was not acquainted with the dilatability of the air, and he was therefore apprized of one of the difficulties that have attended experiments of this nature. The first person who discovered the use of the atmosphere on these principles was Kepler; but having, from ill-conducted experiments, very erroneous ideas of the proportional specific gravities of mercury and air, he flated it at only two or three English miles. The Honourable Mr. Boyle, deducing from experiments the proportion of the specific gravity of mercury to that of air to be as 1 to
BAR

14000, and supposing the atmosphere to be equally dense, estimated its height to be twice as great as Kepler's measure, or at least 35000 feet. But when the elasticity of the air was found to be in an inverse ratio of the space which it occupied, or that its condensation was proportional to the weight that compriised it, and of course that its dilatations were in the inverse proportion of the compressing weights, a property first discovered by Mr. Richard Townley, and demonstrated by Mr. Boyle, the height of the atmosphere was more accurately ascertained. Mr. Boyle's experiments to this purpose were published in 1661, in his "Defenio Doctrina de Aëris Elatere contra Linum," and exhibited the preceding year before the Royal Society. The law of the dilatation of the air was discovered also by M. Mariotte, and he published an account of his experiments for ascertaining it, in 1676, in his "Éssai sur la Nature de l'Air," and "Traité des Mouvemens des Eaux." This law was generally admitted by philosophers, and it was confirmed by observation in all climates and at all altitudes. To this purpose, M. Bonguer (Mem. Acad. Roy., Sc. 1753.) gives us the result of the experiments made by himself and M. de la Condamine in America; and he says that he found, without any exception, that the elasticities of the same mass of air exactly corresponded to the ratio of the densities. M. Mariotte applied this general law to the investigation of the total height of the atmosphere. With this view, he collected all observations of the barometer made at small heights; and he was the first person who suggested the use of logarithms in estimating heights by the declination of the mercury in the barometer, though this method has been generally ascribed to Dr. Halley and Halley indeed first employed the words logarithms in the calculation of atmospheric altitudes. See Phil. Trans. N° 181, or Abrig'd vol. ii. p. 14. Dr. Halley, assuming the specific gravity of the air to water, when the barometer stood at 30 inches, and in a mean state of heat and cold, to be as 1 to 800, and that of mercury to water as 135 to 1, (so that the weight of mercury to air is as 1080 to 1, or a cylinder of air of 1080 inches or 900 feet is equal to an inch of mercury,) inferred from these premises, that if the air were of equal density, like water, the whole atmosphere would be no more than 5.1 miles high; and that for an ascent of every 500 feet, the barometer would sink an inch. But the expansion of the air increasing in the same proportion as the incumbent weight of the atmosphere decreases, the upper parts of the air are much more rarified than the lower, and each space corresponding to an inch of quicksilver is gradually enlarged, and therefore the atmosphere must be extended to a much greater height. As these expansions of the air are reciprocally as the heights of the mercury, they may be represented for any given mercurial height by means of the hyperbola and its asymptotes. Thus, in plate XI. Pneumatics, fig. 68, the rectangles ABCE, AKGE, ALDE, &c., are always equal; and consequently the sides CB, KG, LD, &c. are reciprocally as the sides AB, AK, AL, &c. (See Hyperbola.) If then AB, AK, AL, &c. be supposed equal to the heights of the mercury, or the corresponding preffures of the atmosphere, the lines CB, KG, LD, &c. answering to them, will be as the expansions of the air under those preffures, or the bulbs which the same quantity of air will occupy, and if these expansions be taken infinitely numerous and infinitely small, their respective fans will give the spaces of air between the several heights of the barometer; i. e. the sum of all the lines between CB and KG, or the area CBKG, will be proportional to the distance or interval intercepted between the levels of two places in the air, where the mercury would stand at the heights represented by the lines AB, AK; and, therefore, the spaces of the air answering to equal parts of mercury in the barometer are as the areas CBKG, GXL, DLMF, &c.; but these areas are proportional to the logarithms of the numbers expressing the ratios of AK to AB, of AL to AK, of AM to AL, &c. Thus, by the common table of logarithms, the height of any place in the atmosphere, having any asigned height of the mercury, may very easily be found; for the line CB in the hyperbola, the areas of which represent the tabular logarithms, being 0.0144765, we shall have the following proportion: as 0.0144765 is to the difference of the logarithms of 30 and of any lesser number, so is the space answering to an inch of mercury, if the air were equal; prefixed with 30 inches of mercury, and every where alike 500 feet, to the height of the barometer in the air, where it will stand at that lesser number of inches. By the converse of this proposition, the height of the mercury may be found corresponding to the given altitude of the place. It should be observed, that the number 0.0144765 is the mean between 0.0147232, the difference of the logarithms of 30 and 29; and 0.0142904, the difference of the logarithms of 30 and 31. The first difference represents the mean density of the air between the heights of 30 and 29 inches indicated by the barometer; and the second difference represents the mean density between 30 and 31; and the density of the air at 30 inches is the mean between these two densities. This calculation of Dr. Halley is founded on the supposition of equal and uniform gravity; but Sir Isaac Newton resolved the problem more generally (Princ. Philol. Nat. Math. t. i. § 5.) and extended it to the true state of the case, where gravity is as the square of the distance inversely; and he showed, that when the distances from the earth's centre are in harmonic progression, the densities are in geometric progression. He also showed, in general, what progression of the distances, on any supposition of gravity, will produce a geometrical progression of the densities so as to obtain a series of lines which will be logarithms of the densities. See also Cotes's "Hydrostatical Lectures," and "Harmonia Mensurarum," and the article Height of the Atmosphere, and Atmospheric Logarithms in this dictionary. By these rules Dr. Halley calculated the following tables:

Upon these suppositions it appears, that at the height of 41 miles, the air is so rarified as to take up 5000 times the space it occupies here; and at 53 miles high it would be expanded.
expanded above 50,000 times: but it is probable, says Dr. Halley, that the utmost power of its spring cannot exert itself to so great an extension, and that no part of the atmosphere reaches above 45 miles from the surface of the earth. However, it follows from the principles above stated, that the air has a finite density at an infinite distance from the centre of the earth, or such as would be represented by an ordinate drawn through the centre. But at great distances its rarity would be so great, that its refraction would be immeasurable, though the retardation occasioned by it has been accumulated for ages. At the moderate distance of 500 miles, the rarity is so great that a cubic inch of common air expanded to that degree would occupy a sphere equal to the orbit of Saturn; and the whole retardation sustained by this planet, after some millions of years, would not exceed what would be occasioned by its meeting with one particle of matter weighing half a grain. Hence it may be reasonably inferred, that the visible universe is occupied by air, which, by its gravitation, will accumulate itself round every body in it, in a proportion depending on their respective quantities of matter; the larger bodies attracting more of it than the small ones, and thus forming an atmosphere about each.

Dr. Halley observes, that as the weight of the atmosphere is different at different times, its lower parts will be unequally pressed, and consequently its specific gravity will be also variable. This variation he partly ascribes to the effect of heat and cold, and also to the influence of other causes; but he was of opinion that the condensation and rarefaction, occasioned by cold and heat, and by the various mixtures of aqueous and other vapours, contributes another; for he says, that when the air is rarefied by heat, the vapours are most copiously raised; so that though the air, properly so called, be expanded and consequently becomes lighter, yet its interfaces being crowded with vapours and other matter, in a manner heavier, the weight of the compound may continue much the same. He alleges an experiment of Mr. Cavendish upon the summit of Snowdon hill to prove that the first inches of mercury have their portions of air sufficiently near to what he has determined; for the height of the hill being near 6,000 yards, Cavendish found the mercury to have subsided to 25.6 inches, on a 4 inches tube, to the mean altitude of it at the level of the earth; and by his own calculation the space answering to 4 inches should be 1288 yards.

Mr. De Luc has given an historical and critical detail, in his "Recherches," vol. i. p. 159, &c. of the attempts that have been made, and of the rules that have been proposed, by Maraldi, Scheutz, Caffini, D. Bernouilli, Horreebow, and Bauguer, as well as those of Pascal, Perrier, Mariotte, and Halley, for applying the motion of the mercury in the barometer to the measurement of altitudes. But the subject has been further pursued, and with a peculiar degree of accuracy, by De Luc himself, Sir Geo. Shuckburgh, and Gen. Roy, as we shall shew in the sequel of this article.

From the experiments of Boyle, Mariotte, Amontons, and others, it was inferred that the elasticity of the air is very nearly proportional to its density; and this principle, denominated the "Boylean law," was assumed by almost all writers on this subject. These experiments, however, were not very nice; nor were they extended to any great degrees of compression, as the density of the air was not quadrupled in any of them. By the latter and more accurate experiments of Sulzer (Mém. Berlin, vol. ix.), Fontana (Opera Phylic-Math.), M. De Luc, Sir George Shuckburgh, and Gen. Roy, it has been found that the elasticity of the air does not increase quite so fast as its density. From the Berlin experiments it appears, that the elasticity of the air at the temperature 55°, or the compressing force, increases so much more slowly than the density, that if the compressing force be doubled, the density will exceed the double by about a tenth part, &c. The law of this variation is expressed with tolerable exactness, by supposing that if D be the density of the air, and F the force compressing it, then \( D = F^{33} \), a being a very small fraction, nearly 0.05. But new experiments are wanting to ascertain the law of this inequality with precision. Nevertheless, the general result has been, that the elasticity of rarefied air is very nearly proportional to its density; and the Boylean law may in general be affirmed in cases of the greatest practical importance, or when the density does not much exceed or fall short of that of ordinary air. See Elasticity of the Air.

If we suppose the air to be of the temperature of 32° of Fahrenheit, and the mercury to stand in the barometer at 30 inches, we must allow 1/14th of an inch for its defect if it be elevated 87 feet; and, accordingly, if the air were equally dense and heavy everywhere, the height of the atmosphere would be 30 x 10 x 87 feet, or about 5 miles. But as the air is an elastic fluid, whose density is always proportional to the compressing force, the altitude of the atmosphere will be much greater; and the method of estimating it by Dr. Halley and others, admits of a familiar illustration. Suppose then that a prismatic or cylindrical column of air, reaching to the top of the atmosphere, were divided into an indefinite number of layers or strata of very small but equal thickness, and that every one of the particles of air that form these strata were of the same weight at all distances from the surface of the earth; it is plain, that the quantity of air in each stratum is as the density of the stratum, or as the compressing force, that is, the weight or quantity of matter of the superior and incumbent strata; consequently, the quantity of air in each stratum is proportional to the superincumbent air; but the quantity in each stratum is the difference between the column on its bottom and on its top, and, therefore, these differences are proportional to the quantities of which they are the differences. But in a series of quantities proportional to their differences, the quantities themselves and their differences will be in continued geometrical progression: e.g. let a, b, c be three such quantities; then \( b : c : c : a - b : b - c \); and, by alternation, \( b : a - b : c : b - c \); and, by composition, \( b : a + b + c : b + c \). Hence it appears that the densities of the strata decrease in a geometrical progression; that is, when the elevations above the centre or surface of the earth increase, or their depths under the top of the atmosphere decrease, in an arithmetical progression, the densities decrease in a geometrical progression. This principle may be applied to the purpose of measuring atmospheric altitudes in the manner of Dr. Halley above stated, or by means of that species of logarithmic curve, called from this application and use of it the "atmospheric logarithmic." (See Logarithmic Curve, and Atmospheric Logarithmic.) Let \( AB \) (fig. 99) represent the section of the earth by a plane passing through its centre O, and let \( m \) \( OA \) be a vertical line, and \( AE \), perpendicular to \( OA \), will be an horizontal line passing through \( A \), a point on the surface of the earth. Let \( AE \) represent the density of the air at \( A \); and let \( DH \), parallel to \( AE \), be taken in proportion to \( AE \), as the density at \( D \) is to the density at \( A \); and hence it is evident, that if a logarithmic or logarithmic curve \( EHN \) be drawn, having \( AJ \) for its axis, and passing through the points \( E \) and \( H \), the density of the air at any other point \( C \), in this vertical line, will be represented by \( CG \), the ordinate to the curve in that point; because it is the property of this curve, that if portions \( AB, AC, AD \), of its axis be taken in arithmetical
metrical progression, the ordinates \( AE, BF, CG, DH \), will be in geometrical progression. It is another fundamental property of this curve, that if \( EK \) or \( HS \) touch the curve in \( E \) or \( H \), the subtangent \( AK \) or \( DS \) is a constant quantity. Moreover, the infinitely extended area \( MAIE \) is equal to the rectangle \( KAIL \) of the ordinate and subtangent; and the area \( MDHI \) is equal to \( SD \times DH \), or to \( KA \times DH \); and, therefore, the area lying below any ordinate is proportional to that ordinate. These properties are analogous to the principal circumstances in the constitution of the atmosphere, on the supposition of equal gravity. The area \( BCGN \) represents the whole quantity of aerial matter above \( C \), for \( CG \) is the density at \( C \), and \( CD \) is the thickness of the stratum between \( C \) and \( D \); and, therefore, \( CGHD \) will be as the quantity of air in it, and so of all the others, and of their sums, or of the whole area \( BMCGN \); and as each ordinate is proportional to the area above it, so each density, and the quantity of air in each stratum, is proportional to the quantity of air above it; and as the whole area \( MAIE \) is equal to the rectangle \( KAIL \), so the whole air of variable density above \( A \) might be contained in a column \( KA \); if, instead of being compressed by its own weight, it were without weight, and compressed by an external force equal to the pressure of the air at the surface of the earth; and, in this case, its uniform density would be expressed by \( AE \), the measure of the density at the surface of the earth, and it would form what may be called the homogeneous atmosphere. Hence it follows, that the height of this atmosphere is the subtangent of that curve, whose ordinates are as the densities of the air at different heights, on the supposition of equal gravity. In order to determine this subtangent, we may compare the densities of mercury and air; for a column of air of uniform density, reaching to the top of the homogeneous atmosphere, counter-balances the mercury in the barometer. From the bell experiments it is inferred, that when mercury and air are of the temperature of \( 32^\circ \) Fahrenheit, and the barometer stands at 30 inches, the mercury is nearly 10440 times denser than air: consequently the height of the homogeneous atmosphere is 10440 x 30 inches = 313200 inches = 26100 feet = 8760 yards = 5 miles wanting 100 yards. Or one may find this height by observing the variations of the barometer at known altitudes, thus: when the mercury and air are of the above temperature, and the barometer on the sea-shore stands at 30 inches, an ascent of 884 feet will cause it to fall to 20 inches. Moreover, in all logarithmic curves having equal ordinates, the portions of the area intercepted between the corresponding pairs of ordinates, are proportional to the subtangents; and the subtangent of the curve belonging to the common tables is 0:43429045; and the difference of the logarithms of 30 and 29, which is the part of the axis intercepted between the ordinates 30 and 29, or 0:01472333; 0:43429045 : 883 : 26046 feet = 8680 yards = 5 miles wanting 120 yards, differing from the former result 20 yards. This difference results from the difficulty of accurately ascertaining the respective densities of mercury and air, and also of duly estimating the elevation which causes a fall of one inch in the barometer. This investigation, however, proceeds upon the supposition of equal gravity; whereas it is well known, that the weight of a particle of air decreases as the square of its distance from the centre of the earth increases. In order, therefore, that a superior stratum may produce an equal pressure at the surface of the earth, it must be denser, because a single particle of it gravitates less: consequently, the density at equal elevations must be greater than on the supposition of equal gravity, and the law of its diminution must be different.

Make \( OD : OA :: OA : Ob \); \( OC : OA :: OA : Ob \), &c. so that if \( Oa, Ob, Oa, Ma \) may be reciprocals to \( OD, OC, OB, OA \); and through the points \( A, B, C, D \), draw the perpendiculars \( AB, BE, CE, DB \), proportional to the densities in \( A, B, C, D \); and let \( CD \) be supported exceedingly small, so that the density may be supported uniform through the whole stratum. Then we shall have, \( OD \times OD = OA \times OC \); and \( Od \times Od = OD \times OD ; Oc \times Oc = OD \times CD \); and \( Oc \times Od \times Od = OD \); or because \( OC \) and \( OD \) are ultimately in the ratio of equality, we have \( od : CD :: Oc : OC = OA \); and, \( cd = CD \times OA \times OC \), and \( cd \times cg = CD \times CG \times CD \); but \( CD \times CG = \frac{CG}{CD} \); is as the pressure at \( C \) arising from the absolute weight of the stratum \( CD \); for this weight is as the bulk, as the density, and as the gravitation of each particle jointly. But \( CD \) expresses the bulk, \( CG \) the density, and \( \frac{OA}{OC} \) the gravitation of each particle. Consequentially \( cd \times cg \) is as the pressure on \( C \) arising from the weight of the stratum \( CD \); but \( cd \times cg \) is evidently the element of the curve \( AMNE \) formed by the curve \( EFGH \), and the ordinates \( AE, BF, CG, DH \), &c. &c. &c. &c.

Therefore the sum of all the elements such as \( cdg \), that is the area \( cmag \), below \( cg \), will be as the whole pressure on \( C \), arising from the gravitation of all the air above it; but by the nature of air, this whole pressure is as the density which it produces, that is, as \( cg \). Hence it appears that the curve \( EGN \) is such, that the area lying below or beyond any ordinate \( cg \) is proportional to that ordinate; and this being the property of the logarithmic curve, \( EGN \) is a curve of this nature. Besides, this curve is the same with \( EGN \); for let \( B \) continually approach to \( A \), and ultimately coincide with it. It is evident that the ultimate ratio of \( BA \) to \( AB \), and of \( BF \) to \( BF \), is that of equality; and if \( EFK \), \( EFK \), be drawn, they will contain equal angles with the ordinate \( AE \), and will cut off equal subtangents \( AK \), \( AE \). The curves \( EGN \), \( EGN \), are, therefore, the same in all appropriate positions. Moreover, if \( Oa, Ob, Oc, Od \), &c. be taken in arithmetical progression decreasing, their reciprocals \( OA, OB, OC, OD \), &c., will be in harmonic progression increasing (see Progression); but, from the nature of the logarithmic curve, when \( Oa, Ob, Oc, Od \), &c. are in arithmetical progression, the ordinates \( AE, BF, CG, DH \), &c. are in geometrical progression. Consequentially, when \( Oa, Ob, Oc, OD \), &c. are in harmonical progression, the densities of the air at \( A, B, C, D \), &c. are in geometrical progression; and thus the densities of the air at all elevations may be discovered. Thus, to find the density of the air at \( K \), the top of the homogenous atmosphere, make \( OK \) \( : OA :: OA : OL \), and draw the ordinate \( LT \); \( LT \) is the density at \( K \).

The correction for the diminished gravity of the air stated by professor Playfair (Edimb. Trans. vol. i. p. 111.) is a third proportional to the semidiameter of the earth, and the height as computed by the ordinary rule; and for different mountains, this correction is in the duplicate ratio of their heights. Dr. Hordely finds (Phil. Trans. vol. biv.), that in a height of 4 English miles, the diminution of density or volume from the accedative force of gravity would be only 1/4th part of the whole, or about 4 feet; and this affect, being in the duplicate ratio of the heights, becomes at one mile high only three feet. Below the surface of the earth, it is but half the quantity; gravity within the earth being simply as the distance from the centre.
As the heights of the mercury in the barometer in all accessible elevations indicate the densities of the air at these elevations, the method of taking heights by this instrument may be illustrated in the following familiar manner.

It has already been observed, that if the mercury in the barometer stand at 30 inches, and the air and mercury be of the same temperature of 32°F. Fahrenheit, a column of air 87 feet thick has the same weight with a column of mercury of an inch thick; and therefore if in ascends the mercury sinks to 26.9 inches, the interval of ascent is 87 feet. Suppose the mercury at a higher elevation to stand at 29.8 inches, and it be required to know the height to which the barometer has been carried. The stratum through which it has been raised, as the air is less compressed and rarer, must of course be thicker. The density of the first stratum may be called 300, estimating the density by the number of tenths of an inch of mercury which its elasticity proportional to its density enables it to support. In the same manner the density of the second stratum must be 299. But when the weights are equal, the bulks are inversely as the densities; and when the bases of the strata are equal, the bulks are as the thicknesses. In order therefore to obtain the thickness of the second stratum, say 299 : 300 :: 87 : 87.29, which denotes the thickness of the second stratum; and therefore the whole interval of the elevation of the barometer has been 174.29 feet. When the barometer at a higher elevation, shews the density to be 298, say 298 : 300 :: 87 : 87.584; the thickness of the third stratum, and 261.875 will be the whole ascent. By this method may be computed the following table, in which the first column is the height of the mercury in the barometer, the second column is the thickness of the stratum, or the elevation above the preceding stratum, and the third column is the whole elevation above the first stratum.

</table>

In order to measure any elevation within the limits of this table, observe the barometer at the lower and at the upper stations, and write down the corresponding elevations; subtract the one from the other, and the remainder is the height required. E. G. Suppose that at the lower station the mercurial height was 29.8, and that at the upper station it was 29.1.

29.8 - 29.1 = 0.7

619,353 the elevation required.

Without the aid of the table, let m represent the medium of the mercurial heights, and d their difference in tenths of an inch; then say, as m is to 300, so is 8.7 to the height.

Vol. 111.

required \( b \) or \( b = \frac{300 \times 8.7d}{m} \). Thus in the preceding example, \( m = 29.45 \), and \( d = .7 \); and therefore, \( b = \frac{29.45 \times 8.7}{29.45} = 82.70 \), differing only one foot from the former value. The whole error of the elevation 883 feet, 4 inches, the extent of the table, estimated in either of these methods, is only \( \frac{1}{300} \) of an inch. It is needless however to recur to approximations, when the scientific and more accurate method first practised by Dr. Halley is equally easy. Upon the supposition of equal gravity, as we have already shown, the densities of the air are as the ordinates of a logarithmic curve whose axis is the line of elevations. It has been also shown, that, in the true theory of gravity, if the distances from the centre of the earth increase in a harmonic progression, the densities decrease in an arithmetical progression; but if the greatest elevation above the surface be but a few miles, this harmonic progression will scarcely differ from an arithmetical one. Thus if \( AB, AC, AD \) are 1, 2, and 3 miles, the corresponding elevations \( AB, AC, AD \) will be feebly in an arithmetical progression also; for the earth's radius \( AC \) is nearly 4000 miles. Hence it follows that \( LC - AB \) is

\[
\frac{3000 \times 4001}{16004000} = 0.19052249
\]

which is a quantity altogether insignificant. We may therefore assume, that in all accessible places, the elevations increase in an arithmetical progression, while the densities decrease in a geometrical progression. Consequently the ordinates are proportional to the numbers which are taken to measure the densities, and the portions of the axis are proportional to the logarithms of these numbers. Hence it follows, that we may take such a scale for measuring the densities, that the logarithms of the numbers of this scale shall be the portions of the axis, that is, of the vertical line in feet, yards, fathoms, or any other measure; and we may, on the other hand, chuse such a scale for measuring our elevations that the logarithms of our scale of densities shall be parts of this scale of elevations; and either of these scales may be found scientifically. For it is a known property of the logarithmic curves, that when the ordinates are the same, the intercepted portions of the abscissæ are proportional to their subtangents. But the subtangent of the atmospheric logarithmic is known; it is the height of the homogenous atmosphere in any measure we please, e. g. fathoms; and we find this height by comparing the gravities of air and mercury, when both are of some determined density. Thus in the temperature of 32°F. Fahrenheit, when the barometer stands at 30 inches, it is known, as the result of many experiments, that mercury is 10443.68 times heavier than air; therefore the height of the counter-balancing column of homogenous air will be 10443.68 times 30 inches, that is, 4342.945 English fathoms. It is also known that the subtangent of our common logarithmic tables, where \( t \) is the logarithm of the number 10, is 0.4342945. Consequenly the number 0.4342945 is to the difference \( D \) of the logarithms of any two barometric heights as 4342.945 fathoms are to the fathoms \( F \) contained in the portion of the axis of the atmospheric logarithmic, which is intercepted between the ordinates equal to these barometrical heights; or that 0.4342945 : \( D \) :: 4342.945 : \( F \), and 0.4342945 : \( D \) :: 4342.945 : \( F \); but 0.4342945 is the tenth thousandth part of 4342.945, and therefore \( D \) is the ten thousandth part of \( F \).

Thus it accidentally happens, that the logarithms of the densities,
densities, measured by the inches of mercury which their
equality supports in the barometer, are just the ten thou-
sandth parts of the fathoms contained in the corresponding
portions of the axis of the atmospheric logarithmic.

Therefore if we multiply our common logarithms by 10,000,
you will express the fathoms of the axis of the atmospheral
logarithmic. Our logarithms contain the index or charac-
teristic, which is an integer, and a number of decimal
places. Let us then remove the integer place four figures
to the right hand; thus, the logarithm of 5712791513 is
multiply this by 10,000, and we obtain 1775817942.

This reasoning may be easily applied to practice, thus;

obtain the heights of the mercury in the barometer and at
the upper and lower stations in inches and decimals; take
the logarithms of these, and subtract the one from the other;
and the difference between them, accounting the four dit
decimal figures as integers in the manner now proposed, is
the difference of elevation in fathoms.

E. C.

Mercurial height at the lower station 29.8 - 14742163
At the upper station 29.1 - 14638930

Difference of logarithms $\times 10000$ - 00103233
or 103 fathoms and $\frac{222}{100}$ of a fathom, which is 619.192
feet or 619.192 $\frac{222}{100}$ inches, differing from the approximated
value before found about $\frac{4}{4}$ an inch. We have thus allowed
ourselves of the familiar and very intelligible illustration of
the method of measuring heights by means of the barometer
proposed and reduced to practice by Dr. Halley, given by
an ingenious anonymous writer in the "Encyclopedia
Britannica" art. "Pneumatics." By this method it was
found that when the temperature of air and mercury was
32° of Fahrenheit, the difference of the logarithms of the
mercurial heights was precisely equal to the number of fathoms
of elevation; and it was verified upon the whole in
practice, by geometrical surveys and measurements.

The utility of it, however, was of very limited extent; and
it was seldom adopted, till M. De Luc first and after him for
George Shuckburgh and general Roy, introduced in con-
sequence of numerous observations and well-conducted ex-
periments such improvements and corrections as were found
to be necessary for expediting the practice of it and render-
ing the result of it accurate.

M. De Luc's apparatus of portable barometers, and their
annexed thermometers, with which he made his observations,
had been already described. In the construction of his
barometers he guarded as much as possible against the im-
perfections and faults to which those of the common fort are
subject. The error arising from the repulsion of the mercury
by the glass tubes he remedied by substituting a fihn bar-
ometer instead of the simple upright tube, so that the repu-
ulsion of the two legs of the fihn might counteract itself. An-
other error resulting from air and moisture in the barometrical
tube he obviated by boiling the mercury in the
tube, and by other precautions. And he also shows how to
correct mistakes in the elevation of heights that are owing
to variations of the density of the mercury, and also of the
air, occasioned by heat and cold; by means of allowances de-
pending on two thermometers, one attached to the frame of
the barometer itself and the other exposed to the open air
for viewing its degree of heat; and these thermometers are
to be noted both at the top and bottom of the hill. From
the use of this apparatus in a great variety of observations
he deduced a rule for calculating the heights of places,
which he verified by numerous experiments. Dr. Malke-
lyne and bishop Horiley have reduced his rule from the
French to the English measure, and adapted it to the ther-

mometers of Fahrenheit's scale. M. De Luc (see Recherches,
&c. vol. i. p. 362—364) in the winter season, heated the air
of his room to as great a degree as possible, and observed
the rise of the barometer occasioned by the diminution of
its density or specific gravity by heat; and he also noted
the height of the thermometer, both before and after the
room was heated. Hence he deduced a rule that when the
barometer is at 27 French inches, which was the case in
this experiment, an increase of heat from freezing to that of
boiling water will raise the barometer 6 lines, or $\frac{2}{14}$th part
of the whole. But when the barometer is higher than 27
inches, this variation must increase in the same proportion;
and it will be always $\frac{2}{14}$th of the height of the barometer.
Consequently if the height he called $B$, the rise of the baro-
 meter corresponding to an increase of heat from freezing to
boiling water, will be $B \times \frac{2}{14}$; and as it will be less for a less
difference of heat, if the number of degrees marked on the
thermometer between freezing and boiling water be called
$K$, and the rise of the thermometer from any given point
be called $H$, the corresponding rise of the barometer will be
$B \times \frac{2}{14} \times \frac{H}{K}$, by the increase of heat from the given point
$\frac{2}{14}$ by the number of degrees $H$. With a decrease of heat, $H$
would signify the degrees of decrease, and the barometer
would sink by $B \times \frac{2}{14} \times \frac{H}{K}$. The fixed temperature
heat to which M. De Luc reduced his observations of the
barometer is $\frac{2}{14}$ th of the interval from freezing to boiling wa-
ter above the former point; and if the thermometer was
higher than this degree, he subtracted $B \times \frac{2}{14} \times \frac{H}{K}$, if it was
lower, he added this quantity to the observed height of the
barometer; and he thus obtained its exact height, or such as it
would have been, if the density of its quicksilver had been
the same as answers to the fixed degree of temperature.
He thus corrected the height of both his barometers, that
at the bottom and that at the top of the hill, for the par-
ticular degree of heat indicated by a thermometer attached
to the barometer at each station. These corrected heights
of the barometers were those which he used in his calcula-
tions. Then, calling these two altitudes of the barometer
at the lower and at the upper stations $b$ and $b$, and using log. $b$
and log. $b$ for their logarithms, taken out of the common
tables, and assuming the four first places of figures after
the index as integers, and the three remaining figures as deci-
mals, and putting $C$ for the mean height of a thermometer,
exposed to the air at the top and bottom of the hill, the
freezing point being o, and the point of boiling water at 80,
he found by his experiments that the height of the hill
would be given in French toises, when $C$ was 164, by mer-
ely taking the difference of the logarithms of the heights
of the barometer, or log. $B$ — log. $b$; and in any other degree of heat, would be greater or less in propor-
tion as the rarity of the air was greater or less than in
the fixed temperature; or greater or less, by $\frac{2}{14}$th part
of the whole, for every degree of the thermometer reckoned
from the fixed temperature 164; and consequently the
height of the place would be expressed generally in French
toises by this formula, viz. log. $B$ — log. $b$ + log. $B$ — log. $b$
$\times \frac{C - 164}{215}$ = log. $B$ — log. $b$ $\times$ 1 + $\frac{C - 164}{215}$. The re-
duction of this formula to English measure and to the scale of
of Fahrenheit's thermometer is performed by the astronomer royal (Phil. Trans. vol. lv. p. 162), in the following manner: The French foot is to the English foot as 1.06575 to 1 (Phil. Trans. vol. lxxiiii. p. 336); and the Fahrenheit's point of freezing is 32, and that of boiling water 212, having an interval of 180 degrees. But M. De Luc's point of boiling water or 80 was marked when the barometer was at 27 French inches, that being its mean height at Geneva; but our English workmen mark the same point on Fahrenheit's scale, when the barometer stands at 30 inches, which is equal to 28 inches 13 lines French measure, or 13.8 lines higher than M. De Luc's barometer, when he adjusted the point of boiling water on his thermometer; and it is well known, that the heat of boiling water varies with the weight of the atmosphere. M. De Luc from his experiments inferred, that an increase of one line in the height of the barometer raises the mercury of the thermometer, placed in boiling water, 1/33 part of the interval between the freezing point and that of boiling water, though the rule will not apply to large variations of the barometer occasioned by very great heights above the earth's surface. The change of the boiling point in Fahrenheit's scale corresponding to a change of one line in the barometer, will be 49.4° = 0.16°, and therefore 3.8 lines will produce 0.16° x 13.8 = 2.2 degrees of Fahrenheit's scale, and a thermometer, whose point of boiling water was marked 212, when the barometer stood at 30 English inches = 28 inches 13 lines French measure, will, when the barometer descends to 27 French inches, sink 2.2 degrees in boiling water, or to 209.8 or in round numbers to 210 degrees, which is dillerent only 178, from 232 the point of freezing. Hence it appears that an extent of 80° of M. De Luc's thermometer corresponds to an extent of 178 of our Fahrenheit's thermometer; and putting 

\[ b \] for the degrees of this thermometer, corresponding to \( C \) of M. De Luc's, we shall have \( C = F - 32 \times 80 : 178, \) and \( C = F - 32 \times 80 : 178, \) which, substituted in Fahrenheit's formula, gives \(
\log \frac{b - \log b}{215} = \log \frac{215}{215} \times 80 - 162 = \log \frac{215}{215} \log b
\)

\[ + \frac{F}{215} - 32 \times \frac{80}{215} - 162 \]

\[ \times 1 + \frac{F}{178} - 32 \times \frac{80}{178} - 162 \]

\[ \times 1 + \frac{F}{478.38} - 32 \times \frac{80}{478.38} - 162 \]

\[ \times 1 + \frac{F}{692.27} \]

in French toises. To reduce these to our English fathoms of 6 feet each, multiply the above expression by 1.06575, and we shall have

\[ \log \frac{b - \log b}{1.06575} = \log \frac{1.06575}{1.06575} \times 80 - 162 = \log \frac{1.06575}{1.06575} \log b \]

\[ + \frac{F}{1.06575} - 32 \times \frac{80}{1.06575} - 162 \]

\[ \times 1 + \frac{F}{1.06575} - 32 \times \frac{80}{1.06575} - 162 \]

\[ \times 1 + \frac{F}{478.38} - 32 \times \frac{80}{478.38} - 162 \]

\[ \times 1 + \frac{F}{692.27} \]

in English fathoms.

In these expressions \( b \) and \( b \) denote heights of the barometer, at the lower and higher stations, corrected for the difference of heat between a fixed temperature, viz. 1/4th of the interval between freezing and boiling water, and the present heat, indicated by the thermometer attached to the barometer at each station: but it will be sufficient, and more convenient, to correct one barometer for the difference of the heat of the two. Suppose then the upper barometer to be corrected, to reduce it to the temperature of the lower one, and that \( b \) signifies the height of this barometer, as observed and not corrected; the correction, from what has been already said, if we call \( D \) the difference of height of the thermometer attached to the barometer at the two stations, c. e. at the top and bottom of the hill, will be

\[ \frac{D}{54 K} \]

as the thermometer stands highest at the lower or upper station; and the upper barometer corrected, instead of \( b \), will be

\[ b + \frac{D}{54 K} \]

which substituted in the formula, gives

\[ \log \frac{b + D}{54 K} = \log \frac{b + D}{54 K} \times 1 + \frac{F}{449} - 40 \]

But the correction, on account of the difference of height of the barometer at the two stations, may be reduced to a more easy expression, in which the variable quantity \( b \), the height of the upper barometer, shall not appear. The fluxion of a logarithm is to the fluxion of its natural number as the modulus of the system to the natural number; and 4343 is the modulus of the common logarithms, when the four places, next the index or characteristic, are taken as whole numbers, instead of decimals, which is meant to be done in the use of the preceding formula.

Consequently, being very small with respect to \( b \), we shall have variation of \( \log b \) : variation of \( \log b + \frac{D}{54 K} \) : 4343 : \( b \) nearly very nearly, and hence variation of \( b \)

\[ = \pm \frac{D b}{54 K} \times 4343 = \pm \frac{D b}{54 K} = \frac{4343 D}{54 K} = \frac{4343 D}{54 K} \]

(putting \( K = 178 \))

\[ \pm 0.452 D. \]

Hence \( \log \left( b \pm \frac{D b}{54 K} \right) = \log b \pm 0.452 D \); which, being substituted in the above formula, will give the difference of height of the two stations, in English fathoms, in a more convenient expression, viz. \( \log \frac{b + D}{b} - \frac{449}{449} \times \frac{449}{449} \times \frac{449}{449} \); where the upper sign, +, is to be used, when the thermometer of the barometer is highest at the lower station, and the lower sign, - , is to be used, when the said thermometer is lowest at the lower station. When \( F \), the height of Fahrenheit's thermometer, is less than 40°, \( \frac{F}{449} \), becoming negative or subtractive, must be accordingly applied in the calculation. In the foregoing formula, \( B \) denotes the observed altitude of the barometer at the lower station, and \( b \) that at the upper station; \( \log B \) and \( \log b \) denote their logarithms taken out of the common tables, by ascribing the four first figures, next following the index, as whole numbers, and considering the three remaining figures to the right hand, as decimals; \( D \) signifies the difference of height of Fahrenheit's thermometer, attached to the barometer at the top and bottom of the hill; and \( F \) signifies the mean of the two heights of Fahrenheit's thermometer, exposed freely for a few minutes to the open air in the shade, at the top and bottom of the hill.

The formula, for the measure of heights, may be adapted to
to thermometers of particular scales, for the convenience of calculation; but the fakes will be different from those of M. De Luc. The thermometer, attached to the barometer, will be divided with the interval between freezing and boiling water, consisting of 81.4 degrees (=180 x 0.452); the freezing point may be marked 9, and the point of boiling water will be 213; for then, if the difference of height of this thermometer, at the two stations, be called d, we shall have 

\[ d = 0.452 \times X \]

for \( d = 180 \); and the number of degrees expressed by \( d \) will be immediately the correction for the difference of heat of the two barometers. If the thermometer, designed to show the temperature of the air, be divided with the interval between freezing and boiling water = 500, and the freezing point be marked 9, and the boiling point 191, and the heights of this thermometer, at the two stations, be called \( G \) and \( I \), we shall have

\[ \frac{F - 40}{449} = \frac{G + I}{2 \times 500} + \frac{G + I}{1000} \]

For \( F - 40 = F - 32 - 8 \) is the height of Fahrenheit's thermometer, reckoned from 8 degrees above freezing, and \( F - 32 - 8 \) increasing both the numerator and denominator in the ratio of 449 to 500, will become

\[ \frac{F - 32 \times 500}{449} \]

Hence, if the thermometer of the barometer has the freezing point marked 0, and the point of boiling water 81.4, and the difference of its height, at the two stations, be called \( d \); and the thermometer for measuring the temperature of the air be divided with the interval of 500 between the freezing point and that of boiling water, and the first be marked 9, and the latter 191, and the degrees, shown by this, at the two stations, be called \( G \) and \( I \); the formula, that will give the height of the upper station above the lower one, in English fathoms, will be

\[ \log B - \log d + \frac{G + I}{1000} \]

by 6, will give the height in English feet. It is to be observed, that \( + d \), or \( - d \), is to be used, as the thermometer, attached to the barometer, is highest at the lower or upper station; and if \( G \) and \( I \) should happen to fall below 0 of the scale, or to be subtractive, they must be applied accordingly in the calculation.

The rules, expressed in the above formula, will be in common language as follows:

1. The rule adapted to Fahrenheit's thermometer is this.

Take the difference of the tabular logarithms of the observed heights of the barometer at the two stations, considering the four first figures, exclusively of the index, as whole numbers, and the three remaining figures to the right as decimals; and subtract or add \( \frac{1}{700} \)th part of the difference of the height of the Fahrenheit's thermometer, attached to the barometer at the two stations, according as it was highest at the lower or upper station; thus you will have the height of the upper station above the lower in English fathoms nearly. This is to be corrected in the following manner: say, as 419 is to the difference of the mean altitude of Fahrenheit's thermometer, exposed to the air at the two stations, from 419, in the height of the upper station found nearly to the correction of the same: which, added or subtracted, according as the mean altitude of Fahrenheit's thermometer was higher or lower than 419, will give the true height of the upper station above the lower, in English fathoms, and multiplied by 6 in English feet.

II. The rule adapted to two thermometers of particular scales is as follows. Take the difference of the tabular logarithms of the observed heights of the barometer, at the two stations, considering the four first figures, exclusively of the index, as whole numbers, and the three remaining figures to the right as decimals; and subtract or add the difference of the thermometer, of a particular scale, attached to the barometer, at the two stations, according as it was highest at the lower or upper station, and you will have the height of the upper station above the lower one, in English fathoms nearly; subject to the following correction: say, as 1000 is to the sum of the altitudes of the thermometer of a particular scale, exposed to the air at both stations, as 0.452 is to the difference of the altitudes of the thermometers, exposed to the air, or positive or negative, will give the true height of the upper station above the lower, found nearly, to the correction of the same: which, added or subtracted, according as the sum of the altitudes of the thermometers, exposed to the air, is positive or negative, will give the true height of the upper station above the lower in English fathoms, and multiplied by 6, in English feet. Dr. Horley, the present bishop of St. Alban, has given a comparison of M. De Luc's rules with theory, reduced them to English measures of length, and adapted them to Fahrenheit's scale of the thermometer, and added tables and precepts for expecting the practical application of them in the Phil. Trans., vol. iv. p. 214, 25. Atmospheric Logarithmic, and Fixed Points of Thermometers.

The scene of M. De Luc's first observations was mount Saleve, near Geneva. Here he selected 15 stations at different elevations; and the following table abridged and from his minute details (Recherches, &c. vol. ii. p. 213, &c.) shows the result of his operations:

</table>

The latest and most accurate experiments and observations relating to this subject, are those of Sir George Shuckburgh, and General Roy. In order to render the method of measuring altitudes by the barometer more perfect, it is necessary to ascertain by appropriate experiments the expansion of mercury by any increase of temperature, and also the expansion of air by the same, and also the variations to which its effusiveness is subject.

It has been already stated, that M. De Luc estimates the expansion of quicksilver, between the temperatures of melting ice and boiling water, to be exactly 6 French lines, or .532875 decimal parts of an English inch. But he supposed the barometer to stand at 27 Fr. inches, or 28.77525 Eng. inches; whereas, if it had stood at 30 inches, it would have been
been \(0.55556\), because the expansion is proportional to the length of the column. It has also been found, that M. De Luc's boiling point is 2.2° lower than that of English thermometers, reducing it to 209.8 of Fahrenheit and making the interval between freezing and boiling only 177.8 degrees. Hence the expansion \(0.55556\) must be augmented in the proportion of 177.8 to 180, which gives for the total, 0.562407 or 0.56243, on a difference of temperature of 180°. Thus the expansion for each degree, supposing it to be arithmetical, or uniformly the same in all parts of the column, will be \(0.00312461\). But from information communicated by M. De Luc to general Roy, it appears that the difference of temperature in his experiments amounted to about 31° of Reaumur, or 72° of Fahrenheit, above freezing; and therefore, \(0.00312461 \times 72 = 0.225\) nearly will denote the rate of expansion, from which he deduced that it was 180°.

The experiments of general Roy for ascertaining the expansion of mercury are minutely detailed in the Phil. Trans. vol. lxvii. p. 659—682. He exposed 30 inches of mercury, sustained in a barometer by the atmosphere, in a nice apparatus, by which it could be made of open uniform temperature, throughout its whole length; and he noted the expansions of it in decimals of an inch. The result appears in the following table; of which the first column expresses the temperature by Fahrenheit's thermometer, the second column expresses the bulk of the mercury in consequence of its expansion, and the third column shows the expansion of one inch of mercury for an increase of one degree in the adjoining temperatures.

</table>

By this table the observed height of the mercury may be reduced to what it would have been if it were of the temperature 32. Suppose that the mercurial height is observed to be 29.2, and that the temperature of the mercury is 72°; let \(30.1362 : 30 : 29.2 : 29.0738\), which would be the true measure of the density of the air of the standard temperature. In order to obtain the exact temperature of the mercury, the observation should be made by a thermometer attached to the frame of the barometer, that it may warm and cool along with it. This, however, may be done, with sufficient accuracy, without a table; as the expansion of an inch of mercury for one degree decreases very nearly 1/48 part in each succeeding degree. If therefore we take from the expansion at 32° its thousandth part for each degree of any range above it, we obtain a mean rate of expansion for that range. When the observed temperature of the mercury is below 32°, this correction must be added in order to obtain the mean expansion. This rule will be more exact if we suppose the expansion at 32° to be 0.0014427; as in the table. Then, by multiplying the mercurial height by this expansion, we obtain the correction to be subtracted or added as the temperature of the mercury was above or below 32°. Thus, in the former example of 72°, take 40, the excess of 72° above 32°, from 0.0001127, and we have 0.0001087. Multiply this by 40, and we have the whole expansion of one inch of mercury = 0.043348. Multiply the inches of mercurial height, viz. 29.2 by this expansion, and we have for the correction 0.125965; which, subtracted from the observed height, leaves 29.07334, differing from the exact quantity less than the thousandth part of an inch. This correction may be made by another process, still more simple: or by multiplying the observed height of the mercury by the difference of its temperature from 32°, and cutting off four cyphers before the decimals of the mercurial height: and this method will seldom err one hundredth of an inch. Having thus corrected the observed mercurial heights by reducing them to what they would have been if the mercury had been of the standard temperature, the logarithms of the corrected heights are taken; and their difference, multiplied by 100000, will give the difference of elevations, in English fathoms. Another method of applying this correction, more expeditious and not less accurate, is as follows. As the difference of the logarithms of the mercurial heights is the measure of the ratio of those heights, so likewise the difference of the logarithms of the observed and corrected heights at any station is the measure of the ratio of those heights; and, therefore, this last difference of the logarithms is the measure of the correction of this ratio. But the observed height is to the corrected height as 1 to 1.000102; and the logarithm of this ratio, or the difference of the logarithms of 1 and 1.000102, is 0.00000444. This is the correction for each degree by which the temperature of the mercury differs from 32. Therefore multiply 0.00000444 by the difference of the mercurial temperatures from 32, and the products will be the corrections of the respective logarithms. The following method of applying the logarithmic correction is more easy than the former. The correction will only be necessary, when the temperatures at the two stations are different, and it will be proportional to this difference. Therefore, if the difference of the mercurial temperatures be multiplied by 0.00000444, the product will be the correction required on the difference of the logarithms of the mercurial heights. Moreover, since the differences of the logarithms of the mercurial heights are also the differences of elevation in English fathoms, it follows, that the correction is also a difference of elevation in English fathoms; or that the correction for one degree of difference of mercurial temperature is \(\frac{1}{546.9}\) of a fathom = 32 inches = 2 feet 8 inches. This correction of 2.8 for every degree of difference of temperature must be subtracted

</table>

Sir George Shuckburgh has given the following table for the expansion of mercury by heat.
Sir George Shuckburgh, in his barometrical observations, reckoned the equation for the expansion of mercury = .00325 of an inch for every degree of Fahrenheit's thermometer in a column of 30 inches, instead of .00312 used by M. De Luc: but this difference, he says, will not occasion an alteration in the result of any one of his observations of more than 5 inches; and he considers it as of no account. In another part of the same paper (Phil. Trans. vol. lxvi. p. 567.), he estimates this equation, allowing .00432 for the effect of the expansion of glass for 1° upon a column of 30 inches, at .00364 of an inch for each degree, when the barometer stands at 30 inches. He adds, that there is ground for the suspicion, that the expansion of mercury is not directly as the heat flown by the barometer, but in a ratio somewhat different; owing, as he conceives, to some of the mercury being converted into an elastic vapour in the vacuum that takes place at the top of the Torricellian tube, which precludes upon the column of mercury and thus counteracts in a small degree the expansion from heat. It does not, however, appear to be a considerable quantity, not amounting to above 1/48th of the whole expansion in a range of 40° of temperature. General Roy was incommodeled in his experiments by the alternate expansion and condensation of the elastic vapour contained in the upper part of his tube. Lord Charles Cavendish found the difference between the expansion of mercury and glass, from 180° of heat, to be .459. And taking into the account Mr. Smeaton's dilatation of glass, the total expansion of 30 inches of mercury, says General Roy, will be .544, which gives a rate of expansion of only .003022 for each degree. Phil. Trans. vol. lxviii. p. 671. 673. 678.

After all, there will be a difference in the specific gravity of the mercury that is used, which will occasion irregularities that are not easily obliterated. Mercury has been thought sufficiently pure for a barometer, when it is so far cleared of all calculable matter as not to drag or fill the tube. Nevertheless in this rate it may contain a considerable portion of other metals, particularly of silver, bismuth, and tin, which will diminish its specific gravity. It has been obtained by rectification from chilliars of the specific gravity of 1.429, and it is thought very fine if it be 1.569. The specific gravity of the mercury in the barometers used by Sir George Shuckburgh was 1.561 with 68° of heat; but it is seldom found so heavy. These variations must affect the ultimate results; and in order to obtain precision, it is absolutely necessary to know the density of the mercury that is employed. The subtangent of the atmospherical logarithmic, or the height of the homogeneous atmosphere, will increase in the same proportion with the density of the mercury; and the elevation corresponding to 1/4th of an inch of barometric height will vary in the same proportion.

Another circumstance which demands attention in this business is the temperature of the air; as the change that is produced by heat in its density is of much greater moment than that of the mercury. The relative gravity of the two, on which the subtangent of the logarithmic curve depends, and consequently the unit of our scale of elevation, is much more affected by the heat of the air than by the heat of the mercury. M. De Luc was led from his observations to conclude, that at a certain temperature, marked +16½ in his scale, and nearly 69°4 of Fahrenheit's, the difference of the logarithms of the heights of the mercury in the barometer, at the upper and the lower stations, gave the height of the former of those stations above the latter in 1000ths of a French toise; but that at every other temperature above or below 69°4, a correction of .00225 of the whole was to be added or subtracted for every degree of the thermometer. By observations still more accurate, it has been found, that the temperature at which the difference of the logarithms gives the height in English fathoms is 32°, and that the correction at other temperatures is .00243 of that difference for every degree of the thermometer. The manner of estimating the temperature of the air, adopted in all these observations, was the same; an arithmetical mean was taken between the heights of the thermometer, at the upper and lower stations, and was supposed to be uniformly diffus'd through the column of air intercepted between them. M. De Luc, however, was apprised of the inaccuracy of this supposition; and General Roy, too, has observed, that one of the chief causes of error in barometrical computation proceeds from the mode of estimating the temperature of the column of air from that of its extremities, which must be faulty in proportion as the height and difference of temperature are great. Indeed it seldom or never happens, that any particular stratum of air is uniformly of the same temperature. It is commonly much colder above; and it is also of different constitutions. Below it is warm, loaded with vapour, and very expanisible; above it is cold, much drier, and less expanisible both by its dryness and its rarity. Currents of wind, also, are often difposed in strata, which retain their places for a considerable time; and as they come from different regions, are of different temperatures and constitutions. It is neither certain that the whole intermediate stratum expands alike, nor that the expansion is equal in the different intermediate temperatures. Rare air expands less than that which is denser; and there is a particular elevation at which the general expansion, instead of diminishing the density of the air, increases it by the superior expansion of that which is below. But no general rule has been establisht by which we can obtain a more accurate correction than by taking the expansion for the mean temperature.

Sir George Shuckburgh has exhibited the result of several experiments on the expansion of air by a change of temperature in the following table; where is seen the increase in bulk of 1000 parts of air of the temperature of freezing and prellure of 38 1/4 inches, by an addition of 1 degree of heat in Fahrenheit's thermometer.

The mean of these two sorts of observations, made with different instruments, is 2.43, viz. 1000 parts of the air at freezing become by expansion from 1° of heat equal 1002.43 parts or 1002.385 parts with the standard temperature 39°.7. Whereas
Whereas M. De Luc's experiments reduced, give this quantity equal 1002.23 parts. General Roy compared a mercurial and an air thermometer, each of which was graduated arithmetically; that is, the units of the scales were equal bulks of mercury, and equal bulks of air. Their progress is exhibited in the following table.

</table>

As equal increments of heat produce equal increments in the bulk of mercury, the differences of temperature are expressed by the second column, and may be considered as equal; and the numbers of the third column express the same temperatures with those of the first. They directly express the bulks of the air, and the numbers of the fourth column expresses the differences of these bulks. These are evidently unequal, and they shew that common air expands most of all when the temperature is 62 nearly. In order to determine what was the actual increase of bulk by some known increase of heat, general Roy took a tube of a narrow bore, with a ball at one end. He measured the capacity of both the ball and the tube, and divided the tube into equal spaces, bearing a determined proportion to the capacity of the ball. This apparatus was placed in a long cylinder filled with frigid and mixtures or with water, which might be uniformly heated to the boiling temperature, and it was accompanied by a nice thermometer. The expansion of the air was measured by means of a column of mercury, which rose or sunk in the tube. The tube being of a small bore, the mercury did not drop out of it; and the bore being chosen as equal as possible, this column remained of an uniform length, whatever part of the tube it chanced to occupy. By this contrivance, he was able to examine the expansibility of air of various denities. When the column of mercury contained only a single drop or two, the air was nearly of the density of the external air. If he wished to examine the expansion of air twice or thrice as dense, he used a column of 30 or 60 inches in length; and to examine the expansion of air that is rarer than the external air, he placed the tube with the ball uppermost; the open end passing through a hole in the bottom of the vessel containing the mixtures or water. By this position the column of mercury was hanging in the tube, supported by the pressure of the atmosphere; and the quantity of the included air was measured by the difference between the suspended column and the common barometer.

The following table shews the expansion of 1000 parts of air, nearly of the common density, by heating it from 0 to 212. The first column shews the height of the barometer; the second shews this height augmented by a small column of mercury in the tub of the manometer, and therefore expresses the density of the air examined in inches; the third contains the total expansion of 1000 equal parts of air by 212°; and the fourth shews the mean expansion for each degree.

If this expansion be supposed to follow the same rate that was observed in the comparison of the mercural and air thermometer, we shall find that the expansion of a thousand parts of air for one degree of heat at the different intermediate temperatures will be as in the following table.

</table>

In order to have a mean expansion for any particular range, as between 12° and 92°, which is the most likely to comprehend all the geographical observations, we need only take the difference of the bulks 26.038 and 222.006 = 195.968, and divide this by the interval of temperature, 80°, and we obtain 2.4496, or 2.45, for the mean expansion for 1°.

This table, which in its present form shews the expansibility of air originally of the temperature 0°, may be easily adapted to a map of 1000 parts of air of the standard temperature 32°, by saying (for 212°), 107.718: 1484.210:: 1000: 134.89; and so of the rest. Thus the following table is constructed.

Table
From the experiments to which we have above referred it appears, that the expan-sibility of air is great, if when the air is about its ordinary density, and that in small densities it is greatly diminished. It appears, upon the whole, that there is little difference in the actual expansion or elastic force of air, ured with an atmosphere + or - one third part; yet, when it is rendered extremely rare, its elasticity is wonderfully diminished. It should seem, indeed, that the elastic force of common air is greater than when its density is considerably augmented or diminished by an addition to or subtraction from the weight with which it is loaded; and this observed difference contradicts the experience of Boyle, Mariotte, &c. It also appears, that the law of comporestation is altered; for in the preceding specimen of the rare air half of the whole expansion happens about the temperature of 99 °, but in air of ordinary density at 105 °. As this is the case, the experiments of M. Amontons, in the Memoirs of the Academy at Paris for 1702, &c. are not incon-sistent with those of general Roy. Amontons found that whatever was the density of the air, at least in cases where it was newly denser than common air, the change of 180 ° of temperature increased its elasticity in the same proportion; for he found, that the column of mercury, which it supported, when of the temperature 50 °, was increased 1/3 at the temperature 212 ° and hence he hacily inferred, that its expan-sibility was increased in the same proportion: but this is by no means the case, unless we are certain that in every temperature the elasticity is proportional to the density; which still remains to be decided.

From another class of experiments made by general Roy, we learn that the elastic force of moist air is greatly inferior to that of dry air; and that a very uniform increasing progression is perceived to take place from the zero of Fahrenheit, as far as 152 ° or 172 °, and even to the boiling point. From the mean result of these experiments, which are arranged in a table, it appears, that the expan-sibility of air, however moist, having that moisture condensed or separated from it by cold, differs not sensibly from that of dry air. Thus the rate for 32 ° below freezing 2.27590 is nearly the same as in dry air; but as soon as the moisture begins to diffuse and mix with the air, by the addition of 20 ° of heat, the difference is perceptible; for instead of 2.45075, the rate for 20 ° above 32 ° in dry air, we have 2.588 for that which is moist. In the next step of 20 °, the rate for dry air is 2.5809; whereas that for moist is 2.079. In this manner the progression goes on continually increasing, so as to give 7.80854 for the mean rate on each degree of the 212 °, which is near 5/8 times the expansion of dry air. And, finally, the rate for the 20 ° between 152 ° and 212 ° is twice and one-half the mean rate, and about nine times that which corresponds to the zero of the scale, but the comparison being drawn from the mean of some particular experiments, as being probably nearest the truth, the total expan-sibility of moist will be more than four times that of dry air; and the rate for the temperature at boiling will be nearly 15 times that which corresponds to the zero of Fahrenheit. This circumstance will probably account for the deviations from the rules established for determining heights by the barometer, which take place in the province of Quito in Peru, and at Spitzbergen, within 100 degrees of the pole. In the former situation, which is at a great elevation above the level of the ocean, the heights obtained by these rules fall considerably short of the real heights; and at the latter place they considerably exceed them. Near the surface of the earth there is a greater degree of humidity and heat in the air than there is in the higher regions of the atmosphere; and the elasticity or expansion of the lowermost section of 4 T every
For 30 Expansion Subtract Reduce 25.151 order of cool and air, the great
otherwife, cool to a given high 39 vapour detached

thermometer, the Spitsbergen, thermometer, &c. as

1. Subtract the logarithm of the barometrical height at the upper
   elevation from the logarithm of that at the lower, and count the
   index and four first decimal figures of the remainder as 
   fractions, the rest as a decimal fraction. Call this the elevation.

2. Note the different temperatures of the mercury at the two
   elevations, and the mean temperature. Multiply the
   logarithmic expansion corresponding to this mean temperature
   (in Table II.) by the difference of the two temperatures, and
   subtract the product from the elevation, if the barometer
   has been cooled at the upper elevation; otherwise, add it.
   Call the difference, or the sum, the approximated elevation.

3. Note the difference of the temperatures of the air at the two
   elevations by a detached thermometer, and also the mean
   temperature and its difference from 32°. Multiply this
   difference by the expansion of air for the mean temperature,
   and multiply the approximated elevation by 1 ± this product
   according as the air is above or below 32°. The product
   is the correct elevation in fathoms and decimals.

Example.

Suppose that the mercury in the barometer at the lower
elevation was at 29.4 inches, that its temperature was 50°
and the temperature of the air 45°; and let the height of the
mercury at the upper elevation be 25.19 inches, its temperature
46°, and the temperature of the air 39. Here we have

Mere. heights Temp. merc. Mean Temp. air. Mean
29.4 25.19 50 48 45 42

1. Log. of 29.4 25.19 -16.02427
   Log. of 29.4 25.19 -16.02282

Elevation in fathoms 671.191

2. Expansion for 4.5° -1.473
   Multiply by 4 -4 -1.892

Approximated elevation

3. Expansion of air at 42 -0.00238
   Mulit. by 42 x 32 = 10° 0.0238
   Multiply - - - - - -
   By - - - - - -

Product = the correct elevation 685.228

II. Sir George Shuckburgh's method.

1. Reduce the barometric heights to what they would be
   if they were of the temperature of 32°.

2. The difference of the logarithms of the reduced barometrical
   heights will give the approximate elevation.

3. Correct the approximate elevation as before.

Example. The same as before.

1. Mean expansion for 1° from Table I. -0.000011
   18° x 0.000111 x 29.4 = 0.059
   Subtract this from 29.4

Reduced barometric height 29.341

Expansion from Tab. I. is 0.000011
14° x 0.000111 x 25.19 = 0.059
Subtract from - - 25.190

Reduced barometric height 25.151

2. Log. 29.341 - - 1.4874749
   Log. 25.151 - - 1.4005553

Approximated elevation 669.196

3. This multiplied by 1.0238 gives 685.125

Sir
Sir George Shuckburgh has computed a series of tables, and given precepts for estimating the heights of mountains by means of their tables; for which we refer to his own account, ubi supra.

Obs. 1. If \( 0.000101 \) be supposed the mean expansion of mercury for \( 1^\circ \); the reduction of the barometric heights will be had with sufficient exactness by multiplying the observed heights of the mercury by the difference of its temperatures from \( 32^\circ \), and cutting off four more decimal places; thus \( 29.4 \times 0.000101 = 0.0003 \) gives the reduced height 29.347. A similar example for \( 25.19^\circ \) gives 25.155, and the difference of those logarithms gives \( 669.4 \) fathoms for the approximated elevation, which differs from that given above by no more than 15 inches.

Obs. 2. If \( 0.0024 \) be taken for the expansion for \( 1^\circ \), the correction for this expansion will be had by multiplying the approximated elevation by 12, and this product by the sum of the differences of the temperatures from \( 32^\circ \); counting that difference as negative when the temperature is below \( 32^\circ \), and cutting off four places; thus, \( 669.196 \times 12 = 07 \times 10.533 = 16.061 \), which added to \( 669.196 \) gives 885.257, differing from the former only 9 inches.

III. Another rule may be derived from the same premises; and it will be sufficiently exact for all geological purposes. It requires no tables, and may be easily remembered.

1. The height through which we must rise in order to produce any full of the mercury in the barometer, is inversely proportional to the density of the air; that is, to the height of the mercury in the barometer.

2. When the barometer stands at 30 inches, and the air and quicksilver are at the temperature \( 32^\circ \), we must rise through 87 feet, in order to produce a depression of \( 1/13 \)th of an inch.

3. But if the air be of a different temperature, the 87 feet must be increased or diminished by \( 0.21 \) of a foot for every degree of difference of the temperature from \( 32^\circ \).

4. Every degree of difference of the temperatures of the mercury at the two stations makes a change of 2.833 feet, or two feet ten inches in the elevation. Hence is deduced the following rule.

1. Take the difference of the barometric heights in tenths of an inch; and call it \( d \).

2. Multiply the difference \( d \) between \( 32^\circ \) and the mean temperature of the air by 21, and take the sum or difference of this product and 87 feet. This is the height through which we must rise to equalize the barometer to fall from 30 inches to \( 29.9^\circ \); call this height \( h \). Let \( m \) be the mean between the two barometric heights. Then \( \frac{30h}{m} \) is the approximated elevation very nearly. Multiply the difference \( m \) of the mercurial temperatures by 2.833 feet, and add this product to the approximated elevation, if the upper barometer has been the warmest; otherwise subtract it. The result, that is the sum or difference, will be the corrected elevation.

Example, as before.

\[
\begin{align*}
d &= 29.4 - 25.19 = 4.21 \\
h &= 87 + 10 \times 0.21 = 89.1 \\
m &= 29.4 + 15.19 = 44.59 \\
2
\end{align*}
\]

Approximated elevation \( = \frac{30 \times 4.21 + 89.1}{27.29} = 115.34 \) feet.

Correction for temp. of mercury \( = 4 \times 2.83 = 11.32 \)

Corrected elevation in feet \( = 115.34 + 11.32 = 126.66 \) feet.

The same in fathoms \( = 4 \times 11.32 = 45.28 \) feet.

Differing from the former only 15 inches.

This rule may be expressed by the following formula, which is simple and easily remembered; \( a^\circ \) being the difference between \( 32^\circ \) and the mean temperature of the air, \( d \) the difference of barometric heights in tenths of an inch, \( m \) the mean barometric height, \( e \) the difference between the mercurial temperatures, and \( E \) the correct elevation.

\[
E = \frac{30(\bar{d} + 0.21 a)}{2} = 2 \times 2.833.
\]

BAROMETERS, ANIMAL. See SEA-ANEMONITES. BAROMETRICAL Phosphorus. See Phosphorus.

BAROMETZ, in Botany. See POLYPodium.

BARON, a person who holds a barony.

- Baron is a term whose origin and primary import are much contended. Some will have it originally denote a man, who, some a hero, or valiant man; some a liberator, or free man; some a great or rich man; some a souful or high man.

- Menge derives it from the Latin baro, which we find used in the pure age of that language for any, an or valiant man; whence, according to this author, it was that those placed next to the king in battles were called barones, as being the bravest men in the army; and as princes frequently rewarded the bravery and fidelity of those about them with fees, the word came to be used for any noble person who holds a fee immediately of the king. Ifnord, and after him Camden, take the word in its original sense, to signify a mercenary soldier. Melleurs of the Port Royal derive it from baro, a height, weight, or authority. Cicero uses the word baro, for a stupid brutal man; and the old Germans make mention of bestowing a baron, i.e. a villain; as the Italians still use the word barone, to signify a beggar. M. De Marco derives baron from the German bar, men or free men; others derive it from the old Gaulish, Celtic, and Hebrew languages. But the most probable opinion is, that it comes from the Spanish cabro, a stout, noble person; whence wives come to call their husbands, and princes their tenants, barones. In the Saltic law, as well as the laws of the Lombards, the word baron signifies a man in the general, and the old glossary of Philomene translates baron by over, mon.

Baron, the title of a lord or peer of parliament, being the next degree below that of a viscount. A baron hath the title of Right Honourable, and in all acts and proceedings is styled Most noble Lord. The parliamentary robe of a baron is scarlet cloth, lined with white satin, having on the right side two guards of Miniver, or ermine, which signifies his degree. The coronet of a baron is a sim of gold, having therein six pearls; this coronet was granted them by Charles II. by patent bearing date 6th July 1661, before which they wore a crimdon cap turned up with ermine, and on the top a taffel of gold, now called a baron's cap. A baron may appoint his e chapelains. In ancient records, the word barons included all the nobility of England, because regularly all noblemen were barons. The word baron of itself originally did not, more than peer, signify an immediate subject of the king; for a patrician lord had their barons, that is, their immediate tenants; and in old records, the citizens of London are styled barons, and so are the representatives of the curfews called to this day. Baron, therefore, at first signified only the immediate tenant of that superior whom baron he is said to be; but by length of time it became reserved to those who, properly and exactly speaking, were baroni regis et reginae: and even not to all of these, but to such only as had manors and courts therein; for though, by the principles of the feudal constitution, every immediate military tenant of
the crown, however small his holding, was obliged to afflit the king with his advice, and entitled likewise to give or refuse his assent to any new law or subsidy, that is, to attend in parliament; this attendance was too heavy and burdensome upon such as had only one or two knight's fees, and could not be complied with without their ruin. Hence arose the omission of filing writs to fuch, and which, being for their ease, they acquiesced in, attendance in parliament being considered at that time as a burthen. Thus they lost that right they were entitled to by the nature of their tenure, until the method was found out of admitting them by representation. Hence arose the distinction between tenants by barony or tenure, and tenants by knight's service in the capite of the king. The former were fuch military tenants of the king, as had estates so considerable as qualified them without inconvenience to attend in parliament, and who were therefore entitled to be summoned: the quantum of this estate was regularly thirteen knight's fees and one third, as that of a count or earl was twenty; that is, as a knight's fee was then reckoned to 20l. per annum, the baron's revenue was 400 marks, or 262l. 13s. 4d.

Such was the nature of all the baronies of England, for about two hundred years after the conquest: and they are called baronies by tenure, because the dignity and privileges were annexed to the lands they held; and if these were alienated with the content of the king (for without that they could not), the barony went over to the alleece. Of these Matthew Paris tells us there were 250 in the time of Henry III.; and whilst they ftood purely on this footing, it was not in the king's power to increase the number of the baronies: though of barons perhaps he might; for as William the Conqueror was obliged to gratify several of his great officers, according to the number of men they brought, with two or more baronies, whenever these fell into the hands of the crown by escheat, either for want of heirs, or by forfeiture, it was in the king's power, and it was his interest, to divide them into separate hands. The fame thing likewise happened, when, by an intermarriage with an heiress, more baronies than one came into the hands of a nobleman, and escheated to the crown.

But the number of these feudal baronies could not, strictly or properly speaking, be increased by the king; for they could be created only out of lands, and there were no lands vacant to create new ones out of, for the king's definition were in those days unchangeable. However we find, at the end of Henry the Third's reign, and even in John's, that the number of baronies were actually increased, and a distinction made between the baronii majores and minores.

The majores were those who float on the old footing of William, and had lands sufficient in law, namely, the number of the king's fees requisite. The minores were such as held by part of a barony; and when an old barony was defecled to, and was divided among fifters, in which case, when the husband of the sister whom the king pleased to name was the baron of parliament, or else it was newly carved out of the old baronies that had fallen in by escheat; as supposing the king had granted fix knight's fees of an old barony to one to hold with all the burdens and to the service of an entire barony, and the remaining seven and one-third to another on the fame terms. But the attendance of these minor barons also at length became too burdensome for their circumstances, and many of them were glad to be excused. The king took then the power of passing by fuch as he thought unable, by not fending them writs of summons; and John extended his prerogative even to omit summoning fuch of the majores as he imagined were inclined to oppose him: this however at length he was obliged to give up; for in his magna charta it is said, "ad habendum commune consiliwn regni faciemus summoere archiprincipos, archiprincipos, abbates, comites, & majores barones regni, jure successorum." The barones majores were there fully and plainly distinguished from the minores; and we apprehend it will not be doubted they were such as had the full complement of a knight's fees that made up an ancient barony; and accordingly we read, in 1255, when Henry the Third had neglected summoning some of these, the others refusing to enter on any business, "quia omnes tune temporis non fuerunt, justa tenorem magnum chartam fuga, vacati; et idoneo, fine paribus suis ture alienumibus, nullum voluerunt ture reponendum dare, vel auxilium concedere, vel pretari." No king since ever omitted to summon all the greater nobility, until Charles the First was prevailed upon to forbid the fending a writ to the earl of Bridtol, by Buckingham, who was afraid of being accused by that nobleman; but on the application of the house of lords, and their adjourning themselves from day to day and doing no business, the writ at last was issued.

In the reign of Henry the Third also, the king's prerogative of summoning or omitting the leifer barons was likewise ascertained by an act of parliament since lost, as we find by these words from history: "Ille enim rex (felicit Henricus Tertius) post magnas perturbationes & enormes vexationes inter ipsum regem, Simonem de Montefelti & alios barones, motas & fapitas flatuit et ordinavit, quod omnes illi comites & barones regni Anglie, quibus intex & dignatus ed brevia dirigitre, venerent ad parliamentum suum, & non ali, nisi forte dominus rex alicula brevia illis dirigere voluisset," and from henceforth no nobleman could fit in parliament without a writ. But there was this difference between the greater and the leifer barons, that the former had a right to their writ ex debito jure, to the latter it was a matter of favour; but when summoned, they being really barons, had the same rights with the rels, though sitting not by any inherent title, but by virtue of the writ. The other leifer barons, who were generally omitted to be summoned, by degrees mixed with the other king's tenants in capite, and were thenceforth represented by the knights of the shires.

But these baronies by tenure being long since were out among the laity, it is proper to proceed to the two ways now in being of creating peers; by writ, and by letters patent. It was lord Coke's opinion, and in this he has been followed ever since, that a writ to any man, baron or no baron, to fit in parliament, if once he hath taken his seat in pursuance thereof, gains a barony to him and the heirs of his body; and though the law, principally on the authority of that great lawyer, is now so settled, certainly it is comparatively but a novel opinion, and very ill to be supported by reason. The words of the writ are: "Res talis habet qua de avditamento & assentiendo constieti nobis, pro quibusdam arduis & urgentibus negotiis situum & defendendis regni nostri Anglie concernentibus, quoddam parliamentum nostrum apud Welfonnaff, tali die talis mensa proximo futuro teneri ordinavimus & ibidem vobiscum, ac cum praelatibus magnis & proceribus dicti regni nostri, colloquium habere & tractatus; vobis in fide & ligeantia quibus nobis tenemini firmiter injungendo mandamus, quod consideratis dictorum negotiorum arduitate & periculis imminentibus, clemente excitatione quacunque, dictis die & loco personaliter intestatis nobiscum, ac cum praelatis magnis & proceribus super dicti negotii tractatus, velrumque consiliwm impenitentur, & hoc facta nos, & honorem nostrum, ac expeditionem negotiorum predictorum diligere, nullatenus omittatis."
That this writ must be obeyed there is no doubt, for every subject is by his allegiance obliged to assist the king with faithful counsel; but what right the party summoned acquired thereby, is the question. The words are not only personal to him, but restricted likewise to a particular place and time; and, accordingly, in ancient times we find many persons summoned to one parliament, omitted in the next, and summoned perhaps to the third. There is not a word therein that hints at giving the last right to an heir; and what reason can be assigned why a man by this writ should gain an estate of inheritance in a peerage, when in letters patent it is admitted that he gains only an estate for life, without the word heirs. That anciently there was no such notion appears from the summons to parliament, where frequently we find the grandfather summoned, the father passed by, and the grantee afterwards summoned; nay, in the rolls there are instances of ninety-eight persons being summoned a single time only, and neither themselves nor any of their posterity ever taken notice of afterwards. Or if we were to allow that this writ created an inheritance, what reason can be given why it should be an estate tail only, and be confined to the heirs of the body, and not, as all other new inheritances created generally, go to the collateral heirs?

But in order to discover plainly what privileges persons so called by writ had, or could obtain in those times, it will be proper to distinguish them into three kinds of persons: first, then, they were either some of the minor barones by tenure, and thence, when called, had certainly all the privileges of the greater, or else they were not barons at all, but plain knights or gentlemen; and in respect to these, it is plain they had a right to deliberate, debate, and advise; but the better opinion is, they had no right to vote, but were attendants and Advisers only, as the judges are at present, for it is absurd to suppose in those times, when the commons were low and inconsiderable, and the barons were more powerful than the crown, that the latter should suffer their resolutions to be overruled at the pleasure of the king, by calling in such numbers as we find he often did, which must have been the case if all he had summoned had votes. But these two kinds of persons gained by their writ or sitting in consequence of it, originally, no farther right than to be present at that time. However, by many of these persons and their heirs having been constantly summoned, especially since Henry the Seventh's reign, and the ancient practice of omitting any who had been very frequently so going into disuse, the distinction between the greater and lesser barons was forgot, and that opinion prevailed which my lord Coke had adopted, and which is now the law, that a man having once sat in parliament in pursuance of the king's writ, acquires thereby an estate tail to him and his heirs of his body.

There was yet another kind of persons, not peers, that might be summoned by writ: these were the eldest sons of peers, to whom the father's barony must descend; and in such case, if the heir was called by the name of a barony that was in his father, he was a baron to all intents and purposes. But it seems very plain that this was not a new creation of a barony, for in that case the son so called should have been the lowest peer, whereas the practice is contrary; and we find no instance of a baron's son sitting on such a summons, unless the father had another barony by which he might sit: if the father indeed had a higher title, that has been reckoned sufficient to support his seat, though his only barony was transferred to the son. This then being no new creation, but a temporary transfer only of an old peerage, it should seem that this title, when once merged in the greater by the father's death, should go according to the old limitation; but of late we find them considered as new creations. On the death of the earl of Derby, Sir Edward Stanley, his sixth cousin, succeeded, and sat in parliament as baron Strange by Henry the Seventh's creation; but an eldest son of a former earl of Derby, having been called by writ while his father was living, the duke of Athol, as his heir by the female line, sat by the name title of baron Strange of King Charles the First's creation.

The defect of these two kinds of baronies is directed by the rules of the defect of other inheritances at common law; and, consequently, females are capable of succession, but with two exceptions: first, that half-blood is no impediment, and, consequently, the half-brother excludes the heir; secondly, that the honour is not divisible; and, therefore, if there be two or more fathers heirs, the title is in abeyance, that is, is suspended until the king makes choice of one of them and her heirs; though by constant usage the law seems to be verging fall to a constant defect to the eldest.

The third method of creating peers is by letters patent, which is the most usual, and esteemed the most advantageous way; because a peerage is thereby created, though the new nobleman has never taken his seat, which is not the case of a barony by writ. As to the manner of these creations, there has a notable difference intervened since the accession of Henry the Seventh, from what was the practice before Richard the Second. In his eleventh year began this method of creating by patent, in favour of John de Beauchamp, who, though summoned, never sat there, but was attainted by the next parliament, and afterwards executed. But the attainer out of the case, his patent in law could never have been deemed valid, because Michael de la Pole was the lord chancellor who affixed the seal to it, which had been before taken from him by act of parliament, and he declared incapable of ever having it again. This then was a single and ineffectual attempt of that weak prince to create a new peer without the assent of parliament, which was the usual way, above thirty having been made so in that very reign.

His successors were too wise to follow his example; for every barony newly created, till the union of the rotes, which were about fourteen, was every one of them, as appears on the face of the patents, by authority of parliament; if we except two or three: and even these, on a close examination, will appear not to be new baronies, but regrants of old feudal baronies by tenure, which undoubtedly were all in the sole disposition of the king.

But Henry the Seventh having trodden down all opposition, was fortunate enough to carry the point Richard had vainly attempted; and acquired for his successors that prerogative which they have since enjoyed, of creating peers at pleasure. The defect of these titles created by patent is directed by the words of the creation: if heirs are not mentioned, it is only an estate for life; if to a man and heirs of his body, females are not excluded: but the general way is, to the heirs male of the body lawfully begotten of the grantee, perhaps with remainders over, and they descend as other estates entailed. The case of the duchy of Somerset was singular: Edward Seymour having three sons by two venters, was created duke of Somerset, and his heirs male of his second marriage, remainder to his heirs male by his first. This title continued nearly two hundred years in the younger branch, until upon its failure in Charles the sixth duke of Somerset, Sir Edward Seymour, the heir by the prior marriage, succeeded by virtue of the remainder.

Barons by Ancient Tenure were those who held by certain territories of the king, who still reserved the tenure in chief
to himself. We also read of barons by temporal tenure; who are such as hold honours, castles, manors, as heads of their barony, that is, by grand seigniory; by which tenure they were anciently summoned to parliament. But at present a barony is no lord of parliament, till he be called thither by writ.

The barons by tenure, after the Conquest, were divided into majores and minores, and were summoned accordingly to parliament; the majoris, or greater barons, by immediate writ from the king; the minoris, or lesser barons, by general writ from the high sheriff, at the king's command.

The ancient distinguished the greater barons from the lesser, by attributing high and even sovereign jurisdiction to the former, and only inferior jurisdiction over smaller matters to the latter. By the late jurisdiction act (20 Geo. II.) the civil jurisdiction of a baron in Scotland is reduced to the power of recovering from his vassals and tenants the rents of his lands, and of compelling them in mills services; and also of judging in causes where the debt and damages do not exceed 40s. sterling. His criminal jurisdiction is, by the same statute, limited to nuisances, batteries, and other smaller offences, which may be punished by a fine not exceeding 20s. sterling, or by setting the offender in the stocks in the day-time not above three hours; the fine to be levied by poinding, or by one month's imprisonment. The jurisdiction formerly competent to proprietors of mines and coal or saltworks over their workmen, is reserved; and also that which was competent to proprietors who had the right of fairs or markets, for correcting the disorders that might happen during their continuance; provided that they execute no jurisdiction inferring the loss of life or demobration.

Barons of the Exchequer are four judges, one of whom is called the chief baron, and the other three puisne barons, to whom the administration of justice is committed in causes between the king and his subjects touching matters belonging to the exchequer, and the king's revenue. They are called barons, because barons of the realm were used to be employed in that office.

The chief baron is created by letters patent to hold this dignity quamdeo fereum gestoris, wherein he hath a fixed estate; for the law intends this an estate for life. He alone without the other barons sits at Guildhall the afternoon in term time upon nisi prius in London, takes audits, accounts, recognizances, preceptures of offices, and many other things of importance. In the absence of the lord chief baron, the other three barons supply his place according to their seniority.

Their office is also to look to the accounts of the king, to which end they have auditors under them; as well as to decide causes relating to the revenue, brought by any means into the exchequer; so that of late they have been constantly engaged in the law; whereas formerly they were majoris et dispositores in rege, free de chiro effinis, free de curia. See Court of Exchequer.

Barons of the Cinque Ports, are members of the house of commons, elected by the five ports, two for each port. See Cinque Ports.

Those who have been mayors of Corfe Castle in Dorsetshire, are also denominated barons; as were formerly likewise the chief citizens of London.

Baron, in Law, is also used for the husband in relation to the wife; which two, in law, are called baron and femme, and are considered as one person, so that in title of any fort they are not allowed to be evinced for or against each other. See Husband and Wife.

Baron and Femme, in Heraldry, are terms used to express the arms of husband and wife; as thus, he beareth baron and femme. The modern expression is, he beareth impaled.

Baron, Court. See Court.

Baron, prender de. See Prender.

Baron, Robert, in Biography, a dramatic author, who lived during the reign of Charles I. and the protectorate of Oliver Cromwell. From Cambridge, where he received part of his education, he removed to Gray's Inn, of the honourable society of which he became a member. At the university he wrote a novel called the "Cyprian Academy," containing two dramatic pieces, entitled "Deorum Dona," a tragedy, and "Gripus and Hegio," a pastoral. His tragedy of "Mirza," which is a more regular play, was probably written at a ripen age.

Baron, Michael, a celebrated French actor, was the son of a shop-keeper of Lodon, who himself went upon the stage, and born at Paris in 1672. He first joined the company of Rainis, and afterwards that of Mohers, in which connection he was universally admired and applauded. Baron was equally successful both in tragedy and comedy; although it is said he acquired his principal reputation in the former department. Racine, on occasion of introducing his Andromache on the stage, gave instructions to the other actors with respect to the performance of their several parts; but addressing Baron who was to act Pyrrhus, he said to him, "To you, sir, I have no instructions to give; your own heart will tell you more than my lessons can inform you." Preachers are said to have attended a greater box to study his action; and thence (says Voltaire) went to declaim against the theatre. Such was his vanity, that in allusion to the title that was bestowed upon him of the "Rofeum" of his age, he said, that every century produced a Caesar, but that it required 2000 years to produce a Baron. He was highly cared for by persons of distinction, although he sometimes was mortified by their reflections. At length, disgraced by this circumstance, or influenced by some other motive, he withdrew from the stage in 1691, and enjoyed a pension from the king. After an interval of 29 years he resumed his profession, and at the age of 68 was as much applauded as ever. In September 1729, his infirmities reduced him to the necessity of retiring, and he survived only two months. Baron was a writer as well as an actor, and composed several comic pieces for the stage; which are said to be lively and amusing, and to exhibit much knowledge of the stage and of the world. He also wrote some poems. A collection of his works was printed at Paris, in two vols. 1700, in 1756; and in three vols. in 1756. But some of the pieces contained in this collection are supposed not to be his. Voltaire's Age of Lewis XIV. Nouv. Dict. HItor.

Baron, Bonaventure, whose true name was Fitzgerald, was a native of Clonmel, in the county of Tipperary, in Ireland, and educated under the care of his uncle Luke Wadding, a Franciscan friar at Rome, who induced him to assume the habit of this order. He resided at Rome, where he was for a considerable time preacher of divinity in the college of St. Isidore, founded by his uncle in 1625, about 60 years, and died there, after having lost his sight, and at an advanced age, in the year 1696. He was distinguished by the purity of his Latin style, and wrote many books both in prose and verse in that language. His chief work was his "Theologus," in 6 vols. printed at Paris in 1676. Bigl. Brit.

Baronet of England, an hereditary dignity by patent, next to that of a baron insituted by king James the First on the 22d of May 1611. The first baronet that was created was Sir Nicholas Bacon of Redgrave in Suffolk, whole
whole successor is therefore styled Prima Baronorum Ang.

At the first initiation of this order the king engaged that the number should not exceed two hundred, and that each should pay into the exchequer as much as would pay thirty foot folders at eight-pence per dim to serve in the province of Ulster in Ireland; and for their distinction, as an honourable augmentation, they bear in their coat of arms either in a canton, or in an escutcheon of pretence, the arms of the ancient kings of Ulster, being argent a hand, gules, gules. Barto

net and their eldest sons have this peculiar privilege; and

they may be knighted if they please, upon knowledge thereof given, to the lord chamberlain of the household, or vice-chamberlain for the time being, or in their absence, to any other officer attending his majesty's person; and in all commissions, writs, and other deeds, the style of baronet is to be placed at the end of their surnames, as a necessary and legal addition of dignity, as the addition of sir to be placed before their Christian names, and to their wives the title of lady or

dame. Barons have precedence before all knights, except those of the garter, and knights banneters. No patent for creating a baronet can now pass the great seal until the following certificate is obtained:

"To all and singular to whom these presents shall come, we, the king's heralds and purveyors of the College of Arms, London, do hereby certify that the family, arms, and pedigree of have been duly registered in this college pursuant to the tenor of his majesty's warrant under his royal signet and

f

manual, bearing date the day of 1783, for correcting and preventing abuses in the order of baronets. In witness, &c."

Baronets of Ireland, an hereditary dignity instituted 30 Sept. 1619, the same as those in England, and bearing likewise the arms of Ulster as an augmentation.

Baronet of Nova Scotia. This order is also hereditary, and was instituted in Scotland by king Charles I. 28th May 1625, for advancing the plantation of Nova Scotia in America, and for settling a colony there, to which the aid of these baronets was designed. As an augmentation to their arms, they bear either in a canton or in an escutcheon the crest of Nova Scotia, being argent a crest of St. Andrew's cross charged with an escutcheon of the royal arms of Scotland: supported on the dexter by the royal unicorn, and on the sinister, by a savage, or wild man, proper; and for the crest, a branch of laurel, and a shield issuing from two hands joined, the one being armed and the other naked, with this motto, Salus

bus et altera sanitatis: and for their greater honour and dignity they were, by royal signet manual, bearing date 17th Nov., 1629, allowed to wear and carry about their necks in all time coming an orange-tawny silk ribbon, whereto shall hang pendant in an escutcheon argent a fencer over thereon an escutcheon of the arms of Scotland over an imperial crown above the escutcheon, and inscribed with this motto, Fons mentis bonae gloriae."

Baronets of Caput. See CAPUT.

Baronius, Caesar, in History, a learned cardinal, was born at Sora, in the kingdom of Naples, in 1528, and educated first at Veroli, and then at Naples. Having finished his studies at Rome, he entered in 1560 into the congregation of the oratory founded by St. Philip de Neri, and having received the order of priesthood, he was elected superior-general of the congregation, upon the death of its founder in 1583. Pope Clement VIII. chose him for his confessor, made him apostolical prothonotary, and in 1596 raised him to the dignity of cardinal. He was afterwards

made librarian of the Vatican. On the death of Clement, he had many votes in the conclave for the pontificate; but the Spanish party prevented his election, because he had affented in his annals, that the crown of Spain founded its title to Sicily on false evidence. His assiduous application at length to demolish his frame, that he died in 1607 at the age of 68 years. His character was distinguished for piety and probity, and mildness of disposition, as well as for extensive erudition. His chief work was his "Excelestial Annals," which he began at the age of 30, and prosecuted through the greatest part of his life. Of these he lived to publish 12 vols. in folio, the first of which was printed in 1588, and the last in 1697; and he brought down the history of the church to 1698. This voluminous and elaborate work was undertaken with a view of counteracting the influence of the protestant compilation by the centurions of Magdeburg, which was intended to expose the abuses and inconformities of the Romish church; and the author, adhering rigidly to his main object, and approving himself a bigoted partisan of the see of Rome, has on many occasions sacrificed truth to the prejudices and interests of a party. He has been charged even with intentional misrepresentations; and he has been betrayed by his imperfect acquaintance with the Greek language into many errors, and by his credulity into the recital of many fables, which have been rejected by many judicious writers of his own party. The work, however, is a monument of affability and labour. It is methodically conducted, and upon the whole is a useful, though sometimes a fallacious, guide in the chronological history of the events that happened under the Roman emperors. The style, though not pure and elegant, is generally periphrastic. Amongst the critics and cenfurers of this work, we may reckon both protestants and catholics. The learned Isaac Casaubon undertook a refutation of the Annals of Baronius, in a work intitled "Excer
citationes, &c.;" and though he closed it with the 34th year of the Christian era, he pointed out a great number of palpable errors into which the Roman annalists had fallen during that short interval. Even the Roman catholic literati acknowledge the inaccuracies and faults of Baronius; and hence Pagi, Norris, and Tillemont, &c. have been employed to correct them. Accordingly, a new edition of the "Annals" was published at Lucca, in 1735, with the corrections of the reviewers at the foot of every page. The original work was first printed at Rome, and soon after at Antwerp by Plantin; and editions have also been published at Cologne and Venice. Abridgments of it have also been published by several persons. About two years before the appearance of the "Annals," Baronius published a kind of prelude, intitled, "Martyrology Romanum, rellitutum," &c. or "Notes on the Roman Martyrology," folio, 1586; and afterwards often printed with corrections. Mosheim's Eccl. Hist. vol. iv. p. 226. Cave's Hist. Lit. tom. i. Prolegomena, p. 6, &c. Baroni

Baroni, Theodore, of Cremona, in Italy, published in 1609, in 4to, De operationibus iii trilliis libri et curandis, libri duo, in quibus morbi umnes resum, et veere, ex Galeni praestitum. Mart, praeceptatorum. He was a fierce, and a favourite of the defences of Galen, whom, with whom, is said to have declared, it is more creditable to err, than to reason right on any other system: but he has in some points left his guides. He recommends the use of anthocyanides internally in affections of the kidneys and bladder, a practice it is probable Greenvelde learned from him: he also injected medicated liquors into the bladder, with the view of facilitating the ejects of calculus, or of dissolving them. Hall. Bib. Mod.
Baronius, Ivoventius, a celebrated Italian physician, published in 1635, 4 gr. "De Peripatetica. anno 1635, et alia temporibus. Flaminius, alique regiones, papaliter inflantae, ac a nemini haecmis obserbati, libri duo, Foro-
lish," a work of considerable merit, giving a particular ac-
count of the dis ease, and of the method found most inef-
culor in combating it, wi th the appearances observed on dis-
fec ting the bodies of those who died of the complaint. The
epidemic was attended with fever, pain in the chest, cough,
difficulty of breathing, and an inextinguishable thirst. Those
who expectorated freely, early in the complaint, particularly
if they had been plentifully blooded, usually, he says, re-
covered. The lungs of those who died were universally in-
flamed; sometimes, but not always, the pleura was also
affected; and in some of the subjects, serum was found ex-
fused in the cavity of the thorax. The diseas e was not, he

BARONTHAL, in Geography. See LASSA.

BARONY, Baronia, or Baronagium, the lordship or feof of a baron, either temporal or spiritual; in which fente barony amounts to the fame with what is otherwise
called a honor.

A barony may be considered as a lordship held by some
fence in chief of the king, coinciding with what is otherwise
called grand seigneurie.

Baronies, in their real creation, moved from the king him-
s elf, the chief lord of the whole realm, and could be holden
immediately of no other lord. For e xample, the king en-
feoffed a man of a great seigneurie in land, to hold to the
peron enfeoffed and his heirs, of the king and his heirs,
by baronial service, to wit, by the service of twenty, forty,
sixty knights, or of such other number of knights, either
more or fewer, as the king by his enfeoffment limited or
appointed. In the ages next after the Conquest, when a
great lord was enfeoffed by the king of a large seigneurie,
such seigneurie was called a barony, but more commonly an
honour as the honour of Gloucester, the honour of Wal-
lingford, the honour of Lancaster, the honour of Rich-
mond, and the like. There were in England certain hon-
ours, which were often called by Norman or other for-
ign names; that is to say, sometimes by the English, and
sometimes by the foreign name. This happened when the
same person was lord of an honour in Normandy or some
other foreign country, and also of an honour in England.
For example, William de Forz, de Force, or de Fortibus,
was lord of the honour of Albemarle in Normandy, he was
also lord of two honours in England, to wit, the honour
of Holdernesse, and the honour of Skipton in Craven.
These honours in England were sometines called by the
Norman name, the honour of Albemarle, or the honour of
the earl of Albemarle. In like manner, the earl of Brit-
taine was lord of the honour of Brittainie in France, and
also of the honour of Richmond in England: the honour
of Richmond was sometines called by the foreign name,
the honour of Brittainie, or the honour of the earl of Brit-
taine. This serveth to explain the terms, honour of Albe-
marle in England, honor Albemarle, or comite Albemarle in
Anglia; honor Brittainie, or comitatus Britanniae in Anglia, the
honour of Brittainie, or the earl of Brittainie in England.
Not that Albemarle or Brittainie were in England, but that
the same person reposable was lord of each of the said ho-
nours abroad, and on such of the said honours in England. The
baronies belonging to bishop is are by some called regalia, as
being held solely on the king's liberality. These do not
confit in one barony alone, but in many; for, tout crant ba-
rone, quia majora predicta. See Bishop.

A barony, according to Braham, is a right indivisible:

wherefore, if an inheritance he to be divided among the copar-
ceners, though some capital messuages may be divided; yet
if the capital messuage be the head of a county or barony,
it may not be parcelled; and the reason is, left by this divi-
sion many of the rights of counties and baronies by de-
grees come to nothing, to the prejudice of the realm, which
is fised to be composed of counties and baronies.

BARONY is in Ireland the name of the divisions of the
counts, answering to the English hundreds. According to
these, county taxes are ascribed; and they are often noticed
in the proceedings of parliament. The number of baronies
in Ireland is 252.

BARONYCHIA, in Botany. See ASPLENIUM RUTA
MARGARIN.

BAROPHTHAS, in Ancient Geography, a town of Per-
thus proper, according to Zoilus.

BAROPTIS, or BAROPTINUS LAPIS, in Natural His-
tory, a name given by the ancient naturalists to a species of
flake, supposed to have wonderful virtues against common
bites, externally applied. Piniy has left us but a very short
description of it: he says, it was black in colour, but varie-
gated with large spots of red and white.

BAROS, in Ancient Geography, a place of Asia, in Me-
opotamia.

BAROSCOPE, derived from Ang. own, and terv, video, a machine contrived to shew the alternation in the
weight of the atmosphere. See BAROMETER.

BAROSILENITE, or Barosilicate of Potash, in Mineralogy. See PONDEROUS SAP.

BAROVSK, in Geography, a district of the government
of Kaluga in Russia, situate on the river Protva, which falls
into the Ocea.

BAROWECZ, a town of Poland, in the patinate of
Lublin, 76 miles north of Lublin.

BAROZZI, James, in Biography. See VIGNOLA.

BARPANA, in Ancient Geography, Carthage, an island
of Italy, in the Tuscan sea. according to Piniy.

BARQUES POINT, in Geography, a cape on the north-
east of Sagana bay in lake Huron.

BARQUETTE, or Barchetta, in the Mediterranean,
denotes a leffer fort of bars, used for the service of galleys
much as boats and botllons are for other ships, as to fetch
provisions, water, carry perons ahore, and the like.

BARR. See Bar.

Bar, Barr, or Barro, in Commerce, denotes a Portug-
uese long measure, used in the menufuration of cloths,
flulls, and the like; fix whereof are equivalent to ten
castus or cabidos; each castus equal to ¼ of a Paris ell.

The Spanish Barra is the fame with the yard of Seville.

Bar of Valenfia is equal to ½ of the Paris ell; the bar
of Cadife is equal to ½ of the Paris ell; and the bar of
Arragon is equal to ½ of the Paris ell. See BAR. Com.
p. 273. See MEASURE.

Barr is also ufed by the Portuguese in the East Indies
for a weight, more frequently called Bazar.

Bark or Bear, in Geography, a town of France, in
the department of the Lower Rhine, and chief place of a canton,
in the district of Benfelden, 7 miles W.N.W. of Benfelden.

Barr-Dier, a species of fally dice, or formed as that they
will not easily lie on certain sides, or turn up certain points.
Barr-Dier stand opposed to flat dice, which come up on
certain points oftener than they should do.

BARRA, in Geography, an island of Africa, near the river Gambia,

BARROA or Barrejy, one of the western islands annexed to Inver-
Invernessshire, in Scotland, has remained for many ages in the possession of the Macnich of Barray or Barra. It is well skirted with black cattle, and fruitful in barley and oats. The manufacture of kelp is carried on with considerable profit in this island. Cod and ling are caught on the east coast in great quantities; and the fishermen also take some dry-fish, the oil of which they burn in their lamps, and they sell that which is not consumed by themselves at 1d. or 2d. the Scots pint. Shell-fish, and particularly cockles, are abundant: and the cockles are found in the great sand at the north end of the island, and afford a very plentiful supply of subsistence to the inhabitants. The fisheries, however, has been much neglected. This island is somewhat hilly; in extent it is nearly 8 miles long and 4 broad: it is populous, notwithstanding the late emigrations to America, and it is said to contain about 1604 inhabitants. The natives are in general Roman Catholics. It is situated nearly south from South Wilt, and almost communicates with Benbecula at low water, and on this account they are both comprehended sometimes under the name of Long island. Its coast on the west side is low and flat, but on the east side steep and irregular. N. lat. 57° 2'. W. long. 7° 30'.

Barray, a lake of Ireland, in the county of Donegal, through which the river Guibbarr flows: 20 miles north of Donegal.

Barraba. See Barray.

Barraba, a town of Africa, in the country of Magadoxa.

Barrac, a lake of Ireland, in the county of Monaghan, on the western side of which is situated the town of Castle Blaney.

Barracks. See Barracks.

Barracol, or, in hydrology, a name given by Artej with, from the Venetians, to express the species of ray-fish, called by Bellonius and Graven mera, and by others euxella lice. The specific name of Artesian carries in it a much better character of the fish; he calls it the ray, with a smooth back and belly, and with the eyes surrounded with a series of spines, and three other rows of them on the tail. Barray, a town of Africa, in the country of Nigritia, seated on the river Gambia.

Barraco or, as the sailors call it, Barea, or Bera, lies on the west coast of Africa, 6 or 7 leagues W.S.W. from Aera, and is known at sea by two very high mountains behind it, one of which is double at the top with a saddle, and they are covered with trees. Some rocks lie off in the sea just before it, and form a kind of haven.

Barracope, lies on the west coast of Africa, seven leagues E.S.E. from St. Mary's, and at the same distance from the river Jum in the same direction on the other hand. This coast abounds with negro towns, and also with trees and water.

Barrad, a town of Arabia, 40 miles south-east of Saade.

Barray. See Barray.

Barragan, or Barray, in commerce, a kind of fluff belonging to the clasts of camblet, only a grain of much coarser than the rest, manufactured in divers parts of France and Flanders, chiefly at Abbeville, Amiens, Rouen, and Lille, and now in England.

The word is barbarous Latin, formed, as some suppose, from the q. d. barratun formam reserens. Du Cange. The chief use of barragan, called also by the French barray, is for fortoutes, or upper garments against the rain, being, when good, of so close a grain, that the water will not leak through, but only run upon them.
made responsible for the barratry of the master and mariners. With us the law permits the owner of the ship to be injured against the misconduct of the captain and crew, though they are his own agents, and the persons of his own choice. If the captain be the injured, no agreement on the part of the insurers can make them liable for barratry committed by himself; but they may be liable, in such case, for the barratry of the sailors, in which he has no part. With us no fault of the master or mariners amounts to barratry, unless it proceed from an intention to defraud the owners of the ship. Therefore if the master from ignorance, unskilfulness, or from any motive which is not fraudulent, depart from the proper course of the voyage; this will be a deviation which will avoid the policy, but it will not amount to barratry.

In France, if by the policy the injured be protected against the barratry of the master, the underwriters are answerable for the misconduct of the mariners also; because the term barratry (patron) comprehends all the persons on board who are in the ship's pay. Our policies are more explicit, and distinctly specify barratry of the master and mariners. Hence it has been concluded, that with us, as in France, the masters may commit barratry, without the concurrence of the master, or against his will. Nevertheless it has been held by lord C. J. Lee, at Nisi Prius, that a deviation to which the master was compelled by a very daring act of violence and disobedience on the part of the seamen, did not amount to barratry, because the ship was not actually run away with in order to defraud the owners. The insurers, therefore, were held to be answerable, and the plaintiff had a verdict. This learned judge seems to have thought, that nothing short of running away with the ship, with intent to defraud the owners amounted to barratry: and yet in another case, the conduct of the master was held to be barratry, though certainly much more venial than that of the sailors in the former case. Hence it has been inferred, that though the captain conceive that what he does is for the benefit of the owners, yet if it be contrary to his duty to them, it is barratry. An owner himself cannot commit barratry; neither can it be committed against the owner, with his consent. If the master of the ship be also the owner, he cannot commit barratry, because he cannot commit a fraud against himself. Although it be a maxim in law, that fraud shall never be presumed, but must be distinctly proved; and it is a rule in questions of insurance, that he who charges barratry must substantiate it by conclusive evidence; yet a case has occurred, in which it was determined, that proof of the master's having carried the ship out of the regular course of the voyage for fraudulent purposes of his own is prima facie sufficient to entitle the plaintiff to recover, without shewing negatively that he was not the owner, or that any other person was the owner, or that this was not done with the owner's consent. Though the words "in any lawful trade," be inserted in the policy, all the insurer is liable, if the captain commit barratry by frauding on his own account. It appears, that if a loss do not happen within the time prescribed by the policy for the duration of the risk, the insurer will not be liable for it, though it be the undoubted consequence of the act of barratry.

The offence of barratry, in itself so mischievous, and so injurious to commerce, is punishable as a public offence, according to the guilt of the offender, by every commercial state in Europe. In France, any fraud practised by the master or mariners, with or without the privity of the owners, and frauds committed by the owners themselves, are accounted barratry, and very severely punished. The captain of a ship was sentenced to the galleys for life, for forging false bills of lading in order to change the voyage and carry away the goods; and the owner, who was convicted of being an accomplice in this crime, and of robbery in caufling the ship to be carried to a wrong port, and converting the goods on board to his own use, was sentenced to the galleys for five years. With us the flat. 1 Ann. R. 2. c. 9. § 4 & 5, makes it felony to destroy any ship to the prejudice of the owners of the ship or goods on board; and takes away the benefit of clergy from such offences, committed on the high seas. By flat. 4 Geo. I. c. 12. § 3, if any owner, captain, master, mariner, or other officer of any ship, shall wilfully cast away, burn, or otherwise destroy the ship of which he is owner, or to which he belongs, or in any manner direct or procure the same to be done, to the prejudice of the persons or perons that shall underwrite any policy of insurance thereon, or of any merchant that shall load goods thereon, he shall suffer death: and the flat. 11 Geo. I. c. 29, takes away clergy from such offenders in all cases. Marshall's Treatise on the law of Insurance, vol. ii. chap. 13. See PIRATE.

BARRATRY is also used in the law of England for the offence of flinging up frequent suits and quarrels among his majesty's subjects. The term, however, is of foreign origin; and in Italy and other countries seems ordinarily to have been applied to the traffic of ecclesiastical benefices; but was afterwards used in a more general sense, as applicable to all corrupt buying and selling of justice. In Scotland it signified the corrupt purchasing of benefices or offices of collection, from the see of Rome, by persons who left the realm for that purpose; a practice, which had become frequent, and was in various respects injurious to the realm; as a means of carrying money out of it, without any return of value, as prejudicial to the right of patronage in the king or others, and to the free elections of the monks in the monasteries, both which the pape by prevention pretended to exclude, and as contributing to raise the rate of taxation upon benefices, by the false accounts which those tutors for the office of collector carried to the pope.

BARRE. See Barre.

Barre, Lewis Francis Joseph De La, in Biography, was born at Turnour in 1688, and educated at Paris; where he applied to the study of the ancient languages and to the collection of MSS with such assiduity, that he was recommended to Anfelm Banduri, the learned Benedictine, as a proper assistant in his antiquarian researches. In consequence of their joint labours, they published the "Imperium Orientale," and the collection of the medals of the Roman emperors from Decius. For these services Barre had a pension from the grand duke of Tuscany. He also gave a new edition of the "Spicilegium" of Luke d'Achery, in 3 vol., fol. printed at Paris in 1723. He had also a considerable share in the new edition of "Master's Dictionary" of 1725. In 1727, he was elected a member of the Academy of Inscriptions, the memoirs of which he enriched by several valuable papers, historical, chronological, geographical, and miscellaneous. He also published, in 1729, in one vol. 4to, "Memoirs for the History of France and Burgundy," known under the title of the "Journal of Charles VI." Besides other publications of a less important nature, he finished more than 100 select articles of a new and ample dictionary of Greek and Roman antiquities; but he was prevented by death, in 1738, from completing his undertaking. Moreri.

Barre, Joseph, a learned historian, was born in 1602; and entering into the church, he became first a regular canon of St. Genevieve, and afterwards chancellor of the university of Paris. He was distinguished for piety and erudition, and for his industry as a writer. His principal works

BARRE, in Geography, a town of France, in the department of the Loozer, and chief place of a canton in the district of Florence, 2 leagues S. of Florac, and 6½ W.W. of Alais.

BARRE, La, a town of France, in the department of the Eure, and chief place of a canton in the district of Bernay, 3 leagues S.S.E. of Bernay, and 61 W.S.W. of Evreux.

BARRE, a township of America, in Worceletter county, and state of Massachusetts, containing 1613 inhabitants; 24 miles N.W. of Worcester, and 66 W. of Boston; deriving its name from that of the late Col. Barre, a British senator, and an advocate for the cause of America, in the war which terminated in the separation of the two countries. The township has good pastures, fattens a multitude of cattle, and produces more butter and cheese for the market than any other of the same extent in the state.

BARRE is also a township of Huntington county in Pennsylvania.

BARREA, a circuit or district of Hindostan, in the country of Guzerat.

BARREY BAY. See BAYA.

BARREGES LES BAINS. See BAREGES.

BARREL, an oblong vessel, of a spheroidal, or rather a cylindrical figure, used for the holding divers sorts of goods both liquid and dry.

Barrels are of divers uses in Artillery, as for powder, small shot, flints, fulprub, salt-petre, rosin, pitch, quick-match, and many other things.

Barrels filled with earth serve to make a parapet to cover the men, like gabions and canvas bags.

Fire-barrels are casks of divers capacities, filled with bombs, grenades, fire-pots mixed with great quantities of tow soaked in petrol, turpentine, pitch, &c. used by the besieged to defend breaches. These are sometimes also called thundering barrels, being to be rolled down on the enemy on their entering the breach.

Barrel is also used for a certain quantity, or weight of several merchandises; which is various as the commodities vary.

The English barrel, wine measure, contains the eighth part of a tun, the fourth part of a pipe, and the moiety of a hoghead, that is, thirty-one gallons and a half; of beer it contains thirty-six gallons, and of ale thirty-two gallons.

The barrel of beer, vinegar, or liquor preparing for vinegar, is to contain 34 gallons, according to the standard of the ale quart. 10 and 11 W. III. cap. 21.

The barrel of herrings is to contain 32 gallons, wine measure; being about 28 gallons, old standard: usually amounting to about 1000 full herrings, 13 Eliz. cap. 11.

The barrel of salmon is to contain 42 gallons, 5 G. cap. 18.—And the barrel of eels the same, 22 Ed. IV. cap. 2.

The barrel of soap is to contain 256 pounds, 10 A. cap. 10.

A barrel of Eflle butter weighs 160 pounds, and of Suffolk butter 256 pounds.

In some parts of Ireland, particularly in the city of Cork, coal and salt are measured by the barrel. The barrel used to contain 7 bushels Winchester, but that lately introduced for coal is, according to law, 4 bushels; i. e. 40 English, or 50 Irish gallons. Salt is still measured in the barrel of 7 buhels, but irride measure; whereas the coal was sold by heap measure, which put it into the power of the measurer to cheat either the seller or buyer at pleasure. The abuse was found so great that this kind of measurement has been abolished.

The barrel or barile of Florence is a liquid measure containing 20 sartives, sartives, or one-third of a barrel or flao.

The barrel, barique, of Paris, contains 210 pints, or 26 feptiers and a half; four bariques make three muits, or one tun.

Barrel, in Anatomy, denotes a pretty large cavity situated behind the drum of the ear, lined with a membrane in which there are several veins and arteries. It is said to be full of a purulent matter in children; and in its cavity there are four small bones; viz. the malleus, the incus, the stapes, and the is articulare.

Barrel of a Clock, in Mechanic, is a cylindrical part, about which the spring is wound. And the barrel of a watch is the cylinder which contains the spring, and about which the chain coils.

Barrel of a Gun, Piolfel, &c. is the cylindrical tube through which the ball is discharged.

Barrel of a Jack, is the cylindrical part whereon the line is wound.

Barrel of a Pump, is the wooden tube which makes the body of the engine, and wherein the piston moves.

BARRELET, in Heraldry. See BARRLET.

BARRELLIER, James, in Biography, a Dominican monk, was born at Paris, in 1665, of a noble family. Having received a liberal education, and being well skilled in Latin, Greek, and several modern languages, he applied himself to the study of medicine; but entering among the Dominicans, in 1633, he now confined himself to acquiring a knowledge of plants. With this view, he embraced an opportunity offered him, of accompanying the head or general of the Jacobins, as an assistant, with whom he travelled over a great part of France and Spain, collecting every where whatever rare plants could be found, of which he procured drawings to be made. At the end of 23 years, a great part of which was spent in Italy, he returned to Paris. He now applied himself in arranging the plants he had collected, preparing to publish accounts and delineations of them, in the manner adopted by Tournefort, and had proceeded so far as to get engravings of 1324 of the plants finished, when he died of althemia in 1672. His manuscripts, drawings, and plates, were deposited, after his death, in the library of the Jacobins at Paris, where they remained until the year 1714, when Antoine Juffieu undertook to publish them, under the title of "Plantae per Galliam, Hispaniam, et Italiam observata, et iconibus suis exhibita, a R. P. Jacobo Barreleri, opus posthumum," Parissis, 2 vol. fol. The engravings are on a small scale, frequently borrowed from other works, Haller says, and many of them repetitions of the same plants. Many of them, however, he adds, are new, and of scarce and valuable plants, which entitles these volumes to a place in all botanical libraries. Haller. Bib. Botan. Eloy. Dict. Hist.

BARRELLING, the art of putting up certain commodities in casks or barrels.

Gun-powder for the land service is often barreled double, the barrel it is put in being inclosed in another barrel, partly to prevent the powder catching moisture in the subterraneous places it is kept in, and partly to enable the better to bear the motion and jolting of carriages, when it is to be conveyed to another place.

Barrelling of Herrings, imports the cutting off their heads as they are thrown into the bins, and afterwards pull-
ing out the guts, salting them, and putting them up in barrels. There are two sorts of barrelled herrings; one wherein they are laid orderly, layer over layer, called by some packed herrings; the other wherein they are thrown at random, called herring in wrack.

The difference arises thus: as fast as the fishermen catch the herrings, they throw them on the deck of the vessel; where having gutted and salted them, they throw them at random into the barrel, to be carried home; this is the herring in wrack.

When arrived ashore, they take the fish out of these barrels, call them into a tub, and salting them anew, range them handomely in their barrels again, laying salt over them, to prefer them; these are the packed herrings. And it is in this flate they are usually sold.

BARRELL's Sound, in Geography, lies on the N.W. coast of America, and is called by the natives Conset-bai-toi.

It is situated about 6 leagues from the southern extremity of Washington or Charlotte islands, in a N.W. direction, about N. lat. 52°. W. long. 131°. It has two inlets, one on the east, the other on the west side of the island; the latter is the belt, the other is dangerous. The shores are of a craggby black rock; and the banks are lined with trees of various kinds; as pines, spruce, hemlock, alder, &c. This found was visited by Capt. Gray in the Washington in 1789, and derived its name from Joseph Barrell Esq. of Charlestown.

Barrels, the name given to rocks near the south coast of the county of Wexford, in the Irith fea, 5 miles S.W. of Carnfore point.—Also, to rocks near the south coast of Ireland, in Courtaulchery bay.

Barreme, a town of France, in the department of the Lower Alps, and chief place of a canton in the district of Digne, 10 miles S.S.E. of Digne.

Barren, is a term of Saxon origin, and means, applied to animals or vegetables, unfruitful, sterile, incapable of producing or propagating its like. Land is called barren, on which no plants, fit for the sustenance or nourishment of man or animals, will grow. Metaphorically applied to the human mind, it means dull, stupid, uninventive.

In man and animals barrenness is usually occasioned by some defect in the organs of generation. Both sexes are liable to this deficiency; but it is thought to be more incident to the female than the male. It is remarkable, that hybrid animals, as the mule, are incapable of propagating their like. See Hybrid.

Barrenness may also be occasioned by general debility, or ill health; and yet women in nearly the last stage of consumption, are not unfrequently found to conceive, to carry the fruit to its full term, and at length produce it in a sound and healthy state; the progress of the consumption being stopped during the time of uterine-gestation. See Consumption.

Defects, occasioning barrenness, or sterility, are either external or internal. The most usual external deficiency in man is, a penis too short, slender, or feeble. This state of that organ is often attended with a degree of curvature, the end being held down by a strong bridge. In these cases, the orifice of the urethra, instead of being at the end is in the under part of the penis, within half an inch of its extremity; whence there is not only considerable difficulty in introducing it into the vagina of the female, but in the vesical organ, the semen, instead of being thrown forwards towards the os uteri, is ejected backwards, and loit.

In the female, fritaines of the vagina, or coheison of its sides, preventing the intromission of the male organ, may occasion barrenness. These defects may sometimes be remedied by appropriate operations. (See Vagina, Diseases of.) The same effect, a straitness of the vagina, may be occasioned by cleftish affections of its sides (see as above). But a more common cause is an expansion of the membrane called the hymen, swelling up the entrance of the vagina, and it only having, at the anterior part, a small hole for the passage of the urine. Midwives are therefore cautioned, on the birth of female children, to examine whether the passage into the vagina be open, and if they find it covered by a thin membrane, to separate it with their nails, and to inspect the part for a few subsequent days, that it may not coalesce again. If this caution has been neglected, the membrane, which at the birth of the child is so tender as to yield to the slightest force, becomes, in a few years, thick, firm, and feithy, and can only then be divided by a painful and troublesome operation. See Hymen, Imperforated.

The vagina is also sometimes found divided into two canals or passages, by a strong, feithy, membranous partition, running its whole length, or nearly so, rendering the introduction of the male organ difficult or impracticable. These two passages sometimes communicate at the upper end, and receive a single os uteri; at others, they continue separate, terminating, or each of them leading to an os uteri; the uterus having, in these cases, two cavities, or there being two uteri. (See the articles Vagina, and Uterus.) Thence, however, may be considered as causes rendering impregnation difficult, but not impossible. More certain and invariable causes of barrenness in women are, imperviousness, feith, or other difeases of the os uteri, fallopian tubes, or of the ovaries, which are generally incurable.

Debility, occasioning barrenness in men particularly, is most commonly caused by the too early, or too frequent, and inordinate use of venery, by maniffrupation, or self-pollution (see Onanism), by repeated attacks of gonorrhoea or lymphis; by gleet, and by frequent and long continued courses of mercury. For the cure of these complaints, see Gonorrhoea, Lues Venereal, Gleets; see also Conception, Causes impeding.

Barren Corn, in Agriculture, a term applied to a difterner in corn, in which the ears of such kinds as are affected, as wheat and rye, which are the most subject to it, are long, lean, and white; in rye, the flamin, or small threads in the middle of the flower, are dry, transparent, and horned; the female organs are small, whiter, and less velvety than in healthy ears; in others, the filaments are swelled, the apices or knobs on the tops of the flamin void of dust or farina, and the stigma badly unfolded. The ligaments of all the blossoms of an ear are sometimes dried and parched, and at other times: the apices are much swelled out. This difterner of corn has been ascribed to various causes; such as its too sudden growth, the influence of frost or of hot gleams of sunlight after heavy showers; and sometimes, though rarely, to insects. Count Ginnani imputes it to the faultinefs of the soil; and he recommends particular attention to the amendment of it by such means as are best suited to its nature; and he also directs to change the seed every year.

Barren Earth, a term given by some writers to particular sterile soils, and also to the under stratum of earth, or that which lies immediately below the bed of mould, which is most frequently turned up and cultivated for the nourishment and support of plants. The idea of the under strata of soils being improper for the growth and support of plants seems to have originated in error, as it is now well known that every kind of earth, whether placed near the surface or
or at a considerable depth below it, is capable of affording the support of plants, when well broken down and rendered sufficiently mellow by ploughing, and the influence of the atmosphere.

**Barren Lands**, are such as either naturally, or for want of proper tillage and cultivation, do not on being cultivated produce good crops or such as are sufficient for repaying the expenses of the cultivator.

**Barren Money**, in the **Civil Law**, denotes that which is not put out to interest.

**Barren Soils**, in **Agriculture**, are those which, from the nature of their constituent ingredients, are incapable of affording full crops. The materials which enter into the composition of such soils are, according to Mr. Kirwan, *silex*, *argill*, and *calcite*, in the following proportions.

- Silex from 42 to 88
- Argill 20 30
- Calcite 4 20

From which he concludes the Troy pound to contain, allowing 120 grains for water, of

- Silex from 3468 to 4963
- Argill 1128 1622
- Calcite 225 600

The specific gravity in such soils has not been fully ascertained, but the same writer supposes it to be either much above or greatly below that of other kinds, according as they are too close or too open and porous. That of barren sandy land was found by M. Fabroni to be 2.21. See **Soil**.

**Barren Springs**, in **Rural Economy**, such springs as are injurious to lands when suffered to flow or run over them. Waters that flow from coal mines, or through mineral strata, have frequently been observed to have this pernicious quality; and such also as contain either aluminoous or ferruginous materials in a state of solubility in them.

**Barren Flowers or Florets**, called also abortive, in **Botany**, are such as produce no perfect seeds. The barren flowers are such as have filaments, but no pistils; and they are also called male flowers. Flowers which have only pistils, are sometimes barren, owing to the absence of other flowers, which bear the filaments. In the umbelliferous flowers, it is not uncommon to have several of the florets barren, though they are furnished both with filaments and pistils; perhaps owing to some imperfection in the pistils; but future observations must determine this matter.

**Barren Creeks**, in **Geography**, rises in the N.W. corner of Delaware state in America, runs about 9 miles S.W. and discharges itself into Nanticoke river. A triangular tract of land in the N. part of Somerset county, Maryland, is included between this creek on the S., Delaware states E., and Nanticoke river on the W. and N.W.

**Barren Island**, a small isle in Cheapeak bay, N.E. from the mouth of Patuxent river, which is separated from Hooper's island by a narrow channel on the east.

**Barren Island** is also an isle in the East Indian ocean, about 6 leagues in circumference. The whole isle has a singular and volcanic appearance; and there is upon it a violent volcano, which emits immense volumes of smoke, and flowers of red-hot flumes, some of which weigh 3 or 4 tons, and are thrown some hundred yards beyond the foot of the cone. The base of the cone is the lowest part of the island, and very little higher than the level of the sea. It rises with an acuity of 32° 17', to the height of 1800 feet nearly, which is also the elevation of the other parts of the island. Those parts of the island that are distant from the volcano, are thinly covered with withered shrubs and blasted trees. It is situated in N. lat. 12° 15', and 15 leagues to the east of the easternmost cluster of the Andaman islands, and may be seen at the distance of 12 leagues in clear weather. At a quarter of a mile from the shore, there is no ground with 150 fathoms of line. **Asiatic Researches**, vol. iv. p. 395, &c.

**Barren Isles**, lie on the N.W. coast of America, at the entrance of Cook's inlet. These isles, situated in N. lat. 58° 48', and E. long. 208° 30', and cape Elizabeth, situated in N. lat. 59° 9', and E. long. 228° 53', according to Vancouver's chart, form a channel into Cook's inlet.

**Barren River**, a name given to each of the S.E. branches of Green river, in Kentucky; between which lies **Blue Spring**.

**Barrenness.** See **Sterility**.

**Barrenwort**, in **Botany**. See **Erythraea**.

**Barreone**, in **Geography**, a river of Piedmont, which runs into the Vesuvia, near St. Martin, in the county of Tenda.

**Barrere, Peter**, in **Biography**, professor of medicine, physician to the military hospital at Perigyan, his native country, resided three years at Cayenne, as botanist to the king of France, and employed himself in acquiring a distinct knowledge of the plants and animals indigenous to that country, of which he published accounts on his return. He died November 18th, 1755. In 1741, he published "A Description on the Coasts of the Colour of the Skin in Negroes," which he thought was occasioned by the bile being in them blacker than in Europeans; and in 1746, "Observations on the Origin and Formation of figured Stones." But his principal works were, "Essai sur l'Histoire Naturelle de la France Equinoxiale," Paris, 1741, 12mo. in which he gives descriptions of the plants he had collected at Cayenne, many of them not before known, with their use in medicine, diet, &c. "Nouvelle Relation de la France Equinoxiale," Paris, 1743, 12mo.; republished, much improved, 1753: a continuation of the former work. In this he gives accounts of the method of cultivating the foug-cane, of preparing fugar, coffee, cacao, and other valuable articles. In the "Histoire de l'Academie des Sciences," 1753, the method of cultivating rice; and in 1754, at Perigyan, 8vo. "Divers Observations Anatomiques tirées des Ouvrages des Cadavres," containing some curious and instructive facts. Haller. Bib. Anat. et Botan. Eloy. Diet. Hist.

**Barreria**, in **Botany**, a tree so named from Peter Barrere, professor of medicine at Perigyan. Lin. g. Schreb. 1566. Scop. gen. 767. Porequela. Anbl. Guian. Chas. Syngenia monoecian. Gen. Char. Col. perina one-leaved, five-toothed, small. Cor. one-petalled, five-petalled; petals oblong, acute, convex beneath, concave above, with a double pit; the superior ovate, bifid, the wedge-shaped one trifid; excorated for the reception of the filaments. Stam. filaments five, ascending linear, wider above, thick, triangular, borne on a curved; anthers erect, four-covored, magenta-collared; coalescing into the form of a mill-wheel; each, in the closed flower, ansvewing, together with the filaments, to the pits of the two petals. Pyl. germ roundish; style short; stigma trifid.

Species, B. guianensis. Porequela Guian. Aublet. Guian. 1. 47. A tree forty or fifty feet high, and two feet and a half in diameter; the bark is ash-coloured, and the wood is hard and compact, of a reddish-brown colour. From the top proceed many branches, spreading in all directions; these send forth numerous twigs, with alternate, entire, smooth, firm, ovate leaves, ending in a long point; petioles short, convex beneath, channelled above. The flowers are
in small axillary spikes, alternate, and almost sessile. A native of Guiana, in the extensive forests, near the banks of the river Sinemari, fifty leagues from its mouth. It flowers in November.

BARRET, George, in *Biography*, a painter of landscape, was born about the year 1732, in the city of Dublin, and exhibited at a very early age a strong disposition to the art in which he afterwards became eminent. Having gained a premium of 31. offered by the Dublin society for the bell landscape in oil, he visited London in 1762, and in the second year after his arrival, obtained a similar prize from the Society for the encouragement of arts, &c. The establishment of the Royal Academy of Arts, &c. is said to have been much indebted to the efforts of Mr. Barret, who formed the plan, and became one of its members. He had two decided manners of painting, both with regard to colour and touch; his first was rather heavy in both, his latter was much lighter. Scarcely any painter equalled him in his knowledge or execution of the details of nature, the latter of which was particularly light, and well calculated to mark most decisively the true characters of the various objects he represented, forest-trees in particular. His attention was chiefly directed to the true colour of English scenery, with regard to which he was very happy in his bell works. His bell pictures, in this country, executed according to his first manner, are to be found in the houses of the dukes of Buccleugh and Portland, &c. and those of his latter in his great work at Norbury Park in Surrey, confining of a large room, painted with a continued scene entirely round. The idea in general characterizes the northern part of this country; and for composition, breadth of effect, truth of colour, and boldness of manner in the execution, has not been equalled by any modern painter. Barret also excelled in water-colours; and his drawings in chalk, Indian ink, and black-lead pencil, have great merit. In all his studies from nature he was very correct and minute. He also performed some flight but spirited etchings in landscapes. He died at Paddington near London in 1784. Pillington and Sturt.

Barret Bank, Great, in *Geography*, lies at the S. and S.E. end of the island of Oleron, on the coast of France, and forms the N.W. side of the Maumoun puffages, as Point de Cardour, on the main land, forms the S.E. side.

Baretry. See Barraty, and Barrytry.

Barretstown, in *Geography*, a plantation in Hampshire county, in the district of Maine, in North America, having 173 inhabitants.

Barricafe, or Barricado, a military term for a fence or retrenchment, halily made with vessels or baskets of earth, carts, trees, palisades, or the like, to preserve an army from the flot or assault of an enemy.

The most usual materials of barricades are poles, or stakes which are crossed with battens, and fixed with iron at the feet; usually set up in passages or breaches, to keep back the horse as well as the foot.

Barricade, in the *Lexicon*, is a strong wooden rail, supported by pillars, and extending as a fence across the foremost part of the quarter-deck. In ships of war, the intervals between the pillars are commonly filled with cork, junk of old cable, or plaited cordage. About a foot above the rail, there extends a double rope netting, supported by cranes of iron; and between the two parts of the netting are studded hammocks, filled with the seamen's bedding, to intercept small shot fired by flivel-guns and muskets, in time of battle.

Barricourt, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton in the district of Grandpré, 6 leagues S. of Sedan, and 3

N.E. of Grandpré.

Barrier, in *Fortification*, a kind of fence made at a passaige, retrenchment, gate, &c. to flop up the entry thereto. See Defences. It is usually made of great stakes, about four or five feet high, placed at the distance of eight or ten feet from one another, with overthwart rafter; serving to flop either horse or foot that would rush in. In the middle is a movable bar of wood, which opens and shuts at pleasure.

Barrier Islands, in *Geography*, islands which lie off the river Thames, on the E. coast of New Zealand, and called because they shelter it from the sea. They stretch from S.E. to N.W. for 10 leagues.

Barriers, corresponding to what the French call "jeu de barres," i.e. palisiers, have been used to signify a martial exercice of men, armed, and fighting together with short swords, within certain rails or bars, by which they were include from the spectators; now diffused in this country.

Barreries, or Barrières, a name given, in the chief cities of France, and particularly at Paris, to the places where the custom-houses are establisshd, and where the officers receive the duties of importation, according to the tariff settled by the king's council. They are called barriers because the passagess, through which the carriages and merchandises liable to pay duties are to pass, are shut up with a wooden bar, which turns upon a hinge, and is opened and shut at the will of the custom-house officers.

There are at Paris sixty of these barriers, all placed at the entrance of the suburbs.

There are also barrier towns, or places of defence, on the frontiers of kingdoms.

Barrile, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Ballicata; 7 miles W.S.W. of Venaia.

Barring a Vein, in *Farriery*, now obsolete. See Bar a Vein.

Barringdin, in *Geography*, a town of Africa, in the country of Barra.

Barrington, John Shute, Lord Viscount Barrington, in *Biography*, a learned nobleman, particularly distinguished by his attention to theological subjects, was the younger son of Benjamin Shute, merchant, by a daughter of the famous Mr. Caryll, author of the commentary on Job, and descended from the ancient family of Shute in the county of Leicester, of Roman extraction. He was born at Theobald's in Hertfordshire, in 1678, and received part of his education in the university of Utrecht. Upon his return to England he devoted himself to the study of the law in the Inner Temple; and in 1701 commenced his literary career as a writer, if we except his Latin oration "De Studio Philosophico conjugando cum Studio Juris Romani," published at Utrecht in 1698; by an "Essay upon the Interests of England in respect to Protestants differing from the Established Church," 4to. to which chiefs of British subjects he belonged. This was followed some time afterwards by another piece in 4to. intitled "The Rights of Protestant Diffenters, in two parts." At the age of 24, during the prosecution of his legal studies, he was appointed by the recommendation of Lord Somers, to the arduous undertaking of engaging the Presbyterians of Scotland to favour the union of the two kingdoms, and in 1708 he was rewarded for his services by the office of commissioner of the customs. From this situation he was removed by the Tory administration of Queen Anne, in 1711, on account of his avowed opposition to their principles and conduct. In the mean time his fortune was greatly improved by the bequest of two considerable

BAR
BAR

fiderable estates; one left him by John Wildman, Esq. of Becket in Berkshire, who adopted him for his son after the Roman custom, and the other by Francis Barrington, Esq. of Tofts, whose name and arms he assumed by act of parliament. On the accession of George I., he was chosen member of parliament for the town of Berwick upon Tweed; and in 1720, he was advanced by the king to an Irish peerage under the title of viscount Barrington of Ardglas. In confluence of his unfortunate connection with the Harburgh company, as sub-governor under the prince of Wales, and of a lottery projected for defraying the expense of opening the port and a subscription for this purpose commenced during his absence and in opposition to his opinion and advice, he underwent, in 1723, the very severe and unmerited censure of expulsion from the house of commons, which has been attributed to his lordship’s opposition to the reigning minister, Sir Robert Walpole. In 1725, he published in two volumes 8vo. his “Miscellanea Sacra, or a new method of considering so much of the history of the apocryphal, as is contained in scripture, in an abstract of their history, an abstract of that abstract, and four critical essays.” This work traces, with judicious discrimination, the methods taken by the apocryphal, and first preachers of the gospel, for propagating Christianity, and explains the several gifts of the spirit by which they were enabled to discharge that office. Hence he deduced an argument for the truth of the Christian religion which is said to have staggered the incredibility of Mr. Anthony Collins. A second edition of this work, with large additions and corrections, was published by his son the present bishop of Durham, in 1770, 3 vols. 8vo. In the interval between its first publication and the death of the author in 1734, he reviewed, corrected, and enlarged it; and introduced such improvements, as add new force to his arguments and elucidation to his criticisms. In the same year, 1725, he also published “An Essay on the several Definitions of God to Mankind, in the order, which they lie in the bible; or a short system of the religion of Nature and Scripture.” He was also the author of several other tracts, chiefly on subjects connected with toleration in matters of religion, which he ably and zealously defended. He died in 1734, in the 56th year of his age. Lord Barrington had three daughters and six sons, five of whom have been advanced to high stations in the church, the law, the army, and the navy. His lordship was a disciple and friend of Mr. Locke, and adopted his sentiments as to the right and advantage of free inquiry, and the value of civil and religious liberty. As a theological writer, he discovers a high sense of the value of the sacred writings and great judgment in interpreting them; and he contributed in a very eminent degree to the diffusion of a spirit of liberal criticism. In his sentiments and disposition he was distinguished by his Catholicism and moderation; and though he was a rational and steady disserter, he was an occasional frequenter and communicant of the established church. *Biog. Brit.*

BARRINGTON, Daines, the fourth son of lord Barrington, was educated for the profession of the law, and in 1757 was appointed a Welsh judge, and some time afterwards second justice of Cheshire. Although he never attained to distinguished eminence at the bar, he evinced his acquaintance with the law by a valuable publication, entitled, “Observations on the Statutes, chiefly the more ancient, from Magna Charta to 21 James I. c. 27; and with an Appendix being a Proposal for new-modelling the Statutes,” 4to. 1766. This work, which passed through five editions, has been respectfully quoted by many historians and conlitutional antiquaries. In 1773, he published “Orpheus;” with Alfred’s Saxon version, and an English translation and notes of his own, which underwent a severe animadversion from some of our critics. His “Tracts on the Probability of reaching the North Pole,” 1775, 4to. were occasioned by the voyage of captain Phipps (now lord Mulgrave) towards the north pole in 1773. His other writings may be found in the Transactions of the Royal and Antiquarian Societies, of which he was an affiduous member, and of the latter vice-president. In several of these the author manifests some tendency towards singularity and paradox; nevertheless they indicate both diligence and extent of research, and eulogize his talents as a naturalist and antiquarian. Many of his tracts were collected by himself in a 4to. volume, entitled “Miscellanea Tracts on various subjects,” 1781. His experiments and observations on the finging of birds” (see Note of Birds in this Dictionary), and his “Essay on the Language of Birds” are amongst the most curious and ingenious of his papers. In private life he was a man of worth and integrity, unambitious, and devoted to study and literary conversation. He resigned his office of judge of Cheshire in 1785, and from that time to his death, March 14, 1800, lived in retirement in the Inner Temple. *Gen. Biog.*

BARRINGTON, in Geography, a township in Queen’s county Nova Scotia, on the south side of the bay of Fundi, settled by Quakers from the island of Nantucket.

BARRINGTON, a township in Strafford county, New Hampshire, about 22 miles N. W. from Portsmouth, incorporated in 1722, containing 2470 inhabitants. Allum is found in this township, and the first ridge of the “Prothills,” one of the 3 interior summits of Aganaticus, is continued through it. Its situation is very healthy, and favourable to longevity.

BARRINGTON, a township in Bristol county, Rhode island, on the south western side of the N. W. branch of Warren river, about 23 miles N. W. of Warren, and about 7 S. E. from Fox point, in the town of Providence. It contains 633 inhabitants, including 12 slaves.

BARRINGTON, Great, is the second township in rank in Berkshire county in the Massachusettis. It contains 1573 inhabitants, and lies 140 miles W. from Boston.

BARRINGTON, Clays, is the fourth-clay point of lord Egmont’s island, or New Gurney, the largest of the Queen Charlotte’s islands. It is separated by a narrow channel from Cape Proby, on lord Howe’s Island or New Jersey.

Gen. Char. Cal. Perianthi two-leaved, superior; leaflets roundish, concave, coriaceous, permanent. Cor. Petals four, equal, ovate, spreading, coriaceous, larger than the calyx; nectary concave, tubular, coating the base of the style, toothed at the tip; teeth few, unequal. Stam. Filaments very many, monadelphous, (or conjoined from the very base into a cylinder seated on the receptacle), capillary, longer than the corolla; anthers small, roundish. Pet. Germ inferior, turbinate; style filiform, length of the stamens; stigma simple. Pet. Drupe large, ovate, coriaceous, crowned by the calyx. Seed, nut long, ovate, outwardly wrinkled-fibrous, four-celled; kernels ovate, wrinkled.

Li. Gen. Char. Cal.imple, two-leaved, superior, permanent; fruit a dry four-cornered drupe, including a nut one to four-celled.

Species,
Species, Barringtonia speciosa, laurel-leaved D. Lin. Syl. Supp. Cook, Voy. I. 157. 24. f. 54, Fort. J. C. Miller. 16. 7. A lofty tree and the handiwork in the whole equinoxia flora, abounding with thick, shaggy bunches of leaves, every where intermixed with beautiful purple and white flowers; trunk woolly, thick, straight, covered with a dark grey, smooth bark, scored with little chinks; branches expanding widely, variously divided, somewhat bending downwards, and fest with many leaves at the ends; leaves crowded, the upper in a kind of whorl, serrate, wedge-shaped, obtuse, quite entire, expanding from a foot to fifteen inches in length, thick, coriaceous, very smooth, dark green, shining with yellow veins; flowers on a solitary erect thryse, a foot in length; peduncle smooth, a foot long; pedicels five, to twenty, one-flowered, three or four inches long; bracteas roundish, solitary at the base of the pedicels; flowers large, white, transparent; filaments and style diaphanous, purple at the top; anthers gold-coloured; drupe reddish brown. The flowers open during the night, and fall at sun-rise. The seed is said to imbibe silt in the same manner as cuculus indicus, &c. It grows within the tropics, especially on the shores of the ocean and at the mouths of rivers, in the East Indies from the southern coasts of China through the Molucca isles to Otaheite and the other Society isles. It is cultivated in the governor's garden at St. Helena. Introduced here in 1786, by Mr. A. Hove.

BARRISTER, in Law, a person qualified and empowered to plead, and defend the causes of clients in the courts of justice. The word is formed from bar, barre, a name given the place where they fland to plead.

Barristers, in the English law, amount to the name of licentiates, and advocates, in other countries and courts, where the civil, &c. laws obtain.

Anciently they were denominated among us, apprentices of the law, apprentissi juris nobilissimi; now usually counsellors at law; and they seem to have been first appointed by an ordinance of king Edward I. in parliament, in the twentieth year of his reign.

Before they were called to the bar they were formerly obliged to study eight years, now reduced to five; the excises required (if they were not called ex gratia) were twelve grand moats performed in the ins of chancery, in the time of the grand readings, and twenty four petty moats, in term time before the readers of the respective ins, and a barrister newly called was to attend the fix (or four) next long vacations the exercice of the house, viz. in Lent and summer, and they were therupon for those three (or two) years styled a vacation barrister. They are also called Outer barristers, i.e. pleaders ofer or without the bar; to distinguish them from benchers, or those that have been readers, who are sometimes admitted to plead within the bar; as the king's, queen's, or prince's, counsel are; hence called inner barristers, 5 El. cap. 1.

Barristers, according to Fortescue, might be called to the state and degree of serjeants, when they were of sixteen years standing. See Counsel and Serjeant.

Barristers who conically attend the kings bench, &c. are to have the privilege of being used in trantory actions in the county of Middlesex. But the court will not change the venue, because none of the defendants are barristers. Pleas before they are filed, must be signed by a barrister or serjeant.

To become a barrister in Ireland it is necessary in the first place that a memorial be presented by the person dehous of becoming fo, to the Benchers of the Honourable Society of the King's Insns, Dublin, stating his parentage and previous education, and requesting admission into the society as a flu- dent. This memorial certified by a practising barrister of ten years standing who is not a bencher, must be lodged in the office of the treasurer of the society before the eveson day of term; and on its being granted, a certain fine must be paid. After this admission the student must keep eight terms common in Ireland, and the same number in England. Formerly a student was required to attend fewer terms if he had taken a degree in any university, and this was a strong inducement to those who intended their sons for the bar to give them a college education. It has been regretted that this encouragement was discontinued; but the advantages of such an education are so evident, that it is to be supposed few will neglect it; especially as they can attend terms at the society of the King's Insns, at the same time that they are members of the university.

BARRISTER, the name given to an inferior judge established in every county of Ireland, except that of Dublin, whose business it is to sit twice every year to try civil bills, for the more speedy administration of justice.

BARRITUS, in Antiquity, a military shout raised by the Roman soldiers at the first charge on the enemy. This cullum, however, was not peculiar to the Romans; but prevailed among the Trojans according to Homer, among the Germans, the Gauls, the Macedonians, and the Persians. See Classicum.

BARROCHES, in Geography, are two great ranges of rocks close by the west end of Alderney, Avigny or Orna, towards the Caskets.

BARKS, John, in Biography, an eminent Portuguese historian, was born at Vifo, in 1496, and educated at the court of king Emanuel, with the royal children. In 1522 he was appointed to the government of St. George del Mina, on the coast of Guinea; and upon his return to Portugal, after an absence of three years, he was made treasurer of the Indies. When king John conferred upon him the lordship of Parnba in Brazil, on condition of his expelling the native Indians, and propituting with Portuguese, he set out with an expedition for this purpose; but his fleet being almost wholly destroyed, the project failed. Upon this he determined to write the history of the Indies, under the title of "Decades d'Asia," and the first decade was published in 1555, the second in 1555, and the third in 1565. For the completion of this work he retired to Pom- pilia, where he died in 1570, leaving several children. His fourth decade, compiled from his MSS. by order of Philip III. did not appear till 1615. The work has been continued by others as far as the thirtieth decade, and the last edition of it was printed at Lisbon in 1736, in 5 vols. folio. The history of dos Barros, applauded by some and cenured by others, is deemed, notwithstanding the author’s disposition to exaggerate, a work of authority. It was translated into Spanish by Alphonso Ulloa. Barros was the author of several other writings, moral, grammatical, &c. composed principally for the use of his pupil prince John, son of king John III. In some editions of his "Decades," there is an apologue for his life and writings, written by himself. Moveri. Nouv. Dict. Hist. by

BARROW, Isaac, a very eminent divine and mathematician, was the son of Mr. Thomas Barrow, a citizen and linen draper of London, and born in this city in the year 1650. Although at the Charter-house, where his education commenced, he gained no reputation, and was remarkable only for fighting and idleness, his subsequent application and literary progress in a school at Feltread in Elyx, whither he was removed, were such as to retrieve his character, and to induce his master to recommend him to the office of private tutor to a young noble-
nobleman under his care. In 1643 he was admitted a pen- sioner of Peter-house in Cambridge, under his uncle Mr. Isaac Barrow, afterwards bishop of St. Asaph, and then fellow of that college; and in 1645 he was entered a pen- sioner of Trinity college, as his uncle had been ejected together with others who had written against the covenant. The ejection of his uncle, and the losses sustained by his father on account of his attachment to the royal cause, involved our young student in difficulties; and he was indebted to the liberality of Dr. Hammond for his chief support. Such were the sweetness of his disposition and his respectful conduct towards his superiors, that he preferred their esteem and good-will, though he readily adhered to the cause for which his family had suffered and refused to take the covenant. His proficiency in all branches of literature, and particularly in natural philosophy, was so considerable, and his merit so generally acknowledged, that he was elected, notwithstanding the obnoxiousness of the party to which he belonged, fellow of his college in the year 1649; and now perceiving that the circumstances of the times were unfavourable to persons of his opinions in matters of church and state, he determined to devote himself to the medical profession. With this view he directed his attention to anatomy, botany, and chemistry, and made some progress in these preparatory studies; however, upon further consideration, aided by his uncle’s advice, he refrained from the study of divinity in connection with that of mathematics and astronomy. With these severer studies he also blended the amusements of poetry, to which he had a strong propensity. In 1652 he commenced master of arts, and was incorporated in that degree at Oxford. Disappointed with regard to the Greek professorship at Cambridge (to which he was recommended) on account of a fulmination of his Arminian principles, and perhaps influenced by the aspect of public affairs, he resolved to travel abroad; and in order to obtain a necessary supply for this purpose, he sold his books. Accordingly he set out in the year 1655; and in this year his first work, which was an edition of "Euclid’s Elements," was published during his absence. He visited France and Italy; and in 1656 he fell sick from Leghorn to Smyrna; and in the course of his voyage he had an opportunity of manifesting his natural intrepidity by standing to his gun, and defending the ship on which he had embarked, against the attack of an Algerine corsair, and of beating off the enemy. Of his intrepidity, as well as bodily strength, another instance occurred on a very different occasion. As he was once leaving the house of a friend early in the morning before a fierce gale was chanced up, the dog flew at him with violence; but he had the resolution to seize the dog by the throat, and after much struggling to overpower him, and to hold him fast on the ground till some of the domestics rose and parted them. From Smyrna he proceeded to Constantinople, where he read over with peculiar satisfaction the works of St. Chrysolot, the bishop of that see; and having remained a year in Turkey, he returned to Venice, and in 1659 he passed through Germany and Holland into England. Soon after his return he was ordained by bishop Browne; and when the king was restored, his friends expected that his attachment to the royal cause would have been rewarded by some considerable preferment; but their expectations were disappointed. On this occasion Barrow wittily remarked in one of his poems,

"Te magis optavit redditum, Carole, nemo,
Et nemo festis te reddisse minus."

"Thy restoration, Royal Charles, I see,
By none more will’d, by none less felt, than me."

Vol. III.

However, he wrote an ode on his majesty’s restoration, in which he introduces Britannia congratulating the king upon his return. In this same year, 1660, he was chosen Greek professor at Cambridge; and in consequence of this appointment, he read lectures on the Rhetoric of Aristotle. In 1662 he was recommended by Dr. Wilkins, and elected to the professorship of geometry in Gresham college; and he also discharged the duty of the astronomical professor, who was absent. About this time he declined a valuable preferment which was offered him, from scruples of conscience; because it was annexed to the condition of educating the patron’s son, which Barrow considered as a kind of servile contract. In 1663 he was included in the first choice of members made by the Royal Society after receiving their charter; and in the same year he was appointed Lucasian professor of mathematics at Cambridge, on which occasion he delivered an excellent oration on the excellence and use of mathematical science. At this time he resigned both his Greek and Gresham professorships. Although the station to which he had attained was peculiarly adapted to his distinguished talents and acquirements as a mathematician, he determined in 1669 to exchange his mathematical studies for those of divinity; and accordingly, as soon as he had published his "Lectiones Opticae," he resigned his professor’s chair to the illustrious Newton. In 1670 he was created doctor in divinity by mandate; and in 1672 he was nominated to the masterly of Trinity college by the king, who observed "that he had bestowed it on the best scholar in England." To the patent of his appointment was annexed a clause which allowed him to marry; but as this privilege was inconsistent with the statutes of the college, he infurled on the clause being erased. On this occasion he resigned the preferments of a small sinecure in Wales, and of a prebend in the cathedral of Salisbury, which he had previously enjoyed and the profits of which he had distributed to charitable uses. In 1675 he was chosen chancellor of the university; but his services in this high and honourable station were speedily terminated by his death, occuring by a fever, in London, May 1677, in the 47th year of his age. His remains were interred in West- minster Abbey; and a monument, with an appropriate epitaph, was erected for him at the expense of his friends. Dr. Barrow had nothing in his person or external appearance, that was likely to command any degree of attention and respect. He was of a low stature, and of a meagre, pale aspect; and he was singularly negligent with regard to his dress. Pope, his biographer, mentions a circumstance to this purpose, which shews the effect of his inattention to outward appearance. Being engaged to preach for Dr. Wilkins at St. Lawrence Jury in London, his shaven and awkward gait and meagre aspect prepossessed the audience so much against him, that, when he mounted the pulpit, the congregation withdrew and he was left almost alone in the church. Mr. Richard Baxter, the nonconformist divine, however, was one of those few that remained; and his testimony was highly honourable to the preacher, for he declared that he had never heard a better sermon, and that he could with pleasure have listened all day to such preaching; upon which those persons who complained to Dr. Wilkins of his substitute were ashamed of their conduct in deferring the church, and reduced to the necessity of acknowledging that their prejudice was solely the result of his uncouth appearance. His sermons were distinguished not only by their excellence, but by their length. He took great pains in compiling them, and in transcribing them three or four times, as he found it extremely difficult to please himself. M. le Clerc (Bibliothe. Univ. t. iii. p. 325)
selves, "Euclidis Data," Camb. 1657. 8vo., subjoined to the Elements in later editions. "Lectiones Opticae XVIII.; Cantabrigiae in scholis publicis habitae, &c." Lond. 1669. 4to: this work was revised and enlarged by Newton, and has been highly commended by the best judges. "Lectiones Geometricae XIIII. in quibus praefermi generalia linearum curvarum symptomata declaratur;" Lond. 1670. folio: published in 1672 and 1674 with the "Optics." "Archimedes Opera; Apollonii Conicorum Libri IV.; Theodolii Spharicae, methodo nova illustrata, et luculenter demonstrata;" Lond. 1675. 4to: After Dr. Barrow's decease, were published his "Lectio in qua theorematas Archimedis de Spherar et Cylindro, per methodum individihibum investigata, et breviter demonstrata, exhibetur," Lond. 1678. 12mo; and "Mathematica Lectiones, habitae in scholis publicis Academae Cantabrigienis;" Lond. 1683. 8vo. Besides these, Dr. Barrow left several curious papers, written with his own hand, and communicated by William Jones, eq. to Dr. Ward. Hill's Life prefixed to Barrow's Works. Ward's Lives of the Professors of Gresham college, p. 157. &c. Dioz. Brit.

Barrow, in Geography, a noble river of Ireland, supposed to be the Birges or Birges of Ptolemy. It rises in the mountain of Sheeb-bloom in the King's county, and running for a short space north-east, makes a kind of elbow; and continuing afterwards a south-east course, it divides the King's and Queen's counties from that of Killare. At Athy, in the latter county, a branch of the grand canal from Dublin to the Shannon has formed a junction with it: which contributes much to the advantage of the adjoining country. It proceeds next through the heart of the county of Carlow, and then separates those of Kilkenny and Wexford. A little before it reaches the town of Kils, it receives the Nore, and then varying its course from that to the west, meanders its waters with those of the Suir, forming with it the haven of Waterford. The navigation of this river has been deemed of such great importance that 11,000 pounds have been granted by parliament to remove some obstructions in it; and a corporation established for the purpose has been enabled to raise 20,000 l. more to render it completely navigable. It is now (1822) expected that boats will soon regularly ply from Waterford to Athy, and thence by the grand canal to Dublin. The circumstance of the three rivers Barrow, Nore, and Suir, all rising in the same mountain, proceeding from it by different courses, and uniting their streams before they fall into the sea, has been mentioned by many writers. Amongst others, Speer has noticed it in his episode of the marriage of the Thrones and Medway (Fairy Queen, book iv. cant. 11;) in which he represents them as three brothers, sons of the giant Bliomius and the nymph Rhenua. He speaks of the Barrow as abounding in salmon:

"The third, the godly Barrow which doth hooed
Great heapes of salmon in his deeppe boome."

Campbell's Political Survey, &c. &c.

Barrow Little, a river of Ireland, which runs into the Barrow about 4 miles east of Portarlington.

Barrow Harbour is an extensive bay in that of Bonafrica in the island of Newfoundland, divided by Keel's head on the E. from the port of Bonafrica, and from Bloody bay on the W. by a large peninsula joined to the island by a narrow isthmus, which forms Newman's found: which, as well as Chude found, are within Barrow harbour.

Barrow Point, a cape on the south coast of Ireland, in the county of Cork, 5 miles east of Kinfare.

Barrows, or Tomiths, in Topography, a name usually given to those hillocks or mounds of earth which were anciently
ciently raised over the bodies of deceased heroes and persons of distinguished character. This mode of interment may be traced to the remotest antiquity, and instances of it occur in all quarters of the world. A learned antiquarian, well known for his industrious and indefatigable research (see Gough's Sepulchral Monuments of Great Britain), contemners barrows as the most ancient sepulchral monuments in the world. Homer is one of the earliest authors that mentions the construction of barrows, in describing the funeral rites attending the interment of Patroclus and Achilles. The body of Patroclus was first laid on the top of a great pile of wood about one hundred feet square, and covered with the fat of animals offered in sacrifice; the caskets of the beasts, and the bodies of the Trojan captives cruelly slain in cold blood on the occasion, were then thrown on the pile round its edges, and the whole reduced to ashes. The remains of the fire were next day extingui\shed by pouring wine on the embers; and as many fragments of the bones of the deceased as could be collected, were wrapped up in fat, and put into a rich urn, having a linen veil flung over it. The whole army then threw earth upon the spot where the pile had been consumed, so as to cover the bones of the Trojans, of the caskets, and all the ashes that remained, and thus reared a high rude hill, under which, nearly in the centre, the urn was placed. After this ceremony, solemn games were performed, and chariot races were exhibited round the barrow, in honour of the deceased. To this purpose, the elegant translator of Homer, in his account of the funeral of Patroclus, expresses part of the funeral ceremony:

"High in the midst they heap the swelling bed
Of rising earth, memorial of the dead."

Iliad, xxiii. 319.

In Plutarch's Life of Alexander, we find that when that great conqueror arrived at the ruins of Troy, he anointed with much ceremony the stone placed on the barrow of Achilles, poured out libations, and, as the custom was, ran naked round the sepulchre, and crowned the stone with garlands.

Herodotus, the father of history, mentions the barrow of Alyattes, the second of that name, king of Lydia, and father of Croesus, raised 2356 years ago, and seen by Dr. Chandler in A. D. 1764, five miles from Sart, the ancient Sardis. This tumulus or barrow, formed by the joint exertions of the Thracian, the labourers, and the profitters, was about a mile in circumference, and had been adorned with various buildings, and terminated by a piece of water called the Gygean lake, still remaining. Dr. Chandler, in his "Travels through Asia Minor," vol. i. p. 42, describes this and other barrows in their present state; and Herodotus states, that the lower part of it was a mass of large stones, but that the rest of the sepulchre was a tumulus of earth.

It was customary among the Greeks to place on barrows, either the image of some animal, or pile, termini, or round pillars with inscriptions. Panofians describes the famous barrow of the Athenians in the plain of Marathon, on which were pillars of this kind: and on that of Alyattes were five stones, on which were engraved letters, denoting how much each class of the persons concerned had performed towards it, and it appeared that the greater portion was done by the young women. An ancient monument in Italy, near the Appian way, called without reason the sepulchre of the Curiatii, has the name number of termini with that of Alyattes, the baseinent, which is square, supporting five round pyramids. We are informed in the scriptures, that when the king of Ai was slain by Joshua, his carcase was placed at the entrance of the city, and upon it was raised a great heap of stones. Several other passages of the sacred writings lead us to conclude, that though the Jews were prohibited from adopting the superstitious customs of the gentile nations, they did not think themselves restrained from constructing these monuments to their deceased relatives. Diodorus Siculus, speaking of the Buliaks, says, that after preparing together the limbs of a dead body with boards, they cast it into a hollow receptacle, and placed over it a large heap of stones. Virgil alludes to this mode of interment as used in Italy in the times to which the Aeneid refers. Xenophon relates that it obtained among the Persians; the Roman historians record it as taking place among their countrymen; and it prevailed no less among the ancient Germans, Britons, and other nations.

According to Herodotus, the Thracians, a people of Scythia, raised barrows; and the custom of erecting them in various parts of the world continued through a long series of ages. Gough says, that they continued in use till the 12th century.

The ancient barrows are of various sizes, some of them being small, and perhaps designed for children, or the younger branches of the royal family, or for persons of meaner rank; others distinguished by their height and bulk, and visible like hills at a great distance, which might probably have been the sepulchre of some renowned monarch or warrior, or general burying-places.

Stehlenberg, in his description of the northern and western parts of Europe and Asia, informs us, that great numbers of tumuli, called by the Russians "bozhni," are found in Siberia, and in the deserts which border on that country southward; and that in these tombs are found many plates, ornaments, and trinkets of gold. Some of them are raised by earth as high as houses, and appear in the distant plains like a ridge of hills; whilst others are set round with rough-hewn stones. Archæologia, vol. ii. p. 236.

The custom of interring with the dead their arms, their jewels, and sometimes their horses and servants, is traced by M. Legrand D'Aufy (Mem. de l'Institut National des Sciences, &c. Paris, vol. ii.) to the mythology of the northern Asiatic nations, which taught them to believe that they should make an appearance in another world, corresponding to the ornaments and attendants deposited in their tombs; and the remains of this superstition have descended through many ages. According to this writer, a great part of the riches acquired by the northern nations in their irruptions, has been interred in the tombs of the conquerors. Treasures have been frequently found in the barrows so common in Tartary; and, in attempting to rank these monuments, the Siberians have had to many conflicts with the Tartars, that the Russian government has been obliged to put a stop to their researches.

Denmark, Sweden, Lower Saxony, and many other countries on the continent, abound with sepulchral monuments of this kind. Mr. Cox, in his "Travels in Poland," (vol. i. p. 130.) mentions two large barrows in the vicinity of Cracow: one by tradition called the burial-place of Cracus, duke of Poland, who is supposed to have built the town in the year 700; and the other called the sepulchre of his daughter Videa, who is reported to have drowned herself in the Vistula to avoid a marriage with a person whom she detested. As popular tradition records these as favourite characters in their country, it has honoured them with interment under the most conspicuous of those monuments called barrows.

The barrows of England are very numerously strewed over the plains of Wiltshire, the downs of Dorsetshire, Kent, and Surrey. Monuments of the same appropriation
are also abundant in the northern counties of England, North Wales, Scotland, and Ireland; but most of these con- sur, and are designated by the name of "carr," or "cairn." (See CAIRN.) The most considerable barrow in England is that of Silbury Hill in Wiltshire. (See AVEBURY.) A barrow in Derbyshire, situate on the summit of a hill called "Fin-com," has been carefully investigated by Mr. Hayman Rooke. (See Archæologia, vol. xii.) It disclosed two or three skeletons, one of which had an oblong piece of dressed black Derbyshire marble fastened by a strong cement to the skull: some urns also appeared, with ashes and burnt bones, together with arrow-heads of flint, and a spear-head shaped out of a piece of lime-stone, and made very sharp at the point. Mr. Rooke conjectures, that this elevated spot, secured by a double fence, may have been the site of a British town or fortres, and that the barrow was the sepulchre of the chief- tain and his relatives; the weapons of flint and of bronze-stone undoubtedly fogglet a very remote period, and, when found as these were, appear to indicate the relics of a primitive and barbarous people. Dr. Pott takes notice of two forts of barrows in Oxfordshire, one placed on the military ways, the other in the fields, meadows, woods, &c. the former he supposed were of Roman erection, and the latter more probably erected by the Britons or Romans. Some of these barrows appear rude, and constructed only of earth; others are more regular, and reached round, some of them with two or three circumvolutions, and surroundcd with monumental stones. (Platt's Nat. Hist. Oxfordshire, ch. x. § 48.) We have an examination of the barrows in Cornwall by Dr. Williams, in the "Philosophical Trans- actions," No. 458: from whole observations we find, that these barrows are composed of foreign or adventitious earth; that is, such as does not occur on the spot, but must have been fetched from some distance. In one of them was found an urn made of burnt or calcined earth, very hard, and very black within; it had four small handles, and in it were found seven quarts of burnt bones and ashes. As it was the ancient practice to burn the dead, it appears from these barrows, how the people that used this mode of burial ex- pressed their respect for the dead; it was by erecting over them these tumuli or barrows, composed of earth or stone brought from distant places; and the barrow was generally proportioned to the rank and power of the deceased person. Each folder, or friend, might bring some of the earth or stones from distant places where they lived, and thus com- pose the tumulus. Many passages might be quoted from ancient authors to this purpose. The contents of these barrows, as well as their size and form, have been very va- rious: in some have been found flint chells containing en- tire bones; and in others, bones neither lodged in chells nor deposited in urns: arms of various sorts, amber beads, &c, have not been uncommon.

The links or bands of Skail in Sandwich, one of the Ork- ney islands, abound in round barrows, some formed of earth alone, and others of stone covered with earth. In the former was found a coffin made of six flat stones, and as it was too short to receive a body at full length, the skelctons had their knees pressed to the breast, and the legs doubled along the thighs. A bag made of rushes has been found at the feet of some of these skeletons, which contained the bones, probably, of another person of the family. In one of these were discovered multitudes of small beetles; and as similar insects have been found in the bag which in- cluded the sacred Isis, it may be supposed that the Egyp- tians, and the nation to which these tumuli belonged, might have had the same superstitious respecting them. Some of the corpses interred in this island appear to have been burnt; as the ashes deposited in an urn which was covered with a flat stone, have been found in the cell of one of the barrows. This coffin, or cell, was placed on the ground, then covered with a heap of stones, and cased with earth or rocks. This barrow and its contents evince them to be of a different age from the former. These tumuli appeared to be a kind of family vaults, two tiers of coffins having been found in them; and it is not improbable, that on the death of any one of the family, the tumulus was opened, and the body interred near its kindred bones.

Barrows are very numerous in Ireland. Ledwich sup- poses them to have been of Scythian origin, and to have been introduced in Britain after the Romans had left it. It was a law of Odin the great Gothic legislator, that large barrows should be raised to perpetuate the memory of celebrated chiefs: these were composed of stone and earth, and were formed with great labour and some art. At New Grange in the county of Meath is a mount of this kind, the altitude of which from the horizontal floor of the cave is about 70 feet, the circumference at the top is 300 feet, and the bale covers two acres of land. It is founded on an abundant collection of bones, and covered with gravel and earth. In the "breed-tid," or fiery age, which was the first among the Northern, the body was ordered by Odin to be burned with all its ornaments, and the ashes to be collected in an urn and laid in a grave; but in the "hel- tid," or age of hillocks, being the second, the body, un- touched by fire, was deposited in a cave or sepulchre under a barrow; and this mode was practised till the third epoch, called "chirllendoms-old," or the age of Christianness. Governor Pownall, who has given an account of New Grange, in the second volume of the "Archæologia," ob- serves, that the mode of burial, and the species of sepulchral monument at New Grange, may be traced through Den- mark, Sweden, Ruffia, Poland, and the Ilippines of Tartary: and he conjectures that this mount was a Danish work, which was also the opinion of Sir Thomas Molyneaux, M. D., in his "Eassy on Daniht Mounts," published with "Boate's Natural History of Ireland." About 1699, a Mr. Campbell, who resided in the village of New Grange, observing stones under the green sod, carried many of them away, and at length arrived at a broad flat stone that covered the mouth of the gallery. At the entrance, this gallery is 3 feet wide and 2 high: at 13 feet from the entrance, it is but 2 feet 2 inches wide: the length of the gallery, from its mouth to the beginning of the dome, is 62 feet; from thence to the upper part of the dome, 11 feet 6 inches; the whole length being 714 feet. The dome or cave, with the long gallery, exhibits the exact figure of a cros, the length between the arms of which is 20 feet: the dome forms an octagon, 20 feet high, with an area of about 17 feet: it is composed of long flat stones, the upper projecting a little below the lower, and closed in and capped with a flat flag. There are two large oval rock bafons in this cave, one in each arm of the cross: from which, and the cruciform shape of the structure, it is suppod to be the work of semi- barbarous builders in the ninth century. The custom of bur- ying the treasure acquired by piracy, in the barrows of great men, accounts for the Roman coins found at New Grange. For a more particular account, the reader is re- ferred to Mr. Ledwich's Antiquities of Ireland, p. 327— 328. General Vallancey, however, and other antiquaries, consider this cave at New Grange to have been "a trium Mithras," or a cave for the worship of the sun, introduced by
by the Peric-Scythic colony, which they suppose to have come to Ireland from Spain, and to have established the cults of the eastern nations.

Barrows or barrows are also found in great numbers in America; and the American Indians are said to practice a similar mode of burial at this time, generally depositing with the body the implements of war and agriculture used by the deceased. Mr. Jefferson, in his "Notes on the State of Virginia," p. 156, has given a particular account of the American barrows. They are of different sizes, and formed of different materials; some of earth, and some of loose flores. That they were repositories of the dead is generally allowed; but the particular occasion on which they were constructed has been a subject of discussion. Some have thought that they covered the bodies of those who fell in battles fought on the spot of interment. Some ascribe to the custom prevalent among the Indians, of collecting at certain periods all their dead, wherefore deposited at the time of their death. Others again have supposed that they were general sepulchres for towns, conjectured to have been situate on or near those ground; and this is an opinion that has been supported by the quality of the lands in which they are found, those constructed of earth being generally in the softest and most fertile meadow grounds, on the sides of rivers; and also by a tradition descending from the aboriginal Indians, which reports, that when they settled in a town, the first pedon who died was placed erect, and in this posture covered and supported by earth; that when another died, a narrow passage was dug to the first, the second reclined against him, and the cover of earth replaced, and so on. Mr. Jefferson examined one of these barrows, situate in his own neighborhood, on the low ground of the Rivanna, opposite to some hills on which had been an Indian town; and has particularly described its form, which was oblong, and also its contents, which were collections of human bones in a disjointed and scattered state. This barrow, he conjectured, might have contained a thousand skeletons. The circumstances which he has recited militate against the opinion that it covered the bodies only of persons fallen in battle; and against the tradition, which would make it the common sepulchre of a town, in which the bodies were placed upright and touching each other; and indicates, that it has derived both origin and increase from the customary collection of bones, and the deposition of them together. But in what way further this tumulus was formed, it seems to have been well known to the Indians; a party of whom, some years ago, proceeded through the woods directly to it, without any inquiry; and having remained near it for some time with expressions of sorrow, they returned to the high road, from which they had departed about six miles for the purpose of this visit, and then pursued their journey. There are many other similar barrows in other parts of the country. For further particulars relating to sepulchral monuments of this kind, we refer to Gough's Sepulchral Monuments of Britain; Dought's Nennia Brittanica; King's Monuments Brittanica; Archæologia, vol. ii. & xii.; and Britton's Beauties of Wiltshire, vol. ii.

Barrows, in the Sab Works, are cafes made with flat cleft wickers, in the shape of a lof of a sugar-loaf, with the bottom uppermost, wherein the salt is put as it comes, and set to drain. Phil. Trans. No. 53: p. 1065. Hooldt. Collect. N° 211. p. 81.

BARROWBY, William, in Biography, son of Dr. William Barrowby, a physician of considerable reputation and eminence in London. At a proper age he was admitted of Emanuel college in Cambridge; and in 1753 took his degree of Bachelor in Medicine. Soon after, he was made fellow of the Royal College of Physicians in London, and one of the physicians to Bartholomew's hospital. He died suddenly, after eating a hearty meal, December 30, 1759, being only forty-two years of age, and then in great practice. There is a fine print of him, engraved in mezzotinto by Müller, after a painting by Hayman. His father, who survived him, died October 17th, 1758, being then senior member of the college of physicians. Our author published, in 1727, a translation into English of Albriz's treatise "De Morbo Gallico," London, 4to. 8vo. Eboy. Dist. Hill.

BARSIUET. in Biography. See Barney.

BARRY, Edward, in Biography, a native of Dublin, received his medical education at Leyden, under the celebrated Boerhaave, and was created doctor of physic there in 1719. After practising some years at York, he went to Dublin, and was made professor of medicine in the university of that city, firu physician to the army there, and fellow of the Royal Society in London. In 1727, he published "A treatise on the constitution of the lungs, with a previous account of nutrition, and of the structure and use of the lungs," 8vo. London, in which he maintains the doctrine of his predecessor. To the third edition of this work, enlarged and improved, published 1759, he gave the title of "A treatise on the three Digestions and Discharges of the Human Body, and the Dificilises of their principal Organs." Haller. Bib. Anat. Eboy. Dist. Hill.

BARRY, Gerald, commonly called Geraldus Cambrensis, i.e. Gerald of Wales, in Biography, a writer of the twelfth century, was born near Pembroke in South Wales about the year 1146, and descended from a noble family allied to the princes of the country. After an early education at home, he was sent for further improvement to France, where he obtained great reputation for his proficiency in the rhetoric of the age in which he lived. Upon his return in 1172, he obtained several ecclesiastical preferments, of which the principal were the prebendary of Brechin, and the canony of Hereford. As he was active in church affairs, he acquired a reputation which induced the chapter of St. David's to elect him bishop of that see at the age of 30 years; but as he had renounced for apprehending the jealousy of Henry II., he declined this ecclesiastical dignity. However, he was mortified by being under a necessity of refuting what was the great object of his ambition; and in order to divert his chagrin, he visited France; and at Paris he pursued his study of civil and canon law, and of divinity, with such success, that he was offered the professorship of canon law in the university; but he thought proper to decline it. In 1180, he returned to his own country; and as great confusion prevailed at St. David's in consequence of the expulsion of the bishop, he was entrusted with the administration of that see for three or four years. In 1183, Henry II. appointed him his chaplain, and availed himself of his advice in the management of Welsh affairs. In the following year he was sent to Ireland with Prince John as his privy-councilor and secretary; and was there offered the united bishoprics of Ferns and Leighlin, which he declined accepting because he disapproved of the manners pursued by John. During his stay in that country, he was principally employed in collecting materials for two works relating to Ireland.
Ireland which he had projected. After his return to Wales, in 1187, he wrote and revised his "Topography of Ireland," and at Oxford, he publicly recited the three parts of the work on three successive days, seating on the first day all the poor of the city, on the second the principal doctors and scholars, and on the third the adherents of inferior rank, soldiers, and burghers. In the following year he accompanied Baldwin of Canterbury on a journey through the mountainous parts of Wales, for the purpose of inculcating on the people the necessity of a crusade; and he was thus furnished with materials for his "Itinerary in Wales," which he afterwards published. At this time Girald took the cross; but being otherwise employed at home, he obtained a dispensation from the pope's legate for not pursuing his voyage to the Holy Land in the reign of Richard I. Upon some difficulties, he retired from court in 1192, and took up his abode for six or seven years at Lincoln, where he pursued his theological studies and composed various writings. In 1198, he was solicited by the chapter of St. David's, and the chief men of the country, to canvass for the vacant see; but in declining it, he made use of a saying which has become memorable: "Virum episcopalem peti, non petere, debere," i.e. a man fit for a bishoprick ought to be fixed to, and not fixed. However, he soon changed his mind; for being next year unanimously chosen by the chapter, he went over to Ireland to engage his relations in support of his claim. But during his absence, a candidate was offered from the archbishop and justiciary for the election of Geoffrey the prior of Llansadry. Girald appealed to the pope; and after much delay and three journeys to Rome, he only so far prevailed as to annul the election, and to obtain the appointment of a new choice. Geoffrey was at length the successful candidate; upon which Girald resigned his archdeaconry of Brecon to his nephew, and withdrawing from public concerns, devoted himself to his studies. In 1215, he was offered the bishopric of St. David, but the offer was connected with conditions which he did not approve. The time of his death has not been precisely ascertained; but it is known that he was alive after the year 1220.

Giraldo Cambrensis was a voluminous writer; and there were few of the literary topics of his age that did not employ his pen. According to the account given of him by Mr. Thomas Wharton (Hist. of Poetry, diff. ii.), he was an historian, an antiquary, a topographer, a divine, a philosopher, and a poet. Many of his works, he says, are written with some degree of elegance, and he abounds with quotations from the best Latin poets. But his style is in general puerile, affected, diffuse, and full of quibbles and conceits; nevertheless, many of these defects must he attributed to the times in which he lived. Whatever may be thought of the vanity which he manifests in speaking of himself, of his family, and of his performances, he was without doubt in a very great degree credulous, and so much addicted to fables, that his statement of facts is in many cases unworthy of confidence. With the events recited in his "History of the Conquest of Ireland," he has intermixed all the partnerships he could collect of Caledonius, Merlin, and various other impostors; and hence he was led to give to his history the title of "Vaticinal." This work, and also his "Topography of Hibernia," have been charged by the Irish writers with numerous mistakes and falsehoods. They were first printed by Camden, at Frankfurt, in 1602. His "Itinerarium Cambium," was printed with the annotations of David Powel. The purpose of his "Ecclésia speculum, five de monarchiis orbis, ex ecclesiasticis religioni vs variis distinctionum, lib. iv." was to expose the vices of the monks, against whom he had conceived an inveterate hatred, so that he was accused to add to his litany, "From the malice of the monks, good Lord, deliver us." Biog. Brit.

**Barry Island**, in Geography, the westernmost of two islands off Cardiff point, on the coast of Wales, in the county of Glamorgan.

**Barry's Point**, a projecting head land, on the west side of Little Island, up Cork harbour.

**Bary**, in Herculey, is when the shield is divided into equal parts horizontally, consisting of two colours; or thus, butty of six, argent and sable.

**Barry Beady Counterchanged**, is when the bars are crossed by lines bendwise. See Plate of Partition lines.

**Barry Indented**, is when the lines which cross the field to form the bar are indented.

**Barry Fifev and Barry Nebule**, are formed in the same manner by the lines being empty nebule.

**Barry Lezengis Counterchanged**, is when the bars are crossed by lines bendwise, dexter and sinister. See Plate as above.

**Barry Fife**, is when the bars are charged with piles. See Plate as above.

**Barryeras Verme'llias**, in Geography, is a large bay, with very good anchoring on the coast of Brazil, between St. John's island and Sypomba island, 7 leagues north-west from it; fituate in about 2° S. lat. and S. E. of the mouth of the great river Amazonas.

**BARS, a town of Hungary, and chief place of a county of the same name, eight miles west of Leventz.**

**Bars, or Barco, Cape,** lies on the south side of the passage into the White sea, and to Archangel, from the N.W. and is the north point of the gulf of Mezene. N. lat. 66° 30'. E. long. 41° 45'.

**BarSa, in Ancient Geography,** an island near the coast of France, mentioned in the Itinerary of Antonine. See Isle of Bas.

**Barsallium, a town of Afa, seated on the banks of the Euphrates, on the east of Samoata.**

**Barsallach Point, in Geography,** a cape of Scotland, on the coast of the county of Wigton, in Luce bay, 8 miles N.W. of Burrowhead.

**Barsalli, a kingdom of Africa, bordering on the river Gambia, and inhabited by a tribe of negroes called Jaloofs.** The government of this kingdom is a despotic monarchy; and the people are in such an abject state of submision, that they fall on their faces whenever any one of the royal family appears. In time of war, every soldier has his share of booty; and the king contents himself with a very moderate portion. The kingdom is divided into a number of provinces, over which the king appoints governors, who pay him an annual homage and send a certain tribute or revenue to the exchequer. These bomeys, though powerful and absolute within their respective jurisdiction, are subject to the absolute dominion of the sovereign. The king maintains his despotic power so completely, that he admits of no other counsellor besides his prime minister, who is himself in reality his prime slave. This minister is also the general of the king's forces, and the interpreter of his will, from the very letter of which he must never deviate. The king and court profess the Mahometan religion, though they pay little regard to that part of it which forbids the use of wine; for the king cannot live without brandy, nor is he ever more devout than when he is drunk. When he lands in need of a fresh supply of brandy, or of any other necessity, he sends to the governor of James fort, begging that he will dispatch a boat with the merchandise for which he has occasion; and for the payment he plunders the neighbouring towns, and feizes a certain
BAR

a certain number of his subjects, whom he sells for slaves, and exchanges for European commodities. The general drefs of the people is a kind of calico surplice that hangs down below the knee, and is sometimes plaited about the waist; and they also wear a great number of gold trinkets in their hair, ears, noses, and round their necks, arms, and legs. The king of Baratli, whom Moore saw in 1732, had a prodigious number of women; but when he went abroad, he was seldom attended by more than two, who seemed to be drest out in the whole finery and jewels of the kingdom. The preeminent heirs of the crown paid the same servile homage to the sovereign with his lowest subjects; nevertheless it was usual for the king's children to dispute the right of succession with his brethren; and the longest sword generally gained the prize. Mod. Un. Hist. vol. 14, p. 164, 

&c. See Jallops.

BARSANTANI, in Church History, a sect who held all the errors of the Severians and Theodofians.

BARSANTI, Francisco, in Biography, a native of Lucca, born about the year 1690, studied the civil law in the university of Padua; but, after a short residence there, he chose music for his profession. With this view he placed himself under the tuition of some of the ablest masters in Italy; and having attained a considerable knowledge both in the practice and theory of the art, he determined to settle in England, and came hither with Geminiani, who was also a Luccche, in the year 1714. He was a good performer on the hautbois when he first came over, and also on the flute: as a hautbois player, he found employment in the opera band; and derived considerable profit from teaching the flute. He published, with a dedication to the earl of Burlington, fix folios for a flute with a thorough base, and afterwards fix folios for a German flute and base. He also formed into sonatas for two violins and a base, the first fix folios of Geminiani. He continued many years a performer at the opera house. At length, having encouragement to remove to Scotland, he went thither; and it may be said of him with greater truth than of David Rizzio, that he mollified the mutiny of that country by collecting and making faith to a great number of the soul's popular songs.

About the year 1730, Barsanti returned to London; but being advanced in years, he was glad to be again employed in the opera band as a performer on the tenor violin; and in the summer season, in that of Vauxhall. At this time he published twelve concertos for violins, and soon after Sci Antifon, in which he endeavoured to imitate Palestrina and the old ecclesiastical composers. But the profits arising from these publications were so small, that the sale did not cover the expense of printing them. Barsanti was an excellent harmonist; but his productions were dry and fancifl. He acquired small sums by correcting the productions of young composers, and making bases to those of old pretenders to counterpoint. But towards the end of his life, he subsisted chiefly by the industry and economy of an excellent wife whom he had married in Scotland, and the studies and talents of a worthy and ingenious daughter, who, with the most promising voice and disposition for music, had been bound apprentice to a master who had undertaken to prepare her for a public figure, and with whom she had acquired all the difficulties of the art in point of execution; but she totally lost her singeing voice, on going to Oxford to perform at a choral meeting, by ficklef in a stage coach; and never being able afterwards to sing, she was engaged by Colman as a comic actress at his theatre in the Haymarket; and having a great fund of natural humour, and a good figure, acquired great applause. The winter after she went to Ireland, and became a favourite actress in humourous parts, and at length was married to Mr. Da-ly, the manager of the Dublin theatre; but died soon after to the great regret of all who knew her.

BARSCHLING, in Geography. See Baschler.

BARSCHLING, or BORSTLING, in Ichthology, one of the synonymous names of the common perch, percis fluviales. Vide Marigli. Danub. &c.

BARS, an English name for the common perch, a well-known fresh-water fish. It is also the name now in use for the same fish in the Saxon language, and is one of the many Saxon words we have yet retained.

BARSERS, in Geography, a town of Norway, 50 miles N.E. of Romdal.

BARSIR, a town of Persia, in the province of Kerman, 60 miles N.E. of Sirjan.

BARSOUND, lies on the coast of Sweden, in the Baltic, 15 leagues N. by W. from the north end of Oeland island, and nine leagues from the Wetterwyk channel, among a labyrinth of rocks, impassable except by direction of pilots at Oeland.

BART, a port on the southern coast of Nova Scotia.

BART is also a township of Lancaster county, in the state of Pennsylvania.

BARTAPOUR, a town of India, in the country of Kamaon, on an island in the Ganges, 93 miles east of Bereilly, and 90 north of Lucknow.

BARTAS, William de Salluste du, in Biography, a French poet, was born, in 1544, at Montfort in Armagnac; and having entered into the service of Henry IV. he employed by him in commissions to England, Denmark, and Scotland, in which last country James VI. would gladly have retained him. He was a Calvinist, and acquired in times of bad taste the reputation of a poet. His works were numerous, written in a style, sometimes mean and barbarous, and sometimes timid and extravagant, and abounding with ludicrous and disgusting figures. His most famous work was "A Commentary on the Work of the Creation of the World," in 7 books, which was held in high estimation, and passed through 30 editions, was translated into various languages, and formed a part of almost every religious library. Bartas is highly commended by Mont. de Thou for his candour, modesty, and simplicity of manners. Towards the close of his life he retired to his small estate of Du Bartas in Armagnac, and devoted himself to study. He celebrated in verse the victory of his master Henry at Ivry in 1590, and died in the following year. His works were collected and published in folio, at Paris, in 1614. Gen. Dict. Nouv. Dict. Hitt.

BARTAVELLE, in Ornithology, among the French naturalists, the same bird which Linnaeus describes under the name of perdix rustica; which see.

BARTEN, in Geography, a town of Prussia, and capital of a small country called Bartewland, in the province of Nantagen, 40 miles S. E. of Königsberg.

BARTENSTEIN, a town of Prussia, in the province of Nantagen, seated on the river All, 28 miles south of Konigsberg. This town was built in 1331, and at first called Rofenthal.

Bartenstein is also a town and castle of Germany, in the circle of Franconia and principality of Hohenlohe.

BARTERING, in Arithmetic and Commerce, the act of trucking or exchanging one commodity for another of like value.

The word comes from the Spanish baratar, to devise or circumvent in bargaining; perhaps because those who deal this way usually endeavour to over-reach one another.

This is also called barter, 13 Eliz. cap. 7.

In order to solve all questions that occur under this article, find the value of that commodity, the quantity of which
which is given, and then find how much of the other commodity will amount to that sum at the rate proposed.

Example I.—How many pounds of cotton at 10d. per lb. must be given in barter for 5 C. 3 qr. 14 lb. of pepper at 3 l. 10 s. p. C.?

First, find the value of the commodity, the quantity of which is given, thus:

<table>
<thead>
<tr>
<th>Q. lb.</th>
<th>1 s.</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>14</td>
</tr>
<tr>
<td>3 l.</td>
<td></td>
</tr>
<tr>
<td>10 s.</td>
<td></td>
</tr>
<tr>
<td>10 q.</td>
<td></td>
</tr>
<tr>
<td>1 lb.</td>
<td></td>
</tr>
</tbody>
</table>

Or, by decimals,

<table>
<thead>
<tr>
<th>Q. lb.</th>
<th>1 s.</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>14</td>
</tr>
<tr>
<td>0.3 l.</td>
<td>0.14</td>
</tr>
<tr>
<td>10 s.</td>
<td></td>
</tr>
<tr>
<td>10 q.</td>
<td></td>
</tr>
<tr>
<td>1 lb.</td>
<td></td>
</tr>
</tbody>
</table>

And 1.35 : 5.783 : 205625 = 89 : 20 l. 11 s. 3 d. the value of the pepper.

Secondly, find how much cotton at 10d. per lb. may be purchased for 20 l. 11 s. 3 d. thus:

<table>
<thead>
<tr>
<th>Q. lb.</th>
<th>1 s.</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>11</td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>493.5</td>
<td></td>
</tr>
</tbody>
</table>

As the values or prices of the goods bartered are always equal, it is evident that the product of the quantities bartered into their respective rates must be equal. Hence we obtain the following rule by which many questions of this nature may be solved; viz.:

Multiply the given quantity and rate of one commodity, and the product divided by the rate of the other commodity will give the quantity; or divided by the quantity, will give the rate.

Example II.—How many yards of linen at 4s. per yard may be had in barter for 120 yards of velvet at 15s. 6d. per yard?

yards: fixpence.

120 × 31 = 3720, and 3720 ÷ 8 = 465 yards.

See Exchange.

BARTH, John, in Biography, a fisherman at Dunkirk, was born in 1651, and rose by his courage and naval skill, first to the command of an armed galley in 1675, and at length, in 1692, to the rank of commodore of a squadron in the navy of France. By his nautical conduct and intrepid bravery he performed many signal exploits, and rendered himself the terror of the French ships. In consequence of one of his gallant actions, he was ennobled by Louis XIV.; but he still retained the rough manners of a tar. "John Barth," said the king to him one occasion, "I have made you a commodore." John replied, "You have done right." This naval officer, distinguished more by daring and prompt enterprize than by any comprehensive and complicated plan, died in 1702, and was buried in the great church of Dunkirk. Nouv. Dfl. Hist.

BARTHE, Nicholas Thomas, was the son of a merchant at Marseilles, and born in that city in 1733. He was educated under the fathers of the oratory; and obtaining a prize from the academy of his native place, he afterwards became a member of it. His father had defined him for the bar; but his talents led him to the cultivation of polite literature and poetry. Removing to Paris, he devoted himself to the theatre; and in 1764, began to write for the stage. His pieces were "L'Amateur," "Les Fauves Infi- diers," "La Mère jalouse," and "L'Homme parfait." The two first were well received, but the last did not possess sufficient energy and vivacity to please the public. Barthe then ceased to write for the stage, and engaged in a translation of Ovid's "Art of Love." He also published a collection of fugitive pieces in verse, in which his pieces of composition he excelled. His epistles are also admired for their philosophical gaiety. Barthe blended with impetuosity of temper a friendly heart. Attached to social pleasures, he passed his time chiefly at Paris; and after having undergone the operation for an incarcerated hernia, died in this city in 1785. Nouv. Dfl. Hist.

BARTHELEMY, John James, in Biography, a French abbe, distinguished by his literary character, was born in Jan. 1715, at Cires, a small port in Provence. At the age of twelve years he was sent to Marseilles, and pursued his studies in the college of the oratory under the influence of father Renaud. He intended to devote himself to the ecclesiastical profession, but from the Jesuits' college for the study of theology and philosophy; but dissatisfied with his masters, he formed a plan of private study, which comprehended the Greek, Hebrew, Chaldean, and Syrian languages, and in the prosecution of which he brought on a dangerous illness. Upon his recovery he entered into the Seminary, where he received the clerical tonsure; and by the assistance of a young Moravian, he became a proficient in the Arabic language. From Marseilles he retired to his family at Aubagne, and in this domestic retreat pursued his studies with unabated application. Among his friends at Marseilles, whom he occasionally visited, was M. Cary, who presented a choice cabinet of medals and an appropriate library, to which he had access; and he was thus led to indulge the predilection for this kind of study, which distinguished his researches and character in the progress of his life. In 1744 he visited Paris, and was introduced by M. de Boze, keeper of the royal medals and secretary of the academy of inscriptions, to the most eminent members of the three academies, and also recommended to be his assistant in the care of the cabinet of medals. In 1745, he succeeded M. Borelli as associate to the academy of inscriptions, M. Le Beaur declining a competition; and when he was nominated by the minister to the office of secretary to the academy, he waived the nomination in favour of M. Le Beaur, as an acknowledgment of his liberality. In return, M. Le Beaur, when he resigned this office, gave his interest to Barthlemy, who succeeded him. Thus did these distingushed rivals vie with each other in the exercise of a liberality which reflected equal honour on both. Barthlemy enriched the Memoirs of the academy by many communications relating to ancient monuments, and among others, by a valuable dissertation on the inscriptions found at Palmyra by the English travellers. On the death of M. de Boze, in 1773, Barthlemy succeeded him as principal keeper of the medals. In the following year he followed M. de Stainville, afterwards duke de Choisy, and prime minister, to Rome, and made a tour to Naples, where the subterranean treasures of Herculanenum and Pompeia engaged his particular attention, and where he exerted himself with peculiar zeal in the preservation of the Greek manuscripts. As he was not allowed to make any transcript,
transcript, it was by some contrivance and with the help of a retentive memory that he was able to bring away a specimen of the most ancient mode of writing practised by the Greeks. On his return to Rome he gained great applause for a new and ingenious explanation of the famous oracle at Delphi; the ancient Pythia, which, according to him, related not to Sylva, but to the emperor Adrian. In 1755, Barthelemy returned with his patron M. de Saintville to Paris, who, on his accession to the office of prime minister in 1758, anticipated and more than gratified his wishes, which were moderate, by various pensions, and at length by the place of secretary-general of the Swafs. When his patron Choiseul was banished, in 1771, to his seat of Chanteloup, in order to make way for D'Aignillon, Barthelemy accompanied him in his exile, and as he determined to resign his secretariaty, an accommodation took place, by which he retained a pension of 10,000 livres on the post. His income was now about 35,000 livres per annum, which he reduced, by several grants to indigent men of letters, to 25,000. This income he enjoyed with liberality; and he devoted a great part of it to the benefit of his family, and to the purchase of an ample and well-furnished library. Thus twenty years of his life were spent in literary life; but in advanced age he found himself reduced, by the suppression of places and pensions, to more necessaries; and these he was obliged to procure by parting with his library. This reverse of condition, however, he supported not only without complaint, but even with gaiety. His celebrated work, "The Travels of the younger Anacharsis," had been the labour and amusement of thirty years; its plan was laid in 1757; and it was published in 1788. It was received with universal applause, and in consequence of it he was admitted into the French academy by acclamation. Declining the office of king's librarian, which was offered to him in 1790, he continued to employ himself in the cabinet of medals, which had been augmented under his direction, so as to have doubled its number of ancient medals. It was his wish to have published a catalogue of its treasures, with suitable engravings, for the information of the learned throughout Europe; but though he had obtained, in 1787, the concurrence of the ministry, the embarrassment of the finances, and the critical events that disturbed the country, prevented the execution of this favourite project. In 1792, the infirmities of age crowded upon him; and the calamities of the times, which a person of his age and character might have hoped to escape, aggravated his other complaints. Having been denounced under pretence of the crime of malversation by a clerk belonging to the library whom he had never seen, he was arrested, and removed from the house of Mad. de Choiseul, on the 2d of September 1793, to the prison of the Madeleines. With such singular patience did he submit to his fate, that when he was conducted to the cell that had been prepared for him, he quietly reposed. An order, however, was soon issued for his liberation, and he was awakened out of sleep, and carried back to the house of his kind and liberal patrons. By way of explanation for this unexpected aggradation, he was offered the place of chief librarian; but his increasing infirmities were a sufficient apology for declining it. His decay was gradual; but the severity of the winter of 1793 hastened the termination of his life, which happened on the 25th of April, on which day, two hours before his death, he was reading Horace, till the book fell from his cold hands. He then appeared to go to sleep, and in that state expired: having attained to the commencement of his 86th year. His corporeal form is said to have been impregnated with an antique character; and his bust, sculptured by Hondoun, and expressive of the simple tranquillity and candour of a great mind, might suitably be placed between those of Plato and Aristotle. The principal work of this truly eminent person is his "Voyage de jeunes Anacharsis en Grece," 3 vols. 4to, or 7 vols. 8vo., which describes the history, manners, customs, literature, &c. of Greece, under the form of the supposed observations of a traveller Anacharis, a descendant of the ancient Scythian philosopher of that name. (See Anacharsis.) This perfon (see the author's advertisement prefixed to the work) is represented as visiting Greece in the year 363 B.C. and fixing his residence at Athens, whither he makes excursions, not only to the other Greek cities, but to Egypt, Asia Minor, Persia, and the islands of the Aegean sea. On this basis of fiction is formed a real and instructive history, supported by the authority of the most approved ancient writers and by citations from their works. The narrative of Anacharis is addressed to Arsames and Pheidim; a Persian satrap and his lady, whose characters are meant as portraits of the duke and duchesses of Choiseul. It is preceded by an introduction, in which is given a rapid but luminous view of the previous history of Greece. The elegance of style, the beauties of narration, and the judiciousness of reflection, render this the first work (says a biographer of approved judgment and taste) in point of entertainment and instruction, that so brilliant a subject has produced. It has added a capital piece to the literary cabinet of Europe, and its value has already been recognized by various editions, and translations into different languages. To the English edition in seven volumes 8vo. is added an eighth in 4to, containing maps, plans, views, and coins, illustrative of the geography and antiquities of ancient Greece. An anonymous writer (see Monthly Review, Appendix to vol. lxxx.) has suggested, that the learned author of Anacharsis may have taken the hint of his plan from the "Athenian Letters," confining of the imaginary correspondence of a few of Greek gentlemen, the contemporaries of Socrates, Pericles, and Plato; but in reality the actual correspondence of a society of ingenious persons of the university of Cambridge, who, in this affixed mode, communicated to each other the result of their researches into ancient history, and produced the best commentary on Thucydides that ever was written. However, the abbe Barthelemy having seen this in France, says the English translator, wrote a letter in consequence to M. Dutens, a respectable foreign gentleman residing in London, in which he affirms that "it was not till after the publication of his work, that he heard of the Athenian letters; and that chance alone gave him the idea of it." A collection of miscellaneous pieces of the abbe Barthelemy, in 2 vols. 8vo. was published at Paris in 1798. Gen. Biog.

**Barthelemy, St. in Geography, a town of France, in the department of the Lot and Garonne, and chief place of a canton in the district of Lauzun, 24 leagues north of Toulouse.**

**Barthius, Gaspard, in Geography, a learned philosophical writer of the sixteenth century, was born at Toulou, in Brandenburg. In 1587, and received his education at Goa, and in several other academies both in Germany and Italy. His talents and attainments attracted notice at a very early period. At the age of 17 years he translated David's psalms into verse, and in 1597 he printed a collection of all his Latin poems, written from his 15th to his 19th year. In his 16th year he composed a learned dissertation on the method of reading the Roman authors, and at 18 he wrote a commentary on the Aenid of Virgil. His acquaintance...**

Vol. III.
with the modern languages was extensive, and he made transliterations from the French and the Spanish. Such was his attachment to literary studies, that he renounced every other employment and retired to Leipzig for the purpose of prosecuting them without interruption; and so numerous were his works, both printed and manuscript, that, according to the account of Mr. Bayle, four clerks in office have transcribed more papers than Barthus. As to his morals they were not very correct, and like many other men of letters he engaged in several literary squabbles. Towards the close of his life, however, he devoted himself wholly to his religious duties: and it appears from his "Saliheues," published in 1644, that he was thus sedulously employed. He died, after having been twice married, in 1658, at the age of 71 years. The chief of his works are his "Adverfaria," printed at Frankfort in 1624, fol. comprehended in 60 books, and containing numerous emendations and illustrations of authors, both sacred and profane, to which he added two other such volumes left in MS.; his "Latin version of Aneas Gaza on the immortality of the soul," with an edition of the original joined to the work of "Zachary of Mitylene," Leipz. 4to. 1655; "Notex in Claudian," 4to. Frankfort 1650; "Comment. in Statius," 3 vols. 4to. 1644. As he trusted wholly to his memory, and never corrected what he had written, his works abound with mistakes and contradictions. Gen. Dict.

BARTHOLINE, Caspar, son of a respectable clergyman at Melanoe in Scania, a province of Sweden, and born the 12th of February 1525, gave early signs of an uncommon capacity, which his father took care to cultivate, by giving him the best instruction his circumstances would permit in his own country. Being well grounded in the learned languages, he went, prompted by his thirst for knowledge, to Roflock, Wittenburg, and in succession, to the principal schools in Germany, France, and Italy, travelling generally on foot, his finances not permitting him to use the ordinary conveyances. Having accumulated a vast flock of learning, in languages and philosophy, but particularly in anatomy and medicine, to which his genius particularly inclined him, in 1610 he commenced doctor of medicine at Bafi; and the following year, going to Copenhagen, he was first made professor of the Latin language, and in 1613 of medicine, in the university there. This post he continued to fill until the year 1624, till mindful of a vow he had made, when afflicted with a severe illness, that if he should recover he would dedicate a portion of his life to the study of divinity, he abjured medicine for theology, to which he added himself for the remainder of his life; enjoying, with the professorship of theology, to which he was preferred at the university of Copenhagen, a canonry at Rofchild. He died July 30, 1629, at Sora, a small town in the island of Zealand, leaving, as we learn from an inscription on his monument at Copenhagen, where he was buried, two sons and one daughter. His publications were numerous; and though not always well chosen as to the subjects, and adopting in them many popular and erroneous opinions since exploded, yet they were of considerable utility by exciting a spirit of inquiry; to which we may attribute some at least of the discoveries in anatomy, and other branches of natural history, made about that time. A complete catalogue of his works is given by Vander Linden, and by Haller, in his Bib. Anatomi. & Med. The following will be sufficient to be noticed here. "Anatomie inquisitiones, corporis humani utriusque sexus historia et declarationem exhibentes." Wittenburg, 1611, 8vo. This work, much improved and enlarged by his son Thomas, has passed through numerous editions. "Enchyridion philosophicum, ex priscis et recentioribus philosophi accuratissimum concinnatum," Argent. 1625, 12mo. "Opuscula quatuor figurari. 1. De unicorniis, conjunctis affinis et succedentibus. 2. De Lapide Nephriticum, et Amalites. 3. De Pygmatis. 4. De studio medico incerto, continuando, et abolvendo." Hassiae, 1628, 12mo. "Syntagma Medicum & Chirurgicum, de cautercis, prefertim potestate agentibus." Hassiae, 1624, 12mo. Haller. Bibl. Med. et Anatomi. Etyc. Dict. Haf.

BARTHOLINE, Thomas, the second son of Caspar, was born at Copenhagen in 1616. Equalling, perhaps excelling, his father in genius, learning, and industry, with more ample means for prosecuting his studies, and enjoying a much longer portion of life, his advances in literature and philosophy were proportionately greater. After being well grounded in classical learning at Copenhagen, following the example of his father, he travelled over the greatest part of Europe, conversing with the most learned men in every place he visited, to whom the fame acquired by his father gave him ready access. At Leyden, where he commenced his medical studies, he also acquired a knowledge of Arabic under the celebrated Golius. He then went to Paris and Montpellier, and after refusaing a proper time at these places, to Padua, which he describes in his book "De Peregrinatione Medica" as one of the ablest anatomical schools in Europe. At Padua he continued three years, imbibing there the fofeiore of knowledge which laid the foundation of his future honours. Returning to Copenhagen, after an absence of eight years, he visited Bafi, where he was created doctor in medicine, in 1645. At Copenhagen, he was first made professor of mathematics, and the year following, of anatomy, in which he soon became a shining ornament. But though the science of medicine had engrossed the greatest part of his attention, no small portion of his time had been spent in acquiring knowledge in other branches of philosophy, as well as in philology and antiquities, as appears by his numerous dissertations elucidating those subjects. He very early embraced the doctrine of the circulation of the blood discovered by Harvey, an exposition of which he added to a new edition of the "Institutiones Anatomicae," published 1651. To the discoveries of Afulius and Peronct, of the I:z:neals and thoracic duce, he added that of the lymphatics, of which he published an account in 1653, under the title of "Vafa lymphatica, nuper Haffini in animantibus inventa et in homine," Haffini apud G. Holli. 4to. These vesels had been seen about the same time by Jullii and Riddle, and Haller, who examined with attention the claims of the several parties, gives to Ruddle the honour of the invention, but to Bartholine that of having traced and determined them with the greatest accuracy. Having filled the chair of professor of anatomy with the highest reputation for fourteen years, he retired in 1660 to his estate at Horgellat, that he might have more leisure to prosecute his studies. One of his earliest publications from this retreat seems to have been his "Catalogus Operum suorum lacenatus editorum, extantum manuscriptorum effar rarissimi usi medicorum," Hass. 1661, 8vo. This catalogue, though then very large, was afterwards more than doubled. A complete catalogue of his works was published by Thomas B. one of his sons, in 1681. In 1670, his house, with his large and valuable library, and manuscripts containing embryos of intended works, and large collections for further improving and enlarging those already published, were burnt, and he was again driven into the world. As some compensation for his loss he was made physician and aulic counsellor to the
the king (though it does not appear he was ever much engaged in the practice of medicine), and the university of Copenhagen appointed him chief inspector of their library. Of this accident he gave an account the same year in a small work, intitled, "De Bibliothecae Incendio, Difcretatio ad Filios," complaining heavily of the malignity of Vulcan. Among the number of manuscripts destroy by the fire, he lamented in a particular manner those intended to elucidate his "Antiquitates puerperii variorum gentium, imprimis Romanorum." "Opus (he says in his letter to his sons) varia eruditione, nisi me felicit oleo, reperiri, cujus prima lineamenta duxi annis abhine triginta et amplius, susu Cl. Walker, qui id argumentum detederi monuit. Msurus quidem, Graeciae literatura interpres celebris, de Graecorum puerperio folia olim publici juris fecit, sed nimirum brevitate lectorem curium fatare non poterit. Ad plurimae figuras egisse, quicquid autem veterum lectione absque, quicquid phileologorum aliorum observationes, quicquid variorum gentium instituta, mores, ritus, antiquitates supplementatunt, quicquid ad hoc argumentum illuifrandum Ebraei doctores, Graeci fipientes, Romani scriptores conferre potuerunt, cum deleta felegi, et quo ordine redidit, gratia et diffusa varietate nafceendi tempora percurrunt, quid nemen ante nativitatem, quid in puerperio, quid potece actum fuerit. Ornariur librum juftae magnitudinis, varie veterum inscriptiones, et figure paffim Roma, Neapolii, Gaetae, Florentiae, in Sicilia magno frudio ab me collacte ex ruderibus, et dotorum variorum monumentis, quibus eisque temporis fatis proculfent, fidem publico expolure potuiffen. Jam in ipso puerperio fectus, in parto laborans, extuisti, Luciun inimicum nuncum folicitebat, nec profum nec pofveramta. Abit enim illius, unde negant redire quemquam. His honf Caftar, qui had turned his attention to the fame subject, and probably copied many of the notes made by his father, in some small degree repaired the accident by adding them with some of his own to a new edition of his father's works, which he published in 1676. On which occasion the father writes (see epifile affixed to the work), "eripuit nifi Vulcanus argumentum bene de publico me rendit, ut tibi occasionem priferet caligine profundae veritatis obsidibus materiam propagari. Ex me infortunio, tibi gloria reticfa vitceur. Quintamodium Saturnus in caelo Paganorum edere coeptus est filio Volio, &c." The report, however, that was every where paid him, and the letters of condolence he received from his numerous and learned correspondents, seem to have soon consoled him; as there scarce appears to have been any interruption in his labors, every year almost to the end of his life producing fome new publication. The titles of a few of his differtations, in addition to those already named, are here given; for the ref, the reader is referred to Vander Linden de Scriptis Medicis, but particularly to Haller's Biblifio. Anatom. the Bib. Med. Pract. et Chirurg., in which ample lists of the titles of the works, of the different editions they passed through, and analyses of the contents of the most valuable of them, will be found. "Anatomica Anecritum difcreti historia," Panormi, 1634, 8vo. "De Angina Purororum Campania, Sicile que epidemica," Neapolii, 1646, 8vo. "De Luce Homini et Brutorum," Leide, 1637, attempting to account for the emifion of light by putrid fefh. In a later edition he adds, "De varis et admirandis herbi, que metum huc," "De Anoma Anatomica Haffinenis," containing a catalogue of the anatomical preparations, &c. contained in his cabinet, 1662, 8vo. "Centuria quatuor epif- tularum medicarum," containing his correspondence with the most celebrated men of the age in which he lived. This valuable collection has been completed, and republished at the"
of the ancients, under the title, "De Tibiis veterum, et earum antiquo uf, libri tres." This work first appeared at Rome in 1677, dedicated to cardinal Sigilmund-Chigi. The second and third edition was published at Amsterdam, 1679, 12mo, with double the number of copper-plates with which the Roman edition had been ornamented, representing ancient musical instruments from drawings chiefly made from ancient sculpture, which are well executed; and illustrated with quotations from the classics where their use is mentioned. No book of the kind seems to have been written since of equal authority; as recourse has chiefly been had to this little tract, by Fianchin, Bonanni, and others who have written expressly on the subject of ancient musical instruments. In 1678, he was received doctor in medicine at Paris. Returning thence to Copaghagen, he was made professor in medicine at the university there, and was in such high estimation as to be raised by the king, in the latter part of his life, to considerable offices in the state. Besides re-publishing several of the works of his father, and contributing largely to the Acta Hafiensia, his own distinct treatises are sufficiently numerous and valuable to entitle him to rank with the celebrated authors of that age. The titles of a few of them follow; the remainder will be found in the Bib. Anat. and Med. Pract. of Haller.

"Exercitationes musicales vari generis, inprimis Anatomiae," Leid. 1675, 8vo.
In the seventh, he gives an account of a fluyt efficaciously in flipping hemorhaises, taken inwardly. An experiment was tried with it successfully before the king. "De Diasphragmatis structura nova," Paris, 1676, 8vo. Drehicourt claims the honour of this discovery; and, as Caspar B. was only twenty-two years of age when he published this account, Haller seems to decide in favour of the claim of Drehicourt. "De Formatione et Nutruntione Fœtus in Utero," Hafienae, 1687, 4to. "Specimen Historiae Anatomicae Partium Corporis Humani," Hafienae, 1701, 4to. He died early in the last century, but in what year is not known. His brother Thomas was appointed to the professorhip of law and history. One work of merit is attributed to him, "De Causs Moris a Danis gentilibus contempta;" and a dissertation published in the fifth volume of the Acta Hafiensia. "De Vermibus Aceti, et de Vermiculis feminilibus." The rest of the family of Thomas are said to have distinguished themselves so as to be appointed to honourable situations; but these perhaps were rather the homage paid to the virtues and talents of their ancestors than to their own merit, as none of their works have been noticed by bibliographers. Vander Linden. Haller. Bib. Anat. et Med. Pract.

BARTHOLOMEUS DE GLANVILLE, an English writer who flourished about the middle of the 14th century, wrote "De proprietatis rerum," which was first printed in fol. by Caxton, 1480. It was translated into English by Trevisa, and printed by Wynkin de Worde in 1507, and again by Bertholet fol. 1555. The original has passed through many editions. In the seventh chapter, he treats of all diseases a capita ad cæcum; taken, Friend says, principally from Coelantome. Haller. Bib. Med. Pract.

BARTHOLOME, in Geography, a town of Germany, in the circle of Bavaria and provostship of Berchtesgaden, near the Königs, 15 miles south of Reichen-hall.

BARTHOLOMEO DE XONOPANI, St. a town of in North America, in the province of New-Mexico.

BARTHOLOMEO, St. a town of North America, in Mexico and province of Chippa, chiefly peopled with Indians.—Alto, a town of Italy, in the kingdom of Naples, and province of Otranto, 19 miles E.S.E. of Matera.—Allo, a town of Italy, in the kingdom of Naples, and province of Capitanata, 6 miles south of Volturara.

BARTHOLOMEW, St. in Biography, one of the 12 apostles, whose native country was Galilee, is supposed by some writers to have been the same with Nathaniel, one of our Lord's first disciples. It has been generally thought, that he preached the gospel in India; and that he carried thither the gospel of St. Matthew in Hebrew, where Panteus found it towards the close of the second century on occasion of his peregrination into that country for the fame benevolent and laudable purpose. St. Jerome adds, that Panteus brought this gospel home with him to Alexandria; but this fact is disputed; and St. Jerome is supposed to have mistaken the words of Eunapius, who only says that the Christians of India had preserved that Hebrew gospel till the time of Panteus. (See Ruffo, H. E. lib. v. c. 10.) Hieron. de Vir. Illust. c. 56.) It has been also said, that Bartholomeus preached in Arabia Felix and Peræa; and that, returning by way of the more northern and western parts of Asia, he preached at Hierapolis and in Lycaonias; and that he died at Alaba, probably Albania in Albania, on the Caphian sea and confines of Armenia. At this latter place, it is said, that he was slain alive by Altyges, brother to Polemon, king of Armenia, from hatred to the Christian religion, which the apostle had induced Polemon to embrace. But the time, place, and manner of his death have not been satisfactorily ascertained. Dionysius the Areopagite writes the writings of Bartholomew; and Jerome (ubi ibi, and Pref. in Comment. in Matth.) mentions a "gospel of St. Bartholomew," which pope Gal- lius, in his decree, refers to the clas of apocryphal books.

Of this book there are not any fragments extant; unless, as Mr. Jones (Method of settling the Canon, &c. vol. i. p. 211.) inclines to think, it was the same with the "gospel of St. Matthew, which was used by the Hebrews or Nazarenes. This learned writer infers from the relations of Eunapius and Jerome, that this gospel was that which had been found in India; but that it had undergone many interpolations and additions: for, says he, it cannot be thought improbable that those who heard St. Bartholomew preach and explain this gospel to them, should after his departure rather call it by his name, whom they did not know. Besides, Nicephorus affirms us (Hift. Eclef. l. iv. c. 32.), that Bartholomew dictated the gospel of St. Matthew to them from his memory, and did not bring it along with him.

BARTHOLOMEO, of the Martyrs, a Dominican monk, and archbishop of Braga, was born at Lisbon in 1514, and entered into the Dominican order at the age of 14, on which occasion he renounced his family name of Fernandes, and assumed that of the church in which he had been baptized. Having taught theology for 20 years, he as length, with great reluctance, accepted the charge of the archbishopric of Braga, to which he was appointed by queen Catharine. Soon after his appointment, he was deputed, in 1561, to attend the council of Trent, in which he strongly insisted on commencing all reforms with that of the clergy. On his return from the council, he devoted his whole time and revenue to exercises of benevolence. Accordingly, he used to say, "I am first physician to 1400 hospitals, which are the parishes of my diocese." During the famine which afflicted Portugal in 1567, and lasted seven years, the poor of Braga were liberally supplied by the archbishop; and he even extended his donations to those of superior condition who felt the severity of the times. The famine was succeeded by a plague; and on this occasion the archbishop, who remained at Braga and obliged the parish priests to do so likewise,
likewise, contributed in no small degree to the relief and comfort of the distressed. Having, after repeated solicitations for the purpose, obtained leave to resign his archbishopric, he retired to a monastery of his order at Viana, where he spent the eight last years of his life in study and religious exercises; and there he died in 1590. In 1733 he was beatified by Clement XIV. The writings which he left were collected and published at Rome in 2 vols. folio. 1744. Nouv. Dict. Hist.

**Bartholomew's Day, St.** in the Calendar, a festival of the Christian church, celebrated on the 24th of August. On this day, in the year 1662, the act of uniformity which obtained the royal assent on the 10th of May, took place; in consequence of which about 2000 ministers relinquished their preferences in the church, or refused to accept of any upon the terms of this act. See **Uniformity**.

It was also on the eve of St. Bartholomew in the year 1572, that orders were issued for extending the horrid massacre which had been begun at Paris: in consequence of which the matins of Paris, as this massacre was flyed in allusion to the Sicilian vespers, were repeated in Marseilles, Orleans, Troyes, Angiers, Toulouse, Rouen, and Lyons: so that in the space of two months, 30,000 protestants were butchered in cold blood; if that expression may be used, in speaking of people influenced by the most detestable passions.

**Bartholomew's Hospital.** See **Hospital**.

**Bartholomew, St. in Geography.** one of the Caribbean islands in the West Indies, about 25 miles north of St. Christopher's, and in circumference about 24 miles. It was peopled in 1648 by Poineyr, the French governor of St. Christopher's; and enjoyed by the French without molestation till the year 1699, when a defeat was made upon it by Sir Timothy Thornhill, who ravaged the country, and carried off about 700 of its inhabitants, with their cattle and effects.

The English government, however, disapproved of this conduct, and allowed the inhabitants to repose in their island, as subjects of Great Britain. At the peace of Ryswick, it was restored to France; but as long as it continued in their possession, it was a nest of pirates, and it had fifty English prizes in its harbor at the same time. It was ceded by France, in 1783, to the Swedes. The shores of this island are dangerous, and cannot be approached without a good pilot. The only port in the island is "Le Ca-

nagre," near which stands "Guilavir," the chief town in the colony. This port is situated on the western side, and has excellent harbors; but it cannot admit vessels that draw more than nine feet of water. However, it will contain 1000 ton veals; in which respect it is superior both to St. Eulalia and St. Christopher. The bay of "Colombia" is deep enough for large ships, but it has no town on its banks; nor had "Le Carenage" any town belonging to it before the island became the possession of Sweden. Its soil is but indifferent, and only a small part of it admits of cultivation; and yet it produces tobacco, cotton, and cañava, and abounds with woods of various sorts. The plantations that most abound are those of cotton, which succeed very well. The practice of the planters is to sow four or five grains of the seed in a hole, and when the plants appear they pluck up all but the strongest. After the first crop, they cut down the branches, and the plant pulls out new shoots, which bear like the original item; but after the second crop, the seed must be again sown. The fences of these plantations are aloe trees, which are placed in a straight line, and as close together as possible; and when they arrive at maturity, they are impenetrable either by men or animals. St. Bartholomew also furnishes the neighbouring islands with a peculiar kind of limecane; and its birds are very numerous. The climate is in general healthy; though at certain times of the year the weather is variable. For nine months in the year it is pleasant; for, though the heat is scorching, the air is cooled and purified by a breeze, which is very refreshing. Hurricanes prevail from the middle of July till the middle of October. The population of this island is much increased since it has belonged to Sweden. At Guflavia are Swedes, English, French, Danes, Americans, and Jews; but the planters are chiefly French. The natives generally live, without being subject to much illness, to an old age. The men are robust, but the women are frail, feeble, and indolent; and are unusually attended by slaves, who are employed in keeping off the insects that would incommodate them. The houses are made of wood; and some of them are raised upon stone pillars, so that the wind can pass under them. Their windows are mere openings in the sides, with window shutters or lattices. The inhabitants are supplied with fresh provisions, flour, dried fish, and salted meat from the continent of America. Although this island abounds with mountains, it is deficient not only of lakes and rivers, but even of springs. The fresh water is supplied merely by the rain, and is kept in cisterns; and it is sometimes procured from St. Christopher's, and often at the charge of twelve livres per ton. The chief products for exportation are drugs, cotton, lignum vitae, and iron-wood. The coins used in this island are the moidore and the piaffe; and they have also a fictitious money called the pilawett, worth something more than 2 of a piaffe, and a small silver coin called a dott, and another coin called a bött, of the value of 6 doppes. See "A Voyage to the Islands of St. Martin, St. Eulalia, and St. Christopher, undertaken at the expense of the Academy of Sciences at Stockholm." N. lat. 17° 56'. W. long. 63° 11'.

**Bartholomew, St.** an island in the Southern Pacific ocean, being one of the cluster of islands, called the New Hebrides. S. lat. 15° 42'. E. long. 167° 17' 30'.

**Bartholomew's island, lies in the group of Magellan, half a league E.N.E. from Elizabeth island. S. lat. 52° 56'. W. long. 71° 5'.

**Bartholomew's Island, or Whernsbyen, is situated on or near the coast of New Guinea. S. lat. 8° 13'. E. long. 138° 35'.

**Bartholomew, St.** a parish in Charleston district, in South Carolina, which, by the census of 1790, contained 12,666 inhabitants, of whom 10,328 were whites. It sends three representatives and one senator to the state legislature.

**Bartholomew, Cape, St.** in the southernmost point of Staten land, in the islands of Le Maire, at the south end of South America. To the W.N.W. lies Middle Cape, and between them is a bay. To the east of it is a small island.

**Bartholomew is the name of a ledge of rocks, nearly fixed from the S.W. extremity of St. Mary's island, the largest of the Scilly islands between which and St. Mary's island, is a channel called St. Mary's found.

**BARTHOLOMITES, in Ecological History, a religious order founded at Genoa in 1507; but on account of the irregular lives of the monks, the order was suppressed by pope Innocent X. in 1650, and their effects were confiscated. In the church of the monastery of this order at Genoa is preserved the image which, it is pretended, Christ sent to Abgarus.

**BARTSCH, George, in Biography, surgeon and oculist at Dresden, born at Koningberg about the middle of the 16th century, is said to have invented a speculum to fix the eyelids while performing an operation on that organ; which was improved by Verdun, and still further by Rynth or Ray, for they contended for the honour attached to it. He
BAR

He wrote a treatise on the diseases of the eye, in the German language, published at Dr. Delen in fol. 1583. It has since been translated into Latin, and passed through several editions. There are many plates; those representing the different parts of the eye are taken from Velatus. Infected with the superstition of the age in which he lived, he attributes some of the disorders of the eye to witchcraft.

BARTLEMEW Bay, in Geography, lies on the coast of Kent, without the North Foreland, between that and Ramsgate.

BARTLET, a plantation of America, in Hillborough county, New Hampshire, containing 248 inhabitants.

BARTMEISE, in Ornithology, the name of the bearded titmouse. *perus biarmius* in Frinch. Hill. Birds.

BARTOLET, in Biography. See Planckel.

BARTOLI, Daniel, a learned Jesuit, born at Ferrara in 1608; author of many profound and useful works, written in Italian, with a preciosity and purity of style which have inclined his countrymen to rank him among the first scientific writers in their language. The great historical work of Bartoli appeared in 6 vols. folio, printed at Rome in succession from 1650 to 1673. After the life of St. Ignatius, he begins with the establishments and labours of the Society in Asia, comprised in 5 vols. and divided into those of the East Indies, Japan, and China. In two other volumes he treats of England and Italy. This performance was translated from the Italian into Latin by father Giannini, and printed at Lyons. He published at Bologna, in 1680, a work in 4to, intitled, "Dal fuono de tremori armonici e dell' udito" (of harmonical vibrations of sound and of the ear). In this truly scientific and ingenious work are to be found several discoveries in harmonics, that were purposed by posterior writers on the subject. It contains four dissertations; the first treats of the similarity between the circular undulations occasioned in full water when a stone is thrown into it, and the propagation and motion of sound. The second, of the motion of sound compared with that of light; of echoes, or reflection of sound, and of its augmentation in a whispering room or gallery. Third, of harmonic vibrations, and ratios of sound; of sympathetic sounds; of the breaking a glass with the voice. Fourth, of the mixture of sounds; of consonance; harmonics; and the immense increase of sounds in a vessel, or inclosed place, by repercussion. With many other curious enquiries; and ends with the anatomy of the ear.

BARTOLI, Pietro Sante, called Perugino, an engraver of reputation, was born at Perugia about the year 1635, and resided chiefly at Rome, where he died in 1700. He is mentioned as a painter, but his character as an engraver is more established. He drew in a correct, agreeable style; and his plates, which are chiefly etched, are executed in a free, masterly manner. His distinguishing excellence consisted in copying the bas-relief, and other works of the ancients. His manner is original; and though his name is not always marked at full length upon his plates, they are easily distinguished by persons acquainted with his works, as the freedom and lightness of his pencil cannot easily be counterfeited. Among his detached prints are: "St. Charles kneeling, accompanied by an Angel," from Antonio Caracci; and the "Adoration of the Shepherds," from Annibale Caracci. Strutt.

BARTOLO, a lawyer of the 14th century, was born in 1143 at Saissorrato, the ancient Sentinum, in the marche of Ancora, pursued the study of the law at Perugia and Bologna, and attained to such eminence, that he was distinguished by the pompous titles of "Light and Star of Jurisconsults," "Master of Truth," "Lamp of Right," "Guide of the Blind," &c. In 1339, he was elected professor of laws at Pisa; and after remaining 11 years in the exercise of this office, he removed to Perugia, where he opened a school of law, celebrated through Italy, and frequented by a great number of students. When Charles IV. visited Perugia, in 1355, Bartolo secured his friendship to such a degree, that he obtained for Perugia all the privileges usually granted to universities, and for himself the titles of counsellor, and domestic commenial of the emperor, with permission to bear the family arms of the king of Bohemia. Bartolo is said to have acquired great wealth, and to have died at Perugia in the year 1359; but the time of his death is not precisely ascertained. He was of a ftable constitution, and his temperament was such that he is said to have weighed his food. His learning and researches were extended beyond his own profession, and his regard for the libraries induced him to make the Hebrew language the object of his particular attention. His works, comprehended in 10 vols. folio, were printed at Lyons in 1545. Nouv. Dict. Hill.

BARTOLOCCI, Julius, a Cilician monk, was born at Celiano in Abruzzo, in the year 1615, and became famous for Hebrew and Rabbinical learning. Having been 36 years professor of Hebrew in the college of Neophytes at Rome, and also Hebrew writer in the Vatican, he died in 1684. His great work is intitled, "Bibliotheca Rabbinica de Scriptoris et Scriptis Hebraicis," 4 vols. folio. It was printed by the college "Propaganda," and the volume appeared successively in 1675, 1678, 1683, and 1693. The fourth volume was completed by his scholar Imbonati, who, in 1694, added a fifth, intitled, "Bibliotheca Latino-Hebraica." This work furnishes valuable materials for assuiling the interpreters of the Hebrew scriptures. Bartolocci left also annotations on the book of Tobit. Moreri.

BARTOLOMEO, Baccio. See Baccio.

BARTOLOMEO, Breunberg. See Breunberg.

BARTON, Elizabeth, called commonly "The Maid of Kent," was an enthusiastic impartial, first known in 1525, as a servant at Aldington in Kent. Being subject to hysterical fits, which were attended with a variety of agitations and dilortions, the superstitiousness of the age led the common people to believe that she was supernaturally inspired. Matters, the parson of the parish, thought that she was a fit person to be employed in order to support the declining cause of Rome, or to give celebrity to his own chapel, and accordingly resolved to exhibit her as a prophetess. With this view, he and some of his friends took her under their tuition; and taught her to act her part so well, that she not only deluded the common people, but imposed on the credulity of several persons of rank and learning; among whom were Sir Thomas More, Bishop of Rochefeller, and Warham archbishop of Canterbury. The monks and ecclesiastics, who were appointed by the latter to investigate this business, made a favourable report, and encouraged the imposture. The nun, for such was the character she had now assumed, was conducted in triumphal procession, and attended by a mob, to the chapel of the Virgin at "Court of Street;" and when she appeared before the image of our lady, the fell profirate in one of her trances, delivering rhymes, speeches, &c. all of which tended to the honour of that saint, and of the Popish religion. Having for some time performed in this way, very much to the honour and profit of her employers, she was further instructed to denounce menaces against the king on account of his divorce from queen Catharine, and his marriage with Ann Boleyn, and also his eminence to the church, and to declare his subjects abjured.
BAR

solved from their allegiance. Henry, who had for some
time defied the iumpulce and its abettors, being at last
jealously incensed, issued an order that, in November 1533, the
maid and her accomplices should be apprehended, and
brought into the star-chamber; all of whom, upon their
examination, confessed the iumpulce, and afterwards pub-
lieiy confirmed their confession before the people at St. Paul's
Cross. Some attempts having been made to induce the
ump to retract her confession, measures of severity were adopted,
and an act of parliament was passed (25 Hen. VIII. c. 12.)
which attainted them of high treason, for a conspiracy
against the crown and life of the king. Accordingly Elizabeth
Barton, and five of her accomplices, were beheaded at Ty-
burn in April 1534; the deluded nun, who was a simple and
ignorant woman, having made a previous acknowledgement
of her crime and the justice of her sentence. Bagg.

BARTON-Upon-Humber, in Geography, a large market-town
in Yorksborough hundred, Lincolnshire, England, 34 miles from
Lincoln, and 167 north from London. It consists of several
streets irregularly built, and has two large churches. By an
ancient register this appears to have been a much more con-
derable and extensive place than at present; but the destruc-
tive plague which infested it in the reign of queen Elizabeth,
may, in a great measure, have caused its declension. The
most ealy pavement to Hull is from Barton-Ferry. The market
is held on Monday; and it has a fair for horses, oxen, and sheep.
At Horkstow, in this neighbourhood, was lately discovered
a curious Roman teattered pavement, which is particularly
described by Mr. Llions, in the first part of "Reliquiae
Romanae." This town includes 412 houses, inhabited by
1700 persons. N. lat. 53° 40'. W. long. 0° 22'.

BARTON, a township of Orme county, in the shire of
Vermon, America, formerly in that of Orange, lies S.W. of
Brownstown; 6 miles S.W. by W. from Willoughby Lakes,
and 140 N. easterly from Brunswick.

BARTON, in Devonshire, and the west of England, is used
for the supplying lands of a manor. Also for the manor
house. And, in some places, for out-houses, fold-yards,
&c.

BARTRACH, in Geography, an island in the bay of
Killala, at the mouth of the river Moy, about 2 miles long,
and half a broad; 2 miles N.E. of Killala.

BARTRAMIA, in Botany. See TRUMPETEA.

BARTSA, in Geography, a town of Hungary, 14 miles
N.E. of Szepen.

BARTSENLU, a town of Asiatic Turkey, in the
province of Natalia, 32 miles S. of Kutaia.

BARTSIA, in Botany, a genus of plants so named by
Linnaeus, in memory of his friend Dr. Bartisch. It is an
inmediate genus between rhinanthus, euphrasia, melampy-
rum, and pedicularis; distinguished by its colored calyx.
Lin. gen. 739. Schreb. 916. Juss. 100. Clas. dlyma-
nia anguiformis. Gen. char. Cal. perianth one-leaved, tu-
mular, permanent; mouth obtuse, two-lobed; lobes emar-
ginate, coloured at the top. Cor. monopetalous, ringent;
upper lip erect, flendor, entire, longest; lower, reflex, trified,
obtuse, very small. Stem. filaments four, broad-shaped,
the length of the upper lip; two somewhat shorter. Au-
thor, oblong, approximating under the top of the upper lip.
Pist. gern ovate. Style, diliform, longer than the filaments.
Sistema, obtuse, nodding. Per. capsule ovate, compressed,
acuminate, two-celled, two-valved; partition contrary to
the valves. Seeds, numerous, angular, small.

Cor. coloured less than the calyx; upper lip longest.
Capf. two-celled.

Horminum, Morris. "Leaves alternate linear, two-toothed
on each side." This is a very beautiful plant, with a stem
entirely simple. Leaves divided, crowded towards the top
into a spike, having a single flower on each leaf. Calyx-
ised towards the tip of a very deep red, as are also the
trifid bractes. Capsule eliptic. The fructification is not
yet well ascertained. It has been found in Virginia, Mary-
With. Smith Eng. Pot. 1. 361. Flor. Dan. 43. Euphras-
ia rubra, &c. Ray Syn. 285. "Leaves opposite, heart-
shaped, bluntly ferrated; anthers hairy." Smith. Root
perennial, creeping; stems from four to eight inches high,
creep, simple, square, hairy; leaves opposite, sessile, ovate
or cordate, ferrate, rugos. bulky, hairy on the upper side, those
near the top coloured, spike terminal, purple, leafy; calyx
vivid, hairy, purple, its segments nearly equal, acute;
corolla of a violat purple, three as long as the calyx,
compress, clothed with glandular vifid hairs; lower lip re-
flexed; anthers prominent, very hairy; style bifurcate, pro-
gressing beyond the flamens; capsule ovate, downy, of two
valves, with a transverse partition arising from each;
seeds numerous, angular, small. This rare plant prefers a moist
flory soil in alpine situations; it has been found in Welf-
morland, Durham, and in the highlands of Scotland.—
Ray Syn. 285. "Leaves ferrate, uppermost alternate;
flowers diffant, lateral." Root annual, fibrous; item about
a foot high, occasionally simple, unless very luxuriant; erect,
smooth, downy, leafy; leaves sessile, ovate-lanceolate, fer-
rate, nervd, febrous, lower ones only oppofite; flowers
axillary, subfebile, folitary: calyx tubular, hairy, regular,
white at the base; corolla twice the length of the calyx,
yellow, divisions of the lip obtuse, nearly equal; anthers
hairy; style hairy; capsule ovate, roundish, rough at the
apex, the two valves furnished with transverse partitions;
seeds numerous, very small, subangular. The whole of this
plant is vifid or femy. It has been found in Cornwall,
Devonshire, Lancashire, and in Argyleshire, in marhy soils,
flowering in July and August.— 4. B. palifafiella, pale-flow-
er bartfia. Amm. 2. 356. Gmel. Sib. 3. 301. n. 11.
t. 42. "Leaves alternate lanceolate, quite entire; floral
leaves ovate, toothed." Root fibrous; item round, simple,
foemewhat freaked; downy towards the top; leaves fessile,
linear-lanceolate, three-nerved, longer than the internodes;
the lower ones smaller, undivided; the upper longer, broad-
er, with an oblong tooth on each side; floral leaves involv-
ing the calyx; not longer than the fowers, but broader,
coloured, more obtuse, trifid or quinquelid; spike termi-
nating leafy, a little incising to one side; flowers alternate,
fellife; corolla purple. A native of Siberia and Hodfon's bay,
from whence it was introduced into the New garden in 1782.

Petrop. 14. p. 534. t. 18. f. 2. G. borealis, Pall. it. 3.
"Two-stamened; leaves radical, twofold, petioled; item
mostly two-leaved, one-spiked; spike linear, obtuse; whirls
bractit, collected." Stem four inches high, broad, round,
simple; root-leaves fucculent, oval, entire, or ferrate, very
smooth; in the middle of the item they are alternate, ovate,
fellife; spike of collected whips; bractes ovate, bluih;
calyx compressed, three-toothed; corolla pale blue, lower
lip bifid or trifid; capsule four-toothed. This species, which is
very variable in the size and form of the leaves, grows
within the arctic circle, on the north side of the frozen rocks
in Kamtschatka, where there is no other vegetation.—

6. B. Odontites, red barbata. Huds. 268. Smith. Brit. 648. Euphrasia odorontites, Sp. Pl. With. Balc. Curt. Lond. f. i. t. 44. "Leaves lanceolate, ferrate, the alternate upper flowers in racemes, inclining to one side; anthers smooth; root fibrous, annual." Stems branched, square; leaves falcate, lanceolate, ferrate, falcate, inferior ones opposite; racemes terminal, many flowered, leafy; flowers all on the same side; calyx purple, hairy, sometimes quilted; corolla rose-coloured; helmet entire, lips cut into equal parts; anthers smooth; capsule somewhat compressed, hairy; seeds numerous, small, flattened. Common in meadows and pastures, flowering in July and August.

BARTUS, in Geography, a town of Hungary, 16 miles N.W. of Palotza.

BARUCH, in Scripture Biography, was the son of Neriah, of the tribe of Judah, and the faithful disciple and servant of the prophet Jeremiah, who employed him as his secretary or amanuensis. This prophet, having received orders, in the reign of Jehoiachin king of Judah, whilst he was in prison, to write all his prophecies till that time, dictated them to Baruch, by whom they were read to the people assembled in the temple on occasion of the feast of expiation, B.C. 605. Baruch, terrified by the threats contained in the roll which he had read to the people, was encouraged by an assurance, that, notwithstanding all the calamities which would befall Judah and Jerusalem, he should obtain a deliverance. (Jer. xlv.) Archbishop Usher and Dr. Prideaux are of opinion, that this roll was read a second time to the people, in the fifth year of Jehoiachin, B.C. 604.; after which it was committed to the flames by the king himself: and the Jews keep an annual fast, even to this day, in commemoration of the burning of the roll: the day marked for it in their calendar is the 29th day of Cilucl, the ninth month of the Jewish year, and corresponding to our November. After the burning of this roll, another was immediately written, by God's special command, from the mouth of the prophet, by the hand of Baruch; and to this were added many other words, and particularly that prophecy with respect to Jehoiachin and his house, which is denounced against them for this impious fact, in the 50th and 51st verses of the 26th chapter of Jeremiah. In the fourth year of Zedekiah (B.C. 594.), Baruch went to Babylon with his brother Seraiah, and carried thither a written account of the prophecies contained in the 50th and 51st chapters of Jeremiah, which denote the judgments that were to be executed upon Chaldea and Babylon by the Medes and Persians. Baruch, having read these prophecies to Jehoiachin and the other captives, threw the roll that contained them into the Embraces, as the prophet had commanded him. Baruch accompanied Jeremiah into Egypt, and after the death of the prophet, he retired to Babylon, where, according to the rabbins, he died in the 12th year of the captivity. The book of Baruch, contained in the Apocrypha, is an epistle sent, or feigned to be sent, by king Jehoiachin and the Jews in captivity with him at Babylon, to their brethren that were still left in Judah and Jerusalem; with an homiletical preface, in which it is related, that Baruch being then at Babylon, drew up this epistle in the name of the king and the people, by their appointment, and read it to them for their approbation; and that a collection having been made, the epistle with the money was sent to Jerusalem. No Hebrew copy of this book is extant; but there are three other copies, one in Greek and the other two in Swine. The Jews have not received this book into their canon; nor is it found in the ancient catalogues of the scriptures, cited by the fathers and the councils. In the later catalogues, it is annexed to the book of Jeremiah, and cited by some of the fathers as a part of Jeremiah. St. Jerome (Pref. in Jerem.) expressly rejects it out of the canon; nor does he translate it, because it was not in Hebrew, nor received by the Hebrews. On the other hand, St. Cyril of Jerusalem, and the Laodicean council held A.D. 364, mention Baruch among the canonical books of Scripture. In both the catalogues which they have given, these words occur: "Jeremiae cum Baruch Lamentationibus et Epistola." But it has been alleged, that by these words they meant to express no more than Jeremiah's prophecies and lamentations; that by the epistles, is meant merely the epistle in the 33rd chapter of Jeremiah; and that the name of Baruch is added, only because he had collected these together, and annexed the last chapter, which is supposed to be Baruch's, the prophecies of Jeremiah ending with the 32nd chapter, as it is positively said in the last words of it; and it must be acknowledged, says Dr. Prideaux, that as neither in St. Cyril, nor in the Laodicean council, any of the other apocryphal books are named, it is very unlikely that by the name of Baruch, in either of them, should be meant the apocryphal book under this title, which has the least pretence of any of them to be canonical. Although the church of Rome has admitted it, and its authority has been sanctioned, after some hesitation and difficulty, by the canon of the council of Trent, it is condemned by Protestants to the class of apocryphal books. Priv. Comm. pt. i. b. i. vol. i. p. 87, &c. Dupin's Exe. Hist. vol. i. p. 28.

BARUCO, or BARICA, CAFE, in Geography, is the western point of Golfo Dulce, or Fresh-water bay, and distant from it about 4 leagues, on the S. W. side of the isthmus of Panama, in the Northern Pacific ocean, S.S.E. from Cano island, and S.E. from the gulf of Salinas. N, lat. 8° 20'.

BARUD, the name of several small places of Egypt, on the east and west side of the Nile, situated not far from Manosalut, Siout, and Dendera.

BARVER, a town of Germany, in the circle of Weiphalia, and county of Diepholz, 6 miles E.N.E. of Diepholz.

BARVILISKI, a town of Lithuania, in the palatinate of Troki, 28 miles S.W. of Troki.

BARULES, in Church History, a town which maintained that the Son of God had only a phantom of a body; that souls were created before the world, and that they lived all at one time.

BARUM, in Geography, a town of Germany, in the circle of Lower Saxony, and principality of Luneburg; 10 miles south of Luneburg.

BARUTH, in Commerce, an Indian measure containing 17 gantans; it ought to weigh about three pounds and a half avoirdupois.

BARUTH, in Geography. See BAIROUT, and BERRYTUS.

BARUTH, a town of Germany, in the circle of Upper Saxony, 22 miles S.S.E. of Potzdamer, and 54 N.E. of Wittenberg.

BARWICK, Peter, in Biography, of a respectable family of Witherfleck in Westmorland, was at an early age admitted to St. John's college in Cambridge; where, in 1643, he took his degree of Bachelor in Arts. Quitting that seminary during the troubles which at that time disturbed the country, he was entertained at the house of Mr. Sacheverel of Leicestershire, as tutor to his son. In 1665, he took his degree of Doctor in Medicine, and soon after was made physician in ordinary to King Charles II.; which occasioned him to come to London, where he soon acquired consider-
considerable reputation for his skill in his profession. He
is said to have excelled particularly in his treatment of the
small pox, and of putrid and malignant fevers; perhaps
following the method recommended by Sydenham in those
complaints: but he has left no publications on these sub-
jects. He wrote very ably in defence of Harvey's doctrine
of the circulation, at that time much agitated; and M.
Carrera attributes to him a treatise, published in London,
1671, 4to. "De his Medicorum Annum Examinant." But
the work by which he is principally known, is the
Life of his brother John Barwick, late dean of St. Paul's,
written in elegant Latin. It was published in 1724, in large
8vo. by Hillsah Bedford, and an elegant portrait of the
docthor, engraved by Vertue, affixed to it. His defence of the
"Eikon Baphilike," against Dr. Walker, which was writ-
ten in the 74th year of his age, "does not only shew,"
Granger says, "the warmth of his loyalty, but discovery
not a little of the peevishness of old age." He died Au-
gust 1753, in the 86th year of his age, highly honoured and
respected by all who knew him. Granger's Biog. Hist. of

BARWICK, John, an eminent English divine of the 17th
century, and dean of St. Paul's, was born at Wetherfield,
a little village of Westmorland, in 1612; and being de-
digned for the church, he was sent to school at Sedberg
in Yorkshire, where he mastered the rudiments of genius and
piety. In 1631, he was admitted into St. John's col-
lege in the university of Cambridge, where he became fur-
distinguished, that he was chosen, at the age of twenty,
to manage a dispute relating to the election of a master, which
was heard before the privy council, and by his conduct in
this business, he acquired celebrity in the university, and
was also taken notice of at court, and by the ministry. Hav-
ing taken several degrees at the university, he bore an active
part in the civil war, and made one of a party of horse which
conveyed the college plate and a small supply of money to
Nottingham, where the king had set up his standard. He
also published a tract against the covenant, which was so of-
fensive to persons in power, that he was obliged to retire
to London, where he rendered all the service in his power to
the royal cause. As he possessed talents that justified con-
fidence, he was employed on various occasions of importance
by the king and his friends; and he seems to have been
successful in his endeavours to reclaim some persons who
had been induced to abandon the cause to which he was de-
voted. During his majesty's confinement in Carlisbort
castle, Mr. Barwick contrived to preserve for him a free in-
tercourse with his friends; and he also concerted a plan for
his escape, which however did not succeed. After the king's
death, and when the royal cause seemed to be desperate,
Mr. Barwick, though in a very weak state, exerted himself
in maintaining a daily correspondence with the ministers of
king Charles II. This office he was at length obliged to
devolve, first on his brother Dr. Peter Barwick, and then
on another of his brothers, whom he endeavoured to rescue,
at the hazard of his own life, from the danger to which he
was exposed in consequence of a treacherous discovery. When
Mr. Barwick was threatened with torture if he did not im-
mediately disclose the names of the persons who were con-
cerned with him, he kept the secret with invincible firm-
ness; upon which he was committed to the Tower by an
order of council, dated April 9th, 1650. Here he was
confined in a close dungeon, and debauched the use of pen,
ink, and paper, and of all books except the bible. In this
situation he remained many months, during which his diet
was herbs or fruit, and water-gruel made of oatmeal or barley, with currants boiled in it, and sweetened with a
little sugar; and yet such was the benefit which he derived
from this slender diet, that though he was afflicted with a phthisic,
atrophy, and dyspepsy, when he was committed, he recov-
ered beyond all expectation, and grew plump and fat.
This fact has been mentioned by many physicians, as a proof
of the advantage of temperance even in the most inveterate
diseases. After two years' confinement, he was discharged
in 1652, upon giving security to appear at any time within a
twelve month before the council of state. At the expira-
tion of the year, being satisfied by president Bradshaw, who
had been dissimified by Cromwell, that neither he nor his
friends would be expos'd to any danger from the recogni-
zation into which they had entered, he again engaged with
ardour in public business, and conferred with several persons
whom he had drawn over to the king's service, on various
schemes for restoring monarchy. He was also employed in
conducting the king's correspondence, which he did with
 secrecy and success; and when a restoration was likely to
take place, he was sent over by the bishops to represent to
the king the state of ecclesiastical affairs. On this occasion,
he was received with expressions of cordial esteem by his maj-
esty, and appointed one of his chaplains. On the return of
his journey he visited the University of Cambridge, and took the degree
of Doctor in Divinity. Upon the king's restoration, he was
offered a bishopric, which he declined accepting, that
the world might not imagine that his extraordinary zeal for
episcopacy was owing to any secret hope he might indulge
in being made a bishop. Upon this he was promoted to the
deanery of Durham, with which he kept the rectory of
Houghton-le-Spring, four miles distant from the city. The
revenue which he thus acquired, he liberally employed in re-
pairing public buildings, relieving the poor, and maintaining
hospitality. In 1661, he took possession of the deanery of
St. Paul's; and by his interest with his majesty he obtained
two royal grants; one for the repair of the cathedral, to
which he himself contributed; and the other for securing
its privileges. The king also appointed him one of the nine
affiliates to the twelve bishops employed in the Savoy
conference; and he was unanimously chosen by the clergy in
convocation, their proctor. His various engagements
brought on his old complaint, which was aggravated by re-
newed application after a temporary respite, and which ter-
ninated in his death, Oct. 22, 1664. By his will he be-
cathced the greatest part of his estate to charitable uses.
As his time was so much devoted to political and public
matters, we may well imagine that his writings were not
numerous: they consisted only of three sermons; the piece
against the covenant, already mentioned; and the life of
the bishop of Durham, annexed to his funeral sermon. Many
of his letters to chancellor Hyde may be found in Thorloe's

BARYGAZA, in Ancient Geography. See Baraoch.
BARYGAZENUM PROMONTORIUM, a promontory
of India, placed by M. D'Anville at the fourth entrance of
the "Barygauszenus Sinus," or the present gulf of Cambaya.
BARYPPUCNI, in Greek Myth. The ancients gave this epit-
tet to five of the eight liable or fixed sounds of their dia-
gram; namely, the hypate hypaton, the hyaипate melsen, the
uue, the parauee, and the nede diezeugmenon. These
four terms, barypyne, mepoepyne, oxyepyne, and apyne
imply the lower spits or dense sounds; that is to say, the
spits or close intervals, the mean of the spits, the acute of
the spits, and the wide of the spits, meaning in the Greek
muic the hypate, the parhexate, the licanos, and the nede
of the tetrachords of the spits kind. By spits or close, the
intervals of the emfines in the chromatic and quarter
tones in the enharmonic, are implied. See Greek System.

Vol. III.
BARYTES, or ponderous earth; terra ponderosâ, schwerverrende Germ. baryte Fr.
The English and French names of this earth are derived from the Greek σπαρ, heavy, on account of the high specific gravity of the PONDEROUS SPAR or native sulphate of barytes, which is the commonest form in which this earth appears.

§ 1. Historical notices respecting barytes.

It is to Scheele that Chemistry is indebted for the discovery of this substance in 1774. In his valuable essay on manganece, he informs us that the nitric and muriatic solutions prepared from the native black oxyd of this metal contain besides, an earth differing from all those hitherto known by its strong affinity for sulphuric acid, &c. In 1775 Gahn made his analysis of the ponderous spar, and found it to consist of the earth newly discovered by Scheele, and sulphuric acid. Bergman repeated and confirmed the experiments of these chemists, and named the earth terra ponderosa. Morveau proposed the term barote derived from the Greek, which Mr. Kirwan softened into barytes. In this appellation Bergman acquiesced; and it is now adopted by all except the German chemists, who in conformity with their general custom prefer the term schwerverde, which is a literal translation in their own language of terra ponderosa. Wulff and Azelius contributed to enlarge our acquaintance with this substance; and in 1793 Dr. Hope published his valuable experiments in the Edinburgh Transactions. In 1796, Klaproth augmented our knowledge by his masterly analysis of the native sulphates and carbonates of barytes; and in 1797 Pelletier and Vauquelin gave to the world their able memoirs, confirming the facts already admitted and adding to them many new ones.

The only way of procuring this earth in a state of sufficient purity for chemical experiment, is to expel crystallized nitrate of barytes in a platina crucible to a moderate red heat till it becomes quite dry and has ceased to give out any vapours: the nitric acid will be wholly decomposed and volatilized, leaving the barytes behind in the form of a greyish white porous mass more or less adherent to the crucible. The nitrate of barytes is obtained either by dissolving the native carbonat of barytes in very dilute nitric acid; or by heating the native sulphat of barytes in a close crucible with charcoal, and thus converting it into sulphuret of barytes and then treating this with nitric acid, which will diffuse the earth and leave the sulphur behind. A much more economical way however of preparing this earth, is mentioned by Dartigues (Ann. de Chimie, vol. 40.) Take sulphat of barytes, pulverize it together with charcoal, and expel it for half an hour to a full red heat; by this means the greater part will be converted into sulphuret of barytes. Pour boiling water on the mass, and a clear yellow liquor will be obtained by filtration: add to this, carbonat of soda; and a copious white precipitate of carbonated barytes, four times the weight of the soda employed, will be deposited. This being separated from the solution of sulphuret of soda and washed repeatedly, is to be mixed with charcoal and again heated for about half an hour: the carbonic acid will be for the most part converted into gaseous oxyd of carbon, and the barytes will remain in a crystalline state. By a short digestion in boiling water and frequent filtration, a clear superflueate solution of barytes is obtained; from which, by evaporation and gently heating in a silver crucible, the pure barytes is readily procured.

§ 3. Chemical and physical properties.
Barytes obtained by the methods mentioned in the preceding section, is a porous mass of a greyish white colour and easily reducible to powder; its sp. gr. in this state cannot be ascertained with much accuracy; Fourcray states it at 4. Haffenfritz only at 2.574. It is the most active of the alkaline earths; and from its ready solubility, has been arranged by some modern chemists among the proper alkalies. It has a harsh caustic taste, and acts upon the animal economy as a violent poison. It is deficient of smell. It changes fyrump of violets green, and the lemon yellow of turmeric to a brownish orange.

By a strong heat it becomes harder, denser, and acquires internally a blueish green tinge. When strongly urged by the blowpipe or a stream of oxygen gas upon a piece of charcoal, it fuses and is partly imbibed by the charcoal and partly volatilized, communicating a yellow colour to the flame.

Its affinity for water is very considerable. When exposed to the air, it gradually imbibes moisture, swells, and falls to pieces; attaining at the same time the carbonic acid of the atmosphere and becoming mild; hence the necessity of keeping it in dry well-secked vials. When sprinkled with a little water, it exhibits the same appearances as quicklime, but with greater energy; the mass becomes white, is remarkably increased in bulk, and a large quantity of heat is evolved. If shriveled up while hot with an additional portion of water to the confinement of a thin plate, it assumes, as it cools, the state of a solid, made up of confused needle-form crystals; but this by exposure to the air becomes carbonated and falls into powder.

Water boiled upon pure barytes, is capable of taking up half its weight of this earth; the greater part of which it deposits by cooling, in slender delicate crystals implanted into each other, or, by carrying on the process very slowly, in the form of compressed hexahedral prisms terminated by a four-sided pyramid, and of a brilliant fatty lustre. These crystals appear to be composed of 43 parts of water and 47 of barytes. By a boiling heat, they completely liquefy; and at length the water being evaporated a white powder remains behind, which is pure barytes. By mere exposure to the air they become efflorescent, and the earth is found to be carbonated. They are fusible in about 17¾ parts of water at the temperature of 60°. The fluid that remains after the deposition of the crystals of barytes retains ¾ of the earth in permanent solution, and is called barytic water; improperly, baryte line water. This solution is perfectly limpid and colourless, has an acid taste, and possesses properties very analogous to lime water. By exposure to the air it becomes covered with a thin coat of carbonated barytes; and this being removed or falling to the bottom, a fresh crust begins to form till the whole of the earth is thus separated from the water.

Barytes, like the other alkaline earths, combines with all the known acids; and the barytic salts thus produced are for the most part readily crystallizable, and are distinguished by the strong mutual affinity of their elements: sulphuric acid in particular is dissipated by it from every other combination.

Among the simple inflammables, phosphorus and sulphur appear to be the only ones capable of uniting with barytes. If alternate portions of phosphorus and pure barytes are put into a strong glass tube closed at one end and exposed to a red heat, the phosphorus melts, sublimes, and combines with the barytes that is in contact with it into a brown fusable mass of a metallic lustre, the sulphuret of barytes. This substance when breathed upon exalts a strong fetid odour, is luminous in the dark, changes gradually by exposure to the air into phosphat of barytes, and immediately decomposes water giving out phosphorized hydrogen gas.

The
The affinity between sulphur and barytes is very considerable. Pure barytes digested in warm water with sulphur will take up more than a quarter of its weight of this substance; being then evaporated to dryness and heated red hot in a crucible, the product is a reddish yellow inodorous mass, sulphuret of barytes. Its properties have been very little examined into, on account of the great ease with which it is decomposed. Sulphuret of barytes has a remarkably powerful attraction for water, is very soluble in this fluid even when cold, but is still more so in hot water. In these cases however a decomposition of part of the water is effected; the hydrogen unites with a portion of the sulphur, and the oxygen with another portion. The new combinations that take place in this process are very interesting, and having been ably investigated by Berthollet we shall treat of them somewhat at length.  

When sulphuret of barytes is thrown into hot water it immediately dissolves; the liquid becomes of a yellow colour and exudes a strong smell of sulphated hydrogen; a white earthy sediment is deposited, and as the liquor cools a considerable quantity of crystals either aerulent, prismatic, or in plates, make their appearance: which being dried by preflute between filtering paper become perfectly white.  

Thus sulphuret of barytes by the action of water furnishes three distinct products. 1. The earthy sediment is regenerated sulphate of barytes; being produced by the oxygen of the water combining with part of the sulphur into sulphuric acid, and this as soon as forms faturating itself with barytes. 2. The crystals are hydro sulphuret of barytes, a salt remarkable for being the only one of the earthy or alkaline hydro-sulphurets that is capable of being crystallized. It is very little alterable by exposure to the air, is easily soluble in water, and is decomposable by the mineral acids with extraction of sulphuric hydrogen gas. Besides being produced in the decomposition of sulphuret of barytes, it may be made in the direct way by passing sulphured hydrogen gas through a Woulfe's apparatus containing barytes diffused in water. 3. Besides the sulphat and hydro-sulphuret of barytes, there remains from the decomposition of the sulphuret of barytes, a yellow liquor which by the addition of muriatic acid gives out a large quantity of sulphured hydrogen, and yields at the same time a copious precipitate of sulphur; hence it appears to be sulphuret of barytes, intimately mixed or more probably combined with sulphured hydrogen.  

There are therefore three modes in which sulphur can combine with barytes: the first is simple dry sulphuret of barytes, incapable of uniting with water without decomposition; the second is hydro sulphuret of barytes, crystallizable, soluble in water, and decomposable by muriatic acid without depositing sulphur; the third is hydro sulphuret of barytes, soluble in water, not crystallizable, and when decomposed by muriatic acid giving out both sulphur and sulphured hydrogen.  

Barytes, in consequence of its alkaline properties, acts on vegetable and animal matter with great energy; it forms inflable foams with oils, corrodes and disolves mucular fibre, &c.  

In the dry way, barytes diffuses files in the same manner as potash does: three parts of barytes and one of flex being intimately mixed and fused together, produce a yellowish green mass entirely soluble in nitric, muriatic, or acetic acid; from which the flex may be seperated in the usual way.  

In the moist way barytes being mixed with newly precipitated alumine forms a compound insoluble in water, but which is readily taken up by an excess of barytes.  

Barytes diffuses certain metallic oxyds, especially those of lead; but these combinations have not been much attended to.  

Barytes was for a long time suppos'd to be a very refractive metallic oxyd. Bergman, Lavoisier, and other eminent chemists adopted this opinion from its great specific gravity, from the greenish hue that it communicates by fusion with the other earths, and from its being precipitable from its solutions in acids by prussiat of potash. But in answer to these surmises it may be remarked, that metals in proportion as they become oxygenated approach to the state of acids; whereas barytes possibles alkaline properties in a very eminent degree: and that prussiat of potash when quite pure does not precipitate barytes; this appearance being always occasioned by the presence of sulphat of potash, with which the prussiat is generally contaminated.  

Barytes is an active poison to animals; as are most of its salts. It is not made use of in the large way, but is of considerable importance in the laboratory as a tell for sulphuric acid and an effectual reagent to separate this substance from all its other combinations.  

The orde of the affinities to which barytes is subject, as far as they have been investigated, appears to be: in the moist way,—sulphuric acid, oxalic, sucineic, fluoric, phosphoric, sulphuret, nitric, muriatic, citric, tartarous, andreric, fumurc, benzoic, acecous, boracic, sulphureous, carbonic, and prussiat of potash, water, fat oil, sulphur, alumine, flex; in the dry way,—phosphoric acid, boracic, arsenic, sulnphoric, fluarie, and muriatic acids, sulphur, oxyd of lead, flex, and alumine.  

BARYTONE, in Myce. See BARTON.  

BARYTONUM, from bổg, gow, and cotes, accent; in the Greek Grammar, denotes a verb, which having no accent marked on the last syllable, a grave accent is to be underflood.  

BARRAURA, in Ancient Geography, a town of Aisa, in the Parapamisus. Ptolomy.  

BARZETO, a town of Italy, in the duchy of Parma, 17 miles S.S.W. of Parma.  

BARZOD, in Geography, a town of Hungary, and capital of a county to which it gives name, sited on the Hernach, between Calisovia and Agria.  

BAS, JAMES PHILIP LE, in Biography, a modern French artist, flourishing about the year 1754, by whom we have some excellent prints. His great force seems to lie in landscapes and small figures, which he executed in a superior manner. His style of engraving is extremely neat; and yet he proves the freedom of the etching, and harmonizes the whole with the graver and dry point. We have also a variety of pretty vignettes by this artist; among which are most of those that adorn the 6th edition of Rollin's ancient history in English, published by the Knaptons in 1741. Of his most esteemed works, the following may be enumerated: viz. "The Works of Mercy," a set of several "Dutch Merry-Makings, Fairs, &c. both" from Tenier; "The Italian chafe," and the "Milk pot," and also the "Wild boar," from P. Wouwermans; several plates of "Hunting, &c." from Van Falens; the "Sea-ports of France," after Ver-
net; the "Environ de Groningue" and the "Environ de Gueldres," from Raydial. Strutt.

Bas, John Lee, a surgeon and accoucheur of considerable eminence, born at Orléans, was admitted at the academy of surgeons of Paris, in 1756, where he resided. Called upon in 1764 to give an opinion as to the legitimacy of a child born ten months and seventeen days after the death of the sup- posed father, he decided in its favour; but the case being referred to another court, the affidavit and opinion of Bou- vart, Ant. Lewis, Petet, and several other physicians and sur- geons, were demanded, who unanioufly declared against the decision of Le Bas. This gave rise to a furious literary dis- pute, in the course of which several pamphlets were written on each side. Le Bas defended the part he had taken, by the authority of Attilotote and Pliny, supported by Schen- kius and other modern recorders of extraordinary events, as well as by the decisions of the courts of law in various parts of Europe, which had been sometimes given in favour of births protracted to even more than twelve months, which Le Bas thinks might, and, he had no doubt, had happened. Bouvar and Louis, on the contrary, contending against the authority of these pretended cases of protracted gestation brought by their antagonist, which they do not admit to have been completely proved in any one instance, fix the time of parturition in nine calendar months from the time of conception; allowing it may be extended beyond that time ten or twenty days, and denying that in any one well-authenticated case, proof had been produced of a woman’s being delivered of a living child later than that period. This opinion is now, we believe, universally esta- blished. The following are the titles of the books written by Le Bas on the subject: "Quelion important: Peut on détérminer le temps de l’accoucheument," Paris 1764, 8vo. "Nouvelles observations sur les naissances tardives," 1765, 8vo.; written in answer to Louis, who had confuted his argu- ments, and denied the authenticity of the cafes brought in support of them. "Lettre à M. Bouvar, au sujet de fa derniere consultation," 1765, 8vo. Bouvar had taken the same side with Louis. "Réplique à un ouvrage de M. Bouvar," 1767, 8vo. This is written with much acrimony; the last resource, when defending a bad cause. Hal- kr. Bib. Chirurg.

Bas, in Geography, a small island in the English chan- nel, near the coast of France, which has a fort to defend the road, and contains about fifty inhabitants. N. lat. 48° 50’. W. long. 4°.

Bas, Point de, is the southern cape of a bay which runs in eastward from Quiberon bay on the south of Vilacre river, on the west coast of France.

Bas en Basset, a town of France, in the department of the Upper Loire, and chief place of a canton in the district of Montroulez; one league north well of Montroulez.

Bas Relief. See Baso relief.

Basaal, in Botany, the name of an Indian tree, grow- ing about Cochin. Ray’s Hist.

Basaal, in Ancient Geography, an island of the Indian ocean, near Arabia Felix, according to Pliny.

Basalt, artificial, or black porcelain, a composition hav- ing nearly the same properties with the natural basalt, in- vented by Meffrs. Wedgwood and Bentley, and applied to various purposes in their manufactures.

Basalt, in Mineralogy. Argilla basaltae, Werner; fich- rate trap of Kirwan.

The colour of this mineral is generally greyish black, more rarely bluish or brownish black; its surface is usually reddish yellow, from a partial decomposition. It is found in large masses, composing entire inflated mountains of a somewhat conical form. Of itself it is delitative of lustre, but not un- frequently contains shining particles of olivine or basaltic horn- blende. Its fracture is uneven, passing into fine splinterly, sometimes approaching to the even or flat conchoidal. It flies, when broken, into indeterminate rather sharp-edged fragments.

The most usual form of basalt is that of columns, straight or curved, perpendicular or inclined, from three inches to three feet in diameter. These pillars are divided either by simple sections at right angles to their axes, or by articula- tions formed by the convex end of one piece inserted into the concave extremity of the adjoining one. The forms of the columns are pentangular, hexagonal, octagonal, rarely triangular or quadrangular. Basalt also sometimes occurs in tables, of in globular or elliptical concentric masses, called by the French basalt en boules.

It gives a clear ash-grey streak, is almost hard enough to give fire with flints, and is very difficultly broken. It is gen- erally opaque, though sometimes slightly translucent on the edges. It is remarkably porous when struck with the hammer. Sp. gr. according to Bergman, 3; Drifton, 2.854. It is sometimes magnetic.

Before the blowpipe, basalt fuses without addition into a black opaque glass, attractive by the magnet. When heated in a charcoal crucible, according to Klappoth, it fuses into an ash-grey mas, of a dull earthy fracture, and mu- tually an spongy texture, overlaid with grains of iron: it fuses in this process 9 per cent. of its weight. In a clay crucible, it fuses into a dense glass, opaque in mass, but transparent, and of a close-brown colour, in thin splinters.

Its constituent parts, according to Bergman, are:

The geological characters of basalt, and the various con- troversies with regard to its origin, and that of the other Rocks of Secondary Trasformation, will be treated of at large in their proper place. It will be sufficient to men- tion here, that basalt belongs to the stratified mountains, and that it very rarely contains any petrifications. When in maas, it never inclines any metallic veins; and when it occurs in the form of dykes, in coal strata or metallic rocks, it produces a total separation of the ore or coal on each side of the dyke.

It is seldom ever quite pure, being generally mixed with basaltic hornblende, common hornblende, and olivine; more rarely with zoisite, felspar, quartz, schorl, and calcaceous fpars. Mica is sometimes found on its surface, though very seldom penetrating its subsurface. When mingled with these in considerable proportion, it is easily decomposable into a remarkably fertile clayey loam.

The north-east coast of Ireland presents the most perfect and magnificent ranges of basaltic columns in the world; the celebrated Giants’ causeway is an assemblage of many thousand articulated pillars projecting into the sea, at the foot of a lofty basaltic promontory, exhibiting a poly- gonal pavement somewhat resembling a solid honeycomb. The promontory at Fairhead is a vast colonade of upright basaltic pillars, the shafts of which are 250 feet in length. Scotland also contains many beautiful specimens of columnar basalt; the little island of Staffa in particular almost entirely consists of basaltic pillars, both vertical and bending. The central district of Auvergne in France, and the northern parts
parts of Italy at the foot of the Alps, as well as Saxony and Hesse in Germany, are also remarkable for their basaltic columns.

Besides the use of basalt as a material for building and paving, it has of late been employed as an ingredient in the manufacture of glass bottles; it serves instead of more costly substances, and the glass, though black and opaque, has the advantage of being considerably stronger than the common green glass. When calcined and pulverized, basalt is an excellent substitute for pumicola in the composition of mortar, to which it gives the property of hardening under water. Emmerding. Brochant. Kirwan. Ann. de Chimie.

BASANITE of Kirwan, in Mineralogy. See Silicious Schistus.

BASANITES, in Natural History, a name given by many authors to the touchitone, used for trying gold, &c. Pliny speaks of a basanites which yielded a bloody juice, and was good against diseases of the liver.

BASANITUS Lupis, in Ancient Geography, the name of a mountain in Egypt, according to Ptolemy.

BASANUS, in Natural History. See Touchstone.

BASARA, in Ancient Geography, a town of Palestine, in Galilee, 20 stadia from Gabi, in the vicinity of Potemis. Josephus.

BASARTSCHK, in Geography, a considerable town of Romania, in Turkey of Europe. It is tolerably well built, has broad and clean streets and good trade, and is seated on the river Maritz. N. lat. 41° 40'. E. long. 24° 30'.

BASAROCO, in Commerce, a small bafe coin in the East Indies, being made only of very bad tin. Of this coin there are two sorts, good and bad; the value of the base fort is 2 lower than that of the good. Three bafaroco are equal to two rees of Portugal.

BASCARIA, in Antiquity, ridiculous or grotesque figures hung up by the ancient smiths before their furnaces, to divert envy.

BASCARA, in Geography, a town of Africa, in Bildeulgerid. The foil in its vicinity is fertile in grain and fruits, particularly dates, which are excellent.

BASCHINO, a town of Italy, in the kingdom of Naples, and province of Abnaro Ultra, 4 miles S.S.E. of Teramo.

BASCULUMBAL, a town of Astatic Turkey, in the province of Natolia; 36 miles east of Bergamo.

BASE, BASIS, in Architecture, denotes an assemblage of mouldings constituting the lower part of a column, of a pier, or of a pedestal.

In the Grecian remains of the Ionic order, the lower torus, arbalis, or fillet of the base, rests immediately on the upper step of the building; but in those of the Corinthian order, a square plinth is added to the base. This practice is observed in all the Roman works, with the exception of the temples of Vesta at Tivoli and at Rome; small circular buildings, in which a plinth radiating to the centre would have had an unseemly diminution. Modern architects have universally given plinths to their bases; and the following rules may be distilled from their works: the height of the base of columns to be half a diameter, those of pedestals, two thirds of the height of the respective column and pedestal; the plinths of the Tuscan and Doric orders, one half the height of the base; and one third in the Ionic and Corinthian. For the particular proportions of the mouldings, we refer to the plates.

The Attic or Attic-architectural Bases consists of two toruses and fillets, with an intermediate scotia. (See Plate XVI. of Architecture; and Plate I., fig. 1. from the temple of Jupiter Olympius at Athens; and fig. 2. from the temple of Minerva Polia, of the same place.) This base, probably the most ancient of any, is employed in all the Athenian remains of the Ionic and Corinthian orders; in Roman antiquities, it is frequently used in the Corinthian order, and profusely in the Ionic; and it has been adopted in every order by modern architects. It may be observed in this place, that, of the Greek Ionic bases, the upper torus is frequently fluted. See Plate I., fig. 2. and Plate XXVIII.

The Tuscan Base. The remains of antiquity do not furnish any complete specimen of the Tuscan order; and modern architects have accordingly varied in this order more than in any other; the base, however, has been determined by all to consist of a fillet and torus. See Plate XIV. of Architecture.

The Doric Base. It has been the practice of antiquity to execute the Doric order without a base. The massive strength of this dignified order required no additional stability from a base, the projecting mouldings of which would have embarrased the comparative narrowness of the mono-triglyph intercolumniation. But modern architects having adopted a column modelled either on Roman or Grecian proportions, have for the most part, with great propriety, added a base to their slender order. The Doric base invented by Vignola (see Plate I., fig. 3.) consists of a fillet, arbalis, and torus; all other architects have used the Attic base.

The Ionic Base. The base peculiar to this order, as described by Vitruvius (see Plate I., fig. 4.), consists of a torus and fillet resting upon two scotias, divided by arbalis and fillets. Of this base there is an example in the remains of the temple of Minerva Polia at Priene. (See Plate XXVIII.) However, the practice of ancient and modern artists, with few exceptions, has given the Attic base to this order.

The Corinthian Base (see Plate XXIX.) differs from the Attic, in having two scotias with arbalis between the toruses. This base is found in the Pantheon, and in the three columns of the Campo Vaccino. In the other Roman and in the Grecian antiquities of this order, the Attic base is employed.

Bass, Roulotte, is that which has its tores cut like cables. Bass, in Fortification, denotes the external side of the polygon; or that imaginary line which is drawn from the flanked angle of a bastion to that which is opposite to it.

Base of a Figure, in Geometry, denotes the lowest part of its perimeter; in which sense, the base stands opposed to the vertex, which denotes the highest part.

Base of a Triangle, is properly the lowest side, or that which lies parallel to the horizon.

Thus, the line AB is the base of the triangle ABC, Plate III. Com. fig. 38. Not but, on other occasions, the
the lines, AC; or EC in the triangle, may be made the base.

In a right-angled triangle, the base is properly that side opposite to the right angle, i.e. the hypotenuse.

Base of a solid Figure, is its lowest side, or that wherein it stands. Thus the circular plane DPE is the base of the cylinder ABCDE. Plate III. Geom. fig. 39.

Base of a cone Section, is a right line in the hypotenula and parabola, formed by the common intersection of the facet plane, and the base of the cone.

Base, Altern. See Altern.
Base, in Gunnery. See Cannon.
Base, in Heraldry, signifies the bottom of the shield; and the charges thereon are laid to be in base.
Base, Distinct. See Dictionary.
Base of the Heart, in Anatomy, denotes the broader or upper part of that viscus, to the sides of which the two auricles are affixed. This is sometimes also called the vertex or head, \( \text{a} \); in opposition to which, the lesser or narrower part is called \( \text{apex or minor} \), the point or tip of the heart.

Some also give the denomination \( \text{a} \) to the root of the or hydrate.

Base, or Bases, in Chemistry, a term which was applied, by the old chemists, to denote those substances of a fixed, inert, passive nature, which combined with, and were acted upon, by more volatile or active manures. Thus the alkalies, earths, and metallic oxids, which form compound salts by uniting with acids, were called the bases of these salts.

Modern chemists, though they maintain that in every combination the natures or forces of affinity between two ingredients is mutual and equal, have yet retained the term, for the sake of precision, to express either species or families of salts, which differ with regard to the acid, but agree as to the alkali, earth, or metallic oxid which they contain. Thus salts with a base of potash, include all those species which are formed by the combination of the various acids with the particular alkali potash. Again, salts with an alkaline base comprehend the three families of salts with bases of potash, lode, or ammonia, as distinguished from the other salts with earthy or metallic bases. The utility, therefore, of this mode of expression is evident; for though the compound salts are usually divided into genera, according to their acids, as sulphats, nitrats, muriats, &c. yet it is often desirable to arrange them according to their other element or base, for which the Lavoisierian nomenclature has not particularly provided.

The term base is also used on other occasions as a method of denoting species; as when we say, sulphuric acid is composed of oxygen united with a base of sulphur; the vegetable acids of oxygen and a compound base of hydrogen and carbon. Sometimes also the word base is applied in a more indefinite manner; as in the expression, phosphat of lime is the base of animal bone; azot is the base of muscular fibre: where it means merely the characteristic or principal part.

Base, Engl. Base, Fr. Basso, Ital. in Musica, the lowest part in the harmony of a musical composition. We prefer the derivation of the word from \( \text{ba} \), Lat. to base or baffle; as the word bassis is already naturalized in the use that is made of it in architecture, the base of a pillar. Sir Francis Bacon uses it musically for a deep or grave sound: "In pipes the lower the note-holes be, and the further from the mouth of the pipe, the more base sounds they yield." Nat. Hist. No. 170. And Dryden thus expresses the string of an instrument that gives a base sound:

"At thy well-harpen'd thumb, from shore to shore, The trebles squeak for fear, the bases roar!"
college, without knowing that Mr. Noble had discovered it before." As we are now only proving a claim, we need cite no more of this paper; at the end of which another paper is referred to (N° 135, p. 879), which reference says: "Concerning these phenomena, an exquisite solution is given by Dr. Narcissus Marsh, in Dr. Plot's-Natural History of Oxfordhire.'"

D'Alembert (Elémens de Musique) speaks of Rameau as the discoverer of the harmonics, as well as author of the system built upon them. In the preface to the second edition of his Elements of Music, in which he has abridged and methodized the musical tracts of Rameau, he says: "It was Rameau who first began to reduce chaos into order, and throw a light upon the principles of harmony.

"He found in the reliance of a single string or sounding body, the most probable origin of harmony, and of the pleasure which it affords us: he developed this principle, and showed whence the phenomena of music were derived," &c.

And Rouleau, Dicé, de Mus. art. Harmonie, says, that "Pere Mersenne and M. Sauerweerd having found that every sound, though seemingly a simple uniform, was always accompanied by other sounds less distinguishable, which formed with it the common chord major; and M. Rameau, setting off from this experiment, made it the basis of his harmonical system, which M. D'Alembert at length took the trouble of explaining to the public.'"

Rameau himself, in his Nouveau Syllème de Musique, published 1726, says: "we have in our nature the germ of harmony, without knowing it. It is however easy to perceive it in the sound of the string, a pipe, &c. in the tone of which there are three different sounds at once." In a note he adds, "this experiment is cited by different authors." But he does not seem to know their names. Rameau's account seems to have been taken from our Phil. Trans. quoted above, where it was supposed to be an English discovery. But in p. 17 of his treatise, he refers to Mersenne's Harm. Universelle, chap. des Instruments, p. 209, for the invention; but Mersenne, in the very title of the chapter alluded to, relinquishes all claim to the discovery, by merely promising his readers "to explain many circumstunces and properties of motion, natural or forced, oblique or perpendicular, where the ideas and experiments of Galileo are examined."

This puts it out of all doubt who was the first discoverer of this musical phenomenon. But the name of the true claimant does not seem to have been mentioned by any writer in England before the year 1748, when Dr. Smith first published his Harmonies; who begins the first fiction of that scientific work in the following manner. "Sound is caused by the vibrations of elastic bodies, which communicate the like vibrations to the air, and the like again to our organs of hearing."

"Philosophers are agreed in this, because sounding bodies communicate tremors to distant bodies; for instance, the vibrating motion of a musical string puts others in motion, whose tension and quantity of matter dispose their vibrations to keep time with the pulses of air propagated from the string which was struck. Galileo explains this phenomenon by observing, that a heavy pendulum may be put in motion by the least breath of the mouth, provided the blasts be frequently repeated, and keep time exactly with the vibrations of the pendulum; and also by the like art in raising a large bell; and probably he was the first that rightly explained that phenomenon."

And now, having traced this curious discovery to the fountain-head, we shall draw all further information from that source.

The admirable Galileo, perhaps the most acute and useful experimental philosopher of any age or country, in his first dialogue (Opera del Galileo, vol. ii. Edimburg 1655.), after discussing the vibrations of pendulums, which he first applied to the measuring of time, proceeds with his friend Sagredo, an intelligent enquirer into mechanical powers, who asks questions of difficult solution; and Simplicius, a young philosopher, curious concerning the causes of common effects. Galileo, under the name of Salviati, after discussing the doctrine of motion, and the range of cannon-balls, says: "vengo ora da i questi di V.S. dirvi qualche mio figurero sopra alcuni problemi attenti alla musica; and now, at your request, gentlemen, I shall give you my thoughts on some musical problems, a noble subject, on which so many great men have written, and, among the rest, Arifotle himself; concerning which he has left us many curious problems; so that if by such easy and intelligible experiments I shall be able to account for the wonderful phenomena of sound, I may perhaps hope that my reflections would amuse you."

"Sagredo. They will not only amuse me, but are what I most sought. Galileo will far, being extremely delighted with all musical instruments; and though I bellowed much meditation on harmonical confonances, I have always remained perplexed and unable to account for one of these intervals playing me more than another. For some not only give me no pleasure, but are extremely offensive to my ear; and that common problem of two strings tuned in unison, when one of them is caused to sound, the other not only vibrates but actually sounds, I still am unable to solve; nor do I clearly understand the forms of confonances, or many other particulars concerning them."

"Salviati. Let us try whether from our doctrine of pendulums we cannot acquire some information concerning these difficulties. And as to the first doubt, which is, whether it be true that the same pendulum performs all its oscillations, whether its being the greatest, the mean, or the least, exactly in equal times? I shall depend on what our professor told us, who has clearly demonstrated that a pendulum subfintending any arcs whatever, halves them all in equal times, i.e. whether of 180°, or 60, 10, 5; 1 4 a degree, or of four minutes, supposing them all to terminate in the lowest point, which touches the horizontal plane—all is performed in equal times." This accounts for the tone of a string not sinking or changing as the vibrations become more feeble. Here too he gives the ratio of vibrations; and afterwards the history of his discovering in a church, from the swinging of a lamp, the laws of a pendulum, and that all its oscillations were isochronous: This doctrine he applied to the vibrations of musical strings, upon the number of which the gravity and acuteness of sounds more depend than on their length, tension, or thickness. It seems as if few discoveries had been made in the philosophy of sound since this dialogue was written. Galileo has demonstrated that if a string sounding C, for example, be divided by a moveable bridge into half, each half would be an octave to the whole; if divided into three parts, each would be a fifth to the octave; divided into four parts, each would be a fifteenth or double octave to the whole; if into five parts, each would be a major seventeenth (commonly called a tierce or sharp third) to the fifteenth or double octave.

Though these divisions are the same as the ratios ascribed to Pythagoras, and those of Euclid in the fection of the canon; and though long before Galileo's time, the chorus of a full organ had been constructed on the principle of the harmonics to a fundamental base, there can be no doubt that this great philosopher first caught nature in the fact of producing
producing invisibly, and without human aid, the sweetest chord in the whole system of harmony.

Here all the phenomena are represented and explained, of kindred strings being caused to tremble and found merely by the tremors occasioned in the medium by the tone of a neighbouring string or sounding body.

Here too the theory of tuning strings, not only by tension but by weights, is explained: from which proportions, doubtless, the lycichord of Planinus was tuned by weights instead of tension, some fifty years ago.

Having judicially restored to Galileo the discovery of the harmonic proportions into which every single string and sounding body divides itself when caused to found, it seems unnecessary further to explain this phenomenon here. We shall therefore proceed to the system built on this foundation by Rameau, under the title of Basse Fundamentale; concerning which, not only the author, but the French nation, have gloried as much as if he had discovered and conquered a new world in the celestial regions of harmony.

Basse Fondamentale, or Fundamental Base, was first formed into a system by Rameau, and though the Italians meant the same thing by basso principale, to early as the time of Zarlino, it was not so clearly explained; nor were its derivation or derivatives, from a physical experiment, then generally known in Italy.

The natural harmony or common chord to every base, consists of the third, fifth, and eighth above the base: or their octaves, which the Germans call the triad; or rather the unison, or any given found, with its third and fifth, constitute their triad, without the octave. If instead of the fundamental or lowest found (which Rameau calls the generator) the base takes the third or fifth of that chord instead of the lowest found or principal base, the harmony is said to be inverted; and the lowest part, carrying the chord of the sixth, or \( \frac{5}{3} \), is called the superposed base, and sometimes the basso continuo. (See Supposed Base, or Bassa Continuo.) If any found is added to the common chord, except the seventh, the base is no longer fundamental.

The fundamental base should move by consonant intervals; as 3d, 4th, 5th, or 6th: never rising or falling one note or degree with perfect and similar harmony to both; as it would occasion a violation of the rule against 5ths and 8ths in succession, and preclude all relation and connection of chord to chord. Common chords may be given to the following fundamental bases in succession.

In a regular ascent or descent of the scale in modern harmony, the rule for accompanying the octave (see Regle de L'Ocata) allows only common chords to the key note and the 5th of the key; which are consequently fundamental bases: the chords of the 6th and 7th are given to the ref.

Rameau (Traité de l'Harmonie, p. 190,) has made all the following bases fundamental, by accompanying them with common chords.

By contrary motion, however, the principal base may have, and often has had, common chords with good effect, when ascending diatonically.

And if the seventh were added to many of these chords, they would be still more interesting, without divesting the base of the title of fundamental.

Of all the experiments that have been made in physical harmony, there has been no satisfactory origin found of minor modes, or keys with flat 3ds. From whatever grave found the harmonies have been observed to arise, they are all component parts of major chords, or keys with sharp 3ds. In Rameau's Génération harmonique, chap. xii. origine du mode mineur, where we expected all would be cleared up, we found his derivation of this mode more perplexed and perplexing than any part of his book. He tells us that we are to find indications given by nature of the minor mode below the principal found, which carries the 12th and major 17th below it to vibrate through not to found. And M. D'Alembert in the first edition of his "Elements" seems satisfied with this solution. When, after telling us that the 12th and 17th major are produced by every found immediately after it has been heard in its totality: that is, the tone of the whole string or sounding body. That the 12th and 17th arising from this string or principal found, are called its harmonies, and form, when approximated for the convenience of the hand, the common chord major or triad of unison 3d and 5th. But to acquire a natural origin of the minor mode, if we tune the 12th and major 17th below any found, below C for example, which will be an octave below the 5th and a double octave below the inferior major 3d, to C, we shall find when C is struck, that its lower 12th and major 17th will vibrate but not found.

But this
this origin neither satisfied theorists nor practical musicians. And in M. D'Alembert's second edition of his "Elements", he changed his ground, and instead of the chord minor of $F$, he adopted that of $C$: \[ \begin{array}{c}
\text{C} \\
\text{F} \\
\text{G} \\
\text{A} \\
\text{B} \\
\text{C} \\
\end{array} \]
which are instruments any Holstein, and stands and at but the distinguishing this by harmony the gentleman's all not canons the of those land many youth, m.

\[ \begin{array}{c}
\text{F} \\
\text{G} \\
\text{A} \\
\text{C} \\
\text{D} \\
\end{array} \]

A major 7th may be joined to the common chord of $F$ in practice, without taking from it the title of fundamental; but it is not one of its harmonies; ergo, $F$ is not the fundamental base to $A$ minor. Nor does nature give any indication of a minor chord either in the harmonics, or at found produced by two trebles. See Terrza Sonda.

Base-Viol. This instrument is now often confounded with the violoncello, though not of the same kind. In the 17th century every musical family had a chest of viols; all with fix strings, and the finger-board fretted. The base-viol was the largest of these instruments, and called in England the fix-stringed base; but in Italy, viol da gamba, on account of its resting on the leg of the performer. The tenor viol, the next in size of that class, is called viol da braccia, from its resting on the arm or shoulder when played on. The smallest and highest of these instruments is called the treble viol.

A complete chest of viols contained 8 instruments; 2 first trebles, two second trebles, two tenors, and two bases; all strung and tuned alike, by 4ths and 5ths, and the necks fretted. The accorderatura of the open strings is as follows.

\begin{array}{c}
\text{Treble Viol.} \\
\text{Tenor Viol;} \\
\text{or, Viol da Braccia.} \\
\text{Base Viol;} \\
\text{or, Viol da Gamba.} \\
\end{array} \]

From the time of queen Elizabeth till that of Charles II., in all private concerts (we had none that were public then) these, except the common flute, were the only instruments that were admitted into a gentleman's house; and indeed from the feebleness of the tone they may very properly be called aromenti da camera, chamber instruments. At first where voices could not be procured the several parts of full anthems, services, and other choral mu-

fic were adapted to viols. The first music that was composed expressly for them was fantasias; the title for which was brought from Italy previous to sonatas and concertos. The palfages given to these viols, at this time, discover no kind of knowledge of the expressive power of the bow; and even Orl. Gibbons, who composed so well for voices in the church, seems very little superior to his contemporaries in his productions for instruments. Indeed, his madrigals of five parts, as well as those of many others, are laid in the title page to be apt for viols and voices; a proof that with us, as well as the ancient Greeks and other nations, there was at first no music expressly composed for instruments; consequently, the players of these instruments must have been circumstanced; and when this music was merely played, without the assistance of human voices and of poetry, incapable of great effects. The subjects of Orlando Gibbons' madrigals are so simple and unmarked, that if they were now to be executed by instruments alone, they would afford very little pleasure to the greatest friends of his productions and those of the same period. At the time they were published, however, there was nothing better with which to compare them; and the best music which good ears can obtain, is always delightful till better is produced. Air, accent, grace, and expression, were now equally unknown to the composer, performer, and hearer; and whatever notes of one instrument were in harmony with another were welcome to the player, provided he found himself honoured from time to time with a share of the subject, or principal melody; which happening more frequently in canons and fugues than in any other species of composition, contributed to keep them so long in favour with performers of limited powers, however tiresome they may have been to the hearers when constructed on dull and barren themes. See Fantasia, Sonata, and Concerto.

Base, in Law.—Base estate is that estate which base tenants have in their land. Base fee denotes a tenure in fee at the will of the lord; by which it ilands distinguished from fegae, or free tenure. (See Fee.)—Base court, is any court not of record. Such, e.g. is the court-baron. Base tenure, base tenures, denotes holding by villenage, or other customary service; as distinguished from the higher tenures in capite, or the military service.

Base rocket, refeda, in Botany. See Reseda.

Base Knight, bas chevalier, denote the inferior order of knights as distinguished from barons and baronets, who were the chief or inferior knights.

Base Point, in Heraldry. See Point, and Escutcheon.

Base Ring of a Cannon, is the great ring next behind the touch-hole.

BASEDOWN, John Bernard, in Biography, was born at Hamburgh in 1723; and though the early part of his education was neglected by reason of the severity of his father, which obliged him to abscond, and to live almost a year as a domestic with a land surveyor at Holftein, he afterwards returned to his native place, and successfully pursued his studies in the Gymnasmum from the year 1741 to 1744, under professor Reimarus. Here his proficiency was such, that his parents was enabled to maintain plaster of his age of 16 years, independently of his parents. As it was his father's ambition to make his son a clergyman, he went to Leipsic in 1744 for the purpose of studying theology. He continued his two years, and attended the lectures of professor Croftan. These lectures and the writings of Wolff, which he also perused, unsettled his mind with respect to many doctrines which he had imbibed, and excited some doubts in his mind concerning the truth of the Christian revelation;
but by further examination of this interesting controversy, he became a firm believer of the truth of the divine mission of Christ, though he denied many of those doctrines which some Christians deem to be essential articles of the Christian faith. In 1749, he was appointed private tutor to the son of a gentleman in Holstein; in this situation he had an opportunity of submitting to the test of experience the plan of an improved method of education, which he had for some time held in contemplation. The attempt succeeded to his wishes; and though his pupil was only seven years of age, when he undertook the charge of him, he was able in the space of three years not only to read Latin authors, but to translate from the German into that language, and to speak and write it with a degree of fluency. He had also made considerable progress in the principles of religion and morals, in history, geography, and arithmetic. This success advanced his reputation; so that in 1752 he was admitted to the degree of master of arts at Kiel, and in the following year he was chosen professor of moral philosophy and the belles lettres in the academy at Soroe in Denmark. Here he published several works, which were well received; particularly his "Practical Morality for all conditions," containing hints of his improved plan of school education. His lectures on morality and religion were much frequented; but as he spoke with freedom on some points of theology that were generally received, he was removed by the Danish court to the gymnasium at Altona, and allowed the salary which he had enjoyed as professor. In the 40th year of his age he began, in opposition to the advice and remonstrance of his friends, to attack publicly many received tenets of the church, and he published his "Philaletheia," in which he suggested doubts concerning the eternity of future punishment; his "Methodical Instruction in Natural and Revealed Religion," in which he avows his dissent from the common doctrine concerning Jesus Christ, the Holy Ghost, inspiration, baptism, the Lord's supper, &c.; his "Theoretic System of Sound Reason!" and some other works of a similar kind.

In consequence of these publications he was represented by Gotze, Winkler, and Zimmermann, clergymen of Hamburg, as holding opinions hostile to revelation, as a man void of principle, and as an enemy to religion. The populace likewise were incensed, and threatened to stone him. He was preferred, however, from becoming a victim to intolerance, by the protection of Count Bernsdorf and some other friends at Copenhagen. In these circumstances he directed his attention to an improvement of the usual method of school education; and for his encouragement in the prosecution of it, he was released by the Danish court from attendance at the gymnasium of Altona, and allowed a pension of 500 dollars. Having solicited and obtained considerable subscriptions, he published in 1769 the heads of his "Elementary Book," which he submitted to the inspection of many respectable and learned friends, by whom it was approved. In 1771, the sum which he had collected amounted to 15,000 rix-dollars; of which a thousand had been contributed by the emperors of Russia, who read his plan and invited him to Peterburgh. Although he met with some opposition, he obtained very considerable encouragement; and he was invited by the prince of Delfau, with the promise of a pension of 1,000 rix-dollars, to establish the school which he had projected in his territories. Accordingly, he removed to Delfau, which afterwards became the chief seat of his residence. Having published several detached parts of his work, he determined in 1772 to continue it. In the following year he published the principles of "Arithmetic and the Mathematics," and in 1774 his grand treatise in four volumes, with 100 copper-plates, under the title of "Elementary Work," by way of distinction from his "Elementary Book," which he had published in 1770. This publication was favourably received, and was soon translated into Latin and into French. As he had bellowed six years' labour on the completion of this work, his health declined; and in this state he wrote his "Legacy for the Continent," being a work on the principles of natural and revealed religion. The prince of Delfau, having permitted him to establish his school in any place which he found most convenient, he travelled to Frankfort on the Main; and on his 51st birthday, he determined to put his plan in execution, and, on account of its humane object, to give his library the name of the "Philanthropinum." "This school was intended to be a seminary for rearing up young teachers and professors, and a pattern for all the other schools of Germany. The children of wealthy parents were to be admitted for the sum of 250 rix-dollars per annum; all the former errors in education were to be carefully guarded against; and the children of poor people were to be educated in it also, either to render them fit for becoming teachers themselves in schools of lower rank, or for being useful servants in respectable families." At Delfau, whither Bafedow returned from Frankfort, on the 27th of December 1774, the 6th birthday of the hereditary prince of Delfau, he opened his "Philanthropinum," appointing Wolek as head master, and undertaking the direction of it for seven years, promising to read lectures, and to give a few hours' instruction daily to the pupils without any emolument. The plan, however, was not encouraged agreeably to Bafedow's expectations, and he therefore relinquished it. His disappointment and other circumstances led him to seek relief from drinking, by which he impaired his health and injured his reputation. In the melancholy period that elapsed from 1778 to 1783, he employed himself in examining the nature of pure Christianity; and whatever may be thought of his peculiar opinions with regard to some of its doctrines, he appears to have been a friend to truth, and a zealous advocate for religion and virtue. In 1785 he published a plan by which children might be more easily taught to read, and distributed 500 copies of it in various schools. His plan was introduced by himself in two schools at Magdeburg, and it succeeded to his wishes. Having experienced great friendship at Magdeburg, he removed to this city towards the close of his life, and died there in 1790 in the 67th year of his age. Bafedow is reprobated by his biographers as a man of narrow judgement and penetration, and possessed of great finitude and a lively imagination. His works, which relate chiefly to religious subjects or to education, amount to upwards of 50 different treatises. Betygra zur Labens gesehile, &c. or Biographical Anecdotes of Joh. Beruh. Bafedow, taken from his own works, and from other authentic sources. Svo. Magdeburg, 1791.

BASEL, in Geography, a town in Italy, in the kingdom of Naples and province of Capitanata, 7 miles S.S.W. of Volturna.

BASELS, BASEL, in our Old Writers, a kind of coin abolished by king Henry II. 1158.

BASELIA, in Botany. Lin. gen. 382. Reich. 414. Schr. 520. Jaff. 84. Gen. chr. 125. Chas. and order, pentandria trizygia. Nat. Order of Helveticæ ; Aristippe Jaff. Gen. Char. Calyx none. Cor. 7, sejunct, pitcher-shaped; two outer divisions broader, one within the cell, converging above, fleshy at the base. Stam. filaments five, tubulati, equal, falcatus to the corolla, and shorter than it; anthers roundish. Pfl. germ superior, subglobular; styles three, filiform, of the length of the filaments; stigma orbicular, on one side of the styles. Per. corolla permanent,
mament, closed, fleshy, counterfeiting a berry. *Seed*, single, roundish.

17, *Leaves* flat; peduncles simple. *It* has thick, strong, fucculent stalks and leaves, of a deep purple colour; climbing to the height of eighty or ten feet, and producing many side-branches; in the bark-tree living through the winter, and producing great quantities of flowers and seeds. The fruit is a sort of juicy berry, of a very dark red colour, a little flattened, furrowed cross-wise at top, and containing a single nut. *A native of the East Indies, Amb- boina, Japan, &c.; and cultivated, in 1759, by Miller. From the berries a beautiful colour is drawn, but when used for painting, it changes to a pale colour; the juice is said to be used for staining calicoris in India. 2. B. alba, white Malabar night-shade, Gandola alba, Rumph. Amb. Phil. Alm. t. 63, P. 1. Murafakki, Kempf. Amzn. 784. The stalk smaller, the leaves oblong and lanceolat. and the flowers and fruit smaller than in the foregoing. Miller raised from seeds, sent by Jussieu, two varieties; one with purple leaves and stalks, the other having leaves variegated with white. Cultivated by bishop Compton in 1691. *A native of China and Amboina.* 3. B. lucida, shining Malabar night-shade; "leaves subcordate; peduncles crowded, branching." *A native of the East Indies.* 4. B. nigra, black Malabar night-shade; "leaves round-ovate; spikes lateral." Stem peren- nial, twining, slender, round, fucculent, branched; leaves thick, smooth, entire, alternate, petioled; flowers purple and white, lateral, few, in long, solitary spikes. Calyx three, roundish, acuminate, very small scales; corolla one-petalled, with a short swelling tube, and a six-angled corner; stem four- lobed; styles shorter than the flammes; berry roundish, deep black, small, four-lobed, with four blunt conelike efts at top. Loureiro apprehends, that the berry is formed from the germ, and not from the corolla. He thinks that this plant is the same with the "Gandola alba" of Rumphius; but different from the B. alba of Linneus. Perhaps none of these are specifically distinct. *A native of China and Cochim, in the hedges and fences of their gardens.*

Propagation. These plants are propagated by seeds, sown on a hot-bed in the spring, and planted, when fit to remove, each in a separate pot, filled with rich earth, and plunged in a tan-bed, where they must be treated like other vegetables. They may be also propagated by cuttings, which should be laid to dry for a day or two after being separated from the plant, before they are planted, that the wound may heal; otherwise they will rot. The seeds should be treated in the same manner with the feeding plants. These plants flower from June to autumn, and the seeds ripen in September and December. Martin’s Miller’s Did. BASSELL, BENNET, in Biography, son of Mark Raffell, physician of Bergamo, a town in the Venetian territories, studied anatomy and medicine at Padua, affiliated by Fabr. cius ab aqua pendentes, and other celebrated masters, under whom he is said to have made great proficiency in the knowledge of his profession. Returning to Venice in 1594, he was refused admission into the college of physicians there, on account of his practising surgery jointly with medicine. Irritated by the injustice, as he thought it, by the law by which he was rejected, he published at Bergamo, in 1604, a defence of surgery, under the title of "Apologia, qua pro chirurgiae nobilitate flrense pugnatur, libri tres." Troy. Did. Hill.

Soubassement, Fr. The lower part or story of a building when it is in the form of a pediment, with a base or plinth, and cornice or plat-band.

In the Roman antiquities, the temples are generally raised on a base ment which has exactly the members and proportions of a pediment to the columns of the portico; but in modern architecture, the base ment constituting the lower story of a habitation has its proportions regulated by the nature of the apartments which it contains. The Italian palaces have frequently the summer habitations on the base ment, which in that case is often as high as the principal story; but when it only contains offices, it sometimes does not exceed one half of that height. These proportions may be considered as extremes, which it will not be proper to exceed; for the principal story loses its importance when too much elevated, while a very low base ment will not admit any tolerable proportions of windows and doors.

Base ments are commonly decorated with ruffles of various kinds; they are crowned with a cornice or plat-band, and supported on a base or socle. The height of the ruffles, including the joint, should never be less than one module of the order of the principal story, neither should it exceed this measure; the plat-band should be the same height as a ruffle, and the socle or plinth rather more.

When the base ment is finished with a cornice, it should also have a regular moulded base; the height of the cornice may be about one seventeenth of the whole base ment, and the base about twice as much. Chamber’s Civil Architecture. Descriptions. ed. de Rome.

BASSETT LELLE, in Geography, a town of Italy, in Calabria, where the emperor Otho II. was vanquished and made prisoner.

BASHARIANS, a sect of Mahometans, being a branch or subdivision of the Mutasalis.

The Basharims are those who maintain the tenets of Bashar Ebn Motamer, a principal man among the Mutasalis, who varied, in some points, from the general tenets of the sect, as extending man’s free agency to a great length, even to the making him independent. He asserted, that God is not always obliged to do that which is just; for that, if he pleased, he could make all men true believers. Accordingly he taught, that God might doom an infant to eternal punishment; but taught at the same time, that he would be unjust in so doing. These fétaries also held, that if a man repent of a mortal sin and afterwards return to it, he will be liable to suffer the punishment due to the former transgression. Vide Sale’s Prelim. Dic. to the Koran, p. 162.

BASHAW, PASCHA, or PACHA, a Turkish governor of a province, city, or other district. The Arabs pronounce it Bashaw; but the word is Turkish, and properly Pashaw, denoting viceroy; whence is derived Pacha. As some of the provinces of the Turkish empire are too extensive for the government of the Pacha, this officer has a variety of sub dele gates; but it is in reality the sultan who dictates and commands, under the varied names of Pacha, Moustallam, Kaim-Makam, and Aga; nor is there one in this defending fesle, even to the lowest Delibah, who does not represent him.

All Egypt is, on the part of the grand seignior, governed by a bashaw; who has in reality but little power, but seems principally to be meant for the means of communicating to his divan of boys, and to the divans of the several military qisars (that is, their bodies), the orders of the grand seignior, and to see that they be executed by the proper officers.

When Selim, sultan of the Ottomans, put a period to the dynasty of the Mamlouks in 1517, he was fable that
if he established a pacha in Egypt with the same authority which was possessed by the pachas in other provinces, the distance from the capital would be a strong temptation to revolt. For preventing this inconvenience, he projected such a form of government, that the power being distributed among the different members of the flate, should preserve such an equilibrium as should keep them all dependent upon himself. The resource of the Mamlouks who had escaped his first iufiance, appeared proper for this purpose; and he next established a divan or council of regency, composed of the pacha and the chiefs of the seven military corps. The office of the pacha was, as we have observed, to notify to this council the orders of the Porte, to expel the tribute to Conflantinople, to watch over the safety of the country against foreign enemies, and to counteract the ambitious views of the different parties. On the other hand, the members of the council professed the right of rejecting the orders of the pacha on afigning their reasons, and even of deposing him; and it was neceffary that they should ratify all civil or political ordinances. It was also agreed, that the governors or beyfs of the provinces, should be chosen from the Mamlouks. This form of government has not ill corresponded with the views of Selim, since it has subsisted about two centurics; but within the last 50 years, the pacha having relented its vigilance, innovations have taken place, and the power of the Mamlouks has superceded and almost annihilated that of the Turks. In order to retain the pachas, the pacha had suffered the divan to extend its power, till the chiefs of the Janizaries and Azabs were left without control. Hence Ibrahim, one of the Kiyays, or veteran colonels of the Janizaries, about the year 1746, rendered himself in reality master of Egypt; and the orders of the sultan vanished before those of Ibrahim. About the year 1766, Ali Bey (see Ali Bey) rendered himself absolute master of the country. Since the revolution of Ibrahim Kiyas, and the revolt of Ali Bey, the Ottoman power has become more precarious in Egypt than in any other province; so that though the pacha still retains there a pacha, confused and watched in the caflle of Cairo, is rather the prisoner of the Mamlouks than the representative of the sultan. He is deposed, exiled, or expelled at pleasure; and on the mere summons of a herald clothed in black, called "Caraoulook," he must defend from his high station, or be deposed. Some pachas, chosen exprès for that purpose by the pacha, have endeavoured by secret intrigues to recover the power formerly annexed to their title; but the beyfs have rendered all such attempts so dangerous, that they now submit quietly to their three years' captivity, and confine themselves to the peaceable enjoyment of their salary and emoluments.

After sultan Selim I. had taken Syria from the Mamlouks, he subjected that province, like the reft of the empire, to the government of pachas, or vicereys, as the term signifies. (See Syria.) In each province the pacha, being the image of the sultan, is, like him, an absolute despot. All power is united in his person; he is chief both of the military and of the finances, of the police and of the criminal justice. He has the power of life and death; he has the power of making peace and war; and in a word, he can do every thing. These powers in their unlimited extent belong only to the pacha with three tails. The power of the pacha with two tails is not so considerable, nor his department so extensive; he cannot put any one to death without a legal trial; he is, like another, chief of the armed force of his department; but when he takes the field, he is obliged to unite his standards to those of the pacha with three tails, and to march under his orders. The main object of such power vested with the pacha, is to collect the tribute and to transmit the revenue to their master. This duty fulfilled, no other is required from him; and the means employed by the agent to accomplish it is a matter of no concern; those means are left to his discretion; and such is the nature of his situation, that he cannot be delicate in his choice of them; for he can neither advance, nor even maintain himself, but in proportion as he can procure money. The place he holds depends on the favour of the vizier, or some other great officer; and this can only be obtained and secured by bidding higher than his competitors. He must therefore raise money to pay the tribute, and also to indemnify himself for all he has paid, support his dignity, and make a provision in cafe of accidents. Accordingly, the first care of a pacha, on entering on his government, is to devise methods to procure money, and the quickest are invariably the belt. The established mode of collecting the mitra and the customs, is to appoint one or more principal farmers, for the current year, who, in order to facilitate the collection, divide it into keller farms, which are again subdivided, even to the smallest villages. The pacha lets these employments to the belt bidder, willing to draw as much money from them as possible. The farmers, who, on their shave, have no object in taking them but gain, strain every nerve to augment their receipt. Hence an avidity in these delegates always bordering on dilhonnesty; hence these extortions to which they are the more easily inclined as they are sure of being supported by authority; and hence, in the very heart of the people, a faction of men intertended in multiplying impositions. The pacha may applaud himself for penetrating into the most hidden sources of private profits, by the clear-fighted capacity of his subalterns; but what is the consequence? The people, denied the enjoyment of the fruit of their labour, restrain their industry to the supply of their necessary wants. The husbandman only vows to prefer himself from starving: the artisan labours only to support his family; if he has any surplus, he carefully conceals it. Thus the arbitrary power of the sultan, transmitted to the pacha, and to all his subdelegates, by giving a free course to extortion, becomes the main spring of a tyranny which circulates through every class, whilst its effects, by a reciprocal reaction, are everywhere fatal to agriculture, the arts, commerce, population; in a word, to every thing which constitutes the power of the sultan, or, which is the same thing, the power of the sultan himself.

This power is not subject to less abuses in the army. Perpetually urged by the necessity of obtaining money, on which his safety and tranquillity depend, the pacha has entrenched, as far as possible, the usual military establishment. He diminishes the number of his troops, lessens their pay, winks at their disorders; and discipline is no more.

It sometimes happens that the pachas, who are subordinates in their provinces, have personal hatreds against each other. To gratify these, they avail themselves of their power, and wage secret or open war; the ruinous conccquences of which are sure to be felt by the subjects of the sultan.

It also happens that these pachas are tempted to appropriate to themselves the power of which they are the depositaries. The pacha, in order to counteract their ambitious views, often changes the residence of the pachas, that they may not have time to form connections in the country; but as all the consequences of a bad form of government have a mischievous tendency, the pachas, uncertain of to-morrow, treat their provinces as mere transient possessions, and take care to make no improvement for the benefit of their successors. On the contrary, they labour to exhaust them of the produce, and to reap in one day, if possible, the fruit of
of many years. It is true, these irregularities, every now and then, are punished by the bow-firing, one of the practices of the porto which displays the spirit of his government. The oftentimes reason is always for having oppressed the subjects of the sultan: but the porto, by taking possession of the wealth of the extortions, and refusing nothing to the people, leaves sufficient room to think that the government is far from disapproving a system of robbery and plunder which it finds profitable. Every day, therefore, affords fresh examples of oppressive and rebellious pachas; and if none of them have hitherto succeeded in forming a fable and independent government, it is left owing to wise measures of the divan, and the vigilance of the Capidjis, than their own ignorance in the art of governing. The pachas regard nothing but money; nor has repeated experience been able to make them sensible that this, so far from being the pledge of their security, becomes the certain cause of their destruction. They are wholly devoted to amusing wealth, as if friends were to be purchased. As the pacha possesses the power of life and death, he exercises it without formality and without appeal. Wherever he meets with an offence, he orders the criminal to be feized; and the executioner, by whom he is accompanied, stabs him, or takes off his head upon the spot: nay, sometimes he himself does not disdain this office. This duty he frequently commits to a deputy, called Walli. The administration of justice in civil suits is the only species of authority which the sultans have withheld from the executive power of the pachas. The officers appointed for this purpose are, by a wise regulation, all independent of the pachas. See CADIS.

To the governors of provinces were formerly given indiscriminately the names of pacha and of beylerbeg, or beyler-bey: the latter at this day is referred for the pachas of Manafir and of Cutayé: they have the pre-eminence over the other pachas, and generally command the troops which are brought into the field. The beyler-bey of Manafir has under his orders the European troops, and the beyler-bey of Cutayé those of Asia. They are nevertheless subordinate to the grand viceroy, when the latter takes the general command of the armies. Formerly, the name bahash, or pacha, was appropriated to such as had two enigns or horse-tails carried before them; those who had the honour of three tails, called vicer-bashas, were denominated begler-begs; and those who had only one, fashiegoths.

The appellation of bahash is also given by way of courtesy to Constantinople, to the lords about the grand signior's court, the officers in the army, and almost every person of any figure.

A bahash is made with the solemnity of carrying a flag or banner before him, accompanied with music and flags by the miriamel, an officer on purpose for the infidelity of bahashs.

Bahash, used absolutely, denotes the prime viceroy; the rest of the denomination being distinguished by the addition of the province, city, or the like, which they have the command of; as the bahash of Egypt, of Palestine, &c. The bahashs are the emperor's fegers. We find loud complaints among Christians of their avarice and extortions. As they buy their governments, every thing is venal with them. Volney's Travels into Egypt and Syria, vol. i. ch. 10. vol. ii. ch. 33. Olivier's Travels in the Ottoman Empire, ch. 17. Ruffell's Aleppo, vol. i. p. 135, &c.

There are also sub-bashas, or deputy governors under the first. Phil. Trans. N°. 218.

BASHI, Captain, is the title of the Turkish high-admiral, who commands the naval forces of the Ottoman empire, and is at the head of all the maritime establishments. He usually commands in person the fleets and all the naval forces of the empire: he nominates to all places and employments; he orders the building and repairing of ships; but the "Terfana-emini" is properly the naval minister, since he has the administration of the funds appropriated to the navy, the direction of supply of stores to the fleet, the care of the equipment of ships, and the superintendence of all the works. He has under him chiefs, deputis, and different harbor masters, as well for the execution of his orders and for private superintendence, as for the police.

BASHI ISLANDS, in Geography, a group of five islands situated in the Chineese seas, north of the Philippine islands, and south of Formosa. They are said to be called by Dam-pier from the name of a liquor made of the juice of the sugar cane and a small black grain, and used by the inhabitants. This name was given to the most easterly of the group, and at length was applied to them all. The productions of these islands are plantains, bananas, pine-apples, sugar-canes, potatoes, yams, and cotton; their quadrupeds are goats and hogs. The people, according to Dampier, are kind and hospitable. The names of the islands are Orange, Grafton, Monmouth, Isle of Goats, and Bahsee. This group is represented in the "Miflonary Voyage," p. 326. as consisting of six or seven islands; the northernmost of which lies in N. lat. 21°. E. long. 122° 6'. The two to the south-east are high; some of the others are of moderate height; the most northern except one is high and craggy at top; and between these two lie two small rocks above water. Between these islands and those of Botol Tabaco-Xinya, is a channel about 16 miles wide.

BASHI, or Barbi, the most easterly island of the preceding group, appearing of a circular form, and being about 2 leagues in diameter. It has a town of the same name. N. lat. 21°. 45'. E. long. 122° 15'.

BASHKIRS, or Bashkirs, a people of the Russian empire. They call themselves Balkhors; and derive their origin partly from the Nogay-tartars, and partly from the Bolgarians. Probably they are Nogays, whom the Bolgares adopted among them: their country at least is a part of the ancient Bulgaria. They formerly roamed about the southern Siberia under the conduct of their own princes: to avoid the molestation of the Siberian khanas, they settled in their present possessions, spread themselves about the rivers Volga and Ural, and were subject to the Kazan khanate. On the overthrow of that state by tzar Ivan II. they voluntarily took refuge under the Russian sceptre: they afterwards, however, frequently revolted against the government, whereby their prosperity as well as their population have been considerably diminished. In the year 1770, they consisted of twenty-seven thousand families, having their homestead in the governments of Ufa and Perm. The Bashkirs have been long without khanas; and all their nobility have been gradually destroyed in the civil wars. At present every tribe or woltol chics for itself one or more ancients, or starfishins; and the whole nation compomps 34 woltols. The hats or houses, which they inhabit during winter, are built after the Russian fashion; the principal part, which the family commonly poffefes, is furnished with large benches, which serve for beds; the chimney, of a conical form, and of the height of an ordinary man, is in the middle of this division, and thus constructed; that they are very liable to smoke: on this account the Bashkirs are very subject to various complaints of the eyes. In summer this people inhabit what the Russians call Jutes; they are tents or covers of felt, which, like the hats, have several divisions and a chimney in the centre. A winter village
BAS

lage contains from ten to fifty huts; but the summer encampment never exceeds twenty jurtas. These jurtas are a kind of barracks.

The Bashkirs have some knowledge of the art of writing, and have schools; but as it is from their own nation that they eke out their priuitys and the instructors of youth, they remain in the profoundest ignorance. With some knowledge of tillage, they retain a liking to the pastoral life; which fpoils them for agriculture. They few but little grain; consequently their harvests afford them but few resources for the winter, being far from sufficient for their whole consumption. They apply with greater success to the cultivation of bees; making hollows in the trees to serve the purpose of hives; which to secure from the attacks of the bears, they have invented a variety of ingenious contrivances both as weapons and traps. One man, in frequent influences, is known to possess at least five hundred hives. They have the art of finding out the mountains that contain mines; but, like the Tartars, they would think themselves disgraced by working them themselves. It must be owned, however, that they have not the strength of body that that labour requires. Their practice is to let them out for a term of forty years to Russian contractors, affixing to them at the same time a tract of forest necessary for the forges. The poorest of them serve for wages in transporting the ore.

The women understand the art of weaving, fulling, and dyeing narrow coarse cloths; they likewise make the clothes for the whole family. They make a small quantity of linen of hemp; but they prefer weaving the filaments of the common nettle, as that plant requires no culture, and the linen they make of it is extremely coarse. They have not the unwieldy practice of fleecing their hemp or their nettle's in water, but leave them to dry in the air on the top of their huts during the autumn and winter; then stripping off the bark, they pound them in wooden mortars. The men follow the more difficult business of making felt and of tanning leather. Both sexes wear shirts of the cloth made of nettles; they also wear wide drawers, which descend to the ankle-bone, and a sort of slippers, like people in the East. Both men and women wear a long gown, that of the men being generally of red cloth bordered with fur; this they bind round their middle with a girdle, or with the belt to which they fix their scythe. The poor have a winter plisse of sheep skin, and the rich wear a horse skin in such a manner that the mane covers their back and waves in the wind. The cap is of cloth, like the frustum of a cone, and 10 inches high; and that of the rich is usually ornamented with valuable furs. The gown of the women is made of fine cloth or silk, buttoned before as high as the neck, and fastened by a broad girdle, which the richer classes have made of steel. Their necks and throats are covered with a sort of shawl, on which are several rows of coins, or a ring of shells.

The principal wealth of this people consists in their flocks; it is especially from their horses that they derive the necessaries of life; meat, milk, vellums, garments. They have nearly as many and even rather more sheep than horses; and their horned cattle are about half, as numerous; they likewise bring up some goats, and only the rich have camels. A man of the ordinary class has seldom fewer than between thirty and fifty horses, many poijes five hundred, and some a thousand, two thousand, and more. Their sheep are of the broad-tailed species; they eilem the others for the necessities of their wool.

The most opulent of the Bashkirs are those who dwell to the eait of the Ural, and in the province of Yet. Some of them are owners of not less than four thousand horses, who fatten in the richest pastures: the wasps and gnats oblige them in the month of June to quit these fine meadows, and retreat to the mountains: the horses then lose their flesh and pine away, but regain their prilline vigour on coming down again to the plains in the month of July.

Though the Bashkirs experience a long and very severe winter, yet they abandon their flocks and droves to the inclemencies of the season. They have neither granaries nor barns; they only lay up a little hay, which they range in cocks round the trees, referring it for the ditternented cattle. Those that are healthy pick up a little graas or moss from beneath the snow, and are often reduced to the necessity of feeding on the bark of the young elms. No farther attention is paid to the camels, than to leave them in some wretched coverings of felt which they fear about their body. The cattle towards the end of the winter are become lean, weak, and emaciated. Though the females are never kept apart from the males, they rarely bring forth out of season; because the exhausted state of the flocks and herds during the winter, is unfavourable to generation. Neither the Bashkirs nor the Kalinuchs sever the colts and the calves to fack their dams except during the night, their practice being to milk them in the day-time for their own advantage; while, milk, prepared from mare's milk, being their favourite liquor. (See Kinniks.) They are also fond of a mixture of four milk and mead, called Arijan. In the spring they drink the sap of the birch, which they collect by means of deep incisions in the trees.

Their arms are the bow, the lance, the helmet, and coat of mail; from the Russians they obtain sabres, musquets, and pithons. A Bashkirian army presents a truly curious spectacle; observing no order in marching, they only form into ranks when they halt. Every one leads a horse in his hand, which carries all his provisions; the load however is not heavy; consisting only of a chest, some corn dried in the kiln, and a hand-mill to grind it to meal. With the meal they form a ball which they swallow, and which serves them for bread. Each warrior, drest in his long gown, equips himself as he chuses or as he can. One has procured for himself the various kinds of arms, and carries a whole arfaal with him; the other sagaciously poissifies more than one ill-conditioned weapon. Such troops as these rendered the armies of the ancient Persians at once so numerous and so terrible formidable.

They are all well mounted, are skilful in drawing the bow, and dexterously manage their horses. A small number of Bashkirs are easily victories over a numerous squadron of Kirghises; sometimes one of their regiments will traverse a whole horde of Kirghises, put to flight by their very looks all the enemies they meet, and return triumphant without having sustained the slightest loss. The military service in which they are bound to perform, and the only point in which they are called by the Russian yoke, consists in furnishing, in time of war, 3000 cavalry, which form 30 troops of 100 men each. The Bashkirs are the most negligent and slovenly of the Tartars. In commerce they are the most intelligent; but, at the same time, they are the most hospitable, the most lively, and the most brave. Their diversions at any religious festival, or at a marriage, consist in numerous libations of four milk, lining, dancing, wrestling, and horse racing, in which they excel. In their songs they enumerate the achievements of their ancestors, or their own, and sometimes their amorous adventures. Their songs are always accompanied with gestures, which render them very theatrical. Among them old age meets with the greatest respect. In their entertainments, it occupies the place of honour; and the stranger, to whom compliments are paid,
is always set among the old men. The language of these people is a Tartar dialect, very different from that spoken at Kafan. The Bashkirs are, like most of the Tartars, Mahometans; but though they have their mosques, their molacs, and their schools, they are much addicted to superstition and forcery. Their forcers challenge even the devil, and pretend to engage with him in combat; and thus they delude the credulous vulgar, who consult them in their distress, and particularly when they lose any of their mares. Tooke's View of Russia, vol. i. p. 473. Chauntea's Travels, vol. i. p. 281.

BASIL, or BASCHLI, in Geography, a small town on a brook of the same name, at the distance of 4 German miles from the Caspian sea.

BASHYSEN, Henry James Van, in Biography, a learned divine, was born at Hanau, in Germany, in 1679, and educated at Bremen, Leyden, and Franeker. In 1701, he was appointed professor of the oriental languages and ecclesiastical history in the gymnasium of Hanau, afterwards professor of theology, and in 1712, he was elected member of the Royal Society of Berlin. He was afterwards professor of theology, the oriental languages, and history, in the gymnasium at Zelft, where he died in 1758. About the year 1760, he established in his own house a printing-office, in which he printed many Hebrew and Rabbinical works. Among his writings are "Obcrv. Sacr. lib. i. de integratj Sac. Scrip.," Frankf. 1768, 8vo; "Comment. R. if Abbaran, in pentateuchum Mosé, &c." Hanov. 1710, fol. "Dilpit, iii. de Kabbara vera & falsa," Hanov. 1710, 1711, 1712, 1713, 4to.; "Synt. Antiq. Hebr. minus," Hanov. 1712, 8vo; "Mitclamtna Sacra, &c." Witt. 1719, 4to.; "Diff. de Idée, &c." Serv. 1719, 4to.; "Clavis Talmudica, &c." Hanau, 1742, 4to. Gen. Biog.

BASIA UMITNA. See UMITNA.

BASATRAHAGI, in Botany, a name used by some for the common polygonum, or knot-grass.

BASIENTO, in Geography, a river of Naples, which rises near Potenza, in the province of Basilicata, traverses this province, and runs into the gulf of Tarento. This is the ancient Metapontus, or Calaentum, on which Octavius Cæsar and Mark Antony had an interview, brought about by the mediation of Octavia.

BASIL, Sir, denominated the Great, in Biography, was born in Cappodocia, in the year 328 or 329. Having received instruction from his father in polite literature, he pursued his studies at Antioch under Libanius, at Cæsarea in Palestine, at Constantinople, and at Athens; in which latter place he formed an intimate acquaintance with Gregory Nazianzen, and was introduced to Julian, afterwards emperor. In 355, he returned to his native country, and became a professor of rhetoric, and a pleader. His religious zeal, however, soon induced him to visit the monasteries in the desert of Egypt and Lybia; and here his imagination was so impressed with the account of the devout solitaries in these favourite mansions, that he withdrew to a retired spot in the province of Pontus, and embraced the monastic life. He was soon joined by his brother and several friends, to whom he gave a set of ascetic rules; and he is regarded as the founder of all similar institutions in Cappodocia. His monastic life continued, but not without some interruption by other avocations, for twelve years. Having been ordained priest by Eufebius bishop of Cæsarea, he again withdrew to his solitude; but as his fame increased, he was elected to this see on the death of Eufebius in 369, 370, or 371. Here he succeeded Athanasius in the conduct of the Trinitarian controversy. Many attempts were made by the emperor Valens, who was an Arian, partly by friendly solicitation and partly by angry menaces, to induce him to com-
Acadians, in the presence of Constan
tius. However, the Acadians prevailed against him in the council of Constan
tiople, A.D. 550, and procured his deposition; nevertheless he kept possession of his see, and was acknowledged as bishot by the orthodox prelates. Balsi is supposed to have died, either at the end of jovian's reign, or the beginning of that of Valens. Cave, Hill, tom. i. p. 210. Lardner's Works, vol. iv. p. 125.

Basil, in Botany. See Ocyum.

Basil, Field. See Clinodorum.

Basil, American Field. See Monarda.

Basil, Syrian Field. See Ziziphora.

Basil Stone, and Wild. See Thymus.

Basil, Order of St., in Ecclesiastical History, is the most ancient of all the religious orders. It takes its name from St. Basil, bishop of Caesarea, in Cappadoce, about the middle of the fourth century; who is supposed to have been the author of the rules observed by this order, though some dispute it. The order of St. Basil was anciently very famous in the East, and still continues in Greece. The habit of the monks is black, and plain, confiding of a long cappieck, and a great gown with large sleeves; on their head, they wear a hood, which reaches to the shoulders; they wear no linen; sleep without sheets, on straw; eat no flesh; fall often; and till the grounds with their own hands. The historians of the order inform us, that it has produced 1805 bishops, and beatified, or acknowledged as saints, 3010 ab
bots, 11,805 martyrs, and an infinite number of confessors and virgins. They likewise place among the religious of this order of St. Basil 11 popes, several cardinals, and many patriarchs, archbishops, and bishops. It likewise boasts of severals emperors and empresses, kings and queens, princes and princes of, who have embraced the rule of St. Basil.

This order was introduced in the West in 1557, and was reformed in 1570 by pope Gregory XIII, who united the religious of this order in Italy, Spain, and Sicily, into one congregation; of which the monastery of St. Saviour, at Mellina, is the chief, and enjoys pre-eminence over the rest. Each community has its particular rule, besides the rule of St. Basil; which is very general, and prefers little more than the common duties of a Christian life.

Basil, Eagle, or Balle, in Geography, one of the new cantons of Switzerland, which joined the Helvetic confed- eracy in 1501. It is bounded on the south-west and south by the canton of Soleure, on the east by Lower Argow and the canton of Baden, on the north-east by the territory of Rheinfelden, one of the forell towns, and on the north-west by Alfaie, and on the west by the bishopric of Baflae. Its extent is about 165 square miles, and its population is estimated at 40,000 persons. The lower parts of this can
ton are fertile in corn and wheat, and also fit for pasture; but the mountains are extremely barren. It has many medicinal springs and baths, and the air is temperate and salubrious. The religion of this canton is the reformed, or Protestant. As to its ancient government, the bishops of Baflae once pos-
sessed the sovereignty over the city and canton; but when they quitted this town in 1501, and retired, first to Fribourg in Brigueu, and afterwards established their residence at Po
tren, they lost the inconsiderable authority and few preroga
tives that belonged to them. Upon the introduction of the reformation in 1535, the constitution was in some measure changed, and the power of the ariolocacy limited. Before the late revolution, the government was ariolocratic, inclining towards a democracy. The supreme legislative power resided in the great and little councils, consisting of about 300 members, and the authority of these two councils was without control; they enacted laws, declared war and peace, contracted alliances, and imposed taxes; they elected the several magistrates, appointed their own members, nomi
nated to all employments, and conferred the right of burghe
ship. The general administration of government was com-
mited, by the great council, to the senate or little council; that is, to a part of its own body. This senate, composed of sixty members, together with the four chiefs of the re
public, two burgomasters, and two great tribunes, was divided into two bodies, which acted by rotation; the acting division continued in office one year, decided finally in all criminal causes, superintended the police, and exercised cer
tal other powers subordinate to the sovereign council. The collective body of citizens assembled only once a year, when the magistrates publicly took an oath to maintain the constitution, and to preserve the liberties and immunities of the people inviolate. The reciprocal oath of obedience to the laws was administered to the citizens in their respective tribes. But, notwithstanding the boundless prerogatives of the great council, the mennen citizen was legally capable of being admitted into that body, and, by the singular method of election, might possibly be chosen; for the vacancies in the two councils were supplied from all ranks of citizens, the members of the university only excepted. These citizens were divided into eighteen tribes, fifteen elected every four
th year to each of the large towns; and three to the smaller; each of the fifteen tribes returned four members to the senate, and each of the eighteen sent twelve to the great council. As these elections were formerly determined by a plurality of voices, the richest person was always almost certain of being chosen; to prevent which, a regulation, called a "ternaire," was established; that is, three candidates were nominated, and from these the successor was appointed by lot. In 1749, an act was passed, by which the "ternaire" was changed into a "faire," by which six candidates were put in nomi
nation, and drew lots for the charge; fix tickets, contain
ning the names of the respective candidates, and separately placed in silver eggs, were put into one bag, and the same number of tickets, five being blanks, and one marked with the vacant employment, were put into another bag; the reigning burgomaster and the great tribune, appointed to be the drawers of this official lottery, both at the same in
stant took a ticket from each bag, and the candidate whose name came out with the ticket on which the employment was written, obtained the post.—But it is now needless to pursue the detail. In 1798, the Helvetic confed eracy was dissolved by the invading power of France, and, according to the distribution of that year, Balle was constituted one of the eighteen departments into which Switzerland was di
vided: but according to the constitution of 1801, Balle was made one of the departments, with the addition of the lower part of the Frickthal to Seckingen, with the right of deputing three representatives to the diet.

Balle was the first canton which separated from the old Helvetic confed eracy, and adopted the new constitution fab
briicated in France. Its situation near the frontiers, exposed it to the intrigues of the French agents, and without foreign support, rendered it incapable of resistance. The peasants of the canton were likewise dispossessed with the monopoly of power and commerce vested in the burgomasters of the town. Encouraged by the French, and excited by their own turbulent demagogues, they peremptorily required emancipation and independence. The progress of the revolution in this canton was almost instantaneous; the magistrates were incapable of resistance, and obliged to resign their authority; and sixty delegates, appointed by the people, were invested with a provisional government, until the new constitution should be consolidated. Coxe's Travels in Switzerland,
What other changes await the Swiss cantons, time must develop. See Switzerland.

Basel, or Basel, the capital, is the canton of the same name, is the largest, and forms formerly to have been one of the most populous towns in Switzerland. Its extent is capable of containing above 100,000 inhabitants, and it is said to have 220 streets, and fix market-places or squares; whereas it can now scarcely number more than 14,000. Among the canals which have contributed to its decrease, Mr. Coke mentions the jealousy of the citizens with regard to the burgomanship, which they seldom deemed to confer upon foreigners; and, on this account, no supply can be obtained to balance that gradual waste of people which takes place in great cities, from an influx of strangers, who are not permitted to carry on commerce, or to follow any trades. The late law that allows the freedom of the town and the right of burgomanship to be conferred upon strangers, is clogged with so many restrictions, that it by no means answers the purpose for which it was intended.

Basle is beautifully situated on the banks of the Rhine, near the point where the river, which is here broad, deep, and rapid, after flowing for some way from east to west, turns suddenly to the north. It consists of two towns, joined together by a long bridge; the large town lying on the side of Switzerland, and the small town on the opposite bank of the river. Its environs are very beautiful, consisting of a fine level tract of fields and meadows. It was anciently called Basils, as we learn from Ammianus Marcellinus; and in the middle ages, Basala: and it appears in history, soon after the reign of Charles-magne; having succeeded August, or the Angulia Rauracorum. Basle is very favourably situated for commerce; and on this advantage the inhabitants have availed themselves, by establishing a great variety of manufactories, particularly of ribbons and cottons; and by the extensive trade that is carried on by the principal merchants. The cathedral is an elegant Gothic building, and contains the marble tomb of the famous Erasmus, who chose this city as his favourite place of residence, and published from hence the greatest part of his valuable works. Basle has, besides the cathedral, six parochial churches, and several other public buildings; such as a public granary and an arsenal, a town-house, and a fleetly palace belonging to the margrave of Baden Doourlach, a chamber of curiosities, several hospitals, &c. In the town-house is an exquisite piece of the sufferings of Christ, by Holbein, who was a native of this place; and a statue of Munatus Planicus, the Roman general, who founded Augulia Rauracorum. In the arsenal is shown the armour in which Charles the Bald loft his life, with the furniture of his horse, and the kettle drums and trumpets of his army. On the flour-cafe of the council-house is a picture of the last judgment, in which, though painted before the reformation, popes, cardinals, monks, and priests, are represented in the torments of hell. Upon a wall that includes the burial-ground of the church of the Protestant in the suburbs of St. John, is painted, in oil colours, the "dance of death," erroneously attributed to Holbein, as it was painted before he was born, in which the king of terrors is represented as mixing with all ranks and ages, and complimenting them in German verses on their arrival at the grave. From this ancient painting, it is thought that Holbein took the first hint toward composing his famous drawings on the "dance of death." Prints were taken from some of these drawings, by Hollas, which are now very scarce. The university of Basle, founded by Pope Pius II. in 1459 or 1460, was formerly eminent in the literary history of Europe. It was honored by the celebrated names of Occam- padus, Amerbach, the three Baulins, Grunius, Buxtorf, Vol. III.
Basil, or Basile, Bibliography of, a principality of Germany, in the circle of the Upper Rhine, may be described under two general divisions: the first lies to the south of Pierre Pertuis, and forms a part of Swisserland; the second, to the north of the same boundary, includes that district which is properly called within the German empire. The sovereign, that is the bishop of Basle, or, as he is called by the Protestants, the prince of Porrentruy, whose principal residence is Porrentruy, the capital of his dominions, was formerly chosen by the chapter of eighteen cantons, resident at Arlesheim, and confirmed by the pope. He was a prince of the German empire, and did homage to the emperor for that part of his territory which lies in the circle of the Upper Rhine. He was always considered as an ally of the Swiss, by his union with the Catholic cantons, first formed in 1579, and renewed at different intervals, particularly in 1671 and 1677, and by being included in the treaty which those cantons contracted with France in 1715 but as he was not comprised among the allies of the Swiss, in the league between the thirteen cantons and Louis the XVth, in 1775, he was not deemed a member of the Helvetic confederacy. The first particular alliance with France was concluded in 1730, between the bishop and Louis the XVth, and was renewed in 1780. The population of that part of the bishopric of Basle that was allied to the cantons amounted to 24,000. The form of government was a limited sovereignty, the bishop being bound, on all important occasions, to consult his chapter; and his prerogative being confined, by the great immunities enjoyed by his subjects in general, and particularly by those of the reformed communion. He nominated to all employments both civil and military, and appointed the bailiffs or governors; criminal justice was administered in his name, and he had the power of pardoning. In civil proceedings, he received an appeal from the inferior courts; but in his German dominions, when the cause exceeded the value of a stipulated sum, it might be carried to the chambers of Wetzlar or Vienna. The subjects of the bishop are partly Protestants and partly Catholics; the Protestants inhabit the greater part of the valley of Mulier, and the whole district to the south of Pierre Pertuis, and are about 15,000; the Catholics amount to 35,000. The French and German languages are both spoken in the bishop's dominions. The whole bishopric of Basle is now annexed to France. In 1792, their troops overran the country of Porrentruy on the German part, under the pretence of delivering the natives from slavery, and took possession of the famous passes of Pierre Pertuis. This district was ceded to France by the treaty of Campo Formia, and is formed into the department of Mont Terrible. In 1798, the Helvetic part of the territory was taken possession of, in the name of the republic, by general St. Cyr, under a declaration that France succeeded to the property, dominions, rights, and prerogatives of the bishop. This district was also annexed to the department of Mont Terrible. The bishopric of Basle is a fertile country, and many forges are employed in the manufactures of iron and steel.

Basil, among others, denotes the angle to which the edge of an iron tool is ground. To work on soft wood, they usually make their basil 12 degrees; for hard wood 18; it being observed that the more acute or thin the basil is, the better and the more it cuts; and the more obsolete, the stronger and fatter it is for service.

BASILIAN, or BASSILIAN, in Geography, one of the Philippine islands; 12 leagues in circumference, very fertile, especially in fruit and rice; 6 leagues S. W. of Mindanao. N. lat. 5° 51'. E. long. 121° 30'.

BASILARIS Arteria. See Artery.

BASILE, St. in Geography, a town of Italy, in the kingdom of Naples, and province of Ostranto, 18 miles east of Matera.

BASILE, St. is also a town of the kingdom of Naples, in the province of Basilicata; 11 miles N. E. of Turin.

BASILIEUS, Basileus, a title assumed by the emperors of Constantinople, exclusive of all other princes; to whom they give the title rex, king. The same quality was afterwards given by them to the kings of Bulgaria, and to Charlemagne; from the successors of which last they endeavoured to wrest it back again.

The title basilieus has been since assumed by other kings, particularly the kings of England; "Ego Edgar totius Angliae basilieus confirmavi."

Hence also the queen of England was intitled basilea, and basilia.

BASILEUS, in Ornithology, a name by which many of the chief authors called the Regulus Crisatus of Aldrovand, the Motacilla Regulus of the Linnaean system, or the golden-crested wren.

BASILI, in Geography, a river of European Turkey, which runs into the Gulf of Colokita, 4 miles N. N. E. of Colokita.

BASIL, St. a town of European Turkey, in the Morea; 8 miles S. of Corinth.

BASILIA, a town of Poland, in the palatinate of Volhynia; 32 miles W. S. W. of Constantinopul.

BASILLA, or BASILICO, a fortified town north of Corinth, situated upon the coast of the Gulf of Lepanto.

BASILIANS. See Bogomills.

BASILIC, BASILA, is used, in Ecclesiastical Writers, for a church. In which sense this name frequently occurs in St. Ambrose, St. Austin, St. Jerom, Sidonius Appollinaris, and other writers of the fourth and fifth centuries.

M. Perrault says, that basilics differed from temples, in that the columns of temples were without fide, and those of basilics within.

Some will have the ancient churches to have been called basilics, because generally built in the fashion of the Roman halls called by that name; others, because divers churches were formed of those halls. Some have supposed that, on the conversion of Constantinople, many of the ancient basilics were given to the church, and turned to another ufe, viz. for Christian assemblies to meet in; and they refer to that passage in Ausonius, where speaking to the emperor Gratian, he tells him, the basilica, which herefore were wont to be filled with men of business, were now thronged with notaries praying for their safety; by which it is apprehended he meant, that the Roman halls or courts were turned into Christian churches: and hence it has been conceived, that the name basilicas came to be a general name for churches in after-ages. See BASILICA.

BASILICA is chiefly applied, in modern times, to churches of royal foundation; as those of St. John de Lateran, and St. Peter of the Vatican, at Rome, founded by the emperor Constanine.

BASILIC appears also to have been given, in later ages, to churches before consecration.

BASILICS were also little chapels built by the ancient Franks over the tombs of their great men; so called, as resembling the figure of the sacred basilicae or churches.

Perfons of inferior condition had only tumbs, or porticu, erected over them. By an article in the Salic law, he that
that robbed a tumba or porticus, was to be fixed fifteen foidi; but he that robbed a ballica, thirty foidi.

BASILICA, or BASILICUS, in Anatomy, the name of a vein, arising from the axillary branch, and running the whole length of the arm. The ballica is one of the veins opened in bleeding in the arm. See VEN.

Basilica, in Architecture. This word, which has suffered very different acceptations, is derived from Basiliae, king, and sons, house: it means therefore, etymologically, royal house. Perhaps the halls of justice acquired this name in early antiquity, when the judging the people might be regarded as the peculiar regal prerogative; and it was natural that they should retain this appellation, when justice was no longer administered by kings. Among the public edifices composed of a single building, the basilica appears to have been one of the largest. It was, among the Romans, an ample hall adjoining to the Forum, in which the magistrates judged under cover; which distinguished it from the fora, where they held their sittings in the open air. Here the tribunes and centurions administered justice, and the jurists and legists in the pay of the republic, assisted those who came to consult them. Young orators declaimed in separate apartments, and the porticos were occupied by merchants and traders. Thus these edifices were at the same time applied to the purposes of commerce and judicature.

It is to be lamented that the antique basilicas have so entirely perished, that the construction and disposition of them are involved in great doubt and obscurity. Vitruvius, the only ancient architect whose writings have descended to us, gives the following description of the Roman basilica.

"The basilica should be adjacent to the forum on the warmest side, that the merchants may conjoin together without being incommoded by the weather. The breadth is not made les than the third, nor more than the half of the length, unless the nature of the place opposes the proportion, and obliges the symmetry to be different. But if the basilica has too much length, chalcidices are made at the ends, as they are in the basilica of Julia Aquiliana. The columns of the basilica are made as high as the portico is broad. The portico is the third part of the space in the middle; the upper columns are a fourth part less than the lower. The plenum, which is between the upper columns, should also be made a fourth part less than the same columns, that those who walk in the floor above may not be seen by the merchants below. The epistilium, zophorus, and corona, are proportioned to the columns, in the manner explained in the third book."

The basilica, however, which Vitruvius erected at the colony of Julia of Fanum, did not conform to the foregoing precepts. It is thus described: "the middle teftudo (side or nave) is 120 feet long, and 60 feet broad; the surrounding portico between the walls and columns is 20 feet broad. The columns, continued the whole height of the building, are 50 feet, including the capitals, and 5 feet in diameter; having behind them pilasters 20 feet high, which fulfil the beams that bear the floor of the upper porticoes. Above these pilasters are others 18 feet high, which support the ceiling of the upper porticoes, which is laid lower than the roof of the teftudo, the space between being left open in the intercombinations for light. The columns in the breadth of the teftudo are four, including those of the angles; and in the length, of the side next the forum, including the same angles, eight. On the other side there are but six, the two in the middle being omitted, that they may not obstruct the view of the pronaos of the temple of Augustus, which is situated in the middle of the side wall of the basilica.

The tribunal in this building is in the figure of a hemicycle, extending in front 45 feet, and receding in the centre of the curvature 15 feet; so that those who attend the magistrates obstruct not the merchants in the basilica.

From the preceding descriptions it would appear, that the ancient basilica consisted of a great nave in the middle, further surrounded with only one range of porticoes; and it is thus that it has been represented in the designs of all who have restored it from the words of Vitruvius. However, the fragments of the plan of Rome taken under Septimius Severus, which fill exist, show a part of the basilica Amilianis; and in this authentic record we find two rows of columns on each side, which, supposing an exterior wall, would give two ranges of porticoes. But this valuable relic gives reason to doubt, whether the basilicas were surrounded with walls, or whether their porticoes, open on every side, communicated with the public places. The description of Vitruvius explains nothing in this particular; but it may perhaps be inferred from what he recommends relative to the warmth of the exposure, that they were not enclosed.

Supposing the entrance of the basilica to be at one end, the other was terminated by a hemicycle, in which was placed the tribunal; this circular end answers to the abedum of the Christian basilicas. The chalcidices mentioned by Vitruvius have given rise to various conjectures, which it would be useless to detail, as we have no data from which any other inference can be drawn, than that they were some kind of apartments, separated by a partition, at the ends of basilicas.

Before the excavations made at Otricoli, and the discoveries which were the result, we had only conjectures on the form and nature of the ancient basilicas; uncertain vestiges were all that remained of those of Rome, and the situation of the famous basilicas, Amilia and Pulvia, was sought in vain at Prænesta. The monument of Otricoli, therefore, ought to be very precious if we find in it a true basilica, of which the reader will be enabled to judge from the following description.

To discern the essential character of a basilica, it will be useful previously to consider the difference between it and a temple. The original form of a temple is an oblong cella or body, surrounded with porticoes; and even where the lateral porticoes were suppressed, they were never deprived of a pronaos or portico in front. In short, in the basilica the porticoes were internal and external in the temple. Now the edifice of Otricoli has no exterior colonade, neither pronaos nor portico. It is a square building, surrounded with a simple wall. In the middle the entrance is by a rufcical opening, without any vellus of decoration. The interior consists of a great hall, divided by porticos into three naves or aisles. The portico immediately opposite the entrance is composed of three arches; eight Corinthian columns form the remaining three porticoes; the further end of the building is occupied by a hemicycle or tribunal, on each side of which is a small apartment. The tribunal is ascended by several steps; and round the interior of the edifice is continued a pedestal, on which were statues which have been transported to the Museo Vaticanum. The ceiling was probably of wood, as there are no columns of a vault. No velluses lead even to suppute that in the middle there might be a base for a statue, or any thing that indicates a temple.

This monument is certainly deficient in many of the characteristics of a basilica; its plan is an exact square instead of an oblong, and the upper galleries are wanting. However, considering to what variations these edifices were subject, according to the riches, the size of towns, and the diversities of situation; and how much Vitruvius, the author
of the precepts which should fix our ideas on this subject, has departed from his own rules in the construction of his basilicas, it will perhaps be impossible not to recognize, in the edifice of Octavius, an example of the ancient basilica.

But we cannot quit this division of the subject without mentioning a monument, interesting at any rate by the singularity of its architecture, and still more so if it preserve to us the form of the Grecian basilica. This edifice, one of the antiquities of Paestum, is in length the double of its breadth; it is formed by ranges of Doric columns, to the number of nine in each front and eighteen on each wing including the angles. On a line with the central column of each front a range of columns is continued through, dividing the building into two parts; at the foot of these columns the pavement is elevated and adorned with mosaic. The interior columns supported the roof, which was probably a terrace. The uneven number of columns in the fronts, and the narrowness of their intercolumniations compared with those of the wings, prove sufficiently that the principal entrances must have been at the sides; and this circumstance, together with the absence of any exterior wall to inclose a cela, shews that this edifice could not have been a temple. But to the purposes of a basilica it seems very well adapted; open on every side, it admitted an easy access, while the elevation on bank in the middle, would afford a tribunal suited to the simplicity of the age.

The Early Christian Basilica. It is not probable that the ancient basilicas were ever converted into Christian churches; in that case, we should still be in possession of some of these monuments of antiquity. The most ancient basilicas of the Christian, those which date from the first centuries of the public exercise of our religion, were built expensively for their use; and the details of their architecture, announce but too clearly the time of their construction. But these new temples resembled so much the antique basilicas, that they retained their name; and indeed if we examine the buildings of antiquity, we shall find no other so well calculated for the purposes of our religion. These edifices, at once simple in plan and magnificent in decoration, were of a form and disposition the most advantageous that can be imagined for large halls, and their construction combined solidity with economy. Their solidity is proved by the duration of fourteen centuries of soine of these buildings; and their economy conflicts in the lightness of the points of support, and in that of the covering which was only of carpentry. In moli of the basilicas, the walls and the points of support only occupy one tenth of the total space; which, in buildings vaulted and supported with arcades, like many modern churches, take up at least twice that superficially, and require besides materials and modes of construction which quadruple the expense.

It is to Constantine, that the first Christian churches known by the name of basilicas are to be referred. This prince signalized his zeal by the erection of monuments which announced the triumph of the religion which he had embraced. He gave his own palace on the Celian mount to construct on its site a church which is recognized for the most ancient Christian basilica. A modern building has so much marked and disfigured the ancient, that only the situation and plan of this monument can be discovered.

Soon after, he erected the basilica of St. Peter of the Vatican. This magnificent edifice was constructed about the year 324 upon the site of the circus of Nero and the temples of Apollo and Mars, which were destroyed for that purpose. It was divided internally into five ailes from east to west, which terminated at the end in another aisle from north to south, in the centre of which was a large niche or tribunal, giving the whole the form of a cross. The larger aile was inclosed by forty-eight columns of precious marble, and the lateral ailes had likewise forty-eight columns of smaller dimensions; two columns were placed in each wing of the terminating aile. The whole was covered with a flat ceiling, composed of immense beams which were cased with gilt metal and Corinthian bras taken from the temples of Romulus and Jupiter Capitolinus. A hundred smaller columns ornamented the shrines and chapels. The walls were covered with paintings of religious subjects, and the tribunal was enriched with elaborate mosaics. An incredible number of lamps illuminated this temple; in the greater solemnities 2400 were reckoned, of which one enormous candelabrum contained 1360. The tombs of pontiffs, cardinals, and princes, were reared against the walls or incised in the ample porticoes.

This superb temple was repleted by Alaric and Totila, and remained uninjured in the various fortunes of Rome during the lapse of twelve centuries; but crumbling with age, it was at last pulled down by Julius II. and upon its site has arisen the famous basilica, the pride of modern Rome.

The third great basilica built by Constantine, that of St. Paul on the road to Ostia, still exists. The interior of this building resembles precisely that of St. Peter which has just been described. Of the forty columns inclosing the great aile, twenty-four are supposed to have been taken from the mausoleum of Adrian; they are Corinthian, about three feet diameter, fluted their whole length, and cabled to one third: the columns are of blue and white marble, and antiquity preffes nothing in this kind more preciously for the materials and the workmanship. But these beautiful remains seem only to be placed there to the disgrace of the rest of the construction, which is of the age of Constantine and Theodosius, and which most strikingly exemplifies the rapid decline of the arts.

The churches we have hitherto described bear a very complete resemblance to the antique basilica in plan and proportion. The only remarkable difference is, that the superior galleries are suppressed, in the place of which a wall is raised upon the columns of the great aile, which is pierced with windows, and supports the roof.

The church of St. Agnese out of the walls, though not one of the seven churches of Rome which retain the title, is however a perfect imitation of the antique basilica. This resemblance is so complete, that without the testimony of writers who inform us that it was built by Constantine at the request of Constantia his sister or daughter, and without the details of its architecture which forbid us to date it higher, it might be taken rather for an ancient tribunal of justice than a modern church. It forms an oblong internally, three sides of which are surrounded with columns forming the porticoes; the fourth side opposite the entrance is recessed in a semicircle; this is the tribunal. The frieze order of columns carries a second, forming an upper gallery, above which begins the ceiling of the edifice. The shortening of the columns, recommended by Vitruvius, is observed in the upper order.

We have hitherto observed in the Christian basilicas but small variations from the antique construction; they were still simple quadrilateral halls divided into three or five ailes, the numerous columns of which supported the flat ceiling; but the crofs form, the emblem of Christ\'sunicity, which began to be adopted in these buildings, operated the most essential changes in their shape. The interfection of the croffing ailes produced a centre, which it was natural to enlarge and make principal in the composition; and the invention of domes
domes supported on pendentives enabled the architects to
give size and dignity to the centre, without interrupting
the vista of the aisles. The church of St. Sophia at Con-
stantinople was the first example of this form.

The seat of the Roman empire being transferred to Con-
stantinople, it is natural to suppose that the disposition of the
ancient St. Peter's of Rome, erected at that time the most
magnificent church in the world, was imitated in that which
Constantine erected for his new capital under the name of
St. Sophia. This last did not exist long; Constantinus the
son of Constantine, raised a new one which experienced
many disasters. Destroyed in part, and rebuilt under the
regn of Arcadius, it was burnt under Honorius, and re-
established by Theodosius the younger; but a furious sedi-
tion having arisen under Julianus, it was reduced to ashes.
This emperor having appeased the tumult, and wishing to
immortalize his name by the edifice he was about to erect,
assembled from various parts the most famous architects.
Athenaeus of Tralles and Isidore of Miletus were chosen;
and as they had the boldness to attempt a novel construction,
they experienced many difficulties and disasters: but at last
they had the glory of finishing their design.

The plan of this basilica is a square of about 250 feet.
The interior forms a Greek cross, that is, a cross with equal
arms; the aisles are terminated at two ends by semicircles,
and at the other two by square cells, in which are placed
two ranges of tribunals. The aisles are vaulted, and the
centre, where they intersect, forms a large square, upon
which is raised the dome, of about 110 feet diameter. The
dome, therefore, is supported upon the four arches of the
naves and the pendentives or spandrels which connect the
square plan of the centre with the circle of the dome.

The general effect of the interior is grand; but whatever
praises the bold invention of this immense dome may merit,
it must be confessed that there are times in which princes,
however great and liberal, can only produce imperfect
monuments, of which this edifice is a striking example. All
the details of its architecture are defective and barbarous.

However, from the communication established between
Greece and Italy at the revival of letters, this basilica, the
last as well as the most magnificent of the lower empire, was
that which influenced most the form and architecture of the
new temples. The Venetians, in the tenth century, copied
with success the belt parts of the disposition of St. Sophia in
the church of St. Mark. This is the first in Italy which was
constructed with a dome supported on pendentives; and it
is also this which first gave the idea, which has been imita-
ted in St. Peter's of the Vatican, of accompanying the great
dome of a church with smaller and lower domes to
give it a pyramidal effect.

From this time to the erection of the basilica of St. Peter's
we find the churches approach, more or less, to the form of
the ancient basilica or the new construction. The church
of Santa Maria del Fiore of Florence, from the magnitude
of its dome and the skill which Brunelleschi displayed in its
construction, acquired a celebrity which made the fable of
domes prevail; and this fable was finally established in the
noble basilica of the Vatican, which has become the type
and example of later ones. The form of the antique basilica
was entirely lost, and the name, which has been retained, is
the only remain of their ancient resemblance.

In the pontificate of Julius II. the beginning of the sixteenth
century, the basilica of St. Peter's was begun from the de-
signs of Bramante. This great man formed the idea of
fulfilling in the centre of the building a circular temple as
large as the pantheon, or, as he expressed it, to raise the
pantheon on the temple of peace; and, in fact, we find great
resemblance in size and disposition between these two edifices
and the project of Bramante. He was succeeded in his
office by San Gallo, who almost entirely lost sight of the
original plan; but Michael Angelo, to whom at his death
the undertaking was committed, concentrated the discordant
parts, and contracted the whole into the form of the Greek
crofs. Michael Angelo died in 1564, while he was engaged
in erecting the dome; but he left plans and models, which
were strictly adhered to by his successors Vignola, J. de la
Porte, and Fontana, who terminated the dome. The build-
ing was carried on under many succeeding pontiffs; and at
last, by lengthening the longitudinal naves, it acquired the
form of the Latin cross; in that particular, approaching to
the original design of Bramante.

The general form of this edifice externally is an oblong,
with circular projections in three of the sides; the plan of
the interior consists of a Latin cross, the interfecion of the
arms of which is enlarged and formed into an octagon; the
head of the long aisles and the ends of the cross aisles are
termimated in hemicycles, and the great naves are accompa-
nied with lateral aisles and with several inclosed chapels.
The octagon centre supports a circular wall enriched with
piasters and pierced with windows, above which rises the
magnificent dome.

Thus we have traced the progress of the basilica from
the quadrilateral hall of the ancients with its single roof and
flat ceiling supported on ranges of columns, to the cross-
shaped plan, central dome, and vaulted aisles supported on
molly piers of the modern cathedral. It only remains to
treat of the

Modern Basilica. We give this name with Palladio to the
civil edifices which are found in many Italian cities, and the
decoration of which is entirely similar to the antique basilica.

In imitation of the ancients, says this celebrated archi-
teD, the cities of Italy construct public halls which may
rightly be called basilicas as they form part of the habita-
tion of the supreme magistrate, and in them the judges ad-
minister justice. The basilica of our time (he continues)
differ in this from the ancient; that those were level with
the ground, while ours are raised upon arches in which are
shops for various arts and the merchandise of the city. There
the prisons are also placed, and other buildings be-
longing to public busses. Another difference is that
the modern basilicas have the porticos on the outside, while
in the ancient they were only in the interior. Of these halls
there is a very noble one at Padua; and another at Brescia,
remarkable for its size and ornaments.

But the most celebrated is that of Vicenza; the exterior
part of which was built by Palladio, and the whole so much
altered that it may pass for his work. The body of the
building is of much greater antiquity, though the date of
it is unknown.

Time and various accidents had reduced this edifice to
such a state of decay, that it was necessary to think seriou-
ly of preventing its total ruin: for this purpose the most emi-
nant architects were consulted, and the design of Palladio
was approved. He removed the ancient loggias, and substi-
tuted modern porticoes of a very beautiful invention. These
form two galleries in height, the lower order of which is ornamented
with Doric engaged columns, at very wide intervals, to
answer to the internal pillars of the old building; the space
between each column is occupied by an arch reposing on
two small columns of the same order, and a piaster at each
side against the large columns, which leaves a space be-
 tween it and the small columns of two diameters. The upper
portico of Ionic columns is disposed in the same manner,
and a balustrade is placed in the archways. The
entablature
entablature of the large orders is profiled over each column.

The building is about 150 feet long, and 50 feet broad; the hall is raised above the ground 20 feet. It is formed by vaults supported on pillars, and the whole is covered with a wooden dome. See Plate II. of Alexander, the Roman basilica, from the description of Vitruvius. Plate III. the basilica at Parum. Plate IV. the plan of the old basilica of St. Peter, founded by Constantine. Plate V. plan of the modern St. Peter's of the Vatican. Vitruvius. Arch. de A. Palladio. Costaggii Pontani del Vaticano. F. Exe. Meth.

BASILICS, Basilica, a collection of the Roman laws, translated into Greek by order of the emperor Basil and Leo, and which were of force in the eastern, empire till its dissolution.

The basilicae comprehended the constitutions, digests, code, and novels, and some edicts of Julian and other emperors. The collection consisted of sixty books, for which reason it was called "De rebus societatis." It is supposed to be chiefly the work of the emperor Leo, the philosopher, who deposited it in his father Basilus Macedus, who first began it in 867, and carried the work to forty books. It was published by Leo, with the addition of twenty books more, in 980; and thirty years after, corrected and improved by his son Constantine Baphyrogenitus. Six books of the basilica were translated into Latin in 1537, fol. by Gentianus Herretus. Of these sixty books, there are now remaining only forty-one; an edition of which, with a Latin version, was published by Charles Anshall Fabrottus, at Paris, in 1647, in 7 tomes folio: the other nineteen are in some measure supplied by Fabrottus, from the "Synopsis Basilicorum," 4°. Four other books have been since discovered, and are inferred in Girard Meerman's "Novus Thesaurus Juris Civ. et Canon." tom. v. Of the whole work, the sixty books, fol. Leucelavius has printed at Basil, in 1575, an edition or synopsis. Of the subject of the basilica, Fabricius (Bibl. Graec. t. xii. p. 425-514.), Heinennius (Hift. Juris Romani, p. 396-399.), and Giannone (Itiner. Civile di Napoli, tom. i. p. 450-458.), as historical civilians, may be usefully consulted.

BASILICATA, in Geography, a province of the kingdom of Naples, bounded on the north by the Capitanata and the Terra di Bari, on the east by the gulf of the Tarento, on the south by the Principato Citera and Calabria Citera, and on the west by the Principato Ultra. Its extent is about 1,605,047 moggies, 5 moggies making 4 English acres; and the number of its inhabitants about 325,682. Its rivers are Bradano, Baisento, Salandrella, Acri, and Sinoa; its lakes are Lagonagro and Olmo; its mountains are for the most part branches of the Apennines; and its principal places are Accerenza, Melii, Monte-Pello, Trircario, Potenza, Anglona, Venusia, and Muro: its ruined cities are Metapontum and Heraclea. This province produces corn, wine, oil, sappan, cotton, honey, and wax.

BASILICI, basilica, in the Greek Empire, was a denomination given to the prince's mandatories, or those who carried his orders and commands.

BASILICON, or Basilicum, in Pharmacy, is the pompos designation formerly given to an officinal ointment or plaster, much relishing and superseding the Unguentum Rofae Plante.

BASILICUS, or Basilius, in Aetymology, is the name of a fixed star of the first magnitude in the constellation Leo, called also regulus, and cor leonis.

Basilicus Sinus, in Ancient Geography, the gulf of Melilpo, a gulf of Afa Minor, in Caria, which it separates from Lonia.

BASILIDAE, a people of Scythia, according to Pline. Herodotus says, that their habitation was below the catacombs of Borythene.

BASILDÆ, in Biography, an heresarch of Alexandria in Egypt, who flourished in the former part of the 2nd century. Bagnare refers him to the year 121, Nili to 123, and Cave to the year 112. Grabe says, that he began to spread his notions in the time of Trajan, but chiefly under Adrian; and that he probably did not die before the beginning of the reign of Antoninus Fuis: and this opinion is confirmed by Clement of Alexandria, who informs us, that he or his followers boasted of his having been taught by Glaucis, a disciple of St. Peter. Balfides has generally obtained the first place among the Egyptian Gnostics. He was the author of several works, of which the principal was his "Twenty-four Books of Commentaries," supposed by Beaufobre, Fabricius, and Jones, to be the "Gospel of Balfides," mentioned by Origen, and after him by Ambrose and Jerome. As none of his works are extant, we derive our knowledge of them from those who have detailed and expounded his errors; among whom are Irenæus, Tertullian, Clemens Alexanderinus, Origen, Epiphanius, &c. Balfides acknowledged the existence of one supreme God, self-existent, and perfect in wisdom and goodness, who produced from his own substance seven beings, or worlds, of a most excellent nature. From two of these, called Dynamics and Sympathy, i.e., power and wisdom, proceeded angels of the highest order, who formed a heaven for the habitation of angels: and these angels again produced other inferior angelic beings: these were succeeded by other generations of angels, and new heavens were also created, until the number of angelic orders, and of their respective heavens, amounted, as Irenæus has suggested, and others have believed, to 365, the number of days in the Egyptian year. Beaufobre disputes this account; and it is suggested, that Balfides might possibly say, there were 365 angels, who prefided each over one day of the year; which is a notion that seems to have been entertained by some perons in the east. Balfides ascribed the formation of this lower world to angels: conceiving it to be unworthy of the Supreme Being to give form and beauty to matter, and to be the author of the many evils that are in this world. These angels, perceiving matter, which was eternal, agitated in a tumultuous manner, determined to reduce it to order, and having in their minds the idea of the world of spirits to which they belonged, and which served for them as a model, proposed to form a material world that should resemble it, and to create a race of beings to inhabit it. This design was executed, and approved by the Supreme Being; who added a reasonable soul to the animal life with which alone the inhabitants of this new world were at first endowed, and who gave to the angels the empire over them. These angelic beings became gradually depraved by the influence of malignant matter, and endeavored to efface from the minds of men the knowledge of the Supreme Being, and to arrogate to themselves the worship that was his due. The most arrogant and turbulent of these fallen angels preferred over the Jewish nation. At length the Supreme Deity, observing and compassing the ruined and wretched state of the world, sent from heaven his unfledged Nus, or Christ, the chief of the angels, to restore the knowledge of the Supreme God, and to destroy the empire of those angels that prefided over the world, and particularly that of the arrogant leader of the Jewish nation. The god of the Jews, alarmed at this, sent forth his ministers to seize the man Jesus, and put him to death. They executed his commands, but their cruelty could not extend to Christ, the heavenly being, against whom their efforts were vain. According to Irenæus's
Irenæus’s account, Jesus appeared as man, but was not so in reality, and wrought many miracles: however, he was not crucified; the Jews having, through malice, crucified Simon the Cyrenian in his stead. Many of the ancients have, upon the authority of Irenæus, accused Basilides of denying the reality of Christ’s body, and of mantaking that Simon was crucified in his stead. But this accusation, as far as it refers to Basilides himself, is groundless; for he seems to have considered the divine Saviour, as composed of the man Jesus, and Christ the Son of God. To this purpose Beaufobre says, that, though Basilides did not believe the incarnation, or hypothetical union of the Son of God with flesh, yet he never denied that Jesus was a real person, in whom the understanding, soul, spirit of God, display’d his power, whom he filled with his gifts and illuminations, and invested with extraordinary influence. With regard to the ridiculous story of Simon transformed into Jesus, and crucified in his stead, he represents it as a fable which Irenæus derived from some unknown source. As Basilides believed the death of Jesus, who was a real and most excellent man, in whom the first-beginning of the Father chose to dwell, though not of the Son of God, he probably believed his resurrection; that is, that his soul ascended to heaven, and the body was left to lie in the grave, or was disipated into the air, and among the elements of which it was composed. As the ancient Catholic writers do not particularly say that Basilides denied the resurrection of Jesus, though they affirm us he and his followers denied the resurrection of the body; it is not unlikely that he admitted the resurrection, or the advancement and glorification of the soul of Jesus. Basilides believed the fact of the baptism of Jesus; and his followers, as Clement informs us, celebrated the day of his baptism as a festival, which was the 15th day of the Egyptian month Tobi, corresponding to the 9th or 10th of our January, in the 15th year of Tiberius; and they spent the whole preceding night in reading, and probably in prayers. Some persons have supposed that Basilides denied the necessity or rea/onables of our suffering martyrdom for Jesus; and yet it appears from the testimony of Clement, that he esteemed martyrdom an honourable suffering, though it is the punishment of sins committed either in this life, or in a pre-exilient state. Basilides taught, that the soul only would be saved; but that the body is in its nature corruptible, and incapable of immortality. As for the spirits of the disobedient, it is said to have been his opinion, or that of his followers, that they would be subjected alive to the hells. Basilides has been falsely accused of believing that angels are indifferent in their own nature, and of allowing and encouraging the practice of wickedness. On the contrary, he is represented by those whose testimonies are most credible, as strongly recommending the practice of virtue and piety, and condemning not only the actual commission of iniquity, but even every inward propensity of the mind to a vicious conduct. However, some of his practical opinions gave offence to the orthodox Christians; for he allowed men to conceal their religion, and even to deny Christ, when their lives were in danger, and to partake of the feasts of the Gentiles that were instituted in consequence of the sacrifices offered to idols: not to add, that the irregular lives of some of his disciples seemed to justify the unfavourable opinion that was entertained concerning their matter. The Basilidians have been also accused of magical practices: but Terullian says nothing of this kind; and the passage of Irenæus upon which this charge is founded, is suppos’d to have been corrupted. Besides, the ancient fathers perpetually confound astronomy and astrology with magic; and hence Lardner is induced to be very doubtful about the truth of this accuation. Irenæus says, that the Basilidians called the prince of the heavens Abraxas, that name having in it the number 365; and the gems, or figures, bearing this name are supposed to have originated from Basilides. However, many of these Egyptian talismans appear to have an earlier date; and the magic of this sect was probably no more than the practice of certain superstitions, rather of a foolish than of a malignant nature. See Abraxas.

BASILIDIAN, the followers of Basilides, of whom an account has been given in the preceding article.

BASILINESIA, in Entomology, a species of Palaena that inhabits Austria. The wings are greyish-brown undulated, with a little black line at the base; crest of the thorax bifold. Fabricius.

BASILINOPOLIS, or Basanopolis, in Ancient Geography, an episcopal town of Asia Minor, in Bithynia.

BASILIPOTAMO, in Geography, the ancient Eurusas, a river of the Morea in ancient Europe Turkey, which falls into the gulf Calochina.

BASILIPPUM, in Ancient Geography, a town of Bética in Spain, about 20 miles from Hipalai or Seville; now Castillana, a city of Andalusia, on the Guadalquivir.

BASILIS, a town of Peloponnesus, in Arcadia, founded, according to Paulaner, by Cypiculus, and situate near the Alpheus. In his time it was in ruins, among which was a temple of the Eleusinian Ceres.

BASILISSICUS, in Ornithology, one of the synonomous names of the golden-crowned wren, among old writers. This name is a diminutive of the word balaicus, king; and was given it on account of its golden crown.

BASILISCU, in Zoology, a species of Lacerta, which, according to Linnaeus, has the tail long and round; dorso-fuscus red, and of the head ericled. This is the basilisk of modern naturalists, and seems to unite the two genera of Lacerta and Draco. The marks of Dr. Shaw (in the Gen. Zool.) on this extraordinary creature are highly intereting, and ought not to escape attention. It is, according to this writer, particularly distinguished by a long and broad wing-like procus or epaulets continued along the whole length of the back, and to a very considerable distance on the upper part of the tail, and furnished at certain distances with internal radii analogous to those in the fins of fishes, and still more so those in the wings of the draco vulgaris, or flying lizard. This procus is of different elevation in different parts, so as to appear strongly inflated and indented, and is capable of being either dilated or contracted at the pleasure of the animal. The occiput, or hind part of the head, is elevated into a very conspicuous pointed hood, or hollow crest.

Notwithstanding its formidable appearance, adds this author, the basilisk is a perfectly harmless animal; and, like many others of the lizard tribe, resides principally among trees, where it feeds on insects, & c. It has long ago been admirably figured in the work of Seba; and as it is an extremely rare species, has sometimes been confounded, from the strangeness of its form, as a fictitious representation. There is, however, in the British Museum, a very fine speciment, well preserved in spirits, and which fully confirms the excellence of Seba’s figure; from which, in all probability, Linnaeus himself (who never saw the animal) took his specific description. The colour of the basilisk is a pale ci-
brown, with some darker variations towards the upper part of the body. Its length is about a foot and
half. The young or small specimens have but a flight ap-
pearance either of the dorsal or caudal process, or of the
pointed occipital crest. The basilisk is principally found
in South America, and sometimes casually exceeds the
length before mentioned, nearly three feet, or even more,
from the nose to the extremity of the tail. It is said to be
an animal of great agility, and is capable of swimming occa-
sionally with perfect ease, as well as of springing from tree to
tree by the help of its dorsal crest, which it expands in order
to support its flight.

Among the French naturalists, the Iguana is a distinct
species of the oviparous quadrupeds, in which the Linnean
*Lacerta basiliscus* is included under the name of basilisk.

The basilisk of the ancients existed only in the glowing
fancy of their poets: they feigned it to be the most malign-
ant of all poisonous serpents; as a creature whose breath
empoisoned the very air, and whose baleful glance would
alone prove fatal to all other animals. A creature gifted
with such extraordinary powers could have no common or-
igin, and therefore it was affected to be the produce of the
egg of a cock brooded upon by a serpent. Galen says its
colour is yellowish, and that it has three little elevations on
its head, speckled with whitish spots, that have somewhat
the appearance of a crown. Pline, Matthiolus, Pliny, Lu-
can, and others of the most distinguished ancients, relate
many marvellous properties of this creature; but, notwith-
standing their authority, the basilisk, as they represent it,
is most unquestionably fabulous. It is needful to add to
this article any of the fables of Jerome Lobo, although
Dr. Johnfon has received some of them with an unwar-
nantable degree of credulity. The learned Proser Alpinus in-
forms us, on the authority of some relations, which he seems
to have credited, that near the lakes contiguous to the
horeses of the Nile, there is a number of basilisks, about
a palm in length, and the thickness of a middle finger; that
they have two large fleshes which they ufe as wings, and
crests and combs upon their heads, from which they are
called basiflæ or reguli, that is, crowned, crested, or kingly
serpents. And he fays, that no perfon can approach these
lakes without being destroyed by these crefted snakes. Our
traveller, Mr. Bruce, observes, that having examined the
lake Goodroro, thofe of Count Ohna and Tzana, the only
lakes near the fhores of the Nile, he never faw one ferpent
there, crowned or uncrowned; and that he never heard of
any; and, therefore, he believes this account as fabulous as
that of the Acontia and other animals mentioned by Proser
Alpinus, lib. iv. cap. 4. The basilisk is a species of ferp-
ten frequently mentioned in fcripture, though never de-
dcrifed farther than that it cannot be charmed fo as to do
no hurt, nor trained fo as to delight in music; which all
travellers who have been in Egypt allow is very poffible, and
frequently fen. (Jerem. viii. 17. Palm i. 13-13.) How-
ever, it is the Greek text which calls this ferpent basilik;
the Hebrew generally calls it tépha, which is a species of
ferpents real and known. Our English translation very im-
properly renders it cockatrice, a fabulous animal that never
did exist. The basilisk of fcripture feems to have been a
snake, not a viper; as its eggs are mentioned (Isaiah, ix. 5):
whereas it is known to be the characteristic of the viper to
bring forth living young. Bruce’s Travels in Abyssinia,
vol. v. p. 201.

Basiliscus is also mystically ufed by the alchemists, to de-
note the sublimate mercury of the philofophers.

Basiliscus, or Basilisc, in Artillery, also denotes a great
piece of ordnance; thus denominated from its resemblance
to the fuppofed ferpent of that name. The basilisk throw-
an iron ball of two hundred pounds weight. It was much
talked of in the time of Solmyan emperor of the Turks,
in the wars in Hungary; but feems now out of ufe. Maffius
speaks of basilisks made of brass, which were drawn each
by a hundred yoke of oxen. Modern writers also give the name
basilisk to a much smaller and fizable piece of ordnance,
which the Dutch make fifteen feet long, and the French
only ten. It carries forty-eight pounds.

BASILICUM Flumen, in Ancient Geography, a river of
Africa, which, according to Strabo, flowed between the
Euphrates and Tigris; but Ammianus Marcellinus fays that it
was a branch of the Euphrates, directed towards Ctesiphon,
and defigned for conveying water into the interior part of
Babylonia. The emperors Trajan and Severus opened this
canal after it had been filled up, and formed by it a commu-
nication between the Tigris and Euphrates.

BASILISUS, in Biography, a physician and monk of
Bulgaria, in the 12th century, was the founder of the fect
called Bogomili. After teaching his doctrine many years
in fecret, he was endeavoured to Contantimpos by the em-
peror Alexius Connenus, who, under pretence of learning his do-
ctrines at a private audience, placed a secretary behind a cur-
tain, who penned down what Basilus delivered. The em-
peror afterwards convoked a council, which, on the refufal of
Basilus to retract, committed him to the flames in 1118.
See Bogomili.

BASILuzzo, in Geography, one of the Lipari islands in
the Mediterranean, about two miles in circumference, and
raised some poles above the surface of the sea. On the south
side is a narrow bay; and on the summit is a plain of no great
extent, and the only part capable of cultivation, though it
produces only a little corn and pulse. This featty vegeta-
tion is nourished by a thin crust of decomposed lava, un-
der which is soon discovered the solid lava, which, in many
situations, is granitous, the quartz, felpar, and mica, being
very apparent in it. Two little cottages, which belong to
the proprietors of this ungrateful soil, are the only buildings,
near which are some ancient ruins. Rabbits are the only
animals found in this island; and as they were very
mischievous to the corn, the inhabitants introduced cats,
which followed them into their subtetanacean holes. This
island, as well as those that are in its vicinity, have been
produced by volcanic fires. Spallanzani’s Travels in the

BASIN of MINAS, a body of water of considerabe extent
and irregular form, situated in Nova Scotia, at the eaf-
t end of the bay of Fundy, and connecting with its north-ea-
t branch by a fhort and narrow strait. The country on its
banks is generally a rich foil, and is watered by many small
rivers. The spring-tides rise here 40 feet.

BASINET, BACINET, or BASSET, in Ancient Armour,
a species of light helmet, much ufed, both here and abroad,
in the thirteenth and fourteenth centuries. Its name was
undoubtedly taken from its form, and means a little bafoon.
The helmet of Don Quixote gives the reader an exact idea
of it. In the manuscript illuminations of the time it fre-
cently occurs; but as it materially differed from the flate
helmet, it is rarely, if ever, found upon papular monuments.
Fauchet (Œuvres, t. ii. p. 24, ed. 1610.) cites Frollart
(vol. iii. c. xix.), to prove that it had a vizor like the helmet,
and observes, that the French warriors of that era thought
the bell lances came from Bourdeaux, and the bell helmefts
and baiinetts from Paris, where, in his time, a “Rue de la
Heuramicie” existed. The baiinet is particularly men-
tioned in the flates of Robert King of Scotland; and its frequent
ufe in England may be judged of from an inquisition,

22 Edw.
22 Edw. III., whence Laurence de Halings, earl of Pembroke, appears to have held the manor of Alton Cantline, in capite, by the singular tenure of finding, in every war with Wales, for forty days, a foot-follower, armed with a bow without a string, and a buckler (cum uno bafinet fine cappa).

See Cowes.

BASINGSTOKE, or BASINGE, JOHN, in Biography, a man of distinguished learning in the thirteenth century, was born at Basingstoke in Hampshire, and educated partly in the university of Oxford, and partly in that of Paris. From Paris he travelled to Athens; and on his return to England brought with him a great number of Greek MSS., and introduced the use of the Greek numeral figures into this country. It is very competent instrumental in promoting the study of the Greek language; and with this view he translated from the Greek, into Latin, a grammar, which he intitled "The Donatius of the Greeks." His other works were "A Latin translation of the Harmony of the Gospels;" a volume of Sermons; and "A Latin Commentary upon Lombard's Sentences." He was preferred first to the archdeaconry of London, and afterwards to that of Leicester; and died in 1252. Gen. Dict.

BASINGSTOKE, in Geography, a large populous town of Hampshire, in England, 16 miles N.E. of Winchester, and 46 W. from London, whence it is a great thoroughfare to the western counties. It appears that this place was of inferior consideration to Basing, in its neighbourhood, previous to the conquest; the latter being the head of the barony of Ports. In 1233, Peter de Rupibus, bishop of Winchester, was poffessed of the advowson of both the churches, and gave the presentations to the priory of Selborne in Hampshire. These afterwards were given, among other estates, by bishop Wainfleet to Magdalen college, Oxford, in which the patronage is now vested. In the church lies buried the mother of Walter de Merton, bishop of Rochester, founder of Merton college. Basingstoke gave birth to John de Basingstoke, a learned Grecian scholar, in 1252, and the intimate friend of Matthew Paris, and bishop Groskhead. Henry III., at the desire of bishop Merton, founded an hospital at this place for aged priests from his college at Oxford: of this collegiate chapel, which was endowed in 1251, there are now no remains. A beautiful ruin overlooks the town on the north side, called Holy Ghost chapel. This was founded by Sir William, afterwards lord, Sandes, who, with bishop Fox, obtained a licence from Henry VIII. to found a brotherhood, to continue in perpetual succession, for the maintenance of a priest to perform divine service, and for the instruction of youth in literature. The town is a corporation, governed by a mayor, high-steward, recorder, &c. Its trade consists in the manufacture of daggers and huzzings, and the market, held on Wednesday, is very considerable for corn; the trade of the town also is much benefited by a navigable canal. Basingstoke canal is nearly 44 miles. Warner's History of Hampshire, 4to.

BASIOGLOSSUS MUSCLE, in Anatomy, the front part of the Hyoglossus; which see.

BASIOURA, in Geography. See Bagiura.

BASIRE, or BAIER, ISAAC, in Biography, a learned and active divine in the seventeenth century, was born in 1657, according to Wood (Athen. Oxon.), in the isle of Jersey, but according to others in France, and after an education in some school or university, not ascertained, he became master of the free-school at Guernsey. At length he obtained some preferments in England, the last of which was the archdeaconry of Northumberland, with the annexed rectory of Howick; and in 1694, he received the degree of doctor in divinity at Cambridge by mandate. In the beginning of the civil wars, he was plundered and compelled to fly; upon which he repaired to King Charles at Oxford; and in 1641, a licence was granted to him, under the public seal of the university, to preach the word of God throughout England. Upon the surrender of Oxford to the British parliament, he determined to leave the kingdom, and to propagate the doctrine of the English church among the Greeks, Egyptians, and Hebrews. Accordingly he first went to Zante, an island near the Morea; and there imparted to the Greek inhabitants the doctrine of the Established church; a vulgar Greek translation of our church catechism. From hence he was compelled by the Latins to retreat to the Morea, where, at the desire of the metropolitan of Achaia, he preached twice in Greek, at a meeting of some of the bishops and clergy. He afterwards embarked for Syria, and during his abode at Aleppo, furnished the patriarch of Antioch with an Arabic translation of our church catechism. From Aleppo he travelled, in 1672, to Jerusalem, and through the whole of Palestine. At Jerusalem he was honoured by the Greek patriarch with his bull, or patriarchal seal, and he received many tokens of respect from the Latins. At his departure from Jerusalem, the pope's vicar gave him his diploma in parchment, under his own hand and seal, in which he was styled "a priest of the church of England, and doctor of divinity." On his return to Aleppo, he passed over the Euphrates into Mesopotamia, intending to convey the church catechism in Turkish to some of their bishops, who were mostly Armenians. In 1675, after wintering at Aleppo, he travelled by land to Constantinople, where the Turkish Protestant defied him to be their minister, promising to secure him a competent stipend. Before he quitted the eastern parts, it was his intention to have passed into Egypt, to visit the Coptic churches, to confer with the patriarch of Alexandria, and to impart to them a competent knowledge of the doctrines and forms of the church of England. But it is not known whether he accomplished this design. In Transylvania, whither he next removed, he was honoured by the prince of that country, with the divinity-chair in his new-founded university of Alba Julia or Weissenburg, and endowed with a very ample salary. During his travels, he collated the several confessions of faith of the different sects of Christians, Greeks, Jews, Mahometans, &c., and he published them in his own language; and it was his constant endeavour, as long as he remained in the East, to persuade the several sects of Christians to introduce a canonical reformation of some errors, and to unite with the church of England. But it is said, that his good intentions for this purpose were defeated by the artifices of the court of France. Upon the restoration of king Charles II., Dr. Baiere was recalled by his majesty to England, and restored to his preferments and dignities. Having quietly enjoyed his ample revenues for several years after the restoration,
he died in 1676, in the 69th year of his age, and was buried in the yard belonging to the cathedral of Durham. He appears to have been learned, active, and industrious, zealously attached to the church of England, and eminently distinguished by his loyalty. His publications were not very numerous: the principal of them were his "Deo et Ecclesiae Sacrum," or facielega renarraged and condemned by St. Paul, Oxford, 1646, 4to. and London, 1668, 8vo; "The History of the English and Scotch Pretendees," Lond. 1659, 1668, 8vo; "The dead man's real speech," a funeral sermon for Dr. Cofin bishop of Durham, to which is annexed his life; Lond. 1673, 8vo; and his "Diatriba de antiqua Ecclesia Britanniae Libertate," printed at Brougel by a royal exile in 1666, 8vo, and translated into English under the title of "The ancient Liberty of the Britanic Church, &c." Annexed to it is "A Letter, written by Dr. Bafre to the Hon. sir Richard Brown, resident at Paris for his Majesty of Great Britain; relating his travels and endeavours to propagate the knowledge of the doctrine and discipline established in the Brittish church, among the Greeks, Arabians, &c.; dated from Perampur Constantinople, 28th July 1653." Of this letter sir R. Brown observes, "that he could never read it but as a kind of nine-and-twentieth of the Acts." This book was printed at London in 1661, small 8vo. Biog. Brit.

BASIS, in the Ancient Music and Poetry, denotes the equality of sounds proceeding in the same tenor. In which sense, basis stands contradistinguished from ars, or elevation, as well as from thesis, or depression.

Basis, in Architecture and Chemistry. See BASE.

Basis, in Oratory, denotes the fourth member of a complete exordium, being that which succeeds the apodosis, and prepares the way for the proposition.

BASKERVILLE, Sir Simon, in Biography, son of Thomas Baskerville, an apothecary at Exeter, was, at the age of eighteen years, sent to Exeter college, Oxford, where he soon distinguished himself by his superior ability and industry, which procured him a fellowship in the college before he had taken his degree of bachelor in arts. In 1666, he was chosen senior proctor in the university. He now applied himself solely to the study of anatomy and physicks, and in 1611, was admitted to the degree of bachelor, and doctor in medicine, at the same time. Having acquired considerable reputation for his skill in his profession, he removed to London, and was chosen fellow, and some years after, president of the college of physicians there. He had also the honour of being appointed physician to king James, and afterwards to king Charles the First, by whom he was knighted. As his practice extended with his fame, he acquired so much wealth as to be called the rich Sir Simon; which will not be wondered at, if it be true, as was reported of him, that he had 100 patients on his list at a time. He died July 5th 1651, aged sixty-eight years, and was buried in the cathedral of St. Paul's. It does not appear that he left any manuscripts for publication, or any offspring to inherit the wealth he had accumulated. Wood's Athenae Oxon. Biog. Diæt.

BASKERVILLE, John, an ingenious artist, entitled to commemorating on account of his improvements in printing and type-bounding, was born at Woverley in Worcestershire, in the year 1726, and inherited a small estate. Having acquired in early life a skill and taste for fine writing and cutting in stone, he removed to Birmingham at the age of twenty, where he settled as a writing-matter; but he soon directed his attention to the art of japanning, which he followed with singular ingenuity and success as long as he lived. In 1750 he turned his thoughts to letter-bounding, which he pursued with great labour and expense. An edition of Virgil in royal 4to. in 1756, was his first great performance, which has since fetched thrice its original price. He afterwards printed many of the Latin classics, and several English ones, in 4to. and smaller sizes. The paper and ink, as well as the type, were prepared by himself; and the beauty of his workmanship was unrivalled. The type was distinguished by a peculiar fineness and sharpness, which gave the printing a strong resemblance to fine print-hand writing; and the paper had a remarkable gloss, which set off the type, but not without offending the eye. It is observed, however, that Baskerville's editions are not remarkable for their correctness. Deriving little encouragement from booksellers, he set up a typefoundry for sale, which business was for some time carried on by his widow, after his death in 1775. After many intellectual attempts for the difpofal of his types and matrices, they were suffered, not much to the credit of this country, to be removed to Paris, where they were purchased by a literary society for 370£, and employed in a splendid edition of Voltaire's works. Mr. Baskerville was distinguished by the elegance of his taste in his house, and every thing that belonged to him. The panell of his carriage were elegant pictures, and he was drawn by a beautiful pair of cream-coloured horses. He seems to have been inclined to ostentation and singularity; however, he was polite and hospitable to strangers, and ambitious of cultivating acquaintance with ingenious men. He was not connected with any religious sect, and was buried under a mausoleum in his own grounds. Biog. Brit. Gen. Biog.

BASKET, a kind of vessel made of osier, wicker, rushes, or the like, of different figures and sizes, according to the purpose which it is intended to serve.

Baskets have their uses not only in the economical, but military affairs; at sieges, they make use of a small basket filled with earth and ranged on the top of the parapet.

They are about a foot and a half high, as much in diameter at top, and eight or ten inches at bottom; so that being let together, they have a sort of embrasures at the bottom, through which the soldiers fire, without exposing themselves.

BASKET also imports a kind of measure or quantity of certain commodities.

BASKET, carville, in Architecture, a kind of vase, or figured piece of sculpture, in form of a basket, filled with flowers or fruits, serving to terminate some decoration.

BASKET-fish, in Natural History, a name given by the English in North America to a very remarkable fish, sometimes caught in the seas thenceabout, though not frequently any where.

Mr. Hooke, to whom it was referred by the Royal Society to name it, has called it Psepo eelinothelaris oviformis, the body of it resembling an egg-fish, or eelinius marinus, and the arms a flax-fish, and finally, the dividing of the branches being more like that of the branches of millet than any other natural production we are acquainted with.

This fish spreads itself from a pentagonal mouth-piece, or root, in the centre of which the mouth is placed, into five main limbs or branches; and each of these, at its first issuing out of the body, is divided into two: this makes ten. Each of these ten again divides into two, which makes twenty, and so on, each dividing to the fourteenth time; at which place they make more than four thousand thousand limbs. These are too small to be traced farther by the eye, or preferred in carriage: but it is very probable that even these were again divided, perhaps several times.

The branches between the joints are not all equally of a length, though, for the most part, they are pretty nearly so. The arms or branches are never very strong; but when they
are dry, they are much more brittle than before; the leaf force imaginable destroying them.

The shoals of Nantucket, an island on the coast of New-England, at times furnish the fishermen with this creature; but it is remarkable, that they are never seen there unless when taken by hooks in fishing for other fish. They clasp the hook-bait fast, and enbrace with all their arms, coming up, when drawn by it, in form of a wicker basket; whence the name; but when they have been some time out of the water, they become flat.

The use of the numerous arms of this fish is plainly to catch its prey. It probably extends them to their full length while under the water, and then claps hold of any thing fit for food that chances to swim over them. The fishermen have sometimes found the arms containing small mackerel, or pieces of larger. Phil. Trans. N.° 57 and 74. It is evident from the description, that this fish is of the *pella arborifera*, or branched fan-fish kind; but whether the same with the commonly known kind, called the *caput medusa*, is not evident from this description. The body of this fish, by what is related of its protuberance, and resemblance to the *echin murem*, may probably be the *astestrum in its fossil state*. See Asterias, and Asteropodium.

BASKET FISH. This is brine fish, made from the water of our salt springs in Cheshire, and elsewhere, differing from the common brine fish in the incumbrance of the grain, and its whiteness and purity.

In the preparing of this kind of fish, some use refin, and other additions, to break the grain and make it small; others effect this by keeping up a very brisk fire under it, and firing it all the while; but the most approved method is only to take out of this kind the third draught of every pan that is working for the common brine fish, and to do this before the granules or crystals are perfectly formed. By this means the salt is very fine; and when it has been hard pressed down into small wicker baskets, it is dried at the stove in them, and so kept for sale.

BASKING-SHARK, in Leibholgy, the English name of *Squalus Maximus*.

BASKING-SHARK, in Geography, a town of America, in Somerset county, New Jersey, on the W. side of a N. W. branch of Passaic river, nearly 6 miles N. E. from Pluckemin, and 7 S. S. W. from Morristown.

BASNAVE, BENJAMIN, in Biography, son of a French minister, first settled at Norwich, in England, and afterwards at Charenton; in Normandy, was born in 1580; and devoting himself to his father's profession, succeeded him at Charenton, where he spent the remainder of his life. In 1634, he affixed at the Synod of Charenton, as deputy from the province of Normandy; and he was chosen, on account of his distinguished talents and prudence, moderator of the national Synod of Alençon, in 1637. He was afterwards associated to the moderator of the Synod of Charenton in 1644, and being deputed by this Synod to the queen-mother, received from her tokens of esteem. He was also deputed by the protestant churches in France, to king James V. of Scotland; and being allowed to visit that country, he was eminently useful in serving the interests of his constituents. Basnage had several disputes with the Catholics, and wrote: "A Treatise on the church" which was much esteemed. He also left an imperfect "Work against the indirect worshipers of the blessed virgin." He died in 1653, in the fifty-third year of his ministrity, and left two sons of distinguished merit. Gen. Dict.

BASNAVE, ANTOINE, eldest son of the former, was born in 1620, and became minister of Bayeux. He distinguished himself by his firmness and resolution during the persecution of the protestants; and after having been imprisoned at Havre-de-Grace, at the age of 75 years, he was released by the revocation of the edict of Nantes, and fled to Holland. He died at Zutphen in 1694. Gen. Dict.

BASNAVE, HENRY, younger son of Benjamin, was born at Sainte Mere Eglise, in Lower Normandy, in 1615. Educated to the profession of the law, he became one of the most learned and eloquent advocates of the parliament of Normandy, into which he was admitted in 1635; so that he was employed in every cause of importance. In 1677 he was appointed commissioner for the affairs of religion, and discharged the office with great honour. He was highly esteemed as an author, as well as an advocate; and in 1678 he published the "Coutume de Normandie," with ample commentaries, of which a second edition, in 2 vols. folio, was published in 1694. At the same time was published a third edition of his "Traite des Hypothese," a Treatise on Mortgages. He died at Rouen in 1695. Gen. Dict.

BASNAVE, SAMUEL, DE ROTTEMANYVILLE, son of Antony, was first co-patrol with his father at Bayeux, and afterwards at Zutphen. He was eminent for his learning; and published in Latin a continuation of Caiusbon's Critical Examination of Baronius's Annals, entitled "De Rebus Sacris et Ecclesiasticis Exercitaciones Historico-criticis," 8°. 1692; and also "Annales Politico-Ecclesiastici," 3 volis, folio, 1706. He died in 1721. Gen. Dict. Nouv. Dict. Fr.

BASNAVE DE BEAUVAS, JAMES, eldest son of Henry, the most illustrious of the name, and sitter, says Voltaire, for being minister of State than of a parish, was born at Rouen in 1653. Having acquired a competent knowledge of Greek and Latin, and several modern languages, he went, at the age of seventeen, to Geneva, where he studied philosophy and divinity. Upon his return to Rouen, he commenced the exercise of his profession as pastor of the church in 1676, and in consequence of the revocation of the edict of Nantes, retired to Holland, and settled as minister at Rotterdam. Such was the reputation he acquired for political sagacity, that when the Abbe du Bois came to the Hague, in 1706, under the character of ambassador plenipotentiary, to negotiate a defensive alliance between France, England, and the States-General, he was ordered by the duke of Orleans, regent of France, to consult Mr. Basnage, and to be directed by his advice: and as a reward for his assistance on this occasion, he obtained a retribution of his estate in France. His works are very numerous and valuable; the principal are as follow, viz. "A History of the Church," in French, 2 vols. Rotterdam, 1659; "The History of the Reformed Churches," part of the above work, printed separately in 2 vols. 4to. 1725; "The History of the Jews, from Jesus Christ to the present time, being a connection of the history of Josephus," written in French; of this work, distinguished by erudition and critical skill, the best edition is the second of the Hague, in 15 vols. 12mo. 1715; "The Republic of the Hebrews," 5 vols. 8vo. Amst. 1705; "Jewish Antiquities," 2 vols. 8vo. 1713; "Dissertation on Deeds and Chiavary," 8vo. 1720; "Annals of the United Provinces, since the Peace of Munster," 2 vols. folio. Hague, 1719 and 1726; "A Treatise on Confidence," 2 vols. 8vo. "Sermons;" "On the Holy Communion;" "Thesaurus Monumentorum Ecclesiasticorum et Historiorum," &c. 4 volis. Amst. 1725, being a new edition of the "Editiones Antiquae" of Henry Capinio, enriched with learned prefaces and remarks. The matter of Basnage is good, but his style, though sufficiently periphrastic, is stiff and inelegant. In the latter part of his life he removed to the Hague, and died there in 1723. He was polite and affable, benevolent and friendly, and more mild in his disposition than most con-

BASNAG DE BEAUVIL, Henry, younger brother of the preceding, was born at Rouen in 1659, and became a counsellor in the parliament of Normandy. Attached to his religious profession he quitted his prospects at the bar, and took refuge in Holland, where he published in 1684, a small but valuable tract "On Religious Toleration." He also wrote a sequel to the "Nouvelles de la Republique des Lettres" of Bayle, under the title of "L'Histoire des Ouvrages des Savans," commencing in 1687, concluded in 1709, and comprehending 21 vols. 12mo. This work is reckoned judicious and impartial, but the writer's own reflections are sometimes too intermixed with those of the authors whose works he reviews, that they cannot be easily distinguished. His new edition of "Furetière's Dictionary," 3 vols. fol. was printed in 1720. He died at the Hague in 1716. Gen. Dict. Nouv. Dict. Hittor.

BASON, Pelvis, in Anatomy. See Pelvis.

Bason, or d'ly, among Glass Grinders. These artificers use various kinds of bason, of copper, iron, &c. and of various forms, either a flatter, or other flatter, according to the size of the glasses that are to be ground. In these bason convex glasses are formed, as concave ones are formed on spheres or bowls.

Glasses are worked in basons two ways. In the first, the bason is fitted to the arbor, or tree of a lathe, and the glasses (fixed with cement to a handle of wood) are turned and held fast in the right hand within the bason, while the proper motion is given by the foot of the bason. In the other the bason is fixed to a stand or block, and the glasses with its wooden handle moved. The moveable bason are very small, seldom exceeding five or six inches in diameter; the others are larger, sometimes above ten feet in diameter. After the glasses have been ground in the bason, it is brought smooth with gauze and emery; and polished with tripoly, and finished with paper cemented to the bottom of the bason. See Grinding.

Bason, among Hatters, is a large, round shell, or cage, ordinarily of iron, placed over a furnace; wherein the matter of the hat is moulded into form.

The hatters have also basons for the brims of hats, usually of lead, having an aperture in the middle, of a diameter sufficient for the largest block to go through.

Bason, in Hydraulics, is also used on various occasions for a small regenerative of water: as the bason of a jet-d'eau, or fountain; the bason of a port, of a bath, &c. which has in Travain calls laminar. Bason are made either with clay, cement, or lead; but they are most usually made with clay. In the making of them this way, the diameter must be made four feet longer on each side than the bason is to be. This will be taken up by the walls of clay. For the same reason, it must be dug two feet deeper than the intended depth of the water; because it is to be laid over eighteen inches thick with clay, and fix inches with gravel and paving. The wall is to be made with flax, rubbitch, or flax, with the natural earth for mortar: and the clay must be well worked, and trod firmly down with the naked feet.

The way of making them with cement is, to allow one foot nine inches every way for the work; then cut the banks perpendicularly, and raise a wall of mullary a foot thick, made of pebble flounces, or the like, laid in mortar of lime and sand; the bottom is then to be covered to the same thickness; and then the solid lining of the cement is to be backed up against the walls, and over the bottom. This is to be made of small flints in beds of mortar made of lime and cement. When this solid is eight inches thick, it must be plastered over the whole surface with cement well fitted, before it is mixed with the lime; and with this it is to be wrought over smooth with a trowel. The proportion of this cement should be two-thirds of the cement, or powdered tile, to one-third of lime; and this cement has the property of hardening to under water, that it will become like stone or marble, and it will not be subject to decay for a long time.

After the finishing, the bason should, for four or five days, be anointed very often with oil, or bullock's blood, to keep it from flaying or cracking in the drying; and after this, the water should be let in as soon as may be.

The leaded bason are made with walls a foot thick, and a bottom of half a foot. These must be of rubble flounces, cemented with plaster; for the lime will injure and eat the lead. The sheets of lead are to be spread over the top of the bason, and fixed with folder. These bason, however, are but little in use now, from the expense of making them, and the danger of the lead being stolen.

The whole pipes of fountains ought always to be made large enough for fear of choking. When the whole water is to be carried off into common fews, it may be carried away in drains, or earthen pipes; but when it is to serve for bason that lie below it, it is to be conveyed in leaden ones.

Muller.

There are divers sorts of bason: as

Bason figured, that whole plan or circumference makes several turns and returns, either straight, circular, or the like. Such are most of the bason of fountains at Rome.

Bason with a lallygirdle, that whole cavity is surrounded with a balladade of stone, marble, brons, or the like.

Bason with a trench, or bason à rigole, that whole border being of marble, or other stone, has a trench cut in it, from whence, at certain distances, spouts out a thread of water, which lines the trench, and forms a kind of spire or gargoyle around the balladade. Such is that of the fountain of the rock of the Belvidere at Rome.

Bason en coquille, that shaped like a shell.

Bason is likewise used for a Dock.

Bason of the sea. See Sea.

Bason, dyle by the, in Commerce, at Amsterdam, is used for the public fules made under the direction of the ven du meeter; thus called, by reason that, before adjudging the lot or commodity to the last bidder, they usually strike a bason to give notice of it.

Bason harbour, in Geography, lies on the east side of Lake Champlain, in the township of Ferrisburg, and county of Vermont, 41 miles south-westly from the mouth of Otter Creek.

Bason of a balance, in Mechanics, two pieces of brons, or other matter, fastened to the extremities of the strings; the one to hold the weight, the other the thing to be weighed.

Basova, in Geography; a town of Siberia, on the river Lena, 20 miles south of Ongen.

BASOUEDA, a large town of Hindoostan, belonging to the district of Burlih, in the route from Agra to Oujen.

BAQUE, E., a country of France, before the revolution. Inmate between the sea, Spain, the river Adour, and Bay towards the Pyrenia mountains, and comprehending Labour, Lower Navarre, and the district of Soule.

BAQUE ROA, lies on the coast of France, south-east from the island of Rhô, north-east from the island of Oloron, north from the island of D'Aix, and south from the west point of the entrance into Rochelle, and directly west without the bay of Chateaillon.

BAQUEVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Dieppe, 3 leagues S.S.W. of Dieppe, and 74 N.N.W. of Rouen.
BASS

BASSRAH. See Bassora.

BASROUCHE, a town of Persia, in the province of Tabriziian, 27 miles west of Farzabat.

BASS, among Gardener's, a sort kind of hurdle or rush, used in binding plants, &c.

Bass, in Geography, an island, or isolated rock, on the coast of Scotland, near the mouth of the Orkney; at a small distance from the town of North Berwick in East Lothian. On the south side it has a conical form, and towards the north it gradually overhangs the sea. The castle, or ancient state prison, is on the edge of the precipice. It is accessible only on the south-west side, and here only by one person at a time, with the assistance of a rope or ladder. On the top of it is a spring, and a crenel passeth through the rock from north-west to south-east. This island is about a mile in circuit, and in summer abounds with birds and their eggs, &c. The sound geese arrive here in March, and retire in October or November. It contains a small warren for rabbits, and affords pasture for a few heep.

At the revolution it was supported by a party of the adherents of King James, and it was the last place in the three kingdoms that submitted to the new government; upon which its fortifications were neglected. This island is the fourth entrance into the frith of Forth; and the island of May, seven miles from it, at N. N. E. of the north entrance. N. lat. 56° 3'. W. long. 2° 53'.

Bass Harbour, a harbour of Mount Desert island, in the district of Maine, North America, seven miles from Soo Cove.

Bass Strait, so called from its discoverer Mr. Basset, a surgeon, is more than 50 leagues wide, containing a chain of small islands that run north and south, and separates Van Diemen's land, hitherto considered as its southerly extremity, from New Holland. Mr. Basset, accompanied by Mr. Finders, a naval gentleman, entered this strait between the latitudes of 39° and 40° south, and actually circumnavigated Van Diemen's land. This discovery forces to expedite the passage from the cape of Good Hope to Port Jackson; for, although a line drawn from the cape of Good Hope, and to the longitude of the south cape of Van Diemen's land, would not sensibly differ from one drawn to the latitude of 45°, to the same longitude; yet a ship will be four degrees nearer to Port Jackson in the latter situation, than in the former. But besides a saving of four degrees of latitude along the coast, the passage through this strait would avoid the north-east winds, which have retarded and endangered ships on opening the sea round the south cape and cape Filler. This strait, likewise, presents another advantage. From the prevalence of the north-east and easterly winds off the south cape, many suppose that a passage may be made from thence to the westward, either to the cape of Good Hope or to India; but the fear of the great unknown bight between the south cape and the south-west cape of Leven's land, lying in about 35° south and 118° east, has hitherto prevented the trial from being made. The strait evades a part of this danger, by presenting a certain place of retreat, should the ship be opposed by a gale at the first end; and should the wind come at north-east, the need not fear making a good stretch to the W.N.W., which course, if made good, is within a few leagues of going clear of all. There is besides King George the Third's found, discovered by Capt. Vancouver, situated in 8. lat. 37° 35', and E. long. 118° 12'; and it is hoped, that a few years will diffuse many others upon the coast, as well as confirm or disprove the conjecture that a fold larger than Basset's straits remains New Holland. Collins's Account of New South Wales, p. 193, 193.

BASS, in Music. See Base.

BASSAD, or Besd, an Arabian name for the purple flower of the Greeks, used by the women to paint their cheeks, and by the dyers of cloth. It is been to far misunderstood by late authors as to be interpreted by the word coral; but the error of this is evident, since coral has none of their properties. See Margian.

BASSAM, in Geography. See Basseeen.

Bassamuer Rock lies on the coast of France, in the English channel, and is a shoal that bears a about a league N. by W. from La Clarte church, near the point so called, to the south from the seven islands.

BASSAN, GIACOMO, in Biography. A celebrated painter, whose real name was Giacomo de Posto, was called Basan from the town of Bassano on the river Brenta, where his father lived and followed the same profession. He was born in 1510, and became a disciple of Bonifacio, and after having improved himself in his art by studying and copying the works of Titian and Parmeggiano at Venice, he returned to his native town. Here he formed a style different from that of his masters, and guided by his own genius, he affected a manner of colouring and designing peculiar to himself, and copied all his objects from nature. His subjects were generally taken from such parts of scripture as afford the rural scenery of animals and landscape connected with some story; such as the journeyings of the patriarchs, the Israelites in the desert, the flight of Joseph and Mary into Egypt, &c. In all these subjects his figures were well designed; most of them were formed from his wife, children, and servitors, and the animals in his court-yard; and they had of course a pleasing resemblance of nature. Although his compositions cannot boast of any great degree of elegance or dignity; they are distinguished by force and truth; his colouring was admirably lively and natural; and his chiaroscuro and perspective were correctly displayed. His touch was free and spirited; and in his landscapes his distances were always true. Although he had many excellencies, his drawing was incorrect, and his draperies were delineated with variety. His works are easily distinguished from those of other painters, by the similitude of characters and countenances in the figures and animals; by his talent in the buildings, utensils, and draperies, and by a violet or purplish tint that predominates in every one of his pictures. Basan painted much, and with ease; so that his pictures were sent by wholesale to merchants, who dispersed them over Europe. His real pictures, however, are not common; as many of those that are called originals are copies by his sons, who were inferior to himself, or by some painter of meaner abilities. Basan practised also in portrait, and painted several excellent likenesses of the doges of Venice, of Ariotho, Tasso, and other personages of eminence. His house at Bassano, to which he was attached, and which the solicitations of the emperor Randolph could not induce him to leave, was the place of resort to many persons of distinction, and the receptacle of the arts, particularly of music, of which he was a master. In his private conduct Basan was regular; and his charity was so profuse, that his wife was under a necessity of restraining his liberality. He lived to the age of 82, and died in 1592. Several of his capital pieces are in the churches of Bassano, Venice, Vicenza, and other cities of Italy. Some of his smaller works may be found in most of the principal collections of Europe; but those that are really originals fetch a high price. Many of them have been engraved.

Giacomo Bassan had four sons, who were painters. Francesco, the eldest, was the most eminent. He was born in 1550. He painted in the style and manner of his father, and
and greatly excelled his brothers in designing, drawing, and colouring. He was employed in the church of St. Mark at Venice, in conjunction with Tintoretto and Paolo Veronese. By incessant application he increased the natural melancholy of his disposition, and put an end to his life in 1594, by throwing himself out of a window. 

Leandro was born in 1528, settled at Venice, painted in the style of his father and brother, but with inferior merit, and particularly excelled in portraits. The portrait of the doge Grimani procured for him the honour of knighthood. His life was irregular, and he disdained himself by a constant suffocation of the intention of his companions to poison him. He died in 1623. The other two brothers, viz. Giovanni Battista and Girolamo, the former born in 1533 and dying in 1613, and the latter born in 1560 and dying in 1622, chiefly employed themselves in copying the works of their father and elder brother. 

Pilkington.

BASSANI, Giovanni Battista, in Musical Biography, was chiefly known in England, at the beginning of the last century by his Motets, which were more graceful and pleasing than those of any of his countrymen, except Cavalli and Stradella. But he has many titles to an honourable place in musical history. He was not only author of thirty-one different works in favour all over Europe during the limited longevity of musical productions, but the first composer for the violin in Italy, who seems to have written for it with the spirit and intelligence of a real master of the instrument. He was a native of Bologna, maestro di capella of the cathedral, Academico Filarmonico of that city, and violin-master to Corelli. 

Baffani, who flourished from about the year 1675 to 1703 (the date of his last work), was a man of extensive knowledge and abilities in his art; having been not only a successful composer for the church, the theatre, and the chamber, but an excellent performer on the violin, as we were assured by Padre Martin, his townsmen, who was old enough to have formed his opinion from those who had often heard him perform. And, indeed, his sonatas for the violin, and accompaniments for that instrument to his motets, motetti, pfbms, and cantatas, manifest a knowledge of the finger-board and bow, which appears in the works of no other composer, anterior to Corelli, which we have been able to find; and the lovers of the pure harmony and simple melody of that admirable master would still receive great pleasure from the performance of Baffani's sonatas for two violins and a bass; in which they would hear, not only the general musical language of the time, but the mild accents and grateful tones of Corelli's own mellifluous voice.

BASSANIA, in Ancient Geography, a town of Macedonia, on the frontier of Illisia, situate, according to Livy, about 9 miles from Lilius, and belonging to the Carians. 

BASSANO, in Geography, a town of Italy, belonging to the state of Venice, in the Trevisano, on the Brenta, 12 miles north of Vicenza. 

Bassano, a town of Italy, in the state of Venice, near which Dolabella defeated the Etruri and Boii, 3 miles west of Orta. 

BASSANTIN, James, in Biography, a Scots astronomer, in the sixteenth century, was the son of the lord of Baffantin, in the Mers, and born in the reign of king James IV. He had the rudiments of knowledge, and particularly of that skill in various branches of the mathematics for which he was afterwards so distinguished, he acquired in the university of Glasgow. For further improvement he travelled through various parts of the continent, and at length settled at Paris, where he taught the mathematics with applause in the university of that city. During his abode in this city, he imbied that zeal for the delusions of judicial astrology, which was then so prevalent, and which few astronomers had judgment or resolution sufficient to discontinue.

After having acquired great reputation and some fortune in France, he returned to his own country in 1562. At York, in his journey through England, he had an interview with Sir Robert Melvil, brother of Sir James Melvil, who, in his "Memoirs," relates the conversation that passed between them. It appears that Baffantin communicated to Melvil certain predictions relating to his millrefs, Mary queen of Scots, who was then treating with Elizabeth after having taken refuge in her dominions. Of these predictions some were true, and others were false; but such was the political sagacity of Baffantin, that we may ascribe them to this source rather than to his skill in the occult sciences, for which however he seems to have been ambitious of being thought distinguished. Of his mode of life during the remaining period of it, we have no account; but he appears to have been a zealous protestant, and a partisan of the earl of Murray. He died in 1568. To a flight acquaintance with polite literature, Baffantin added a considerable degree of mathematical and astronomical knowledge, considering the dark period in which he lived. His principal work in astronomy was written in French, and translated into Latin by Turneufis, and published at Geneva by 1599, folio, under the title of "Astronomia, Jacobii Baffantini Scoti, opus absolutissimum, &c. &c." He also published "Paraphrase de l'Astrolobe, avec un amplification de l'usage de l'Astrolobe," or an ample explanation of the astrolobe, printed at Lyons in 1555, and at Paris in 1617, 8vo. "Super Mathematica Genethlaca," or of the calculation of nativities; "Arithmetica;" "Mofica fecondum Platonii," and "De Marthi in generic. Biox. Brit. 

Bassano, in Ornithology, a species of Pelecanus, as large as a common goose, with a wedge-shaped tail; body white; bill and primary quill feathers black; and face blue. 

Gmelin. Latham, &c.

This is the common gannet, or island goose; a bird found in great plenty on all the northern coasts of Britain, but rather less common to the southward. The adult birds have the plumage nearly all white, but during the first years it is of a dusky colour, and only speckled with white. The bill is bluish-ash colour, about six inches in length, and has the nictrits placed in a narrow; the mouth within is black; the throat is bare; and the skin very dilatable, forming a pouch of sufficient size to contain five or six herring; the legs are black, marked with a stripe of pea-green before; and the claw of the middle toe is pectinated. The male and female are very much alike in plumage. The gannet is particularly abundant in the isle of Alia in the firth of Clyde; the rocks adjacent to St. Kilda; the islands of Soleilkerry, near the Orkneys; the Skedig sits off the coasts of Kerry, Ireland; and the Bafis island in the firth of Edinburgh.

Dr. Hervey gives some account of the latter in these words. "There is a small island, called by the Scotch Bassi island, not more than a mile in circumference; the surface is almost wholly covered during the months of May and June with nells, egges, and young birds; so that it is scarcely possible to walk without treading on them; and the flocks of birds in flight are so prodigious as to darken the air like clouds; and their noise is such that you cannot without difficulty hear your next neighbour's voice. If you look down upon the sea from the top of the precipice, you will see it on every side covered with infinite numbers of birds of different kinds, swimming and hunting for their prey; if in failing round the island you survey the hanging cliffs, you see in every crag or fissure of the broken rocks innumerable birds of various forts and fizes, more than the flars
flights of heaven when viewed in a serene night; if from afar you see the distant flocks either flying to or from the island, you would imagine them to be a vast swarm of bees.

"The gannet," observes Dr. Latham, "inhabits the colder parts of this kingdom, and more especially several of the northern isles, and in particular that of Baff in Scotland, whence the name. It generally frills its appearance in March, and after making a circuit of the island, departs in October or November. This race seems to be in pursuit of the herrings and pilchards, whose motions it watches; and the fishermen know the coming of these fish by the appearance of the birds. That this is the inducement seems probable, as they are likewise seen, in the month of December, as far south as the coast of Lisbon and Gibraltar, plunging for fardine. The gannet is also common on the coasts of Norway and those of Iceland, and now and then met with on the southern coasts of Greenland. In America, it is found on the coasts of Newfoundland where it breeds, migrating in winter as far as Carolina: said also to have been met with frequently in the southern ocean; but we are not clear whether the fort meant by them is the common gannet, or the lewer one."

"The gannets," Mr. Pennant remarks, "are birds of passage. Their first appearance in those islands being in March, and their continuance till August or September, according as the inhabitants take or leave their first egg; but in general the time of breeding and that of their departure seems to coincide with the arrival of the herring, and the migration of that fish, which is their principal food, out of those seas."—"I have in the month of August," he adds in another place, "observed in Caithnesh their northern migrations. I have seen them paffing the whole day in flocks, from five to fifteen each. In calm weather they fly high, in storms they fly low and near the shore; but never cross over land, even when a bay with promontories intervenes, but follow at an equal distance the course of the bay, and regularly double every cape. I have seen many of the parties make a fort of holt for the fake of fishing; then darting headlong into the sea, make the water foam and spring up with the violence of their descent; after which they pursue their route. I enquired whether they ever were observed to return southward in the spring, but was answered in the negative; so that it appears, they annually encircle the whole island."

They are well known on most of our coasts by different names. In Cornwall and in Ireland they are called barren, and by the Welsh gann. It comes on the coasts of Cornwall in the latter end of the summer or beginning of Autumn, hovering over the fwools of pilchards that come up through the St. George's channel from the north sea. The gannet seldom comes near the land, but is constant to its prey; and when the pilchards retire, which happens about the end of November, they are seen no more.

The nest of the gannet is composed of various materials, such as grass, and water-plants intermixed with any thing the bird finds floating on the water. Each bird, if undisturbed, would lay only one egg in the year; but if that be taken away, they will lay another; and if that be taken away also, they will lay a third, but no more. The young gannets, as well as the eggs, are eaten. Martin affirms us, that the inhabitants of St. Kilda consume annually no less than 22,600 young birds of this species, besides an amazing quantity of their eggs; those being their principal support throughout the year; they prefer both eggs and fowl in pyramidal stone-buildings, covering them with turf ashes to preserve them from moisture. This is a dear-bought food, and earned at the hazard of their lives, either by climbing the most difficult and narrow paths, where to appearance they barely cling, and that too at an amazing height above the raging sea; or else, being lowered down from above, they collect their annual provision, thus hanging midway in the air, and placing their whole dependence on the uncertain footing of one person who holds the rope by which they are suspended at the top of the precipice. The young birds are a favourite dish with the North Britons in general; during the season they are constantly brought from the Baff to Edinburgh, and are roasted and served up a little before dinner as a whet; the price they are sold for in the markets is about twenty-pence a piece.

The following account of the gannets in the isle of St. Kilda is given by Mr. Macaulay. "The rocks are in summer totally covered with foland geece and other fowl, and appear at a distance like so many mountains covered with snow. The nests of the foland geese, not to mention those of other fowls, are so close, that when one walks between them, the hatching fowl on either side can always take hold of one's clothes; and they will often sit till they are attacked, rather than expose their eggs to the danger of being destroyed by the sea-gulls: at the same time an equal number fly about, and furnish food for their mates that are employed in hatching, and there are, besides, large flocks of barren fowls of the different tribes that frequent the rocks of St. Kilda.

"The foland geese equal almost the tame ones in fize. The common amusemen of the herring-fishers shows the great strength of this fowl. The fifiers fix a herring upon a board, which has a small weight under it to fink it a little below the surface of the sea: the foland geese observing the fih, darts upon it perpendicularly, and with fo much force, that he runs his bill irrecoverably through the board, and is taken up directly by the fiechers.

"The foland geece repair to St. Kilda in the month of March, and continue there till after the beginning of November. Before the middle of that month they, and all the other sea-fowls that are fond of this coast, retire much about the same time into some other favourite regions; so that not a fingle fowl belonging to their element is to be seen about St. Kilda from the beginning of winter down to the middle of February. Before the young foland geece fly off, they are larger than their mothers, and the fat on their breast is sometimes three inches deep. Into what quarter of the world these tribes of wild fowl repair, after winter sets in, whether into the northern ocean, the native country and winter-quarters of herrings in general, or into some other region near the fims, or whether they be of the sleeping kind, they who prey into the mysteries of natural history, or have converfed much with writers of voyages can best explain. I shall only pretend to fay that these different nations of the feathered kind are taught to change the proper effects and feeding places, and to shift their quarters seasonably by the unerring hand of God.

"From the account given above of the multitudes of sea-fowls that feed their food on this coast, we may justly conclude that there must be inexhaustible stores of fish there. Let us for a moment confine our attention to the consumption made by a single species of fowls. The foland geese is almost infatiably voracious; he flies with great force and velocity, toils all the day with little intermission, and digests his food in a very short time; he consumes to eat any thing worse than herring or mackerel, unless it be in a very hungry place, which he takes care to avoid or abandon. We shall take it for granted that there are a hundred thousand of that kind around the rocks of St. Kilda; and this calculation is by far too moderate, as no less than twenty thou-
sand of this kind are destroyed every year, including the young ones. We shall suppose, at the same time, that the inland geese sojourning in these tens for about seven months in the year, or two, each of them draw ten or five herring in a day, a sufficiency infinitely poor for so greedy a creature, unless it were more than half supported at the expense of other fishes. Here we have 100,000,000 of the finest fish in the world devoured annually by a single species of the St. Kilda sea-fowls,” &c.

In concluding this account of the geese, it is proper to observe that the grand feu of Belfin and Builin, and great Iddsby of Catsby, an inhabitant of the sea-shores of Florida, is supposed to be the young or at least a variety of *pelicans fuscus*; and that observed by navigators so common on Alcubnic island *pelicans psittaco*, a different species.

**BASSAWS**, or Bona *Shona*, in Geography, lie on the west coast of Africa, beginning about west, or to the south of west from Sierra Leone, and running out far to sea in rounds and hollows, so that ships cannot clear them without standing off out of sight of land.

**BASSE, Bass, or LA Basse**, a town of France, in the department of the north, and chief place of a canton in the district of Lille; celebrated by the Spaniards to France by the treaty of Aix-la-Chapelle, in 1665; formerly a place of considerable strength, but dismantled by Louis XIV. It is situated on the Dyle, 2 leagues east of Bethune, and 33 south-west of Lille. N. lat. 50° 54'. E. long. 2° 6'.

**Basse**, in *Ichthyology*, the English name of a fish found on some of the British coasts, and named *perca labrax*. Linn. Syst. 453. ed. 12.

**Basse-Cour, in Building**, a court separated from the principal one, and defined for the flasks, coach-houses, and liveries-ervants.

**Basse-Cour of a country-seat**, is the yard or place where the cattle, fowls, &c. are kept.

That where strange creatures of divers sorts are kept for curiosity, is called by the French *menagerie*. The Romans gave the name of *vivarium* to that place, where beasts were kept for the public fews.

**Basse**, in Middle Age Writers, denotes a collar for carthorses, made of flags. Hence also the round matted cushions of flags, used for kneeling in churches, are called *bafie*; in Kent, a *brushe*.

**Basse de Flute trouvères**, Fr. in *Music*, a side-flute, a fifth below the usual compass of the German flute, now out of use in France; and we never remember its use in England.

**Basse-Flute.** When, at the beginning of the last century, the flute-a-bec, or common flute, was in general use and favour, there were flutes of every size and pitch. F natural being the best in use, and the easiest key on the common flute, all fongs and other favourite airs were transposed for the flute into that key, or into C natural, at the bottom of the plate, when printed. The bass flute was an octave below this F, and the octave flute an octave higher. See *Flute*.

**Basse-Tongue, the base of the key-note, or Tartini’s third sound, produced by the confluence of two treble notes perfectly in tune, and readily sustained with two voices, violins, flutes, hautbois, or by two flutes in double stops on one violin, or two keys on the organ. See *Terza Suona*.

**BASSENE**, or BACAIN, in Geography, a fortified city, situate on the point of the continent, on the western coast of the peninsula of India, opposite to the north end of Salsetta. It lies in N lat. 19° 19', and under the same meridian as Bombay. This place fell into the hands of the English, after a smart siege in 178c, but was relowered to the Mahattaes, together with all the other conquests made on that side of India, at the peace of 1783; Salsetta and the small islands excepted.

**BASSETTO**, a river of Italy, in the kingdom of Naples, which runs into the Grati, near Cofenza.

**BASESTORE**, a town of Swiderland, in the canton of Zurich, 4 miles N. E. of Zurich.

**BASSET, or Basset**, a game with cards, said to have been invented by a noble Venetian; for which he was punished. It was first introduced into France, by Sigismond Fuzitiari, ambassador of Venice in 1674. Severe laws were made against it by Louis XIV, to clade which they disfigured ballet under the name of *tour & compère*, that is, for and against, which occasioned new arrests and prohibitions of parliament. The parties concerned in it are, a dealer or banker, his attendant, who supervises the long cards, and the punter, or any one who plays against the banker.

Besides thefe, there are other terms used in this game: as, 1. The *jack, or fico*, which is the first card turned up by the *tailleur* belonging to the pack, by which he gains half the value of the money laid down on every card of that fort by the punters. 2. The *couche, or ffrill* money which every punter puts on each card; each person that plays having a book of fifteen several cards before him, on which he may lay his money, more or less, at discretion. 3. The *paroli*, which is, when a punter having won the first flake, and having a mind to perfect his good fortune, crooks the corner of his card, and lets his prize lie, aiming at *sojct et le voa*. 4. The *mijou*, when having won the first flake, the punter is willing to venture more money on the same card. 5. The *pay*, when the punter having won the first flake, bet at a flaking, half crown, guinea, or whatever he laid down on his card, and not caring to hazard the paroli, leaves off, or goes *pay*; in which case, if the card turn up wrong, he loses nothing, having won the couch before; whereas, if it turn right, he by this adventure wins double the money flaked.

6. The *albace*, much the same with paroli, and used when a couche is won by turning up, or crooking the corner of the winning card. 7. *Sept et le voa*, the first great chance or prize, when the punter having won the couche, makes a paroli, and goes on to a second chance; so that if his winning card turns up again, it comes to *sept et le voa*, which is seven times as much as he laid down on his card. 8. *Quinze et le voa*, is the next higher prize, when the punter, having won the former, is resolved to pull his fortune, and lay his money a second time on the same card, by crooking another corner; in which case, if it come up, he wins fifteen times the money he laid down. 9. *Trent et le voa*, is the next higher prize, when the punter crooking the fourth corner of his winning card, if it turn up, wins thirty-three times the money he first flaked. 10. *Soixant et le voa*, is the highest prize, and entitles the winner to fifty-seven times his first money; which, if it were considerable, stands a chance to break the bank; but the bank stands many chances first of breaking the punter. This cannot be won, but by the *tailleur’s* dealing the cards over again.

The rules of the game of ballet are as follow: The banker holds a pack of fifty-two cards, and having shuffled them, he turns the whole pack at once, so as to discover the left card; after which he lays down all the cards by couples. The punter has his book of thirteen cards in his hand, from the king to the ace; out of these he takes one card or more at pleasure, upon which he lays a flake. The punter may, at his choice, either lay down his flake before the pack is turned, or immediately after it is turned, or after any number of couples are down. Supposing the punter to lay down his flake
flakes after the pack is turned, and calling 1, 2, 3, 4, 5, &c. the places of those cards which follow the card in view, either immediately after the pack is turned, or after any number ofcouples are drawn. Then if the card, upon which the punter has laid a flake, comes out in any odd place except the first, he wins a flake equal to his own. If the card, upon which the punter has laid a flake, comes out in any even place except the second, he loses his flake. If the card of the punter comes out in the first place, he neither wins nor loses, but takes his own flake again. If the card of the punter comes out in the second place, he does not lose his whole flake, but only one half; and this is the case in which the punter is laid to be faced. When the punter chooses to come in after any number of couples are down, if his card happen to be but once in the pack, and is the last of all, there is an exception from the general rule; for though it comes out in an odd place, which should entitle him to win a flake equal to his own, yet he neither wins nor loses, from that circumstance, but takes back his own flake.

This game has been the subject of mathematical calculations. Mr. De Moivre solves this problem; to estimate at billiard the losses of the punter under any circumstance of cards remaining in the pack, when he lays his flake, and of any number of times that his card is repeated in the pack. From a solution he has formed a table, shewing the several losses of the punter in whatsover circumstances he may happen to be. See Dr. of Chances, p. 55.

From this table it appears, 1. That the fewer the cards are in the pack, the greater is the loss of the punter. 2. That the leafless of the punter, under the same circumstances of cards remaining in the pack, when his card is but twice in it; the next greater when but three times; still greater when four times; and the greatest when but once. The gain of the banker upon all the money ventured at billiard, is 15 3d. per cent. De Moivre, Dr. of Chances, p. 69, edit. 3.

Basset, in Zoology, the name given by Buffon to that kind of dog which is called in English the turnspit, canis veteris Gmelin. Of this kind he makes two varieties; le basset à jambes droites, and le basset à jambes Torres; the first having straight legs, and the last crooked ones.

Bassetterre, in Geography, a general name given by the French to the low lands of the West India islands; such are the S.W. part of the two parts of Guadalupe island, separated by a small arm of the sea, called the Salt river; and also the N.W. part of the island of Martinique.

Bassetterre Town, a sea-port town on the S.W. coast of the island of St. Christopher in the West Indies, and capital of the island, situated at the mouth of a river, opening into a bay, called Bassetterre road. The town contains about 800 houses, and is defended by three batteries. N. lat. 17° 24'. W. long. 62° 37'.

Bassetterre Town, is also a sea-port town on the S.W. coast of the island of Guadaloupe, regularly built, with some handsome houses, and defended by a citadel. N. lat. 15° 59' 30'. W. long. 61° 59' 15'.

Bassetting, in the Coal Mines, denotes the rife of the vein or coal towards the surface of the earth, till it come within two or three feet of the surface itself. This is also called by the workmen cropping, and stands opposed to dipping, which is the defeat of the vein to such a depth that it is rarely, if ever, followed to the end.

Bassi, Laura, an Italian lady, distinguished by her acquirements, was the wife of Dr. Joseph Verati of Bologna. She understood the Greek, Latin, and French languages, as well as her own, and was eminent for her literature and science. In 1732, she was honoured with the doctorial dignity, and the kept up a correspondence with many learned persons in Europe, who admired her talents and accomplishments. She commenced a course of lectures in philosophy in 1745, and continued them to her death. Her works were pure, and her character amiable; and she was liberal in her acts of charity to the poor and orphans. She died at an advanced age in Bologna in 1778. Nouv. Dict. Hist.

Bassia, in Botany, so named by Kennic in honour of Ferdinandus Bassi, curator of the botanic garden at Bologna. Lin. gen. Reich. n. 645. Schreb. 805. Juss. 132. Gaertn. t. 104. Clas and order, dodecanandra monogynia. Nat. Ord. Danajfe & Sapoje of Jull. Gey. Char. Cal. perianth four-leaved; leaflets coriaceous, ovate, permanent. Cor. monotelous, bell-shaped; tube inflated, ovate, fleshy; border shorter than the tube, eight-parted; divisions ovate, almost upright. Stam. filaments sixten; eight below the jaws, and eight in the middle of the tube; anthers linear, fagittate, acute, villose on the inside, shorter than the corolla. Fig. germ superior, ovate; styicle pubescent, twice as long as the corolla; illicia acute. Per. drupe fleshy, milky. Seed, nuts five, oblong, three-cornered.

Bass, Char. Cal. four-leaved. Cor. eight-cleft; tube inflated. Stam. 161 drupe five-seeded. (Brey five-celled, with a seed in each cell.)

Spectr. 1. B. cypriophiia, Filippo Malabaris, and Nicle Ceylonensis. "Leaves ovate-lanceolate, peduncles axillary." A lofty tree, with the outward branches recurved, thickish, and covered with a grey down; leaves on them alternate, approximating, petioled, entire, veinless, naked, half a foot long, and deciduous; petioles roundish, short; peduncles axillary, from one to five, subiform, one-flowered, upright; after flowering, prolonged and pendulous; berry oblong, slightly compressed, smooth, shining, and yellow, with a white band. A native of Malabar and Ceylon. 2. B. dubia. Seed large, half-moon shaped; flattened like a lens, smooth and shining, of a dark chestnut colour, excepting an oblong, rugged, umbilical area, which is almost white. The shell is thick, fleshy, and very hard. The seeds of baphia are not easily distinguished from those of pata, without attending to the albumen, of which baphia is entirely destitute; and the inner integument is also commonly wanting. 3. B. obovata. Forth. Florul. n. 200. "Leaves obovate; peduncles heaped, terminating." A native of the isle of Tanna, in the South Seas. Martyn's Miller's Diet.

Bassiano, Launi, in Biography, born at Placentia, discovering early a propensity to the knowledge of medicine, was sent to Padua, where he studied under Baptif Monti, and, having performed the usual exercises, in 1544 he was admitted doctor in philosophy and physis. In 1547 he was made professor in those sciences, and acquired considerable reputation as a public teacher. Going to his house, in 1502, he was assailed by an assassin, who killed him by stabbing him in several parts of his body with a bayonet. He left several publications, of which the principal are, "Historia prima logici duo, in quibus de universae artis medicae, precipue vero morborum omnium et cognoscendorum et curandorum abolutiurum methodo, illustratur," Basileae 1543, 4to.; "De origine et causa pestis," Patav. 1553, 8vo.; "De prodigiosi partibus," Haller, ibid. Med. Eloy. Diet. Hist.

Bassin's River, in Geography, is situated on the coast of Labrador, in North America, nearly opposite to the north point of Newfoundland.

Bassing, a town of France, in the department of the Meurthe, and chief place of a canton in the district of Dieuze, 1½ leagues from Dieuze.
BAS

BASSIIUS, Henry, in Biograph., son of Gerard Bassius, or Bafs, a surgeon of eminence at Ercume born in 1690. In 1713, he went to Halle, where he studied medicine under Frederic Hoffman, in 1715 to Strasburg, and two years after to Bafe; attaching himself particularly to acquiring a knowledge of the improvements that had been lately made in anatomy and surgery. Returning thence to Halle, he was created doctor in medicine; and soon after professor in anatomy and surgery, which office he continued to hold till the time of his death, March 31, 1754. His works are, "Differratory de fistula ani fecliter curanda," Svo. 1718; "Observations anatomico-physicorum," Halle 1731, with figures, representing the instruments invented by the author,--a work much commended by Haller; "Prataturati de morbis veneris," Lepine 1712, 8vo.; a poëtomous work, to which the editor has added some valuable observations. He also published, in the German language, "Commentaries on Neck's Art of Surgery," Svo. 1728. Haller, Bib. Anat. et Chir. Lloy. Diet. Hilt.

BASSO Continuo, in Musico, originally meant the accompaniment to the higher parts of a sonata, concerto, or chorus, in whatever style it was written, which served as a base, when the real base was silent; as in fugues, and other movements; to let the accompanist on the organ or harpsichord know what was being done by the other instruments, while his part was at rest. This may still be seen in the organ part (organo) to Corelli's Sonatas, Op. 1, from which they were composed in the seventeenth century, after which the custom was discontinued, there being no instance of it in his other works. Though in the sonatas of Baffani, his master, and in those of Torelli, it is confonant. Handel, in his hautbois concertos, and in his twelve grand concertos, calls the ripieno base, basso continuo.

It was this kind of chordal base for the organ or harpsichord, in ecclesiastical music, that the harmony of the whole score, without a treble part, was first expressed by figures over the base notes. Basso continuo, by an awkward translation, is, in English, synonymous with thorough-bass which see.

It was in the beginning of the seventeenth century that Ludovico Viadana (not Viana, as erroneously written by Roussel, and copied from him in both editions of the Encyclopedie) one of the most distinguished ecclesiastical composers of that time, invented the indication of chords by figures, in what the Italians call the basso continuo, and the English thorough-bass, or accompaniment on key instruments, lutes, harps, and, in recitatives, even violoncellos; but we have found several instances of the minute beginnings of this expedient before the time of Viadana; though he was doubtless the first who drew up general rules for expressing harmony by figures over the base in 1615. Drudius, in an ample list of his ecclesiastical compositions, which were very numerous, tells us of one that authenticates his claim to this invention, which was a collection of all his choral pieces, of one, two, three, and four parts; "with a continued and general base, adapted to the organ according to a new invention, and useful for every finger as well as organist; to which are added short rules and explanations for accompanying a general base, according to the new method." Viadana was therefore the first who composed an organ-base different from the voice-part, in the execution of which the new-invented figures enabled the performer to give the fingers the whole harmony of the several parts of a full composition, without seeing the score.

In 1731, Mattheus, in his "Grosse general base sechze oder twz exemplarischen organisten proben," a treatise on thorough-bass, has given a list of twenty-two writers on accompaniment from the time of its invention in 1606. The invention has been indisputably ascribed to Viadana in Drudius's Catal. ii. (Dramatic Bibliotheca Clas- fic, vol. 4, parts 16, 1635), where there is a list of all his works, and among the rest, "Dr. Ludovici Viadamit, opera omnia sacraeque concertationum, 1, 2, 3, & 4, voc. cum basso continuo & generali, organo applicato, varie inventioni proorni generes et sorte cantione vel organarium accommodati. Adjuncta insector in basso generali huys novae inventiones instrucione et lucubrata explicatione, Latina, Ital. & Germ. ap. Steynum 1615."

In the lib which Mattheus has given of twenty-two authors on accompaniment before 1731, it is observable that only one tract is in English; and that written by Killier a German, who lived in queen Anne's time, and dedicated to her mainly five sonatas for two flutes and a basso.

In Ramen's system, and still lefts in that of the abbé Feyron, as the fundamental base can have no melody, but what arises from its own harmony or single common chord, la basso-continuo may be regarded as a kind of low treble under the violins and tenor, or as a variation of the fundamental bass.

Basso Sostituto, Ital. a base confined to a few bars or notes, repeated to different and varied treble parts. The English call this kind of monotonous movement a ground. During the seventeenth century, the Italians and their imitators were very fond of writing upon a ground-bass; Stradella and Porcell frequently manifested their ingenuity under such reflections; nor had the fashion quite subdued in Handel's time, as may be seen in the last chorus of his Dettingen Te Deum, and elsewhere in his numerous and admirable works. See Ground, Ciaccona, and Ciacconne.

Basso Cantando, Ital. Bajofr, Fr. the vocal base-part, or the base funder in an oratorio, opera, or concert.

Basso Relievo, Italian. Bar-relievo, French, in Sculpture, is the representation of figures on a back ground, in such a manner that no part of them is detached from it; alto relievo, high relief, has the greater parts attached to the back ground whilst the smaller parts are free from it; some dindicuing a third kind, or mezzo relievo, middle relief, between both; although it must be acknowledged that all three kinds are implied, in a general mode of speaking, by the common term of basso-relievo, or base-relief, because almost all figures in relievo, even alto relievo, are more compriessed or flattened than their infulated archetypes in nature. This, like many other terms in the art of design, is of modern date, and was most likely invented or at least compounded and applied, in the eleventh or twelfth centuries, when sculpture and architecture began to revive in Italy, and these kinds of works became a very considerable decoration to the new cathedrals. The Greeks, to whom we must look for the best definitions in this art, as well as the most excellent works, called this species Simply naglypta, carved (Pliny, lib. 33. c. 11.) that we call alto-relievo was dindicuing by them from the low-relief, by the word, tarentae, rounded. Pliny, l. 34. c. 8.

Basso-relievo, although a considerable province of sculpture, is in a particular manner allied to architecture and under its dominion; as any considerable work of this kind must be made for the peliment, frieze, or panel of a building, or architectural form, such as a sarcophagus or pedmet; and therefore the general shape of the ground, the distribution and projection of the figures, must be subverient to the surrounding and containing parts, in order that they may produce a beautiful whole.

It is well remarked by the authors of the French Encyclopedie, that "the origin of basso-relievo is confounded with that of the hieroglyphic; that is to say, it owes its birth
birth to figured writing. Under this point of view, it is common to all people, and is found among the most savage. It was invented by necessity, appropriated by religion. The progress alone of the arts of imitation could perfect these primitive figures and give them life. This honour was referred for the Greeks. In Greece the arts were in some sort the miniatures of religion; in Egypt and in Asia they were the flaves. A religions respect for these primitive characters, which worship had sanctified, seems perhaps to change the idea in changing the form to which they were attached; all contributed, among the Egyptians, to retain the arts in a kind of infancy, from which religion prevented them from emerging.

All the larger hieroglyphics engraved in the surface of Egyptian architecture, or on the figures of men and inferior animals may be considered as bas-reliefs; and as of the most simple, it may be consequently of the most ancient kind; because the figure was linked in such a manner, that the surface of the ground was left, forming an enclosure or outline where the greatest depth was equal to the greatest projection of the figure, which was productive of these advantages. As many of the hieroglyphics were cut in granite, a very brittle marble, it prevented the danger of spoiling the outline in sinking the background, one-third of the labour was saved, and a strong shadow all round the figure, particularly when the fun shone on it, defined its form to the sight. All the temples and palaces enumerated by Ripaud, and described by Denon in the late expedition of the French into Egypt, shew that the greater part of those edifices, as well as inferior works, were covered with hieroglyphics, or figured writing in the kind of bas-relief above described: the largest of these formed regular ornaments to the friezes, centres over the doors, corresponding tablets, or panels where the symmetry of the architecture required. The principal of these figures, according to a comparison of what we find in Orus Apollo, Jamblichus on Hieroglyphics, and other authors, with the hieroglyphics themselves, seem to be the representation of some characteristic or attribute of the divinity, and the operations of his providence in nature, accompanied by acts of adoration: the inferior figures and characters are ranged in lines like writing.

Besides the hieroglyphics, the Egyptians employed bas-relief, with the ground levelled to the lowest part of the figure, to describe the political or military proofs of their heroes, and for other historical purposes. Of this kind are those in the palaces of Karnac, engraved by Denon, and those described in the Bird's Well, of which there is a specimen in the hall of the British Museum. It is in a soft calcareous stone in very low relief: the subject, men laying oxen. The human figures are in violent action, which they seem to have attempted in historical more than in sacred subjects. Nor is it surprising that such actions are extravagant, and not well rendered; when we see by the works themselves, that the flocks of knowledge which the sculptors possessed, was insufficient to account for the parts of the body by a fine proportion, beautiful outline, and the anatomical changes of appearance in the different circumstances of motion. But the prodigies quantity of this kind of labour still remaining must have occasioned the diligence of so many hands for a series of ages, that they could have had little leisure to make advances, either in the sentiment or scientific perfection of their figures. This may account, in part at least, for the execution of the quadruped being better than that of the human figure, which is so much more difficult.

It is necessary to give a general account of the character and style of design in the Egyptian figures, because what is said on this subject will be in a great measure applicable to the early progress of the arts among the Hindoos, Persians, and Greeks, allowing for some peculiarities in each nation. The arts of design are strictly imitative in the early attempts; and we find in the Egyptian figures, compounded of different animals, that each part is a copy of nature. In the human figure, the body and limbs were represented in general forms. The face, as being the most interesting part of the person, was more minutely expressed. The form of the face was a rounded egg, lines of the eye-brows and lids, simple curves, inclining upwards from the nose, the bottom of the nose and the line of the mouth inclined upwards in the same direction with the eyes. The eyes were full, nearly on a level with the forehead and cheeks, and the lines of the eye-brows, lids, and borders of the lips, marked with precision. The chin appeared small and bony, the neck round, the shoulders high and broad, except the marking of the breast. Little distinction of the muscular forms in any part of the body and limbs, the limbs narrow, the limbs round, rather straight and slender, their joints slightly indicated, the hands and feet rather flat, the fingers and toes round, without the appearance of joints, and nearly of the same length. According to a figure Denon found, measured by 22 figures in length, the half of the figure each way was from the division of the thighs, the head was rather less than a fourth part of the figure's height. See Denon's Voyage, plate 124, fig. 1.

The quadruped on Egyptian monuments, are represented in profile, and in the simplest attitudes. The parts of which those are composed, are fewer and more general than those in the human figure. This is one reason why the Egyptians excelled in their animals; the mechanical manner in which the shoulder is drawn of the lion and sphinx (where they have displayed more anatomy than in any other part) presents a simple, but not just account of the structure of that member of the body: these observations apply to the state of sculpture before the time of Alexander the Great; after which period, it partook of the improvements introduced by its Grecian conquerors.

Baffo relieves are found in India, which decorate the excavations of Ellora and Elephants in an astonishing profusion. The subjects are sacred, suitable to the temples in which they are carved; the drawing of the figures and their parts bears a strong resemblance to the Egyptian style; but inferior in this, that many of the figures have very large heads, the limbs and bodies disproportioned. It seems likely that the Egyptian hieroglyphics are more ancient, because more simple than the Hindoo baffo relieves; the former having the ground left even with the highest relief, the latter having the ground cut level with the lowest outline of the figure. For the most extensive, accurate, and valuable publications of these subjects we are indebted to the abilities and unwearyed labour of our countryman Thomas Daniell, Esq. R.A.

The Persians employed baffle relieves like the other ancient nations as a figured writing, at once to record and represent the symbols of Almighty power and operation, their religious ceremonies, and the prowess of their heroes. The bas-reliefs on the palace of Persepolis and the royal tombs are arranged in lines, horizontal and perpendicular, to answer the double purpose of description and architectural decoration: the style of drawing resembles that of the figures in the later hieroglyphics, although the dresses are extremely different. The Egyptians are particularly distinguished by the hood, the mitre, the full hair artificially curled, the cloke tunic, the apron of papyrus; the Hindoos by the necklaces, bracelets, and anklets; the Persians have long beards and hair ending in small curls, caps, full tunics with regular folds and large sleeves; the Medes in the same ruins of Persepolis have close tunics. The drapery in these bas-reliefs is rather more
more like nature than that in the Egyptian hieroglyphics and other bas-reliefs, but this may be the consequence of what the artists had more frequently to imitate, instead of a proof that the arts were more advanced in Persia than in Egypt, which seems still less probable when we consider, the different positions of the human figure, the variety and extent of the historical compositions in the palace of Karne, the Theban tombs, &c. and the exquisitely neat and perfect execution of the hieroglyphics on the obelisk of Seboziris, lately erected on Monte Citorio by Pius the Vth, far exceeding the workmanship of any figure at Persepolis. See Denon's Egypt. Le Bruyn's Travels, vol. 2.

The earliest Greek sculpture extant is still more like the Egyptian in the principles of design, than that of any other nation. The face of the human figure has the same oval, the features described by the same simple curves, the eye kept full as the eahell to execute, being more distinguished by the lines of which it is formed, than by its appearance in profile; and nearly the same general parts represented the body and limbs. That there should be this similarity in different nations in the imitative arts, is strictly agreeable to reason; because conformably to their limited progress in science, they will represent in a simple and grovous manner those objects, the detail of which their minds have neither comprehended nor understood, and which in that stage of progress the hand would be as little likely to perform with the requisite accuracy. It is equally reasonable to expect such imitations should resemble each other; being made from examples of general likeness, and done without the influence of manner, which is the consequence of imitating art instead of nature.

It is most likely that some imitations in sculpture of the human figure were made in Greece, previously to the introduction of letters by Cadmus, because modern travellers have found such imitations among many barbarous people acquainted with letter-writing, and because the Greeks appear to have used figure-writing before they were acquainted with letters; see Wolf's Prolegomena to Homer, page 81: who believes that figure-writing only was known in the time of Homer. But it is equally certain that small bronze figures exist with inscriptions of Cadmean letters on them, which are very poor and barbarous imitations of the human form; so that we may fairly infer, that the sculpture previous to this period could not have been very superior to the productions of Mexico, Onathletae, or the Sandwich Islands. In the popular story of the Maed of Corinth, related by Pliny, lib. 37. cap. 12. he says, Dibutades, the Sicyonian potter, her father, first invented a method of casting likenesses, the process of which is described as follows: "His daughter being in love with a young man who was going to a foreign country, the circumstanced the shadow of his face with lines upon the wall by lamp-light; her father took the impression in clay, and baked it in the fire with his vases." It seems, therefore, that as this was the first invention of portraits in clay, and as this portrait was only the relief imprinted from a line scratched on the wall, that it must have been the very first stage of baffe-relievo. Pliny proceeding says, that Dibutades made another addition to baffe-relievo, by ornamenting the lowest row of rounded tiles, used to terminate roofs, with masks faces. These may be considered as two inventions, which distinguised the Sicyonian school. Pliny does not say at what time Dibutades lived, but he mentions him before Demaratus the father of Tarquinius Priscus, who must have been 630 years before Christ.

Independently of what may be deduced from these quotations, concerning the progress of baffe-relievo in Greece, examples in this branch of sculpture exist in marble and bronze, which, with the aid of coins and gems, if properly arranged, would form a complete chronological series from the introduction of letters in Greece. As the most ancient subjects to be chiefly selected are those which bear inscriptions, this arrangement would necessarily follow: the inscriptions of Cadmean letters first, the Boutrhopoden manner of writing next, and the more modern as circumstances point out their propriety. This method would be found perfectly agreeable to the progress of science discernible in the works themselves, as well as the perfection of execution; and thus the antiquarian or the artist having acquired an accumulation of testimony, would be in little danger of mistake. A passage in Paulinus, the first Epistles, or fifth book, shows the propriety of this method: he says, the elder coffit which Cyphus was preferred by his mother (about 600 years before Christ), was dedicated by his proficiency in Olympia. This ceht is described as being covered with baffe-relievo of allegorical and heroic subjects, explained by Boutrhopoden writing, which the author describes as very old and difficult to read.

The earliest Greek sculpture which has come down to us is equal in the proportion of the figures to the Egyptian, and superior in the drawing of the body and limbs. Vitruvius informs us, that as the height of the human figure was six times the length of the foot, that was made the rule for the Doric column. (Book iv.) Thus we see the Greeks had been in the habit of measuring the human figure by its own parts, previous to the establishment of architectural proportions; and we find very tolerable general forms of the muscles and bones most commonly seen in the living body, those early Greeks copied by close attention to the naked figures they constantly saw before them, without the aid of anatomical fystem; for Pliny (lib. xxix. c. 1.) says, the art of medicine remained in the darkest night from the siege of Troy to the time of Hippocrates. A few examples from the many existing will shew the progress of sculpture in baffe-relievo, from the introduction of letters in Greece to the time of Phidias; these shall be set down according to their apparent antiquity, and followed by general observations.

In Winkelmann's "Monumenti inediti," plate 3, is a print from a scarabaeus of Jupiter in his car, holding the thunder with one hand, and trident with the other. This has the appearance of great antiquity in design and character, and perhaps is the oldest work cited in this article. The next is a pattern of bronze in the British Museum, on which is carved Minerva subduing Hercules, or wisdom prevailing over strength. The next is an engraving of five of the seven chiefs who besieged Thebes. The last is Hercules bearing away the tripod from Apollo, which, by the improved style of drawing, seems to approach the time of Phidias. The first observation that occurs in this part of the subject is, that antiquarians have fallen into a considerable mistake in pronouncing many early works to be Etruscan, which later discoveries have almost certify to be Greek. The Greek subjects cut on gems, the backs of which were formed into scarabaei like the Egyptian seals, have been positively called Etruscan by Winkelmann; notwithstanding that the style of the figures is early Greek, the subjects are Greek, and the letters upon them are Greek; besides which, Mr. Hawkins, a late accurate and highly-qualified traveller, has brought a Cornelian scarabaeus found in that country to England, which has a Mercury engraved on it in that early style called Etruscan. How many more of these might travellers, if they fought for them, find in that country? And is it not likely that the Roman lords of the world would bring into their own country as many curious Greek gems as statues, when a dozen of the former may be conveyed in the palm.
BAS

palm of a man's hand, whereas vast operations are necessary to transport only one marble or bronze statue? These arguments alone are sufficient to account for the gems of this description which have been found in Italy; besides some which may have been wrought in that country by Greek colonists, or the scholars of Greeks. A crowd of evidence might be adduced in this place to shew, that the vases formerly called Etruscan have been found in great abundance in Greece. Mr. Stuart and Mr. Parry brought many fragments of them from Athens, which are lodged in the British Museum; Mr. Graves brought several entire and beautiful painted vases from Greece, some of which were afterwards in the possession of Sir William Hamilton; and to these might be added many other testimonies and collections on this part of the subject.

One error more should be refuted before we proceed: Winkelman (vol. i. lib. 3. c. 4.) in his history of the art, affords, that "the Etruscans gave their Fauns horsetails; whereas the Greeks represented Fauns and Satyrs with short tails like goats." The head-piece (p. 23, chap. 3, vol. ii.) of "Stuart's Athens," is a sufficient answer: it is a bas-relief of a Bacchalian dance, in which two Satyrs have horsetails. It was found in the ruins of the theatre of Bacchus, is of the style commonly called Etruscan; but, in fact, according to the time when this theatre was built (nearly 500 years before Christ), it is of the style of sculpture which prevailed in Greece immediately prior to the time of Phidias.

The general remarks on these works, during the period of about 550 years from the time of Cadmus to the time of Phidias, shall be confined to the three following: the manner of representing the gods; the manner of drawing the human figure and its actions; and, lastly, some observations on the draperies and utensils.

From the two proofs adduced that Grecian sculpture has been called Etruscan from the want of sufficient knowledge of the subject, and to which other proofs equally certain might be added (for instance, that all the early Greek coins are of the same style with that called Etruscan), it will seem to be a safe conclusion, that all ancient sculpture representing Greek subjects, should be considered as the work of Greeks, their colonists, or scholars, excepting in such cases as there is sufficient reason to believe the contrary. — Conformably to this regulation, the following observations may be offered on Greek sculpture preceding the time of Phidias. As the ancients represented their divinities in human forms, in the early times those forms were gross and imperfect, their aim being only to copy human nature; thus, in the gem above cited, of Jupiter with the thunder and trident, in Winkelman's "Monumenti inediti," pl. 23, his body and limbs are formed of few parts, grosso and inelegant, his face is bearded, and his hair is thick and matted. Nearly the same may be said of the Hercules on the bronze plate in the British Museum, above mentioned; a figure of Neptune on the oldest coins of Peuitum; and the other monuments of the same ages, which represent Jupiter, Neptune, Mercury, and Hercules, by such figures as they employed to represent common men, equally devoid of beauty and character. The face of Minerva is not more delicate than that of Hercules, nor do his limbs appear more robust than those of Apollo. The gods were only known by their symbols: Jupiter by his thunder, Neptune by his trident, Mercury by his caduceus, Minerva by her helmet and wings, &c. The gem of Jupiter with the thunder and trident above mentioned, which has also a four-footed animal under his car, perhaps a horse, agrees with Orpheus's hymn to that god, in which earth and sea are said to be his; in this respect agreeable to the most ancient religion, and an argument of the high antiquity of the workmanship.

Concerning the manner of drawing the figure, it has been judiciously observed by the authors of the French Encyclopedic, "that the Greeks began where the Egyptians left off;" and some of the better sort (not perhaps the very bell) of the Egyptian figures, are nearly fac-similes of the beginnings of Grecian art. However, improvements were soon made: they began to distinguish between muscle and bone, and the surface of the body and limbs were carefully marked with their greater subdivisions; the molloid mufcles and gullet marked the neck, the collar-bones were marked by nearly straight ridges, the edges of the ribs by an high arch, the abdomen by a double row of three nearly-square muscles on each side of the linea alba, and the division of the trunk from the limbs is strongly indicated by the edge of the pelvis; the shoulder is rounded, the biceps of the arm defined, the elbow expressed; a gentle indentation down the back of the lower arm shewed the situation of the ulna, the arm tapered downwards with the graceful flow for the mufcles, and flatness for the part composed of bones and tendons; the indies of the thighs were flattened in the proportions of the factorious muscles, the lower tubercle of the thigh-bone was thrown immediately above the knee, which was expressed by the form of the patella; the indies of the shin was strongly expressed, as were the calves of the legs; the ankles were neat and small, rounded at the bottom; the feet and hands partook more of the forms of nature than the Egyptian, and the fingers and toes were more neat, distinct, and various in the outline; on the back, the blade bones were marked as being little disguised by flesh, and the glutaei small and firm. Upon the whole, they are men in an early state of society, whose hard and confident exercise in leaping, running, scats of dexterity in war and hunting, has made the covering of their bones tendinous and elastic, tapered their limbs, and whose quick and strong digestion has kept the joints narrow and the abdomen flat, whilst a free and powerful respiration expanded and raised the chest. The first essays of sculpture in the round figure, required that the arms should be attached to the body, and the legs joined together, for support, and to prevent the unskilful artist from breaking his work: but this restraint did not extend to bas-relief in the same early compositions of this kind; in which you see such simple positions as approach to formality. There are also figures in violent actions; as dancing latyrs, groups contending, and such exertions as shew the figure with sprawling, angular, and extravagant appearances: for hitherto the indications of grace were as small as those of beauty.

The draperies in the early bas-reliefs are thin, showing the forms of the body and limbs; the folds regular, small, and defined, containing chiefly of perpendiculars and zig-zags. Some of the head-dresses consist of small curls, very like the fashionings of barbarous nations defaced and drawn by modern travellers; and in the bronze plate in the British Museum above mentioned, the club of Hercules is ornamented with spiral flutes, like one brought by captain Cook from the Sandwich islands.

The bas-relief of Hercules bearing the tripod from Apollo, mentioned above, seems to be nearer the time of Phidias than any of the other examples; not only from the superior elegance of the design, but likewise from its being in line very similar to the Bacchian dance found in the theatre of Dionysus at Athens. This subject of Hercules bearing the tripod from Apollo, is described by Pausanius in
logical and moral, as they represent the gods, their operations in the government of the universe, and providence in the disposition of human affairs; the heroes are exerted in the exuile of justice, and the destruction of monsters.

Mr. Fuseli, the able and learned professor of painting in the Royal Academy of London, has judiciously applied Aristotle's division of poetry to the arts of design; and he considers the greater productions, as either epic, dramatic, or historic. According to these classes, the sculpture in each tympanum was entirely epic, as the gods only were represented in single acts; the groups in the metopes are dramatic, because they represent a series of actions; and the frieze which goes round the temple is epic, inasmuch as the gods are prevailing; and are perhaps also historic, as particular persons and events may be represented in the procession. In the Temple of Theseus, the alto-relievo formerly in the pediments are gone entirely; nor do we know even what the subjects were. In the frieze round the pronaoi is the battle of Marathon, in which the apperition of Theseus calls great figures on the Persian; Jupiter, Juno, and Minerva. Neptune, Apollo, and Diana, sit, behold, and determine the victory, the trophy of which is raised by the Athenians. The battle of the Lapithae and Centaurs is in the frieze of the portico: the metopes are filled with the labours of Theseus and Hercules.

The execution of these works is equal to the conception; the sentiment is elevated and fit, the composition is noble, full, and various; the gods are sublime and beautiful, their postures pretent dignity and repose; the heroes are vigorous and active, and an admirable simplicity reigns through the whole; whether you are roused by the terrific engagement of a Centaur and a Lapith, or captivated by the mouldy of the virgin chorusses. In the battles, the figure is shown in those classic curves and varied movements, those uncommon but advantageous situations, which equally excite surprise and admiration; every part is intelligible; they occupy such spaces of the ground as leave sufficient blank to render the outline distinct; and their quantities are so distributed, that one part is not bare while another is crowded: the lines themselves also become an ornament. The stories are told by one plan or ground of figures; and, like the principal characters in the tragedies of Æschylus, Euripides, and Sophocles, their effect is weakened by no under-plot of inferior heroes. The drawing of the figures is of the finest style, the outline and forms are chiseled, the greater parts boldly expressed, the lesser parts delicately indicated, but not more than necessary. The heads fine, the drapery rich in folds, but perfectly natural; some of the remaining hands and feet of the most perfect beauty; and the horses may be described in the words Sir George Wheeler used to express his opinion of those he saw in the eastern tympanum of the Parthenon: "The horses are made with such great art, that the sculptor seems to have outdone himself, by giving them a more than seeming life; such a vigour is expressed in their prancing and stamping, natural to generous horses." The edges of the figures have been kept square in the working, to give the bolder effect to the relief; which was not high in the procession round the frieze under the portico of the Parthenon, in order that the sculpture might not overpower the architectural members. The sculpture in the two pediments of the Parthenon, the metopes in that temple and the temple of Theseus, as well as that round the frieze of the latter temple under the portico, are in alto-relievo. This Phidias discovered; it is called toretices, rounded, by Pliny (lib. 34. cap. 8); and he says, Polyclus "so taught toretices, alto-relievo, rounded work,
work, as Phidias had invented it:—et torentium sic erudisse, ut Phidianis aperisse."

Besides the baso-relievo above mentioned, several others in Athens are of the highest beauty; the figures on the Temple of the Winds; the story of Deceus and the Tyrrhenian mariners transformed into dolphins, on the Choragic Monument of Lycurgus (Stuart's Athens, vol. ii.), raised in the time of Alexander the Great; and two altarelievos of the battle of the Athenians and Amazons, with another battle, subject unknown. (See the last two plates, vol. ii. of Stuart's Athens.)

Before we quit the subject of baso-relievo among the Greeks, it is proper to observe, that foliage ornaments in baso-relievo seem to have been introduced in Ionia about the same time with the Ionic capital; in the reign of Alexander the Great. (See the capital of an Ionic pilaster enriched with foliage, in the ruins of the temple of Apollo Didymus, tail-piece, p. 55. Rivett's Ionia.) These inventions are two characteristics of the Ionian school.

Soon after this period, the most eminent Greek sculptors and architects were almost entirely engaged in decorating the capital of their Roman conquerors. Most of their public works at home were inferior in beauty and spirit, in proportion as the intention was debased, which was chiefly that of paying fervent compliments to their masters; and the buildings raised, with a very few exceptions, were distinguished by a colonial inferiority from those of Rome, which the genius of Greece, and the spoils of the world, rendered the most magnificent of the times.

We may begin the observations on the baso-relievo executed or existing in Italy, by some notice of those cut in the rock. In the garden of the Capuchins' convent at Palazzuolo, on the lake of Albano, is a tomb; and in the tufo beneath, on the sides of the rock, are carved the fucures, the curule feet, the diadem, and the sceptre. M. D'Hankerville believes this to have been the tomb of Tarquin the Elder, because he received these regalia from the Etruscan ilates, and because the tomb stands on the elate which belonged to him. There are other baso-relievo cut in the tufo, representing the combats of lions and gladiators, with other apparently domestical subjects, on the sides of a tomb at Corneto, the ancient Tarquiniun: and although these works may be considered as Etruscan, yet there are reasons for thinking they are of Grecian origin; for Pliny (lib. 35. c. 12.) says, "that Demaratus, the father of Tarquin the Elder, in Etruria, who was afterwards king of Rome, flying into the Cotinus, was accompanied by the modellers (Euchira and Engrammisi, by whom modelling was brought into Italy." There are, indeed, works known to be Etruscan, in the gallery of Florence; among which are many figure cinerary urns of terra cotta: some of them bear baso-relievo of Greek subjects, and these are much the best; the rest are of an execution and manufacture equally ordinary. A terra cotta frieze of small figures, seven different subjects, was found some years since at Velletri, and preserved in the Borghian Museum. This seemed to be of the oldest Etruscan style: but still, as antiquaries have believed the stories to be Greek, and the frieze itself to be copied from a Greek original, so far this likewise must be considered as a production of the Grecian school. There is a print from one of these subjects, representing two women in a car drawn by two winged horses; the first head-piece, vol. iii. of Winkelman's History of the Arts of Design, Fca's edition.

The taflie for carved or chafed plate of gold and silver was introduced at Rome, by the immense quantity which Lucius Scipio brought in triumph from the spoils of Asia, con-
able for its sculpture, part of which was done in the reign of Trajan, and the rest under Conodantine; some of the former as remarkable for its grandeur, beauty, and boldness, as the latter for its barbarity; shewing the miserable decay of the arts in the course of 250 years. The two battles, the figures in which are as large as life, forming friezes under the cornices of the imposts in the middle opening of the arch, are grand and animated compositions, in a noble style of sculpture (see plate 42. and the following, in the Veteres Arcus Augulforum). Two observations on the arch of Severus will shew, that sculpture had declined considerably from the best ages. The principal bas-relievo occupy very large figures, containing figures, animals, cities, forts, and great warlike machines, on different plans, irregularly distributed, without regard to perspective; and thus, when viewed at such a distance that the detail becomes indistinct, they present the appearance of rustic work irregually rough, and disagreeable as mixed with regular and magnificent architecture: unlike the friezes in the temples of Athens, which, as they have only one plan of figures, each simply and beautifully conceived, when viewed at a distance in which the detail disappears, they present to the eye a composition of lines distinct and harmonious, forming an ornament. It is also to be observed, that the small figures in these great friezes are so boldly relieved, that they interfere with and destroy the effect of the smaller architectural members near them.

The triumphal columns demand our particular attention, not only for their magnificent design, structure, and materials, but also for the immensity of bas-relievo which covers them. But here we may observe, that imperial grandeur, by the endeavour to outstep, falls short of real grandeur; and that where too much is expected or intended, too little is the result. With respect to the very conception of the Trajan column, a doubt has been entertained, whether a tower might not have allowed of a more grand and simple design for the purpose of a stupendous structure, than a Tuscan column mounted on a Corinthian pedastal. But notwithstanding the doubts of some judicious and unprejudiced persons on this point, the column has been the wonder and delight of all beholders for 1600 years. The spiral bas-relievo, reaching from the bottom to the top of the shaft, represents Trajan's first and second expedition against the Dacians, and his victory over their king Deccbalus. Vasi (in his Itinerary of Rome) says, 'they count upon it upwards of 2,500 figures, without reckoning horses, elephants, arms, machines of war, and an infinity of other objects; to which may be added the four eagles on the corners of the pedastal, bearing trophies of laurel, and the arms on the die of the pedastal, all of mather, and the last mentioned of the most delicate and laborious execution. But here a defect must be noted, in justification of the first observation on this noble monument, that although the figures increase somewhat, both in size and projection, as they approach the top of the column, yet it is certainly true, that any person standing on the ground cannot see the objects distinctly above one-third of the height of the shaft, beyond which all is confusion. Does it not follow, that if figures of that size were intended to be seen, they should not have been raised above one-third of the column; and if they were intended to be seen at a greater distance, their size should have been proportionately increased? That this is an optical defect cannot be denied; yet critics have taken pains to make their readers believe, that every thing relating to perspective in this column was beyond the reach of most modern comprehension for excellence; when any person acquainted only with the very first principles of perspective, must perceive no attention whatever has been given to linear perspectives from the top to the bottom of the column: such injudicious praise proves only the absurdity of modern opinion of the excellence of the colosseum. Certainly the ancient sculpture contains whatever is truly excellent and admirable in the art; but let us choose the objects which are really possessed of those qualities, always distinguishing between beauty and the want of it; and then we cannot be said to praise too liberally, or flily with too much diligence those performances we would imitate, or be thoroughly acquainted with. The Antonine column is covered with bas-relievo, representing the victories of Marcus Aurelius over the Marcomanni. The sculpture is inferior to that on the Trajan column, and figures, having more projection, deform the outline of the shaft at a near view. The Theodorian column at Constantinople, drawn by Gentil Bellini (see Montfaucon), induce us to believe that sculpture did not decline so hastily in the East as in Italy.

Marble sarcophagi do not seem to have been used in Rome much before the time of Cnflus, whose wife Cecilia Metella was buried in one. The fronts and ends of these columns, from that time for many ages afterwards, were decorated with figures. Some of the finest compositions of the ancients are to be found upon them, most probably copied from Greek originals, by Roman manufacturing flatuans; one of whom lived on the Appian way, and occupied an extent of two miles in his works, as has been supposed from the quantity of sculpture finished and unfinished found on the spot, as well as an inscription which confirms the fact. The subject of the subjects leads us to think, that some have derived their origin from Phidias, Polycletus, and other of the greatest masters; as it is fearcely possible such groups and such expression as we see in these had copies, could at first have been produced by inferior artists. Among them are the statues of Prometheus, Medea, Phaethon, Orestes, Alectoe, the anger of Achilles, Bacchus and Ariadne, the fall of the giants, the judgment of Paris, &c. &c. These continued to be repeated till after the time of Constantine, when subjects from the Old and New Testament succeeded; but these were so barbarous that they merit no farther notice at present; and indeed the removal of the seat of empire to Constantinople had disfigured Rome of riches and ability; that little effort could be expected in the West, and the little that was left became the successor prey to the Northern invaders, and the unavoidable destruction of time, for the following fix centuries. Bas-reliefs of the eighth century, round the capitals of columns, representing Charlemagne and other figures, are in the Museum of French Monuments at Paris. There is also a bas-relief of Samson killing the lion, on a capital in the crypt of St. Peter's church, Oxford, done in the time of Alfred. Like all the works of these ages, they are barbarous and unmeaning.

In 1663 the Pisans began to build their cathedral, the old bronze gate of which contains a series of subjects from scripture in bas-relief; but so rude and gross, that they must be considered as the very beginnings of art. There is a bas-relievo of the acts of Abraham forming capitals to a group of columns, in the well door of the cathedral of Carrara, carved between 1100 and 1200, which is rather more detailed, though the figures are gross and disproportioned, not being above five heads high. Similar specimens may be seen of this age in different countries of Europe, from the first feeble efforts to revive sculpture. In such attempts as have been just mentioned, little improvement was made till towards the year 1230, when Nicolo Pifano having diligently studied some antique bas-relievo on sarcopahgi at Pisa, was employed in carving similar ornaments of sacred subjects, in several
several cathedrals building at that time in different parts of Italy. He was afflicted by his son John, and among other pupils, by two who seem to have been particularly esteemed, Arnolfo and Lapo. Besides being architect to several cathedrals in Italy, Nicola, with the assistance of his pupils, carved some baiio-relievo in marble; which were works of wonderful merit in that age, and would certainly deserve considerable admiration and respect in any other time or country, for sublimity, sentiment, truth, and beauty of execution. The following deferve particular notice: Stories from the Life of our Saviour, on the pulpit and baptistery of Pisa; similar subjects on the pulpit of St. John Baptist, in Padua, and in Florence; the Dormition of St. Mary; and Pieta. But the great and most eminable of these works is on the front of the cathedral of Orvieto. This front is one of the most splendid, both for materials and art, that the mind can conceive, or the resources of nature furnish. It is built of flatiron marble, wrought with the ticide care, and ornamented with the most delicate labour: the bolder buildings and smaller pillars are relieved by Mosaic tiles of the most splendid colours and gold; and magnificent Mosaic paintings of sacred subjects fill the decoration immediately under the cornice. The basements between the great and two side doors, from the height of six feet to that of twenty feet, is covered with subjects from the Bible in a great number of divisions representing all the principal facts, and concluding with the Resurrection, Judgment, and final delination of the good and wicked; the subjects are divided by running ornaments of vine, and other foliage, of uncommon delicacy and fancy. There is an alto-relievo by Nicolo, on the church of St. Martin at Ucena, of the Deacon from the Cross, which is extremely pathetic and simple. The baiio-relievo on the oldest bronze gate of the baptistery of Florence, by Andrea Uguolino of Pisa, after designs by Giotto, of the Life of St. John the Baptist, is simple and grand. Donatello, born in Florence 1379, executed bronze baiio-relievo on the two pulpits of St. Lorenzo in that city: the principal subjects are the Crucifixion and Interment of our Saviour, in which the expression is admirable. Vellano of Padua, his fellow, made some fine baiio relieves of bronze in the church of St. Antony in that city. But the work of this description which obtained the highest reputation in that age, was the second bronze gate, executed by Lorenzo Ghiberti, his father, and other assistants, for the before-mentioned baptistery of St. John in Florence. On it, ten compartments are filled with subjects from the Old Testament, beginning with the Creation and ending with the meeting of Solomon and the Queen of Sheba; the spaces between the pannels are adorned with foliage, heads, and beautiful figures of prophets and sibyls; the architrave is ornamented with festoons of flowers and birds, of so perfect an execution that they seem to be cut from nature; the whole is of gilt bronze. Vafari relates that Michael Angelo said, "It deferved to be the gate of Paradise." Certainly an admirable fancy, delicacy, execution, and execution, are to be found in every part of it; but its general character is rendered triisful by the introduction of so many plans, so much landscape and architecture in perspective, with the affectation of picturesque effect in the chiauro churo. But this fault must be palliated by the remembrance, that perspective was a new discovery to the moderns, wonderfully admired at the time: it had turned the brains of Paolo Uccello, a painter of great merit; and it is not to be wondered at, if Lorenzo Ghiberti, who had practiced painting, should have fallen into the delusive hope of adding a new charm to sculpture, which in fact belongs to painting exclusively.—From this time little can be said in commendation of the practice of baiio-relievo. Memory was substituted for imitation, fancy for nature; and the consequence was, that various species of affectation which are called manners. The schools of John of Bologna, Algarvii, Bemun, will justify this remark; and whoever takes the trouble to examine their productions in this department of sculpture will see, that art more than nature has been their object. Within the last century a number of circumstances have combined to develop the principles of sculpture, and a considerable emulation has been excited to attain its real perfections. A prodigious number of ancient statues, groups, and baiio-relieves in marble and bronze, as well as pictures, have been discovered; these have been magnificently and judiciously arranged, not only in the public museums of Italy, but in private collections of all the different countries of Europe. Such admirable works have excited universal curiosity and interest; the number of books on the subject have been increased by learned men and elegant critics; students have repaired in greater numbers than formerly from all parts to copy these works with great diligence; the number of competitors has produced emulation, each one endeavouring to distinguish himself above his competitors: they have laid up a large flock of ability for employment in their own countries, where the arts for the arts of design has been gradually increasing; so that now there are sculptors in Italy, France, England, Germany, &c. who have produced baiio-relieves of great merit, as well as other works of sculpture.

Winkelman has said, "that Sculpture, like an elder sister, has introduced and led her younger sister, Painting, into the world;" this is elegantly said, and on that account is likely to obtain currency more than for the certainty of its truth. What additional value does one art acquire over the other by being older? Both arts are noble and virtuous pursuits; the fine productions of both afford intellectual and rational delight; and there is difficulty enough in the way to excellence in both, to exercise the utmost stretch of the most powerful geniuses who have engaged, or may engage, in the study of them. It should seem from Puy's account, lib. 55; c. 3. and c. 12. that the beginning of painting and baiio-relieve were alike; for the first advances towards baiio-relieve were made by Dibutades's taking the impression of an outline. Aricles the Corinthian, and Telephane the Syracusan, made the first efforts towards painting, before colour was used, by outline also. But to leave this question of little moment, let us go to those considerations which are of real importance to the subject we are treating. It has already been shown, that baiio-relieve, from the earliest ages, was used as representative writing, and the right and only good purposes to which writing as well as speaking can be applied is to honest and to recommend and to determine whatever is virtuous in public or private, and useful among men. Thus was baiio-relieve employed in the best ages by the ancients, according to their several systems of theology, philosophy, and ethics; and thus only it should be employed; for when it is applied to other purposes, it is a deviation from the original intention, canes to be useful, and must engage the artist in the representation of persons and things below that standard at which he should constantly aim. Phidias gave a perfection to his Jupiter which astonished all men, and induced them to believe he had been favoured with a revelation of the god, by the human representation of power, majesty, benignity, and wisdom. And we shall find that whatever appears admirable, perfect, or lovely, in the representations of the ancient deities or heroes, is some mental or bodily perfection. The Christian religion presents personages and subjects no less favourable to painting and sculpture than the ancient classic: angels and archangels should be as perfect in youth and beauty as the youthful divinities of Greece. The heroes of the Old Testament bear to striking a resemblance to those of Greece, that eminent moderns have mistaken
them for the same persons. Nothing can be found in the pages of Greece, more august or sublime than in the patriarchs or prophets: they were equally inhabitants of warm climates, favourable to the display of the human figure; and their cloathing and arms were nearly similar. Indeed it may be safely affirmed, that the basso-relievo is the Left Judgment by Niccolo Pizanti, the Crucifixion and Entombing of our Lord by Dancello, and some of the panels in Ghiberti's gate, prove that the Bible presents subjects, and those almost innumerable, of greater interest, and as abundant in all the excellence of composition, as any to be found in the classical authors: such subjects are the proper decorations for churches and other public edifices of most importance to society, which should have the richest schools of instruction.—After the choice of subject, the economy and manner of treating are next to be considered. And here several hints may be found in Aristotle's poetics, and in the conduct of the Greek tragedies, as useful for the composition of a basso-relievo as a poem; with this difference, a poem embraces a succession of times, but a basso-relievo one moment only: and where this rule has been trespassed, the same peron has been introduced twice over. That one moment must represent an action, into which no more figures should be admitted than are necessary; because the increase of number is the distraction and loss of expression. The sentiment, the expression, and every part should be as elevated and advantageous as the nature of the subject will admit.—Concerning the execution, the basso-relievo of the Parthenon temple of Theseus, the others in the ruins of Athens, and a few more which are truly Greek, must be set up as the perfection of what has hitherto been done: the compositions are intelligible, because the figures are distinctly seen on the back-ground and not crowded one behind another; the drawing of the figures is from chosen examples, feelingly, forcibly, and faithfully copied; the pathos of the subject is not weakened by the introduction of building in perspective, or the affection of chiaro fermo, which attempts to introduce the distances of painting in basso-relievo. Agatharchus employed perspective in painting scenes, but Phidias and Polycletus knew that the form and expression of the human figure was the object of their sculpture.

Some very fine and extraordinary antique basso-relievo enrich the collections of England—
The tomb-stone of Xanthippus, and a man curving a horse, both about the time of Phidias, are in the collection of Charles Townley, esq.
The marquis of Lansdown has a Greek bas-relief of Chalcos, as large as life.

At Wilton House there is a fine example of the death of Melager, and a small but curious Hercules and Antigone, a basso-relievo composed of mosaic, in natural colours, which is supposed to be the only one of the kind.

The celebrated Barberini vase, in the possession of the duke of Portland, is of dark blue glass, bearing figures in basso-relievo of white enamel or glass of admirable workmanship. (See Bellori Sepolcri Antichi, Plate 84.) Fragments of basso-relievo in similar materials have been found in the ruins of the Caesars' palace in Rome, where they had been fixed in the walls.

John Hawkins, esq., the Grecian traveller, possession a beautiful small bronze basso-relievo of Paris, Helen, and two Gens, which he brought with him from Greece.

Plate I. 1. Contains an Egyptian hieroglyphical sphinx. 2. An Hindoo bas-relief. 3. A Persian bas-relief. 4. Jupiter with the thunder and trident, a Greek gem of the oldest style.

Plate II. 1. Minerva subduing Hercules, from a very ancient Greek patera of bronze in the British museum. 2. Apollo and Hercules contending for the tripod.
BASSORA, BASSORA, or BASSIRA, in Geography, a famous city of Aisa, in the Arabian Iraq, situated on the western banks of the Shat al Arab, which is a navigable canal, formed by the junction of the Euphrates and Tigris. This canal is navigable for vessels of fifty tons to the Euphrates, and thence to the gulf of Persia, from which it is distant about 15 leagues north-west. This city was founded in the year 636 by order of Omar, the second caliph, to hinder the commerce that subsisted between the Indians and Persians, and to secure the commerce of the two rivers by which goods imported from India were conveyed into all parts of Asia. The first colony was composed of 800 Moors; but the situation was so widely chosen that it soon became a flourishing and populous capital, and a place of trade, fearfully inferior to Alexandria. The air, though excessively hot, is pure and healthy; the meadows are covered with palm-trees and cattle; and one of the adjacent vallies has been celebrated among the four paradies or gardens of Asia. Under the first caliphs, the jurisdiction of this Arabian colony extended over the southern provinces of Persia. The city has been factitious by the tombs of the companions and martyrs; and the vessels of Europe still frequent the port of Bassora as a convenient station and pagage for the Indian trade. Merchants of Arabia, Turkey, Armenia, Greece, Jews, and Indians refold here; the English and Dutch have their consuls, and their ships come from India loaded with various kinds of merchandise. Those from Bengal, which arrive from the mouth of March to June, bring white linens, silk, muslins, baltard-fashin, fan-dal, and other woods, benzoin, vanuiril, rice, lead, European tin and iron. From the coast of Coromandel they bring thicker cloths, white or blue; which are used by the Arabs for their garments. From the coast of Malabar they bring cardamom seeds, pepper, &c. From Surat they receive all kinds of gold and silver stuffs, turbans, blue cloths, indigo, and flet; of which the Persians are the chief purchasers for the manufacture of their fabrics. The principal merchandise of the Dutch are spices and coffee from Java. Some Arabsians bring faves, and others bring pearls from Bahrein, and coffee from Mocha. The neighbouring countries also furnish merchandise for exchange; of which the most considerable are the ancient copper of Persia in small cakes, drugs of various kinds, grain when it is allowed to be exported, dates, wine, and dried fruits. The merchandise is sold for ready money, and passes through the hands of the Greeks, Jews, and Armenians. The Banians are employed in changing the coin current at Bassora for that which is of higher value in India. The abbé Raynal values the merchandise annually brought to India at 350,000l.; of which the English furnish 175,000l. the Dutch 87,500l. and the Moors, Banians, Armenians, and Arabs furnish the remainder.

Bassora has been subject to the Turks ever since the year 1668; and, like other cities tributary to that dominion, is governed by a cadi appointed by the prince of Bassora. But it may now be regarded as belonging to an independent Arabian prince, who pays dubious homage to the Ottoman Porte. This prince allows full liberty to all nations to come and trade to his capital; and the police of the city is so well maintained, that a person may pass safely through the streets at any time of the night. The prince derives his chief revenue from the exchange of money for the horses and camels that are bred here, and also from his plantation of palm-trees, which is said to be 90 miles in length. The horses that are bred in its vicinity are in great repute, and are sold at a high price. The income of the prince from the several articles of money, horses, camels, and dates, is so great, that he has a considerable surplus after discharging all the expenses of his tribute and government. The opulence of Bassora is owing partly to the extensive commerce which is carried on by the intervention of this town between Asia and Europe, partly to its being a place whence letters may be dispatched into all parts of Europe, particularly England and Holland, by way of Damascus and Aleppo, for which purpose Arabs, who are very swift-footed, are employed; and partly to the resort of Persian caravans in their pilgrimages to Mecca, where they pay considerable duties to the government, and exchange many valuable commodities. The number of inhabitants is computed to be about 50,000; the majority being Arabs; the rest are principally Turks and Armenians. The latter are the merchants, and some of them are very respectable. As to the religion of Bassora, besides Mahometans, there are Syrian Jacobites and Nefiorians, and monks from Europe, and also some modern Saraeans, whom they call disciples of St. John. The town is of great extent, and surrounded by a wall of clay, said to be twelve miles in circumference. The Bazar, or marketplace, is about two miles long and well supplied. The buildings of this city are molly constructed after the Turkish manner. The whole country about it is so low, that it is prevented from being inundated by a dyke or baak extending between three and four miles along the coast, and built of large square stones so well cemented together that the sea cannot affect it, though the sea runs strongly against it at the extremity of the Persian gulf. Bassora is 210 miles S. W. of Ipahan, and 600 S. E. of Aleppo. N. lat. 29° 45'. E. long. 47° 40'.

BASSOS, or BAXOS, Cape, lies in the Indian sea, on the east coast of Ajan in Africa, in N. lat. 4° 12'. E. long. 47° 7'.

Bassos de Bankos, shoals in the Indian ocean, lying off the east coast of Zanguebar in Africa, in S. lat. 5°. E. long. 48° 8'.

Bassos de Chaga, or shoals of Chaga, are situated in the Indian ocean, in S. lat. 6° 42'. E. long. 68° 20'.

Bassos de Indias, shoals of India, are situated N. E. easterly from the cape of Good Hope, and are called in some charts Jews Rocks, between Madagascar island on the east and the coast of Africa on the west, off Sofala. S. lat. 22° 30'. E. long. 40° 41'.

BASSOUES, a town of France, in the department of the Gers, and chief place of a canton in the district of Mirande, 5 leagues W. S. W. of Auch.

Species. B. ferrugina. Abl. Guian. 217 t. 85. Stems herbaceous, three or four feet high, branched; leaves alternate. Ovate, acute, smooth, entire, on a petiole about an inch long; the largest 10 inches long and 4½ broad; flowers in axillary corysmb, green, and very small. A native of Guiana, in wet forests, flowering and fruiting in June. Martyn's Miller's Dict.

BASSEUL, in Geography, a town of France, in the department of the Marne, and chief place of a canton in the district of Vitry la Françoise, 6 miles N. E. of Vitry, 5 E. 2.
BASSUEI, Peter, in *Biography*, born in Paris in 1704, was early initiated in the knowledge of surgery, by attending the hospitals and the lectures of the principal teachers there. In 1730 he was admitted to practice; and the academy of surgery being instituted the following year, he was nominated by the king one of the first members. In 1744, he was chosen demonstrator royal in therapeutics. He took part in the dispute on a question then much agitated, whether the heart was threatened in its felicity, or contagion, to expel the blood from the ventricles? But his opinion was formed. Hallier says, from theory only. His dissertation on the subject was published in one of the medical journals of the time. He died June 4th 1757. 

BASSUE, in *Hist. Sec. Bass-Vul.*

BASSU, in *Geography*, a town of Germany, in the circle of Welfphalia, in the county of Hoya, with a noble abbey; 16 miles west of Hoya.

BASSURE SUND, begins at Amblesinde, a little to the south of St. John's, on the coast of France, close to the shore, and stretches out S.W. by S. and S.W. by W.

BASTA, in *Biography*, an Epitome of bastardy, by defendant, was born at La Roche, a village near Tarentum; and devoting himself to the military profession, he was commander of an Epitome or Albanic regiment of horse, when the prince of Parma assumed the government of the Low Countries in 1579. Under this great general he perfected himself in the military art, and was preferred by him to the post of commissary-general of cavalry, and also employed in many important enterprises. The principal theatre on which his talents were exhibited, was the war in Transylvania and Hungary, where in 1601, he gained a signal victory over Sigismund Battori, and took the town of Clauffenborg. Having completed the ruin of Battori, he granted him peace on condition of his renouncing all rights over Transylvania. However, the severities exercised by Balta against the partisans of that country did great injury to the cause of the emperor; and the Imperialists, under the count Beligio, were defeated. Although Balta, in 1605, could not prevent the Turks from taking Strigomino or Gran, he made a judicious arrangement before Cenmpora, which hindered their further advances. Having made a peace, he soon after died in 1607. Balta was the author of two professional works that are much esteemed: the "Mastro de campo general" (Quarter-maier general), printed at Venice, in 1606; and "Governo della cavalleria lagguera" (Discipline of the Light Horse), Frankf. 1612.

GEN. DICT.

BAST, in *Ancient Geography*, a town of Italy, in Iapygia, on the eastern coast, at a small distance N.E. of the Salentine promontory.

BASTA, or Bajawa, a place of trade on the coast of Africa, before which is a road with 20 to 23 fathoms of water, and tolerably good ground.

BASTA, or Bajaw, a species of Spongia, found in the Indian sea, and called by Rumphius Bajawa marina, bajawa-tut. It is somewhat rigid, blackish, with undulated divisions; item round. Pallas. Found adhering to corals, and is about the thickness of a finger. Gmelin, &c.

BASTAGARII, in *Antiquity*, a college or company at Rome, who carried the fiscal species out of the provinces to Rome or Conftantiopolis. The directors of these were called pofitivi bagariorum. The word is derived from bajawo, which properly imports the office of carriage or conveyance; from baxa-wa, portare, to carry. The denomination bajawari has also been given to those who carry the images of saints at processions. Du Cange.

BASTAL, in *Geography*, the name of a romantic and fertile vale of Switzerland, lying in the direct road from Basle to Soleure, through the midst of the Jura mountains.

BASTAN, a town of Asia Minor, in the province of Natura, 30 miles S.W. of Amnias.

BASTARD, Thomas, in *Biography*, a clergyman and poet of the sixteenth century, was born at Blandford in Dorsetshire, and educated at Winchester school; whence he was removed to New college Oxford, and chosen perpetual fellow in 1588: but indulging too much his talent for satire, he was expelled the college for a libel. He afterwards became chaplain to Thomas earl of Suffolk, lord-treasurer of England, and, by his interest, vicar of Bere-Regis, and rector of Hamer in his native county. He was a person of great natural endowments, and skilled in the learned languages, a celebrated poet, and, in his later years, an excellent preacher. Towards the close of his life, he was deranged and involved in debt; and being confined in prison at Dorchester, he died in an obscure and mean condition in 1618. He was thrice married: first, as he informs us in one of his epigrams, in his youth for love; again, in mature age, for money; and a third time, in his old age, for a nurse. His poetical performances, which were admired in that age, were "Epigrams," and a Latin poem, entitled, "Magnis Britannia," London 1605, 4to. He also published a collection of "Five Sermons," and another of "Twelve Sermons," Lond. 1615, 4to. Biog. Brit.

BASTARD, in *Law*, a natural child, or one that is not only begotten, but born, out of lawful wedlock.

The word is of Saxon etymology, and is compounded of baste, vile or ignoble, and sert, or serct, original.

According to the civil and common laws, a child doth not remain bastard, if the parents afterwards intermarry; but it is an indispensible condition of legitimation, according to our law, that it shall be born after lawful wedlock. In this respect our law is far superior to the Roman; because marriage being principally designed for ascertaining some person to whom the protection, maintenance, and education of the children should belong, this end is better answered by legitimating all issue born after wedlock than by legitimating all issue of the same party, even born before wedlock, as weewlock afterwards cnues; in proof of which, Blackstone alleges the following arguments.

1. Because great uncertainty will generally attend the evidence, that the issue was really begotten by the same man; whereas, by confining it to the birth, and not to the begetting, our law has rendered it perfectly certain, what child is legitimate, and who is to take care of the child. 2. Because the Roman law, by which a child may be continued a bastard, or made legitimate, at the option of the father and mother, by a marriage "ex post facto," opens a door to many frauds and partialities which our law prevents. 3. Because by those laws a man may remain a bastard till forty years of age, and then become legitimate by the subsequent marriage of his parents; and thus the main end of marriage, or the protection of infants, is totally frustrated. 4. Because this rule of the Roman law admits of no limitations as to the time or number of bastards so to be legitimatized; but a dozen of them may, 20 years after their birth, by the subsequent marriage of their parents, be admitted to all the privileges of legitimate children. This is plainly a great discouragement to the matrimonial state; to which one principal inducement is usually not only the desire of having children, but also the desire of procuring lawful heirs. Whereas
Whereas our constitutions guard against this indecency, and at the same time afford sufficient allowance to the frailties of human nature. For if a child be begotten while the parents are single, and they will endeavour to make an early separation for the offence by marrying within a few months after, our law is so indulgent as not to baflardize the child, if it be born, though not begotten, in lawful wedlock: for this is an incident that can happen but once, since all future children will be begotten, as well as born, within the rules of honour and of civil society. Upon reasons like these, Blackstone supposes the peers to have acted at the parliament of Merton, when they refused to enact that children born before marriage should be deemed illegitimate. Stat. 20 Hen. III. c. 9. See the introduction to the great charter, edit. Oxon. 1759, tub anno 1253.

Hence it appears, that all children born before marriage are baflards by our law. But if a man marries a woman grossly big with child by another, and within three days after, she is delivered, the child is no baflard. 1 Danv. Abridg. 739. If a child is born within a day after marriage between parties of full age, if there be no apparent impossibility that the husband should be the father of it, the child is no baflard, but supposed to be the child of the husband. 1 Roll. Abr. 358. Moreover, all children born so long after the death of the husband, that by the usual course of gestation they could not be begotten by him, are baflards. But this being a matter of some uncertainty, the law is not exact as to a few days. It appears, upon the whole, that what is commonly considered as the usual period is 40 weeks or 280 days; but if the child be born some time after, it only affords presumptuation, not proof, of illegitimacy. This uncertainty of the period of gestation has given occasion to a proceeding at common law, where a widow is suspected to feign herself with child, in order to produce a suppositional heir to the estate; an attempt which the rigour of the Gothic constitutions esteemed equivalent to the most atrocious thefts, and therefore punished with death. In this case, with us, the heir presumptive may have a writ "de ventre inspiciendo," to examine whether she be with child or not; and if she be, to keep her under proper restraint till delivered; which is entirely conformable to the practice of the civil law: but if the widow be, upon due examination, found not pregnant, the presumptive heir shall be admitted to the inheritance, though liable to lose it again on the birth of a child within forty weeks from the death of a husband. But if a man dies, and his widow soon after marries again, and a child is born within such a time, that by the course of nature it might have been the child of either husband; in this case, he is said to be more than ordinarily legitimate: for he may, when he arrives to years of discretion, choose one of the fathers he pleases. (Co. Litt. 8.) To prevent this, among other inconveniences, the civil law ordained that no widow should marry "infra annum lactus;" a rule which obtained so early as the reign of Augustus, if not of Romulus: and the same constitution was probably transmitted to our early ancestors from the Romans, during their stay in this island: for we find it established under the Saxon and Danish government. L. L. Ethelr. A.D. 1008. L. L. Canut. c. 71.

As baflards may be born before the coverture or marriage is begun, or after it is determined, so also children born during wedlock may in some circumstances be baflards. As if the husband be out of the kingdom of England, or as the law somewhat loosely phrases it, "extra quattuor maria," for above nine months, so that no access to his wife can be presumed, her issue during that period shall be baflards. (Co. Litt. 241.) But generally, during the coverture accesses of the husband shall be presumed, unless the contrary be shewn: (Salk. 123. 3 E. Wms. 276. Str. 295.) which is such a negative as can only be proved by shewing him to be elsewhere; for the general rule is, "presumitum pro legimatione." There are some determinations by which it appears, that the child of a married woman may be proved a baflard by other circumstantial evidences besides that of the husband's non-access. 4 Term. Rep. 251. 356.

In a divorce a "mens et thoro," if the wife breeds children, they are baflards: for the law will presume the husband and wife confomrable to the sentence of separation, unless access be proved; but in a voluntary separation by agreement, the law will suppose access unless the negative be shewn. (Salk. 123.) So also if there be an apparent impossibility of conception on the part of the husband, as if he be only eight years old, or the like, the issue of the wife shall be baflards. (Co. Litt. 244.) Likewise, in case of divorce in the spiritual court, "a vinculo matrimoni," all the issue born during the coverture are baflards; because such divorce is always upon some cause that rendered the marriage unlawful and null from the beginning. Co. Litt. 235.

If a man or woman marry a second wife or husband, the first, being living, and have issue by such second wife or husband, the issue is a baflard. (Bott. 397. pl. 351.) Before the statute 2 & 3 Ed. VI. c. 21. one was adjudged a baflard "quia filius faceroctis." If a woman bequeath issue, a son, by a woman before marriage, and afterwards marries the same woman, and hath issue, a second son, born after the marriage; the first of these is termed in law a "baflard eigné," and the second a "mulier," or "mulier puifn.;" By the common law, a "baflard eigné" is as incapable of inheriting as if the father and mother had never married. However, there is one case in which his issue was let into the succession, and that was by the consent of the lord and person legitimate; as if upon the death of the father the "baflard eigné" enters, and the "mulier" during his whole life never disturbs him, he cannot upon the death of the "baflard eigné" enter upon his issue. In this case the "mulier puifn.;" and all other heirs, are totally barred of their right. This indulgence, however, is shewn to no other kind of baflard; for if the mother was never married to the father, such baflard could have no colourable title at all. (Litt. sect. 599, 400. Co. Litt. 245.) To exclude the "mulier" from the inheritance, there must not only be an uninterrupted possession of the "baflard eigné" during his life, but a defect to his issue. Co. Litt. 244. 1 Rol. Abr. 624.

The duty of parents to their baflard children, by our law, is principally that of maintenance. The method in which the English law provides maintenance for illegitimate children is as follows. When a woman is delivered, or declares herself with child, of a baflard, and will by oath before a justice of peace charge any person as having got her with child, the justice shall cause such person to be apprehended, and commit him till he gives security, either to maintain the child, or appear at the next quarter sessions to dispute and try the fact. But if the woman dies or is married before delivery, or mischiefs, or proves not to have been with child, the perfon shall be discharged; otherwise, the feotions, or two justices out of session, upon original application to them, may make an order for the keeping of the baflard, by charging the mother or the reputed father with the payment of money or other satisfaction for that purpose; and if the party disobeys such order, he or she may be committed to gaol, until they give security to perform it, or to appear at the sessions. The justices may commit the mother of a baflard, likely to become chargeable, to the house of correction for a year; or, for a second offence, till they give security for her good behaviour. And if such putative father, or lewd mother, run away from the parish, the
overseers, by direction of two justices may seize their rents, goods, and chattels, in order to bring up the said bastard child. Yet such is the humanity of our laws, that no woman can be compulsively questioned concerning the father of her child, till one month after her delivery. *Stat. 13 Eliz. c. 3.*

As to the rights of a bastard, they are very few; being only such as he can acquire: for he can inherit nothing, being regarded as the son of nobody, and sometimes called "nullus filius," sometimes "filius populii." Fortesc. de L. L. c. 49. Yet he may gain a family, and make his fortune, though he has none by inheritance. *Co. Litt. 3.* Where a remainder is limited to the eldest son of Jane S. whether legitimate or illegitimate, and the heir illegitimate, a bastard shall take this remainder; because he acquires the denomination of his issue by being born of her body. *Noy. 35.* All other children have their primary settlement in their father's parsi; but a bastard in the parish where born, for he hath no father. *Salk. 427.* However, in cases of fraud, as if a woman be sent either by order of justices, or comes to be a vagrant, to a parish to which she does not belong, and drops her bastard there, the bastard shall, in the first case, be settled in the parish from which she was illegally removed (Salk. 131); or, in the latter case, in the mother's own parish, if the mother be apprehended for her vagrancy. *17 Geo. II. c. 5.* Bastards also born in any licensed hospital for pregnant women, are settled in the parishes to which the mothers belong. *13 Geo. III. c. 8.* When a parish becomes charged with the maintenance of a bastard, then, and not before, the authority of the churchwardens and overseers commences (Say. 93); and they may act without an order from the justices. *3 Term Rep. C. P. 253.* It feems, however, that until a bastard attain the age of seven years, it cannot be separated from its mother (Cald. 6); but may be removed to the place of her settlement, while the age of nurture continues (Carth. 279.); and must under these circumstances be maintained by the parish where it was born. *Doug. 7.*

The incapacity of a bastard conficts principally in this, that he cannot be heir to any one: neither can he have heirs, but of his own body; for being "nullus filius," he is therefore akin to nobody, and has no ancestor from whom any inheritable blood can be derived. As a bastard has no legal ancestors, he can have no collateral kindred; and therefore if a bastard purchases land, and dies feised thereof without issue, and intestate, the land shall escheat to the lord of the fee. *Co. Litt. 244.* Finch. Law. 117.

By the Roman law, the mother inherited from her bastard child, and vice versa; but there was a great difference between bastards, "nothi," and those they called "famous." The law did not own the latter, nor allow them fullness, because they were born in common and uncertain prostitution. "Is non habet patrem, cui pater est populus." The former, born in concubinage, which resembles marriage, inherited from their mothers, and had a right to demand fullness of their natural fathers. They were looked upon as domestic creditors, that ought to be treated the more favourably, for being the innocent product of their parents' crimes. Solon would have it, that the parents should be deprived of their paternal authority over their bastards; because, as they were only parents for pleasure, that ought to be their only reward. *Aristot.*

Anciently in Rome, natural children were quite excluded from inheriting after their fathers ab intestato: but they might be appointed heirs in general. The emperors Aereadius and Honorius made a restriction: and when there were legitimate children, the bastards should only come in for a twelfth, to be shared with their mother. *Julianus after wards ordered, that they might come in for half; and succeed ab intestato for a sixth, when there were legitimate.*

Bastards might be legitimated by subsequent marriage, or by the emperor's letters. *The emperor Anaelius allowed fathers to legitimize their bastards by adoption alone: but this was abolished by Justinian and Juliaus, left by this indulgence they should authorize concubinage. The pope has sometimes legitimated bastards. Nay, the holy see has on some occasions dispensed not only with illegitimates, but with the offspring of adultery, as to spiritual considerations, in allowing of their promotion to episcopacy.*

Accordingly the civil law differs from ours in this point, and allows a bastard to succeed to an inheritance, if after its birth the mother was married to the father (Nov. 89, c. 8:); and also, if the father has no lawful wife or child, then, even if the concubine was never married to the father, yet she and her bastard son were admitted each to one twelfth of the inheritance (Ibid. c. 12:); and a bastard was likewise capable of succeeding to the whole of the mother's estate, although she was never married ; the mother being sufficiently certain, though the father is not. But our law, in favour of marriage, is much less indulgent to bastards.

An attempt was once made to introduce the civil law here in this respect, by declaring children legitimated by a subsequent marriage: but it was rejected: and it was upon this occasion that the barons of England assembled in the parliament of Merton, A.D. 1272, made that famous answer, "Nolimus leges Anglie mutate." *20 Hen. III. c. 9.*

But though bastards are not looked upon as children to any civil purposes, yet the ties of nature hold as to maintenance, and many other intentions; as, particularly, that a man shall not marry his bastard fitter or daughter. *I. Raym. 695. Comb. 356.*

A bastard was, in fraticid of law, incapable of holy orders; and though that were dispensed with, yet it was utterly disqualifed from holding any dignity in the church. *Fortesc. c. 49. 5 Rep. 58.* But this doctrine seems now obsolete: and there is a very ancient decision, that a felon should have benefit of clergy, though he were a bastard. *Bro. Clergy 29.* In all other respects, there is no distinction between a bastard and another man: whereas the civil law, which has been extolled for its equitabile decisions, made bastards in some cases incapable even of a gift from their parents. *Cod. 6. 57. 5.* A bastard may even be made legitimate, and capable of inheriting, by the transcendent power of an act of parliament, and not otherwise (4 Inll. 36:); as was done in the case of John of Gaunt's bastard children, by a statute of Richard II.

Bastardy with regard to the several modes of its trial, is distinguished into general and special bastardy. Till the statute of Morton already recited, the question whether born before or after marriage, was examined before the ecclesiastical judge, and his judgment was certified to the king or his judges, and the king's court either received or rejected it at pleasure. But after the colonn prettot of the barons at Morton against the introduction of the civil and canon law in this respect, special bastardy has been always tried at common law; and general bastardy has alone been left to the judgment of the ecclesiastical judge, who in this case agrees with the temporal. *2 Inll. 29. Reeves's Hist. Eng. Law. 85. 201.*

General bastardy, tried by the bishop, comprehends two things. 1. It should not be a bastardy made legitimate by a subsequent marriage. 2. That it should be a point collateral to the original cause of action. If the ordinary certify or try bastardy without a writ from the king's temporal courts, it is void; and the certificate must be under the seal of the ordinary. *1 Rol. Abr. 361, 362.*

Special bastardy is two-fold: 1st, Where the bastardy is the gift of the action, and the material part of the issue; zdy, Where
Where those are bastards by the common law that are "mul- 
rizers" by the spiritual law. (CoLitt. 134. 1 New Abr. 514. 
1 Rol. 367. Hub. 117.) If a man receives any temporal 
damages by being called a bastard, and brings his action 
in the temporal courts, and the defendant justifies that the 
plaintiff is a bastard, this must be tried at common law, and 
not by writ to the bishop. 1 Brownl. 1. Hub. 179. Godol. 
479. Co. Ent. 29.

In an ancient MS. of the time of Edw. III. it is said 
that he who gets a bastard in the hundred of Middletown in Kent 
shall forfeit all his goods and chattels to the king. If a 
 bastard be got under the umbrage of a certain oak in Knebworth 
in Staffordshire, belonging to the manor of Tresley-cadle, no 
punishment can be inflicted; and neither the lord nor 
the bishop can take cognizance of it. Plott's Stafford. p. 279.

By the lat. 21 Jac. 1, c. 27, a mother of a bastard child, 
concealing its death, must prove by one witness that the child 
was born dead; otherwise, such concealment shall be evidence 
of her having murdered it. But of late years it hath been 
usual, on trials for such offences, to require some sort of 
presumptive evidence that the child was born alive, before the 
other presumption be admitted, that becaufeth death was 
caused it was killed by the parent. If a woman be with child, 
and any one give her a potion to destroy the child, and it 
kills the woman, this is murder. If a woman great or quick with 
child takes, or any person gives her, any potion to cause 
birth, or if a man strike her so as to kill the child, this is not 
murder nor manslaughter by the law of England; but the offender 
may be indicted for a misdemeanor at common law. But if 
the child be born alive, and afterwards died of the potion or 
brutes it received in the womb, it is murder on the part of 
such as administered or gave them. Thus also, if a man 
procure a woman with child to destroy her infant when born, and 
the child is born, and the woman in pursuance of that 
procurement kills the infant, that is murder in the mother, and 
the procurer is acc seeded. 1 Hal. P. C. 429, 430, 433. 

Bastard, in respect of Artillery, is applied to those 
pieces which are of an unusual or illegitimate make or 
proportion. There are of two kinds, long and short, according 
as the defect is on the redundant or defective side.

The long ballards, again, are either common or uncom-
mon. To the common kind belong the double culverin 
extraordinary, half culverin extraordinary, quarter culverin 
extraordinary, falcon extraordinary, &c.

The ordinary bastard culverin carries a ball of eight 
pounds. See Cannon.

Bastard, in Botany, is applied to several species of 
plants: as bastard alkanet, for which see Lithospermum;
—balm, see Melittis; —cabbage-tree, see Geoffroya; 
—cedar, see Theodora Guaranica; —crees, see Thulas-
pi; —feverfew, see Parthemium; —flower-fence, see Ad-
mantina; —gentian, see Saraha; —hare's ear, see 
Phyllis; —hatchet-vetch, see Biserulca; —hemp, see 
Datissa; —hibiscus, see Achania; —jefuit's bark-tree, see 
Iva; —indigo, see Amorpha; —knot-grass, see Cor-
rigiosa; —lupine, see Trifolium Lupinago; —opine, see 
Andracine; —pimpernel, see Centunculus; —plantain, see 
Heliconia Bibai, and Centunculus; —quince, see 
Mesphileus Chamamaitius; —rocket, see Nasada; —
salmon, see Carthamus; —star of Bethlehem, see Albu-
ca; —wood-flax, see Thesium; —vetch, see Pacha.

Bastard, in Sea Languages, is used for a large fall of a 
galley, which will make way with a slack wind.

Bastard is also used adjectively, or in composition with 
divers other words, to denote things of inferior or diminu-
tive value. In this sense we meet with bastard coral, baf-
tard aballer, bastard ananthes, &c.

Bastard Scarlet is a name given to red dyed with bale 
madder, as coming near to the bow-dye, or new ferdik.

Bastards are also an appellation given to a kind of 
faction or troop of baudith, who rose in Guienne about 
the beginning of the fourteenth century, and mocery with 
some English parties, ravaged the country, and set fire to 
the city of Xaintes.

Messoy supposes them to have consisted of the natural 
sons of the nobility of Guienne, who being excluded the 
right of inheriting from their fathers, put themselves at 
the head of robbers and plunderers, to maintain themselves.

BASTARDY is a defect of birth objected to one born 
out of wedlock.

Enlathnus maintains, against the course of antiquity, 
that bastards among the Greeks were in equal favour with 
legitimate children as low as the Trojan war: others, how-
ever, have shown that there never was a time when bastardy 
was not in disfavour. (See Homer. I. 6, v. 281. Sophoc. 
Ajaq.v.11152. Euripid. Ion. v. 539.) In the time of William 
the conqueror, bastardy seems not to have implied any dis-
graces; for that monarch does not scruple to assume the 
appellation of bastard. His epistle to Alan, count of Bre-
tagne, begins, "Ego Willielmus, cognoment bastardus." 

Bastardy, Arme of which is a name in Heraldry, should 
be crossed with a bar, fillet, or traverse, from the left to the right. 
Bastards were not formerly allowed to carry the arms of their 
father, and therefore they invented arms for themselves; and 
this is still done by the natural sons of a king.

Bastardy, Right of. Droit de Bastardie, in the French 
Law, is a right, in virtue of which the effects of ballards 
dying intestate devolve to the king or the lord.

Bastardy, Trial of. See Bastard.

BASTARNAE, in Ancient Geography, a people who at 
first inhabited that part of European Sarmatia that corre-
sponded to a part of Poland and Prussia, towards the Vistu-
la, and who afterwards approached the more southern parts, 
and established themselves to the left and right of the Tyas 
or Danaiter. The sea of their war with the Goths, and 
of their conquest of these territories, is not precisely ac-
tained. M. Freret refers it to the interval between the years 
282 and 280 B.C. Tacitus says, they had houses; and 
hence it has been inferred that they were not Sarmatians, 
because they dwelt in huts. Livy considers them as Gauls, 
and Strabo furnishes that they were a nation of Germans. 
They seem, however, to have inhabited the region that lay 
north of the Carpathian mountains, and to have gradually 
extended themselves towards Poland and the Borythenes. 
Many learned persons have represented them as a colony left 
by the Gauls on the other side of the Carpathian moun-
tains, when they made their progres, under the conduct of 
Brennus, from the east towards the west. M. de Peyronel 
says, that they may be regarded as the founders of the Ruf-
ians and Scavonians.

BASTATAL, in Geography, a small island on the easter-
nt coast of the island of Sumatra. S. lat. 1°. W. long. 
101° 30'.

BASTAVOE, a bay on the easter side of Yell, one of the 
Shetland islands.

BASTELLICA, a town of the island of Corsica, 5 
leagues E.N.E. of Ajaccio.

BASTERIA, in Botany. See Calkyanthus.

BASTERNA, in Antiquity, a kind of vehicle or char-
riot used by ancient Roman ladies.

Papias thinks, that basterna was first written for伸出.
Rosculel says, it should be **viso flava**, which he concludes from Hidore, who says, **balteus**, **viso flava**. But the word feeder better derived from the Greek **βάλτιος**, **πέρον** to carry.

Salmaeus observes, that the balterna succeeded the **littera**, or litter; from which it differed very little, except that the litter was borne on the shoulders of slaves, and the balterna borne or drawn by beasts. Caffonbon says it was borne by mules. F. Daniel, Mathillon, &c. affect it was drawn by oxen, to go the more gently; and Gregory de Tours gives an instance of its being drawn by wild bulls. The nilde they called the **caren**, or cage; it had soft cushions or beds, besides glaikes on each side like our chariots. The mode of balternas paffed from Italy into Gaul, and thence into other countries; and to this we owe our chariots, which, though we call them **curru**, yet have they no conformity to the ancient **curru**, but are in effect balternas improved. The balterna appears also to have been used in war, for the carrying of baggage.

**Bastia**, now **Baza**, in **Ancient Geography**, a town of Spain, in **Bretica**, north-east of Acci, and near the mountains which separate **Bretica** from **Tarragonensis**.

**Bastia**, in **Geography**, a sea-port town of **Albania**, in Turkey in Europe, over against the island of **Corfus**, at the mouth of the river Calamiu. N. lat. 39° 40'. E. long. 20° 35'.

Bastia, a city and sea-port of **Corfica**, the capital of the island, is situated on its north-east side, and commanded by a lofty mountain, in the centre of which the sea forms a small bay, defended by a mole. It is divided into two parts, called **Terra Nova** and **Terra Vecchia**; in the former of which is a citadel, surrounded with fortifications. Its harbour, though good, is not large; and affords convenient anchorage for vessels of a small size, but is unfit for the reception of ships of war: and its commerce is inconsiderable.

In 1736, **Corfica** revolted from **Genova**; and in 1794, it was attacked by lord **Hood**, and captured by the British fleet and army. The number of inhabitants is supposed to be about 6000. N. lat. 43° 35'. E. long. 9° 30'.

**Bastia Marina** (**Rumpflis**), in **Natural History**, a kind of sponge, supposed to be the **Sposia ventolobra** of Gmelin.

**Bastide**, in **Topography**, an appellation given in the southern departments of France, to small country-houses, built by individuals of cally circumstances, in the vicinity of the towns.

**Bastide de Montfort, La**, in **Geography**, a town of France, in the department of the Tarin, and chief place of a canton in the district of Gailac, 5 miles N.E. of Gailac.

**Bastide de Serres, La**, a town of France, in the department of the Arriege, and chief place of a canton in the district of Tarascon; 4 leagues N.W. of Tarascon.

**Bastide, La**, a town of France, in the department of the Lot and Garonne, and chief place of a canton in the district of Caftel-Jaloux, 21 leagues W.S.W. of Tonneins, and 2 N. of Caftel-Jaloux.

**Bastide de Sourdans, La**, a town of France, in the department of the mouths of the Rhone, and chief place of a canton, in the district of Apt, 4 leagues S.E. of Apt.

**Bastide d'Armagnac, La**, a town of France, in the department of the Gers, and chief place of a canton in the district of Nogaro, 44 leagues N.N.W. of Nogaro.

**Bastide de Beaur**, a town of France, in the department of the Lower Pyrenees, 4 leagues W. of Orthez.

**Bastile** denotes a small antique caftle, fortified with turrets. Such was the bastille of Paris, which seems to have been the only caftle that retained the name: it was begun to be built in 1369, by order of Charles V. and finished in 1383, under the reign of his successor. Its chief use was for the custody of state prisoners.

Of the plan and structure of this edifice, which was for several ages appropriated to the clandestine purposes of unfeeling dissipation, and which might be justly confidered as the abode of human misery, and of the regulations by which it was governed, it is now needful to record any particulars; as it was affailed and totally destroyed at an early period of the revolution in France, viz. on the 13th of July, in the year 1789. Those who are curious in acquainting themselves with its history, will find their curiosity gratified in a volume entitled "The History of the Bastile, &c." published in 1790, 8vo.

The most satisfactory information relating to the prisoner in the iron mask, who was confined in this wretched dungeon for many years, and concerning whom many conjectures have been made, is communicated to the public in a work entitled "Memoirs of the Marechal Duc de Richelieu," published at Paris in 1790, in 4 vols. 8vo. The secret is said to have been extorted from the agent by his daughter, who disclosed it to the duke de Richelieu. From the account given in this work it appears, that this unfortunate person was the twin-brother of Louis XIV. born eight hours after this monarch, and who was the unhappy victim of superstition and cruelty. His father, Louis XIII., being weak enough to give credit to a prediction of some impollors, that if the queen should be delivered of twins, the kingdom would be involved in civil war, ordered the birth of this prince to be kept a profound secret; and had him privately educated in the country as the illegitimate son of a nobleman; but on the accellion of Louis XIV. the young man gave indications of having discovered his parentage, of which his brother being informed, ordered him to be imprisoned for life, and to wear a mask, in order to prevent his being recognized.

**Bastimentos**, in **Geography**, small islands near the illusns of Darien, at the mouth of the bay of Nombre de Dios. They form a good harbour; and one of them has an excellent spring. N. lat. 9° 30'. W. long. 79° 45'.

**Bastinado**. See **Bastoado**.

**Baston**, in the **Modern Fortifications**, a huge mass of earth usually faced with fods, sometimes with brick, rarely with stone, standing out from a rampart, whereof it is a principal part; and answering to what in the ancient fortification was called *propgynactiuem*, or a bulwark.

Ballions, some say, were first introduced by Zfca the Bohemian; others attribute the invention of them to Achetel Dalhaw, in the year 1480, mentioning the fortification of Otranto as the first instance in which they were used. However, they were well known soon after the year 1500; for Tartalea gives a plan of Turin, which had been completely fortified for some time with four ballions, in his *Quelli & Inventivori diversi*, published in 1546. The first ballions, such as those of Turin, and of Antwerp, which was fortified about the year 1540, were small, and removed at a great distance from each other; but they were made much larger, and brought nearer to each other in the citadel of Antwerp, erected under the direction of the duke d'Alva, about the year 1566.

A ballion consists of two faces and two flanks, and an opening towards the centre of the place called the *coron*. The faces are the lines BC and CS (Plate I. Fortification, fig. 1.) including the angle of the ballion. See *Facs.* The flanks are the lines BA, SD. The union of the two faces makes the outmost or salient angle, called also the angle of the ballion, BCS.

The union of the two faces to the flanks makes the side-angles called the shoulders, or epancles of the ballion.
And the union of the two other ends of the flanks to the
two curtains, the angles of the flanks of the bastion.

The foundation of the bastion, i. e. of a work consist- ing
of flanks and faces, is that great rule in fortification, viz.
that every part of a work must be seen and defended from
some other part: mere angles therefore are not sufficient,
but flanks and faces are indispensably requisite.—Thus,
if the bastion consists of flanks and faces, as ABCDE, fig. 1.
all the points may be defended from the flanks; there being
none, v. gr. in the face BC, but what may be defended
from the opposite flank EL, nor any in the curtin AE, but
may be defended from the adjacent flanks BA and ED; nor
in any one flank BA, but may be defended from the other
EL.

For the proportions of the faces, they are not to be less
than 40 toises, nor more than 60; or differing little from
100 yards.

The flanks of bastions are better as they are longer, pro-
vided they stand at the same angle under the line of defence:
hence the flank must stand at right angles to the line of
defence. Indeed, in the ancient fortification, the flank is
made perpendicular to the curtin, so as to have the angle
out of the enemy’s eye; but this is now provided for, by
withdrawing the lower part of the flank two or three
perches towards the curtin; which part, thus with-
drawn, is better, if made concave, than rectilinear; and if
double, with the ditto between, than ifingle.

The business of defacing the flanks of bastions makes
the principal part of the art of fortification; it is that on
which the defence principally depends, and which has intro-
duced the various forms and modes of fortifying.

If the angle of the bastion be less than sixty degrees, it
will be too small to give room for guns; and besides,
so acute as to be easily beaten down by the enemies’ guns:
at which may be added, that it will either render the line of
defence too long, or the flanks too short: it must therefore
be more than sixty degrees; but whether or not it should
be a right angle, some intermediate angle between sixty and
ninety, or even whether or not it should exceed a right
angle, is still disputed; though those are generally preferred,
which are not much less than 90°, and not exceeding 120°
or 130°. Hence it follows, that a triangle can never be
fortified, because either some or all of the angles will be
either sixty degrees, or less than sixty.

Bastions are of divers kinds, solid, void, flat, cut, &c.

Bastions, solid, are those that are filled up entirely, and
have the earth equal to the height of the rampart, without
any void space towards the centre.

Bastions, void, or hollow, are those surrounded with a
rampart and parapet, only ranging round their flanks and
faces, so as to leave a void space towards the centre;
where the ground is so low, that if the rampart be taken,
no re酒ment can be made in the centre, but what will
lie under the fire of the besieged.

Bastion, flat, is a bastion built on a right line in the
middle of the curtin, when it is too long to be defended by
the bastion at its extremes.

Bastion, cut, is that whose point is cut off, and in lieu
thereof has a re-entering angle, or an angle inwards with
two points outward: this is sometimes also called bastion
with a tenaille; and is used either when, without such a con-
trivance, the angle would be too acute, or when water, or
some other impediment, hinders the carrying on of the bastion
to its full extent.

Bastion, compound, is when the two sides of the interior
polygon are very unequal, which makes the gorges also un-

Vol. III.
The birданас is a punishment used among the ancient Greeks, Romans, and Jews, and still obtains among the Turks.

The Romans called it *flagitatio, flagium admissit, or fistulam cede*, which differed from the *flagellatio*, as the former was done with a stick, the latter with a rod or scourge. The *fistulum* was a lighter punishment, and inflicted on freemen; the *flagellation* a severer, and reserved for slaves. It was also called *tymporum*, because the patient here was beat with flicks, like a drum.

The penalty is much in use in the East to this day. The method there practised is thus: the criminal being laid on his belly, his feet are raised, and tied to a stake, held fast by officers for the purpose; in which posture he is beaten by a cudgel on the soles of his feet, back, chin, &c. to the number of one or more hundred blows. Calmet, Dict. Bib. tom. i. p. 260.

For the method of inflicting this punishment at Algiers, see Algeria. Dr. Shaw (Trav. p. 253.) suggests that it was probably in this manner, that St. Paul was "three times beaten with rods." 2 Cor. xi. 25. The Choufes, whole office it is to inflict this punishment at Algiers, appear to be no other than so many Roman factors armed with their fauces. The frighten of all the Choufes punishments is the *baldmado*, which is only used for chastising those who have been guilty of very trivial faults. The criminality of the offender determines the number of blows which he must receive; but the lowest number is twenty. The punishment in this case is considered merely as a simple paternal correction, without any infamy attached to it; and it is ordered by the emperor to be inflicted on his courtiers, who are afterwards received into favour and treated with respect. The baton, or "pantiffe," used for this punishment, is a piece of bamboo, a little flattened, broad at the bottom, and polished at the upper extremity for the convenience of being more easily handled. Every mandarin may use it at pleasure in certain cases, either when any one forgets to salute him, or when he administers public justice. On such occasions he fits gravely behind a table, upon which is placed a bag filled with small flicks, while a number of petty officers stand round him, each furnished with some of these "pantife," and waiting only for his signal to make use of them. The mandarin takes from the bag one of the little flicks which it contains, and throws it into the hall of audience. The culprit is then seized, and stretched out on his belly towards the ground; his breeches are pulled down to his heels, and an athletic specimen applies five smart blows of his "pantife," another succeeds, and below five more, if the mandarin draws another small baton from the bag, and thus, by gradation, until the judge is pleased to make no more signals. The criminal, who has undergone this chastisement, must then throw himself upon his knees before the judge, incline his body three times to the earth, and run him for the care which he takes of his education. Grolier's China, vol. ii. p. 52, &c.

BASTONIER, or Batonier, in the French Law, an ancient advocate, elected yearly according to seniority, to be the head or master of the community of advocates and attorneys. He is presidant of the board held for maintenance of the order, and discipline of the palais. To him also belongs the commission of the inferior judges, when put under inspection, & long as the interlocution lasts.

Bastion is also used for him who keeps the staff of a community, and occurs or follows in processions.

BASTOVA, in Geography, a town of European Turkey, in Albania, 18 miles south of Durazzo.

BASTIAD, in Geography, a sea-port town in the island of Martinico.

BASSEZEL, a river of European Turkey, which runs into the Pith, near Stepishanaw, in Moldavia.

BAT, in Zoology. See Vespertilio.

BAT, Sea. See Sea Rat.

BAT, in Commerce, a small base silver coin, current in divers parts of Germany and Switzerland, at different pieces. The bat or hedermaue, at Nuremberg, is equal to four crowns; at Zurich, to 1/2 of the French crown; at Basel, Schaffhausen, &c. to 1/3; and at Bam and Frieburg to 3/5 of the same crown. These half are called short bats.

BAYTA, in Botany. See Musa.

BATA, in Geography. See LATTA.

BATAANO, a town on the south side of the island of Cuba in the West Indies, seated near a large bay, opposite Pina.
BATACARANG Point, lies on the east coast of the island of Sumatra.

BATALHA, a monastery in Portugal, in Geography, lies on the east coast of the island of Cypros, in N. lat. 5° 55', E. long. 81° 5'. It extends to the south between the main island and a narrow tract of land on the east side of it, and is well sheltered from most winds. The Port town, so called, is on the west side of this bay or gulf, 53 leagues N. of Colombo. The bay is about 20 leagues to the S. S. E. of Trincomalee. Batacolo is a place of comparatively small importance; but the surrounding country, and the bold grotesque rocks which skirt its shores, have deservedly attracted particular attention.

BATAVIAN, See Batavo.

BATTABLE, See Batavo.

BATAVIA, a town of Asia, Turkey, in the province of Natoia, 20 miles south of Kottaw.

BATTALION, See Batonian.

BATTALION, See Convulvulus.

BATTAS, in Botany. See Convolvulus.

BATTAS. See Potato.

Batatas, in Entomology, a species of Acarus, found on the potato in Surinam and some other parts of South America. It is rather rough and fangous; anterior legs as long as the body. Fabricius.

BATAVI, in Ancient Geography, are supposed to have been originally the same people with the Catti or Catans, who dwelt beyond the Rhine; and being driven from their country by a domestic insurrection, they settled at the extreme borders of Gaul, in an island called "Incola Batavorum," formed by the mouths of the Rhine and the ocean. According to this description, the Batavians opposed South Holland, part of the country of Utrecht, and the island of Bataw in the dukedom of Guelderland. The early history of the Batavi is involved in considerable obscurity. It is certain, however, that about 54 years before the Christian era they were distinguished by their valour, and attracted the attention of Caesar, who formed an alliance with them. He encouraged them to serve in the Roman armies; and they appear to have fought with him against Pompey at Pharsalia, and to have assisted Augustus in the battle of Actium. They assisted Caesar in his attacks upon the Gauls, and they everywhere routed and dispersed that ferocious and warlike people. The Batavian cavalry bore the highest reputation, and the infantry fought with the fame order, discipline, and intrepidity in the marshes and waters as upon the firm land; and even the Romans dreaded their retribution. They became the body-guard of the emperors, who repose equal confidence in their fidelity and courage; and they retained this honourable trust till they were disfranchised by Galba, though with tokens of favour and esteem. In all important expeditions, in every dangerous enterprise, and where obstinate boldness was required, the Batavians were selected. They generally composed the forlorn hope of the Roman army, fullained the brunt of the enemy, and made the first attack with an impetuosity peculiar to themselves. They were not only honoured by the title of allies to the empire, but distinguished by the appellation of the friends and brethren of the Romans; which denomination was particularly applicable to the inhabitants of Betav, an island formed by the Rhine and Vathal or Waal. Their government seems to have been monarchical, and it is conjectured that Claudius Civilis was defended from their kings. But though the Romans indulged them in an exemption from tributes and taxes, it was not consistent with the views they had adopted of universal dominion to allow them the enjoyment of their liberty. They built towns, and made establishments in their territories; and this rude people, flattered by the luxury and the amusements which they introduced among them, did not immediately perceive the dangerous policy which directed them. They were fond, however, informed of the treachery of their allies, by the oppression and injustice which they began to execute. When Vitellius and Otho disputed the empire, and the German nations attempted to recover their liberty, the Batavians followed their example. Alarmed for the interest and the rights of their nation, Julius Paulus and Claudius Civilis set themselves to oppose the practices of the Romans, and to emancipate themselves from their dominion. But Fonteins Capito, the Roman commander, confederating them as rebels, made himself master of their persons; and having beheaded the former, he loaded the latter with chains, and sent him to Rome. The death of Nero, however, which happened about this time, delivered Civilis from the danger which threatened him; and the weak and impolitic Galba suffered him to return to his country, without inquiring into his crime, or into his merit. This illustrious chief then prepared to gratify his resentment, and to recover and vindicate the liberty and honour of his nation. He called an assembly of his community, and representing the evils of tyranny, inculcated a distain of submission and servitude. His countrypeople submitted themselves without referne to his conduct; and uniting with the Frilii and the Coninifates, he declared war against the Romans. Gaining an accession of strength from the Teutoni, who defaced the Romans, and from some natives of Batavia, who served as rowers in the Roman fleet, he was enabled to defeat the Romans and put them to flight. He was afterwards joined by eight Batavian cohorts, who abandoned Vitellius, by whose orders they were marching to Rome, and also by some other German tribes; and thus aided and encouraged, he obtained some further successes. But upon the arrival of Cerialis, the Roman general, he received a total overthrow, and was at length obliged to abandon his own island, whether he had retreated, to retire beyond the Rhine, and to submit to the Romans. A conference taking place between Cerialis and Civilis, the issue of it was an entire submission on one side, and an unreserved pardon on the other. The Batavians remained in the same condition in which they were before the war broke out; that is, exempt from all tributes, and only obliged to supply the Romans with troops when required. We know little more of the ancient history of the Batavians than that the fierce and warlike spirit of the people obliged the Romans to maintain strong garrisons on the banks of the Rhine; that they revolted against Candida; that they performed signal services to Theodosius in Britain; and that, with the rest of the empire, they fell under the power of the Franks, and were governed by Charlemagne, and his descendants, until, upon the decline of that house, the great lords and officers of the crown, taking advantage of the weaknesses of the reigning princes, rendered their governments hereditary in their families. From the Batavi, the seven united provinces derived the name of Batavia, which since the French revolution has been recognized in the appellation of the Batavian

BATAVIA CASTRA, a citadel of Vendelicia, so called from the color Batavia, in garrison under the commander in Rhetia; now PASSAU, situated in Bavaria, at the confluence of the Danube, Ian, and Ils.

Batavia, in Geography, the colebrated capital of the Dutch possessions in the East Indies, and denominated the "Queen of the East," on account of the beauty of its building, and its immense trade, is a sea-port town on the north coast of the island of Java, situated very near the sea, on a fertile plain, bearing evident marks of having been left or thrown up by the sea, in the kingdom of Jaceatra, upon the river of that name, which, running through the middle of the town, divides it into two parts. To the north of the city is the sea-hore; behind it to the south, the land rises with a gentle, and scarcely perceptible, acclivity towards the mountains, which he 15 or 16 Dutch miles, or leagues, inland; one of which, as being very high, bears the name of the Blue mountain. This city was founded in 1619 by the governor-general, John Peterz Koen, who captured and destroyed the town of Jaceatra, near the spot where the former town was situated; and he gave it the name of Batavia, though it is said he much wished to have called it "New Horn,* from the place of his nativity, "Horn," in North Holland. Although it was then an inconvenient place, with regard both to strength and beauty, he declared it the capital of the Dutch settlements in Indies; and his choice of the situation was so just, and his plan so well contrived, that it rose with unparalleled rapidity to that degree of magnificence and importance which has rendered it both the admiration and terror of all the more eastern nations of India. It still retains a very considerable rank and influence; although, for the last 50 years, it has much declined both as to opulence and population. The form of the city is an oblong square, 4 of a mile long, and 3 1/2 a mile broad, intersected by the river already mentioned, which runs from north to south, and is crossed by three bridges. The breadth of the river, within the city, is about 180 or 180 feet; and palling the castle and admiralty wharf, it discharges itself into the sea. On both sides of its mouth are long piers of wood and brickwork; about 3,800 feet long, taken from the moat of the city: between which, on the west side, the vessels belonging to the free merchants are laid up and repaired; but along the east side, the passage lies open for the lighters, which go in and out of the city with the cargoes of the ships. Opposite to the outward point of the easter pier is a hornwork, commonly called the "Water-fort," constructed of a kind of coral rock, and having, mounted or dismounted, fourteen guns, and two howitzers. It consists of a parapet, retained by a wall; but the parapet has been much neglected, and the wall is nearly destroyed by the constant working of the sea. This fort is protected on the land side by a moat, and on the sea side, by extensive flats, over which even boats cannot pass. The only good approach is that by the channel, which it feas and defends. On the west shore, about a quarter of a mile from the water-fort, is a battery, mounting seven guns, bearing down the river; and opposite to this is a battery of two guns, facing the river, and two to the castle. Each division of the city on either side of the river has two canals, running parallel with the longest sides, and intersected at right angles by cross-canals. These canals join the great canal, or river, at the distance of half a mile from the entrance; and below their junction is laid a boom of wood, armed with iron spikes. The city is encompassed by a wall of coral rock, serving as facing to the rampart behind it; and also by a moat, having several sluices, into which water is conveyed from the river. Sir George Staunton says, that a part of the town-wall is built of lava, which is of a dark blue colour, and of a very hard dense texture, emitting a metallic sound, and very much resembling some of the lava of Vesuvius. It is brought from the mountains in the centre of Java, where a crater is still smoking. The rampart is defended by twenty or twenty-one bastions, which, as well as the wall, are in a ruinous state. Small projections, of various forms, are constructed at intervals of about 350 feet, each of which generally mounted three guns. At short distances from the town, three or four small fort-berths of earth are erected in particular places, probably for defense against the inhabitants of the island. The castle on the island of Batavia, which was formerly on the sea-side, is now, by the continual increase of the mud banks before it, distant from the sea more than 100 roods, and is seated on the east bank of the river. It covers about 200 roods of ground, and is a regular square fortress, built of coral-rock brought from some of the adjacent islands, composed of that material. It has neither ravelins nor outworks. Two guns are mounted on each flank, and two, or sometimes three, on each face: neither "en barbette" nor "en embrasure," but in a situation between both, having the disadvantages of both without the advantages of either. The wall is of masonry, about 24 feet high. It has no ditch, but a canal accompanies it at some distance. It has no cordon; and the length of the exterior side of the work is about 700 feet. Between the moat and the buildings within the fort, on the south side, is a large area or esplanade. In the centre of the buildings that look towards the city, is a great gate, and then a broad piazza, with warehouses on each side, leading to another esplanade, on the north side, enclosed between the ramparts and the buildings, which are appropriated to the use of the company. The government-house, which forms the left wing of the buildings looking to the south, is provided with numerous and convenient apartments, but uninhabited. In it is a large hall, in which the council of India generally assemble twice a week. Near this is a little church or chapel, called the cathedral church; and at a small distance is a corps-de-garde, where a party of dragoons always mount guard. Over the castle-bridge is a spacious plain or square, planted with tamarind trees, which afford an agreeable shades; and the entrance into it from the city is over a bridge and through a large fluted gate, mounted with a lofty cupola, from which arises an octagonal turret with a large clock, the only public one at Batavia. On the left side of the gate is a large building, serving as a corps-de-garde, having in front a long gallery, resting upon a row of pillars; which is usually posted a captain's guard of grenadiers. On the west side of the square stands the company's artillery-house, and the dispensary or provision-magazine, both of which extend to the side of the river, so that the goods are taken in and out of the lighters with the greatest ease. On the opposite side is the iron-magazine, and the guns-plat or place of execution, which is an artificial square eminence, upon which are a gallow and some poils; and behind it is a small building, with windows, opening towards the place of execution, where the councillors of justice may behold the completion of their sentences. Upon the plain are arranged pieces of iron and brass artillery, and other ordnance implements.

Batavia has five gates; and near to that on the north side, to the west of the river, is the admiralty wharf; and near this, the warehouses for naval stores, and the workshops of the carpenters, cooperers, tail-makrs, and smiths, with other offices and houses that relate to the shipping. In the south-east corner of the city, close to the ramparts, lies the workmen's quarter;
quarter, called "Ambagi6 wartier," in which all the workmen and labourers employed by the company reside. Besides a great number of Europeans, there are more than a thousand slaves who belong to this quarter.

Besides the public buildings already mentioned, Batavia has a town-hall, which is well situated; in two large and convenient hospitals, and several churches; three of which, within the city, are appropriated to the reformed religion, in which service is performed in the Dutch, Portuguese, and Malay languages; and one without the gates, called the outer Portuguese church. There is also a Lutheran church not far from the castle, provided with a fine organ and a very handsome pulpit. These churches are supplied every Sunday by twelve clergymen of the reformed religion, and three Lutheran ministers. One of these clergymen is deputed, once every year, or sometimes only once in two years, upon a visitation to the company's possessions on the west coast of Sumatra; and to the individuals thus employed, the visitation is rendered lucrative by the merchandise which they take with them for sale. The Chinefe have also several temples, which are tolerated by government; but the exercise of the Roman Catholic religion is obliquely prohibited.

In the districts round Batavia, immediately subj ect to the Dutch, it is calculated, says Sir George Staunton, that near 50,000 Javane family families are settled, containing upon an average fix persons to a family, or 300,000 persons in the whole. The city of Batavia, including the suburbs, contains near 8,000 houses. Valentyn (cited in the Mod. Un. Hist.) states the number of houses in the city and suburbs at 47,792. Huylers, a more recent Dutch writer, who was long resident at Batavia, and who published his account in 1778, enumerates the number of houses in Batavia at 3,500: but he does not say whether he included the suburbs. The number and description of inhabitants in 1778, according to this writer, were as follows: viz. 468 Europeanburghers, 5582 native Christians, 4,873 Mardykers or manumitted slaves of all nations, 23,509 Chinefe, 289 Amboyne, 278 Banda-me, 966 Moors, 254 Gentoo, 1,852 Malays, 224 Bat-tammers, 1,983 Mazaciers, 3,707 Bougain, 204 Timorese, 189 Mandarines, 85 Sumbawere, 13,073 Balers, 33,408 Javans, and 20,072 flaves; making in all 119,816, exclusively of women and children, and of the company's servants. The company's establishment consisted, in 1776—1777, of 613 persons in civil, and 33 in ecclesiastical employments; 99 surgeons and assistants, 125 belonging to the artillery, 875 seamen and marines, 1,571 soldiers, and 963 mechanics; in all, 4,221 Europeans, besides 703 natives in their service. The houses at Batavia, belonging to the Dutch, are well built, chiefly of brick, clean and spacious, and their construction is, for the most part, well adapted to the climate. The doors and windows are wide and lofty; the ground-floors are covered with flaxed marble, which being sprinkled frequently with water, gives a pleasant coolness to the apartment; but when Sir George Staunton visited the place, a considerable proportion of the houses was untenanted; a circumstance which indicated a declining settlement. The houses of the Chinefe are low, and crammed with people. Most of them dwell in the southern and western suburbs, which are called the Chinefe "Campon." Before the revolt of the year 1740, they had the belt quarter of the city allotted them, to the west of the great river; but when in that commotion all their houses were burnt to the ground, the whole quarter was converted into a "paffar," or market, where at present all kinds of provisions are daily exposed to sale. Before the perpetration of this mischief, several thou-

land Chinefe adventurers returned to Batavia, allured by the prosperity of their countrymen already settled there. The number of these colonists, together with the robberies and murders committed by them, excited a considerable degree of apprehension; which induced Van Imhoff, who was at that time a member of the council, to propose, that those who could not prove that they were gaining an honest livelihood, should be seized and transported to Ceylon, and there employed in mining and other labour for the service of the company. The execution of this order produced a tumult and an insurrection; and thousands of the Chinefe retired from the city, and collecting a strong force, ravaged the country and assaulted the capital. The civil and military inhabitants united in repelling them. But a fire taking place soon after among the Chinefe buildings in the city, several of the owners were accused of opposing with arms the extinguishment of it, with a view, as it was said, of allowing the conflagration to spread through the whole town, that in the moment of confusion they might affallinate the Europeans, and become masters of the place. The alarm was such, that the Dutch government gave instant orders to put all the Chinefe heads of families to death; and the sailors from the vessels in the road were brought ashore, and induced, for the fake of plunder, to share in executing the bloody edict. All the Chinefe, without distinction, men, women, and children, were put to the sword; and the innocent and guilty were indiscriminately exterminated. Whence this barbarous order issued has been a subject of unsatisfactory investigation. The governor-general Valkenier, and his brother-in-law Helvetius, were accused by the public voice of directing the massacre; but their guilt was never proved. The deed itself was condemned by the directors of the company in Holland; and much apprehension being entertained that the fact would excite the indignation of the emperor of China, deputes were sent to him in the following year, to apologize for the measure on account of the necessity of the case. These deputies were accordingly surprized to find that the emperor calmly answered, that "he was little solicitous for the fate of unworthy subjects, who, in the pursuit of lucre, had quitte6 the country, and abandoned the tombs of their ancestors." The Chinefe, however, are said to be now as numerous as ever in and about Batavia; and it is acknowledged by the Dutch, that the settlement could scarcely flourish without their industry and ingenuity. The quarter of the suburbs which they occupy is crowded with shops containing all kinds of goods; those of their own manufacture, and such as they receive annually from China, or purchase from the European importations. The number of Chinefe, who live both within and without the walls of the city, cannot be precisely determined; but it must be very considerable, as the company receives a poll-tax from them of more than 40,000 rix-dollars. Every Chinefe who has a profession is obliged to pay a monthly poll-tax of half a ducatoon, or 5 rix-dollars; but women, children, and those who have no trade, are exempted from this tax. They are under a chief of their own nation, called the Chinefe captain, who lives within the walls, and has under him six lieutenants in different districts. A flag is hoisted at his door on the first or second day in every month, and the Chinefe that are liable to the tax are then obliged to repair to him for the payment of it. Each house in Batavia pays annually an assessment of half a month's rent, which is expended in dragging and cleansing the canals, and in repairing the town-hall and other buildings belonging to the city. The churches are repaired out of the duties levied upon funerals. At Batavia a bank of circulation has been established for some
....
is laid before the corpse, and wax figures of servants placed on each side as attendants upon it. The Chinese visit the graves of their ancestors from time to time, lighting them with odorous flowers; and when they depart, they leave a few small pieces of silk or linen before the entrance, and sometimes boiled rice or other viands, which are speedily made away with at night.

The mode of living practised by the Europeans, either from Holland or any other nation, that reside at Batavia, is very nearly the same. In the morning at five o'clock, or when the day breaks; they rise; and the table is spread at an early hour. Beside tea, coffee, and chocolate, fish and flesh are served for breakfast; and when this is finished, Madeira, claret, gin, Dutch small beer, and English porter, are laid out in the portico before the door of the great hall, and pipes and tobacco are presented to every guest, with a bright brass jar for a smoking-dish. Those who have business appear at their proper stations at eight o'clock, and remain employed till between the hours of eleven and twelve. Their dinner hour is one o'clock; but immediately before dinner, two men slaves go round with Madeira wine, of which each takes a large glass. Then follow three female slaves, one with a silver jar, containing plain or rose water for washing; a second with a silver basin and low cover of the same metal, pierced with holes, to receive the water after it has been used; and the third with towels for wiping the hands. During dinner, a band of music plays at a little distance. The musicians are all slaves who have been instructed for this purpose. A considerable number of female slaves attend at table, which is covered with many dishes. Dinner is immediately followed by coffee. After drinking coffee, each person retires to a bed, confining of a mattress, bolster, pillow, and chintz counterpane, but no sheets; and puts on his night-dress, a muffin cap, and loose long cotton gown. A bachelor is attended by a female slave, who fans him while he sleeps. About six they rise, dress, drink tea, take an airing in their carriages, and form parties for the evening. The morning meetings are composed generally of men, as the ladies seldom choose to appear till evening.

"Married men," says Stavrovius, "seldom give themselves much concern about their wives, nor shew them much regard. They seldom converse with them, at least on useful subjects, and such as concern society, with which of course they are little acquainted. Few of these ladies are natives of Europe, but many are descended from Dutch settlers here; and they are educated with some care. The features and outlines of their faces are European; but the corneal lions, champlevs, and mode of life, approach more to those of the native inhabitants of Java. A pale languor overpowers the conversation. In their own houses, they dress like their slaves, with a long red chequered cotton gown descending to the ankles, with large wide sleeves. They wear no head-dress, but plait their hair, and fasten it with a silver bodkin on the top of the head. The colour of their hair is almost universally black; they anoint it with the oil of the coccanut, and adorn it with chaplets of flowers. When they go abroad, and particularly to their evening parties, they dress magnificently in gold and silver spangled muffin robes, with a profusion of jewels in their hair, which is worn without powder. They never attempt to mould or regulate their shape by any foreign idea of elegance, or any standard of fashion; and, therefore, exhibit a striking contrast to the Dutch ladies. Every native lady is constantly attended by a female slave, who sits at the feet of her mistress on the floor, holding her gold or silver box, the compartments of which contain aracea-nut, cardamum seeds, pepper, tobacco, and flaked lime; all which, mixed together in due proportions, and rolled within a leaf of betel, constitute a masticatory of a pungent taste, that is in general use. In public assemblies, when the ladies are accommodated with heat, they retire to change their dresses, and return, without ceremony, in a more light and loofe attire. Their example is followed by the gentlemen, who appear in white jackets, sometimes adorned with diamond buttons. The elderly gentlemen lay aside their wigs, and put on night-caps. The members of the government, except on public occasions, appear abroad in crimson velvets; their carriages being distinguished by peculiar ornaments; and they receive homage from others of the first rank. One of the gates of the city is opened only to let them pass. The Indian women marry young, generally at twelve or thirteen years of age; they have seldom many children, and they are old women at thirty. They are remarkably fond of bathing and ablutions; and use for this purpose a large tub containing three hogsheads of water, in which they immerse the whole body at least twice a week; and some do this in the morning, in some of the running streams out of the city. They manifest a most excessive jealousy both of their husbands and of their female slaves: and when they discover the slightest familiarity, punish the latter with a variety of tortures; and of the former they avenger themselves in kind. The coaches used at Batavia are small and light, and for keeping these a yearly tax is paid to the company. Services of a domestic or menial kind are chiefly performed at Batavia by slaves. Three thousand of both sexes are annually brought hither from the coast of Malabar, Bengal, Sumatra, and other parts; but in the greatest number from Celebes. Their treatment is in general mild and gentle, though some instances of barbarity and inhumanity occur. They are not forced to excessive labour, and they are allowed sufficient sustenance. However, many of the males, who had formerly, perhaps, led an independent life before they were made captives in war, have taken offence against their masters upon flight occasions, and wreaked their vengeance by affantonishment. To the apprehension of such an event is ascribed the preference given at Batavia to female slaves, for every use to which they can be applied; and therefore the number of those that is purchased far exceeds that of the other sex. The slaves that are determined on revenge, often swallow, for the purpose of acquiring artificial courage, an extraordinary dose of opium, and soon becoming frantic as well as desperate, they not only stab the objects of their hatred, but fallly forth to attack in like manner every person they meet, till self-prevention renders it necessary to destroy them. They are said in that latt to be 'running a muck.' So called because, during their frenzy, they continually cry out, "amok! amok!" which signifies "kill! kill!" and their fury has been erroneously ascribed to opium, whereas in reality it is the effect of unruly passion. Instances of it are not more common among slaves than among free natives of the country, who in the anguish for losing their money, effects, and sometimes their families, at gaming, to which they are violently addicted, or under the urgency of some other passion or misfortune, have recourse to the same remedy, with the same fatal effects. A fondness for play, and also for opium, is not uncommon among the Chinese also at Batavia; but by habits of restraint and moderation, they are prevented from falling into the same frantic excesses. The Chinese at Batavia are accustomed to keep gaming-houses, which are the means of seduction and ruin to the greatest part of the slaves in the city; and these parts of society are under the protection of the municipal government, the officers of which pay to the company, as a consideration for the profits accruing from them, a monthly contribution.
contribution of 3,100 six-dollars, or upwards of 8,000l. acre per annum.

The chief government of Batavia, and of all the possessions of the Dutch East India company in Asia, is vested in the council of India, at the head of which is the governor-general, who resides at a superb mansion near Batavia, possessing unbounded power, affuming a flute, and exacting tokens of respect, much greater than any European monarch. The next in rank is the director-general, who is the elder councillor of India; and to him are entrusted the direction and control of the trade of the company throughout all India, and to Europe. Next in order follow the five ordinary and two extraordinary councillors of India. To the servants of the company justice is administered by an assis-by called the council of justice, independent of the council of India; and consisting of a president, eight ordinary members, and two adjutors, taken from the company's servants. The citizens and free merchants of India, who are not in the company's service, are amenable to a separate municipal court of justice, called the board of scheepers or aldermen, eight in number, with a president who is a member of the council of India. The punishments inflicted at Batavia are exceedingly severe, especially such as are inflicted upon the Indians; of these, the chief, and the most terrible, is impeachment. For taking alive those slaves who are guilty of the act of murder called "mucks," the officers of justice are provided with a pole ten or twelve feet in length, at the end of which is a kind of fork, made of two pieces of wood three feet long, which are furnished within with sharp iron spikes; this is held before the object whom they wish to apprehend, and in his frenzy he runs into it, and is thus taken. If he happen to be mortally wounded, he is immediately broken alive upon the wheel, without any form of trial, in the presence of two or three of the councillors of justice.

The orphan-chamber at Batavia serves for the whole of the Dutch possessions in India; and the board consists of a president, who is a councillor of India, and fix regents, who are appointed by the council of India, with subordinate clerks. There are several other courts or boards; as the commissioners of dyers and drapers, those of bankruptcies, a court of common pleas, a board of control over marriages, and several others.

The establishment of regular troops at Batavia, according to the report of captain Parth, cited by sir George Staunton, consists of 1,200 Europeans, of whom 300 are artillery, and the rest infantry. But as this number cannot be maintained complete in this unhealthy climate, 500 natives were employed, and thus the establishment of European regulars was reduced to 700. Three hundred volunteers of the town are also formed into two companies, but not disciplined. The irregulars are very numerous, consisting of enrolled natives of Java, who have never been embayed, and of Chinese, whom the jealousy of the Dutch allows to be armed only with lances. This establishment appears too small for any effectual resistance. Although every man whosettles at Batavia must take up arms in its defence, it is acknowledged by one of the councillors of the Indies, that their chief dependence was on the havock which the climate was likely to make amongst the enemy's forces. The chief protection to their ill-named well-lying in this port, is afforded by the fortified island of Onrust, which is well situated to command the channel that forms the principal passage into the road.

The climate of Batavia is singularly unhealthy, and has proved the occasion of diphtheria and of death to many of the Dutch settlers, and other Europeans who have transiently visited this place. The city is situated in the midst of swamps and stagnated pools, whence proceeds every morning a collection of pestilential vapours, whenever the sea-breezes sets in and blows over its morasses. The meridian sun raises from the shallow and muddy canals which intersect the town, deluging them into the air; and the trees, with which the quays and streets are crowded, impede the course of the air, by which the putrid effluvia would in some degree be diffipated. Besides the noxious circumstances of a local kind peculiar to this place, the sudden transition from a cold northern region to the middle of the torrid zone, without the adoption of those habits that are requisite in the latter, must render the human frame more liable to be affected by any causes of disease. Hence it happens that preventive medicines are taken almost as regularly as food, and everybody expects the return of sickness, as we do the feasons of the year. There are few examples of strangers who remain long in Batavia without being attacked by fever, which is the general denomination in that place for every kind of illness. The disorder at first is commonly a tertian ague, which after two or three paroxysms becomes a double tertian, and then a continued remittance that frequently carries off the patient in a short time. The Penman bark is seldom prescribed in any stage of the disease, or it is given in such small quantities as to be producute of little benefit. The chief, or rather the sole medicine administered, is a solution of camphor in spirit of wine. It is supposed, that of the Europeans of all classes who come to live in Batavia, not always half the number survive the year. The place resembles in that respect a field of battle, or a town besieged. The frequency of deaths render familiar the mention of them; and little signs of emotion or surprize are manifested, on hearing that the companion of yesterday is today no more. When an acquaintance is laid to be dead, the common reflection is, "Well, he owed me nothing!" or, "I must get my money of hisexecutor." It appears by a calculation, that the company lost, in general, every year, full one-fifth of their servants. It is observed, however, that this climate is not so fatal to the female Europeans as to the other sex. They seldom expost themselves to the heat of the sun, make frequent use of the cold bath, and live more temperately than the men; and, for these reasons, they may suffer less from the infalubrity of the climate. In the lower town, on the north side, the mortality is greater, where uninhabited houses contract a foul and infections air, than in the other parts of the city that are more fully inhabited. On this account, people do not only leave the lower town, but abandon the city altogether, and reside in gardens without the walls, and at as remote a distance as their employments will allow. This kind of migration increases from year to year, and will probably, in the lapse of time, produce the total abandonment and ruin of Batavia. The most tolerable season here is from March or April to November, when the rains begin, which last the rest of the year. The sea-breeze sets in about ten o'clock in the morning, and continues till four or five in the afternoon; it becomes then calms till seven or eight, when the land-breeze commences, and continues at intervals till day-break, followed by a calm for the remaining hours of the twenty-four. The heat of the weather at Batavia is not so excessive as in some other parts of the east. From July to November, Stavovius observed, that his thermometer, which hung in the shade in the open air, stood generally between 84 and 90 degrees of Fahrenheit's scale, in the hottest part of the day; once indeed the mercury rose to 92°; in the morning, it seldom fell lower than 75°. The barometer fearlessly ever varies from the mean height. Sir George Staunton, who
who arrived at Batavia in March, informs us, that in the road, Fahrenheit’s thermometer, during his continuance, was from 85 to 88 degrees; and in the town, from 88 to 92 degrees; but that its variations by no means corresponded to the variations produced by the heat on the human frame; the latter being tempered by any motion of the air, which circumstance has little effect upon the thermometer. In the night, the thermometer, instead of rising as it does in colder countries, sometimes 20°, keeps generally within 4 or 5 of what it attains in the shade when the sun is at its highest elevation. The unhealthy air of the place, as Stavorinus justly observes, is owing not so much to the heat, as to the morasses by which the city is surrounded, and particularly to the mud which the sea throws up, and which it leaves, at low water, exposed to the sun. With care and attention on the part of the government, it is reasonable to suppose, that this evil might be greatly diminished, if not wholly removed. The general apprehension of the unhealthy air of Batavia for Europeans, deter the majority of those who can reside at home with any comfort, from seeking a settlement there, notwithstanding the temptation of fortunes to be quickly amassed in this place. From this circumstance it happens, that offices and professions are often unnecessarily entrusted with persons little qualified for occupying them. One of the clergymen, and the principal physician of the place, are said to have originated the disease. The United Provinces furnish very few military recruits; the rest are chiefly Germans, many of whom are said to have been kidnapped into the service.

All goods which are carried into or out of Batavia, are subject to duties which are levied at the bar at the entrance of the city. These, as well as the other taxes and imposts, are annually farmed out, generally to Chinese. The whole of them amount together, upon an average, to 32,000 rix-dollars per month, or about 83,800l. sterling per annum. The important revenues arising from these imports and export duties, &c. and the valuable productions which the country round it affords, the principal of which are pepper, rice, sugar, cotton, and indigo, might lead us to suppose, that Batavia, or rather the colony of Java, for that is the account in the books of the company, to which all that relates to Batavia is carried, would be adequate to its own support; yet this is far from being the case. Batavia is the metropolis of the Dutch East India possessions; it is the seat of their government; a large garrison is constantly maintained in it; most of the company’s ships touch here, both outward and homeward bound; their cargoes are landed and shipped; all recruits are received, maintained, and paid here; in short, almost all the charges of the marine and military establishment of the company are carried to the account of Batavia, and of course a considerable balance appears every year against it. Formerly there used to be a considerable surplus after defraying all these charges; but in the year 1779, the charges exceeded the receipts by about 51,327l.

The coins current at Batavia are the following: viz., the milled Dutch gold ducat, the Japan gold coinage, the Spanish dollar or piastra, the milled silver ducat and (which is the current coin of the company throughout their possessions, except on the Continent of India), the unlinked ducat, the milled Batavia rupee, other rupees, half and quarter rupees. The smaller coins are skillings, two-penny pieces, and doits. Of the skillings there are two sorts: the old, worth 66p. and the new, worth 7s. The old two-penny pieces pay 2p. for 2p. the new, for 4s. the doits are flamped with the mark of the East India company, and are equal to a farthing in value.

Vol. III.
of government. Towards the close of the year 1794, and
the commencement of the following year, the French forces,
favoured by the frost of winter, by the discontents that
prevailed in the provinces, and the ineffectual support afforded
to the Dutch by the British troops, took possession of their
principal towns; and on the 27th of January 1795, the
provisional representatives of the people of Holland assembled,
and chose Pierre Paulus for their president. On this occasion,
several decrees were immediately passed for the future
regulation of the government, and for the deposition of the
fladholder from all his offices. Among these decrees were
the following: viz.: the sovereignty of the Dutch people,
and the declaration of the rights of man—the abolition of
the fladholdership; as also of the offices of admiral and cap-
tain-general of the United Provinces, with all their appen-
dages;—the release of the citizens and inhabitants of Hol-
land from their oaths to the old constitution:—the suppre-
sion of the college of the deputy council, and that of the
chamber of accounts; and the establishment in their room
of a committee of public safety, a committee of military af-
fairs, and a committee of finance:—and the recall of the
commission of the deputies to the assembly calling itself the
flates-general. It was also decreed, that the commissioners
of the assembly of the provisional representation of Holland
should immediately begin their sittings in the hall of the
present flates-general, in order to advance the general in-
terests of the people. A treaty of peace and alliance was
concluded between the French and Batavian republics, at
the Hague, May 16, 1795; in which the French stipu-
lated to restore immediately all the conquered places and
countries that belonged to the seven United Provinces; the
frontier towns of the generality, such as Maastricht, Venlo,
Dreda, Bergen-op-Zoom, with their territories, excepted.
It was also stipulated that the French, as well as the Bata-
vians, should enjoy, without paying any tolls, the free navi-
gation of the Scheldt, the Rhen, and the Meuse, and all
their branches as far as the sea; that the Batavians should
pay to the French the expences of the war which the latter
had been compelled to make against the former; that the
French republic acknowledged the independence and sove-
reignty of the Batavians; that an alliance offensive and de-
defensive should be established between both republics; and
that neither the French nor Batavians should conclude
peace, or make any other treaty, in which both parties did
not participate.

In 1796, the national convention of the Batavian republic
made some considerable alterations in matters relating to
religion. It was determined, that all the inhabitants of the
republic were free to exercise without molestation any mode
of public worship whatever to which their opinions might
lead them; that there should be no established religion in
the republic; that the use of bells in convoking persons to
public worship, should be prohibited; and that Jews should
be allowed to become citizens of the republic, and empower-
ed to purchase lands in the same manner as other citizens.
On the 11th of January 1797, the new plan of the con-
stitution was discussed; and it was decreed, that the Bata-
vian people are one and indivisible; that the sovereignty
appertains to the whole Batavian people; and that the Bata-
vian people shall elect representatives to exercise its sove-
reignty. It was also resolved, that all citizens born and re-
sident in the republic, and twenty-one years of age, should
be involved with the right of voting; and also strangers,
after having resided within the republic six years successively.
It was also resolved, that the republic should be divided into
eleven departments. Towards the close of the year 1797,
the French directory issued their mandate for a revolution.

The execution of this mandate was intrusted with Charles
Le Croix, and the plan of operations for accomplishing it
was connected with the Dutch general Daendels, who was
an original moved, and principal agent in the revolution.
Accordingly it was effected on the 22d of January 1798.
This revolution gave birth to a new form of government in
the Batavian republic, which was introduced and established
by acts of violence. An assembly formed by revolutionary
depotism and military force, and assuming the name of the
constituent assembly of the Batavian people, abolished those
provincial divisions, and other administartions, that had been
established under the constitution; which was a constitution
grounded on principles deemed more popular than those
which formed the basis of this, which was about to be pre-
lected when this revolution took place, and against which a
formal protest had been previously made by forty mem-
bers of the constitution, when it was offered to the pri-
mary assemblies for their consideration. The people,
weared with continual agitations, and indeed incapable of
effectual resistance, accepted this project formed on the
model of the French constitution, as the best remedy
against further convolutions; and thus Holland sunk for a
while into the state of a dependent province, under the pro-
tection of Le Croix, the revolutionary delegate of the
French directory. The principal articles that constituted
the basis of this new government are the following: viz.
—The abolition of the division into provinces:—Separation
of church and state:—No corporation or society to have
rules contrary to the laws of the state:—Exclusion from
the right of voting of all the adherents of the Orange fa-
family:—The formation of a democratic representative go-
vernment by means of a legislative body composed of two
councils, and a provisional executive directory consisting
of five members, having under it the agents of the executive
power:—The formation of a new plan of finance, founded
upon the relative means of the citizens:—The commissi-
iners of the treasury are to be appointed by the executive
power:—Those of the chamber of accounts by the legisla-
tive assembly:—The territory of the republic to be divided
into a suitable number of departments; and accordingly,
the nine provinces were divided into eight departments, the
extent of which was measured by the population and the
limits formed by the great rivers; these departments were
again divided, each into ten circles; and each department
was previded to contain 235,000 inhabitants; and the gen-
ger population of the republic was estimated at a million
eight hundred and ninety-two thousand individuals:—A
distinct division of three powers, the legislative, the execu-
tive, and the judiciary:—The right of individual petition to
the citizens:—Revision of the constitution after the expira-
tion of the fifth year:—The oath of hatred to the go-
vernment of the fladholder, federalism, arithocracy, and
anarchy, to be taken by all the persons employed by the
republic:—No power to have the right of interfering with
the banks of circulation in the different towns of the repub-
lic:—Institutions for public instruction in arts and sciences:
—And alliance with the French republic.

In the year 1801, a new constitution for the government of
the Batavian republic, consisting of 168 articles, was in-
introduced. This constitution abolishes the executive direc-
tory, and substitutes a state directory, consisting of twelve
persons, one of whom goes out annually. The legislative
body is to consist of 35 members. The territory of the re-
public is to be divided into eight departments, whose bound-
daries are to be the same with those of the old provinces.
The allowance of the members of the legislative body is to
be 4000 florins. They are to meet twice in the year, and,
to fit from the 15th of April to the 18th of June. And from the 15th of October to the 15th of December. The government has the power of convoking them at pleasure. For further particulars, see Holland, and United Provinces. By the treaty of peace concluded at Amiens, March 27, 1802, the Batavian republic ceded and guarantees to his Britannic majesty, in full property and sovereignty, all the posessions and establishments in the island of Ceylon, which before the war belonged to the republic of the United Provinces, or to the Dutch East India company.

**BATAVIENSIS, in Entomology, a species of Cryptocephalus; the head, thorax, wing-cases, and legs of which are livid. Hornt. Sch. Berl. Natur. Inhabits Java.**

**BATAVODURUM, in Ancient Geography, a town of the Batavi, in the island called after their name. According to Tacitus, the Romans had a bridge in this place, and the poft was defended by a Roman legion, when the Germans, who retired to the succour of the Ceesalis, were defirous of penetrating into the island; and here they were repelled after great slaughter, and at length obliged to throw themselves precipitately into the river. Some have supposed that this town was the same with the modern Duersfede; but others conjecture that it was not on the same side of the river.**

**BATAVORUM INSULA, the island of the Batavi, was formed by the Vahalis or Wael to the south, and a branch of the Rhine to the north. This fall branch, and also the Vahalis, rejoin afterwards, and form the Moa or Meuffe. According to Tacitus, the Rhine was divided at its entrance into Batavia into two rivers: one of which retained its name, and purified its course through Germany, till it discharged itself into the ocean; the other, washing the coast of Gaul, with a broader and more gentle stream, was called Vahalis, which on its joining the Moa, assumed its name. From this account it seems that the island of the Batavians was bounded by the Ocean, the Rhine, and the Vahalis. Caesar extends it to the Moa; but Pliny's account coincides with that of Tacitus. It appears, however, that this island was of greater extent in the time of Tacitus than in that of Caesar; as Drusus, the father of Germanicus, had by a new canal conveyed the waters of the Rhine into the ocean at a considerable distance to the north of the former mouth of that river. It is not certainly known who were the first inhabitants of this island. Some historians say, that they had been removed by the Cimbri and Teutones, when they invaded the Roman territories; and it is not improbable that the prospect of a more commodious establishment might induce them to abandon a country which was, constantly exposed to the inundations of the water that accompanied it. The Batavi, when driven from their own country by the Catti, took possession of it, and became a very powerful people. A part of this country still bears the name of Betou, formed from Batavi; and is probably the same with the ancient "Infula Batavorum." This name, however, is given only to the eastern part of the island, and is the same with that which has the river Leck to the north, and Vahal to the south, to the north of Nimfegen.**

**BATAVORUM Oppidum, Batatungor, a town which seems to have been the Batavodurum of Tolemy, but different from that of Tacitus. Tolemy places it upon the Moa, or Meuffe; and the Batavodurum of Tacitus was more to the north upon the Rhine.**

**BATBERGEN, in Geography, a town of Germany, in the circle of Westphalia, and bishopric of Osnaburg.**

**BATCHJOWE, a town of Afa, in Armenia, 90 miles to the North of Erivan.**

**BATCHLOR. See Bachelor.**

**Batchelor's Buttons, in Botany. See Lychnis.**

**Batchelor's Pear. See Solanum.**

**Batchelor's River. in Geography. See Bachelors.**

**BATCHURISKOI, a town of Ruffia, in the government of Archangel, on the east coast of the White Sea; 8 miles north of Archangel.**

**BATCOLE, or Batkuil, a sea-port on the coast of Malabar, in the peninsula of India, situate between Onore and Barcelo. The English had a factory here till 1670, when they were massacred by the natives. It was ceded to the British by the treaty of 1799. N.lat. 13° 58'. E.long. 74° 37'.**

**BATE, George, in Biography, born at Maid's Merton, in Buckinghamshire, in 1628, was sent to Oxford at the age of 14 years, where he soon distingjuished himself by his diligence and application to study; and having made choice of medicine for his profession, he was admitted to practice as soon as he had taken his degree of bachelor in that line. In 1637 he was made doctor in medicine; and when Charles the First kept his court at Oxford, he was appointed his physician. Removing soon after to London, he was elected fellow of the college of physicians, and physician to the Charter-house; and conforming to the circumstances of the times, he soon obtained such favour with the reigning party in the state, that he was sent to Scotland, in 1651, in conjunction with Dr. Wright, to attend Oliver Cromwell, then confined there with an intermitting fever, and was appointed his first physician. This, however, did not prevent his being made physician to king Charles II. on his accession to the throne, and being elected fellow of the newly constituted Royal Society. These honours were procured him, Anthony Wood says, by a report industriously circulated by his friends, that he had hastened the death of the protector, by administering a deleterious medicine; a story, which, if believed, whatever reward it might otherwise have procured him, would never have placed him in a confidential post about the person of the sovereign. He died in 1668, and was buried in the chancel of All Saints church, at King's-Heath upon Thames, where a monument is erected to the memory of him and his wife, who died the year before. The only material work in which he engaged, was in contributing a part towards a treatise "De Rachitide," published by Dr. Glisson in 1650. His prescriptions, collected by Shipton, an apothecary in London, were published some years after his death, under the title of "Pharmacopoeia Batana," and have passed through many editions. He published, in 1649, "Elencus motuum nuperorum in Anglia, simul ac juris regii et parliamentarii, brevis narratio," 12mo. Paris. A second part of this work was printed at London, in 1661. In composing this, he was assisted by papers furnished by the chancellor Hyde. A third part appeared in 1676, written by Dr. Skinner. He is also said to be the author of the "Royal Apology, &c." 1647. Biog. Brit.**

**Bate, in Ancient Geography, a village or canton of Greece, in Attica, belonging to the tribe of Aegides, where reposed Abro, the commentator of Callias, who wrote concerning feasts and sacrifices, and Amyromachus, to whom Epicurus bequeathed his property. Steph. Byz. Bate, or Bait, in Geography, one of the principal ports in a district of India, inhabited by a piratical tribe called Sangarians, on the south coast of the gulf of Cutch. The other part is Aramay.**

**BATEAH, a town of North America, in the province of Yucatan, 190 miles S.S.W. of Merida.**

**BATEAU, in Navigation, a particular kind of boat, very generally used upon the large rivers and lakes in Canada. Its bottom is perfectly flat, and each end very sharp. S. G. 25. and.**
and exactly similar. The sides are about four feet high; and for the convenience of the rowers, four or five benches are laid across, and sometimes more, according to the length of the bateau. It is a heavy and awkward vessel both for rowing and sailing; but it is preferred to a boat with a keel for two very obvious reasons: first, because it draws less water while it carries a larger burden; and secondly, because it draws much safer in lakes or wide rivers, where storms are frequent. An oil-cloth awning may be thrown over the widest part of it, and supported by hoops similar to those of a waggon; and thus may be formed a very excellent cabin, which shelter from the inclemency of the weather, and at the same time allows a view of the beauties of the scenery on each shore.

BATECUMBE, or Badecombe, William, in Biography, an eminent mathematician, suppos'd by Pits (De Hum. Angl. Script., tom. 14, p. 784.) to have flourished about the year 1420, in the reign of Henry V. He studied at Oxford, and made great proficiency in mathematics; which appears from his writings. It is not known where he died. He wrote "De Sphaera concavis fabrica et usus," "De Sphaera solida," "De Operatione Astrorabilii," and "Conclusions Sophizi." Biog. Brit.

BATELIER, in Ornithology, a name given by Sonini and others to Falco Ecaudatus of Latham, &c.

BATELLO, Str. in Geography, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, three miles north of Reggio.

BATEMAN Bay, lies on the fourth point of land Up- right, on the east coast of New Holland, in which are three or four small islands. The north point is in S. lat. 35° 35'.

Bateian's Drops, in Pharmacy, are the acodyne balsam made with a weaker spirit, so that a larger dose can be taken; they are tinted with aniseed.

BATTENBURG, or Batternburg, in Geography, a town of the duchy of Gueldres, seated on the north side of the Meuse, nearly opposite to Ravelin. N. lat. 50° 35'; E. long. 6° 35'.

Bateni, in Ancient Geography, a people of Asia, placed by Pliny and Solinus towards the Oanes and Baetia-
nis.

Batenites, a fict of apotaphes from Mahometanism, divided over several parts of the Earl, who professed the same abominable principles with the Infidels and Karmis-
tians. The word signifies Eforierics, or people of inward or hidden light or knowledge. Sale's Koran, p. 186.

Batenketos, in Aethrasy, a star about the third magnitude, in the constellation of Cetus.

Bates, William, in Biography, an eminent non-con-
formist divine, was born in 1625, and educated at Cam-
bridge, where he took his degree of B. A. in 1647. He afterwards became a celebrated preacher among the pree-
byterians in London. Upon the restoration, he was appointed chaplain to Charles II.; and received a degree of doctor in divinity, by royal mandate from Cambridge. He was one of the commissioners at the Savoy conference for reviewing the liturgy, and one of the disputants on the side of the prebendaries against Dr. Pearson and other episcopali-
s. He took the oath required of non-conformists by the five-
mile act, and was concerned in several unavailing efforts for effecting a comprehension of the dissenters by certain alterations and confessions. Moderate in his temper, and accom-
mplished as a scholar, he was a fit person to be employed for such purposes; and he was always treated with respect by the members of the establishment. He was also much re-
garded by king William, and queen Mary frequently perused his writings. Dr. Bates, towards the close of his life, re-
-sided at Hackney, where he died in 1699. His works, consisting chiefly of sermons and discourses, were collected after his death, and published in one volume folio. Besides his posthumous volume appeared in 16v, consisting of "Sermons on the everlasting Rest of the Saints." He likewise edited a volume of the lives of eminent person, written in Latin, and entitled, "Vita selectorum aliquid Vitorum, qui doctrina, dignitate, aut pietate nudderuus," Lond. 1681, 4to. The style of Dr. Bates has been commended for its elegance; and he appears to have read many books in polite literature, as well as in theology. Biog. Brit.

Bates, John, Esq. late commissioner of customs, was
born at Halifax, in Yorkshire, where he began his school education under the celebrated Dr. Ogden, with whom he remained till the doctor returned to reside at Cambridge. During this time he received the rudiments of music from Mr. Hartley, the organist of Rochdale. When Dr. Ogden quitted Halifax, Bates was removed to the school of Man-
chester, under Mr. Parnell; and it was there, as he has frequently told his friends, that the grand style of organ-
playing, in which he so eminently excelled, was suggested to him by the performance of old Wainwright on the or-
gan in the collegiate church. While he remained at Man-
chester, he had made such a proficiency in music as to be able frequently to officiate for his old master Hartley, when his avocations called him away from Rochdale.

Bates, on quitting that university, was removed to the
foundation at Eton; but there his progress in music received a considerable check, and was in danger of being totally flopped; for it was contrary to the rules of that society for any of the boys on the foundation to be permitted the use of musical instruments. In this state of musical priva-
tion Bates remained some months, and had no other means of practicing than by playing on imaginary keys on the table, which for a considerable time was his cullom every day. At length, having by chance had an opportunity of touching the college organ, his talents for music were re-
ported to Mr. George Graham, one of the assistant masters, who having a harpsichord, invited him to his rooms; and finding what an extraordinary performer he was, obtained permission for him to pursue his musical studies, accommo-
dated him with the use of his harpsichord, and procured him liberty to play on the college organ at his leisure hours.

When he went to Cambridge, the vacancies for King's college were so few, that he was in danger of being super-
annuated, and was actually entered at Chrift's college, where, while he was a member, two of the university schol-
archips became vacant, and he declared himself a candidate. It proved on this occasion a fortunate circumstance, that he had not gone off to King's; for as Dr. Heath and Mr. Keate, both of King's college, and his seniors, were candi-
dates, the custom of that college would not have permit-
ted a junior to become a candidate. But though he was now a member of Chrift's, that circumstance did not pre-
vent his being a candidate for a university fellowship; the examination for which is considered as the most severe of any classical examination in the university of Cambridge. Some of the most distinguished under-graduates were at this time candidates; and after an examination of several days, Zouch of Trinity, and Bates, were elected.

This success established his literary character in the uni-
versity as high as his musical had been before; and soon after, as the term of superannuation was expired, a va-
cancy happening at King's, he was admitted a scholar, and
in three years, fellow. The regularity of his conduct during his scholarship, recommended him so much toprovit Sumner, that he was appointed tutor to the college soon after his admission as fellow. While he was in this situation, among his private pupils he had not only students of his own college, but the present lord Bolton, and Mr. Coxe the traveller, both then scholars of King's, were his private pupils; as was the Hon. William Augustus Montagu of Trinity college, second son of the Earl of Sandwich. This produced a connexion with that nobleman, which ended in his lordship's tempting him to resign his fellowship, and reside with him at the admiralty in the capacity of private secretary.

Few dilettanti musicians have ever acquired or deferred more fame for their knowledge in music, judgment, and experience in its effects, and abilities in conducting a complete orchestra and numerous band of fingers, than Mr. Bates, who, at the university of Cambridge, distinguished himself as a fine performer on the harpsichord, as well as a zealous votary of the works of Handel; and as long as he resided at college, he performed the famous Coryphus at all public and private concerts. It may perhaps not be thought unworthy of notice here, that at this time (about the middle of the last century), the university of Cambridge was in possession of four very extraordinary dilettanti musicians: Dr. Smith, master of Trinity college, for the theory of sound; the Rev. Thomas Twining, an admirable performer and leader on the violin, and an excellent judge of every species of music; the late worthy and ingenious Mr. Lobb of Peterhouse, the most correct and certain sight's man on the harpsichord or organ with whose performance we have been acquainted; and Mr. Bates for his masterly performance on keyed instruments, and abilities in conducting a band. There being at this time no very able prof-foir in the university, these gentlemen regulated and performed at all public and private concerts during their residence in college.

No one flood higher in character, or was more courted in society, while at Cambridge, by performers of all ages than Mr. Bates; in particular by the late Dr. Smith, the master of Trinity college, with whom he spent most of his evenings, and who, at his death, left him a legacy.

Before he quitted the university, an organ was built for the church of his native place, Halifax; and determining that it should be opened with eclat, he, for the first time that any oratorio had been performed north of Trent, attempted the Messiah. With the assistance of the Rev. Mr. Allott, of Kirkheaton, who had trained up the country people in his parith to sing choruses in a very superior style, and with the addition of Bates's own exertions, with the fingers of Halifax, the choruses were performed with a precision that astonished every one; and it was universally acknowledged by the best judges, that the Messiah had never been so well performed. The first violin, on this occasion, was performed by the celebrated Dr. Herchel, the astronomer; and his profession being then music, he was immediately elected organist.

It was the succefs of this undertaking that inspired the late commissioner with the idea of reforming the compositions of old masters; and having them executed by a numerous and select band of vocal and instrumental performers; and after being settled in London as private secretary to Lord Sandwich, he had an opportunity of communicating his plan to persons of the first distinction, and the establishment of the Concert of Ancient Music in Tottenham street was the consequence, being formed and executed entirely under Mr. Bates's direction; and as many of the works of Handel, which had not been performed for many years, and never so well as at this establishment, were revived, the number of that truly great, and often sublime, composer's admirers was much increased.

His majesty, a constant and steady patron and protector of the works of Handel, soon after the establishment of this concert, graciously condescended to become a subscriber; and together with her majesty and the princesses, constantly to attend the several performances. The nobility and gentry, who were enrolled among the original subscribers to this respectable institution, have been likewise steady in their patronage and attendance. And it is now (1802), from the splendor and celebrity of its admirable performances, in higher public favour, than at any former period of its establishment.

After remaining some years with the Earl of Sandwich at the admiralty, Mr. Bates was appointed commissioner of the victualling office; and soon after, he married his celebrated pupil, Mrs Harrop, who had been educated under his eye from his first arrival in London; and whose erudite voice, and disposition for music, he so highly cultivated, as to render her one of the most enchanting fingers which this or perhaps any country ever produced.

The victualling office on Tower hill now became the repository of persons of the highest rank; and at his residence there, was planned that most stupendous musical performance, the Commemoration of Handel in Westminster abbey and the Pantheon, which was conducted by Mr. Bates in a manner never to be forgotten by those who had the happiness of being present. The great splendor and success of this Commemoration will unite the name of commissioner Bates with the renown of Handel, as long as such a memorable event shall remain in the records of the musical art. And the performance of Mrs. Bates, particularly in the pathetic songs of Handel, has rendered it to difficult for her successor at the concert of ancient music, to satisfy the old subscribers in such songs as the need to perform there, that something will always force want to complete their happiness.

Soon after the commemoration, Mr. Bates was promoted to a seat at the board of customs; but previous to his quitting the victualling-office, having officially experienced the difficulties which the capital of the kingdom often labours under for want of flour, he projected the plan of the Albion Mills; on the success of which he was so sanguine, that he vested his whole fortune, and even that of his wife, in the capital stock of that company, to the amount of 10,000l. By the conflagration which happened to this building, he was completely ruined. His whole fortune was not only vested in the company, but his credit for a large part of the stock in hand, which was all consumed by the fire; so that he was totally bereft of the means of making any provision for his family, and of guarding against the vicissitudes to which humanity is subject. He submitted to this event with dignity and fortitude; but the circumstances of having involved his wife in the ruin, and sacrificed her professional acquirements without her approbation, preyed so continually on his mind, as at length to produce a complaint in his sleep, which finally proved fatal, and brought him to the grave, the 8th of June 1790, at the age of 70.

BATESON, THOMAS, an English Madrigalist of the beginning of the seventeenth century, not devoid of merit as a vocal composer. He was organist of the cathedral of Cheltenham in 1650. Ant. Wood says, that he was a person esteemed very eminent in his profession, especially after the publication of his English madrigals to three, four, five, and six voices. About 1618, he became organist and master of the children of the cathedral church of the Blessed Trinity in Dublin; and in the university of that city, he obtained the degree of bachelor of music.
BAT

BAT-FOWLING, a method of catching birds in the night, by lighting some straw or torches near the place where they are at roost; for, upon beating them up, they fly to the flames, where being amazed they are easily caught in nets, or beat down with bushes fixed to the end of poles, &c.

BATGAN, or BHATGAN, in Geography, a city of Hindostan, situated in the extensive plain of the kingdom of Nepal or Napat, to the east of Lelit Bhatan; and 10 miles south of Kathmandu, the capital of Nepal. It contains about 12,000 families, extends towards the east to the distance of five or six days' journey, and borders upon another nation, so independent, called Ciratas, who profess no religion. In 606 B.C. the king of Gorka took possession by force of the city of Batgan. See Father Giuseppe's account of the kingdom of Nepal in Asiatic Researches, vol. ii. p. 328.

BATH, a city of Somersetshire in England, is situated in N. lat. 51° 22' 30", W. long. 2° 21' 30", at the distance of 107 miles west from London, and 12 east of Bristol. This ancient and elegant city is singularly favoured by nature and art, whose joint co-operations have conspired to give it importance and celebrity. The beauty and peculiarity of its situation are perhaps unequalled by any town in England. Planted originally in the bottom of a deep and narrow valley, where its hot waters boil up, it continued for ages to be confined to the dimensions which the Romans had first marked out; and till within the last century, the ancient Roman walls (including a space of about fifty acres) formed the boundaries of Bath. But the fashion and celebrity which it afterwards obtained, induced many builders and speculators to extend the streets in all directions, by additional houses, which were instantly occupied upon completion. Built of the fine edict, or granulated egg-like freestone, which forms the bases of the surrounding hills, the houses are remarkable for their exterior neatness and splendour; and being raised on the sides of the broad acclivity of Lansdown (which rises to the north), in irregular groups of streets, squares, parades, circuses, and crescents, they present to the eye an appearance equally singular, magnificent, and beautiful. Nothing, indeed, can be more picturesque than the views of this city from various stations on the surrounding eminences; where houses rise above houses in progressive order, and the more elevated seem to look down with proud superiority on the no less elegant and extensive structures below.

Bath, Ancient History of. Various names have been given to this city at different periods. Its British appellation was Cæsar-Badlon. In Latin, it was called Aquæ Solis, Fontes Caldi, Achaiaennam, Thermae, Badonia, &c. and in Saxon, Accemannas-caerpe, Accemannes-bepi, Lebher-bun, &c. Most of these names refer to its situation, and its springs or baths. But the origin of this place as a settlement or town, is lost in the lapse of ages; and its early history is enveloped in legendary tales and monstrous fables. The strange story of Bladud and his leporaceous pigeons is disbelieved by all rational thinkers, though it formed a part of the cred of the Bath citizens till within the last fifty years. "But the present generation (observes Mr. Warner) are wiser and more prudent than their forbears, and rather attentive to the voice of the ages than that origin, have at length forsaken the antiquity of that discovery, in the agreeable conviction of the large rents which they throw into the common chest." The city is, however, not without many interesting considerations. It was one of the principal, if not the most considerable of the Roman stations in England, is satisfactorily proved by the many architectural and military antiquities which are found within its precincts. It is probable that if Bath was not originally built by the Romans, it was at least reduced under their power, and embellished by their arts, as early as the middle of the first century; when, in the reign of the emperor Claudius, according to Tacitus, about the year 44, the western and south-western parts of this island were completely subdued by Flavius Vespasian. Attracted by the medicinal and warm springs which they found here, and which afforded every means of indulging in that prime enjoyment of Roman luxury, the bath, the Roman soldiers fixed in this place one of their principal stations. "Aquæ Solis," the name by which they distinguished this delightful residence, was from then established as a colony; and of course became entitled to the privilege, which all the Roman colonies enjoyed, of minting its own money. It is to be conjectured, also, that a military fortress, or college of auxiliaries, was erected here for the fabrication of legionary arms, under the authority of a Roman government. In the reign of Adrian, about A.D. 118, the first detachment of the second legion, which had been stationed here, was joined by a division of the sixth; and in that of Severus, a part of the twentieth legion, removed from Devana, or Chelester, had its station in Aquæ Solis, which was then become the most capital city in Roman Britain, and the principal, if not the only, place in this part of the island, for preparing the legionary arms and ensigns. The form of the city then constructed, according to that uniformly affected by the Romans, approached to a parallelogram, swelling out on one side, so as to describe an outline somewhat pentagonal, and stretching in length, from east to west, about 400 yards, and 380 yards in the broadest part from north to south. The walls, which rose upon the outline of the settlement, appears, from subaqueous discoveries, to have been twenty feet above ground in height, and in thicknesses eighteen feet at the base, and eight at the summit. It was strengthened with five towers, raking at the angles; and had four ports, or entrances, facing the cardinal points, which were connected together by two grand streets, dividing the city into four parts, and intersecting each other at the centre.

The place thus fortified and strengthened for security, was next adorned with houses for the officers, temples, and those magnificent baths, the remains of which were discovered, in digging to a considerable depth, in the year 1755. These baths were seated near the centre of the city, betwixt the north and south gates, on the eastern side of the great street. The judicious, tymanum, fluted-columns, cornices, pilasters, and sculptured ornaments, found here, prove that the buildings were constructed of elegant deligns, and of similar characters to some structures described by Pliny and Varro. Many altars have also been found here bearing the inscriptions of Dee Sulini Minervae, Dee Sulini, &c., concerning which many conjectures have been adduced. Mr. Warner affirms the gods of Sulini to be a local deity; Mr. Lyfons asserts that the name is of Gothic origin; whilst Mr. Whitaker more appropriately and happily explains it to be the British characteristic appellation for Minerva as the tutelary goddess of medicine, deriving her influence immediately from the sun. This great dispencer of health was denominated Sul in the Celtic language. The ancient baths occupied a space measuring 240 feet in length from east to west, and 120 feet at the broadest part from north to south. (These baths, and remaining fragments, have been particularly described and illustrated by governor Pownal and Mr. Warner, in publications expressly on the subject; and the fragments are represented and described by Mr. S. Lyfons in a volume lately published.)

The Romans being established here, constructed four of their great military roads to communicate between this place (Aquæ
(Aquae Sulis) and the Antonia of Durocorninium (Cirencester), Verulam (Hedington), Isfaal (Ilchester), and Abone (Aunsford). The conquering Romans had enjoyed the possession of Bath and England for nearly four centuries, at length left the whole island to the possession of the Britons, who were afterwards subdued by the hardy Saxons. It was not till the year 577 that Aquae Sulis fell into the hands of these destroying conquerors, who, under the command of Cælinus and Cathwine, overcame Commal, Candidan, and Farinmail, the three British kings of Gloccester, Cirencester, and Bath, at a place called Dyrmah, eight miles from the latter place, and took possession of their respective dominions.

Bath now received the privileges of a Saxon burg; had its Gerefa or judiciary appointed to it, who presided in the monthly meeting of its citizens, called the burgomote or foemote; councils instituted for the regulation of the police, and administration of the laws within the burg. Bath was afterwards taken by Offa king of Mercia; and during the civil wars and Danish invasions which prevailed in the eighth century, it was torn to pieces and nearly exterminated as a town. During the brilliant reign of Athelhelm, this place again rose to consequence; and a mint was established here by the Saxons, who also gave several large donations of charters to Offa's abbey. King Edgar was crowned and inaugurated here, and settled his regard for the place by granting it several privileges. The inhabitants from that time on were to be as prodigiously as the Saxons could add to the city.

The Norman conquest had produced much general evil to the country; and Bath, with several other cities, experienced, in consequence of it, great deterioration. But this was partial and light, compared to the miseries which happened to it in Rufus's reign; when in the intercourse raised by Odo Bishop of Bayeux, Geoffrey Bishop of Cowntance, and Robert de Mowbray; the latter took the town by assault, and, in the spirit of the times, delivered it over to plunder and burning.

Bath was indebted for its restoration to John de Villula; who purchased it of Rufus, in 1092, for 500 marks, and obtained permission to remove the pontificial seat from Wells bishop. He rebuilt the city, erected a new monastery upon the ruins of the old one, and united the bishopric to this institution. Thus reinstituted, Bath gradually increased its monastic possessions, in consequence of the munificence of monarchs and private persons, but the sequestration, by a decree of Henry VIII., drove the monks from their monastery, and the abbey-house, with its lands, &c. was granted to private individuals.

The citizens of Bath returned Members to the English parliament as early as the 26th of Edw. I. and writs were regularly sent them for the same purpose every time parliament was summoned to meet. But as these privileges were attended with heavy charges on the burgesses, who generally paid the expenses of their members, the city was not represented during the 16th and 17th years of Edward II. It now sends two members, who are elected by the body corporate, consisting of thirty-one persons. The government of Bath was originally vested in a sheriff; but the first that appears to have borne this office was Adam, who is said to have been a great benefactor to the city, and died A.D. 907. It had afterwards a provost or bailiff. Its first charters were confirmed by King Edward III., Richard II., Henry V., and Henry VI. Queen Elizabeth, in the 32d year of her reign, granted the city a new charter, declaring it to be a sole city of itself, and the citizens to be a body corporate and politic, by the name of mayor, aldermen, and citizens of the city of Bath. This charter was renewed in 1794, when two additional franchises were granted the citizens; and under that charter the corporation derive their authority, power, and rights.

The commerce of this city, abstracted from the expenditures of fashionable company, is considerable, nor is there any manufactory deserving particular notice. Bath was formerly distinguished for its clothing trade; and at the time of the restoration, it is said, there were no less than sixty broad-cloth looms used in the parish of St. Michael.

The river Avon, which winds round the southern part of this city, was made navigable by an act of parliament in the 10th of queen Anne; and the first barge, laden with deals, pig-lead, and meal, was brought here December 15th 1727.

In the earlier part of the civil wars, this city was garrisoned for the Royalists, and the sum of 7000l. is said to have been expended on its fortifications; notwithstanding which, it was speedily surrendered to the enemy, and was made one of the principal posts for the parliament's forces. Sir William Waller lay here for a considerable time with his whole army, making fords into the country, and inviting together all the dissatisfied from the neighbouring clothing towns and villages. But after the battle of Roundway-down, July 13 1643, in which Waller was defeated, and the withdrawal of the garrison for the reinforcement of Bristol, the king's troops took possession of the city.

Having stated a few particulars relating to the early history of Bath, we proceed to a brief description of its principal public structures, and other prominent objects which characterize this fashionable place.

The Public Baths are four in number, besides two private baths. These are all constructed with particular attention to the convenience and accommodation of invalid bathers; and the laws and regulations are very equitable and fair.

(For an analysis of the hot waters of Bath, and an account of their medicinal powers, vide Dr. Gibbs's Treatise on the Bath Waters.)

The King's Bath is supposed to be so denominated from some of the Saxon kings having made this city their residence. It is situated to the west of the abbey church, and forms a parallelogram, 65 feet 10 inches in length, and 40 feet 10 inches in breadth; the bottom of which is 12 feet below the surface of the ground. The spring or main source is from the centre, which is covered with a large leaden reservoir, to restrain its rapid motion, and to disperse the water more equally, both for bathing and drinking. There are also two commodious rooms with pipes, fire-places, and other conveniences for the bathers. This bath fills in nine hours. The Queen's Bath, which receives its waters from the former, forms a square of about 25 feet in diameter. The Cross Bath forms a handsome termination to Bath-street, and is a very elegant building, constructed after a plan of Mr. Baldwin's; its shape is triangular. The Hot Bath is erected to the south-west of the latter, and is called from the superior heat of its water; this also forms a parallelogram, and is perfectly convenient with regard to an open bath, private baths, dry-pump, and dressing rooms. Certain regulations are prescribed respecting these baths and the persons belonging to them; as well as particular fees for every process of bathing, pumping, &c. Adjoining to the king's Bath,
in Statt-Avret, are some new private baths, which were erected by Mr. Baldwin in 1784. These baths belong to the corporation. There are also the private baths, called the duke of Kingham's, or the abbey baths, belonging to lord Newark, and in the occupation of Mr. Sloper. See Bath water.

Bath, Public Buildings. The Guildhall is a very handsome structure, built after a design of Mr. Baldwin, and contains a number of useful and convenient rooms for public business. In the common-council room, one of the most elegant of the kind in England, are portraits of the king and queen, the late prince and princesses of Wales, and the late earl Chatham and Camden. The Pump-room was constructed, by the same architect, in the year 1796; its length is 85 feet, including the recedes at the ends; in breadth 46 feet, and 34 feet in height. The inte: is set round with Corinthian three-quarter columns; and lighted by a range of large windows below, and of lighter ones above. Here is a marble statue of Richard Nafi Esq., the arborist elegantian of Bath, a gentleman to whom this city is principally indebted for its fashionable celebrity. The pump is held under a benefial kafe from the corporation for three years, the rent being 800 guineas, exclusive of taxes; whi., however, is sufficiently low to enable the lease to lay up 1200l. at 1500l. during the term. Most of the elegance of street-building in Bath is owing to the late Mr. Wood, who commenced his operations with spirit, and conducted them with taste. To him the city is indebted for Queen-square; the northern side of which presents a chanste and neat range of structures, decorated with all the ornaments of the Corinthian order.

The Circus is of his designing; here the house parts take of the three orders, Doric, Ionic, and Corinthian, highly ornamented. To the grandeur of his designs, the North and South Parades bear ample testimony; as do several streets stretching to the northward of the old city, which strongly mark his judgment and execution. Subsequent architects have followed Mr. Wood's example, and hence arises a profusion of new squares, crescents, parades, and streets; thus increasing Bath to six times its original size; and the beauty of the city is equal to its extent.

The new Assembly Rooms are the most elegant of the kind in Europe; these were built by Mr. John Wood in 1771, at an expense of 20,000l. The ball-room is 105 feet 8 inches long, 42 feet 8 inches wide, and 42 feet 6 inches high; the other parts of the building are composed of the octagonal room, the tea-room, and the card-room, all of equal beauty. The regulations to preserve order and decorum in these rooms are simple and satisfactory. The lower rooms, near the north parade, have a convenient suite of apartments appropriated to the elegance of the place; and here are to be seen the original regulations by Mr. Nafi, which he wrote for the purpose of reducing politenes and urbanity to a system. A neat small Theatre was erected in Orchard-Street by the late John Palmer Esq. who obtained a patent for dramatic entertainments in 1768; and here plays are performed on Tuesdays, Thursdays, and Saturdays. Sydney gardens are laid out in a very pleasant and elegant style, for the purpose of evening promenades; where galleries and public music and dancing are given similar to the entertainments at Vauxhall gardens of London.

Hospitals, &c. Buildings and institutions of this nature form a striking feature of Bath; and no place in the realm, according to its size, exhibits so many foundations for the extermination of disease and wretchedness, for the support of the poor, and the instruction of the ignorant. The general hospital, from the munificence of its plan, is an institution open for all the sick poor in the united kingdom, who labour under diseases to which the hot waters of Bath particularly apply, with an exception to those persons inhabiting the city, who have the waters at their own houses for a small expence. Mr. Nafi had the honour of suggesting the idea for its foundation, in 1715, and the first stone was laid in 1738. St. John's hospital, originally built by Reginald Fitz-Jocelin in 1176, and the chapel attached to it, stand near the eves bath, and were built in 1728, upon the site of an old structure for the accommodation of six infirm men and women. St. Catherine's hospital, called also the Black arms and Bimbberries, is another asylum for ten poor persons. Belb's hospital entertains twelve poor men and women, who have each an apartment, the liberty of bathing, and a small weekly allowance. The Bath city Dispensary and asylum, is equally open to the inhabitants and strangers in cafes of physical and surgical emergency; and is a most excellent institution. The Casualty hospital is appropriated to pacpers who have been injured by accidents. The Puerperal, or child bed charity, is another benevolent institution, whose objects are explained by its name.

Bath has, besides these establishments, a public grammar school, charity and Sunday schools, with many humane and scientific societies. The principal of these are, the strangers friends society, and the Bath and well of England society. The first is established and conducted on the most benevolent principles of universal philanthropy; and the only recommendation for relief, is a sufficient proof of evident distress. The second was established by Mr. Edmund Rack, in 1777, for the encouragement of agriculture, arts, manufactures, and commerce; and from the judicious management of its founder, and late secretary Mr. W. Matthews, it has acquired some celebrity, and proved of extensive utility. The philosophical society was established in the year 1799, by some respectable literary characters at Bath, upon a plan somewhat similar to that at Manchester, for the promotion of science and the diffusion of knowledge.

Parishes. Bath is divided into the parishes of St. Peter and St. Paul, St. James, St. Michael, and Walcot. Bathwick, though connected by Pulteney bridge, and consisting of a great number of handfree houses, is out of the jurisdiction of the city. Each of these parishes has its church; and in that of Walcot are several chapels of ease. Of these, the principal is the Abbey Church, which presents a noble specimen of English architecture. It is built in the form of a cross, from the centre of which rises a tower 162 feet high, ornamented with beautiful light perforated buttresses. The length of the building, from east to west, is 210 feet, from north to south, 120; and the breadth of the body and side aisles, 72 feet. The grand entrance at the west is through a noble arched doorway; and the chaft uniformity, proportion, and harmony in the structure of the interior of this stately building, powerfully arrests the attention of the beholder. The west window is of extreme richness, and the whole of this front displays a representation of allegorical carving, not usually met with. The roof, confiding of two parts, the nave and the choir, is equally remarkable; the ribs which compose its tracery being the only solid work, the intermediate spaces having been originally left open, and afterwards filled up with lead and plaster. The windows are all large, of admirable and nearly uniform constriction; this has occasioned the church to be called "The Lantern of England." A profusion of marble monuments adorn another crowd up, the inside; among which may be noticed those of bishop Montague, Quin, Beau Nash, lady Miller, and sir William
B A T

The analysis of Bath water has been the cause of much controversy among chemists, but it seems now to be well understood. To the taste it is neither brisk, nor acid, nor alkaline, nor saline, nor sulphureous, but simply hot and chalybeate; and it is truly remarkable that the chalybete taste is entirely lost as soon as the water cools, before anyensible precipitation of the iron takes place. The actual quantity of the iron is so minute as never to have been estimated with any accuracy; probably a quarter of a grain in a gallon is a ample allowance, a quantity so small as only to be perceptible to the taste when fresh drawn and hot. Bath water contains no other ingredients of any importance. It is hard, and holds some calcareous earth in solution, and (as Dr. Gibbs has discovered) a portion of silex. It is perfectly free from sulphur. A considerable quantity of azotic gas rises from the earth along with the water, and a certain portion is held by it in solution or rather weak affinity. Of carbonic acid it only contains about $\frac{1}{20}$ of its bulk.

The diseases for which the Bath water has been recommended are very numerous. It has long enjoyed a high celebrity in the cure or relief of gout, chiefly of the atomic kind; of rheumatism; paralysis, especially that partial palsy of the limbs induced by rheumatism; and diseases of the urinary organs. When drunk fresh from the spring (the only time when it possessions any peculiar virtues), it sometimes raises the pulse, causes the face to flush, and heats the body very considerably; and hence there are many invalids who cannot bear its operation, or who must be gradually accustomed to it. This heating effect, however, is by no means constant or universal. It often produces a collybistic state of body, and generally keeps the skin perspiring and coolly perspirable. Its use as a hot, warm, or tepid bath, is full as extensive and probably important as when taken internally. It has been thought by many that the practice of drinking our Bath waters in Somerfetshire is not very ancient, and that their ancient use was in bathing; but Dr. Freind endeavours to shew the internal use of those waters to have been very early. Dr. Guidot, in whole time this usage revived, and who has given us an historical narrative of these waters, goes no higher for their internal use than the latter end of the sixteenth century. But they appear to have been in use in the thirteenth century. Gilbert, surnamed Angliens, who, according to Bayle, lived in 1210, in the reign of king John, or more probably in that of Edward I. mentions a peron cured of a leucopilagmy attended with a swelling, &c. by the fulphureous baths: which Dr. Freind understands of the Bath waters; and that the cure was wrought by drinking, not bathing, which had been improper in such a cafe.

Dr. Mufgrave makes it probable, that they were referred to in the time of Ceta; there being still the remains of a statute erected to that general in gratitude for some benefactions which he had conferred on the place. Some pretend that these waters were in use 800 years before Christ. Phil. Trans. N° 49. 346.

The two diluted feasons for drinking the Bath waters are spring and fall; though they may be used whenever they are found necessary.

B A T

William Draper. The vestry contains a small library, founded by bishop Lake. Oliver King, bishop of Bath and Wells, in the time of Henry VII. undertook this building we have described; but by a neglect of his four successors, cardinals Adrian and Wolsey, and bishops Clerk and Knight, the undertaking was so dilapidated, that at the dissolution it was proffered to the citizens for 500 marks. They refusing the purchase, under an idea of offending the king, the glafs, iron, bells, and lead were stripped from it, and sold at a foreign market. Thus it continued in a ruinous state till the reign of queen Elizabeth, when subscriptions were let on foot to restore it; and Thomas Belbot Elq. steward of her household, repaired the choir for divine service; bishop Montague, in the next reign, at the expense of 1000l. completely refrooled the whole to its former state; and with the assistance of several munificent noblemen and gentlemen, the abbey of Bath became again a consecrated temple to divine worship and a grand ornament to the city.

St. James's church was erected in 1768, and is a freestone structure, with a square tower rising at the west end, containing eight mulchical bells. St. Michael's church was begun in 1774, and is inappropriately situated in the middle of a street. Walcot church, dedicated to St. Swithin, is a neat modern structure, rebuilt in 1780. In this parish are four chapels of ease, and a church for the use of the poor: of these, Christ's church was built by voluntary subscription for the use above mentioned; and the whole area is therefore appropriated solely to accommodate the poor clerfs of inhabitants. There are also in Bath other chapels and meeting-rooms for divine service: the Octagon and Laura chapels are of the established religion. The Unitarians, Quakers, Baptists, Methodists, Moravians, and Roman Catholics have each a place for divine worship.

Bath is furnished with 438 lodging-house, and 19 boarding-houses, where individuals and families are accommodated with every domestic convenience during the winter, which is the fashionable season. The shops of bath are particularly splendid, and its libraries are numerous and respectable.

Civil Government. The judicial business of the city is transacted in the guildhall, where quarter-sessions, a court of record, and a court of quarter-sessions are held. The corporation consists of a mayor, ten aldermen, two sheriffs, and eighteen common-council men, besides town-clerk, constables, &c. The principal markets are kept on Mondays and Saturdays.

For further particulars concerning the history and description of this city and its environs, see Warner's History of Bath, 4to. and the Bath guides published at this place.

Bath Water. Bath has been long celebrated for its thermal waters. There are three principal sources of the water; called the King's bath, the Cross bath, and the Hot bath. The supply of water is abundant and inexhaustible. The temperature of the hottest of these is uniformly 116°, when fresh drawn, and of the coldest 112°; and no variety of feason appears in any degree to influence this temperature. By some accurate observations that were made on the heat of Bath and Bristol water, by Mr. Canton, it appears, that a Fahrenheit's thermometer held in the stream from thecommon pump of the king's bath after pumping about a quarter of an hour, was raised to 112°. The stream from the common pump of the hot bath raised it to 114°. At the pump of the Cross bath it stood at 110°; the heat of the shaded air at noon being 60°, and of common water exposed to it 61°. And the Bristol water raised the thermometer to 76°, whilst in common water exposed to the shaded air it stood at 62°. Phil. Trans. vol. iv. N° 22.

Vol. III.
the west side of Kennebec river, about 13 miles from Wiscasset, 60 N.E. from Portland, 32 from Hallowell, and 165 N.E. from Boston. N.lat. 43° 49'.

Bath, a thriving town, in Berkley county, in Virginia, seated at the foot of the warm-spring mountain. The springs in the vicinity of this town, though less efficacious than the warm springs in Bath county, draw upwards of 1000 people here, during summer, from various parts of the United States. The country in the environs is agreeably diversified with hills and valleys; the soil rich and well cultivated; 269 miles S.W. from Philadelphia.

Bath, a township of America, in Crafton county, New Hampshire, containing 493 inhabitants; and lying on the east bank of Connecticut river; 35 miles N.E. by N. from Dartmouth college, and 97 N.W. from Portsmouth.

Bath, or Port Bath, an ancient town in Hyde county, North Carolina, on the north side of Tar river, about 24 miles from Pamlico sound, 61 S. by W. from Edenton, and in the port of entry on Tar river. It contains about 12 houses, and is declining. N. lat. 35° 31'. W. long. 77° 15'.

Bath, a village in the county of Renfleather, New York, pleasantly seated on the east bank of Hudson river, nearly opposite to the city of Albany, at the head of Sloop navigation. A mineral spring has been discovered in this place, and a commodious bathing house has been erected, at a consider:able expense, containing hot, cold, and shower baths.

Bath, a thriving post-town in Steuben county, New York, containing about 50 houses, situate on the north bank of Cohocton creek, a northern head-water of Togga river, 42 miles south-east from Williamsburg, 10 from Niagara, and 221 west from Hudson city. N. lat. 45° 15'. W. long. 77° 10'.

Bath, a village in the eastern parish of St. Thomas, in the island of Jamaica. It owes its name to a hot spring near it, which is said to be very efficacious in the cure of the dry belly-sore. The sulphureous water flows from a rocky mountain about a mile distant, and is so hot that the hand cannot be held in it.

Bath, Balneum, a convenient receptacle of water for persons to walk or plunge in, either for health or pleasure. Baths are either natural or artificial. Natural, again, are either hot or cold.

Baths, Natural, hot and cold. See Mineral Waters.

Baths, Artificial or Medicinal. The very accurate imitations of most of the mineral waters for the purpose of drinking which are now met with, have induced some ingenious artists to extend the imitation to larger quantities of water sufficient for the purpose of bathing. The method of performing each will be explained under the article of Waters, Mineral.

Of artificial baths some are aqueous, others vaporous, others dry, &c.

Baths, Aqueous, are those prepared from common plants and other substances of emollient, relievant, and nervous kinds. Aqueous Baths sometimes consist of milk and emollient herbs, with rote-water, &c. when the design is to humectate; at other times of bran and water, when the design is only to cleanse; sometimes again, they are made of a decoction of roots and plants, with an addition of spirit of wine, when a perfon baths for a great pain or tumor, &c.

In Vapour Baths, the fame or steam of some decoction is received upon the body to promote a perspiration. These are also by some called Balnea Lucienia.

Vapour Baths are, when the patient is not plunged into what is prepared for the bath, but only receives its steam upon those parts of his body which require it; as in some distempers of the fundament and womb, where the patient sits and receives the fumes of some proper fomentation, &c. Mr. James Playfair has published "A Method of constructing Vapour Baths," fo as to render them of small expense, and of commodious use in private families." The principles on which this method is founded are, that in the vapour bath the water being applied, not in the flate of steam, but of solution in air, a much less quantity of the heated fluid than that usually applied will suffice, provided the heat of the enclosed air can be maintained in a sufficient degree; and that dense substances, especially metallic ones, being the greatest conductors of heat, are to be avoided in the construction of the vessel containing the vapours, and the lightest and most non-conducting materials used instead of them. The whole apparatus for the vapour-bath is, therefore, reduced to a tin boiler, tin pipes wrapped in flannel, and a deal box, with a cotton cover, for the reception of the body and circulation of the vapour.

To these may be added the bagno, where people are made to sweat by the heat of a room, and pouring on of hot water; after which they generally go into a hot bath, or bagno. See BATHING.

Baths, Dry, are those made of ashes, salt, sand, shreds of leather, and the like.

The ancients had divers ways of sweating by a dry heat; as by the means of a hot fand, frove rooms, or artificial bagnois, and certain natural hot fleams of the earth, received under a proper arch, or hot-house, as we learn from Celsus. They had also another kind of bath by inhalation, where the body was exposed to the sun for some time, in order to draw forth the superficial moisture from the inward parts; and to this day it is a practice in some nations to cover the body over with horse-dung, especially in chronic diseases, to digest and breathe out the humour that causes the distemper. In New England, they make a kind of flove of turf, wherein the fiek are shut up to bath or sweat. Phil. Trans. N° 284. p. 130. The fame name is sometimes also given to another kind of baths, made of kindled coals, or burning spirit of wine; the patient being placed in a convenient clofe chair for the reception of the fume, which rises and provokes sweat in a plentiful manner: care is here taken to keep the head out, and to secure respiration.

This bath has been found very effectual in removing eldor; finate pains in the limbs, and venereal complaints; and, it is said, will often complete a cure, left unperfomed by salivation.

Baths, Metalline, those made of water impregnated with the fierre of metals. The most common and useful of this kind are those prepared with the fierre of iron, which abounds with the earthy, faline, and sulphureous fubftance of the metal; and these are of excellent service for strengthening and bracing up the part to which they are applied, and recovering weak and decayed limbs; stopping various kinds of bleeding; and reftoring the menstrual and hemorrholial flux, where obftucted; so much as they may well be fubfitted for the natural iron baths.

Adjacent to the melting furnes where metals are run from their ore, are to be found large quantities of the flag of copper, antimony, and cobalt, which abounding with sulphur, vitriolic salt, and an early principle, make serviceable baths for strengthening the loof tone of the fibles, and relaxing them when they are too flifi. These baths have like- wise a deterfive and cleaning virtue; so that, with prudence and due regard to circumstances, they may be used on many occasions. The way of making these artificial baths is, either to take the flags as they come hot from the fur-
BATH

Bath, Balneum, in Chemistry. In many chemical processes it is of the utmost importance both for the security of the vessels, and the facing of the operation, that the application of the necessary heat should be gradual and regulated. This is particularly the case in most distillations, and in digerations at a moderate temperature, and wherever glafs vessels are employed. Hence the contrivance of baths or intermedes between the burning fuel and the vessel containing the subject of the process, in which the vessels are immersed, and whereby they receive the heat in a regular gradual manner. As fluids heat with more uniformity than solids, they are preferable where only a heat a little inferior to the boiling point of the fluid is required; and they possess this important advantage, that the heat is so kept down by evaporation, that it can never rise beyond the known and given point of boiling. But where as much even as a low red heat is required, no fluid can be employed with any convenience, and recourse must be had to some incombustible solid reduced to powder. A great variety of baths were invented by the elder chemists, especially those who were engaged in alchemical pursuits, which were supposed to require long digestions in a very accurately regulated heat; but most of these are now laid aside, and only the following kinds of baths are retained.

The Water Bath, Balneum Aquæ, is of great use in the distillation of essential oils, of the aromatic part of vegetables, of the finer kinds of ardent spirits, in evaporating into dryness the solutions of vegetables employed in medicine whose virtue would be lost by any excess of heat, and in many other processes. The apparatus for this bath forms part of the improved ALEMBIC (which see, in Plate III. fig. 13. A. of Chemistry); but any vessel full of water, capable of being heated to boiling, and of containing a retort or other vessel, may be used as a water bath. As the utmost heat which any substance immersed in a boiling liquid can acquire thereby, falls short by a few degrees of the temperature of the liquid itself, the heat of a water bath cannot amount to 212°. This is considerably increased, however, by using a strong solution of sea-salt, or any other salt, instead of water; as the boiling point of saturated brine is much higher than that of mere water. This forms the ancient Balneum Maris, Bath of Mary (the Virgin, as some have interpreted the term); but others with more plausibility write Balneum Maris, sea-water, or brine-bath.

Mercury, the fusible alloy of bismuth tin and lead, tin alone, and other metals, have been proposed for the purpose of baths, and now and then used, when a higher heat than the salt-water bath was required; but the metals are cumbersome by their weight, expensive, mercury dangerous to the by-farmer from its evaporation, and they all have the inconvenience of requiring more preasure to be used than the mere weight of the substance which they are to heat, to enable it to be immered in the melted metal.

Balneum Steæum. This whimsical term has been applied to the vapour bath, in which the vessel to be heated is enclosed in a kind of cage filled only with the steam of boiling water. It is almost if not quite out of use for chemical purposes, but it forms a valuable implement for the kitchen.

Balneum Alææ, Sand-bath, of all kinds of chemical baths that which is used the most extensively. In experimental furnaces, or smaller chemical operations, the vessel to contain the sand is of cast iron, very much in the form of an inverted round hat, of which the hollow portion is supported by the projecting rim upon the sides of the furnace, and hang down over the burning fuel, the flame of which plays round it and gradually heats the sand which it contains, together with every vessel buried therein. The sand should be of middling fineness, the finer as well as the very coarsest being separated by sifting; for by this means the heat is more gradually distributed. Those distillations, which at any part of the process require as much as a low red heat, are usually performed in sand baths, even in manufactures in the great way, as of aqua fortis. Sand, when thoroughly heated, continues hot for a very considerable length of time.

Bath is also used in another sense, to signify the fusion of metallic matters in certain operations; thus, in refining or cupelling, the metals are said to be in bath when they are melted.

Bath, the name proper to such public or private edifices as are used for bathing.

The practice of bathing is found among all the nations of antiquity. The people of the East were ever accustomed to it, and have continued the habit to the present time; their methods being perfectly conformable to those of the Greeks and Romans. If we may credit Homer, Mofchus, and Theocritus, the first ages of Greece knew no other baths than the rivers; and it was in them that the princeses Naucissa, Europa, and Helen bathed. Homer (lay the French Encyclopedists) indicates, that in his time private baths of a regular form were in use. Telemaochus and Pliithras, they observe, were conducted to baths of uncommon neatness: the most beautiful fables in the palace bathed them, perfumed them, and adorned them with the handiest garments. But all this is an assumption which the text of their author by no means warrants. The passage alluded to is in the Odyssey, book xv. 1. 135.

Χειρον ἐμεθυότος: ἐπηρὰ τρηχοῦντας φιγοὶς
Κοτόν γρατίν, ὑπὲρ αἵρεσ ὅσητον;
Πληθοῦσα.

And the lines which follow show, it was nothing more than a common ablution previous to an entertainment. The Δίας was a kind of vase occasionally placed upon a tripod.

The Romans, who for a long time bathed in the Tyber, borrowed the idea of artificial baths from the Greeks; their various habits of life and dress rendered such accommodations necessary; and, to make short of our relation, all the most splendid and captivating luxuries of the emperors were

H 2

multi-
B A T

multiplied and brought together in the vault buildings of
the thermae.

The thermae, those prodigious monuments of Roman mag-
nificence, were formed in imitation of the Greek gymnasia.
In both were assembled all the institutions favourable to
health, all the exercises of the body, all that could give
relaxation to the mind, or afford amusement to the people.
Although the name of thermae gave, by the Romans to
these edifices, signifies a place defined to the use of warm-
baths, yet the diversity of uses to which they were applied
will not suffer us to comprise the whole in a single article.
All that concerns the immediate use of the baths will be
found here; but for other details, we shall refer to
Thermae.

The most complete and beautiful baths were composed of
six principal apartments.

The first was called the apodyterium, where the frequen-
ters of the bath undressed; it was furnished with tables to
receive the garments of the bathers, and guards named cap-
farit to take care of them. This room was also called by the
Romans the praefurnium. All the baths were not furnished
with an apodyterium. Lucian says, that in those where
without it, the frigidarium was used for the same purpose.
The apodyterium is founded neither in the gymnasia of Vit-
ruvius, nor in the palæstræ described by Lucian. It is very
probable, there was no such apartment in the Greek gym-
nasia, and that the frigidarium supplied its place. Pliny is
the only author who mentions it, when describing the baths
of his country-house.

The second apartment was the cold-bath; named Apera
by the Greeks, and frigidarium by the Romans. This room
was usually exposed to the north, and served, as we have
just related, the purpose of an apodyterium to such baths
as were without one; of course it was then the first apart-
ment. The marquis Galani imagined that the frigidarium
and tepidarium were the same; but ancient paintings prove
the contrary.

The third room was the tepidarium. Its principal use was,
by the temperate air it contained, to prevent any bad effects
that might be occasioned by palling too suddenly from the
warm to the cold apartment. In the paintings of the baths of
Titus, this apartment is found between the frig-
ardinum and the concarera fudatio. The tepidarium, ac-
cording to historians, joined the frigidarium to the warm
bath; and it is for that reason that Pliny calls it cella medii,
the middle room. Galen gives it the same name, and imagines
it acquired this appellation not only on account of its situation
in the centre, but from its temperature; for, says he, this
chamber was as many degrees colder than the third or
warm bath as it was warmer than the first or frigidarium.
The frigidarium and tepidarium, however, were more fre-
quented for the benefit of their air than of their water.

The fourth chamber was that which contained the floe;
and was called laconicum, from the name of the oven
which warmed it. According to Galen, it inclosed a dry
heat; and he advises persons of a warm temperature not to
enter it, but rather to use the warm bath, where the water
absorbed by the pores would hinder the heat from being
attended by any bad consequences. The laconicum also had
its name, as having been originally derived from Laconia.

Martial says to one of his friends (lib. 6. ep. 42.) :
Rutus i tibi placuit tibi laconum,
Contentus potes arido vapore
Cruce virgine Maritâque mergi.

Dion informs us, that they who perpired in the laconicum
anointed themselves with oil, and then entered the cold bath;
nevertheless in its origin the laconicum was only used by old
men and valetudinarians. This room, agreeably to Vitruvius,
as well as to the ancient paintings of the baths of Titus,
joined the tepidarium, and communicated to it a more tem-
perate heat. A fort of furnace was usually suspended at one
corner of the room, of a circular form, terminating in a
small cupola, open at the top; which, as Vitruvius says,
favored to regulate the degree of heat which the bathers
wished to give the room. It seems beyond a doubt that the
laconicum itself was nothing more than a kind of furn-
ace; and the mistakes it has occasioned owe their rise to
the room in which it was placed having taken its name
from it. In the paintings of Titus' baths, it is called the
concarera fudatio; but Vitruvius furnishes us with a
proper distinction, when he says (L. c. 10), "laconicum
fodiantique uero contiguus tepidarium," and explains
himself more fully in the next chapter, where he reckons
the floe as a chamber of the palæstra. There should in
one of its corners, he says, be placed the laconicum, and
in another the warm bath. "Concarnera fudatio longitudi-
dunequam significat nam ubi habit abest ex una
parte laconicum . . . ad ex advero laconi caldum
havationem." It should perhaps have been before observed,
that according to Vitruvius, the laconicum had niches which
were called fudationes, where those who used the dry baths
feted themselves, as we see in ancient paintings.

The fifth apartment was the balneum, or warm bath,
called thermobouia, and was the most referred to. Its fize
was proportioned to the number of those who bathed in it
at once. Its breadth was a third less than its height,
without including the gallery, called febola; which was
thrown round it, and terminated near the balcon with a little
wall for the bathers to lean against. This gallery was suf-
iciently large to contain those who waited for their turns to
bath. The middle of the room was occupied by a balcony
called fisseia, or by a bathing place which had the name of
alteum, as we see in the balneum of ancient paintings. The
bath was placed immediately below the only window by
which the light was admitted, that it might not be dark-
ened by the shadows of those who were walking in the gal-

The sixth room was the eleothefium, or sudarium. Here
were preferred the oils and perfumes used both in entering
and quitting the bath; and it was so contrived as to re-
ceive a considerable degree of warmth from the hypocaul.

The hypocaul was a fort of furnaces, which
Vitruvius calls fuppenatum; the bottom formed an inclined
plane, by a gradual descent from the opening where the
wood for heating it was thrown in; by which means the
heat was increased, and the apartments warmed more expe-
ditionally. It extended under the greater part of the rooms
we have mentioned.

Before these rooms particularly defined to the use of
the bath, there were several others intended for the exercises
previously taken. Such were the philerestium, the con-
ferium, the corneum, the phileum, the epheum, and others:
all forming part of the gymnasia; but which were not always
appendages of the baths, particularly those of private per-
fsons. Private baths, however, differed greatly in construc-
tion from those we have mentioned. Each possessed its own
chamber, either in changing the rooms of which they
were composed, or making the same chamber serve for
different purposes. The description the younger Pliny has
left us of his bath at Laurentium, is a proof of this. In
this building there was neither apodyterium nor tepidarium;
and the arrangement of its other parts was very different
from that of the public baths. You first entered a spacious
frigidarium; where contiguous to the walls, and opposite
to each other, were placed two baths sufficiently extensive to swim in. Nigh this chamber was the circuitarium; you then entered the hypocaust, the propignium, and two other apartments, neat but not magnificent; you afterwards came to a hot bath, from which the sea was discovered; and farther on was the sphaeriferium, exposed to the afternoon sun. In his house in Tulaeum, on entering the bath, we first find a great apodyterium, a spacious and agreeable chamber for undreaffing. This conducted to the frigidarium; which was darkened, and contained a bath of an appropriate size. When it was not found sufficiently spacious, there was in the open air a vault bafon, which might be used for the same purpose. Not far from the frigidarium was a chamber exposed to the sun sufficiently warm, but less so than the floce; this was the tepidarium. This room had three partitions, each having a different degree of heat. The two first were entirely exposed to the sun; and though the last had not all the heat of the former, it was equally light. Above the apodyterium was the sphaeriferium, or place of exercise for different games. Although Pliny does not inform us how the bathers employed themselves after having undressed and anointed, it is highly probable that they went up to the sphaeriferium and exercised, defended by another firecase into the floce, and afterwards returned to the apodyterium; not forgetting in their way to visit the tepidarium and frigidarium.

The following description, according to the Hippias of Lucian, gives another idea of the baths of the ancients, with the various apartments they contained.

"Having passed the great vaultile, to which was an easy ascent, you entered a spacious hall for the use of the domestics who attended the masters. On the left were the chambers, where they who quittd the bath retired; which were the handsomest and most agreeable of all. Farther on was another hall defined for persons of consideration. After this apartment, on each side were galleries, where the bathers changed their dresses. The centre, which was both elevated and well-lighted, contained three baths of cold water, ornamented with Laconian marble; and had likewise two statues of the same material, the one of Hygeia, and the other of Eucalpius. On leaving this part of the baths by a long vaulted passage, the building became infinitely warmer, although the heat was far from disagreeable; this passage led to a light apartment where the oils and effences were preferred, which on the right hand had a communication with the palestra; and the door-polts of which were covered with Phrygian marble. The apartment contiguous to this, as Lucian informs us, was more beautiful in its decorations than any we have mentioned; its very floor was composed of the marble already spoken of. It was of a size sufficiently large for the bathers to walk in, and was furnished with seats. After this apartment you entered a sort of gallery, heated; of sufficient length to admit the exercises of the corps. It was inclosed with Numidian marble; and led to a handsome well-lighted apartment, painted with purple, where were three warm baths. To leave it, it was not necessary you should go back by the way you entered, but across a warm chamber where the heat gradually diminished. All the chambers were lighted from the top; and Hippias shewed great judgment, in contructing the apartments which contained the cold bath so as to face the north. In regard to those which required a greater degree of heat, he exposed them to the south, the south-east, and west."

"It appears from this description, that the bath of Hippias had no apodyterium; there were only at each end of the frigidarium, which contained the three baths of cold water, tables on which the dresses were placed. The bathers entered a warm passage which conducted to the circuitarium; whence having anointed themselves they gained the sphaeriferium, the largest and handomest apartment of the whole. When the exercises were finished, they passed into the hot bath by a gallery where there was sufficient heat to preserve the perspiration first excited in the sphaeriferium. So that when the bathers first entered the warm bath, the difference they found was scarcely perceptible; since the warmth of the water was pretty nearly the same with that of the body. After having used the bath, they returned by a shorter way, and crossed an apartment where the heat diminished in proportion as they approached the frigidarium where their dresses had been left."

The following is the description which Vitruvius has left us of the Grecian baths. Having described the different apartments of the gymnasia, he says: "On the right of the ephebeum is built the curseum, or the room for sharing, dressing, &c.; near which should be the coniferium, where the sand for the wrestlers is preserved; and at the corner of the pellizym, the loutron, or cold bath. On the left of the ephebeum, the eleothium, or apartment for the ollages and oils; near which is constructed the frigida-rium; whence a passage should conduct the bathers to the propignium near the floce in the corner of the portico. Adjoining, on one side the frigidarium, is built the vaulted chamber for perpiration, which is always made twice as wide as long; and at one of its angles, usually, that opposite the warm bath, the laconicum." The disposition of each of the apartments we have mentioned varied till more in the thermes of the Romans, although their plans evince uniformity to a certain extent. As the Romans had two pellizymia in their thermes, it seems right to conclude they had a double order of baths. Varro proves incontestibly, that the women bathed in different apartments from the men; for, in speaking of the public baths of Rome, he says: "Item primum balneum nonum et Grecium introitum in urbem; ubi bina effect conjuncta edificia lavandi caufia; unum ubi vii, alterum ubi mulieres lavorentur." What Martial and St. Cyprian relate of the baths, where the men and women bathed indifferenritely, does not confute this passage; since writers attribute those indecencies to none but women of infamous character:

"Cum te lucernae balneator extinctis
Admitat inter builiriamae nucias."

This separation is conipositive in the baths of Caracalla; a great part of which was surrounded by a vestibule which encompassed the principal buildings of the thermes. This part was divided into fifty vaulted halls separated from, but perfectly resembling each other. One of these yet remains entire, and sufficiently indicates how the others were disposed. It is approached by a small vestibule. The room in which the bath was placed, was thirty-one feet in length by fifteen feet three inches wide; the bafon was of marble, with a border of larger stones extending eighteen inches from the edge of the hollow. The cavity between the sides was twelve feet wide by fifteen long. It was defended to in front by leves or eight steps extending the width of the bath; four above the brink, and three or four went to the bottom of the bafon; and the whole was lighted by a small opening at the top. A thousand persons could bathe in this part of the thermes at once.

When the water flowed into these baths, it seems to have been only lukewarm, as it was brought from the hot baths of the great therms; of which more, as we have already mentioned, formed only the outer circle. The water was conveyed from these baths, by pipes, into a great piscina,
or pool, defined for the use of those who wished to exercite themselves in swimming.

In front, on the right and left, were other baths for people of superior consequence. In the room of bafons they had large bathing vessels, which were of copper, porphyry, granite, or basaltes. They also contained fates of marble or porphyry; of which we yet see a great number at Rome. Olympiodorus affures us, that the baths of Caracalla had no less than sixteen hundred.

The grand hall was a rotunda, 111 feet diameter; which is believed to have been called cultura solidus, or the hall of fadans, of which Spartianus speaks in these terms: "Cellam solidum architecte negat pofe nulla imitazione qui facta cibi fieri." It seems to have had its name from the bars of copper and bronze which, according to some, formed its pavement, and to others its cicling; bearing some resemblance to the farning of the fadans among the ancient Romans. It had also large plates of bronze or copper, which covered and ornamented the piers of the window and other parts of the rotunda. It contained a number of vefels in which the warm bath was taken.

Of all that relates to the baths, nothing has so embaflafled the learned as the manner in which hot water was supplied to all the receptacles for bathing which have been found. For if we suppose, and it may be done without exaggeration, that each bath in the thermes of Diocletian was capable of containing six bathers, 1200 persons might have bathed at once. But as no veiles remain, sufficient to favour our conjectures as to the manner in which the water passed into these vafels, we must content ourselves with what Vitruvius has laid upon it.——Baccius has treated this subject better than any of the moderns. He imagines the water was conveyed from reforsors outside the thermo, and that machines were used for raising it to that height, which, agreeably to his examination of Diocletian's baths, seemed requisite. He was also induced to conclude, that the water was heatd outside the thermo, from the number of pipes which he saw underneath the area of the building; where there had never been any alteration, and which were all surrounded by other pipes from the hypocaust. But this supposition appeared to Baccius himself to replete with difficulties, that he pushed his researches on this matter no farther.

The two figures of the water towers or reforsors for the baths of Caracalla, engraved by Piranesi, will suffice to explain how easily the Romans heated the largest body of water their thermo could contain.

The water tower of Caracalla received its supply from the aqueduct of Antoninus, part of which passed by the Appian way.

It appears from the plan of this reforsor, that it had, immediately above the hypocaust, twenty-eight vaulted chambers; that these chambers formed two ranges of fourteen each; and that they had a communication one with the other. Above there were twenty-eight other chambers, which were connected with each other in like manner, though only one of them communicated with the chambers below. Above all there was a spacious reforsor, not very deep, but which extended the whole length of the water tower; in this, the water received considerable warmth from the heat of the sun, before it passed into the chambers. This reforsor did not receive its water directly from the aqueduct, but from an intermediate cirle. Whenever it appeared necessary to draw off the water of the lower chambers to fill the bathing places, the water of the reforsor became ules, and would have overflowed but for an opening on one side of the cirle, by which it escaped with-

out going into the baths. During all this time the water of the reforsors was tranquil. The cirle answered two purposes; it prevented any agitation in the water of the reforsor, and carried off that which was of no use. When the twenty-eight vaulted chambers, immediately above the hypocaust, began to heat, the warmth they acquired was quickly augmented; as there was only one of them which communicated with the exterior air.

The strength of the walls and vault was quite sufficient to reflect the rarefaction of air within the water, and of consequence to hinder its evaporation from producing danger. It was necessary that it should have pipes to give the water a sufficient heat for the usage of the bath. When the hour of bathing came, the warm water was let into the bathing places from the lower chambers; where it ran with incredible swiftness, and rose to a perpendicular height equal to the surface of the reforsor of the water tower.

To hinder the water from cooling as it passed through the subterraneous pipes, they were introdured in others which came from the entrance of the hypocaust, forming a fort of double tunnel, and acquiring a considerable degree of heat before the water entered them.

Each chamber was within the walls 40 feet long, 27 wide, and about 30 high. The number of figures upon the surface of the lower chamber amounted to 58,500. If we allow for the medium height 30 feet, the quantity of water contained in the lower chambers amounted to 1,143,450 cubic feet.

The ancients do not inform us how they discovered the method of heating such large volumes of water. We are therefore in the dark whether it was an invention of the Romans, or whether they brought it with them from the East. It is reasonable, however, to suppute, that such methods could be of no use before the construction of the thermes at Rome, and of course could not be older than the time of Augustus; in whose reign, Dion Cassius informs us, Mecenas built a warm bath capable of admitting persons to swim in.

This method, or one very similar, was used in all the baths of Rome. That described by Vitruvius was insufficient to furnish water for these vast buildings, which Ammianus Marcellinus compares to provinces (lavacra in modum provinciarum extrada); though it was undoubtedly the cafe in private baths. They heated the water of the bath, says Vitruvius, by means of three vefels of copper, so disposed that the water flowed from one to the other. One was called calldarium, another tepidarium, and the third frigidi-arium. The marquis Galiani observes, that it is no easy matter to give a precise idea of the situation of these vafes above the furnace. Ceferiano and Caporali have engraved one above the other, or rather one within the other, placing the frigidiarium above the tepidarium, and that above the calldarium, which was placed immediately above the furnace. But the great difficulty is, that in this arrangement the heat, by the aeration of the flame, ought to warm the upper vafe, or frigidiarium. Perault, on the contrary, places the three vases on a level; and he imagines that fphyons carried the water of one vafe into another; but how, without a piton, or some such expedient, the water could be raifed so as to re-edefned, he has not explained.

The ancient paintings of Titus's baths place these vafes upon three repes, in such a manner that the bottom of the water of one vafe shall be upon a level with the aperture of the other; so that it is easy to comprehend how the water was conveyed. But the marquis Galiani believes, that this disposition is not altogether agreeable to the truth; and that it was adopted by the painter, only to afford a more clear idea how the water was transferred.

I believe,
I believe, he says, that the three vases were upon a kind of level; the caldarium immediately above the furnace; the tepidarium a little backward, so as to receive a reverberation of the heat more than the fire itself; and the frigidarium upon a mossy pedestal, so that the warmth could not reach it. From the caldarium to the baths was a pipe, which, by means of a cock, supplied any quantity of water that was requisite. Another pipe carried the water of the referrai to the frigidarium, and kept it at the same level. All the figures which Vitruvius has given of this process, seem to require that an attendant should overlook this transfusion of the water; but that author himself tells us, that the operation was performed without afflitzit; ita collocanda ut ex tepidario in caldarium quantum aqua calde exerit inflat de frigidario in tepidarium ad eundem modum.

They had also other means of heating the water of the baths. We construct, says Seneca, a species of vases high and narrow, in the form of dragons and other fanciful shapes, in which we place pipes of native copper, of a spiral form, through which the water passes till it acquires a sufficient degree of heat. In the same degree as the cold water enters the pipes, the warm passes out; so that all the water which runs through, acquires the same temperature. Seneca explains the advantage of this process, and informs us the tube through which the water passes having no communication with the fire, the vapours are not mixed with smoke; nce trahit vaporem, quin clauids perturbation.

The parallel which Seneca has given in his letters between the baths of Scipio Africanus and those of his own time, is highly interesting, and will probably elucidate much that has been already written on the subject.

"Scipio's bath," he says, "was small and somewhat dark, agreeable to the ancient custom; for our ancestors thought that a bath could not be warm enough unless it was close. It was therefore a great pleasure to me to compare the manners of Scipio with our own. In this little nook did Scipio (the dread of Carthage, and to whom Rome was indebted for having once taken it) use to bathe his body when fatigued with useful labours. Under this low and forlorn roof he stood, and disdained not to tread so vile and mean a floor. But who is there in our time who would condescend to bathe in this way? A man thinks himself poor and mean, unless the walls are decorated with large and precious embellishments; unless Alexandrian marble is poured and laid in Numidian rough call; unless a rich and curiously variegated platter be spread upon them in pictureque; unless the roof is covered with glauf-work; unless the Tholian stone, once reckoned a scarce and curious ornament, even in some temples, now compassed the pool in which we bathe our bodies when enfeebled with fatigue at some trifling sport: in short, unless the water is conveyed by a silver spout. I am speaking as yet of common houses; but what shall I say when I come to speak of our freedmen? What noble statues! What vail pillars supporting nothing; but placed there for mere ornament, and the vain ostentation of expense! What large and far-looking cascades! We are arrived to such a pitch of delicacy and extravagance, that we cannot tread but upon the most precious marbles.

"In Scipio's bath there are some chinks, rather than windows, cut out of the stone wall to let in the light without hindering the strength of the building. But now we call the baths moth-houses and dungeons, if they are not so contrived as to admit the whole day's sun through the most spacious windows, whereby men are tanned as well as washed; and from the bathing vessels have a prospect both of the meadows and the sea. So that these baths, which, at their first con-
That the Romans, who enjoyed dominion in our island near four hundred years, had their baths, is evident from the frequent ruins of them which are found; and some instances occur where the builders had undoubtedly the thermal baths of their parent country in view. At Hovingham in the north riding of Yorkshire, 1745, a Roman bath was discovered, which had its fudaria and vapourium (Camden, ed. 1789, iii. 157) and ten years after, in taking down the abbey house at Bath, to build a new set of baths called the duke of Kingston's, the workmen found remains of very noble Roman baths and fudatries, whose springs and drains were made use of for the present baths. The plan and elevation of them were engraved by Mr. Gough. (Ibid. i. 79.)

Nor while mentioning the ancient baths in England, must we forget one instance where a magnificent building of the kind occurs among the monastic conveniences of the middle ages. Hugh, the archbishop of Bury, we are told, early in the twelfth century finished the aulae hospitum and balneatorium of his house; and Sambus, who was elected abbot in 1162, appears to have completed the latter edifice upon a scale, for those times, peculiarly grand. (Aqueductum et aquam per rivulos derivavit et lavatoria operis mirifico et magnum et mirandum consanuitat.) See Leland, Itin. vol. iv. App.

But it must be owned, that in spite of all the advantages derived from the habitual use of baths with respect to health and cleanliness, the moderns have till lately very much neglected to employ them; though from this century we must except the Orientals and the Turks, among whom the practice of the bath has been more easily preferred, on account of its connection with religious worship. Their manner of bathing is very similar to that of the ancients; they have full vall edicines for the purpoze, which are heated by means of pipes, and receive light from the top; and though the use of the litiqygl (see Architecture, Plate III.) may not have been preferred, proper frictions for the excitement of perspiration are still used; and the instruments adopted by the ancients are replaced by rough cloths and flannels. The rich among them have private baths, in the construction of which they are expensive, and devote to them the most considerable part of their mansions.

Among the modern Europeans, the practice of bathing, generally speaking, has returned to the same condition it was in when Homer described it in the earlier ages of Greece. It is in the river, during the heat of summer, that the multitude bathe; and that more for pleasure than on any other account: without once reflecting on the accidents which are likely to result from the crudity of the water, the intertemporature of the air, or the action of the fun, to which they are frequently exposed.

At Florence, on the bank of the Arno, public baths were constructed by the late duke, with such accommodations as seemed most appropriate for general use: adjoining which there are other baths belonging to private persons; and gardens of promenade.

What are called public baths at Paris, are far from uniting the bath advantages; they are no other than large boats, called toise, covered with a cloth, with small ladders attached by cords, to facilitate the purposes of bathing. The French have also private baths for hire, similar to those in England; and many of their larger mansions are furnished both with domestic baths of the larger kind, or bathing vessels formed of metal.

Those which are called natural baths, are usually buildings constructed nigh the sources of mineral waters; such as the baths of Puzzuoli, Baix, and St. Germano, near Naples.

Fiftis, in Tuscany; Bourbon and Vichi, in France; Buxton, Bath, and Harrogate, in England.

Of the engravings which accompany this article, Plate 1 exhibits the plan of the baths of Caracalla; of the references in which we give the following explanation.

1. The great square, surrounded by a portico, for the exercitio of the stadium.
2. Those parts of the portico which served for entrance to the vestibules of the palestra.
3. The cella solare of the palestra: the gates of which were furnished with lattice work of bronze.
4. Vestibules of the great hall.
5. The great hall, furnished with the xystum.
6. Other vestibules belonging to the lateral apartments of the palestra.
7. Others, narrower than those already mentioned, leading to the same apartments.
8. Halls, open at the top, whose sides were ornamented with basio-relievas in marble. A fragment of one of the last of these was lately in the possession of cardinal Albani.
9. Anti-rooms belonging to the xystum.
10. Common entrances to the same.
11. Openings to give the xystum light.
12. A spacious xystum in the middle of the palestra, for the exercitio of the athletes.
13. Apartments in which the athletes anointed themselves and left their vestments, with staircases ascending to the upper part of the cella solare.
14. Receivables for the rain-water from the roofs of the porticoes (fig. 19.), which was conveyed by pipes to the lower baths.
15. Other uncovered receivables, for the same purpose, formed in the side walls.
16. The portico, whence passing through the xystum you reached the great bath: it was exposed to the S.W. and was sometimes warmed by the fun, and at other times by furnaces.
17. Chambers or baths belonging to the wrestlers, and other combatants, of the theatre and xystum.
18. The cistern of water in the centre.
19. Porticoes, ornamented by niches, with magnificent fountains, serving as a shelter for the populace from the rain and fun.
20. Double portico before the theatre.
21. Seats for the spectators at the games; in front of which, upon occasion, the stage, and scenes for theatrical representation, were erected.
22. Open spaces between the porticoes and the great hall or facade.
23. Uncovered halls.
24. The athenaeum.
25. Open space in front of the philosophic walks.
26. The philosophic walks.
27. Quarters for the pretorian guard.
28. The great exedra, for trials of strength.
29. Apartments appertaining to the exedras, subdivided into smaller ones for the accommodation of the officers and exerciters in the different games.
30. Apartments for the scenes, and other theatrical apparatus.
31. Openings with iron gratings, for the admission of light to the lower story.
32. Staircases from the lower to the upper story.
33. Vestibules of the upper story.
34. Other staircases of ascent to the porticoes.
35. Quarters of the pretorian bands; with porticoes in front.

36. Piscinae,
36. Piscine, or pools of cold water.
37. Porticos erected at a later period, by Alexander Severus.
38. Cold bath with fountains in the centre.
39. Walls surrounding the summit of the hill on which the baths of Caracalla were erected.
40. Magnificent fountains.
41. Walls surrounding the fummit of the hill on which the baths of Caracalla were erected.
42. Open space around the reservoirs of water.
43. The aqueduct of Antoninus, which supplied the baths.
44. Intermediate reservoir, into which the water of the aqueduct was discharged.
45. The opening by which the water was conducted to the warm baths.
46. The reservoir.
47. Walls of the city, anterior to those of Aurelian, which were enlarged by Caracalla, for the extension of the thermae.
48. The fountains mentioned in fig. 38.
49. Porta Capena in the city wall.
50. Porta Terentiana.
51. The Appian way.

Plate II. exhibits a painting from the baths of Titus, on a brown ground, representing three flight temples: in the centre one a statue, suppos'd to be Apollo, with a priest on either side; and above each of the lateral temples a bas-relief, representing the sacrifices of Bacchus. The smaller figures in Arabesque.

Here may be remarked, that in strict contradiction to all that is attempted by the French writers, the paintings of the ancients, whether Greek or Roman, are in bad perspective.

Plate III. contains a section of the baths of Caracalla, from Piranesi; with Montfaucon's idea of explaining the relative situation of the different apartments in the Roman thermae.

Bath, in Jewish Antiquity, is the name of a liquid measure, containing the tenth part of an omer.

Some distinguishing kinds of baths: viz. the greater bath, containing 80 pounds of water; or, according to Josephus, 1440 Roman ounces; the second bath, containing 100 ounces; the third, 663 ounces; the fourth, containing 25 ounces; and the fifth, 63 ounces of water. Beverin. Synch. de Mem., p. 137.

Some have estimated the sacred bath at half as much again as the common bath; but there is no sufficient reason for this distinction. Calmet.

Bath, Knights of the. This order was instituted in England at the coronation of Henry IV. in 1399, and revived by George I. by his letters patent, bearing date at Westminster, the 18th of May in the 11th year of his reign, 1725, in the following words:

"George, by the grace of God, of Great Britain, France, and Ireland, king, defender of the faith, &c., to all to whom these presents shall come greeting. Whereas our royal predecessors, upon divers wise and honourable considerations, have, on occasion of certain august solemnities, conferred with great state, upon their royal issue male, the princes of the blood royal, several of their nobility, principal officers, and other per sons distinguished by their birth, quality, and personal merit, that degree of knighthood which hitherto had been denominated the knighthood of the bath; we, being moved by the same considerations, do hereby declare our royal intention not only to re-establish and support the said honour of knighthood in its former lustre and dignity, but to erect the same into a regular military order: and, accordingly, of our especial grace, certain knowledge, and mere motion, and by virtue of our royal prerogative, being the fountain of honour, we have instituted, erected, constituted, and created, and by these our letters patent, do institute, erect, constitute, and create a military order of knighthood, to be and be called for ever hereafter by the name and title of "The Order of the Bath," whereby we, our heirs and successors, kings of this realm, from ever shall be sovereigns; which said order shall consist of a great master, to continue during the pleasure of us, our heirs or successors, and thirty-five companions, to be from time to time nominated and appointed by us, our heirs and successors, wherein a succession shall be always regularly continued; which said order shall be governed by statutes and ordinances, to be from time to time made, ordained, altered, and abrogated, by us, our heirs and successors, at our will and pleasure. And to the end that such statutes may be legally established, we, following the example of our royal predecessor king Edward the Third, of glorious memory, founder of the most noble order of the garter, who gave function to the statutes of that order, by affixing to the same seal which had been by his command made and appointed for the same order, do hereby direct and appoint, that a seal shall be immediately engraven, having upon one side the representation of our royal person on horseback in armour, the shield azure, three imperial crowns or, the arms ususally ascribed to the renowned king Arthur, with this inscriptions, "Sigillum Honorificum Ordinis Militaris de Balnea;" and on the reverse, the same arms enrolling our royal arms: and our royal will and pleasure is, that the said seal shall for ever hereafter be the seal of the said order of the bath; and that the statutes to be perpetually and inviolably observed within the said order, shall be established and sealed by and with the same seal: and we do hereby for us, our heirs and successors, declare and ordain, that the said statutes to be given by us, our heirs or successors, to which the said seal shall be affixed, shall be of the same force and validity as if the same statutes, and every article of them, had been verbatim recited in these letters patents, and had been passed under the great seal of this our realm. And further, we do hereby ordain, constitute, nominate, and appoint our right truly and right entirely beloved cousin John duke of Montagu to be the first great master of the said order, to hold the said office during our pleasure, with such powers, privileges, and emoluments, and subject to such regulations as shall be, in our pleasure and discretion, to be established by us, our heirs or successors, as aforesaid. And whereas it is absolutely necessary, for the dignity and service of this order, that there should be officers peculiarly appropriated thereto, we do by these presents, for us, our heirs and successors, will and ordain, that there shall be for ever hereafter a dean, genealogist, king of arms, regifter, secretary, usher, and messenger, of and belonging to the said order, whose respective duties, privileges, emoluments, and perquisites shall be particularly expressed and declared in the said statutes; and we do hereby for us, our heirs and successors, constitute, create, and appoint the dean of the collegiate church of St. Peter's Westminster, for the time being, to be for ever hereafter dean of the said order, and do for us, our heirs and successors, give and grant full power and authority to the great master of the said order, for the time being, to constitute, nominate, and appoint, under the seal hereby appointed for the said order, a genealogist, king of arms, regifter, secretary, usher, and messenger of the said order; and from time to time to fill up the places of such officers upon vacancies, according to such rules and directions, as shall for that purpose be laid down and expressed in the said statutes to be given as aforesaid. And to the end that the respective
respective fees to be paid to the several officers of the said order of the bath by such persons as shall be nominated unto and accept the honour of a companion of the said order, may be certain and fixed, we do by these presents, for us, our heirs, and his successors, will and declare that all such fees shall be payable and particularly ascertained and established in and by the statutes to be given and ordained to and for the said order, by us, our heirs or successors, under the seal hereby appointed for the said order, and shall be of the like force and effect as if the same had been particularly expressed and set forth in these our letters patents: and, lastly, we do hereby, for us, our heirs and successors, grant that these our letters patents, or the inculmation or exemplification thereof, shall be in and by all things good, firm, valid, sufficient, and effectual in the law, according to the true intent and meaning thereof; any omission, imperfection, defect, matter, cause, or thing whatsoever to the contrary thereof in anywise notwithstanding. In witness whereof we have caused these our letters to be made patents.

Witnesses ourself at Westminster, the eighteenth day of May, in the eleventh year of our reign."

The badge, cognizance, or ensign of this order, is a rose, thistle, and shamrock, issuing from a sceptre between three imperial crowns, surmounted with the motto of the order; viz. "Tria juncta in uno!" the whole of pure gold, chased and pierced, and is worn by the knight elect, pendant from a red ribbon across the right shoulder. The collar is of gold, weighing thirty ounces. It is composed of nine imperial crowns, and eight roses, thistles, and shamrocks, issuing from a sceptre, enamelled in their proper colours, tied or linked together with fourteen gold knots, enamelled white, having the badge of the order pendant thereto. The star consists of three imperial crowns of gold, surmounted by the motto upon a circle of red, with rays issuing from the centre flower, forming a star, and is embroidered on the left side of the upper garment. The insignia dres of a knight of the bath is a furcoat of white fatten, with a mantle of crimson fatten lined with white, tied at the neck with a cordon of silk crimson and gold with gold tassels, and on the left shoulder is embroidered the star of the order; a white silk hat, adorned with a flathing plume of white ostrich feathers, white leather boots, edged and hollow, crimson and gold frills, a sword in a white leather scabbard, with cross hilts gold. The knights receive the order by investiture in the king's cloak, or, if abroad, by warrant. The ceremony of investiture is as follows. The dean, the knights, and the officers of the order attend in the privy-chamber in their mantles and collars, and proceed from thence, after the levee, into the sovereign's presence, making the usual reverence, in the following order; gentleman usher of the order in his mantle, chain, and badge, bearing the scarlet rod; regifter and secretary of the order in their mantles, chains, and badges; knight king of arms in his mantle, chain, and badge, bearing the sceptre of bath, carrying the ribbon and badge of the order on a crimson velvet cushion; the genealogist in his mantle, chain, and badge; the knights of the order with their mantles, collars, and badges; the dean of the order in his mantle, chain, and badge; the first knight and principal companion, acting as great master. Then by his majesty's command the intended knight is introduced between the two junior knights of the order, preceded by the gentleman usher of the order, with reverence as before. The sword of state is then delivered to the sovereign by the second knight of the order in seniority, and the intended knight is knighted therewith. Then the principal knight companion presents the ribbon and badge to the sovereign, and his majesty puts it over the new knight's right shoulder, who, being thus invested, has the honour to kiss the king's hand. The proceed then returns to the privy-chamber in the order above mentioned. After the investiture, the knight wears only the ribbon and badge; as he cannot wear either the collar or star before his being invested, without a letter of dispensation, which is only granted to those on foreign service. On the revival of the order, king George the First allowed the chapel of king Henry the Seventh in Westminster abbey to be the chapel of the order, and ordained that each knight's banner, which shall be placed over his stall, shall be two yards in length, and one yard three quarters in breadth, fringed about with red and white silk; and that, in the lowest margin, the name and title of the knight shall be inscribed with letters of gold upon a black ground; and that the cresset, helmet, and sword stall likewise be affixed to the stall, together with an escutcheon of his arms and supporters, enamelled within a circle gules, having thereon the motto of the order in letters of gold, and his name and title in like manner as the knights of the garter are in St. George's chapel, Windsor; the arms also of his three effuques are enamelled on one plate, with their names and title affixed thereto, and placed under the knight. At an investiture of the order, each knight is allowed three effuques, who must be by the statutes "gentlemen of blood, bearing coat armour;" they precede their knight in the procession, having for their dres a crimson silk waistcoat with sleeves, breeches, stockings, and shoes with roes, the whole of which are of the same colour, with a furcoat of white silk, lined and edged with crimson, having a hood of the same affixed thereto, and on the right shoulder of the furcoat the plain escutcheon of the order, "azure, three imperial crowns or," a black silk bat or couf: for which service each effuque "shall, during the term of his life, enjoy all rights, liberties, privileges, exemptions, and advantages which the effuques of the sovereign's body, or the gentlemen of the privy-chamber, do lawfully enjoy, or are entitled unto by virtue of any grant, prescription, or custom whatsoever; and the eldest son of every of these effuques shall have and use the addition and title of effuque in all acts, proceedings, and pleadings: provided that all these effuques are to be entitled to these privileges, shall have certificates of their qualifications before their respective admittance, and likewise an exemplification of their actual performing their duties upon the creation of any knight or knights of the bath, attested by the great master under the seal of the order." An effuque of the order is allowed to hunt and fish in the king's royalty, and is exempt not only from serving the office of high sheriff, but any parochial office. To prevent any abuses in the claiming these privileges and exemptions, the following notice was inserted in the gazette, previous to the installation of the order in 1803, when twenty-two knights were installed, attended by their effuques, sixty-six in number.

"It is hereby notified, that no exemplification will be intided to any effuque, from his royal highness the duke of York, after the ensuing installation, until it shall be certified to his royal highness by the genealogist, that the pedigree and coat armour of the several knights and their respective effuques have been entered in the genealogical books of the order, in obedience to the said statutes.

Given at the Horfe-guards, this 13th day of May 1803; Frederick, acting as great master of the said most honourable military order of the bath."

The dres of the officers of the order is as follows: viz. the mantle and cordon of the dean are the same as the knights; he wears a golden chain, with the badge of the order, but no collar. The genealogist, king of arms, registrator, secretary, and usher's is a white fatten mantle or robe lined with crimson, having
having on the right shoulder the badge of the order tied about the neck with a cordon, the same as the knight's; under it is a fur coat like the equeire's, with a gold chain about their necks, to which is pendant an elcutecheon of gold, thereon enamelled the badge of the order; except that on collar days, the badge is worn pendant to a red ribbon. The office of

genealogist is a distinct office of record for the pedegrees and coat armour of the knights of the order and their equeires, which are entered in a regular series from the year 3399 to the present time. The office of genealogist has, from the revival, been火炬ily filled by John Anfis Esq., John Susfield Browne Esq., and George Naylor Esq., York herald, its present possessor.

The order of the bath doth not appear to have been of greater antiquity, in this kingdom, than the reign of Henry IV. who, on the day of his coronation, conferred that dignity upon forty-six equeires, who had watched all night before, and had bathed themselves; yet this degree of knighthood may jully boast of a much earlier antiquity. The learned William Camden, and Jean Du Tillet suppose it to have been conferred by the old Franks or inhabitants of lower Germany; with whom Mr. Anfis (who was genealogist of the order on its revival) is of opinion, the Saxons, who invaded England, had the same common decency; and who, upon their settlement in England, introduced the same method of knighthood. Du Tillet further remarks, that those ancient Franks, when they conferred knighthood, observed many solemn rites. Before they performed vigil, they bathed, to signify that such as were admitted to this degree should be of a pure mind and beonst intentions; be willing to conflict with any dangers or difficulties in the cause of virtue; take care, both in their words and actions, to follow the maxims of prudence; and, on all occasions, religiously observe the motto of the order, "Trias juncta in uno," which implied a true belief of the Trinity; which rites and conditions, according to his testimony, still continued to be practised in England; and from the practice of these, gentlemen were denominate knights of the bath. Mr. Anfis, with his usual precision and clearness, hath fully proved that William the Conqueror, and the succeeding kings of England, conferred this degree of knighthood as well in Normandy as in England. We have a very particular detail of the ceremonies that were used in creating knights of the bath, at the coronation of king Henry V.; and our historians and records amply vouch that from that time, till the reign of king Charles II. inclusive, it was the usual practice to create knights of the bath at, or previous to, the coronation of our kings, the creation of princes of Wales, and at the celebration of their nuptials, and those of others of the royal family. King Charles II., previous to his coronation, created no less than sixty-eight knights of the bath; from which time no knights of that degree were created, until the revival by George I. in 1725.

Bath Metal is a preparation of copper with zinc, which gives a more beautiful colour than the calamine used in the preparation of the common brat.

Bath Kol, in Jewish Antiquity, a species of revelation by a voice or echo from heaven.

The word signifies, in the Hebrew original, daughter voice, or daughter of a voice; for it may be interpreted both ways. It seems to have been thus called with respect to the original voice delivered from the mercy-seat, when God was confounded by urim and thummim: this latter was the grand and primary voice of revelation; the former, of secondary dignity, and inferior to it as the daughter to the mother.

The Jewish writers speak of three kinds of revelation among them: the first by urim and thummim, which obtained from the creating of the tabernacle to the building of the temple; the second by the spirit of prophecy, which prevailed from the beginning of the world to the death of Malachi; the third, the bath kol, or filia voceis, which took place when the spirit of prophecy wholly ceased in Israel; and was, says Grotius, the sole oracle which remained during the time of the second temple.

This bath kol says Dr. Prideaux, was no such voice from heaven, as the Jewish, and particularly the Talmudical, writers pretend; but only a fantastical mode of divination of their own invention, resembling the "Sortes Virgilianae" among the heathens. (See Sortes.) Prid. Conn. pt. 2. b. 5. vol. 3. p. 483. Godw. Mofes and Aaron, lib. 4. c. 8. Lightfoot's Works, tom. i. p. 485. Grot. in John, xii. 28.

Danzius has a dissertation on the iniquity and imposture of the bath kol: "De filia voceis nefaanda, divina secula."

BATHA, in Ancient Geography, the ruins of an ancient city of Africa, in the kingdom of Algiers, about 2 leagues south of Oran, which was destroyed in the wars that raged between the African powers, about the beginning of the sixteenth century. It has been remarkable, in more modern times, for a little chapel, erected in memory of a marabout, who lived among these ruins, and by the presents he received for his hospitality to travellers, became rich enough to maintain 500 disciples, whose employment it was to go through a long litany of all the divine attributes, by the help of their beads, at certain hours of the day: but the sect has of late declined and is almost extinct.

BATH, a town of Ethiopia, near Egypt. Pliny.

BATH, Bach, or Bachia, in Geography, a town of Hungary, sittuate near the Danube, and capital of a county of the same name. It was formerly the see of a bishop, now united to Coloeza; 20 leagues south of Buda. N. lat. 46° 40'. E. long. 20° 40'.

BATH, a town of Ethiopia, on the confines of the country called by the Arabs Berbera, and more commonly Zanguebar.

BATH, a name sometimes given to the isle of Bas; which see.

BATHASCECH, a town of Lower Hungary, in the county of Tolna, on the Sarwitz.

BATHENAS, in Ancient Geography, a town of Syria, between Cyrrhus and Edessa. Anton. Itin.

BATHGATE, or BATHGET, in Geography, a market-town in the county of Linlithgow, in Scotland. There are three fairs held annually in Bathget: second Wednesday in April, first Wednesday after Whitsunday, O. S. fourth Wednesday in June, third Wednesday in July, third Wednesday in August N. S. and first Wednesday after Martinmas. The circumsinate country is rather hilly, yet by no means defultive of agricultural improvement: the soil of late is made to yield abundant crops; and rural economy advances daily. In a moras, about a quarter of a mile from Bathget, some flight traces of the principal residence of Waller, high steward of Scotland (the founder of the royal house of Stuart), are still discernible. The mansion, and lands thereto belonging, were the dowry bestowed on the high steward's wife, lady Margery, by her father king Robert the Bruce, in A. D. 1316.

BATHING, the act of using or applying a bath; that is, of immersing the body, or part of it in water, or other fluid. See Bath.

Bathing, on a religious account, is more properly called ABULATION, OR BAPTISM.

Bathing is a practice of antiquity. The Greeks, as early as the heroic age, are said to have bathed themselves in the flood.
fea, in rivers, &c. We even find mention in Homer of hot baths in the Trojan times; but these seem to have been very rare, and only used on extraordinary occasions. Athenaeus speaks of hot baths as usual even in his age. In reality, public baths appear to have been discouraged, and even prohibited, by the ancient Greeks, who were content to wash themselves at home in a fort of bathing tubs. Pott. Archael. 

The method of bathing among the ancient Greeks, was by heating water in a large vessel with three feet, and then pouring it on the head and shoulders of the person seated in a tub for that purpose, who, at coming out, was anointed with oil. Buret, in Hist. Acad. Infer. tom. ii. p. 117. The Romans were also long before they came into the use of baths: the very name of which, thermes, they borrowed it from the Greeks. As the ancient Romans were chiefly employed in agriculture, their custom was, every evening, after work, to wash their arms and legs, that they might fit down to supper with more decency: for it is to be observed, the use of linen was then unknown, and the people of that age went with their arms and legs bare, and consequently exposed to dust and filth. But this was not all; for every ninth day, when they repaired to the city, either to the quinaria, or to attend at the assemblies of the people, they bathed all over in the Tyber, or some other river which happened to be near to them. This seems to have been all the bathing known till the time of Pompey, when the custom began of bathing every day. Mercurai, de Art. Gymn. lib. i. c. 16. Mem. Acad. Infer. tom. ii. p. 414.

The Celtic nations were not without the use of bathing: the ancient Germans bathed every day; in winter in warm water, and in summer in cold. This is what Tacitus seems to allude to, “atinim e quadra-vastator, farius cildia, aut aperit quod plurimum ibiens occupat.” De M. G. Ger. cap. 22.

Bathing, among the ancients, made a part of diet, and was used as familiarly as eating, or sleeping; and cold bathing was in high esteem among their physicians for the cure of diseases; as appears from Strabo, Phai, Hippocrates, and Oribasius: whence occur frequent exhortations to washing in the sea, and plunging into cold water. The first instance of cold bathing, as a medicine, is Melampus’s bathing the daughter of the king of Argos; and the first instance of warm bathing, is the use of it by Medea, who was said to boil people alive, because Pelias king of Thessaly died in a warm bath under her hands. The cold bath was successfully used by Antonius Muza, for the recovery of Augustus; but after the death of Marcellus, who was thought to have fallen a sacrifice to the improper use of it, the practice sunk into neglect. It was again revived towards the close of the reign of Nero, by a physician of Marcellus named Charmis; but it was afterward diffused during the ignorance of the succeeding ages. Among the Turks, bathing forms a part of diet and luxury; and in every town, and even village, there is a public bath, for those who have not the convenience of private baths attached to their own houses. Baron de Tott (Memoirs) gives us the following account of the construction of the private baths. Two small chambers, built with brick and faced with marble or plaster, communicate with each other, and each of them is enlightened by a small cupola cut in chequers. This little edifice is commonly joined to the house by a small room, in which those who bathe undress: double doors, folding over and lifted with false, but in the first and second part of the floor. A wood fire is kept in a subterranean vault, the entrance into which is from without. This fire-place is under the farthermost chamber, and heats a caldron immediately beneath the marble floor, which serves as a ceiling to the vault. Pipes, placed within the walls, proceed from the inlets of the caldron, and go out at the cupola, for the purpose of evaporating the water, which is kept continually boiling. Other tubes, communicating with a reservoir, are likewise contained within the brick work, and furnish the inlets with cold water, by means of cocks placed at the sides of those which yield the warm water. Small seats of smooth wood are made to fit on, and drains cut in the marble to carry off the water which is thrown down. These private baths, always heated twenty-four hours before they are used, by being thus constructed, possess such a degree of heat, that persons, who undress in the exterior chamber, and put on high sandals of wood to prevent the feet from being burnt by the marble floor, cannot enter the first room with safety till they have stopped a moment between the two doors, to let the lungs dilate; after which they cannot enter the second floor, under which the heat is most active, without similar precaution. A sudden perspiration rushing through all the pores, is felt immediately as they are entered; but the violence of this heat does not prevent the women from staying in these baths five or six hours, and returning to them very frequently. The following description is from the public bath, and the method of using it, is abstracted from the account given of the baths at Cairo by Savary, Travels, vol. i. p. 145, &c.

The first apartment, or undressing chamber, is a lofty and spacious hall, which rises in the form of a rotunda, and is open at the top for admitting a free circulation of the air. A spacious erate, or raised floor, covered with a carpet, and divided into compartments, goes round it, on which the persons who bathe lay their clothes. In the middle of the building a jet-d’eau spouts up from a basin, and agreeably entertains the eye. When you are undressed, you tie a napkin round your loins, put on a pair of sandals, and then enter a narrow passage, where you begin to feel the heat. The door being fast, at the distance of twenty paces you open a second door, and proceed along a passage, which forms a right angle with the former: here the heat increases. Those who are afraid of suddenly exposing themselves to a stronger degree of it, stop in a marble hall, in the way to the bath, properly so called. The bath itself is a spacious and vaulted apartment, paved and lined with marble, around which are four closets. The vapour, incessantly rising from a fountain and cistern of hot water, mixes itself with the burning perfumes, when perfumes are dispensed by the persons who bathe. The bathers, extended on a cloth that is spread out, and with the head supported by a small cushion, stretch themselves freely in every posture, whilst they are enveloped by a cloud of odoriferous vapours, which penetrate into all their pores. After reposing there for some time, till a gentle moisture is perceived over the whole body, a serviant pressures you gently, turns you over, and when the limbs are become supple and flexible, he makes all the joints crack without any difficulty. He masses i.e. delicately touches, and seems to knead the flesh, without making you feel the slightest pain. When this operation is finished, he puts on a glove covered with a piece of coarse stuff, and rubs you for a long time; and during this operation, he detaches from the body, running with facet, a turf or sort of small scales, and removes even the imperceptible filth that floats the pores. The skin becomes soft and smooth like satin. He then conducts you into a closet, pours a lather of perfumed soap upon your head, and then withdraws. The closet is furnished with a cistern and two cocks, one for cold, and the other for hot water. After having washed in this apartment, the servant brings a depilatory potion, composed of a mineral called “minima,” which is of a deep brown, and which the Egyptians burn lightly, knead with water, and mix with half the quantity
quantity of flaked lime. This greyish paste, applied to the
hair, makes it fall off in a little time, and it is generally used
both by men and women in Egypt. After being well washed
and purified, you are wrapped up in hot linen, and conducted
through the windings that lead to the outer apartment: and
by this gradual transition from heat to cold, or by stopping
for some time in the hall next the flore, no inconvenience
arises from the use of the bath. On arriving at the atraito,
you find a bed prepared for you, and as soon as you are laid
down, a child presses every part of the body with its delicate
fingers, in order to dry you thoroughly. Here you change
linen a second time, and the child gently grates the callous-
y of your feet with pumice stone. He then brings you a pipe
and Mocha coffee.

By these baths, says Savary, the use of which the ancients
strongly recommended, and which are still the delight of the
Egyptians, they prevent or dippel rheumatism, catarrh, and
such cutaneous disorders as are produced by want of periphe-
ration. Thus the blood is made to circulate with freedom,
the whole body acquires a suppleness and lightness, and the
spirits gain a vivacity and flow, which are not experienced in
an equal degree by those who do not pay so much attention
to external cleanliness. The ancients were particularly fond of
these baths, and frequented them at least once a week. After
undergoing the usual preparations, they wash their bodies,
and more especially their heads, with rose-water. Here the
female head-dressers form their long black hair into tresses,
to which they apply costly essences, instead of powder and
powder-mum. Here they blacken the edges of their eye-lids,
and lengthen their eye-brows with "colot," or a preparation of
tin burnt with gall-nuts. Here also they flain their finger
and toe nails with "heume," (See AlCanna), which gives
them a golden colour. The linen and clothing which they
use are passed through the sweet steam of the wood of aloes.
The days, appropriated to the use of the bath, are festivals
for the Egyptian women; and on this occasion they pay
great attention to the ornamens of their draps, as well as to
the cleanliness of their persons.

Baths similar to that above described, though differing in
size, are constructed in all the principal towns of Egypt.
The necessity of cleanliness in the eastern climates, where
perpiration is so copious, has rendered baths indispensable:
the comfort they provide preserves the use of them; and
Mahomet, who knew their utility, has re-enforced the prac-
tice of ablution and bathing by precept express.

Mr. Tooke (View of the Russian Empire, vol. ii. p. 7, &c.)
informs us, that the common Russians, in general, use but
few medicines; supplying their place in all cafes by the
sweating bath, a practice universal among them, and which
has a decided influence on the whole physical state of the
people. The use of the bath, that venerable relic of the
manners of the ancient world, as this ingenious writer de-
nominates it, is now almost entirely confined to the Oriental
nations, where it minerals both to health and to luxury, and
is perpetuated by religion. In Europe it has been gradually
decaying for several centuries, though it was here also in
some fort interwoven with religion, the holy water of the
Roman catholic church being a slight remnant of it.

Russia and Hungary are at present the only countries in
this quarter of the world, where it is still the custom to
bath in the manner of the ancients. In Russia particularly
the bath forms so essential a part of the system of living,
that it is used by people of every age; and in all circumstantial
cases, by infants, by lying-in women, in almost all fecknesses,
before and after a journey, after hard work, &c. The bath is
a necessary of life so indispensable to the common people, that
they frequent it as often as possible, well or ill, and without
any particular occasion, once a week at least. Perforce of
middle station in good circumstantions, and the great, usually
contrive vapour baths, after the Russian fashion, in their own
houses, though in these classes the practice is declining under
the increasing influence of foreign manners. Baths have
been common in Russia from time immemorial. They are
recommended by Nektor fo long ago as the 11th century, precisely
in their present form. Among the ancients the baths
were public buildings, under the immediate cognizance of the
government. The invention of them was owing to cleanliness
and convenience; but in processes of time all the graces
of architecture were lavished upon them; and at length luxury
and voluptuousness fo perverted them from their primitive
purposes, that they became offensive and shocking to the
moralists of antiquity. Alexander was inflamated at the mag-
nificence of the baths in Perlas. At Rome, under the
emperors, there were once 870 of these edifices, such, with
respect to magnificence and taste, as might pass for master-
pieces of art; and in after ages they were demolished by the
Goths, or converted by bishops into churches. In our days,
however, Hungary is the only country that can fill exhibit
baths, equal in magnificence to those of the ancient Romans.
In Russia, to the contrary, they are always of that simple
construction, which indicates their principally and most essential
delination. Here the public baths, called public because
they are under the care of the police, and let out to com-
mon people on the crown's account, unblitlly consist of mean
wooden houses, situate, whenever it is possible, by the side
of a running stream. In the bath-room is a large vaulted
oven, which, when heated, makes the paving stones lying
upon it red-hot; and adjoining to the oven is a kettle fixed
in masmony, for the purpose of holding boiling water. Round
the walls of the rooms are three or four rows of benches one
above another, like the seats of a field. The room has
little light, but here and there are apertures for letting the
vapour escape; the cold water that is wanted being let in
by small channels. Some baths have an anti-chamber for
dressing and undressing; but in most of them this is done in
the open court-yard, which on that account has a boarded
fence, and is provided with benches of planks. In those
parts of the country where wood is scarce, they sometimes
confit of wretched caverns, commonly dug in the earth close
to the bank of some river. In the houses of wealthy indi-
viduals, and in the palaces of the great, they are constructed
in the same manner, but with superior elegance and conveni-
cence. The heat in the bath-room is usually from 32° to 40°
of Reaumur; and this is much increased by throwing water
every five minutes on the glowing hot stones in the chamber
of the oven. Thus the heat often rises, especially on the
uppermost bench, to 44° of the thermometer. The persons
that bathe lie quite naked, on one of the benches, where
they perspire more or less in proportion to the heat of the
humid atmosphere in which they are enveloped. For promot-
ing perpiration, and more completely opening the pores, they
are first rubbed, and then gently fregilated with leavy bunches
of birch. After remaining for some time in this state, they
come down from the sweating bench, and wash their bodies
with warm or cold water, and at last plunge over head in
a large tub of water.

Many persons throw themselves immediately from the
bathroom into the adjoining river, or roll themselves in the
snow in a frock of ten or more degrees. The Russian baths are,
therefore, "sweating baths," not the Roman tepidaria or caldaria of a moderate warmth,
but very violent sweating-baths, which to a person uninhabi-
tuated to the practice, bring on a real, though a gentle and
almost voluptuous swoon. They are "vapour-baths," not

water
water nor yet dry sweating-baths; differing in this respect from all the baths of antiquity, as well as from those of the modern Orientals; and in this consists their essential excellence, that they are beneficial in such a variety of cases, where hot-water baths would be useless or even pernicious. They are further to salutary baths," as they promote cleanliness, affix the perspiration, render the skin soft and smooth, &c. and not voluptuous baths like those of the Greeks and Romans. All the inventions of efficacy and luxury are entirely elevated; and of anointing after the use of the bath, indispensable in those, the Russian is wholly ignorant. Instead of this the sudden transition from heat to a rigorous frost hardens his body, and adapts it to all the severities of climate, and to every vicissitude of weather; a transition which seems to us unnatural or dangerous, merely from the prejudices of a soft and effeminate age.

Mr. Tooke adds, that, without doubt, the Russians owe their longevity, their robust state of health, their little distillation to certain mortal diseases, and their happy and cheerful temper, mostly to these baths, though climate, aliment, and habits of living likewise contribute their share.

The great lord chancellor Bacon, and other sagacious observers of nature, and of mankind, have lamented, and certainly not without cause, that the practice of bathing has fallen into disuse among the modern nations of Europe, and anxiously wish that it might again revive in all our towns and villages. In fact, when we consider, says Mr. Tooke, that the old physicians to early introduced into their practice this remedy of nature's own invention, and employed it with such great success; when we recollect that Rome for 500 years had no physicians but only baths, and that to this day a multitude of nations cure almost all their maladies merely by baths; we cannot avoid regarding the diffusion of them as the epocha of a great revolution, which has been wrought in the physical state of the human race, in one quarter of the world. The natural perspiration, the most important of all excretions, must naturally go on better in a body constantly kept soft by bathing. Many impurities that passily lay in us the train to tedious and dangerous diseases are removed in time, before they poison the blood and juices. All exanthematic diseases are abated by bathing, and consequently the small-pox; and if this dreadful disorder be actually less fatal in Russia than in other countries, this phenomenon need not be attributed to any other cause besides vapour-baths.

Bathing, medicinally consider'd, ranks among the most efficacious means by which diseases are prevented or cured. Its effects vary according to the variation of temperature, and according to the qualities of the liquid medium employed; that is, according as the bath confits either of common water, or of water containing salt or other mineral ingredients (see Mineral Waters), or of water impregnated with the virtues of aromatic or other herbs. These last, which go under the name of medicated baths, are seldom used; and when they are, we are inclined to believe that it is to the watery medium, rather than to the specific properties, that their beneficial operation is to be ascribed.

Under the present head, we shall confine ourselves to the consideration of the effects produced by bathing; so far as they depend upon a diminution or increase of temperature above or below the natural standard of the human body.

Baths of different degrees of temperature, corresponding to the familiar terms, cold, temperate, and hot, are suited to different and opposite states of the body. The manner of using them is also different; the time of immersion or lying in them varying according to the difference of temperature, and according to the required quantum of impression or effect, as will be particularly noticed in treating of each. And, first of the

COLD BATH, by which is understood water of a temperature from 65 to 33 Fahrenheit. The general effects produced in a healthy person by immersion into an ordinary cold bath (that is, water of the temperature of 38 or 50), are, according to the accurate statement of Dr. Saunders, as follow: "First, there is a general sensation of cold, forming that sudden shock to the whole system, which is one of the most important effects of the cold bath. This is almost immediately succeeded by an equally universal state of warmth, which increases rapidly to a certain point, so as to cause the surrounding water, though actually cold, to feel of a comfortable warmth; and this feeling is sooner produced, and continues longer, in proportion as the person is in full health, and naturally possesses a vigorous circulation. By degrees, however, if the body continues immeasured, it becomes chilled; violent shivering comes on; the extremities grow numb and pale; sometimes sickness takes place; and, at last, the animal powers are exhausted by cold and fatigue. In this process, the most remarkable effects are those which occur first, and are directly consequent to the shock of immersion; and these require particular attention in a medical view, as it is only to the production of these that the cold bathing should be ascribed to proceed. The sensations of returning warmth which take place directly after the cold of the first immersion, constitute what has been called the reaction of the system; and this is certainly a proper and characteristic term, as it imports an action produced in the body itself, to re-establish an external impression. Reaction in this place seems to be a peculiar effort of the living power, and to be excited in a degree proportionate to the force of that power, and to the intensity of the caufe which called it into action. It implies not merely an increase of the production of animal heat, but, superadded to this, a sudden effort within the body, and the whole arterial system, to overcome an impression on the extremities as sudden and powerful. Hence it is, that a mere abstraction of heat, by a cold medium, will not produce that which is precisely meant by reaction, except the external cold be applied suddenly, and to a large surface. These two conditions are fulfilled by sudden immersion into cold water. The superior power of conducting heat which water poiffesses over air, is also a circumstance that is always to be kept in mind in applying cold externally. This is particularly shewn where a person continues long in this cold medium beyond the first effects of reaction. On account of the high conducting power of water, the body must be constantly employed in producing an unusual quantity of heat; and this appears to be a great effort in the constitution, which, if carried too far, goes directly to destroy the animal powers." Thus three effects are produced by immersion in cold water; viz. an instantaneous and powerful shock, a sudden abstraction of heat from the surface of the body, and that exertion of the vital energies to counteract the shock and reëstore the lost quantity of animal heat, which is termed reaction. It is easy to perceive, that when the body is placed under such circumstances for a few seconds, a considerate impression must be made, first, upon the sentient system, i.e. the brain, and its ramifications, the nerves; and, secondly, upon the languidous and absorbent systems; and that such impression may be rendered sublative to the prevention and cure of various diseases. Accordingly, the cold bath is a principal remedy, first, in many convulsive affections, and in maniacal attacks; and, secondly, in certain forms and conditions of fever.
1. In the convulsions to which children are so liable, Dr. Currie of Liverpool (whose observations on the subject of cold bathing have been too often quoted) has found that this application is a most useful remedy, whether the convulsions originated in worms, or other causes. In early infancy, however, he remarks, that he has used it with caution, sometimes tempering the water when the weather was cold, and sometimes pouring it upon the patient, rather than immersing the patient in it; making the application of the cold water in this way sudden and transient, so as to secure reaction, and avoid the remedy entirely in all cases where the vital energy seemed much exhausted. He further remarks, that the chief benefit derived from the cold bath in convulsive disorders, depends on its being used in the paroxysm of convulsion. It not only shortens the duration or abates the violence of the existing paroxysm, but has a remote good effect in retarding or wholly preventing its return. In that convulsive disorder termed *chorea Sic. Vitii*, the cold bath, though strongly recommended by most practitioners, has not succeeded with this author; and he candidly acknowledges, that his experience of its effects in epileptic fits is as yet too limited to enable him to form any satisfactory conclusion. The late Dr. Heberden, whose experience in these affections was considerable, had no great opinion of it. Against *tetaos*, whether idiopathic or arising from local injury, this remedy has been employed with the most decided good effect, particularly in the tropical climates; nor has it proved less beneficial in maniacal paroxysms. See Dr. Currie's work hereafter quoted.

2. In certain forms and conditions of fever. In the sexes, cold bathing, whether by immersion or affusion, is of eminent service when properly applied; as, by abstracting the preterrestrial degree of heat, it aids the body of an exhausting fluxus and irritation, and thereby abates the frequency of the pulse, the delirium, and other febrile symptoms. It may be reftored to in mott fevers (some of the exanthematical fevers excepted) where the skin is hot and dry; but it is especially adapted to the *typhus* or *common contagions* fever of this country, the acutest fevers of the hot climates, and the yellow fever of the West Indies, &c.—"The safest and most favourable time" (says Dr. Currie) for using the affusion or immersion of cold water, is when the exacerbation is at its height, or immediately after its declination is begun; and this has led me almost always to direct it to be employed from fix to nine o'clock in the evening; but it may be safely used at any time of the day, when there is no feell of chilliness present, when the heat of the surface is readily above what is natural, and when there is no general or proflate perpiration." It is of the utmost importance that medical practitioners be careful not to apply this remedy during the cold fit of fever, when it would extinguish life; nor to apply it when the heat of the body is less than natural, or even only equal to the natural heat; nor when the fever-patient is in a state of perpiration. Cold bathing has also been tried in the *febrile*; but in this species of eruptive fever as well as in measles, the application of cold water to the surface of the body is, in our opinion, by no means advisable. Another caution we would subjoin with regard even to fevers that are not eruptive; viz. that when they are complicated (as often happens in this climate) with pneumonic inflammation, cold ablation is inadmissible. Cold bathing has often been recommended in certain glandular diseases, and particularly in *ferulosa*. Accurate observation, however, has proved, that in these cases it is generally hurtful; and that for such complaints, a temperate bath, whether of fresh or salt water, is preferable.

Having thus described the general effects of cold bathing, as well as its particular application to certain flutes of disease; we have only further to add a few words respecting the manner of using it. In the case of *immersion*, the time of staying should in general not exceed a minute or two, where the degree of cold is below $50^\circ$; but in the summer and autumnal fevers, immersion in rivers, and especially in the sea, may be continued as long as is pleasant to the feelings of the bathers; provided the body is at the same time exercised in swimming. Much mischief, however, is frequently done by staying in too long.

It has been commonly supposed, that if a person has made himself warm with walking or any other exercise, he must wait till he becomes cooled before he should plunge into the cold water. Dr. Currie, however, has shewn that this is an erroneous idea, and that in the earlier stages of exercise, before profuse perspiration has dissipated the heat, and fatigue debilitating the living power, nothing is more safe, according to his experience, than the cold bath. This is so true, that he has for some years constantly directed infirm persons to use such a degree of exercise before immersion, as may produce some increased action of the vascular system, with some increase of heat; and thus secure a force of reaction under the shock, which otherwise might not always take place. The popular opinion, that it is false to go perfectly cool into the water, is founded (he observes) on erroneous notions, and sometimes productive of injurious consequences. Thus, persons heated and beginning to perspire, often think it necessary to wait on the edge of the bath until they are perfectly cooled; and then plunging into the water, feel a sudden chilliness that is alarming and dangerous. In such cases, the injury is generally imputed to going into the water too warm, whereas in truth it arises from going in too cold.

Besides immersion, there are other modes of cold bathing; such as *affusion*, which consists in suddenly pouring upon the body a sufficient quantity of cold water from buckets or other vessels. This mode of applying cold water produces a very considerable shock, and consequent reaction. It is this mode of cold bathing that has been reforted to with advantage in the contagious fevers of this climate, and in the yellow fever of the West Indies. What is termed the shower-bath is only another mode of affusion.

As cold bathing is a remedy which is successfully employed for the cure of various disorders, so is it a preservative against others, and particularly against febrile infection. When used by persons in health, it increases the tone of the muscular fibre, strengthens the digestive organs, and by diminishing the sensibility of the whole system, and particularly of the skin, renders the body less susceptible of atmospheric impressions from cold, wet, and sudden changes of temperature; thus contributing to the production of what is termed a robust or athletic constitution. A temperate bath (i.e. from $70$ to $85$, or more) is applicable to the same cases as the cold bath, and may be used in the same manner. It is preferable in many cases where the shock of the ordinary cold bath is too great.

If after going into the cold bath a person feels dull or chilly, or complains of head-ache or tightness across the chest, it is a proof that it disagrees, and it should accordingly be discontinued. It should further be remarked, that this remedy is not suited to those who have a tendency to consumption, nor to such as are constitutionally liable to bowel complaints. The best sessions of the year for cold bathing are the summer and autumn.

We now proceed to the consideration of

*Warm Bathing*: a remedy not less efficacious than the former in diseases of an opposite nature; but concerning
concerning the operation of which, wrong notions have till very lately been entertained by the generality of medical writers and medical practitioners. It has been imagined that the warm bath relaxes (a figurative expression) and weakens, whereas it produces a contrary effect; unless indeed the temperature be so high, or the time of immersion continued so long, as to bring on that degree of debility which is accompanied with debilium. But this arises only from an abuse of hot bathing, and is even then the consequence of an excess of stimulation. So far is immersion of the body in water heated to 96 from having a lowering or weakening operation, that when duly regulated it is found to raise the spirits, to mend the pulse and appetite, and to refresh and invigorate the whole frame. Hence the benefit derived from it after great fatigue; in old age; in atomic gout, accompanied with blushing and pallid swellings of the joints; in paralysis; in chlorosis, in diffusely arising from a certain torpor of the lymphatic and glandular system, such as scrophula, leprosy and other chronic eruptions, &c. In cases of predispition to phthisis, it abates the frequency of the pulse, and tends to retard at least, if it does not wholly prevent, the pulmonary affection. In consequence of its soothing and agreeable impression upon the surface of the body, it produces very beneficial effects in certain disordered states of the alimentary canal, originating in diminished action; and it affords the heat and specific relief in a great variety of painful disorders, whether connected with local inflammation or not; such as chronic rheumatism, certain forms of lues venera, nephritis, calculus vesice, colic, enteritis, &c.

The time of immersion should be varied according to the temperature of the water, and the feelings of the patient. In a bath of 96, a person may remain fifteen, twenty, or thirty minutes, or even longer; but in one of 98 or 100, it will seldom be proper, and indeed there are few persons that can bear, to remain beyond ten minutes, and in the generality of cases not so long. Patients labouring under chronic rheumatism and palpily bear the high degrees of temperature best. When sweating is desired (which will seldom happen except in cases of local inflammation), the warm bath should be used in an evening, and the patient should immediately afterwards be put into a warm bed, and remain there until late the next morning: but in all other cases, where sweating is not required, or in which it would be hurtful, the better time for using the warm bath will be in the forenoon, about two hours after breakfast. In these cases, the bathers should not retire to bed, nor confine themselves within doors, but go about as usual; unless the weather should be particularly damp or inclement. Hot bathing, like cold bathing, is applied typically by pumping on the diseased part, as will be described when we come to treat on mineral waters. Sometimes it is applied to the body instead of warm water. See VAPOR BATH.

Among the works on cold and warm bathing, the following are those which seem most entitled to notice: viz. "Foyler onCold Bathing," 1759. It should be remarked, however, that this author writes without method on this subject; that he is too indifferent in his praises of the cold bath, and that he recommends it in some diseases of debility to which warm bathing is better adapted. "Marcard über die Natur und den Gebrauch der Bänder." Hanover, 1793. Currie's "Medical Reports on the Effects of Water, cold and warm," 1797. And the 6th chapter of Dr. Sanders's "Treatise on Mineral Waters," 1800. Bathing for Wound or Ulcer is, when being weaned from her grange, if a piece, and also hired, rewarded, and thoroughly reclaimed, she is offered some water to battle her.

fell in, in a bafoon, where she may stand up to the thighs, choosing a temperate clear day for that purpose. By the use of bathing she gains strength, with a sharp appetite, and so grows bold.

Bathing, among the Coptic and Æthiopians, denotes the day of Christ's baptism, reputed the 6th of January; when, from an opinion of an extraordinary facility in the waters on that day, they not only, by ancient custom, baptized their catechumens, but were re-baptized themselves. The water of this day they carry home to keep; and Chrysostom affirms us, that it had been often known to remain sweet and uncorrupted for two or three years. Ort. 74.

Bathing-Tub. In the Roman baths there are two kinds of bathing-tubs; the one fixed, and the other moveable. Among the latter, some were contrived in purpose to be suspended in the air; whereby, to the pleasure of bathing was added that of being swang or rocked by the motion given to the bathing-tub. Burette, in Hist. Acad. Inscript. tom. 1. p. 132.

BATHNUS, in Ancient Geography, a river of Pannonia, near which the young men of the country assembled, laid down their arms, and threw themselves at the feet of the victorious Romans.

BATHois, Batoum, a river of Asia, in the territory of Colchis, which ran from the east to the west, and discharged itself into the Euxine sea, 6 leagues south of the mouth of the Phasis.

BATHUS, in Entomology, a species of Papilio (Pheb. rut.) that inhabits Surinam. The wings are two-tailed, with a black ocellar spot; beneath brown, fuscated with white; anal angle rufous. Fabricius.

BATHMONSTER, in Geography, a town of Hungary, separated by the Danube from BATH.

BATHOS, in Ancient Geography, a town of the Peloponnese, in Arcadia, near the river Alpheus, according to Paulyanias; who adds, that they celebrated every third year the mysteries of the greater godstheles in this place.

BATHRACUS, a port of Africa, in Marmeria. Pho.- lemy.

BATHRITITES, the name of a name of Egypt, whence, according to Eusebius, king Vaphres sent fuccour to king Solomon.

BATHRUM, a name given by ancient surgeons to a kind of fluid or bench proper for the reduction of dilated bones. This is called Βαθρον τερατωτικα, or the Hippocratic fluid. Its description and use are represented at large by Schulerus, Arm. Chir. p. 1.

BATHURST, Ralph, in Biography, born at Howths, a small hamlet belonging to the parish of the old southworth in Northamptonshire, in the year 1620, received the rudiments of his education at the free-school in the city of Coventry; where his progress in the Latin and Greek languages was so rapid and extensive, that he was sent to Oxford, and entered in Gonville Hall (now Worrcler College), October the 10th, 1634, being then only fourteen years of age. He was however soon removed to Trinity College, where his father had been educated, and of which two of his brothers, George and Edward, were then members. Proceeding in his studies, he was elected scholar of the college, June 5th, 1637. In January following he took his degree of Bachelor of Arts; and in the year 1640, he was appointed Fellow of the College. In 1641, he proceeded Master of Arts; and in 1646, was ordained priest by the bishop of Oxford; his inclination, his biographer says, disposing him to theological studies. Finding however, from the troubles that then and for many years after afflicted the
country, little prospect of advancing himself in that line, he applied to the study of medicine, which, in a letter to a friend some years after, he called "his refuge in bad times, and not his primitive design." But as his mind was vigorous, he soon acquired considerable eminence in this profession; being allotted in his endeavours by Dr. Thomas Willis, with whom he kept up an intimate connection until death deprived him of that valuable friend. In 1654, he took the accumulated degrees of Bachelor and Doctor in Medicine; but he had before far signalized himself, as to obtain the appointment of physician to the sick and wounded of the navy, which office he performed to the satisfaction of the commanders of the ships, and of the admiralty. Quitted the situation, he retired, and settled in Oxford; and, with his faithful friend Willis, attended Abingdon market regularly every Monday, to give advice to such patients as applied. 

He was an associate with Mr. Boyle, Dr. Seth Ward, Christopher Wren, and various other persons, who met every week at the rooms of Dr. Wilkins, to discuss philosophical subjects; which meetings led to the formation of the Royal Society in London, in 1662. A committee or branch of the society continued their meetings at Oxford for several years after, of which Dr. Bathurst was elected president in 1688. On the restoration of king Charles the Second, he quitted the practice of medicine, and refuted his theological studies. In 1663, he was made chaplain to the king; and the year following, president of the college, which was newly rebuilt under his direction. The expense of the building was furnished in part by the college, partly by subscriptions solicited by the doctor, and no small portion of it from his own fortune. About the same time he married the widow of Dr. John Palmer, warden of All Souls College; but had no children by her. In 1670, he was installed dean of Wells. This advancement was procured him by the duke of Devonshire, to whose notice he had recommended himself by an elegant copy of Latin versets to Mr. Hobbes, on his treatise of Human Nature, which was printed with the volume. In 1673 he was made chancellor of the university, and was re-elected to that office the two following years, by which means he had opportunity of reforming many abuses which had crept into the institution, and of establishing many useful regulations which still continue to be observed. As he had contributed largely in rebuilding and beautifying his own college, and was the first in introducing Grecian architecture in Oxford, he now felt about restoring St. Mary's church, which had suffered much during the protectorate. He subscribed 300 l. towards paving the choir with marble, and erecting an organ there. In 1691, he was nominated by king William and Queen Mary, bishop of Bristol, with liberty to keep his deanery and headship of the college; but had the resolution to decline this noble offer, lest it should detain him, he said, too long from the university, and be the means of retarding the improvements he was making there, both in discipline and in the buildings. In the mean while his fame for proficiency in letters became so extended, that he corresponded with most of the first literary characters in the kingdom, who frequently submitted their works to his inspection and criticism before they were published. He was particularly instrumental in advancing Derham, the celebrated author of the "Philosophia Naturalis," from obscurity and indigence; recommending him to the bishop of Salisbury, through whose means he was raised to an eminent situation in the church. As he was a strict disciplinarian, and regularly attended his duty both in the university and at his deanship, he had little leisure for undertaking any extensive works; accordingly, excepting his "Orationes de Respiratione," we have only his "Orations" before the university, on his being appointed vice-chancellor, on laying down his office, and on a few other subjects; with some short poems. These however have been sufficient to establish his character as an elegant Latin scholar. He was very able in his diet, and regular in taking exercise; and had the happiness of enjoying an almost uninterrupted state of good health until he was upwards of four score years of age; when his sight began to fail, and at length he became blind. Walking one day in his garden, the only amusement that remained to him after the failure of his sight, he had the misfortune to break his thigh bone, by what accident it is not said; which occasioned him excruciating torture, and after lingering a few days, he died in 1704. His property, which was considerable, he had directed by his will to be disposed of in the manner he had expended a large part of his income in his lifetime; in donations towards improving his college; in books and medals to different libraries; in donations to the cathedral at Wells, and to the servants of the cathedral and of his own college. The remainder was left among his relations, who were numerous. His directions concerning his funeral, as being singular, and marking somewhat the disposition of the man, we shall transcribe. - "Concerning the place and manner of my funeral (he says) I am not at all folicitous, but shall leave it to the direction of my executor; except it shall please God to give me leisure and opportunity of ordering it at the time of my death, as occasion may then require; only I shall always direct, that it may be performed with all convenient frugality and privacy; and that my mouth and nostrils may be firmly closed up with a plaster of diacol, and my whole head wrapped in cere-cloth; and that I be buried without any cover to my coffin, only with a black pall of woolen stuff loosely nailed on, and hanging loose down." See Life of Ralph Bathurst, by T. Warton. BATHURST, ALLEN, Earl Bathurst, a nobleman not more distinguished by the elevation of his rank, than by his abilities and integrity as a statesman, and by the elegance of his taste and the variety of his accomplishments as a polite scholar, was the son of Sir Benjamin Bathurst, descended from an ancient family of Luneburg, residing at a place called "Batters," and settled in England in the time of the Saxons, at a place called "Batters Hurst," or Batter Grove, in Suffolk, whence the name; and born in Westminster, in the year 1654. At the age of 15 years, he was entered in Trinity College, Oxford, but enjoyed peculiar advantages for improvement under his uncle, Dean Bathurst, who was then president. Having availed himself in an eminent degree of these advantages, he commenced his political career as a senator in 1705, being chosen representative for the borough of Goring in Gloucestershire, which he served in two parliaments. Under this character he distinguished himself in the debates that related to the union of the two kingdoms, and vigorously supported this measure. He likewise concurred in the opposition planned by his two friends, Mr. Harley and Mr. St. John, against the duke of Marlborough and his adherents; and by his spirit and eloquence he was of great service to his party. At the same time he was duly sensible of the merit of those from whom he differed in political principles; and by his conduct toward lord Somers, both in and out of office, he preferred his lordship's esteem and friendship. In his opposition to the whig ministry, he appears to have acted from the conviction of his own mind; for after their dismissal, he accepted no place under government, though his abilities and activity entitled him to notice, and his connection with the principal statesmen of that period might naturally have led him to expect some favourable
able and lucrative prefferent. However, his merit was re-
compenced in 1711, by advancement to the dignity of a peer of
Great Britain, under the title of lord Bathurst, baron Bat-
thurst of Battlesden in the county of Bedford. Upon the
accession of king George I., the political friends of his lord-
ship were in disgrace, and some of them were actually ex-
posed to the profecution of government; and yet his attach-
ment to the unchangeable firm and unchanged. He even
avoided his displeasure in the treatment they suffered,
which he considered as severe and vindictive; and on this
occasion he is said to have observed, in strong and poignant
terms, "that the king of a faction was only the sovereign
of half his subjects." His zeal in defence of his friends
was manifested by his joining in the protests against the
attaintor of lord Bolingbroke and the duke of Ormond; and
by his opposing the prosecution, and concurring in the un-
aminous acquittal, of lord Oxford. In 1716, he opposed the
septennial bill; and united with thirty peers in entering his
reasons for dissenting from it, as a violation of the constitu-
tion. From the commenceinent of the year 1718, he took
an active and distinguished part, for the space of twenty-five
years, in every matter of importance that came before the
upper house of parliament, and he readily opposed the mea-
ures of the court, and the administration of sir Robert Wal-
pole. Lord Bathurst was a zealous advocate for bishop
Atterbury; and distinguished himself, in 1723, on the third
reading of the bill for inflicting pains and penalties on that
ingenious and celebrated prelate. In 1727, he opened the
debate on the king's speech, and strenuously opposed a war
with Spain, which then threatened the country. "What
(faid he) can we get by the war, if it be a successful one? I'll
fay it in one word, nothing. What can we lose, if it be
unprosperous? I'll fay it in one word, in a fyllable, all." In
the year 1731, he supported the bill against permitting
penioners to fit in the house of commons; he moved an
address to the king for discharging the 12,000 Hessian troops
in the pay of Great Britain; and in the next parliament,
he very ably refisted the undue taxation of the poor, on the
bill for the revival of the salt-duty. On another occasion he
disflayed his parliamentary talents, by the support of the
card of Oxford's motion for reducing the number of forces
to 12,000 effective men, and vindicated the expediency and
usefulness of a national militia, as the most proper and con-
stitutional mode of defence in a free country. In a fubse-
fuent debate on the mutiny bill, his lordship declared him-
self, with great eloquence and spirit, against a large fland-
ning army, and in favour of a national militia. Among other
things, he particularly urged the importance of all men in
the kingdom, or at least all freeholders, farmers, and subfi-
tiual merchants and tradesmen, providing themselves with
arms, and training themselves to military discipline. He
likewise declared his utter disapprobation of the method
that had been adopted of alienating the sinking fund, and
applying it to other objects besides the payment of the pub-
lic debts. Lord Bathurst was uniform and active in oppos-
ing the measures of sir Robert Walpole's administration,
particularly with regard to the transactions that regarded
the Spanish depredations, and the convention with Spain,
and the subsequent conduct of the war with that kingdom;
and he exerted himself, with singular ability, in the debate
that lasted two days, on the question, whether this address
should be presented to the king for the removal of this mis-
chief from his majesty's preference and councils for ever.
When his lordship had accepted a place, in conjunction
with some of his friends, his resoeting, in 1743, in vindica-
tion of the propriety and necessity of retaining the Hano-
riac forces in the service of England, was somewhat differ-
ent from the sentiments he had avowed on a former occa-
sion; but he was probably led to approve and defend this
measure by the critical situation of our foreign affairs, and
argued in its favour from a conviction of its prudence and
rectitude. Whatever opinions may be entertained of lord
Bathurst's political principles, and of the general reasons
upon which his opposition to the whig ministry was found-
ed, the history of that period will furnish scarcely any ca-
character, in which we may discover less discrepancy of
conduct than in that of his lordship. We shall clofe this brief
recital of his political history with the testimony of an an-
onymous writer, who delivered it at a time in which his tal-
ents were in their full exertion and display. "Lord Bat-
thurst, in all he says, carries along with him that conviction
which arises from a warm spirit of liberty and virtue, direc-
ted by great abilities and a most exquisite discernment.
He was called to the house of lords by means of the Tory in-
terest, upon a particular exigence of state; and therefore it
might have been presumed, that he was entirely devoted to that
party. Yet he has chosen his principles of government to
happily from what is commendable in both parties, that,
upon whichsoever side he speaks, he is always observed to
lean to the extremes of neither." Gent. Mag. vol. x.

Lord Bathurst was married, in 1704, to Catharine, daugh-
ter and heiress of sir Peter Apsey, by whom he had four
sons and five daughters. Having resigned, in 1744, the
office of captain of his majesty's band of gentlemen penioners,
to which he was appointed in 1732, his lordship was in no
public employment till the year 1757, when he was ap-
pointed treasurer to the present king, then prince of Wales,
in which office he continued till the death of George II.
At his majesty's accession in 1760, he declined the accept-
ance of any employment on account of his age; but in con-
ideration of his distinguished merit, he had a pension on the
Irish establishment of 2000 l. a year. "As his lordship's abil-
ities and integrity," says an impartial and candid biogra-
pher, "in public life, gained him the esteem even of his
political opponents, so in private life, his humanity and be-
nevolence excited the affection of all who were honoured
with his more intimate acquaintance." To his other
virtues lord Bathurst added all the good-breeding, polite-
ness and elegance of social intercourse. No person of rank,
perhaps, ever knew better how to unite "Otium cum dig-
nitate." The improvements he made round his seat at Ci-
rencewill were worthy of his fortune, and showed the gran-
deur of his taste." In this respect Mr. Pope (Works
vol. ii. p. 170. ed. 1775) paid him a just and fine com-
pliment:

"Who then shall grace, or who improve the foil?
Who plants like Bathurst, or who builds like Boyle?"

The same excellent poet, in his epistle to Lord Bathurst on
the use of riches, has no less justly expressed his lordship's
knowledge of the right mode of employing a large for-
tune:

"The fene to value riches, with the art
'T' enjoy them, and the virtue to impart,
Not mealy, nor ambitiously pursued,
Not funk by floth, not raised by fervitude;
To balance fortune by a just expense,
Join with economy, magnificence;
With splendour, charity; with plenty, health;
Oh teach us, Bathurst, yet unsnipp'd by wealth!
That secret rare, between th' extremes to move,
Of mad good-nature, or of mean fell-love."

His lordship's wit, taste, and learning led him to seek the
acquaintance of men of genius; and he was intimately con-

ected
BATHUS, in Entomology, a species of Papilio (Pleh. Rur.), with entire, black wings, glossed with blue; beneath white, with numerous black dots, and a continued fulvous band. Fabricius. Inhabits Austria. This is Papilio Batus of Schmettler, and Papilio Telephi of Eiper.

BATHYCHRUS COLOR, in Planting, a term used by the Greeks to express what the Romans call austerus color. Such a colour was coarse and dull, and wanted the life of the florid colours. See EVANTI Color.

BATHYCOLPUS, in Ancient Geography, a bay and river of Europe, in the Thracian Bosphorus. Hefychius.

BATHYLLUS, and PYLAEDES, in Geography, the inventors of a new method of representing all kinds of theoretical pieces by dancing. Bathyllus was a freedman of Maxenas, the object of his extravagant and licentious attachment; and in compliance with the wishes of Maxenas, Augustus countenanced these players and their act. Bathyllus excelled as a comic, and Pylades as a tragic pantomime. They flourished under Augustus, about the year B.C. 15. From these two competitors for public fame in the respective departments of their art sprang two sects, each of which retained the name and preferred the manner and character of its master. The disciples of Bathyllus were called Bathylli, and those of Pylades were denominated Pyladse. The Romans divided themselves into parties on account of these two pantomimes; and the interest of Bathyllus's was at one time so prevalent as to procure the banishment of Pylades. Upon his return Augustus recommended his behaving better for the future, and not attempting to divide the people into parties or factions. Pylades replied, "Cafar, it is of service to you to have the people bufied about Bathyllus and me." Gen. Dict. Crev. Hill. vol. i. p. 122.

BATHYLLUS, in Ancient Geography, a fountain of Arcadia, in the Peloponnesus, near Megalopolis. Pausanias.

BATHYMI, a people of Arabia Felix. Ptolemy.

BATHYS, a river of Phrygia Salutaris, which flowed in the north of this province, along the plain of the city Doryleum, and discharged itself into the river Sangaris.

BATHYS, Fimn Tautop, a river of Sicily, which runs into the gulf of Castell a Mare.

BATHYS, the name of a port of Ethiopia. Ptolemy.

BATHY, a people of India, on the other side of the Ganges. Ptolemy.

BATIA, a town of Italy, in the territory of the Sabines.

BATIA, a district of Attica, belonging to the tribe of Argides.

BATIAL, a town of Epirus.

BATIANA, Baix, a town of Gaul, on the right side of the Rhine, according to M. d'Anville.

BATIANI, a people of Italy, placed by Ptolemy in Liguria.

BATHILUS, a musical instrument made of metal, in the form of a staff, furnished with metallic rings, which being struck, yielded a kind of harmonical sounds; used by the Armenians in their church-service.

BATINA, in Ancient Geography, a town of Asia, in Media. Ptolemy.

BATINUS, a town of Italy, in Picentinium.

Species, 1, B. marinima. Sloan. Jan. t. 144. Kali. This is a shrub about four feet high; fions brittle, round, ash-coloured, branched, diffused, procumbent; young branches, four-cornered, four-furred, green, opposite and upright; leaves oblong, acute, drawing to a point towards the base, fefibly, fucculent, flat above, convex beneath, fefilile, opposite, fearedly an inch long, numerous; stigma white; fruits yellow or greenish-yellow. The whole plant is very falt to the taste; and is burnt for barilla at Carthagena, &c. A native of the Caribbei iflands and the neighbouring continent; very falt in all the falt marches on the south fide of Jamaica. Linnaeus doubts whether it be different from the bucephalon of Plumber. Martyn's Miller's Diet.

Batis, in Entomology, a species of Phalusa, found in England and some other parts of Europe. The anterior wings are brown, with five rofe-coloured spots on each; posterior ones whitish. This is a rare and elegant insect, and is called by collectors of English insects the peach-blos- som moth. Lin. Donov. Brit. Inf. &c.

Batis, in Ichthyology, a species of Raja, called in England the Skate. It is varied; back smooth in the middle, with a single row of spines on the tail. Linnaeus.

This is the largest fish of the Ray tribe; it inhabits all the northern parts of Europe in immeasurable quantities, though it is certainly less common than the thornback, with which it is sometimes confounded. The usual size is from two to three feet in length, or rather more, including the tail; and they have been taken of the weight of a hundred and fifty
or two hundred pounds. They couple in March and April, and spawn in May. The skin of the kate is thought better than that of the other Rays.

BATISTAN, in Ancient Geography, a people of Spain, who inhabited the northern part of Batia.

BATISTE, in Commerce, a fine white kind of linen cloth, manufactured in Flanders and Picardy.

There are three kinds of batiste: the first very thin; the second, half thin; and the third most thicker, called Holland batiste, as coming very near the goodness of Hollands. The chief use of batiste is for neck-cloths, head-cloths, furnaces, &c.

BATMAN, a weight in Turkey, consisting of fix oks. Forty of these batmans make a camel's load, and amount to about seven hundred and twenty pounds English weight.

Batman, or batamant, is a weight used in Turkey and Persia. The Turkish batman is of two kinds; the larger containing fix oks, or occas, at three pounds three quarters Paris weight the occas; so that the batman amounts to about twenty-two Paris pounds and an half; the smaller, composed of six of these occas, at fifteen ounces the occas, amounting to five pounds ten ounces. The Perian batman is likewise of two kinds: one called the king's weight, batman de chati, or eberay, used for weighing wool; the other called batman of Twelve, equal to fix pounds fourteen ounces Paris or Amsterdam weight. These, at least, are the proportions given by Tavernier. Chardin rates the Perian batmans somewhat lower, viz. the former at twelve pounds twelve ounces; and the latter at five pounds fourteen ounces.

BATMANSON, John, in Biography, prior of the Carthusian monastery, or Charter-house, in London, in the 16th century. He studied at Oxford; and being a great favourite of Edward Lee, archbishop of York, wrote at his request against Erasmus and Luther. He died in 1531, and was buried in the Charter-house. Bale represents him as proud, arrogant, and fond of wrangling; and says, that Erasmus styles him an ignorant fellow, and vain-glorying even to madness. Pits, on the other hand, commends his genius, learning, piety, and zeal; his acquaintance with the scriptures, and his highly exemplary life. His works are "Animadversions in Annotationes Erasmii in N.T."; "A Treatise against some of Luther's writings;" both these he afterwards retracted; "Comment in Prover. Solomonis," &c. in Cantica Cantorum; "De Unica Magdalea;" "Institutiones Noviciorum;" "De Contemptu Mundi;" "De Chri Sto duodenii," a homily on Luke ii. 42; and "On the words Miijas 9f, &c." Biog. Brit. Gen. Diit.

BATNE, in Ancient Geography, a town of Megopota­mias, in Ofrdroen. Ammianus Marcellinus calls it Batne and Batau, and says, that it was a municipal city of Antem­nias, of great trade, built by the Macedonians, at a small distance from the Euphrates. The emperor Justinian made it a place of defence by encompassing it with walls. Propo­cippus calls it a small and obscure town, and says, that it was about a day's journey distant from Edessa. It lay south of Edessa, and east of Zeghama. It was reduced by Trajan, who took it from Choriores, king of the Pahlavians.

Batne was also a small town of Syria, situate between Zenem and Hercopolis, pleasantly seated in a grove of cy­presse, about twenty miles from the latter city. When Julian visited this town, A. D. 363, the feomn rites of fa­trice were decently prepared by the inhabitants, who feemed attached to the worship of their tutelary deities, Apollo and Jupiter.

BATNIR, or BATINDA, in Geography, a town of Hindustan, in the country of Moulten, in a district famous for paludens and fine horses. Timur marched from Adjudin, a town included in one of the large islands formed by the branches of the Selenge, to Batnir, the distance of 60 coffes, 50 coffes being equal to about 95 British miles: and in his way he crossed an extre five defeat; so that Alexander was not mistaken when he was told there was a defeat beyond the Hyphasis. After taking and destroying Batnir, represented as a very strong place, which, however, employed only a few days, he marched by a circuitous road to Saimanah, directly distant from Batnir only 72 geographical miles. Batnir is about 150 miles, E.S.E. of Moulten, and 170 N. W. of Agimer. N. lat. 29° 15'; E. long. 74° 40'.

BATO, one of the Ladrones islands. N. lat. 12°. E. long. 142°. See Ban.

Bato, a river of Italy, in the kingdom of Naples, which runs into the Mediterranean, 2 miles S.E. of Scalea, in the province of Calabria Cita.

BATOA, a small island near the west coast of Sumatra, feated very nearly under the equinoctial line. E. long. 98°.

BATOE, Ikon Batoe, Impo Aloes, & Ikon Pampus Cambodia, names given by Valent. in his work on Indian fishes, to the species of Chraoon, speically called Annularis by Gmelin.

BATON, or Batoon, in Heraldry. See Baston.

Baton, or Bofton, as an instrument of punishment. See Bartonado.

BATON, Fr. in Music, a musical character for silence, during two bars in alto breve time, and four of common and triple time. It fills up two spaces of the five-line staff; and has a 2 or a 4 placed over it, proportioned to the time of the movement. See Breve, Time­table, and Rests.

BATOOGS OF ST. PAUL, Bosphorini di San Paolo, in Natural History, a name given by some of the Italian writers, as Augustino Scala and others, to the lapides Judaici, or other spines of echini. These are found in vast abundance in the island of Malta; and as every thing there is commemorated with some title, with St. Paul at the end of it, these are called bacoli Sti Pauli, or St. Paul's batoons.

BATOPILAH, in Geography, a town of North America, in the province of New Navarre, 120 miles north of Cinalon.

BATOS, in Ichthology. See Batis.

BATRACHA, in Ancient Geography, a town of Asia, in Sarmatia. Ptolemy.

BATRACHIAS Lapis, the frog stone, a name applied by different writers to two very different substances; some understanding by it lumps of common flint, which have accidentally formed themselves into this figure; and others, thin pieces of amber, which contain either a whole frog, or any part of one.

BATRACHITES, among Ancient Naturals, a kind of gem found in Egypt, denominated from its resemblance in colour to a frog. The word is formed from bak$og, rand, a frog. Pliny speaks of three stones under this denomination; unum rana siniltem coheres, alteram-chori (or rather, according to Hardouin's correction, choli), tertium rubentis et nigro. The batrachites differed from the modern byssinites, which does not appear to have been known to the ancients.

BATRACHOIDE, in Ichthology, a genus of fishes of the Jugulaires kind, established by Lacépéde for two fishes; one belonging to the Gundu, and the other to
the *Blenius*, genus of Linnaeus, viz. *G. tau*, and *B. varius*. The character of the eutherioids consists in having the head very large and greatly depressed; opening of the mouth very fancious; and one or more barbs situated about or at the under-side of the lower jaw.

**BATRACHOYOMICIA**. Formed of the Greek *batrachos*, frog, *pygus*, mouse, and *pygus*, mouse, and denoting the battle of the frogs and the mice; the title of a burlesque poem, usually ascribed to Homer. The subject of the poem is the death of Phrygarcha, a mouse, son of Tとう,

**BATRACHUS**. The name given by Klein to the Linnenus *Lophius Piscatorius*.

**BATRACHUS**. The name given by Klein to the Linnenus *Lophius Piscatorius*.—*Batrachus capite, rectique rane, &c.* Klein. The last writer also describes the Linnenus *Vespertilio, as Batrachus capite vomeris infalet cornuto, &c.*

**BATRACHUS**. A species of Silurus, found in Asia and Africa. The dorsal fin is fin, and contains thirty rays; beards of the mouth eight. *Linn. Muf. Fr.*—The tail is entire.

**BATTALION**, or *Batta*, in Geography, a duchy or province of Africa, situate on the south-west of Pangoo, and having Dembo, Amalufa, and the salt-petre mountain on the east, on the south the marquise of Ineffo, and the burnt mountains, and Congo and Embna on the west. It is of considerable extent, was formerly called Anguirima or Aghiramba, and was a kingdom of itself, till both king and people submitted to the kings of Congo. This country is generally fertile, well watered by rivers, and produces several sorts of grain. The inhabitants are more civilized than their neighbours.

**Batta**, the capital of the above duchy, is distinguished in no other respect besides the fertility of its territory, and its being the residence of the governors of this province. These are allowed to have a number of arquebutiers in pay, to defend it from the incursions of the wild Giagas, or Jagas, who inhabit the districts near its eastern frontiers, beyond the mountains of the Sun and Salpetre, and who chiefly subsist by ravaging the adjacent territories. The road between this capital and that of the kingdom of Congo, called St. Salvador, has, it is said, a great number of hovels and hamlets on both sides.

**Batta**, the name of a country in Sumatra, where the English have two settlements. The inhabitants still eat human flesh, but restrict themselves to that of prisoners taken in war, and capital offenders.

**BATTLE GROUND**, denotes land lying between England and Scotland, of which the right of polieffion was disputed, when they were two distinct kingdoms.

**The word imports as much as litigious, or disputable ground, from *battre, to beat or fight*.**

**BATTACKS**, or *Battoges*, a punishment in Russia, similar to the ballinado, or batonado, of China, Turkey, &c. The deliquent is stripped naked, and made to lie on his belly, while two executioners beat him with small sticks, till the judge cries out, enough. The order to desist is frequently not given till the back of the unfortunate sufferer has been mortally mangled. During the whipping, he is obliged to pronounce the word "Winawat," which means "I am guilty," and at the end of the punishment he must go and kiss the feet of him who directed it, and thank him that he did not make it more severe. The highest judges are not exempted from the battoges, and take vengeance for it on their unhappy vassals. This punishment is particularly reserved for the inferior orders whom malversation or rogucry would any where else drive from their employments.

In Ruffia, it is reckoned sufficient to reduce them to an inferior employment, after the correction of the battoges. Chatterie's Travels in Ruffia, vol. i. p. 177. See BASTONADO.

**BATTALLIA**, in Geography, a town of Italy, in the kingdom of Naples, and province of Capitanata, 3 miles N.W. of Viée.

**BATTALIA**, in Ancient Geography, a promontory of Arabia, north-call of Julia Caucasara.

**BATTALIA**, an army ranged in order of battle, or ready for engagement.

In this sense, we meet with the depth of a battalia; to march in battalia, with the baggage in the middle; to break the battalia, &c. In the Roman battalia, the Hasto made the front.

**BATTALION**, in the Military Art, signifies a small body of infantry, arranged in regular order, and instructed to march and to act in concert.

There are different opinions respecting the force of which a battalion should conftitute. If composed of too great a number of men, it cannot perform its evolutions with the necessary facility; if, on the contrary, the troops are not sufficiently numerous, it is incapable of producing by its attack any considerable effect. The number must therefore be so regulated, as to permit the necessary manoeuvres to be executed with promptitude and regularity; and at the same time to compose a solid body, capable both of charging with firmness, and of fływning the attack of other corps to which it may be oppofed without falling into disorder.

The number of the battalion varies according to the usages of belligerent nations, their arms, the manner in which they employ those arms, and the order in which they engage. Europeans formerly differed very widely on all these points; but at present all the continental powers, the Turks alone excepted, observe nearly the same dispositions with respect to the battalion. The term even is adopted in every modern language.

The French have fixed the number of the battalion at about 700 men. Some nations form them still stronger, others weaker. In the English service they usually constiute, in time of war, of ten companies; forming, exclusively of the staff, a total of between seven and eight hundred. When employed on service, the battalions being filled up at the commencement of a campaign, and rarely recruited till its close, are seldom or ever complete; as well from the losses they suffer in different engagements, as on account of sickfews and other accidents inseparable from the military profession.

The arms of the battalion have been frequently and materially altered. In the infancy of modern tactics, one third of the troops were furnished with pikes, and drawn up in the centre; the other two thirds carrying musquets, were posted on the wings, to flank, protect, and second, by their fire, the onset of the pikes. The infantry are now universally armed with firelocks and bayonets, the use of the pike being completely laid aside.

The modern method of arrangement has been decried by the
the ingenious chevalier de Folard (Traité de la Colonne, p. 7.) as rendering the battalions too shallow, weak, incapable of supporting each other, and exposing them to be easily penetrated and broken through, all which he denominates essential faults in tactics. According to him, the real strength of a corps consists in its thickness, or the depth of its files, and their connection and closeness, this rendering the flanks almost as strong as the front. He even lays it down as a maxim, that every battalion arranged deeply, and with a small front, will defeat another much stronger than itself disposed according to the usual method. In fact, a corps whose front is widely extended, and whose depth is but small, manoeuvres with more difficulty, and cannot totally avoid that wavering from which the close order of M. Folard’s battalion or column renders it comparatively exempt. The opinion of the Chevalier has been in a great measure adopted by his countrymen, though his theory has been violently attacked by two French officers formerly in the service of the States General. They admit the superior strength of the column to the modern battalion, were the action to be decided with pikes and swords; but maintain that where fire-arms are used, M. Folard’s column is but ill calculated for the purpose, and must be infallibly destroyed. The late campaigns in Italy furnish the best commentary upon these separate systems.

Battalion, Square, is a battalion the files of which are equal to the ranks, and whose files form an equal front. There are two kinds, the solid, and the hollow: in the former, the ordinary intervals between the ranks and files are the only ones preferred; in the latter, a vacant space is left in the centre, of pretty considerable extent, according to the ground occupied by the battalion. We shall presently give some account of the evolutions necessary in forming both kinds of the square.

The solid square, however ingenious in its formation, and respectable in its appearance on a field of exercise, is of very little utility in actual service. In the first place, it suffers prodigiously from the fire of the enemy, especially if artillery is brought to bear upon it; in the second, it is next to impossible for the troops in the centre of the battalion to employ their own fire effectually. M. de Folard, in his treatise de la Colonne, exposes much at large the defects both of the solid and the hollow square. He indirectly, however, recommends their use; his own column being nothing more than two or three battalions drawn up according to the rules of the solid square, and placed without any intervals in the rear of each other. Regarding, however, the solid square as entirely distinct from the column, of which we shall speak more at large in its proper place, we shall here conclude by observing that the only cæse in which it seems capable of affording any real service is when opposed to an enemy whose forces confinl entirely of cavalry.

The hollow square, which claims for its inventor the celebrated prince Maurice of Nassau, is much less unwieldy in its movements, founer formed, and more easily reduced, than the solid. Its fire too is more regular, better directed, and does much greater execution. It however participates in a great measure of all the disadvantages of the solid square, and its use can only be recommended in cases of the fall extremity, or, as above, when opposed to cavalry.

Battalion, Triangular, is a body of troops disposed in a triangle, whose ranks, augmenting equally, form an arithmetical progression. Many skilful officers have preferred it to the square, from its presenting a greater front, and being able to make head on all sides. The difficulty is to ensure folders to march in this order; and we may conclude the triangular only preferable to the square battalion in close ac-
tion, when it is necessary to preserve an extended front, or when the nature of the ground requires such a disposition.

Battalion, Round, is that in which the ranks form a number of concentric circles. The Romans made frequent use of this manoeuvre in cafes of emergency, and were very perfect in its execution. Cæsar’s commentaries furnish several examples, especially on occasion of the defeat of Sabinus and Cotta by Ambiorix, where the formation and nature of the orb are very satisfactorily elucidated. (De Bello Gall. lib. v.) But in the battle between Cæsar and Labienus in Africa, translators seem to have mistaken for the orb, a disposition perfectly different. (Hist. de Bello Afr.)

Although recommended by M. de Puységur, the round as well as the triangular battalion are now generally diff-
used.

At a crisis like the present, we must the following account of the training the recruit for service, the order and formation of the battalion, and the principal evolutions it is designed to execute, will not prove wholly unacceptable to our readers. Care has been taken to render the narration as little tedious as possible, and as concise as may be consistent with percpacity.

Evil of the Recruit without Arms.

It requires in the instructors to whom this duty is entrusted, and who are answerable for its execution, an unmitting perseverance, an accurate knowledge of the subject, and a clear and concise method of conveying instruction, united with a firmness capable of commanding perfect attention to their directions. They must allow for weaknesses of capacity in the recruit, be patient and not rigorous where endeavour and good-will are not wanting, as quickness is only to be acquired by much practice. Officers and instructors must be critically exact in their own commands, as well as in observing the execution of what they require from others. Without this, all labour will prove ineffectual, and the proposed discipline never be attained.

The recruit must be taught progressively to comprehend one thing before he proceeds to another. In the first circumstances of position, his filelock, fingers, elbows, &c. are to be judiciously disposed by the instructor. When more advanced, recruits should not be touched, but from example and directions be taught to correct themselves when admonished. They should not be kept too long at any particular part of their exercise, so as to fatigue or render them uneasy; and marching without arms ought to be much intermixed with the use of the file-lock. File, or nuifce, must on no account be used. The young soldier is to be confirmed by habit alone in that cadence of step he is afterwards to maintain in marching to the enemy in spite of every variety of noise or circumstance that may tend to derange him.

Each recruit must be trained singly, and in squad, as hereafter described; nor until readied in various points of his duty, is he to be allowed to join the battalion, which is sufficiently incomprehensible by the awkward behaviour even of one man. On return from long absence, every folder must be re-drilled before he can again join his company.

I. Postion of the Soldier. The equal squareness of the shoulders and body to the front is the first and great principle of the position of a folder. The heels must be in a line, and closed; knees straight, without flinches; toes a little turned out, so that the foot may form an angle of about fifty degrees; the arms are to hang near the body, but not stiff, the flat part of the hand and little finger touching the thigh; the thumbs as far back as the fingers of the breeches; elbows and shoulders to be kept back; the belly rather drawn in, and the breast advanced, but without constraint; the body upright, but inclining forw-
ward, so that its weight principally bears on the fore part of the feet; the head to be erect, and turned neither to the right nor left. The position in which a folder should move, determines that which he is to observe when standing still. No method must be left untried to supple the limbs, and banish the air of the rustic. But that excess of position which stiffens the person, and tends to throw the body backward instead of forward, is contrary to every true principle of movement, and must therefore be most carefully avoided.

II. Standing at Ease. 1. On the word Stand at Ease, the right foot must be drawn back about six inches, and the greatest part of the weight of the body be brought to bear on it; the left knee a little bent, the hands brought together before the body; but the shoulders to be kept back and square; the head to the front, and the whole attitude without constraint. 2. On the word Attention, the hands are to fall smartly down the outside of the thighs; the right heel to be brought up on a line with the left, and the proper position of a folder to be immediately resumed. After standing at ease for any considerable time in cold weather, the men may be permitted, by command, to move their limbs, but without quitting their ground, so that on the word Attention, no one shall have materially lost his dreeing in the line.

III. Eyes to the right, &c. On the word Eyes right, glance the eyes to the right, with the slightest possible turn of the head; Eyes left, turn them in the hike manner to the left; Eyes front, the look and head are to be directly in front, the habitual position of the folder. Throese motions are only useful on the wheeling of divisions, or when dreeing is ordered after a halt. Particular attention must be paid, in the several turnings of the eyes, to prevent the recruit from moving his body, which should be preferred perfectly square to the front.

IV. The Faccings. In going through the facings, the left heel neither quits the ground; the body must rather incline forward, and the knees be kept straight. At the word, to the right, face, first, place the hollow of the right foot smartly against the left heel, keeping the shoulder square to the front; second, raise the toes, and turn to the right on both heels. To the left, face; first, place the right heel against the hollow of the left foot, shoulders square to the front; second, turn, as before, to the left on both heels. To the right about, face; first, place the ball of the right toe against the left heel, shoulders square to the front; second, raise the toes, and turn to the right about on both heels; third, bring the right foot smartly back, in a line with the left. To the left about, face; first, place the right heel against the ball of the left foot, keeping the shoulders square to the front; second, turn, as before, to the left about; third, bring the right foot smartly up, in a line with the left. The utmost precision must be observed in the facings, for if they are not exactly executed, a corps, although previously properly dreeed, will lose their dreeing on every small movement of facing.

V. Position in Marching.—March! The folder must here, as much as possible, maintain the position of his body, as directed in sect. i. He must be well balanced on his limbs. His arms and hands, without stiffness, must be kept steady to his sides, and not suffer to vibrate. He must not flop forward, still less lean back. His body is to be kept square to the front, and thrown rather more forward in marching than when halted, that it may accompany the movement of the leg and thigh, which movement must spring from the ham. The ham must be stretched, but without stiffening the knee. The toe a little pointed, and kept so near the ground, that the shoe-soles may not be visible to a person in front. The head to be well kept up, straight to the front, and the eyes not sufferer to be cast down. The feet, without being drawn back, must be placed flat on the ground.

VI. Ordinary Step. The length of each pace, from heel to heel, is 30 inches, and the recruit must be taught to take 75 of these steps in a minute, without tottering, and with perfect readiness. Ordinary time being the pace on all occasions whatever, unless greater celerity be particularly ordered, the recruit is to be carefully and thoroughly trained to this most essential part of his duty, and made perfectly to understand, that he is to maintain it for a long time together, in line, in column, and in marching over rough or smooth ground. This is the slowest step which a recruit is taught, and is also applied in all movements of parade.

VII. The Halt. On the word, halt, let the rear foot be brought upon a line with the advanced one, so as to finish the step which was taking when the command was given.

VIII. The oblique Step. Having acquired the regular length and cadence of the ordinary pace, the recruit is next to be taught the oblique step. At the words, to the left oblique—march! he will, without altering his squareness of personal position, when he is to step with his left foot, point, and carry it forward 19 inches, in the diagonal line, to the left, which gives about 13 inches to the side, and nearly the same number to the front. On the word two, he will bring forward his right foot 30 inches, thus placing the heel of that foot 13 inches directly before the left one. Here he will pause, and on the word two, continue the same mode of marching, by advancing his left foot 50 inches, pausing at each step, until confirmed in his position, as it is etessentially necessary to take the greatest care in preserving the shoulders square to the front. Combining these two movements, the obliquity gained will amount to an angle of about 25 degrees. When the recruit is habituated to the step, he must be made to continue it firmly, without pausing, and in the cadence of the ordinary pace, viz. 75 steps in the minute. As all marching (the side step excepted) commences by the left foot, whether the oblique commences from the halt, or on the march, the first diagonal step taken, is by the leading foot of the side inclined to, when it comes to its turn, after the command is pronounced. Squareness of person, and the habitual cadenced step are, consequently, the great descriptions of the oblique, as well as the direct march.

Each recruit should be separately and carefully instructed in the principles of the foregoing eight sections of the drill. They form the basis of all military movements. Three or four recruits will now be formed in one rank, at very open files, and instructed in the following manner.

IX. Dressing when halted. Dressing is taught equally by the left as by the right. On the word, dress, each individual will call his eyes to the point to which he is ordered to dress, with the smallest turn possible of the head, but preserving the shoulders and body square to the front. The whole person of the man must move as may be necessary, and being backward and forward is not to be permitted. He must take short, quick slips, thereby gradually and exactly to gain his position, and on no account be permitted to attempt it by any sudden or violent alteration, which will infallibly derange whatever is beyond him. The faces of the men, not their breasts, or feet, are the line of dressing. Each folder is to be able just to dilligent the lower part of the face of the seconnd man beyond him. In dressing, eyes are always turned to the officer who gives the word; who is posted at the point by which the body halts: and who from that point corrects his men on another, at or beyond the
the opposite flank. Faults to be avoided, and generally committed in drilling, are, passing the line; the head forward, and body kept back; shoulders not square; or the head turned too much.

Two or more men being moved forward, or backward, a given number of paces, and placed in the new line and direction, the following commands will be given: 1. by the right (or left) forward—left; 2. on the right (or left) backward—right. The drilling once accomplished, eyes front will be given, that heads may be replaced, and remain square to the front. No rank, or body, ever should be drilled, without the officer on its flank determining a line on which to form it, and for that purpose taking as his object the distant flank man, or a point behind him, or a man purposely thrown out. Drilling must then be made gradually, and progressively, from the fixed point, towards the distant flank one; and each man successively, but quickly, must be brought up into the true line, so as to become a new point, from whence the instructor proceeds in the correction of the others; and himself, while thus occupied, must take care, that his person, at least his eyes, be in the true line, which he is then giving.

X. Stepping out. The squad marches, as already directed, in ordinary time. On the word, step out, the recruit must be taught to lengthen his step to 33 inches, by leaning forward a little, but without altering the cadence. This step is necessary, when a temporary exertion in line, and to the front, is required; or when the rear divisions of a column are to move up in line with the leading ones, and is applied both to ordinary and quick time.

XI. Mark time. On this word, the foot then advancing completes its pace. The cadence is then continued, without gaining any ground, but alternately throwing out the foot, and bringing it back square with the other. At the word, ordinary time, or forward, the usual pace of 30 inches will be taken. This step is necessary marching in line, when any particular battalion is advanced, and has to wait for the coming up of others.

XII. Stepping short. On the word, step short, the foot advancing will finish its pace, and afterwards each recruit will step as far as the ball of his toe, and no farther, until the word, forward, be given, when the usual pace is to be taken. This step is useful when a momentary retardment either of a battalion in line, or of a division in column, is required.

XIII. Changing the Feet. To perform this in marching, the advancing foot completes its pace, and the ball of the other is brought up quickly to the heel of the advanced one, which instantly makes another step forward, so that the cadence may not be lost. This is required of an individual who may be stepping with a different foot from the rest of his division; in doing which, he will, in fact, take two2 successive steps with the same foot.

XIV. Side, or stepping Step. This is performed from the halt in ordinary time, at the following command: Close to your right, or left (a caution)—March! On the latter word, eyes are turned to the right, and each man carries his right foot about 12 inches directly to his right; or, if the files are closed, to his neighbour’s left foot, and instantly brings up his left foot, till the heel touches his right heel; he then pauses, so as to perform this movement in ordinary time, and proceeds to take the next step in the same manner: the whole with perfect precision of time, shoulders kept square, knees not bent, and in the true line on which the body is formed. At the word halt, the whole halt, turn their eyes to the front, and are perfectly steady.

XV. Back Step. This is performed in the ordinary time and length of pace, from the halt, on the command step back—March! The recruit must be taught to move straight to the rear, preferring his shoulders square to the front, and his body erect. On the word halt, the foot in front must be brought back square with the other. A few paces only of the back step can be necessary at a time.

XVI. Quick Step. The cadence of the ordinary step having become perfectly habitual to the recruits, they are now to be taught to march the quick time, which is 108 steps in the minute, each of 30 inches, making 320 feet in a minute. The word of command, Quick—March! is given with a pause between them. The word Quick, is to be considered as a caution, and the whole to remain perfectly still and steady. On the word March! the recruits step off with the left foot, keeping the body in the same posture, and the shoulders square to the front. The foot to be lifted from the ground, that it may clear any stones, or other impediments in the way, and to be thrown forward, and placed firm. The whole of the sole to touch the ground, and not the heel alone. The knees are not to be bent, neither are they to be stiffened, so as to occasion fatigue or constraint. The arms to hang with ease along the outside of the thigh; a small motion to prevent restraint may be permitted, but not to swing out, and thereby occasion the least turn, or movement of the shoulder. The head is to be kept to the front; the body well up, and the utmost readiness to be preserved. This is the pace to be used in all filings of divisions from line into column, or from column into line; and by battalion columns of manoeuvre, when independently changing position. It may occasionally be used in the column of march of small bodies, when the route is smooth, and no obstacles occur; but in the march in line of a considerable body it cannot prudently be required, nor often in a column of manoeuvres. Fatigue will otherwise arise to the folder, and more time be lost in hurry and inaccuracy than is attempted to be gained by quicksteps.

N. B. The word March given singly, at all times denotes that ordinary time is to be observed. When the quick march is meant, that word will precede the other. The word March marks the commencement of movements from the halt; but is not given when the corps is in previous motion.

XVII. Quickest Step. The quickest time, or wheeling march, is 120 steps of 30 inches each, or 300 feet, in the minute. The directions already given for the march in quick time are equally applicable to the march in quickest time. This is adapted chiefly to the purpose of wheeling, and is the rate at which all bodies accomplish their wheels; the outward file stepping 33 inches, whether the movement is from line into column, into column during the march, or from column into line. In this time also divisions should double and move up, when passing obstacles in line, or when in column of march it becomes necessary to increase or diminish the front.

Three or four recruits in rank, with intervals of twelve inches between them, should be practised in the various steps, that they may acquire a firmness and independence of movement. Many different times of march would only perplex the folder: the three already mentioned must suffice. Plummets, which vibrate the required times of march in a minute, are of great utility, and can alone prevent or correct uncertainty of movement. They must be in the possession of, and occasionally referred to, by each instructor of a squad. The several lengths of plummets swinging the times of the different marches in a minute, are as follows:

<table>
<thead>
<tr>
<th>Movement</th>
<th>Length</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ordinary time</td>
<td>75 steps</td>
<td>12 min, 30 sec</td>
</tr>
</tbody>
</table>
A musket ball, suspended by a string which is not subject to stretch, and on which are marked the different required lengths, will answer the above purpose, and should be frequently compared with an accurate standard. Accurate distances of steps may also be marked out on the ground along which the soldier is practised to march, and thereby accustom him to the just length of each.

Six or eight recruits will now be formed in a rank, at close files, having a steady well-drilled soldier on their flank to lead; and file marching may be taught them.

XVIII. File Marching. The recruits must first face, and then be instructed to cover each other exactly in file, so that the head of the man immediately before may conceal the heads of all the others in his front. The strictest observance of all the rules for marching is particularly necessary in marching by files, which is first to be taught at the ordinary, and afterwards in quick time. On the word March, the whole immediately step off together, gaining at the very first step thirty inches, and continuing each step without increasing the distance betwixt each recruit, every man looking or placing his advanced foot on the ground, before the spot whence the preceding man has taken up his. No looking down or leaning backward is to be tolerated on any pretence. The leader is to be directed to march straight forward to some distant object given him for that purpose, and the recruits made to cover one another during the march with the most furtive exactness. Great attention must be paid to prevent them from marching with their knees bent, which they will at first be extremely apt to do, from an apprehension of treading down the heels of those before them.

XIX. Wheeling in Single Rank, from the Halt. At the word to the Right Wheel, the man on the right of the rank faces to that flank; on the word March, they step off together, the whole turning their eyes to the left (the wheeling flank), except the left hand man, who looks inwards, and during the wheel becomes a kind of base line for the Rifl conform to and maintain the uniformity of front. The outward wheeling man always lengthens his step to thirty-three inches. The whole observe the same time; but each man shortens his step, in proportion as he is nearer to the standing flank on which the wheel is made. During the wheel, the whole remain closed to the standing flank, i.e. they touch without incommoding their neighbour; nor must they step forward, but remain upright. Opening out from the standing flank, or closing in upon it, during the wheel, are equally to be avoided. On the word Halt—Dress, each man halts immediately, without jumping forward or making any false movements. When able to perform the wheel with accuracy in the ordinary time, the recruits must be next practised in the quickest. Nothing sooner tends to enable them to acquire the proper length of step, according to their distance from the pivot, than continuing the wheel without halting for several revolutions of the circle.

XX. Wheeling, in Single Rank, from the March. The recruits are first taught to perform this wheeling at the ordinary, afterwards in the quickest time, the proper wheeling step. The rank marching to the front in ordinary time, receives the word of command, Right—Wheel. The man on the right of the rank instantly halts, and faces to his right. The rest of the rank turning their eyes to the wheeling flank (as above directed), immediately change the step together to wheeling time. As soon as the portion of the circle intended to be wheeled, is completed, the words Halt—Dress will be given, (a pause of two or three seconds may be made), and then March, at which the whole rank steps off together in ordinary time.

XXI. Wheeling backwards, in Single Rank. At the word On your Right, backwards,—Wheel, the right-hand man of the rank faces to his left. At the word March, the whole step backward in wheeling time, dressing by the outward wheeling man; those nearest the pivot making their steps extremely small, and those towards the wheeling man increasing them as they are placed nearer to him. The recruit in this wheel must not bend forward, nor be suffered to look down; but by calling his eyes to the wheeling flank, preserve the dressing of the rank. On the word Halt, the whole remain perfectly steady, still looking to the wheeling flank, till they receive the word Right—Dress. The recruits should be first practised to wheel backwards at the ordinary step. At all times it will be necessary to prevent their hurrying the pace, an error soldiers are very subject to, particularly in the backward wheel. Where large bodies wheel from line into column, this wheeling is necessary to preserve the covering of pivot flanks, and the distances of the divisons, which the line has broken into.

XXII. Wheeling in Single Rank, on a moveable Pivot. In performing this wheel, both flanks are moveable, and describe concentric circles round a point, which is removed a few paces from what would otherwise be the standing flank; and eyes are all turned towards the directing pivot man, whether he is on the outward flank or the flank wheeling to. When the wheel is to be made to the directing pivot flank (suppose the left), the rank marching at the ordinary pace, receives the word Right Shoulders Forward; on which the pivot man, without altering either the time or length of his pace, continues his march on the circumference of the outer circle; and tracing out a considerable arch, on the principle of dressing, gradually brings round his rank to the direction required, without obliging the other flank, which is describing the circumference of a larger circle, and thus escapes the great hurry. On the word Forwards, shoulders are squared, and the pivot marches directly to his front. When the directing pivot is on the outward flank, and has to describe the circumference of the larger circle, on the word Left Shoulders Forward, he will (preserving the time and length of his pace) gradually bring round the rank to the required direction, so as to enable the inward flank to describe a similar arc of a lesser circle, concentric to the one he himself is moving on. During both these wheels, the rank dress to the proper pivot; and when he describes the smaller circle of the wheel, the other flank which has more ground to go over, will quicken its march and step out. When the pivot describes the greater circle of the wheel, the other flank having left ground to go over, will step shorter and gradually conform. In the first case, the recruit must be cautioned against opening out from the pivot; and in the latter, from crowding on him. The just performance of this mode of wheeling depends so much on the directing pivot, that a well-drilled soldier should at first be placed on the flank named, as the proper pivot, and changed occasionally. It is used when a column of march (to follow the windings of its route) changes its direction in general less than the quarter circle.

Drill of the Recruit with Arms.

I. Position of the Soldier. When the firelock is given, and is shouldered, the person of the folder remains in the position described in section I. of the drill without arms, except that the wrist of the left hand is turned out, the better to embrace the butt; the thumb alone is to appear in front, the four fingers to be under the butt, and the left elbow a little bent inwards, without being separated from the body, or being more backward or forward than the right one. The firelock is placed in the hand, not on the middle
of the fingers, and so carried, that it shall not raise, advance, or keep back, one shoulder more than the other. The butt must therefore be forward, and as low as can be permitted without restraint; the fore-part nearly even with that of the thigh, and the hind-part of it profiled by the wrist against the thigh. The piece must be kept steady and firm, its lower hollow of the shoulder. Should the firelock be drawn back, or attempted to be carried high, in that case one shoulder will be advanced, the other kept back, and the upper part of the body distorted, and not placed square with respect to the limbs. Each recruit must be separately taught the position of shouldered arms, and not allowed to proceed until he has acquired it.

II. Motions of the Firelock. The following motions of the firelock will be taught and practiced, until each recruit is perfect in them; being necessary for the ease of the folder in the course of exercise. 1. Supporting arms; 2. Carrying arms; 3. Ordering at closed arms; 4. Standing at ease; 5. Attention; 6. Shouldering; 7. Trailing arms; 8. Shouldering from the trail. The recruit must be accustomed to carry his arms for a considerable time together; it is most essential he should do so, and not be allowed to support them so often as is practiced; under the idea that long carrying them is a position of too much restraint.

III. Forming the Squad. When the squad, or division, of fix or eight files, is ordered to Fall in, each man, with carried arms, will, as quick as possible, take his place in the ranks, beginning from the flank to which he is ordered to form. He will dress himself in line by the rule already given, assume the ordered position of a folder, and stand perfectly still and steady, until ordered to stand at ease, or that some other command be given him. Attention must be paid, that the files are correctly close; that the men in the rear ranks cover well, looking their file leaders in the middle of the file; that the ranks have their proper distance of one pace, or 30 inches, from each other; that all the ranks are equally well dressed; that the men do not turn their heads to the right or left; and that each man has the proper unconstrained attitude of a folder.

IV. Open Order. The recruits being formed in three ranks at close order, on the caution Rear ranks take open order, the flank men, on the right and left of the centre and rear ranks, step briskly back, one and two paces respectively, face to the right, and stand covered, to mark the ground on which each rank is to halt, and dress at open order: every other individual remains ready to move. On the word March, the dressers front, and the centre and rear ranks fall back one and two paces, each dressing by the right, the infantit it takes its ground.

V. Close Order. On the word Rear ranks take close order, the whole remain perfectly steady. At the word March, the ranks close within one pace, marching one and two paces, and then halting.

VI. The Manual Exercise. The following is the regulation for performing the manual exercise, the recruit standing at the position already described, with his firelock shouldered. The manual is not to be executed by one word, or signal, but each separate word of command is to be loudly and distinctly given by the officer who commands the body, performing it. Three seconds are the time allotted between each motion, except that of fixed bayonets, in which a longer time must be given.

Order Arms. Bring the firelock to the trail in two motions; first, bringing it at the first, at the lower loop, just above the swell; at the second, bring it down to the right side, the butt within two inches of the ground; at the third, drop the butt on the ground, placing the muzzle against the hollow of the right shoulder, and the hand flat upon the swing.

Fix Bayonets. At the word, fix, place the thumb of the right hand, as quick as possible, behind the barrel, taking a grip of the firelock. As soon as the word of command is fully out, push the firelock a little forward, at the same time drawing out the bayonet with the left hand, and fixing it with the utmost celerity. The infantil is this is done, return as quick as possible to the order as above described, and stand perfectly steady.

Shoulder Arms. As soon as the word shoulder is given, take a grip of the firelock with the right hand, as in fixing bayonets; and at the left word, arms, the firelock must be thrown with the right hand, in one motion, and with as little appearance of effort as possible, into its proper position on the left shoulder. The hand crosses the body in so doing; but must be instantly withdrawn.

Project Arms. First, seize the firelock with the right hand, beneath the guard, turning the lock to the front, but without moving it from the shoulder; second, bring it to the poise, seizing it with the left hand, the fingers extended along the fling, the wrist upon the guard, and the point of the left thumb equal in height with the eyes; third, bring down the firelock, with a quick motion, as low as the right hand will admit without constraint, drawing back the right foot at the same instant, so that the hollow of it may touch the left heel. The firelock in this position is to be totally supported in the left hand, the body to rest entirely on the left foot, both knees to be straight.

Shoulder Arms. First, by a turn of the wrist, bring the firelock to its proper position on the shoulder, as described above, the left hand grasping the butt; second, quiet the right hand, and bring it briskly down to its place at the side.

Charge Bayonets. First, at one motion throw the firelock from the shoulder across the body, to a low diagonal recovery, a position generally denominated porting arms, or preparing for the charge, in which the lock is to be turned to the front, and at the height of the breast, the muzzle flitting upwards, so that the barrel may cross opposite the point of the left shoulder, with the butt proportionally depressed. The right hand grasps the small of the butt, and the left holds the piece at the swell, close to the lower pipe, the thumbs of both hands pointing towards the muzzle; second, make a half face to the right, and bring down the firelock to nearly a horizontal position, with the muzzle inclining a little upwards, and the right wrist retting against the hollow of the thigh, just below the hip. N B. The first motion of the charge is the position which the folder will, either from the shoulder, or after firing, take, in order to advance on an enemy whom it is intended to attack with bayonets fixed. The word of command, for that purpose, is Prepare to charge. The second position is that which the front rank takes when arrived at a few yards distance only from the body to be attacked. The first motion of the charge is also that which sentries are to take, when challenging any persons who approach their posts.

Shoulder Arms. First, face to the front, and throw up the piece into its position on the shoulder, by a turn of the right wrist, instantly grasping the butt, as above described, with the left hand: second, quiet the firelock briskly with the right hand, bringing it to its proper place by the side.

The men must likewise be taught to port arms at three motions, throwing the first and second nearly into one. First, they seize the small of the butt under the lock with the right hand, bringing the butt in front of the groin, and keeping the lock somewhat turned out; second, they bring their left arm under
under the cock; third, they quit the right hand. In carrying arms, from the support, the motions are exactly reversed. In marching any distance, or in standing at ease when supporting, the men are allowed to bring their right hand across the body, to the small of the butt, which latter must, in that case, be thrown still more forward; the fingers of the left hand being uppermost, must be placed between the body and the right elbow. The right hands are to be instantly removed, when the division halts, or is ordered to dress by the right. In regard to the motions of securing, grounding, and trailing, as well as piling arms, it will be sufficient for the soldiers to be taught to perform them in the quickest and most convenient method. Unfixing bayonets is to be done from the order, in the same manner as fixing them.

Sentinels posted with shouldered arms, are permitted afterwards to support, but not to slope them. On the approach of an officer, they immediately carry their arms, and put themselves into the proper position; not at the instant he passes, but by the time he is within twenty yards of their post, so that they may be perfectly ready before he comes up. If a field officer, he is entitled to the present arms. Corporals marching with reliefs, or commanding detachments or divisions, will carry their arms advanced.

VII. The Platoon Exercise. When perfect in the manual, the troops are next to be taught this part of their duty, and the manner in which to execute the several firings. The recruit standing at shouldered arms, the first word given is:

Make Ready. This is done by bringing the firelock to the recovery, and instantly cocking.

Pretend. Slip the left hand along the sling as far as the swell of the firelock, and bring the piece down to the present, stepping back about six inches to the rear with the right foot.

Fire. Having fired, drop the firelock briskly to the priming position, and half cock.

Handle Cartridge. First, draw the cartridge from the pouch; second, bring it to the mouth, holding it between the forefinger and thumb, and bite away the top of it.

Prime. First, shake a little powder into the pan; second, shut the pan with the three last fingers; third, seize the small of the butt with the same three fingers.

Load. First, face to the left on both heels, so that the right toe may point directly to the front, and the body be a very little faced to the left, bringing at the same time the firelock round to the left side, without linking it. It should, while in this position, be nearly perpendicular (having the muzzle only a small degree brought forward); and, as soon as it is steady there, it must instantly be forced down within two inches of the ground, the butt nearly opposite to the left heel, and the firelock itself somewhat sloped, and directly to the front. The right hand at the same instant catches the muzzle in order to steady it; second, shake the powder into the barrel, putting in after it the paper and ball; third, seize the top of the ramrod with the fore-finger and thumb.

Draw Ramrods. First, force the ramrod half out, and seize it, back-handed, exactly in the middle; second, draw it entirely out, and turning it with the whole hand and arm extended from you, put it one inch into the barrel.

Ram down Cartridge. First, push the ramrod down, holding it, as before, exactly in the middle, till the hand touches the muzzle; second, flip the fore-finger and thumb to the upper end, without letting the ramrod fall further into the barrel; third, push the cartridge well down to the bottom; fourth, strike it two very quick strokes with the ramrod.

Return Ramrods. First, draw the ramrod half out, catching it back-handed; second, draw it totally out, turning it very briskly from you, with the arm extended, and put it into the loops, forcing it as quick as possible to the bottom; then face to the proper front, the finger and thumb of the right hand holding the ramrod, at the position immediately previous to drawing it, and the butt raised two inches from the ground.

Shoulder Arms. Strike the top of the muzzle firmly with the right hand, to fix the bayonet and ramrod more firmly, and at the same time throw it nimbly up at one motion, to the shoulder. N.B. Though the butts are not to come to the ground in calling about, as accidents may happen from it, yet they are permitted, while loading, to be so raised; but it must be done without noise, and in a manner imperceptible in the front.

In priming and loading quick, 1st, bring the firelock down in one brisk motion to the priming position, the thumb of the right hand placed against the pan cover or seal, the fingers clenched, and the elbow a little turned out, so that the wrist may be clear of the cock. 2d, Open the pan, by throwing up the feel with a strong motion of the right arm, turning the elbow in, and keeping the firelock steady in the left hand. 3d, Bring your hand round to the pouch, and draw out the cartridge. The rest as above described; except that in the quick loading, all the motions are to be done with the utmost dispatch possible, the soldiers taking their time from the flagell-man in front, for calling about and shouldering only.

In firing three deep, the priming position for the front rank is the height of the wallband of the breeches; for the centre rank, about the middle of the stomach; and for the rear rank, close to the breast. The firelocks in all these positions is to be kept perfectly horizontal.

As Front Rank kneeling—make ready. Bring the firelock briskly up to the recover, catching it in the left hand, and, without flopping, sink down with a quick motion on the right knee, keeping the left foot flat, the butt of the firelock at the same moment falling upon the ground. Then cock, and instantly seize the cock and feel together in the right hand, holding the piece firm in the left, about the middle of that part which is between the lock and the swell of the flock; the point of the left thumb to be close to the swell, and pointing upwards. As the body is finking, the right knee is to be thrown fully back, that the left leg may be right up and down, the right foot a little turned out, body straight, and the hand as much up as if shouldered. The firelock must be upright, the butt about four inches to the right of the inside of the left foot.

Pretend. Bring the firelock down firmly to the present, by sliding the left hand to the full extent of the arm along the sling, without letting the motion tell; the right hand at the same time springing up the butt by the cock so high against the right shoulder, that the head may not be too much lowered in taking aim; the right cheek to be close to the butt, the left eye shut, and the middle finger of the right hand on the trigger. Look along the barrel with the right eye, from the breech-pin to the muzzle, and remain steady.

Fire. Pull the trigger strong with the middle finger, and, as soon as fired, spring up nimbly upon the left leg, keeping the body erect, and the left foot flat, and bringing the right heel to the hollow of the left. At the same instant, drop the firelock to the priming position, half cock, handle cartridge, and go on with the loading motions as before described.

As Centre Rank—make ready. Spring the firelock briskly to the recover. As soon as the left hand seizes it above the lock, raise the right elbow a little, placing the thumb of that hand upon the cock, with the fingers open on the plate of
the lock, and then, as quick as possible, cock the piece, by dropping the elbow, and forcing down the cock with the thumb. **Step at the same time** with the right foot a moderate pace to the right, and keeping the left fall, seize the small of the butt with the right hand. The piece must be held in this position perpendicular, and opposite the left side of the face, the butt close to the breast, but not pressed, the body straight and full to the front, and the head erect.

**Preface,** as in the foregoing explanation.

**Fire.** Pull the trigger strong with the middle finger; and, as soon as fired, bring the firelock to the priming position. Prime and load as before, with this difference only, that the left foot is to be drawn up to the right, at the same time that the firelock is brought down to the priming position; and that, immediately after the firelock is thrown up to the shoulder, the men spring to the left again, and cover their file leaders.

**As Rear Rank—make ready.** Recover and cock as before directed for the centre rank. **As the firelock is brought to the recover, step briskly to the right a full pace, at the same time placing the left heel about six inches before the point of the right foot. The body to be kept straight, and as square to the front as possible.**

**Preface,** as in the foregoing explanation.

**Fire,** as before; remembering only the difference of the priming position for this rank. After firing and recovering the shoulder, the men step as the centre rank does.

In firing with the front rank standing, that rank makes ready, &c., as mentioned in the first part of the platoon exercises. The platoon exercises are always to be performed with ranks closed, except at the drill.

**VIII. Firings.** When the recruits have acquired the management of their arms, and are perfect in the motions of the manual and platoon exercises, they will be instructed in closed ranks, at firing, 1st, direct to their front; 2dly, obliquely to the right and left; and, 3dly, by files.

**IX. Marching to the front and rear.** The division, or squad, is to be particularly well drilled, files correct, arms carried, the rear ranks covering exactly, and each individual to have his just attitude and position, before the squad is ordered to move. The march will be made by the right or left flank, and a proper trained man will therefore conduct it. The word _march_ may be given as a caution; and at the word _march_, each man steps forward a full pace. The recruit must not turn his head to the hand to which he is drilling, as a turning of the shoulders would undoubtedly follow. His elbows must be kept steady, without constraint: if they are opened from his body, the man must be pressed upon; if they are closed, there arises an improper distance, which must be filled up. In either case, walking on the march will take place, and is therefore to be avoided. The going to the right, or left about, in march, is not to be at first practised, but the squad is to halt, front by command, and then march. As the being able to march straight forward is of the utmost consequence, the officer commanding the drill will take every pains to perfect his squad in it. For this purpose, he will often go to the rear, place himself behind the flank file which regulates the march, and take a point or object exactly in front of that file. He will then command, _march_; and remaining in his place, will direct the advance of the squad, by keeping the flank file always in a line with the object. It is also from before he will found perceive the leaning back of a shoulder, or the bringing it forward; faults which ought instantly to be rectified, as productive of the worst consequence in a line, where one man, by bringing forward a shoulder, may change the direction of the march, and oblige the wing of a battalion to run, in order to keep dressed. In short, it is impossible to labour too much at making the folder march straight forward, keeping always the same front as when he stepped off. This is effected by moving slowly from the haunches, keeping the body steady, the shoulders square, and the head to the front; and will without difficulty be attained by a strict attention to the rules for marching, and a careful observance of an equal length of step, and an equal cadence or time of march.

Changing from ordinary to quick time, and from quick to ordinary, must always be preceded by a halt. Although this may not appear essential for the movements of a division or battalion, it is absolutely so for those of a larger body, and is therefore required in small ones. Turning on the march, in order to continue it, though inaccurate and improper for a large body, is necessary, and must often be allowed, in the movements of small divisions in file or front, when connected with others in line or column. As helps for fixing the true cadence of the march, the plummet must often be referred to. The words left, right, may, when necessary, be repeated; slowly for ordinary, and more rapidly for quick time. Strong taps of the drum, regulated by the plummet, may be allowed to be given immediately before the word _march_, to impress the required measure on the mind of the recruit; but they are on no account, or in any situation, to be given during the march.

**X. Open and close Order, on March.** The squad, when moving to the front in ordinary time, receives the word, _rear ranks take open order_; on which the front rank continues its march without altering the pace, and the centre and rear ranks mark the time, viz., the centre once, and steps off at the second pace; the rear rank moving forward on the third. On the word _rear ranks take close order_, the centre and rear ranks step nimbly up to close order, and instantly resume the pace at which the first rank has continued to march.

**XI. March in File to a Flank.** The accuracy of the march in file is so essential in all deployments into line, and in the internal movements of the divisions of the battalion, that the soldier cannot be too much exercised in it. The whole battalion, as well as its divisions, is required to make this flank movement, without the least opening out, or lengthening of the file, and in perfect cadence and equality of step. After facing, and at the word _march_, the whole squad steps off at the same instant, each replacing, or rather overlapping, the foot of the man before him, i.e., the right foot of the second man comes within the left foot of the first, and thus of every one; more or less overlapping, according to the closeness or openness of the files, and the length of step. The front rank will march straight along the given line, each folder of that rank looking along the necks of those before him; never to the right or left; otherwise a waving of the march will take place, and of course the loss and extension of line and distance, whenever the body returns to its proper front. The centre and rear ranks must look to, and regulate themselves by their leaders of the front rank, and always dress in their file. Although file marching is generally in quick, yet it must also be practised in ordinary time. The above position of feet takes place in all marching in front, where the ranks are close, and looked upon. With a little attention and practice, this mode of marching, apparently so difficult, will be found by every folder to be easier than the common method of marching by files, when, on every halt, the rear must run up to gain the ground it has unnecessarily lost.

**XII. Wheeling in File.** The squad, when marching in file, must be accustomed to wheel its head to either flank; each
each file following in succession, without losing or increasing
distance. On this occasion, each file makes its separate
wheel, or a pivot movable in a very small degree, but with-
out altering its true line of march, or the eyes of the rear ranks,
being turned from their front rank. The front rank men,
whether pivot-men or not, must keep up to their distance;
and the wheeling men must take a very extended step, and
lost no time in moving on.

XIII. Oblique Marching in Front. When the squad is
marching in front, and receives the word to the right oblique,
each man, the first time he raises the right foot, will, instead
of throwing it straight forward, carry it in the diagonal di-
rection, as has been already explained in § 8. of the drill
without arms; taking care not to alter the position of his
body, shoulders, or head. The greatest attention is to be
paid to the shoulders of every man in the squad, that they
remain parallel to the line on which they first were placed,
and that the right shoulders do not fall to the rear, which
they are very apt to do in obliqueing to the right, and which
immediately changes the direction of the front. On the
word forward, the incline centres, and the whole march
forward. In obliqueing to the left, the same rules are to be
observed, with the difference of the left leg going to the
left, and attention to keeping up the left shoulder. The
same instructions that are given for ordinary time, serve also
for quick time; but this movement, though it may be made
by a small division, cannot be required from a larger body.
Obliqueing to the right is sometimes to be practiced with eyes
to the left; and obliqueing to the left, with eyes to the
right; as being absolutely necessary on many occasions:
for if one of the battalions of a line in advancing be ordered
to oblique to the right or to the left, the eyes must still con-
tinue turned towards its centre.

XIV. Oblique Marching in File. In obliqueing to the
right or left by files, the centre and rear rank men will con-
tinue looking to their leaders of the front rank. Each file
is to consider itself as a rank entire, and is to preserve the
same front, and position of the shoulders, during the oblique,
as before it began. This being a very useful movement, rec-
cruits are to be often practiced in it.

XV. Wheeling forward from the Halt. The directions
already given for the wheeling of a single rank, are to be
strictly attended to in this wheel of the squad. On the word
right, or left wheel, the rear ranks, if at one pace distance,
lock up. At the word march, the whole step together in
the quickest time, and the rear ranks, during the wheel, in-
cline so as to cover their proper front rank men. At the
word halts, the whole remain perfectly steady.

XVI. Wheeling backward. The squad must be much
practised in wheeling backward in the quickest time. In
this wheel, the rear ranks may preserve their distance of one
pace from each other. Great attention should be paid to
prevent the recruits from fixing their eyes on the ground.

XVII. Wheeling from the March. The directions for
wheeling on a halted, and on a moveable pivot, have already
been given under the drill without arms. The squad should
now be practiced in both, until thoroughly confirmed in those
movements.

XVIII. Stepping out, &c. The squad must likewise be
practised in stepping out, stepping short, marking time, changing
the feet, the file step, and stepping back; the instructions
for which have been fully detailed in the first part of the
drill.

It can neither be too strongly inculcated, nor too often
remembered, that upon the correct equality of march, esta-
ablished and practised by all the troops of the same army,
every joint movement and maneuvre depend. If this is not
attended to, diffusion and confusion will necessarily take
place on the junction of several battalions in corps; al-
thought taken individually, each may be in most respects
well trained. It is in the original instruction of the recruit
and squad, that this great point is to be laboured at and
attained. The time and length of step, on all occasions,
are prescribed. The time is infallibly ascertained by
the frequent corrections of the plummets, which, when so ap-
plicated, will soon give to each man that habitual measure so
much desired. Every driller must therefore have it at hand
and, as already observed, before any squad or larger body
is put in march, five or six strong taps of the drum may be
given, in exact time, as regulated by the plummets, which
will imprint the true measure on each ear, and prepare for
taking an accurate step at the word march. The length of
step is only to be acquired by repeated trial; and therefore,
before the recruit is put in motion, each instructor should
ascertain the space on which he is to drill his men; he will
therefore (supposing that he himself is accurate in his paces,
and that there is ground for that purpose) mark out an ob-
long square of forty paces by twenty or thirty, the corners
of which he will ascertain by halberts, staves, or any other
visible manner. Along the sides of this figure he will march
the pivot flank of his squad, making correct wheels and halts
at the angles. The time of march being exactly ascertained,
he will then see that the sides of the oblong are gone over at
the known number of steps; and if there be any inaccuracy,
he will lengthen or shorten the step, till the squad marches
with the utmost precision, every man preserving his just
position, and all the other indisensible attentions in march-
ing being strictly observed. Where there is a sufficiency of
ground, the squads will occasionally march over larger
spaces; but the distances should in the same manner be ex-
cactly determined, so that there may be no doubts as to the
true length of the step. In proportion to the strength of
squads or drills, one or more formedfolders should accom-
pany each, to march on the flank, give distances, and in other
points regulate the motions of the drill.

Formation and Exercise of the Platoons, or Company.
The recruit being thoroughly grounded in all the preced-
ing parts of the drill, is now to be instructed in the move-
fments of the platoon, as a more immediate preparation for
his joining the battalion. For this purpose, from ten to
twenty files are to be assembled, formed, and told off in the
following manner, as a company in the battalion.

I. The platoon falls in three ranks, at close order, with
shouldered arms; the files lightly touching, but without
crowding. Each man will then occupy a space of about
22 inches. The commander of the platoon takes poit on
the right of the front rank, covered by a serjeant in the
rear rank. The other serjeants will form a fourth, or su-
pernumerary rank, three files from the rear rank. The
platoon will be told off into subdivisions, and, if of suffi-
cient strength, into four sections; but as a section should
never be less than five files, it will often happen that, for the
purposes of march, three sections only can be formed.
The four best-trained folders are to be placed in the front
rank, on the right and left of each subdivision. When thus
formed, the platoon will be practiced in opening and closing
of ranks; dressing to the front, to the rear, or in an oblique
direction, by the right or left; and exercised in the several
motions of the firelock. Close order is the chief and pri-
mary order in which the battalion and its parts at all times
assemble and form. Open order is only regarded as an ex-
ception from it, and occasionally used in situations of para-
des and flrew. In close order, the rear ranks are closed up to
within one pace; the length of which is to be taken from
the
the heeds of one rank to those of the next. At open order, they are two paces distant from each other.

11. Marching to the Front. In the drill of the platoon, the person instructing must always consider it as a company in battalion, and regulate all its movements upon that principle. He will therefore, before he puts it in motion to front or rear, indicate which flank is to direct, by giving the word Eyes Right, or Eyes Left, and then March. Should the right be the directing flank, the commander of the platoon himself will fix on objects to march upon, in a line truly perpendicular to the front of his corps. When the left flank is ordered to direct, he and his covering serjeant will shift to the left of the front rank, and take such objects to march upon. To march on one object only, and to preserve a straight line, is an operation not to be depended upon. The conductor of the platoon therefore, before the word to march is given, will endeavour to remark some distinct object on the ground in his own front, and perpendicular to the directing flank. He will then observe some nearer and intermediate point in the same line, such as a stone, tuft of grass, \\&c. These he will move upon with accuracy; and as he approaches the nearest of those points, he must, from time to time, chuse fresh ones, in the original direction, which he will by this means preserve, never having fewer than two such points to move upon. If no object in the true line can be ascertained, his own squareness of person must determine the direction of the march. A person placed in the rear of a body can, more readily than if placed in its front, determine the line which is perpendicular to that front; and, could we suppose ranks and files perfectly correct, the prolongation of each file would be a perpendicular to the front of the body. As the march of every corps, except in the case of inclining, is made on lines perpendicular to its then front, each individual composing that corps must in his person be placed and remain perfectly square to the given line; otherwise he will naturally and inevitably move in a direction perpendicular to his own person, and thereby open out or close in according to the manner in which he is turned from the true point of his march. If the distortion of a single man (and all turnings of the head do so distort him) operates in this manner, it may easily be imagined what that of several will occasion, each of whom is marching on a different front, and whose lines of direction are crossing each other. Accuracy and squareness of position, the equality of cadence and rep, the light touch of the files which is never to be relinquished, just distances, and true lines of movement, will give, without apparent constraint, the head being turned, or the least trouble taken in dreffing, the most decisive exactness in the marches and operations of the largest bodies.

The platoon, during its march in line, will occasionally be ordered to flip out, mark time, open and close ranks, and oblique, as already described.

111. Side Step. The side or crossing step must also be frequently practiced. It is very necessary and useful on many occasions, when halted, and when a very small distance is to be moved to either flank: for instance, to open or close files; to join one division to, or open it from, another; to regain an interval in line; to move a whole battalion or parade twenty or thirty paces to a flank; to regulate distances between close columns, before deploying, &c. Alterations made in this manner are imperceptible from the front, and better made than by facing and file-marching. The words of command must be decided and strong. When the whole platoon is to clofe; at the word, to the Right—Clofe, the platoon officer takes one flip to the front, and instantly faces about, the covering serjeant replacing him. On the word Mark, the whole move together. On the Halt, the platoon officer resumes his place, having flapped in the same manner as the men, but fronting them, and thereby affihed in preserving the direction.

111. Back Step. The platoon must be accustomed, at the halt on the words Back Step—March, to step back any ordered number of paces in the ordinary time and length, as it is an operation that may be sometimes required from a battalion.

V. File Marching. In marching by files, the commander of the platoon will lead the front rank. If therefore the movement is to the left, on the word to the Left—Face, he and his covering serjeant will instantly shift to the left flank of the division. At the word Quick—March, the whole flips off together; and on the Halt, Front, the leader and his serjeant will return to their posts on the right.

VI. Wheeling from a Halt. In wheeling, whether forward or backward, from a halt, the commander of the platoon, on the word Right or Left Wheel, moves out, and places himself one pace in front of the centre of his platoon. During the wheel, he turns towards his men, and inclines towards that flank which has been named as the directing or pivot one; giving the word Halt—Drefs, when his wheeling man has just completed the required degree of wheel. He then figures his platoon, but without moving what was the flancing flank, and takes his post on the now directing flank.

VII. Wheeling forward by Subdivisions from Line. On the word By Subdivisions, to the Right, Wheel, the commander of the platoon places himself one pace in front of the centre of the right subdivision; at the same time, the men on the right of the front rank of each subdivision face to the right. At the word March, each subdivision flaps off in wheeling time, observing the directions above given for wheeling forward. The commander of the platoon, turning towards the men of the leading subdivision, and inclining to its left (the proper pivot flank), gives the word Halt—Dress, for both subdivisions, as his wheeling man is taking the left step that finishes the wheel square; and instantly posts himself on the left, the pivot flank. The covering serjeant, during the wheel, goes round by the rear, and takes post on the pivot flank of the second subdivision. It is to be observed, that the commander of the platoon invariably takes post with the leading subdivision; therefore, when the platoon wheels by subdivisions to the left, the commander of the platoon moves out to the centre of the left subdivision, and during the wheel, inclines towards the right, now become the proper pivot flanks of the subdivisions. The proper pivot flank in column, is that which, when wheeled up to, preserves the divisions of the line in the natural order; and to their proper front; the other is denominated the reverse flank. In column, divisions cover and drefs to the proper pivot flank; to the left when the right is in front, and to the right when the left is in front.

VIII. Wheeling backward by Subdivisions from Line. The platoon will also break into open column of subdivisions by wheeling backwards. When the right is intended to be in front; at the word, By Subdivisions, on your left backwards Wheel, the commander of the platoon moves out briskly, and places himself in front of the centre of the right subdivision; the man on the left of the front rank of each subdivision at the same time faces to the right. On the word March, each subdivision wheels backward in quickest time. During the wheel, the commander of the platoon turns towards his men, inclining at the same time to the left, or pivot flank; and on completing the wheel, gives the word Halt—Dress, to both divisions. He and his covering
covering serjeant then place themselves on the left flanks of their subdivisions. It may be considered as a rule almost general (the reasons for which are subsequently given), that all wheels of the battalion or line (when halted, and when the divisions do not exceed sixteen or eighteen files) into column, should be backward, and all wheels from column into line, forward. The only necessary exceptions seem to be in narrow ground where there is not room for such wheels.

IX. Marching on an Alignment, in open Column of Subdivisions. The platoon having wheeled backwards by subdivisions from line, as just stated, and a distant marked object in the prolongation of the two pivot flanks being taken, the commander of the platoon, who is now on the pivot flank of the leading subdivision, immediately fixes on his intermediate points to march on. On the word March, both divisions step off at the same instant, the leader of the frontmost corps marching with the utmost readiness and equality of pace on the points he has taken; and the commander of the second division preserving the leader of the left in an exact line with the distant object, at the same time he keeps the distance necessary for forming from the preceding division, which distance is to be taken from the front rank. These objects are in themselves sufficient to occupy the whole attention of the leaders of the two divisions; therefore they must not look to, nor endeavor to correct, the march of their men, which care must be entirely left to the non-commissioned officers of the supernumerary rank.

X. Wheeling into Line From open Column of Subdivisions. The platoon being in open column of subdivisions, marching at the ordinary step on the alignment, receives the word Halt from the instructor of the drill. Both divisions instantly halt, and the instructor sees that the leaders of the divisions are correct on the line in which they have moved. He then gives the word (supposing the right of the platoon to be in front), By Subdivisions, to the left wheel into Line. On this the commander of the platoon goes to the centre of his subdivision; the two pivot men face to their left, exactly square with the alignment, and a serjeant runs out and places himself in a line with them, so as to mark the precise point at which the right flank of the leading subdivision is to halt, when it shall have completed its wheel. At the word March, the whole wheel up in quickest time. During the wheel, the commander of the platoon, turning towards his men, inclines to the wheeling flank, and gives the word Halt—Drifs, the moment the wheel of the division is completing. He also, if necessary, corrects the internal dressings of the platoon on the serjeant and pivot men. This dressling must be quickly made; and when done, the commander of the platoon gives the word Eye Front, in a moderate tone of voice, and resumes his post in line. In all wheels of the divisions of a column (either from the halt or from the march) that are made on a halted pivot, the flank firelock of the front rank on the hand wheeled to, is such pivot; not the officer who may be on that flank, and whose busines is to conform to it. All wheels by subdivisions or sections from line into column, or from column into line, are performed on the word given by the commander of a battalion, when the whole of a battalion is at the same instant fo to wheel; or on the word given by the captain of the company, when companies singly, or successively, so wheel. They are not to be repeated by the leaders of its divisions.

XI. In Open Column of Subdivisions, wheeling into a new Direction on a movable Pivot. The commander of the leading subdivision, when at a due distance from the intended new direction, will give the word Right or Left Shoulders Forward; and he himself carefully preferring the rate of march, without the least alteration of step or time, will begin to circle in his own person from the old to the new direction, so as not to make an abrupt wheel, or that either flank shall be stationary. The rest of his division, on the principle of dressing, will conform to the direction he is giving them; when this is effected, he will give the word Forward. The leader of the second subdivision, when he arrives at the ground on which the first began to wheel, will in this manner follow the exact track of the first, always preferring his proper distance from him. Thus, without the constraint of formal wheels, a column, when not confined on its flanks, may be conducted in all kinds of winding and changeable directions; for, if the changes be made gradual and circling, and that the pivot leaders of divisions...
divisions pursue their proper path, at the same uniform equal pace, the true distances will be preferred, which is the great regulation object on this occasion, and to which every other must give way.

XIII. Countermarch by Files. The platoon, when it is to countermarch, must always be considered as a division of a battalion in column. The instructor of the drill will therefore, previous to his giving the caution to countermarch, signify whether the right or left is supposed to be in front, that the commander of the platoon and his covering sergeant may be placed on the pivot flank, before such caution is given; as it is an irremovable rule in the countermarch of the divisions of a column by files, that the standings be made from the flank, then the pivot one, to the one which is to become such. On the word To the Right or Left Face, the platoon faces; the commander of it immediately goes to the other flank; and his covering sergeant, advancing to the spot which he has quitted, faces to the right about. At the word Quick March, the whole, except the sergeant covering, steps off together; the platoon officer wheeling short round the rear rank (viz. to his right, if he has shifted to the right of the platoon; or to his left, if he remains on the left of it); and proceeds, followed by the platoon in file, till he has conducted his pivot front-rank man close to his sergeant, who has remained immovable. He then gives the words Halt, Front, Draft; squares, and closes his platoon on his sergeant, and then replaces him. All countermarches by files necessarily tend to an extension of the files. Unity of step is therefore absolutely indispensable, and the greatest care must be taken, that the wheel of each file be made close, quick, and at an increased length of step of the wheeling man, so as not to retard or lengthen out the march of the whole.

XIV. Wheeling on the Centre of the Platoon. The platoon must be accoumlomed to wheel upon its centre, half backward, half forward, and to be pliable into every shape which circumstances can require of it; but always in order, and by a decided command. The words of command are, Platoon — on your Centre, to the Right Wheel, to the Left Wheel; to the Right about wheel; to the Left about wheel; &c. When the wheel is to be made to the right, or right about, the right half platoon is the one to wheel backward, and the left forward. The reverse will take place when the wheel is to be made to the left, or to the left about. On the word March, the whole move together in the quickest time, regulating by the two flank men, who, during the wheel, preserve themselves in a line with the centre of the platoon. As soon as the required degree of wheel is performed, the commander of the platoon gives the word Halt—Drafts, and instantly figures it from that flank on which he himself is to take post.

XV. Oblique Marching. The instructor of the drill will have the oblique march frequently practised in platoon, in subdivisions, and in file. He will see, when in divisions, that the rear ranks lock well up, and cover exactly; when in file, that the exact distances are preserved between the files; and in both cases, that the platoon, during its march, continues parallel to the position from which it commenced obliquing.

XVI. Increasing and diminishing the Front of an open Column, when halts. 1. Increasing. The company standing in open column of subdivisions (suppose the right in front) receives from the instructor of the drill the caution to form platoon. The commander of the platoon instantly orders Rear Subdivision, to the Left oblique—Quick March. When it has obliqued, so as to open its right flank, i.e. when its right flank has room to march past the left flank of the division that was in its front he gives the word Forward; and, on its arriving in a line with the first division, he orders Halt—Drafts, and takes post on the left, the pivot flank of the platoon. 2. Diminishing. On the cautionary command, from the instructor of the drill, to form Subdivisions, the commander of the platoon orders, Left Subdivision—to the Right Face; and instantly on facing, the three leading files disengage to the rear, the sergeant-cover running round to head them. On the word Quick March, the sergeant conducts the subdivision in file, to its proper distance, in the rear of the first subdivision. The commander of the platoon, having moved to the left flank of the leading division, as soon as he sees the rear file of the second in line with his own person, gives the words Halt—Front and Left—Drafts. The sergeant-cover at the same time moves briskly to his post on the left flank of the rear subdivision, and figures it. It is to be observed as a general rule, in diminishing the front of a column by the doubling of subdivisions or sections, whether the column be halted or in motion, that the subdivision or section on the reverse flank is the one behind which the other subdivisions or sections double. Thus, when the right is in front, the doubling will be in rear of the right division, and vice versa when the left is in front; by which means the column is at all times in a situation to form line to the flank, with its subdivisions in their natural order, by simply wheeling upon the pivot flanks. In increasing the front of a column, the rear subdivisions or sections oblique to the hand the pivot flank is on; so that when the right is in front, the obliquing will be to the left; and the reverse when the left is in front.

XVII. Increasing and diminishing the Front of an open Column on the March. 1. Increasing: The platoon marching at the ordinary time in open column of subdivisions (suppose the right in front), receives from the instructor of the drill the cautionary command Form Platoon. The commander of the platoon instantly gives the words Left oblique—Quick March; on which the rear subdivision oblique to the left, and as soon as its right flank is open, receives the word Forward. When it gets up to the first subdivision, which has continued to march with the utmost steadiness at the ordinary pace, the commander of the platoon gives the words Halt—March, and takes post on the pivot flank. 2. Diminishing: When the instructor of the drill gives the caution to form subdivisions, the commander of the platoon immediately orders Left Subdivision, March Time. This it does to: the right one, which continues to march steadily at the ordinary pace, has cleared its flank. He then orders the left subdivision, Quick oblique; and when he perceives that it has doubled properly behind the right one, he gives the word Forward, on which it takes up the ordinary march, and follows at its due distance. The same directions that apply to increasing or diminishing by subdivisions, apply equally by sections, which individually repeat the same operations. The words for the subdivisions or sections increasing or diminishing the front of a column, are given by the commander of a company, and not repeated by those of its subdivisions. Increasing and reducing the front of a column is an operation that will frequently occur in the march of large bodies; and it is of the utmost importance that it be performed with exactness. The instructor of the drill must therefore be particularly attentive, that the transition from one situation to the other be made as quick as possible; that the leading division continues its march at the regular time and length of pace; and that the exact distances between the divisions be accurately preferred. During the operation, the ranks must be well closed, arms carried, and the greatest attention required from each individual.

XVIII. The
XXVIII. The Platoon in open Column of Subdivisions: to pass a short Distance by breaking off Files. We suppose the platoon in open column of subdivisions, with the right in front, marching in ordinary time. When the leading division is arrived within a few paces of the defile, it receives from the instructor of the drill an order to break off a certain number of the files (suppose three); the commander of the leading division instantly gives the words, *Three Files on the Left, Right turn.* The named files immediately turn to their right, and wheel out in rear of the three adjoining files. The commander of the subdivision himself closes into the flank of the part formed. When the second subdivision comes to the front, where the front subdivision, having terminated its front, will receive the same words of command from its own leader, and will proceed in like manner. Should it be required to diminish the front of the column one or two files more, the commander of the leading division will, as before, order the desired number of files to turn; on which those already in the rear will incline to their right, so as to cover the files now ordered to break off, and which are wheeling out in the manner already prescribed. In this movement, the files in the rear of the subdivisions must lock well up, so as not to impede the march of the succeeding division. As the defile widens, or the instructor of the drill shall direct, the commander of the leading subdivision will order files to move up to the front, by giving the word *One, two, or three Files to the Front;* on which the named files turn to their front, the left, and lengthening their pace, march up, file by file, to the front of their subdivision, and immediately resume the ordinary pace. Those files which are to continue in the rear, will oblique to the left, lengthening also their step, till they cover, and are closed up to the three files on the left flank of their subdivision.

XIX. Marching in quick Time. The platoon must frequently be practiced to march in quick time, particularly in file, until the men have acquired the utmost precision in this movement, which is essential in all deployments from close column. The platoon will also occasionally be marched in front at the same step, as it may be sometimes required from small bodies.

XX. Forming to the Front from File. The platoon, when marching in file, may form to its front, either in sections, sub-divisions, or in platoon. The right flank being supposed to lead, on the word *halt front,* the platoon instantly halts, and faces to the right. The word *halt* is given, by sections, sub-divisions, or platoon, on your left backwards wheel; and at the word *march,* the wheel ordered is performed in the manner already directed in sect. viii. But in situations where it may have been necessary to order an extension of files (such as will sometimes occur in marching through the streets of a town), a body thus moving, in order to avoid incorrect distances between the divisions, may form to the front in the following manner, either by platoon, sub-divisions, or sections. On the word *to the front form platoon,* the front rank man of the leading file halts alone, and is instantly covered by his centre and rear rank men. Every other file of the platoon makes a half face to the left, and successively moving up, drefs on the right file. When the commander of the platoon sees it is properly dressed, he gives the word *eyes left,* and places himself on the pivot flank. Should the order have been, to the front form sections or sub-divisions, the leading sub-division or section will proceed in the manner already detailed for the platoon. The succeeding sub-divisions or sections will each continue moving on, until its front file arrives at the proper forming distance from the division in its front, when it will receive from its commander the word to the front form, and will instantly form up by files in the manner already described.

XXI. Forming from File to either Plank. The platoon marching in file, suppose from the right, has only to halt and front to be formed to the left flank. To form to the right, it will receive the word to the right form. The front rank man of the leading file instantly turns to his right, and halts; his centre and rear rank men move round and cover him. All the other files of the platoon make a half turn to their left, and move round successively in a line with the right hand file; the centre and rear rank men of each file keeping closed well up to their file leaders.

XXII. To form to either Plank from open Column of Subdivisions or Sections. The platoon marching in the ordinary time in open column of sub-divisions or sections, to form to its left receives the words *hghts, left wheel, and form, march,* &c., and proceeds as has already been shewn in sect. x. To form the platoon to its right flank, the instructor of the drill gives the cautionary word of command, to the right form platoon; on which the commanders of the severai divisions shunt to the other flank, and the commander of the leading sub-division or section instantly gives the word to his division, *right wheel;* and when it has wheelèd square, he orders *halt, right dress,* goes to the right flank of his division, and dresses it on the intended line of formation. The commander of the other sub-divisions or sections, on the leading one being ordered to wheel, gives the word to the left oblique, and gradually inclines so as to be able to march clear of the rear rank of the division forming. This being effected, the word *forward* will be given to each division, and they move on in the rear of the one formed. When the second sub-division or section is arrived at the left flank of the first, its commander gives the word *right wheel,* then *halt, dress,* on which the division moves up into the line with the one formed; and its commander instantly places himself two or three files from the left of his first division, and dresses his own on it as quickly and as accurately as possible. Thus each succeeding section should proceed, until the whole be formed.

XXIII. The Platoon moving to the Front to gain Ground to a Flank, by a March in Echelon by Sections. In the drill of the platoon, when the battalion is completely formed, it may be taught to march in echelon by sections. This is a very useful movement for a battalion or larger body moving in line, that is required to gain ground to a flank, and may be distinguished instead of the oblique march. It will be performed in the following manner: the platoon marching to the front in the ordinary time, receives the word *by sections to the right.* The right hand men of the front rank of each section turning in a small degree to their right, mark the time for three paces, during which the sections are wheeling in ordinary time on their pivot men. At the fourth pace, and at the word *forward,* the whole move on directly to the front that each section has now acquired, and the commander of each section having taken post on the right of his division, the platoon continues its march in echelon. On the word *form platoon,* the pivot men mark the time for three paces, turning back in a small degree to the left, their original front; and the sections instantly wheel backward into line. At the fourth pace, the whole move forward. When the platoon is in two ranks only, two paces instead of three will be sufficient to mark time, and to step off at the third instead of the fourth pace.

XXIV. From three Ranks, forming into two. The platoon halted, is ordered *form two deep.* The rear rank men of the left sub-division instantly step back one pace. On the word *left face,* the rear rank of both sub-divisions face.
The word quick march is then given, on which the men of the rear rank of the left sub-division file short, until three of the right get up to them; they then move on with them in file. As their rear is clearing the left flank of the platoon, the commander, who has shifted to this flank during the movement, gives the words half, front, drefs up, instantly dresse them on the standing part of his platoon, and refumes his poít on the right. One third or one more sub-division is thus added to the front of the company, which is here supposed standing as one in a battalion column.

XXV. From two Ranks, forming into three. The platoon being halted, and told off into three sections, it receives the word form three dreep; on which the third section instantly steps back one pace. The word right face is then given, and the man on the right of its front rank, on facing, difies a little to his right. On the word quick march, the front rank men of the third section step off, those of the other mark the time, till they have passed, and then follow. When the leading man has got to the right of the platoon, the commander gives the word halt front; on which, each man halts, faces to his left, and infantly covers his proper file leader.

In pursuance of the foregoing instructions, and on the principles they contain, every company of a battalion must be frequently exercised by its own officers, each superintending a rank, or an allotted part of the whole. On a space of seventy or eighty yards square, every circumstance can be practiced that is necessary to qualify it for the operations of the battalion. That space being pointed out by under officers, or other marks, as directed at the latter end of the drill with arms, the company will practive, both at open and close files, without and with arms.

By ranks. 1st, March in single file, by successive ranks, along the four sides of the square; the same by twos. 2d, March and wheel by ranks of fours; file off singly and double up, preserving proper distances, and not quickening on the wheel. 3d, March and wheel by sub-divisions of ranks. 4th, March and wheel by whole ranks. 5th, March to front and to rear, ranks at ten paces adumer. 6th, March the company in a single rank to front and to rear, by a flank and by the centre. 7th, Oblique, by ranks. 8th, Open and close files, and intervals, by the side file. 9th, March in file to either flank. 10th, Ranks successively advance fix or eight paces, halt, and dres; ranks successively fall back the same number of paces, halt, and dres. 11th, Advance or retire two or three flank men, the ranks dres to them. 12th, Open and close ranks.

At close ranks and files. 13th, March and wheel in all directions, by sub-divisions and by company; shorten file, and lengthen it; the march to be made both in ordinary and quick time; the wheels to be made in wheeling time. 14th, Advance and retire two or three flank files, and dres to them. 15th, Open and close to the flank by the side file. 16th, Change front by the countermarch by files. 17th, March in file to the flanks, close, and without opening out, form to the front, or to either flank. 18th, March oblique. 19th, Sub-divisions double on the march, and again form up by obliquing. 20th, Wheel backwards by sub-divisions, march along the line to prolong it; form to the flank by wheeling up, or to the front by obliquing. 21st, File from the flank of company to the rear, as in the passage of lines; halt front, close into pivot file, wheel up as in forming line. 22d, From three deep, form two deep. 23d, From two deep, form three deep. 24th, Exercise of the filelock, mantal and platoon, by ranks and company. 25th, Firings by Files, sub-divisions, and company.

The necessary pauses and formations between these movements in order to connect them, must of course be made. They may be practiced in whatever succession shall at the same time be found proper. The greatest precision must be required and observed in their execution, according to the rules already laid down.

Every officer must be instructed in each individual circumstance required of a recruit, or a solder; also in the exercise of the sword; and accustomed to give words of command with that energy and precision which is so essential. Every officer, on first joining a regiment, is to be examined by the commanding officer; and if he is found imperfect in the knowledge of the movements required from a soldier, he must be ordered to be exercised, that he may learn their just execution. Till he is master of those points, and capable of instructing the men under his command, he is not to be permitted to take the command of a platoon in the battalion. Squads of officers must be formed, and exercised by a field officer. They must be marched in all directions; to the front, oblique, and to the flank. They must be marched in line, at platoon distance, and marched as in open column. They must change direction, as in file, and cover anew in column. In these, and other similar movements, the pace and the distances are the great objects to be maintained. From the number of files in division, they must learn accurately to judge the ground necessary for each, and to extend that knowledge to the front of greater bodies. They must acquire the habit of readily ascertaining, by the eye, perpendiculars of march, and the squareness of the wheel. An officer must not only know the poll which he should occupy in all changes of situation, the commands which he should give, and the general intention of the required movement; but he should be master of the principles on which each is made, and of the faults that may be committed, in order to avoid them himself, and to instruct others.

These principles are in themselves so simple, that moderate reflection, habit, and attention, will soon shew them to the eye, and fix them in the mind; and individuals, from time to time, when qualified, must be ordered to exercise the battalion, or its parts. The complete instruction of an officer enlarges with his situation, and at last takes in the whole circle of military science. From the variety of knowledge required of him, his exertion must be unremitting, every one striving to make himself master of his own part. Besides the instruction peculiar to the non-commissioned officers, they should be exercised in the same manner as the officers are, as they are frequently called on to replace them. The necessity also of order, readiness, silence, and of executing every thing deliberately, and without hurry, should be strongly inculcated on the infantry folder.

Formation of the Company.

The company is always to be fixed from flanks to centre. It is formed three deep. The files lightly touch, when filelocks are shouldered and carried, but without crowding, and each man will occupy a space of about twenty-two inches.

Close order is the chief and primary order, in which the battalion and its parts at all times assemble and form. Open order is only regarded as an exception from it, and occasionally used in situations of parade and review. In close order, the officers are in the ranks, and the rear ranks are closed up within one pace. In open order, the officers are advanced three paces, and the ranks are two paces distant from each other. Each company is a platoon. Each company forms two sub-divisions, and also four sections. But as sections should never be less than five files, it will happen, where
where the companies are weak, that they can only, for the purposes of marching, form three sections.

When the company is singly formed, the captain is on the right, the ensign on the left, of the front rank, each covered by a Jerfiant in the rear rank. The lieutenant is in the rear, as also the drummer and pioneers in a fourth rank, at three paces distance. The left of the front rank of each subdivision is marked by a corporal. The right of the left subdivision may be marked by another corporal. When necessary, the places of absent officers may be supplied by Jerfiant; those of Jerfiant by corporals; and those of corporals by intelligent men. When the company is to join others, and the battalion, or part of it, to be formed, the ensign and his covering Jerfiant quit the flank, and fall into the fourth rank, until otherwise placed.

When the company is to take open order from close order, on the command Rear Ranks—take open Order, the flank men on the right and left of the rear ranks, file back to mark the ground on which each rank respectively is to halt and drefs at open distance. They face to the right, and stand covered. Every other individual remains ready to move. At the word of command March, the rear rank drefs front; and the rear ranks fall back one and two paces; each dresfing by the right, and the Jerfiant arrives on its ground. The officers move out in front three paces, and divide their ground. One Jerfiant is on each flank of the front rank. The pioneer remains behind the centre of the rear rank. The drummer places himself on the right of the right Jerfiant.

When the company is to take close order from open order, at the word of command Rear Ranks—take close Order, the officers, Jerfiant, and drummer face to the right. On the word March, the ranks close within one pace, marching one and two paces, and then halting. The officers move round the flanks of the company to their respective posts: the Jerfiant and drummers fall back, and each individual resumes his place, as in the original close order. The above regards the company when single; but when united in the battalion, other posts are allotted to the drummer and pioneer.

**Formation and Order of the Battalion.**

A perfect uniformity in the formation and arrangement of all companies and battalions is indispensable for the execution of joint and combined movements. The strength of the battalion is ten companies: one grenadier, eight battalions, and one of light infantry, comprising most commonly of three officers, three Jerfiant, three corporals, two drummers, and fifty-seven privates. When these companies join, and the battalion is formed, there is to be no interval between any of them, grenadier, light company, or other; but every part of the front of the battalion should be equally strong. Each company which makes a part of the same line, and is to act in it, must be formed and arranged in the same manner.

The companies will draw up as follows, from right to left. Grenadiers; first and third captains; fifth and seventh captains; eighth and sixth captains; second and fourth captains; light infantry. The four eldest captains are on the right of the grand divisions. Officers commanding companies or platoons are all on the right of the front rank of their respective companies. The eight battalion companies will compose four grand divisions, eight companies or platoons, sixteen subdivisions, and thirty-two sections, when sufficiently strong to be so divided, otherwise twenty-four, for the purposes of march. The battalion is also divided into right and left wings. When the battalion is on a war establishment, each company is to be divided into two platoons. When the ten companies are with the battalion, they may then, for the purposes of firing or deploying, be divided into five grand divisions, from right to left. The battalion companies will be numbered from the right to the left, 1, 2, 3, 4, 5, 6, 7, 8; the subdivisions will be numbered 1, 2, of each; the sections will be numbered 1, 2, 3, 4, of each. The files of companies will also be numbered 1, 2, 3, 4, &c. The grenadier and light companies will be numbered separately in the same manner, and with the addition of those distinctions. These several appellations will be preferred, whether faced to front or rear.

The companies must be equalized in point of numbers, at all times when the battalion is formed for field movements; and could the battalions of a line also be equalized, the greatest advantages would arise. But though, from the different strengths of the battalions, this cannot take place, yet the first requisite always must, and is indispensable.

**Pl. III. fig. 2.** When the battalion is formed in close order, ranks are at the distance of one pace, except the fourth or supernumerary rank, which has three paces. All the field officers, and the adjutant, are mounted. The commanding officer is the only officer advanced in front, for the general purpose of exercise, when the battalion is single; but in the march in line, and in the firings, he is in the rear of the colours. The lieutenant-colonel is behind the colours, fix paces from the rear rank. The major and adjutant are fix paces in the rear of the third and fourth companies. One officer is on the right of the front rank of each company, of platoon, and one on the left of the battalion. All these are covered in the rear rank by their respective Jerfiant, and the remaining officers and Jerfiant are in a fourth rank behind their companies. It is to be observed, that there are no coversers in the centre rank to the officers or colours.

The colours, which in most regiments are carried by the two youngest ensigns, are placed between the fourth and fifth battalion companies both in the front rank, and each covered by a non-commissioned officer or ready man in the rear rank. One Jerfiant is in the front rank between the colours; he is covered by a second Jerfiant in the rear rank, and he by a third in the supernumerary rank. The sole business of these three Jerfiant, is, when the battalion moves in line, to advance and direct the march. The place of the first of these Jerfiant, when they do move out, is preferred by a named non-commissioned officer, who moves up from the supernumerary rank for that purpose. Of the officers appointed to carry the colours, the eldest carries the king's, the youngest, the regimental colour. Whenever the right wing advances or retires, the king's colour accompanies it on its flank, and to it the men's eyes are directed as their point of dresfing. In the same manner, the regimental colour accompanies the left wing.

The fourth rank is at three paces distance when halted, or marching in line. When marching in column, it must close up to the distance of the other ranks. The essential use of the fourth rank is to keep the others closed up to the front during the attack, and to prevent any break beginning in the rear. On this important service too many officers and non-commissioned officers cannot be employed. The pioneers are assembled behind the centre, formed two deep, and nine paces from the third rank. The drummers of the eight battalion companies are assembled in two divisions, fix paces behind the third rank of their second and seventh companies. The grenadier and light infantry drummers and fiders are fix paces behind their respective companies. The ficers are three paces behind the pioneers in a single rank, and at all times, as well as the drummers and pioneers, are formed at loose files only, occupying no more space than is necessary.

The slafs of chaplains, surgeons, quarter master, and surgeon's
affiliated, are three paces behind the music. Officers in general remain posted with their proper companies; but commanding officers will occasionally make such changes as they may find necessary. Whenever the officers move out of the front rank, in parade, marching in column, wheeling into line, or otherwise, their places are taken by their sergeant coverers, and preferred until the officers again resume them. When the line is halted, and especially during the firings when engaged, the sergeant coverers fall back into the fourth rank, and observe their platoons.

P. III. fig. 4. When the battalion is to take open order, at the word of command, Rear Ranks take open Order, the flank men on the right of the rear ranks of each company step briskly back to mark the ground on which each rank respectively is to halt. They face to the right, and cover as pivots, being regulated and drilled by the adjutant or sergeant major on the right. Every other individual remains ready to move. At the word March, the flank dressers face to the front, and the whole move as follows:—The rear ranks fall back one and two paces, each dressing by the right the instant it arrives on the ground. The officers in the front rank, as also the colours, move out three paces. Those in the rear, together with the music, move through the intervals left open by the front rank officers, and divide themselves, viz. the captains covering the second file from the right; the lieutenants the second file from the left; and the ensigns opposite the centre of their respective companies. The music form between the colours and the front rank. The sergeant coverers move up to the front rank, to preserve the intervals left by the officers. The pioneers fall back to six paces distance behind the centre of the rear rank. The drummers take the same distance behind their divisions. The major moves to the right of the line of officers. The adjutant to the left of the front rank. The flail places themselves on the right of the front rank of the grenadiers. The lieutenant colonel and the colonel (dismounted) advance before the colours, two and four paces. The whole being arrived at their several polls, the words Halt—Dress are given to the respective companies, and the battalion remains formed for parade in the order in which it should receive a superior officer. When the battalion is reviewed singly, then in order to make more show, the division of drummers may be moved up, and formed two deep on each flank of the line. The pioneers may form two deep, on the right of the drummers of the right; and the flail may draw up on the right of the whole.

When the battalion is to resume close order, the words Rear Ranks take close Order is given. The lieutenant-colonel, officers, colours, flail, and music face to the right. The drummers and pioneers, if on the flanks, face to the centre. The serjeants, if in the front rank, face to the right. At the word March, the rear ranks close within one pace, moving up one and two paces, and then halting. The music marches through the centre interval. The serjeants, drummers, pioneers, &c. resume their places, each as in the original formation of the battalion in close order. The officers move through and into their respective intervals, and each individual arrives, and places himself properly at his poll, in close order.

On particular occasions, and when necessary, officers commanding platoons, who in line are on the right of their platoons, shift to the left to conduct the heads of files, or the pivot flanks of their divisions, in echelon, or in column. When the battalion wheels by companies, or subdivisions, to either flank into column, both colours, and the file of directing serjeants always wheel to the proper front, and place themselves behind the third file of the new pivot.

There is no separate colour before, the pioneers, music, &c sufficiently strengthen the centre; but in the firings, the two files on each side of the colours may be ordered to reverence their fire.

The constant order of the light company, when formed in line, and united with the battalion, is at the same close files as the battalion. Their extended order is an occasional exception. When the light company is detached, and the grenadier company remains, it will be divided on one flank of its battalion, whenever there are several battalions in line; but when the battalion is single, it is permitted to be occasionally divided on each flank. When the grenadier or light companies are detached, and make no part of the line, they may be formed two deep, if it is found proper.

With a very few obvious alterations, these general rules take place when a company or battalion is permitted or ordered to form in two ranks only; and which, on the low establishment of our battalions, may often be done for the purposes of exercise or movement on a more confiderable front. It is also evident that they generally apply, whether the companies are strong or weak, and whether a greater or lesser number of them compose the battalion.

We shall now proceed to give a sketch of the most essential general attentions required in the movements of the battalion, and which may be found more fully detailed in the rules and regulations for the battalion and the line, as published by his majesty's command.

1. **Attentions of the Soldier.**

Quick time is in general confined to wheelings and firings. The other movements of the platoon or battalion are made in ordinary time. It is seldom that they will, or ought to be, required at quick time. All wheelings, forward or backward, are made quick. Eyes are turned to the wheeling flank, at the word March, and not before. The wheeling flank man steps out firm at a pace of thirty-three inches, till he receives the word Halt. It is the business of the rest of the rank to keep up to him. Eyes remain in all cases to the wheeling hand, till a new order is given by the commanding officer. All firings are made quick, close, and at the lock step. Files are at no time open out, on occasions of exercise, parade, or manœuvre; but they will often be formed and ordered, when marching in the streets; or in common route marching, when the march by divisions cannot be conveniently take place. All firings must be accurately made on the left heel. Pivot men must cover carefully and exactly. In wheeling backward, the flanging man faces the opposite way to that he does in wheeling forward. Pivots, whether in wheeling into column, or in wheeling into battalion, when once posted are to remain immovable, and do not alter their position in consequence of platoon dreeing, nor on any account, but by order of the commanding officer of the battalion, when he finds it necessary to require a more correct dreeing from the whole.

The greatest observance of the soldier in the ranks, and under arms, is the squareness of the shoulders and body, the head to the front, and the eyes only glanced to the point of dreeing. When the battalion is halted, and a more accurate dreeing is ordered, the head may be a little turned during that operation only, and each man should just distinguish the lower part of the face of the second man from him. Whether in movement, or halted, each man is just to touch, without crowding, his neighbour's arm, towards which he drees, to depend on that chiefly for his line, and at no time to separate from him. At the word March, the flamp of the foot is not to be made, but the first step is to be taken as firm and long as any other, and the body of each man, if in his true position under arms, is prepared for it by an inclination forward.
forward. On the perfect execution of this, depends much of the accuracy of march. On the word March, the first step in all situations is taken with the left foot. When the commanding officer of the battalion gives that word, the whole file off together, whether in line or in column. When he gives the word Halt, the whole halt at that instant. At the word March, the eyes are directed to the pivot flank, if in column; or to the head of the file, if filing; to the colours, if marching in battalion; and in general to that point by which they are conducted. At the word Halt, the foot in the air finishes its step, and the other is brought up to it. Eyes remain directed to the pivot flank if marching in column; to the colours, if in line; or to the wheeling flank, if wheeling; and in general to the point to which they were turned when in movement, until a new order commands a new direction. Whenever the word Drop is given by platoon officers to their platoons, eyes are turned to the pivot where the officer is, and from whence he corrects them upon a distant object. In marching in line, each man must preserve his bodily perfectly square, and just the touch of his neighbour, who is nearer than himself to the directing point. The rear ranks are to be well locked up, particularly when firing. In marching in battalion, or when halted, rear ranks will be locked up; but in marching in column, they may in general be at one pace distance. The steps are to be taken firm, and marked.

All alterations in carrying, supporting arms, &c. are done by the whole battalion at once, whether in line or column, and not by the divisions of it separately. The commanding officer gives the word, and not the platoon officers; and no such change is at any time made, but in consequence of his command. The men therefore, in all cases, wheel, halt, march, drop, &c. with their arms carried, supported, trailed, or fisted, according as the last-given command directed them. The fame is to be observed whenever the battalion, moving in line or in column, changes its time of march.

In column, when the right of the battalion is in front, the left is the pivot flank; and when the left is in front, the right is the pivot. In marching in column, the pivot files of men next to the officers must have great attention in covering, when the movement is made in a straight line, as they are points on which the formation is made; and therefore for that purpose, they must remain close to their pivot officers, who in that situation cover and give distance.

Supported arms should only be allowed when halted in line, or when moving in column. But the march in line, and in general all wheelings up into line, and all formations of the line or dressing it, should be made with carried arms, as the only situation which preserves the true distance of files, or can give an accurate line.

II. Covering Platoon Sergeants.

The covering sergeant accompanies and affists the platoon officer in all his movements, and prefers his place in line, or on the pivot flank in column, whenever the officer’s duty requires him occasionally to quit it. In battalion, he covers in the rear rank. At open order he moves into the officer’s place in the front rank. At close order, he leaves it for the officer to take it. In the march in echelon, he is on the outward flank of the front rank. When the battalion breaks into column to the right or left, the sergeant falls back two paces; and when the wheel is finished, he covers his officer on the pivot flank. When the column marches if the officer is in front of the platoon, the sergeant is on the pivot of the front rank, and is answerable for the platoon distance; if the officer remains on the pivot flank, the sergeant then falls behind the rear rank, and covers the second file from the pivot. When from column the right in front platoons wheel up to the left into line, the sergeant at the word Wheel, goes to the right of the front rank of the platoon, and wheels up with it, thereby preferring the officer’s place. If the wheel is to the right, the sergeant is behind the right file, ready to move up to the officer’s place at the conclusion of the wheel. On all occasions, when any platoon, which is then separated, joins in line to one on its right; at that instant must the covering sergeant be on its right, to prefer the place of his officer, who may be employed in dressing his platoon.

When the platoons wheel either into line or into column, the sergeant of the leading platoon runs out, and marks the point in the line of pivots where its flank is to halt. When platoons countermarch in column, the sergeant moves into the officer’s place on his quitting it to lead in file, faces to the right about, flanks fall, and becomes the pivot point for the front rank leader to close to after the countermarch is finished, and its place is occupied by the officer after dressing his division. When the platoons from columns file, in order to take a new line either to the front or rear; the sergeant of each successively, as it arrives within thirty yards of that line, and no sooner, runs out, takes distance, places himself upon it, and remains as a point to which his officer is to bring and close in the pivot flank of his platoon, and as a point which the officer himself is afterwards to occupy. Whenever the battalion halts to fire, the sergeants fall back, and in concert with the supernumerary rank, keep the rear ranks well locked up and attentive to their duty. When the battalion again moves, the sergeants resume their places. When the battalion is in column of sub-divisions, if the officer is ordered to march in front of his platoon, the sergeant is on the pivot of the leading sub-division. If the officer is on the flank of his leading sub-division, the sergeant takes the flank of the second. In column of sections, the sergeant also takes the flank of the second section. In close column, the sergeant is on the flank of the rear rank, behind the officer; and in forming line after the Halt, Front, of the platoon, he remains on its outward flank, and marches up with it.

The pioneers, in column of march, are in front; in line, they are formed two deep behind the centre, and nine paces from the rear rank. Drummers, in column of march or close column, are with their companies, and on the flank not the pivot one. In line, the grenadier and light drummers are six paces behind the rear rank of their companies. The battalion drummers are in two divisions, and formed fix paces behind the third and seventh companies. In parade, at open order, the drummers prefer their fix paces from the rear rank. Whenever the platoon is cautioned to wheel forward or backward any number of paces, the sergeant immediately pols himself before or behind the eighth file from the flanding flank, and takes the ordered number of places; when his platoon has conformed, he places himself on its outward flank. The music, in open or close column, are on the flank which is not the pivot one; in line, they are in a single line behind the centre, twelve paces from the rear rank. On parade, at open order, they are between the colours and the front rank. Drummers, music, pioneers, &c. will take care not to impede the flank movements of the close column, nor its formation into line, but will get into the rear of their respective battalions, as soon as they are disengaged from each other.

III. Attentions in Platoon Officers.

When the battalion is formed in line, company or platoon officers are all on the right of their platoons. In column, they are on the pivot flank, unless particularly ordered into the front of each platoon, if a march for any considerable distance is to be made. When on the pivot flanks, they are
are answerable in their own persons for distances and covering. When in front, their serjeants, under their direction, preferve the ordered distance.

In wheeling from line to column, each moves out, and places himself one pace before the centre of his platoon. Each turns towards his men during the wheel, and inclines to his pivot flank. Each gives his word, Halt—Dress, when his wheeling man has just completed his degree of wheel. Each squares his platoon, but without moving what was the flanding flank. Each then places himself on the proper pivot flank. After the wheel into column is completed, no one is to caufe his platoon to shift, by way of covering on the pivot flank, unless fo ordered by the commanding officer, or that in the course of marching a straight line is gradually taken up. In wheeling from column into line, the officer places himself one pace before the centre of his platoon, turns towards his men during the wheel (inclining towards the pivot of his preceding platoon), and gives the word Halt—Dress, when his wheeling man, on whom his eye is fixed, is just arrived at the next flanding pivot man. He then, from that pivot man correcting the interior of his platoon upon his own pivot man, takes his place, and remains steadily on the right of his platoon.

If the column is in movement, and platoons are successively to wheel into a new direction, each officer, to whatever hand he is to wheel, gives the word from the point he is then placed at, whether in front or on the flank. If on the wheeling flank, he conducts it; if on the flanding flank, he fleps out two or three paces, the better to fee that his platoon wheels quick, with a proper flep, and that he may time his word Halt. This done he is to fall back to his place on the pivot flank, no longer to look to his platoon, but having his eye fixed on the officer of the preceding platoon, he is to give his word March at the instant that officer is taking the last flep which establishes the proper distance between the platoons. When an officer is marching on the pivot flank, he is to be answerable for distance and covering. These circumstances alone must steadily engage his attention: he can only occasionally give a glance of his eye towards his platoon, which must direct to him of course, and without any particular direction. When platoons in column are each to countermarch on its own ground, the officer, when his platoon faces, goes to that flank which is to become the pivot flank, conducts his platoon in file, and clofes its leader to the serjeant, who has remained to mark the pivot, Halt, Front, and dresses it square. He then places himself where the serjeant stood.

When the battalion marches in line, officers then become individuals, equally attentive as the soldier; nor can officers then be attentive to any thing but to the correctness of their own personal march. Every operation then depends on the word from the commanding officer, who moves, halts, and dresses the battalions. Whenever the battalion is in line, officers give no commands except in flings. When the platoons of a column file separately to a flank, the officer conducts the head; and when he arrives within thirty paces of the new pofition in which he is to form, he detaches his serjeant to mark the point at which he is to place his pivot front rank man, either in flining to front or rear. The officer flops at that serjeant, and halts, fronts, and dresses his platoon close to the serjeant. He then himself, after correcting his platoon, replaces the serjeant, who falls back to the rear rank. In flining, distances and dressing are taken from that hand to which, by a face of the platoons, the whole would land fronted in column, and the line breaks into column towards the directing point. The leaders of the third, fourth, &c. platoons from the directing flank are never to overpass the straight line which joins the heads of the first and second, but are, if any thing, to be behind it, till they arrive and halt exactly in the new line. In movements to the rear, distances and dressing are always taken from the same point to which they would be made, if the movement was to the front; that is, from the left in going to the rear, if it should be from the right in going to the front.

On the leading platoon officer of the column much of the precision of march depends. He must lead at an equal, steady pace, and on two objects either given to him, or which he himself takes up on every intermission of position. This demands his utmost attention; nor must he allow it to be diverted by looking at his platoon, the care of whose regularity depends on the other officers and non-commiffion-eds officers belonging to it. The second platoon officer must also be shewn, and know, the points on which the first leads. He is always to keep that first officer and those points in a line; and those two officers, together with the placed mounted officers, thus become a direction for the other pivot officers to cover. In marching in open column, the covering serjeants are placed behind the second file from the pivot officers, that the officers may the more correctly see and cover each other in column. In the column of march, after the word Halt is given, no one is to move, and pivots particularly must remain where they are then placed. In this situation, when ordered to form, each platoon wheels up to its adjoining pivot; the whole will then perhaps, as in the case of marching upon a road, along the different turnings of a height, &c. &c. be on a winding line, and must not attempt to get into a straight line, unless so ordered by the commanding officer to answer some particular object. When the platoon wheels backwards from line into column, the situation and business of the officer are the same as when wheeling forwards; and he halts and dresses from his pivot flank, which he gains during the wheel.

In close column, division officers are on the pivot flanks. In forming line, before the divisions face, they are shifted to the leading flank, if necessary. The officer of each flops in his own person, when the division nearer to the forming point than himself, receives the word Halt, Front, allows his serjeant to proceed with the division; at the due instant gives his word Halt, Front, Dress, and as soon as the front of his division is clear, he word March, conducting it into line. Before the division arrives within three or four paces of its ground, the officer will have flipped out nimbly to the flank of the preceding division, and will be thus ready to give the word Halt—Dress at the instant his inward flank man joins the preceding division. The men dress by the formed part of the line, and the officer corrects them on the known distant point. He then resumes his platoon place, which has been preferred by a serjeant. When the close column, or part of it, forms line on a rear division, the officer of each, when the one behind him halts, fronts, will flip nimbly round the rear, and without impeding his division, allow his serjeant to proceed. From hence he can better judge the proper moment of giving his words Halt, Front, to his division. He then places himself on his inward flank, and marches up when his front is clear. The officer of one of the centres platoons is always in open column, to preferve distance for the colour flies. The colours wheel up into column, with the leading centre platoon, and place themselves behind the third file of men from its pivot flank. When the line forms, they close in to that flank.

When officers march in front of their divisions, they must in their own persons keep so close to the preceding ones, as not to hinder the flank of their own division from preferv-
ing its proper distance. When the head of a column of march changes its direction, and that marching in an alignment is not in question, instead of making regular wheels on fixed points, the officer who conducts the leading division will often be directed to bring it gradually round to the new direction, by the turn of the outward shoulder, making both its flanks continue moveable; but each succeeding division, without the formality of command or halt, does the same thing, the whole attention reposing on each pivot flank, which at no rate must increase its distance, but during this operation preserves the same equality of time and length of step at which it was before moving. On all occasions of forming in line, either by wheeling up from open column, or in moving up from close column, or in marching up from echelon, &c., the commanding officer moves nimbly to his point of appui, some pages before the arrival of his division in the line, and from thence gives his word to halt, and instantly dresses it.

Officers and sergeants of the supernumerary rank are in the rear of their respective companies. When the battalion is halted, or marching in line, they are three paces from the rear rank. In open column, they are within one pace of the rear rank. In close column, they go on the flank of their division which is not the pivot. Their greatest attention during movements is to keep ranks are correct, ranks kept up, and that perfect order is preserved among the soldiers; circumstances in which they greatly assist the platoon officer, who having the more important objects of distance and the covering of pivots to observe, cannot in such situation be giving minute directions to his platoon, without losing sight of his more material duties. During the firings, the supernumerary rank, assisted by the platoon sergeants, are to keep the rear ranks well closed up to the front, and to prevent any break beginning in the rear.

The staff (aduliant excepted), in line, are three paces behind the music; in parade, at open ranks, they are on the right of the grenadier front rank. It is the particular business of the adjutant at all times to ascertain the direction on which the column is to move, or on which the formation of the line is to be made. For this purpose he is mounted; otherwise he could not properly discharge this important duty; and he can be much assisted in it, by having two or three camp colour men, or non-commissioned officers, properly trained to line themselves quickly with any two given points. He is to take care that the point where the battalion in column enters an alignment is ascertained to it; when it is moving in that alignment, that two points a-head of the column are always prepared; when it wheels up into line, that a point beyond each flank of that line is ascertained; when the line is to be prolonged, and has wheeled backward by divisions, that two points in the exact line of the pivots are ready for its march; when the close column is to form in line, that a point to each flank is given; when the battalion changes position, either by files, or by the diagonal march of divisions, that there are points given on which the pivots of files will cover, and can dress their divisions upon from their several points of appui; in short, that upon all occasions, fixed points of forming, dressing, and march, are given, except in advancing in line, where the ascertaining such points does not depend on the adjutant.

When the battalion changes position, by the echelon march, the named division wheels its eighth file into the new direction. The other divisions wheel their eighth file half the number of paces as the named one. The file is on the outward flank, the officer on the inward flank of each division. At the word March, they move on, preferring their relative distance, and covering of pivots from before them, and just before the inward flank of each division arrives at the outward flank of its preceding one, which is already halted in line, its officer places himself before that flank; and when his inward man touches it, he gives his word Halt—Dress up, if the movement is to the front, and dresses his division on the distant prepared flank point, so that his division is steadied before the arrival of the next one. When the change is made to the rear, the retiring part faces about before the division wheels are made, proceeds as above, and each officer gives the word Halt, Front, Dress Back, to his division when its inward man touches the preceding formed one.

IV. Attention of Commanding Officers of Battalions.

The battalion may be considered with respect to the line, what the platoon is to the battalion.

Commanding and field-officers are always to be mounted, and unless they are active on horseback, it is impossible for them to see, to correct, to prevent mistakes, or to move with that dispatch which is necessary from one point to another. Whatever operation is to be performed by the whole of the battalion at once, is done upon the word from the commanding officer, without any repetition being made by platoon officers. He gives the order, it is repeated, and halted it, whether in line or column. He wheels it from line into column, and from column into line. He orders arms to be carried, supported, &c. He dresses it from the centre, when it has marched in line, and halts; and from what was the leading flank when it has wheeled up from column into line.

Before the column marches, the commanding officer ascertain points to the leading officer; and when he intends to change the direction of the march, he gives new points, and he watches over the just leading of the column. He takes care that all wheels of platoons are made at the identical point where the leading platoon wheeled; that all doublings of subdivisions are made successively in the same manner and at the same point; and that forming up to platoons is made at the spot where the first forming up is made; that in all diminutions of the front, the natural order of the column is preferred, whether the right or left of the battalion leads; that a column of half platoons occupies no more space than a column of whole platoons, viz. just enough to wheel up into battalion.

When the open column marching in an alignment is to form in a straight line, and for that purpose halts; the instant that it does halt, the commanding officer from the head of the battalion corrects the pivot files of men (which however ought not to be necessary) in the true line, and upon a rear point. But if the march is making in a winding direction, and that the intention is not to form, or not to take up a straight line, the platoons remain on the ground on which they halt, and do not move in any shape, until they receive a further order, either to form in line, or first to cover, and then to form or to continue the march. The commanding officer always conducts the head of his battalion column to the point at which it is to enter a new line, and he takes care in time to dispatch a mounted officer to ascertain that point. When the platoons wheel up into line, he immediately, if necessary, corrects the dressing of the battalion from the flank which led when in column, and that generally upon a point beyond the other flank.

When acting in line with others, the commanding officer of each battalion conforms to the movements of the regulating one, and from it takes, and rapidly repeats, his words of Halt, Wheel, March, &c.; and the least delay in repeating any of these words must undoubtedly disorder the line in proportion to that delay, for the whole of a line should march or halt at the same instant. In line, the commanding officer
officer is in the rear of the colours. From thence, by marked
cautions, he makes his battalion file out, or file short, or
incline, as is necessary to preserve its place in the general line.
His great attention is to see and prevent the beginning of
faults, and not wait till they have had their effect. By
watching and regulating his advanced serjeants, he best regu-
lates his battalion. The squareness of the march, the com-
paUness of the files, and the equality of clip, are the great
objects he is to have in view. The other mounted officers
are behind the wings, and can assist much in preventing faults,
and in correcting them.

All the battalions of a line must halt at the same instant
in consequence of that word, repeated by commanding
officers, whether they are then correct, or not in line. Each
half battalion from its own colour, and the men looking to
it, will be immediately drest on the colours of the next
adjoining battalion. By this means a general continued line
will be obtained, or, at any rate, a straight one between each
two colours; and if all the colours should have truly halted
in one line, the whole corps will be completely formed in a
straight line. But if the halt is not justly made, and that a
better line must be obtained, the colours of the defective
battalions will be brought into the general line; the platoon
officers will quickly arrange themselves, eyes will be or-
tered to the right, and the men will in an instant move up.
Too much celerity cannot be used in completing this opera-
tion.

A single battalion, when it halts, is drest on its right or
left centre company, and is therefore in a straight line.
Two battalions dress each from its centre on each other's
colours, their outward wings conforming, and are therefore
in a straight line. Three or more battalions dress from the
centre of each, on their next colour; and therefore if all the
colours halt in a line, the line of the whole will be straight;
if they are not so halted, the general line will not be drest
till a special correction is made, but no flank will be thrown
out of the general direction. When a battalion retires and
halts, it ought never to remain in that situation, but be im-
miediately faced about, and drest to the proper front. The
greatest fault that a battalion in line can make, is increasing
its interval. Bad dresting may be remedied without danger,
but a false distance presents a weak part to the enemy, and
is not to be clofed without a hazardous movement, and great
operation of the line. Commanding officers cannot take
too much precaution to ascertain true points in the line in
which they are to form, before the arrival of their battalions
in it. When a battalion is exercising finely, a commanding
officer may have two camp colour bearers behind each flank,
properly trained, and ready to run out to that flank, to give
points of marching, forming, or dresting upon the true line;
in doing which, one flank of the battalion is generally con-
idered as in that line, and often both.

Words of command cannot be specified for all the variety
of circumstances and situations that occur, but commanding
officers, being themselves clear in what is to be done, shoud
by dint of explicit and explicit orders, which they divide and adapt
for the occasion, lead their battalions through all the points
of execution with precision. This will always be found
the shortest path, nor on any account should any operation,
more especially the correction of an error or mistake, when
once a battalion is assembled under arms, be performed in a
careful or foven manner, which will always be the case if
the commander's orders be not pointed, loud, and sufficiently
explanatory.

A battalion close column forms in line on its front division,
on a rear division, or on a central one, according as circum-
stances require; and in all cafes the line formed upon is that
on which the head of the column or columns is halted before
the formation begins. Therefore the division on which each
battalion at any time forms, moves up at the proper instant,
and halts on that line. When several close battalions, stand-
going on the line, are to extend and form, the regulating and
named battalion only can be obliged to form on a central division.
Each of the others will form on its front or rear division, viz. on that which first arrives at its ground where
it halts, fronts, and occupies its proper place, while the
others move on, and successively come up to it. In forming
line from close column, points must be given beyond both
flanks in the direction of the line, and a mounted officer
halts, and fronts each division, which is especially necessary
for those that form upon a rear one, although lefts for
those that form upon a front one. The dresting and cor-
rection of the line is from the first formed division towards
the other flank, and all the eyes of the battalion are of course
turned to that first formed division.

The fame number of points are required for the march
into an alignment, and wheeling up into line of an open col-
umn of one battalion, as for that of several battalions; viz.
one where the line is entered, and always two beyond the
head of the column. Therefore, although these precautions
may appear formal for the movements of the battalion when
ingle, yet they are necessary in all its exercizes, when it is
recollected, that such battalion is in the place of, and must
consider itself as the leading one of the column, on whose
correct position that of every following one depends. The
same exactness is required in every extention from close
column into line, and in every forming and change of posi-
tion that the battalion makes. In line, in order to qualify
the battalion for acting in the general line, it must at its
ingle exercizes work on points fixed and relative, and make
no chance and accidental movements or formations. Al-
though on most occasions of movement and formation, and
at all times in instruction, determined points marked by
detached and mounted officers are given; yet such helps can-
not be expended or depended upon, when the line is ad-
vancing on an enemy, when a corps is harassed in its retreat,
and when it is unsafe to lend out officers, &c. In such situa-
tions every thing will depend on the eye and judgment of
conducting officers, who must confer such direction of
movement, and seize such accidental points as present them-
sefes, and lead to the object which is to be accomplished.

In whatever shape a battalion is moving, the commanding
officer is never to lose sight of this great principle, that the
battalion should at no time cover more ground than its proper
extent when formed in line. Therefore if he is marching in
line, he must take care that his files do not open; if in col-
umn, his great attention should be, that his divisions do not
open. For this purpose his march must be jilt and comp-
act, his wheels quick, and all doubings up, or back, which
alter the extent of front, must be made so as not to impede
the general movements of the column, or to change its
distances. When the front is to be diminished, he must see
that the doubling division slackens its pace, and when dif-
engaged from the other division, that it inclines well up,
quick, and covers, so as not to impede the division in its rear.
When the front is to be increased, the moving up division
does it quick, and by oblique marching.

The commanding officer must recollect, in the winding
movements of the open column of march, that the wheeling
distances must be jilt; that the pivots are to follow on the
exact tract which the leading one has traced out; that the
whole, when ordered, halt on the precise ground they then
occupy; and that when they wheel up and form, the line
will not then be a continued, but probably an irregular curved
one.
one. But if a straight line is to be entered, and formed upon, from the point where the head enters, and not sooner, and where a mounted officer remains posted, does every platoon pivot officer begin to cover in the true line, to march in that line, and to preserve his true distance; nor must any obstacle that can possibly be surmounted, ever force the pivot officers out of that line, although the men of their platoon, when it becomes necessary, may open or widen their files from them. If the pivots, on account of any material impediment, are thrown for a time out of the line, they should always, if possible, move to the hand which carries them behind the line, and again re-enter it if they can; for which purpose an officer, or non-commissioned officer, should be placed where they are to re-enter it. In marching in the alignment, the commanding officer should frequently place himself in it, see with a glance of the eye whether his files preserve it, and correct them if necessary.

As one field officer at a time must command the battalion, the others present can only act in aid of him, nor can their situation in all cases be ascertained; but should the commanding officer not be at the head of the open column when it marches, and particularly when it halts, to correct if necessary the pivots in the general line, another field officer, or the leading officer, if no field officer is there, should instantly attend to it, that the wheeling up may not be delayed. If in the course of exercise and instruction, the commanding officer is not behind the centre when the battalion marches in line or halts, another field officer from that situation can immediately give every proper aid in movement, or in lining as it ought when halted; and in every case it must be evident in what manner the commanding officer can be affixed.

When the line is to break and wheel into open column of march, in almost all cases it is better done by wheeling backward than forward, for the wheel is in this manner made on the pivot flanks; and although divisions may be unequal, yet these flanks cover after the wheel, an advantage which is lost if the heels be made forward. When a battalion makes a retired echelon, or part of an echelon of a considerable line, the commanding officer must take great care to regulate his movements by those of the one preceding him, viz. that he preserves his parallelism, his ordered distance, his proper flank interval, and when the leading echelons halt, and that he is to move up into line, that the outward flank is not thrown too forward (which without great attention will happen), and thereby perhaps be exposed to the enemy's enfilade.

Commanding officers of regiments, brigades, or larger bodies, are moveable according to circumstances, and should, by no means, consider the centre of such bodies as their general pivot in exercise or movements, or expect by the exertion of one voice, from one fixed situation, to command and direct the whole. Their presence is more frequently required near one or the other flank. In general, they should be at the conducting point of movement or formation, and to that address their orders by voice or message; for if that point is led or placed in the direction it should take, there is little danger of the other parts of the corps not properly and successfully conforming to it. There are many situations in the movements of great bodies, where commands, that are not immediately to influence the whole, are not given loud, but quietly, to the directing body, to whose situation the left by the eye conform: as when the head of an open column is ordered to halt, that the rest of the divisions may move on, and successively stop in close column; and on all occasions where parts only of a large body are to march, or halt, successively. In these cases, commanding officers of regiments should have an attention to give their commands in such manner as not to produce an alteration in those points that are not meant to be influenced by them at that instant.

Where a large body is marching in column or columns, through a narrow ground, and when its parts are to be assembed beyond the defile in several lines, in a compact manner behind each other, such parts are not to begin to assemble when the leading one does, but the head of each line is successively first to come up to the ground on which it is to stand, and when it there halted, its proper followers, and not before, move into line with it; thus not impeding the divisions that are still behind them in the defile, and are to perform the same operation.

Precision of movement depends altogether on the instant circulation of commands of execution, and that on the attention of officers to the point they may be expected to come from. Unless the whole of a body, however large, is put in motion at the same instant, a column will be extended badly, and a line will be ill directed, and with false intervals. Officers must particularly attend to the difference between changes of direction made by wheel, and by shoulders forward. In the first case, one flank remains fixed, while the other is on the wheel; in the second, both flanks are in motion. Shoulders forward applies to a small front, and to a column of march, where the change of direction is to be made gradually, without an alteration of the pace. In proportion to the front of the body so changing, must be the degree of sweep made by both flanks; and in all cases, the reverse flank conforms to the pace of the pivot flank. In no case can it be made short and quick, otherwise it becomes a wheel.

Regulations in Firing.

1. The advance of the battalion should instantly succeed the forming of the line, and when it arrives and halts at the point where it is to fire, the firing ought instantly to commence at the word Halts, for the battalion having been apprized, during the march, of the nature of the required firing, no improper delay need therefore be made. The greatest care should be taken by the officers and non-commissioned officers in the rear (whose principal attention is) that the rear ranks are well locked up in the firings, and that in leading they do not fall back.

2. The pause betwixt each of the firing words Make ready—Present—Fire, is the same as the ordinary time, viz. the 7th part of a minute, and no other pause is to be made betwixt the words.

3. In firing wings by companies, each wing carries on its fire independent, and without regard to the other wing, whether it fires from the centre to the flanks, or from the flanks to the centre. If there are five companies in the wing, two paws will be made betwixt the fire of each and the make ready of the succeeding one. If there are four companies in the wing, three paws will be made in the same interval. This will allow sufficient time for the first company to have again loaded, and shouldered at the time the last company fires, and will establish proper intervals between each. In firing by wings, one wing will make ready the instant the other is shouldering. The commanding officer of the battalion fires the wings.

4. In firing by grand divisions, three paws will be made betwixt the fire of each division and the make ready of the succeeding one. In platoon firing, two paws will be made. In firing by subdivisions, when one fires, the next presents, when one presents, the next is ready; thus keeping up an incessant fire.

5. In firing companies by files, each company fires independently;
pendently; when the right files present, the rest make ready, and do on. After the first fire, each man as he loads comes to a recover, and the file again fires without waiting for any other. The rear rank men are to have their eyes on their front rank man, and be guided by, and present with them.

6. In general, after the march in front, and halt of the battalion, company, or platoon firing, should begin from the centre, and not from the flanks. In other cases, and in successive formations, it may begin from whatever division first arrives, and halts on the ground.

7. The line, if retiring, Halt, fronts, at one command, and instantly begins firing, from the centre, and not from the flanks.

**Objects of Fire.**

1. **Against Cavalry.** The chief object of the fire against cavalry is to keep them at a distance, and to deter them from the attack. As their movements are rapid, a reserve is always kept up. But when fire commences against infantry, it cannot, consistent with order, and other circumstances, be too heavy or too quick while it lasts, which should be till the enemy is beaten or repulsed, or till the contest becomes too unequal.

The fire of three ranks standing is hardly, with our present arms, to be required, especially if the ground should be broken, and the folders loaded with their knapsacks. The fire of the rear rank, therefore, is generally reserved.

11. **Defensive Fire.** Where infantry are posted upon heights that are to be defended by the fire of musqueteers, the front rank will kneel, that one-third of the fire that may be given should not be lost; otherwise the rear rank in such a situation could not sufficiently incline their pieces to rake the slope. As folders generally present too high, and as fire is of the greatest consequence to troops that are on the defensive, and who are posted if possible on commanding grounds, the habitual mode of firing should therefore be rather at a low level than a high one; and the fire of the front rank kneeling being the most efficacious, as being the most effective, cannot be dispensed with when it can be safely and usefully employed.

111. **In Line advancing.** When infantry march in line to attack an enemy, and in advancing makes use of its fire, it is preferable to fire the two front ranks only standing, than to oblige the front rank to kneel, thus firing the whole. But volleys, fired at a considerable distance, or on a retiring enemy, may be given by the three ranks, the front one kneeling.

IV. **Platoon Firing.** A line posted, or arriving at a fixed situation, will fire by platoons, each battalion independent, and such firing generally commencing from the centre of each. The first fire of each battalion will be regular, and establish intervals. After the first, each platoon shall continue to fire as soon as it is loaded, independent of any other, and as quick as it can, till the battalion or line is ordered to cease.

V. **Independent, or File Firing.** If behind a parapet, hedge, or abatis, the two front ranks only can fire, and such firing may be file firing, and may be made deliberate and cool, the two men of the same file always firing together. It may begin from the right or left of platoons, and should be taught in situations adapted to it, not in open ground. Should the parapet, hedge, or abatis be but little raised, platoon firing may be used.

VI. **Running Fire.** Troops should be often practiced in executing the file lends, or running fire. This should begin on the flank files, and when once commenced, continued without the folder being subject to any other rules than keeping silence. This sort of firing is the only one which infantry should make use of in engagements. It is the most lively, and more slaughtering than any. It emulates and warns the folder, and renders him insensible to danger. The grand point is to accustom troops to leave it off when a signal is given, and afterwards remain silent.

VII. **Oblique Firing.** Oblique firing by battalions is advantageous on many occasions. As when attacked in an oblique direction; when time does not allow to give an obliquity to a greater part of the line; and when their fire can in this manner be thrown against the opening of a defile, the flanks of a column, or against cavalry or infantry that direct their attack on some particular battalion or portion of the line.

VIII. **Regularity of Firing.** As long as the fire by battalion, by wings, or by platoons, can be kept up regularly, it is highly advantageous, and can at any time be stopped; but should file firing be allowed, and one begun, unless troops are exceeding cool and well disciplined, it will be difficult to make it finish, and to make them advance and charge in order. When a line halts at its point of firing, no time is to be lost in scrupulous discipline, and the fire is instantly to commence; but a line that halts, and is not to fire, or when its firing ceases after the halt, may immediately be ordered to dress from colours to colours.

IX. **Street-Firing.** It is so called from being obliged to engage in a street, highway, lane, or narrow pellage, where no more than 10, 12, 16, or 20 files can march abreast; so that, according to the breadth of the place, the platoons must be stronger or weaker. When the column is in motion, and arrived where the firing is to begin, the commanding officer, from the rear, gives the word Hold. The officer commanding the platoon instantly gives the words ready, present, fire; recover arms, outwards, face, quick march. At the word recover arms, the platoon immediately in the rear of the one that has fired, recover their arms also, and cock, and when their front is open by the march of the others down their flanks, they march on with recovered arms, until they receive from their officer the words halt, present, fire, &c. As soon as the platoon has got down the flanks, it must form instantly in the rear, and immediately prime and load again without halting, keeping always their exact distance from the division before them, which would not be the case if they halted to load and shoulder.

When this is to be put in practice on real service, the front of the platoons must not be equal to the breadth of the place they are to engage in: but there must be a small space of ground, or interval, left on the flanks, for those who have fired to have room to march back, and form in the rear. It is in this manner, when there is not time to raise a breach in a bridge, road, bridge, or street to be maintained against the enemy, by the platoons sustaining one another, and firing in their turn, which may be continued as long as there is occasion, almost without intermission, by one battalion only. In firing as above described, the colours, &c. must at the first be placed in the rear, and kept there by the subdivisions, as they come down the flanks after firing, forming constantly in their front, till the whole business is over.

There are, however, different methods of retiring the platoons from the front to the rear. Some are instructed, after the word fire, to recover their arms, and wheel out the platoon by subdivisions from right to left, load, and remain in that position till the last platoon passes them, when they wheel back, and form. another method is, supposing the file to be filled by the platoon, and no room left on the flanks, then by throwing back or retiring a central section
of each platoon, the retiring division may pass through the centre of the column to the rear. It looks well, and has a good effect on a day of parade; but it is too complicated to be attempted with safety in the presence of an enemy.

**General Observations.**

There is no doubt but that the fire of the musketry may be reduced to a theory; but far from that being the case, the field has no principle given him, for at the distance or situation of the objects, be what they may, he fires at random. It is principally owing to the exigence of the target being so little practical, that this ignorance and deficiency of principle is so severely felt.

In our firings, the field has instructed always to fire low, yet no reason is given him why it should be so, but that the ball rises. To consider this a moment; the line of level [The line of level is the straight line by which is seen the object on which the ball should be carried to.] and the line of fire [The line of fire is the straight line which represents the axis of the musket.] are by no means parallel; for according to the different weights of metal which the barrel has at its breeching, and at its aperture, so they describe an angle more or less acute beyond the tube. As the eye seeks its aim from the length of the line of level, it is therefore fixed at the exterior of the barrel. But entirely different to this principle, the motional body, the bullet, is impelled from the interior part of the instrument, and the length of the line of fire; therefore the line of fire and the line of level cut each other.

From the law of attraction imposed on all bodies obliquely thrown, at its delivery from the mouth of the cylinder, the bullet or ball describes a curve, which rising from the muzzle, cuts the line of level at a small distance from the mouth of the barrel. It will, at about the distance of 60 toises, or 360 feet, be found to be at a foot and a half or two feet, its greatest elevation above the line of level. From thence drawn to the earth by that gravitation to which all bodies are subjected, it again inclines to the former line, and at the distance of about 120 toises, cuts it a second time. It is this second point of intersection which is called the musquet-shot, or point blank, after which the bullet finishes to describe its parabola to the end of its fall.

What is here said is a common property to all fire-arms.

It follows, that to make the ball arrive at the mark intended, the flight must not be always precisely levelled at that mark. Suppose a mark fixed fifty feet high, divided into three equal parts, if the distance from it is 50 or 60 toises, or 360 feet, then to strike the upper dimension aim must be taken at the middle one, two feet under the mark. If meant to strike the middle, aim must be taken at the lower dimension, &c.

If at 100 toises, the aim must be taken one foot below the mark in order to hit it. If the distance is more than 100 toises, to strike any of the dimensions, aim must be taken above the mark, and so keep rising in proportion to the distance.

Suppose a battalion of the enemy in front; if at 300 toises distance, aim should be taken three feet over the battalion. If at 200 toises, about a foot and a half. If at 150, aim should be taken at their hats. If at 100, at the middle of the body, &c. Although the horizontal shot of a musquet may be computed at 180 toises, yet, where the fire of a line of infantry can have effect, it is seldom more than 80 toises, or 160 yards.

We shall close this article with some account of the form of a review of a battalion of infantry, and the method of performing the eighteen manoeuvres, as practised by his majesty's forces.
three paces behind the fourth battalion company; covered by their sergeants. Staff officers do not march palt.

The officers, when within six paces of the general, prepare to salute, by recovering their swords. They drop them when in a line with the general, and recover them when ten paces from him, bringing them afterwards to the port, without altering the rate of march, or impeding the front ranks of their companies. The commanding officer, when he has saluted at the head of the column, places himself near the general, and remains there till the rear has marched past. The drummers give a roll each, when the officers of their own companies salute. The officers commanding companies will, each successively, when he has passed the general by thirty paces, give the words rear ranks, take close order, and will immediately shift to the left, the proper pivot. Officers bring their swords to the advance, and each individual of the company resumes the palt which he held when the column was first put in motion.

When the third wheel is completed by all the companies, and the leading company is near to where the left of the battalion stands in its original position, the colonel gives the word halt. The whole halt, and the music ceases. At the words support arms—quick march, the whole march off in quick time. No music. The column makes three or four wheels; viz. at the point where the left of the battalion stands, at the point where the first wheel was made, and just before the third wheel commences, the colonel gives the word carry arms.

When the third wheel is completed, which pates the column on the line of passing the general, the music begins to play. The leading officer of each company shifts to its right, by its rear, giving the word eyes right, and when he has passed the general thirty paces, he will resume his proper pivot flank, giving the word eyes left. The supernumerary officers and sergeants march in a rank, in the rear of the several companies, at one pace from the rear rank, and officers' swords are carried steadily against the right shoulder. The colonel, lieutenant-colonel, major, and adjutant, are in the same places as in marching palt in ordinary time; as also drummers, pioneers, and music. In marching palt in quick time, no compliment is paid by officers.

When the head of the column approaches to the left of the ground on which it originally stood, the music will cease. The colonel gives the word halt, and, after a pause, march. The men carry their arms, and the column takes up its ordinary march, for the purpose of moving on an alignment. When at the point on the left of the alignment, each officer gives the words halts, left wheel, halt drop, march. It is absolutely necessary to observe, that these words are repeated at every wheeling point. The column proceeds, till arrived at the point where its head or right is to be placed, viz. where it originally stood. The colonel then gives the word halt. Pivots are corrected, if necessary, but should be done instantly, and if possible, ought to be avoided, as nothing can more clearly point out how bad discipline, and how inattentive the commanding officers of companies must be, when this operation is necessary to be done in the face of the general. On the word, companies, to the left, wheel into line, pioneers and music go to their polls behind the centre, officers move to the front of their companies, and at the word quick march, the battalion wheels up again into line.

When the line is formed, the colonel then cautions the battalion, that it will perform the manual and platoon exercise. He immediately goes to the rear, and the major, advancing to the front of the battalion, gives the commands rear ranks take open order, march—order arms—mufïÆ bayonets—shoulder arms—officers take palt in the rear. The officers recover their swords, and face to the right. On the word march, they, as well as the colours, &c. march through the several intervals occupied by the sergeants, three paces beyond the rear rank. At the word front, they face about, and bring their swords to the port. The colonel, lieutenant-colonel, adjutant, pioneers, music, supernumerary sergeants, drummers, and files, are at their polls in the rear, as when the battalion is formed at close order, where they remain perfectly steady.

The major proceeds with the manual as directed by regulation, observing only the front rank comes down to the left position of the charge bayonets, the others remaining posted. The sergeants who prefer to the front rank the places of the platoon officers, remain there steady during the whole of the manual, except that they charge their pikes at the same time as the bayonets. When the manual is over, the major gives the words rear ranks take close order, march, on which officers, sergeants, colours, and every other individual, take their places as when the battalion is at close order. The major then gives the word platoon exercise, and proceeds with it, according to regulation. When finished, the major goes to his palt, the colonel comes into the front, and gives the word with carver and load. The corps is now ready to commence the ordered movements. The flagman stands opposite the centre of the battalion, with his front to the general, and goes through the motions as directed for the manual exercise, &c. Of course he is not to perform any of what are called the flagman motions.

Method of performing the Eighteen Manoeuvres.

First Maneuver. Close Column on a Rear Division.

The colonel gives the word the battalion will form close column of companies, in rear of the grenadiers. Remaining companies—right face. All the companies, except the grenadiers, face to the right. The captains and their covering sergeants palt themselves at the head of their files, ready to lead. Two or three leading files of each company disengage a little to the right. The captain of the grenadier company, with his covering sergeant, shifts to the left of his company, the pivot flank. The colonel then gives the word quick march. All the companies, except the grenadiers, step off at once, and move on in file till they come near the company to be formed on, when the sergeants who were leading, the files step briskly forward to mark the situation of their companies in the perpendicular of the front of the column. The covering sergeant of the front company halts one pace in the rear of the covering sergeant of the grenadier company, carefully covering him, and standing perfectly square in his own palt. His own captain also halts close to him, and allows his company to move on in the rear of the sergeant, taking care that the right hand, or leading file of the company, does not pass beyond, but mark time when it comes up to the right hand file of the grenadiers. As soon, therefore, as the captain sees that the left hand file of his company is in with his covering serjeant, he instantly gives the word halt, front, eyes left; and having draffed his company correctly on his covering serjeant, he gives the word eyes front, takes his proper palt, which his serjeant had kept for him, who immediately covers him, while the captain himself correctly covers the captain and covering serjeant of the grenadier company. In this manner each succeeding company proceeds till the column is completely formed. The colours precede the fifth company, and remain on its rear flank, covered by their sergeants.

The close column being now formed, with the right in front, the colonel gives the word, form column of grand division.
divisions. At this caution, all supernumeraries, but not the colours, go to the rear of the column, if not there already. Left companies, left face. The left companies immediately face, always to the pivot flank, and their captains take one file step to the right, so as to be clear of their rank. At the word march, the captain stands fast, the serjeants conduct the divisions, and the captain of each, when it has cleared the flanking division, gives the word half, front, drifs. He then steps nimbly to the third file of the flanking company, and from that gives the word march, half, drifs. The captains commanding the right companies are now on the right of each grand division. The captains commanding the left companies move to the left flanks of the grand division, their intervals being kept by their serjeants. The colonel now gives the word, the column will close to the front, march. All the divisions step off, except the front one, and each, when within one pace of the division in its front, gets the word half, drifs, from the pivot captain of each division. The close column of grand divisions is now formed, and ready to deploy. The colours are with their proper division in the column, and that division must, of course, out-flank on the hand, not the pivot. To obviate this inconvenience, some regiments leave a space between the third and fourth grand divisions, for the colours.

The colonel then gives the word, the column will take ground to the right, and on its march deploy on the rear grand division. At this caution, a serjeant immediately steps out from the rear division, and places himself on the pivot flank of the front grand division, following it in file. When the rear grand division is halted, this serjeant halts also, and inantly fronts, remaining perfectly steady to mark the ground for the rear grand division to march up to. The colonel gives the word right face, quick march, and when the column, in obedience to these orders, has marched as far as he sees necessary, generally twenty or thirty paces, he gives the word rear grand division, half, front, and when he sees that the division immediately before the rear one has cleared its front, he gives the word, fourth grand division, half, front. As soon as the rear division, which has halted and fronted, finds its flank free by the half, front, of the division that was immediately before it, at that instant the captain on the left gives it the word march. The grand division marches steadily till it places its pivot flank; the left, close to the serjeant who had stepped out to mark the ground for it. It then receives the word half, drifs, from the colonel on the left. He dresses the grand division, from the flanking serjeant (the point of appui) to the camp colour (the point of formation) on the right. As soon as the dressing is finished, he shifts to the right of his company. The rear grand division being dressed, the fourth is marched up, and dressed on it, exactly as the rear one had dressed on the flanking serjeant, and to the third, second, and first, till all are in line. If the deployment be correctly made, the first grand division has only to half, front, as it is already in the true line. Much of the exactness of this, and every deployment of the same kind, must depend on the accuracy of the mounted officer, who halts and fronts each grand division. For this purpose he must be in the rear of the column. If he is confounded, all will be deranged. Supernumerary officers and serjeants, drums, music, and pioneers, halt with their respective grand divisions, and as they are halted and dressed, take their proper stations in the rear. The line is now formed to the general’s left.

Observe, when the column deploys on the rear division, it faces from the pivot flank, which then becomes the following one.

Second Manoeuvre.—Close Column on a Front Division.

The colonel gives the word, the battalion will form close column of companies in front of the right infantry; remaining companies—left face. The captains and their covering serjeants post themselves at the head of their leading files. Heads of files disengage. At the word, quick—march, the covering serjeant of the eighth company steps briskly forward till he comes in front of the light infantry captain, and three paces from him he faces him. Then, being certain that he is in a true line with him, he immediately faces to the right about, and flanks perfectly steady, and square to his front. The captain of the eighth company leads on his company till he places his pivot man close to the serjeant. He then gives the word half, front, drifs, replaces his serjeant (who immediately covers him), and gives the word eye front. In this manner, each succeeding company proceeds, till the column is completely formed, with the grenadiers in front. The colours move in rear of the fifth company.

The column of grand divisions is then formed, and closed up, exactly as directed in the first manoeuvre.

The colonel then gives the word, the column will take ground to the left, and on its march deploy on the front grand division, left, face—quick, march. When the column has marched thirty or forty paces, or as many paces as the colonel sees necessary, he gives successively, and in due time, to each grand division the words half, front, till all are halted, beginning with the front division. The inward captain of each grand division (that is, the captain on the right,) when it has halted and fronted, gives his words, drifs, march, half, drifs, and the outward captain (the captain on the left) remains on the flank of the division in the line, till the succeeding captain, having to dress his grand division, comes to replace him. He then replaces his covering serjeant on the right of his proper company. In this manner, grand division after grand division comes up till the whole are in line, and the supernumeraries also take their places gradually in the rear.

Observe,—When the column deploys on a front division, it faces to the pivot flank, which then becomes the leading one.

Third Manoeuvre.—Close Column on a Central Division, facing to the Rear.

The colonel gives the word, the battalion will form close column on the right centre company, facing to the rear. Right centre company, right face. Right counter-march, quick march. The captain at the head of his company, which has faced immediately on receiving the order, turns short in file to his right hand, and leads his company till he places his front rank in line with the rear rank of the fifth and third companies. He next gives the word half, front, and then drifs, from the right of his company, where he remains. The colours and centre serjeants counter-march with this company. At the word remaining companies, outwards, face, the companies on the right of the right centre companies face to the right, those on the left face to the left. Captains and their covering serjeants move to the heads of files. On the word to the left counter-march—quick march, the captains lead the files; the whole step off at once. The companies of the left wing, No. 5, 6, 7, 8, and light infantry, file one after another in the front of the right centre company. The right wing, No. 3, 2, 1, and grenadiers, file one after another into the rear of the right centre company. The serjeants must be very careful to follow the instructions, as in the first and second manoeuvres. Each company, as it completes its counter-march, receives the word, half, front, drifs.
fifes, from its own captain, who is now on the pivot flank, the right; the left of the column being in front.

At the word column, left face. The column immediately faces to the left, captains, &c. moving to the heads of files to lead them. All the covering ferjeants stand fall. At the word, the left hand companies will lead out, quick march, the left, or alternate companies, that is, No. 1, 3, 5, 7, and the light infantry, march out in quick time, until their rear has cleared the standing companies about four or five paces. The colonel then gives the command halts, the whole will counter-march to the left, left counter-march, quick march. The whole, except the covering ferjeants, who face to the right about, instantly counter-march. The right companies, viz., the grenadiers, 2d, 4th, 6th, and 8th, counter-march on their own ground exactly. The left companies, i.e. the 1st, 3d, 5th, 7th, and light infantry, march on towards the column, until they fill the intervals they have quitted, and are again in column in their proper place. The captain of each company gives the words, halts, front, fifes, as their companies finish the counter-march, which is completed when the leading man of each front rank arrives at his respective ferjeant. When the counter-march is finished, the column stands with its right in front, as in the old manœuvre, and its centre opposite the general.

The colonel gives the word, the column will deploy on the right centre company, remaining companies, outwards face. The right centre company stands fall. The companies on the right of the right centre company, face to the right; those on the left of it, face to the left. At the word quick march, the covering ferjeant of the right centre company steps up to the left flank of the grenadiers, and remains there.

As soon as the flanks of the right centre company are clear, its captain gives the word march, and when he arrives close to his covering ferjeant who occupies the exact ground quitted by the grenadier captain, he then, with great correctness, halts, and dresses his company on the ferjeant (the point of appui) to the point of formation on the right, and then, giving the word eyes front, shifts to his poll, the right of his company. When the remaining companies are clear of each other’s flanks, they get the words halts, front, march, from their own captains. The third company dressés from the right of the right centre company, its point of appui, to the distant point of formation on the right. The other companies of the right wing fifes in the same manner on the standing companies as they severally come up into line. When the fifth, or left centre company, has marched up to its point of appui (the left flank of the right centre company), its captain from that point dressés his company to the point of formation on the left. In this manner each company proceeds, till all are in line on their original ground, the centre opposite the general.

Fourth Manoeuvre. Change of Position in open Column.

On the word by companies on the left backwards, wheel, left hand men of companies face inwards to their companies. Captains step nimbly to the front of their divisions. The ferjeant of the right company steps back, and remains to mark the spot where the wheeling man of his company is to wheel when the quarter circle is completed. The other companies conform to this, each standing perpendicular to the base line on which its pivot is placed. At the word quick march, all the companies wheel back the quarter circle on the principle already laid down. Captains halts, fifes, their companies, and then giving the words eyes front, remain on the pivot flank of their companies. The battalion is now in open column of companies, the right in front.

The colonel gives the word column march. The column marches thirty or forty paces in ordinary time. The adjutant, having been apprized by the commanding officer, that the battalion is to change its direction to the left, and having the spot pointed out to him where the change is to commence, and also the direction which the column is to take, will immediately move forward, and place a camp colour at the spot where the leading company is to wheel. He will place a second colour as the point of direction on which the leading flank of the column is to move in the new alignment; and he will place a third camp colour, the point of formation, oblique to the right of the column, covering exactly the other two colours, so that a line drawn from the second colour to the first, and continued to the third, will be a right line, which line will be oblique to, and cut the original line on which the column was marching at the point where the leading company began its wheel, which point is on the new alignment. These matters being all quickly arranged, when the colonel sees that the leading company is near the point of wheeling, he will give the words

The column will change its direction to the left. The captain of the leading company, on the principle of the moveable pivot, gives the words right flankers forward, and when the company has made the required wheel, he gives the word forward, and keeps his eyes fixed on the distant camp colour, to which he steadily marches. Each company as it approaches the wheeling point (the left camp colour), conforms exactly to what has been done by the leading company. When the colonel sees as many companies wheeled into the new direction as he judges to be sufficient, generally three, he gives the word halts. The leading companies, and each others as have already wheeled into the alignment, being now at their proper points, remain so.

The rear companies will file into the new alignment. Rear companies, right, face. At this word, all the companies who are still in the old direction face to the right, i.e. to the flank which conducts to their place in the new line. Captains and their covering ferjeants shift to the heads of files, to lead them. At the word quick march, the ferjeants step briskly forward, to mark their points in the line where the pivot flanks are to be placed. Each captain leads his company to his covering ferjeant, where he halts, and lets his company pass in rear of the ferjeant, till its left flank is in with him, and he then gives the word, halts, front, fifes.

At the word, column, to the left wheel into line, quick march. The ferjeant of the grenadiers moves quickly to the right, and places himself in line with the pivots. The rest of the covering ferjeants go as usual to their right flanks, to keep the place for their captains. When the wheel is completed, the captains give the word halts, fifes, from the file on their right to the camp colour on the left, and immediately replace their covering ferjeants.

Fifth Manoeuvre. Wing thrown back.

The colonel gives the following words of command; the left company will wheel four paces backwards on its left. The remaining companies will go to the right about, and wheel two paces to the right. The covering ferjeant of the left company, now on the circle, steps to the rear, and on the eighth file from the pivot marches the named number of paces, and comes to the right about, lining himself with the camp colour, placed by the adjutant on the right, to mark the new line, which is to be parallel to the original line of formation.

The command is then given, left company, four paces on the left backwards wheel, quick march. The company’s ferjeant halts the company in a low tone of voice, and the captain accurately dressés it on the colour to the right. At the
the word, remaining companies, to the right about face, they face accordingly. On that of, two paces to the right wheel, march, each covering serjeant steps out two wheeling paces on the circumference of the circle, and when the men wheel up to him, he halts them in a low tone of voice. The captain draws the company. The battle now stands in echelon, with its rear ranks in front, the captains having shifted to the inner flanks of their several companies, and their covering serjeants to the outside flanks. The battalion will march in echelon, and form line on the left company, march. The companies march with their rear ranks in front. The captain of the company next to the formed one, gives the word left flanks forward, and then having disengaged himself from his division, the moment his leading flank man of his (now) front rank touches the flank of the company that is already formed, he will give the word, halt front, draw back, on which his company fronts, and, without hurry, draws back on him and the formed part of the line, he correcting them on the more distant given point, the camp colour on the right, which having done, he goes to his post, the right of his company. Every other captain does the same, till the line is formed. It is then parallel to its original line of formation, but more retired by the length of seven companies, according that three wheeled into the oblique alignment. The battalion is now to the general's left. It is to be observed, that the greater activity must be used by each captain in this drilling, otherwise the point of appui will not be ready for the next company, and the distant point will be obscured; whereas it must be kept open and distinct, so that the direction of the line may run at the distance of one file from the given object of drilling.

To follow the plan as laid down in the rules and regulations, the battalion should now go to the right about, retire fifty or sixty paces, and then halt, front.

Sixth Manoeuvre.—Counter-march, formed square, and change of position.

On the word, battalion, by companies on the left backwards wheel, quick march, the battalion breaks into open column of companies, the right in front. The colonel then gives the word, the column will change its front by the counter-march of companies to the rights, companies, right face. At this word, the whole face to the right. Each captain will immediately quit the pivot, and place himself on the right of his company, and his covering serjeant will advance to the front which he has quitted, and face to the right about. At the word, right counter-march, quick march, the whole move. Each captain wheels short round to the right, and proceeds, followed by his files of men, till he has placed his pivot front rank man close to his serjeant, who remains immovable. Each captain instantly gives the words, halt, form, to his company, so as to have it squared, and closed to the right, which is now the pivot flank. The captain replaces his serjeant, who falls back behind the rear rank. The column now stands faced to its former rear, with the left in front.

Column march. The column marches thirty or forty paces. At the word column will close to the front, the leading company immediately halts, and the remaining companies each halt within one pace of the company in its front. Captains must be very careful to halt, draw their companies correctly, as this is preparatory to forming the solid square. Observe, that the column may be closed at the option of the chief, either in this manner, or by the head division continuing its march, and the rear ones being ordered to march quick into close column, and face effectually to resume the ordinary march.

Form solid square. All the companies composing the front half of the column, i.e. the left wing, take one pace forward, except the light infantry, which stands fast. The two left companies close up one and two paces to the company before them. At the word, solid square, one pace to the right and left, march, the whole companies make an interval of two paces in the centre, by their subdivisions taking each one pace to the flanks. Two captains, with their serjeants, place themselves on each of the front and rear intervals. Two captains, with their serjeants, also take post in each of the increased intervals in the centre of the sides. A serjeant takes the place of each flank front rank man of the first division, and of each flank rear rank man of the left division. All the other officers, serjeants, the four displaced men, drummers, &c. assemble behind the centre of the companies which are to form the flank faces.

N. B. The remainder of this manoeuvre cannot be correctly performed, unless each company consists of at least twelve files, formed three deep.

Four files, outwards, face. The two rear companies face to the right about, and four files on each flank of all the companies, except the grenadiers and light infantry, face outwards, the whole lining with the flanks of the front companies, and drilling in ranks from front to rear. On the word quick march, the fifth file from each flank of all the companies, except the first and last, followed by the front rank man of the sixth file, move up to right and left, and respectively fill up the interval between their own and the preceding divisions. The remainder of the men of the file divisions arrange themselves to their right and left, forming clofe in the rear of their own divisions respectively. The whole thus stand faced outwards, and formed at least four deep, with two officers and their serjeants in the middle of each face to command. The captains may fill the intervals as follows: The grenadier and first company in the rear face; the light infantry and eighth company in the front face; second and third in the right face; fourth and fifth in the left face; each covered by his serjeant. All the other officers, as well as serjeants, displaced men, the colours, &c. are in the void space in the centre behind their companies; and the files of the captains in the faces may be completed by serjeants, &c. from the interior, in such manner as the chief may direct. The mounted officers pass into the centre of the square by the rear face. Whatever is the strength of the companies which compose the flank files, the whole of them will face outwards, except their four centre files, which are always referred for filling up the intervals.

Prepare for firing. The two first ranks all round kneel, and slope their bayonets. The two next ranks fire flaming, and the others, if any, remain in reserve. The file covers behind each captain in the files give back, and enable the captains to stand in the third rank. They are replaced by their serjeants, who, with the serjeants in the angle, slope forward their pikes, at the same time that the men slope their bayonets. The colonel then gives the word command independent firing, and, on the close of the preparative, the two standing ranks commence file firing from the right of each face. This ceases on the beat of the general, and the colonel gives the word, kneeling ranks, present, fire. If ordered, the kneeling ranks may load again without riling up. Otherwise they immediately recover their feet after firing, and the word prime and load is given.

When the colonel sees it proper to reduce the square, he gives the words form close column. The files that faced outward, come to their proper front. Those in the intervals, i.e. the fifth file, and front rank man of the fifth, face about. At the word quick march, the front company takes
one pace forward, and the two rear companies, i.e. the grenadiers and first company, one and two paces forward, and then face about. The files from the intervals take their proper places. Officers, sergeants, displaced men, &c. will quit the interior, move to their several files, and the companies that compos'd the flank faces will be completed. Not to multiply words of command, the best method to close the subdivisions, &c. is to move the column immediately, by giving the word, column, march, either in quick or ordinary time, as the colonel thinks proper.

When the column has marched as far as the commanding officer judges necessary, he gives the words, column open from the rear, on which the captain commanding the rear company gives the word to his company, grenadiers, halt, and immediately the caution first company, to the company in his front. When he chooses, at a proper wheeling distance from him, he gives the word halt. The captain of the first company, when he has halted, gives the same caution and command to the second; the second to the third, and so on in succession, till the column is opened out.

The colonel now gives the word, the column will change its head by the counter-march of companies from the rear. Right wheel to the front. The grenadier captain gives the words, grenadiers, left face. He and his covering sergeant immediately shift to the left to lead the files. He then gives the word quick march, till his right flank can freely pass near the left flank of the others. He then gives the word, halt, front, march (in ordinary time) close by the left flank of the first company. The captain of that company, while the other is approaching, gives the word, left face; and as soon as the grenadiers have cleared his flank, quick march, leading his company into the rear of the now leading one. He gives the word, halt, front, when he covers, and march when at the due wheeling distance. All the other companies successively perform the same operation; and when the light company has taken its place in the rear, the whole column is in perfect order.

Column, halt, left wheel into line, quick march. When the column has wheeled into line, it is considerably to the general's right, and with its rear to him. Observe, That some regiments at review, in this counter-march from the rear to the front, face their companies to the right, and bring them out on that side, contrary to the general principle. The divisions which advance come out always on the side to which front is to be made, and on which the enemy is placed; because then, with the divisions that are free, he can be opposed, while the others are moving behind the line.

Seventh Manoeuvre.—Countermarch by Files on the Centre of the Battalion.

This brings back the battalion to its original front. The colonel gives the following words: the battalion will countermarch from its centre, and on its centre, by files—swing inwards—face. The whole face to the colours, which shall fall; and a sergeant remains to mark each flank of the battalion. The word is given, swing—three file steps to the right—march; if the battalion is only two deep, two paces to the right is sufficient. Each wing takes the named number of paces to its flank, that they may be disengaged from each other. At the second word march, or quick march, the whole move on, and each file wheel successively into the centre, as it arrives at and beyond the colours. As soon as each company is in the line from the colours to the flank sergeant, the captain fronts it. When the whole is formed, the colours countermarch, and if necessary, the drilling of the line is corrected.

Eighth Manoeuvre.—March in open Column.

The battalion will form open column in rear of the left company—remaining companies on the right backwards wheel—quick march. All the companies wheel backwards on their right, except the light infantry, which stands fast. On the word left face, they all face to the left, except the light company; and the captains place themselves to lead the files. At the word quick march, the whole will lead to the rear, and the covering sergeants will successively, as before, take up their positions on the new line. The captain conducting each platoon, when he arrives at his sergeant, will flop directly before him, allow his platoon to move on behind the sergeant, till the rear file comes close to, but beyond him. The captain will then halt, front, and direct his platoon, with his front rank closed in to the sergeant. He will himself take the place of the sergeant, and remain steady on the pivot flank.

As soon as the third company has taken its place in the column, the colonel gives the word march. The head of the column moves on in ordinary time, and the remaining companies follow, preserving the proper wheeling distance between each. When the leading company arrives within 12 or 15 paces of the point where it is necessary to diminish its front, the colonel will give a loud caution, that the subdivisions are to double, either by companies successively, or the whole battalion at once. If at once, as is ordered in this manoeuvre, then he gives the words form column of subdivisions—right subdivisions—quick march. Each right hand subdivision marks time, till its left hand subdivision, which marches on steadily, has opened or cleared its flank. At the words quick oblique or left oblique, the right divisions immediately oblique to the left, and cover the left ones correctly. The captains move to the right flank of the left subdivisions. Their covering sergeants lead the right subdivisions.

When the column of subdivisions has marched as many paces as the colonel thinks proper, he gives the words form companies, right subdivisions—quick oblique. As soon as each right subdivision has cleared the right flanks of the left, by the quick oblique, it immediately receives the word forward, and when in line with the left subdivision, each receives the word ordinary from the captain, who had shifted to its right. It may be observed, that the above is in conformity to the general rule, whether the column be halted or in motion, that the subdivision or section on the reverse flank is the one behind which the other subdivision or section doubles. But in this case, were the left subdivisions to double in front of the right ones, the pivots would be better drest, as the right subdivisions, which were marching correctly in the alignment, would not be discomposed. The colonel gives the words column halt—right wheel into line—quick march.

Ninth Manoeuvre.—Echelon Change of Position.

The colonel gives the words, companies on the right backwards wheel—quick march. The battalion breaks into open column, the left in front, each company getting the halt—drift from its own captain, as usual. The colonel continues: The seventh company (the third, reckoning from the left,) will wheel four paces, the remaining companies fix places, on the left backwards—quick march. The companies are drest by their captains, who are now on the inflected flanks of the echelon. The colonel orders eighth and light company right about face. Two camp colours are sent to the right and left in a correct line with the seventh company. At the word the column will march in echelon, and form line on the seventh company—march, the captain of the seventh company shifts to its right flank. Each company, on the right of the seventh, viz. Nos. 6, 5, 4, 3, 2, 1, and grenadiers, as it comes successively into line, receives from its captain the word halt—drift.
—dressed on the camp colour to the right. The captain then shifts to the right of his company. The companies on the left of the seventh, viz. No. 8, and the light infantry, receive the words from their captains halts, front, dress up. They are dressed on the camp colour to the left.

**Tenth Manoeuvre.**—Echelon Change of Position.

The colonel gives the words the light infantry will wheel four paces, the remaining companies two paces to the left. When the covering sergeants have taken the number of paces from the front of the eighth file from the left of their companies, the colonel gives the word quick—march. The captain commanding the light infantry immediately shifts to its left flank. When the company has wheeled up, he gives the word halt, dressed, dressing it correctly on the camp colour, which the adjutant had previously sent to the right for this purpose. The captain, when his company is correctly dressed, gives the word eyes front, and reinforces his place on the right of his company, taking care that his men stand perfectly steady, and with carried arms, until the next company has dressed on them; his right flank being the point of appui. When the colonel gives that every division is ready, he gives the words the battalion will march in echelon, and form line on the left company—march. All the companies march in ordinary time. As they arrive in line successively, they are dressed by their captains from the flanking companies to the camp colour on the right. Each captain, when he has so dressed his company, gives the word eyes front, and then shifts to the right of his division. The whole are now formed in line, parallel to their original front, and considerably to the general’s right.

**Eleventh Manoeuvre.**—Change of Position.

The colonel gives the words the battalion will form open column of companies in the march—right face—march. When the battalion has marched in file as far as is judged necessary, he gives the word form companies. The files instantly make a half face, each marching up quick and diagonally to their respective leading men, who do not alter their pace. As the pivots are in the rear of companies, when they come up, the companies dress to them by their captain giving the word eyes left; and they take up as they form, the ordinary repé. The column marches; and when the colours are opposite to the general, the colonel gives the word halt, and then to the left wheel into line, quick march.

**Twelfth Manoeuvre.**—Retreat in Line.

The colonel gives the word the battalion will retire—right about face—march. It marches fifty or sixty paces in ordinary time, dressing by its centre. No mutiny plays during the retreat of the battalion. The colonel gives the word halt, front, and directly after the battalion will fire twice by companies, from centre to flanks. On the last stroke of the preparative, the captains on the right of companies step out one pace, and give the word of command platoon, ready—present—fire—load. When the first part of the general is beat, the captain falls back into the front rank. The colonel then gives the word, the battalion will retire by alternate companies—right companies, right about face—march. After marching in ordinary time about fifty paces, they receive the word halt, front. In marching, one colour remains on the flank of its proper company in each line. The king’s colour with the right centre, and the other colour with the left centre company. A sergeant will advance fix paces before each colour during the march. Each line directs its movements by its colour; distances are preferred from that colour, and to it the men’s eyes are turned during the march. Each line has a commander. Captains are ordered to be on the inward flanks of their companies, but this makes a perpetual shifting of positions, and is better omitted.

The colonel gives the word left companies, make ready—present—fire. Immediately after firing, the men come to the recover, half-corn, and shoulder arms. At the word right about face—march, the left companies march readily on, dressing by their colour. They pass through the intervals of the right companies, and continue marching until they receive the word from the colonel, halt, front—prime and load. If the chief fires the left companies, the next in command fires the right companies, exactly as the left companies were fired. They retire in the same manner through the intervals of the left companies. The colonel then fires the left companies, and retires them as before, and so on till he thinks it expedient to form line.

The left companies will form line on the right companies—march. When they have marched and filled up the intervals, the word halt is given by the colonel, and dressed by the captain of each company. The right companies may form line on the left in the same manner. Sometimes the right companies are fired in battalion previous to their retiring. The words of command are the same as if they had been separated from the left companies. The light infantry may be divided in the intervals of the first line, retire with it, and charge to the other line, whenever it becomes the advanced one. In this situation, they cover the retreat, and may occasionally fire; and when the line is formed, they resume their post on the left. Unless, however, the battalion is very strong, the light infantry remain in their usual position as a company. When the line is formed, the colonel gives the word the battalion will retire in line—right about face—march. When it has retired as far as lie judges, he gives the word halt, front.

**Thirteenth Manoeuvre.**—March to a Flank in Echelon.

The colonel gives the word battalion, by companies four paces to the right wheel, and form echelon. Covering sergeants take the number of paces as usual. The pivots make a half face to the right, the sergeants dressing by them. On the word quick march, captains on the right of their companies give the word halt, dress. Covering sergeants go to the reverse flank. The colonel then gives the word the battalion will advance in echelon—march. The whole advance to the flank in echelon about two hundred and fifty paces. At the word wheel back into line, the three centre sergeants instantly step out into the front, and mark the time for the battalion. The pivots mark time, gradually turning to their proper front, while the rest of the divisions wheel back the four paces they had advanced. When the fourth pace is completed, the colonel gives the word forward; and the whole, dressing by the centre, step out their full pace, till they receive the word halt. The line is then considerably to the general’s left, and parallel to its original front. In this situation, the colonel commands fire three rounds by companies from centre to flanks. Each captain gives the word platoon, ready, present, fire, load.

**Fourteenth Manoeuvre.**—The Hollow Square, and its Movements.

The colonel gives the word the battalion will form a hollow square on the three centre companies (viz. the fourth, fifth, and sixth), remaining companies—four paces on the right and left backwards wheel—quick march. The companies on the right each wheel back the eighth of the circle on their left, and the companies on the left wheel the same number of paces backward on the right. The colours, at the same time that the companies are forming their echelons, move back three paces into the rear. The fourth company by the side
Two other serjeants or camp colours should be placed in the rear, in a perpendicular line with the outside flanks of the front face, marking out a perfect square. The companies now march in echelon, and by the turning of the left shoulders of the right companies, and the right shoulders of the left companies, they wheel to form square. Their captains halt and front them in a correct line. The first company will wheel round the serjeant placed to mark the angle, and the grenadiers round the proper right of the first company; the light infantry at the same time wheeling round the serjeant on the opposite angle, till its right flank touches that of the grenadiers. They then, as also the first company, get the words halt, front, drefs, from their captains. They have then formed the rear face of the square, and in this manner the proper front rank of the rear face will be outward. The square is now perfectly formed, and composed of four faces. The front face consists of the fourth, fifth, and fifth companies; the right face of the third and second; the left face of the seventh and eighth; and the rear face of the first company, the grenadiers, and light infantry. The mounted officers, colours, musics, drummers, &c. and the battalion guns, are all within the square.

The colonel then gives the words the square will march by the right angle of the front face, left and rear faces—right about face. The two sides that form the right angle, that is, the front face and the right face, stand fast; the other two sides, viz. the left face and the rear face, go to the right about. At the word by subdivisions four faces to the right and left wheel—march, the whole by subdivisions wheel up one eighth of the circle, two sides to the right and two sides to the left, and are thus parallel to each other, and perpendicular to the direction in which they are to move. The pivot flanks are in this manner placed on the sides of the square, each side being thus in echelon, and the colours behind the leading angle. At the word march, captains, who are on the inward flank of their leading subdivisions, carefully preserve the distances they wheeled at, and from the flanks to which they wheeled. At the words halt, front square, or reform square, the whole wheel back into square; and the two sides that require it, that is, the left and rear faces, go to the right about. Captains dret their divisions as usual, in the same manner as is described for the square. The directions given for the march of the square by the right angle of the front face, will equally apply, should it be found necessary to march the square by any of its other angles.

The colonel then gives the words the square will march by the right face. The colours move up behind the centre of the named face, as do the mounted officers, &c. At the word front and rear faces, by subdivisions to the right and left wheel—quick march, the opposite side, that is, the left face, faces about; and the two flank sides wheel up by subdivisions, so as to stand each in open column. At the word by right face—march, the square marches two sides in line and by their centre, and two sides in open columns, which cover and dret to their inward flanks on which they wheeled up, carefully preferring their distances. The same directions that are given for marching by the front face, will apply to the march by any of the other faces. The colonel, when the square has marched as far as he sees necessary, gives the word halt, reform square. The square halts, the subdivisions in column immediately wheel back, and form their sides, and the side which faced about again faces outwards. The captains give the words halt, dres.

On the word prepare for firing, the front rank kneel and present their bayonets sloped. The square is then ordered to fire in whatever manner may be judged proper; the two rear ranks to fire standing; or companies by ranks successively; or by companies independent of each other; or by subdivisions, one firing when the other has loaded; or companies by files; as ordered. The front rank remains as a reserve. Should the battalion be formed only two deep, the front rank will remain kneeling, and the other rank will fire by files. The word is now given square will fire by companies, beginning on the right. When the firing by companies has ceased, the command is given by the colonel kneeling ranks, make ready, present, fire; the men rise up after firing'prime and load. The word is then given the square will form line on the three centre companies—side and rear faces—by companies, fix paces to the right and left wheel, quick march. The captains, as usual halt—dret their companies. The words are then given in echelon march and form line, march. The whole march in echelon, except the three centre companies, the outward companies taking care not to impede the inner ones, which must form before them. This may be done by the facing and filing of each division from its inward flank to its point in the new line, where it will form column. Captains halt—dret their companies, as in the third manoeuvre.

If the square is composed of the eight battalion companies only, then the grenadier and light company may be placed as a reserve in the rear, ready to be applied according to circumstances. In marching the square by any of its faces, some regiments have been instructed to march two sides in file instead of open column; and if the men march tolerably in file, there can be no question but that it is the best method.

Fifteenth Manoeuvre.—Retiring and filing to the Rear.

When the battalion is to retire, it ought to be previously drevled with the same exactness as when it is to advance, and the same care in ascertaining the direction of its march must be taken. Therefore, before the retreat is to begin, an officer or serjeant will have placed himself thirty paces in the rear, so as to stand perpendicular to the front directing serjeant; and of course he will be in the line, or nearly so, of the directing serjeant. Whenever the battalion marches to the rear, it must cover its proper extent of ground. The rear must therefore avoid closing their files more than usual; otherwise the front rank men, who are in general larger, will be crowded in their rank. Musics, drums, supernumerary officers, &c. will take care march with exactness, and not to interrupt, but rather assist the battalion.

The colonel gives the word the battalion will retire. As soon as this caution is given, the three directing serjeants face about. The same centre serjeant that directs to the front, directs also to the rear. He moves on in the line of the advanced officer, six paces beyond the rear rank, and halts. The two other serjeants move up on each side of him. When the line is retiring, music is never to play. On the word right about face, the whole face; and the supernumerary officer, who had replaced the directing serjeant, moves up into the leading rank. A mounted field officer pales through to the rear, and the directing serjeant in the interior prolongs his line, and takes his object betwixt the feet of the polled officer. Immediately after facing about, the word march is given by the colonel. The whole battalion instantly steps off. The replacing officer betwixt the colours prefers, during the movement, his exact distance of
of six paces from the advanced sergeant, and is the guide of the battalion, directing the sergeant conducting on his points under the correction of the colonel, who is ten or twelve paces behind the centre of the battalion. In this retreat, if the light infantry act separate, and not as a company of the battalion, at the word march they move quick and round by the flanks, and form in the rear of the centre, extending so as to cover it during the retreat, and following at the distance of fifty or sixty paces.

The colonel gives the words the battalion will, from the proper right of companies, file to the rear—paus companies by files. Each captain instantly gives the word left, turn, quick march, and wheels out his leading file, the rest of the files following in succession. The heads of companies must observe the proper distance from each other, and are regulated from the left. Circumstances may require that the companies should pafs from their proper left, instead of the right, in which case the leaders will halt and conduct such left until the line is formed, when they will again resume their proper places.

When the companies in file have marched as far as is necessary, the colonel gives the word bats, front. The whole now stand in open column of companies, the right in front. When the column is ordered to halt, the light infantry pafs quickly through it, and take post thirty paces in the rear of the intended line. On the word by companies, left, wheel into line—quick march, captains, as usual, bats, draft their companies. When the line is formed, its centre is opposite to the general.

Sixteenth Manoeuvre.—Filing, advancing, and changing to the Front. The colonel, having previously placed himself ten or twelve paces behind the exact line of the directing sergeant, will remark the line of its prolongation, and thus ascertain the direction in which it should march, and in doing this, he will not at once look out for a distant object, but will hit on it by prolonging the line, from the person of the directing sergeant to the front. Or he will order the covering sergeant to run out twenty paces, and will place him in the line in which he thinks the battalion ought to advance. The directing sergeant then takes his direction along the line which pafs from himself, betwixt the heels of the advanced sergeant, and remarking his object, prefers such line in advancing. The colonel then gives the words the battalion will advance. Before the line so advances, the light company quickly forms, in extended order, thirty paces before the centre, and prefers that distance in advancing. The front directing sergeant of the battalion moves fix accurate and exact paces in ordinary time, and halts. The two other sergeants that were behind him, move up on each side of him, and an officer from the rear replaces in the front rank the leading sergeant. The centre sergeant, in moving out, marches and halts on his own observed point, and the two other sergeants dres and square themselves exactly by him. The directing sergeant, after being assured that he himself is perfectly and squarely placed in the rank, by casting his eyes down the centre of his body, from the junction of his two heels, and by repeated trials take up or prolong a line perpendicular to himself and to the battalion, will observe and take up any accidental small spot on the ground, and within 100 or 150 paces, intermediate ones cannot be wanting, nor the renewal of such as he afterwards successively approaches to in his march. In this manner he is prepared, under the future correction of the colonel from behind, to conduct the march.

The line of direction being thus ascertained, the colonel gives the word march. The whole instantly step off, and without turning the head, eyes are glanced towards the colours in the front rank. The replacing officer between the colours prefers, during the movement, his exact distance of fix paces from the advanced sergeant, and is the guide of the battalion. The centre advanced sergeant is answerable for the direction, and the equal cadence or length of step. To these objects he alone attends, while the other two, scrupulously conforming to his position, maintain their parallelism to the front of the battalion, and thereby present an object to which it ought to move square. They are to allow no other consideration to attract their attention, and will notice and conform to the direction of the commander only. If any small alteration in their position is ordered, it must be gradually and cooly made. When the battalion is advancing in line for any considerable distance, the music may be allowed at intervals to play for a few seconds only, and the drums in two divisions to roll; but it is the wind instruments only which play. The large drum, or any other instrument whatever, which marks time by the stroke, is not permitted.

When the battalion advances fifty paces, the colonel gives the words the battalion will file from the right of companies—pafs, files to the front. Each captain immediately gives the word right, turn, quick march, wheels out his leading file, and pafs on direct to the front, preserving a relative distance from the left, as being the head of the column, or from the other flank, if particularly so ordered. When the column has marched fifty paces, the colonel gives the words bats, front. The whole now stands in open column, the left in front.

The light company pafs quick to the rear, assembles half of it behind each flank, and moves relatively with the flank companies.

The words now given in succession are column, right, wheel into line, quick march. The battalion will advance—march. The battalion marches pafs fifty paces. The battalion will advance by alternate wings, and fire four times—Left swing, bat. The left wing halts, and the right wing continues to move on fifteen paces. Left swing, march. Right swing, bat, ready, fire, load, march. The left wing marches pafs till the right wing, being loaded and shouldered, receives the order to march. Left swing—bat, ready, &c. as directed for the right wing, and thus they alternately proceed, till each wing has fired twice. The left wing will form line on the right—right swing, bat. When the line is formed, the battalion will advance, march. After marching fifty paces, bat. The battalion will fire a volley—front rank kneeling, make ready, fire, prime and load. The battalion will advance—march. When it has advanced twenty paces, it receives the command bat. The battalion will fire a volley, and port arms; when the battalion has fired, it immediately ports arms. Quick march; the battalion advances firm, dreading by the centre. When it has advanced fifty paces, bat; the front rank comes down to the charging position. Shoulder arms—prime and load. The light company, retiring from behind the flanks, pursues, returns, and assemble and join on the left of the battalion. The battalion is now advanced near the general, and with its centre opposite him.

If the battalion is not very strong, the light infantry should not act as such, but only as a company in battalions. In firing by wings, that is, by half battalions, the colonel generally fires the right wing, and the next in command the left. When the battalion has charged bayonets, they may be ordered to move forward on the charge at a very quick step, but by no means to run. A very few paces only can be necessary. Care must be taken that the battalion moves in perfect dres, which it cannot do if it run. The flugel man gives the time for each wing to call about, and should.
Seventeenth Manoeuvre.—Retiring in Line.

The colonel gives the words the battalion will retire—right about, face—march. While it is retiring, he gives the cadence the battalion will fire twice by alternate wings—the two flanks flanking. He then gives the words right wing—

*hold, front.* The light infantry are not ordered by the rules and regulations for the infantry formation, to cover the regiment in this manoeuvre; but it appearing to be as requisite as in advancing, they will be formed separately. On the halt of the right wing, they file round the left flank, and cover the left wing at fix paces in front. Firing and retreating till they occupy the ground quitted by the left wing, dressing by the right. When the left wing has gained fifteen paces, it receives the word from the lieutenant-colonel, *halt, front.* The light infantry cease firing. The colonel orders right wing—ready, present, fire (the men after firing immediately come to the port, or to the recover, as may be ordered). The light infantry face to the right, and cover the right wing at fix paces. On the words right about, face—march, the light infantry fire retiring, till they come into line with the left wing by which they drew, and continue firing. When the right wing has marched fifteen paces beyond the left, it receives the words *halts, front—prime and load.* When loaded, the signal sounds for the light infantry to cease firing. The instant the lieutenant-colonel fires that the right wing has fronted, he immediately gives the word of command, and conforms in every particular to what the right wing has done. The light infantry face to the left, and cover the left wing as they did the right, dressing by the right. In this manner each wing alternately proceeds, every due dispatch being made in reloading. When the wings have fired twice, the colonel gives the words the left wing will form line on the right wing—march—*halts, front—prime and load.* When loaded, the light infantry cease firing, and the signal is given by the bugle for it to form company in the rear of the centre. The colonel gives the word the line will retire; and when it has marched a hundred paces or more, covered by the light infantry, who file round the flanks, *halts, front.* The light infantry, upon signal, form company in the rear of the centre and afterwards resume their post on the left of the battalion.

In retiring by alternate wings, one colour remains on the inward flank of each half battalion, to which the men continue to look when they move, by which they drew, and before which a directing serjeant advances fix paces. The make ready—present—fire of the advanced wing is instantly to succeed the march of the other advancing wing or the *halts, front,* of the retiring one. In the half battalion firing, advancing, and retreating, if formed two deep, both ranks will fire flanking. If formed three deep, the front and centre ranks will fire flanking, and the rear rank will remain shoulder'd in reserve.

Eighteenth Manoeuvre.—Advancing in Line.

The colonel gives the word the battalion will advance—march. It marches a hundred paces, and receives the *halt.* At the words fire a volley obliquely to the right, the men of the front rank turn one-eighth of a circle to the right; those of the rear ranks take a pace to the left, and cover their proper file leaders. The words are then given make ready, present, fire, load. Fire a volley obliquely to the left—make ready, present, fire, load (the ranks execute the reverse of what is directed in the firing to the right). The battalion will advance—march. When it has advanced a hundred paces, *halt.* Fire two volleys to the front—after the left, the men will port arms, and half cock. *Battalion ready, present, fire, load.* Battalion—ready, present, fire—the men will port arms, and half cock. *Shoulder arms—front ranks, take open order—march.* The colonel and lieutenant-colonel now direct, and come through the centre into the front, as do the men. Every one takes his station exactly as they had been placed when receiving the general. The colonel, with his back to the regiment, gives the words the battalion will advance—march. The music plays, and when the line has advanced within fifty paces of the general, the colonel gives the word *halts—general fire—present arms.* The music plays God save the King, and the drummers beat a march. When the music ceases, the colonel, turning the battalion, gives the words shoulder arms—rear ranks, take close order—march, and the review is ended.

Light Infantry. The following is the method usually observed by the light infantry when required to form in extended order, as commenced at the twelfth manoeuvre. Previous to the retreat in line, the colonel directs the horn to sound the signal for their forming company, when the officer commanding it gives the words right face—quick march (in double quick time, to ten paces in the rear of the supernumerary rank, its centre covering the colours)—*halts, front—order arms—unfix bayonets—form two deep* (the left subdivision of the rear rank steps back one pace) *rear rank, to the left face—quick march* (its left subdivision arrives between it and the centre rank, when the whole moves forward)—*halts, front, dereas,* is then given by the senior supernumerary officer. The light infantry being divided into subdivisions, the right is commanded by the captain, and led by his covering serjeant; the left by the senior lieutenant, and led by the second serjeant; the second lieutenant attends the right subdivision. On the retreat of the line, at signal from the horn, the subdivisions face outward, and file, in quickset time, round the flanks of the line, forming (when the retreat is made by alternate companies) at ten paces in front. The right subdivision covering at equal distances the right wing, except the grenadiers, and the other the left wing in the same manner, dressing to the centre. When the word *march* is given to the line, the light company, at the sound of the bugle, commence firing for the first round from centre to flanks. Each man, when he has fired, retires the ordered number of paces, generally four, by the left of his file, comrades, and reloads. On the fronting of the battalion, they form company, as before mentioned, round the flanks, in rear of the line, where they divide into sections. The two sections of the right subdivision form in rear of the first and third companies; those of the left in the rear of the fifth and seventh. All the sections are faced to the left, and on the retreat of the alternate companies, suppose the left move infanlty into the intervals, and form as much extended as is necessary, in line with the right companies, who still remain stationary, firing independently till the companies in line receive the order to make ready. When the right companies retreat, the light infantry move to the right, cover them as they had before done the left, and fire retiring till they arrive at the intervals between the left companies, upon whom they drew. Thus they alternately continue to occupy the intervals, till the line being formed, they wheel round the respective flanks, form subdivisions in rear of the second and seventh companies, form again in front on the retreat of the whole line, in extended order, and at its halt, assemble again in company behind the centre. In advancing in line, and by wings, the movements are similar to those already explained in the seventeenth manoeuvre, with this difference, that the company moves forward instead of retreating. To re-form three deep, when re-assembled in company behind the centre of the line, the officer gives the words form three deep (the third section, or the whole of the proper rear rank, steps back one pace) *rear rank, to the right face—quick march* (the rear
B A T

rear rank of the section marks time till the front rank has passed it, and then moves on; at the word right, front, they cover the centre rank correctly, at one pace distant from it. The company then fixes bayonets, faces to the left and resumes its proper position in line.

Observations.
The number of paces mentioned in the several movements are not positively preordained, but are supposed to be nearly such as will give the intended relative situations. If the ground allows the marches to the rear and front to be longer, it will be so much the better.
The colonel should give all his commands from the rear of the battalion. No commanding officer should attempt, in the face of the general, to put the regiment through any of the manoeuvres without being himself perfectly and minutely acquainted with the principles on which each is performed. He will thus avoid the disgrace of calling to his adjutant for information, or galloping full speed to the flank of the battalion by way of rectifying a mistake which his ignorance and temerity has brought him into, and which he cannot remedy but by recurring for advice either to the other mounted officers, or to the ferjeant-major in the rear.

When the reviewing general has seen the battalion go through such of the ordered manoeuvres as he judges necessary, he will, that he may be able to report on the merits of its performance, among other circumstances, particularly observe and specify, whether or not the original formation of the battalion is according to order.
The marches are made with accuracy, at the required time and length of step, and on such objects as are given. The proper distances in column and echelon are at all times preserved. The wheelings are made just, and in the manner prescribed. The formations in line are made true, without false openings, or necessity of correction. The officers are alert in their changes of situation, exact in their own personal movements, and loud, decided, and pointed in their words of command. The march in line is uniformly steady, without floating, opening, or closing. The march in file close, firm, and without lengthening out. The officers, and supernumeraries give the aids required of them with due quickness and precision. Hurry and unnecessary delay in the movements, are equally to be avoided. In the firings, the loading is quick, the levelling just, the officers animated and exact in their commands.

Form of sending for, and lodging the colours. The battalion being in line, the commanding officer orders the grenadier drummers to beat the drummer's call; on which two youngest ensigns recover their swords, face to the right, and march between the line of officers and the front rank, till they come to the head of the grenadiers, where they halt, front, and bring their swords to the point. The drum-major, with a party of drummers and fifers, will likewise face to the right, and march to the head of the grenadiers, placing themselves between the ensign and the front rank. The grenadier captain then makes his company take close order, and will either wheel them by subdivisions, or march them in one. If by subdivisions, he places himself on the pivot flank of the first, the eldest lieutenant on that of the second, and the other lieutenant in the supernumerary rank of the first; but if the company is marched in one division, the two lieutenants are in the supernumerary rank. The company then marches, in ordinary time, to the quarters where the colours are lodged, when it halts, and rear ranks take open order. The drum-major unfurls the colours, and gives them out of a window to the ensigns, who on halting had sheathed their swords. The captain then orders his men to present arms. Officers salute, and the drummers beat a point of war, which finished, he shoulders arms, closes the ranks, and marches them off in ordinary time, the drummers beating the grenadier's march. On arriving at the left flank of the regiment, the company faces to the right, the ensigns with the colours march in front of the line of officers, the grenadier officers between them and the front rank, as also the drummers and fifers, and the grenadiers in files, between the other ranks. The commanding officer of the regiment, as soon as the colours arrive on the left flank, orders the battalion to present arms, the officers salute; the fifers play God save the king, and the drummers beat the troop. On the colours arriving in the centre of the battalion, the ensigns halt and front, and, when the grenadiers have taken poll on the right, the battalion is ordered to shoulder arms.

When the colours are to be lodged, on the drummer's call being beat, the ensigns, the drum major, and a party of drummers and fifers, march and take poll in the front of the grenadiers. The battalion present arms, officers salute, music plays, and drums beat. On the command of grenadiers marching off with the colours, drummers beat the troop. When they arrive at the house, or place where they are to be lodged, the drum-major receives them at a window, the grenadiers present arms, officers salute, and drummers beat a point of war. The ensigns on quitting the colours, draw their swords, and salute with the other officers. The captain will either march his company back, or dismiss them, as he may be ordered by the commanding officer.

When the colours are not to be received, or lodged in form, the ferjeant-major, with four ferjeants in the centre of the battalion, will take the colours cased, from, or to the place where they are kept, in the following manner. Serjeant-major, the two front rank ferjeants carrying the colours on their shoulders, covered in the rear by the two other ferjeants and the drum-major, who is to receive them when they arrive at the place of their destination. No compliment is paid by the battalion in this case, and they are generally sent away when the ranks are closed. When the regiment is ordered for a field day, the colours should never be received or lodged in form, as it takes up too much time.

The following is at present the detail of the battalion. Field officers—one colonel, one lieutenant-colonel, one major, (by a late regulation field officers have no companies,) ten captains, twelve lieutenants, and eight ensigns. There is no captain-lieutenant. Staff officers—one adjutant, one pay-master, one quarter-master, one surgeon, one serjeant-major. Non-commissoned officers—one ferjeant-major, one quarter-master ferjeant, thirty ferjeants, thirty corporals. Drummers—one drum-major, twenty-one drummers and fifers. Privates—five hundred and seventy.

BATTARDEAUX, in Bridge-building. See Coffer-dams.

BATTATA, in Botany. See Dioscorea.

BATTATAS. See Helianthus.

BATTAWAY, in Geography, a town in Africa on the Grain Coast, easily known at sea by two large rocks, two miles distant from the shore to the west, and also by some high mountains behind the town. This is one of the best built places on the coast; populous and rich, and trades extensively in pepper and ivory. The people, however, are addicted to thefting.

BATTLE. See Bateau.

BATTEN, in Carpenterie, a name which the workmen give to a scantling of wooden stuff from two to four inches broad, and

444044
and about an inch thick; the length being pretty considerable, but undetermined.

The term is chiefly used in speaking of doors, &c. which are not framed of whole deal, &c. with stiles, rails, and panels like wainscot, but are made to appear as if they were, by means of these pieces, or battens, bradded on the plain board round the edges, and sometimes cross them, and up and down.

Hence batten doors, or windows, are such as seem to be wainscot ones, but are not. These are said to be either single or double, as the battens are fitted on to one side, or to both.

Battens of the hatchs, in Sea-language, are nailed along the tarpaulings, and serve to keep their edges close down to the hatches, in order to prevent the water which washes over the deck from penetrating into the lower apartments of the ship.

Batten, in Geography, a town of Germany, in the circle of the Upper Rhine, and principality of Upper Hesse, 15 miles south west of Waldeck, and 16 north west of Marburg.

BATTENBURG. See Batenburg.

BATTEN Kill, a small river of America, which rises in Vermont, and after running north and north-westwardly about 30 miles, falls into Hudson, near Saratoga.

BATTERBURY, or Batterby bay, lies on the west coast of Ireland, about two miles north east from Convitt islands. It has a narrow entrance, but is above 4 miles broad. N. lat. 53° 19'. W. long. 10° 22'.

BATTERIE, is a French term in Music, for that kind of arpeggio; or breaking of chords in a distinct and detached manner, different from common arpeggios, in the execution of which on keyed-instruments, no finger is taken off till the note assigned is again wanted; and when, on the violin, the notes of a chord are not, as usual, swept up and down in one bow, but either all to be bowed or separated by a tremulous motion of the bow.

In this article of the Encycl. Meth. after the definition of the term Batterie, and a necessary addition by M. Framer, are inserted, the Abbé Feytou takes the pen, and in treating the subject metaphorically, manifests deep reflexion and science in the theory of sound; but with a total disregard to the practice of the greatest composers and performers, who have produced pleasing effects by the very means which he prohibits.

BATTERING-Ram. See Artes.

BATTERING-Ram, in Heraldry, a bearing or coat of arms resembling the military engine of the same name.

Batter, the attacking a place, work, or the like, with heavy artillery. See Battery.

To Batter in Breach, batter en breche, is to play furiously on a work, as the angle of a half moon, in order to demolish and make a gap or breach in it.

In this, they observe never to fire a single piece against the top of the wall, but all towards the bottom, from three to six feet from the ground; they also fire par camarade, all together, till they perceive the earth fall from behind the lining of the rampart.

Batter Pieces, or pieces of battery. See Cannon.

BATTEROW, in Geography, lies on the west coast of Africa, 2 leagues from Diacore, and 5 leagues more from Cape. Three points to the north of the east.

BATTERSEA, a village and parish near London, in the county of Surry; where above 300 acres of land are occupied by the market gardeners, of whom there are about twenty, who rent from 5 or 6 to nearly 60 acres each. The gardens at Battersea pay seven shillings and sixpence per acre for tythes to their vicar. Lysons's Environs of London, vol. i. p. 27.
