Art

Artery, in Anatomy, from aer, air, and ervice, to keep, is the name by which those vessels are distinguished through which the blood flows from the heart to every part of the body. The term was first adopted by the anatomists of the Alexandrian school, in consequence of the erroneous opinion which they entertained, that these vessels were designed for the distribution of air throughout the body.

Arteries, Structure of. The larger arteries have thick and elastic sides, so that they remain open when divided, and present a regularly circular aperture. The sides may be separated into three strata of dissimilar substances, which are technically called coats. The innermost, which is generally termed the cuticular coat, is very thin, but very strong and inelastic. Upon this circumstance depends the regularly circular form of an injected artery; for if the cuticular coat bursts from too great force being used in injecting, the exterior elastic coats are distorted into an irregular and uncertain figure. The internal surface of this coat is perfectly smooth, so that the blood slides along it without impediment; the external surface is a little rough, and is connected by cellular substance to that coat which surrounds it. The middle or muscular coat consists of circular fibres which are scarcely visible in the largest arteries, but are very manifest and strong in the smaller ones; they are seen projecting in circular ridges, beneath the thin cuticular coat of a small artery, when it is slit open. The great increase of the muscular power of the small arteries is not only evident to the sight, but has been demonstrated by experiment. Mr. Hunter bled a horse to death, and afterwards examined the flate of the arteries. The aorta was contracted about 1/25th part of its natural area, the iliac 1/25th, the radial 1/2. See his Treatise on the Blood, Inflammation, &c. The external or elastic coat of the artery appears to be made of condensed cellular subsidence; it is powerfully elastic, and abounds in the larger arteries, but gradually diminishes in quantity as the size of the vessel decreases; so that the small arteries are quite flaccid, and collapse when divided. It is easy to perceive the use of these various degrees of elasticity and muscular power, which are given to the different sets of arteries. In the large arteries, muscular power seems unnecessary, for the force of the heart is fully adequate to the propulsion of the blood; but in the smaller arteries, where the effect of the heart's action declines, a proportionate muscular power is allotted to the vessel to urge on the circulating fluids. The arteries have their nutrient arteries and veins, their absorbents, and their nerves. All the arteries proceed from one great vessel, as the branches spring from the trunk of the tree; and we proceed to notice certain circumstances observable in Arteries, the Ramification of the.

1. When a large artery gives off a branch, the conjoined areas of the two vessels make a greater space for the blood to move in, than the area of the original vessel. The increase of dimensions in the branches of a large artery is slight, but in those of a small one it is so considerable, that Haller has estimated it as surpassing by 1/2 of that of the trunk from which they sprang. The conjoined areas of all the small arteries so greatly exceed that of the aorta, that the same anatomist, in opposition to former opinions, says, these vessels may be considered as conical, the axes of the cone being in the extreme arteries, and the apex in the heart.

2. When a large artery sends off a branch, its course does not, in general, deviate further from that of the trunk, than an angle of 45 degrees. Sometimes a branch, which has gone off at an acute angle, returns, and proceeds in a contrary direction to that of the trunk; and these arteries are generally
ART

Generally called circumflex. Sometimes, indeed, a large artery does proceed from the trunk at a greater angle, nearly a right angle, as the renal arteries, &c. Though the large arteries generally ramify at acute angles, there is great diversity in the branching of the smaller ones.

4. Arteries, in general, do not pursue a straight, but serpentine course; in some instances it is remarkably the case; as in the spermatics, those of the face and occiput, and in most of the smaller arteries.

4. Though the ramification of arteries may be compared to the branching of trees, yet it differs materially in this particular, that the different branches frequently conjoint. This conjunction is technically termed, if we borrow the phrase from the Greek language, their "Anastomosis," if from the Latin, their "Infracussion." This union of arteries rarely happens among the larger ones, but frequently among the smaller; and increases in number in proportion to the minuteness of the vessels. The utility of the infracussion of arteries is evident: were it not for this circumstance, if any arterial trunk were accidentally compressed, so that the current of blood in it should be for some time obstructed, the parts which it supplied might perish. But in consequence of the frequent communication of the arteries with one another, the blood can pass from the adjacent arteries into all the branches of any one accidentally obstructed.

When arteries incofulate, two currents of blood, moving in opposite directions, must come together, and retard each other's motion. This probably is the reason that larger arteries, through which it seems necessary that the blood should flow with rapidity, so seldom conjoint, whilst the small arteries, in which it is requisite the blood should move tardily, communicate in surprising numbers, and with a frequency proportionate to their minuteness. The very frequent communication of the minute arteries, almost as effectually prevents the prejudicial consequences of obstruction in the larger trunks, as if those arteries themselves were made to communicate by more direct and larger channels. All these minute arterial tubes are capable of enlargement, and it is an ascertained fact, that even the aorta itself may be gradually obstructed, without the parts which it supplies being deprived of nourishment. From an attentive consideration of all these circumstances, it has been concluded, that the same increase of the area of the branches of large arteries, the acute angles at which they divide, their nearly rectilinear course, and the rare occurrence of incofulation between them, are designed to facilitate the rapid motion of the blood in them, so that it may arrive unchanged and in the same state that it was projected from the heart, at that part of the body for the nourishment of which it is intended; whilst, on the contrary, the great increase of the area of the smaller vesels, the variety of their angles, their tortuous course, and their frequent communications, were designed to check the velocity of the blood's motion, when it has arrived at that part where secretion is to be performed, and nutrition is to take place. Contrary opinions have indeed been maintained; and for the further discussion of this subject, we must refer the reader to the Circulation of the Blood.

Arteries, Termination of. When the arteries have become very minute, they terminate in two ways: they either turn back again and become veins, and return the blood to the heart, or they send off fine vessels which abstract something from the circulating blood, and which are therefore called the secering arteries. Though none but minute arteries are ever reflected so as to become veins, yet many of them are of sufficient magnitude to allow the passage of common waxon injection. The arrangement of the minute veins can be demonstrated by impelling common waxon injection into the arteries, particularly if a degree of putrefaction be suffered to take place previously to the experiment. In the diffusion of such a preparation, the continuity of the arteries and veins is very manifest. It seems therefore to follow from this facility of communication, that the mass of blood is continually and freely circulating, in order to undergo that change which is effected in the lungs, whilst but a small part of it proceeds into the very minute arteries, for the purpose of having secretions made from it. For these arteries, however minute, must be considered large in comparison to the exility of others, which cannot be injected with wax and even reject the red globules of the blood, or admit them in such small proportion, that they do not impart the red colour to the fluid which mantains in these vessels. Now we may venture to affirm, that these globules do not much exceed, in diameter, the 150,000th part of an inch, which circumstance sufficiently shows the minuteness of the former arteries. See the Article Blood. But however minute arteries may become, till they must all end in the same manner; they must be continued into veins, for that is the route which the blood, or subtle injections pursue, and from the most minute arteries those which perform secretion arise.

The secreting arteries are too minute to admit commonly of demonstration; they are however evident in some glands; in the kidney for instance, they may be seen continued into the excretoy vessels or tubuli uninervi. Subtle injections, when thrown into the larger arterial trunks, may be seen oozing out on the surfaces of membranes, and into the cellular luminis of them, and they are generally supposed to be poured forth from the open orifices of the secreting arteries. Analogy therefore, rather than actual demonstration, leads us to believe, that the secreting arteries abstract the particles of nutrition, or the materials which compose the fabric of the body, from the circulating fluids, and deposit them from their open mouths, so as by this means to build up and keep in repair the structure of the body.

Arteries, Distribution of. The great artery, whose branches supply the whole of the body, is named the "aorta." It comes off from the upper and back part of the left ventricle, where it is furnished for a short part of its course by the fibrous fibres of the heart. Its origin appears externally to be divided into three distinct eminences, which denote the situation of its femoral valves.

The aorta emerges from the spine of the heart, between the pulmonary artery, and the right auricle. It ascends at first rather to the right, till it arrives at the upper edge of the second rib. Then it begins to bend backwards across the division of the pulmonary artery and of the trachea, till it reaches the left side of the spine, in which situation it descends from the fourth or fifth dorsal to the left lumbar vertebra.

By the "arch of the aorta," is meant that part of the vessel which arises from the heart, and bends across the chest. It bends off the following branches: viz. the two coronary arteries, whose mouths are situated just above the upper edge of the femoral valves. They depart from the trunk at right angles, and are distributed to the heart itself. The most convex part of the arch sends off three large branches; first, the arteria innominata; secondly, the left carotid artery; and thirdly, the left subclavian artery. Varieties not unfrequently occur in the number of arteries which arise from this upper part of the arch: a long lift of them may be seen in Sommerring de corporis humani fabricâ, tom. v. p. 152.

The right coronary passes in the groove between the right auricle and ventricle, covered by fat, to the flat surface
ART

face of the heart. It gives off five large branches chiefly to the right ventricle; the left of these, which is the longest, anastomoses near the apex of the heart with the left coronary artery.

The left coronary artery is found between the pulmonary artery, and the left auricle. It divides into two branches. The anterior branch takes a ventricle course along the convex surface of the heart, in the direction of the septum ventriculorum; it communicates at the apex with the right coronary. The posterior branch passes between the left auricle and ventricle towards the left margin of the heart, and is distributed to the left ventricle.

Observation. Both the coronary arteries send branches to the roots of the great vessels, as they come off from the heart, and they communicate with the phrenic, internal mammary, and bronchial arteries.

The artery imminiment paffes obliquely in front of the trachea, and behind the subclavian vein. After a course of an inch or an inch and a half, during which it gives off no branch, it divides into the right carotid and right subclavian arteries: the rest of the description of these arteries, is the same on both sides of the body.

The common carotid artery emerges from the chief by the side of the trachea, where it is covered by the insertion of the sternocleidomastoideus muscle. It mounts upwards in front of the vertebral, and parallel with the trachea, till it reaches the upper margin of the thyroid cartilage, without giving off a single branch. During its course along the neck, it is closely connected to the internal jugular vein, and the eighth pair of nerves. At the upper margin of the thyroid cartilage, it divides into the external and internal carotid arteries, the former of which is distributed to the outside of the head, the latter to the brain.

The external carotid continues its course upwards between the ramus of the jaw and the ear, being imbedded in the substance of the parotid gland. About the middle of the ramus of the jaw, it divides into the superficial temporal, and the internal maxillary arteries.

The Branches of the External Carotid Artery.

The superior thyroideus is the first branch of the external carotid artery. It pursues a tortuous course downwards and forwards to the upper part of the thyroid gland, to which it is almost entirely distributed, communicating freely with the thyroid branch of the inferior thyroideal artery. It sends however a superficial branch under the os hyoideus, which unites with its fellow of the opposite side. Another branch goes to the lower part of the thyroid cartilage, and is distributed to the neighbouring muscles. The laryngeal artery is the most constant branch of the superior thyroideal; it enters the larynx between the thyroid and cricoid cartilages, together with the recurrent nerve, or at a hole in the side of the thyroid cartilage, and is distributed to the muscles of the arytenoid cartilages, and to the membrane which lines the larynx.

The lingual artery comes off from the external carotid immediately above the former; it accompanies the lingual nerve, passing above the corner of the os hyoideus, and within the hyoglosus muscle; it gives a branch (the ramus hyoideoideus of authors) to the muscles above the os hyoideus; then it sends a pretty large artery (dorsalis linguae) to the back of the tongue, epithelium, &c. Afterwards the trunk divides into two branches: the sublingual, which passes between the sublingual gland and the geniohyoides muscle to the chin, where it terminates superficially; and the gallo, which is the larger and more important branch: it continues its course along the inferior surface of the tongue, preferring a considerable size to the very apex.

The labial artery, which is also called the facial, external maxillary, or angular artery, arises from the external carotid under the digastric and stylohyoides muscle; it advances in a tortuous manner to the basis of the jaw, pursuing through a deep sulciurse which is made for it in the submaxillary gland; by a bold and sudden turn it bends over the basis of the jaw at the anterior margin of the malleus muscle, and then follows a serpentine course over the check to the side of the mouth and nose, under the zygomaticus muscles.

Before it paffes over the jaw, it sends off the following branches: 1. The ascending palatine artery, goes under the glosso-muscles to the pharynx, Esophagus tube, soft palate, and uvula. 2. An artery to the back of the tongue and tonsils. 3. A number of small branches to the submaxillary gland, the surrounding lymphatic glands, the skin, the membrane of the mouth, &c. 4. The submaxillary comes off just before the artery makes its turn; it runs forward on the mylohyoides muscle towards the chin; there it turns over the lymphatic of the jaw, and is distributed to the skin and muscles of the chin, communicating with the inferior labial artery.

When the artery has passed over the basis of the jaw, it sends off: 1. A branch to the surface of the masseter, which communicates with the malleus branch of the temporal. 2. The inferior labial artery, which supplies the lower part of the lower lip, and communicates with the submaxillary, and with the coronary artery of the lower lip. 3. The coronary artery of the lower lip, which pursues a winding course under the oribularis oris, till it meets and inosculates with its fellow of the opposite side. It is sometimes produced by the inferior labial. 4. The coronary artery of the upper lip may from its superior magnitude be considered as the continuation of the trunk; it follows the edge of the upper lip, lying on the membrane of the mouth, and in the middle of the lip has a large and free communication with the opposite artery; it sends off a large branch to the side of the nose, and two smaller branches which run along the front of the septum nasii; these communicate on the ala nasii with the branches of the opthalmicus and infraorbital arteries. The branches which the labial sends off to the face vary much in size and number; sometimes it terminates in producing the coronary of the lower lip (vide Haller's Icon. facie ii. tab. arter. faciei); sometimes the nasal arteries are entirely given off from the ophthalmicus; sometimes the nasal branches of the labial extend over the nose to the forehead; sometimes the branches of one side differ from those of the other.

The ascending pharyngeal artery of Haller (Halleri Icon. facie ii. tab. arter. pharyng.), which is the smallest branch of the external carotid except the posterior auricular, either arises from the back of the carotid opposite the lingual, or from the point of bifurcation. Its course along the neck is straight; it is found in front of the rectus capitis major, and on the side of the pharynx, being absolutely hidden by the two carotids. Its anterior branches supply the bag of the pharynx; its posterior branches go to the superior cervical ganglion of the great sympathetic nerve, to the par vagunum, and sternocleidomastoideus muscle: the termination of the trunk enters the skull at the foramen jugulare, and ramifications on the dura mater. The occipital artery is covered at its origin by the digastric muscle; it passes in front of the jugular vein, then gets between the mastoid process and the atlas, under the muscles of the neck. Arriving near the ligamentum nuchae, it penetrates the complexus muscle, and becomes cutaneous. It sends off branches to the muscles, along which it paffes, one of which is much larger than
than the reh, descends along the outer side of the complexus, and communicates with the transversalis colli. A branch of the occipital artery enters the skull at the foramen jugulare, and supplies the dura mater of the cerebellum. The trunk of the occipital artery branches over the back of the scalp, being distributed to the occipital portion of the occipito-frontalis, and to the skin. Its branches communicate freely with those of the temporal artery.

The posterior artery of the ear, the smallest branch of the external carotid, is given off higher up than any of the above-mentioned branches. Indeed it does not arise until the trunk has entered the parotid gland. It follows the course of the digastric muscle, ascends behind the external car, and distributes its branches to the car and scalp, communicating with the temporal and occipital arteries. It sends off the arteria stylomastoidea, which entering the foramen of that name, supplies the internal ear.

The superficial temporal artery continues its course through the parotid gland; it mounts over the zygomatic arch, and distributes its widely spreading branches over the side of the head.

**Branches of the Temporal Artery.**

Branches to the parotid gland; one or two small twigs to the front of the ear, called the anterior auricular arteries; a branch to the articulation of the lower jaw; and one or two branches to the malleus muscle. The transverse artery of the face is given off by the temporal, while it is passing through the parotid gland; it emerges from that gland in company with the parotid duct, crosses over the malleus muscle, and advances to the corner of the mouth, communicating with all the arteries of the face. The middle temporal artery, which is to be distinguished from the superficial temporal on the one hand, and the deep-seated temporal on the other, runs under the temporal spongosus, and extends as far as the fronto-occipitalis muscle.

After the temporal artery has passed over the zygoma, it divides sooner or later into the anterior and posterior temporal branches; these communicate with each other; the anterior branch communicates also with the frontal and super-orbital branches of the ophthalmic; the posterior branch communicates with the posterior auricular and occipital arteries.

The internal maxillary artery is much larger than the temporal, and should therefore, if wise be adopted as the criterion, be considered as the continuation of the carotid. It passes forwards and downwards between the external pterygoid muscle and the jaw; then following a serpentine course, it arrives at the sphenomaxillary fissure, where it terminates by dividing into three branches.

**Branches of the Internal Maxillary Artery.**

A small twig entering the tympanum by the bulla Glassei; another entering the skull at the foramen ovale.

The spinous or middle meningeal artery mounts straight upwards through the spinous hole of the sphenoid bone, and is distributed widely over the dura mater; it courses the deep grooves which impress the inner surface of the pericranial bone; it communicates with the posterior meningeal vessels, which come from the vertebral and occipital arteries, and with the anterior ones from the ophthalmic.

The inferior maxillary artery enters the canal of the lower jaw, in company with the nerve of the same name; it sends branches to the teeth and to the substance of the jaws; arriving at the foramen mentale, it divides into two branches; one of these goes forwards to supply the incisor teeth; the other comes out at the foramen mentale, and communicates with the artery of the lower lip.

The pterygoid branches are distributed to the pterygoid muscles.

The deep temporal arteries are two in number, and ramify deeply in the temporal muscle.

The artery of the cheek (arteria bucalis) runs along the buccinator muscle, and communicates with the arteries of the face.

The alveolar artery, or artery of the upper jaw, bends round the tubercle of the jaw, and advances towards the face. Its chief branch enters a canal in the upper jaw, and supplies the teeth.

The infra-orbital artery enters and pales through the infra-orbital canal of the superior maxillary bone, and comes out upon the face at the infra-orbital foramen. It is distributed chiefly to the muscles of the face, and communicates with the coronal artery of the upper lip, and its nasal branches; with the transverse artery of the face, and the artery of the cheek.

The superior or descending palatine artery is one of the three branches, into which the internal maxillary divides at the sphen-maxillary fissure; it passes through the pterygo-palatine canal, and comes out at the palatine foramen. After passing a branch backwards to the soft palate, the artery comes forwards under the arch of the teeth. A small branch of it pales by the foramen incisivum into the nose.

The upper pharyngeal artery is sent to the upper and back part of the pharynx.

The nasal artery, which is the continuation of the trunk, goes through the sphenopatinate foramen to the back of the nostrils; there it gives small twigs to the ethmoid and sphenoid cells, and larger branches to the septum and floor of the nostrils and antrum maxillare.

The internal carotid artery pursues a serpentine course along the front of the bodies of the vertebrae, till it arrives at the entrance of the carotid canal. It is connected with the par vagum, and the great sympathetic nerve, and also with the rectus anterior muscle. It follows the course of the canal of the temporal bone, passing first directly upwards, then turning horizontally forwards, and then ascending again in a straight direction, and entering the cavernous sinus. While in this sinus, it pales from the back of the sphenoid bone to the anterior clinoiod process, where it suddenly doubles back upon itself, and branches out to the brain.

**Branches of the Internal Carotid Artery.**

While in the cavernous sinus, it sends off the two arteries of the receptaculum, which are spread upon the neighbouring parts of the dura mater.

Having risen to the anterior clinoiod process, it sends off the ophthalmic artery, which enters the orbit with the optic nerve. The artery is situated at first on the outside of the nerve; entering the orbit, it crosses obliquely over the nerve, and arrives at the internal angle of the eye. It sends off the following branches. - The lacrimal artery supplies the lacrimal gland, and sends forward two small branches to the tarsus of the upper and lower eyelid. The posterior ethmoidal artery pales through the posterior carotic artery hole to the ethmoid cells. The sphen-orbital or superior muscular artery pales along the upper part of the orbit, supplies the levator palpebrae, the rectus superior, and rectus internus, quits the orbit at the superciliary foramen, and communicates with the arteries of the scalp. The central artery of the retina plunges into the optic nerve, runs along its axis, and radiates beautifully on the retina. One of its branches penetrates the vitreous humour, and is distributed to the crystalline lens. The ciliary arteries do not all come off from the trunk of the ophthalmic, but many are produced by
by its branches. They may be divided into three classes.—The posterior or short ciliary arteries surround the optic nerve; they divide into twenty or thirty branches, which perforate the back of the sclerotics, and are distributed to the choroid. The long ciliary arteries are two in number; they perforate the sclerotics at one-third of the distance between the optic nerve and the cornea; arriving at the orbiticus ciliarii, they divide into two branches, which follow the outer circle of the iris, and communicating together, form the zona major of the iris; the branches of this form the zona minor of the iris. The anterior ciliary arteries penetrate the front of the sclerotics and contribute to the formation of the zones of the iris. These vessels in the fovea produce the arteries of the membrane papillaris. The inferior muscular artery goes to the muscles which are found beneath the globe of the eye; viz., the obliquus minor, the rectus inferior and externus. The anterior ciliary arteries are divided for the upper and lower eyelids. The trunk, arriving at the inner angle of the eye, splits into two branches: the nasal branch crosses the lacrymal bag, descends along the ala nasii, and communicates with the labial artery. The frontal branch is distributed to the scalp, and communicates with the temporal.

After the carotid has arrived at the anterior choroidal processes, it sends off several small branches, some one of which goes to the choroid plexus. Then it sends off the communicating artery, which meeting and anastomosing with a similar branch of the vertebral, contributes to form the celebrated circle of Willis. The artery then divides into an anterior and a posterior branch.

The anterior branch, or the artery of the corpus callellum, comes forward in the division between the two anterior lobes of the brain. Here it approaches the artery of the opposite side, and has a short but large communication with it just above the junction of the optic nerves. This communication completes the circle of Willis in front. The rem of the trunk passes first upwards, and then turns backward over the corpus callellum, and between the two hemispheres of the brain. The posterior branch, or artery of the fissa Sylvii, runs directly outward, and enters the fissura Sylvii; its branches supply the middle part of the brain chiefly.

Observation. All the arteries of the brain and cerebellum ramify first upon the pia mater, and then enter the cortical substance of the brain. They do not follow the directions of the convolutions. They are composed of thinner coats than other arteries, whence the brain may be seen even through the coats of the larger arteries.

The subclavian artery ascends behind the head of the clavicle and the insertion of the pectoralis major muscle, towards the scapular muscles; it passes between the anterior and middle scalene, and then bends over the first rib into the axilla, where it takes the name of the axillary artery. The outer edge of the scalene may be considered as the boundary between the subclavian and axillary portions of the vessel.

Branches of the Subclavian Artery.

The internal mammary artery comes off from the front of the subclavian; it passes behind the articularation of the sternum and clavicle, then goes along the middle of the cartilages of the ribs, and terminates on the rectus abdominalis by communicating with the epigastric, intercostal, and lumbar arteries. It sends an artery to the thymus; a small branch which accompanies the phrenic nerve; two arteries to the pericardium; and some small twigs to the anterior medianum, and back of the sternum. Other branches come off at the intervals between the cartilages of the ribs, communicate with the intercostal arteries, and then go out to the muscles on the outside of the chest.

The inferior thyroidial artery arises from the upper part of the trunk, where it is covered by the sterno-cleido-mastoideus; it divides almost immediately into four branches.

1. The proper thyroid branch bends in a tortuous manner under the carotid artery; till it arrives at the thyroid gland, to which it is distributed, communicating with the superior thyroid artery. This branch sends one or two small twigs down along the trachea. The ascending thyroid branch is a small but profuse artery, which passes upwards in front of the thyro-vertebral processes of the cervical vertebrae, and is distributed to the neighbouring muscles and nerves. 2. The transverse artery of the neck goes along the side of the neck, and is distributed to the trapæzius and neighbouring muscles of the scapula. 4. The transverse artery of the shoulder (transversalis scapularis, or scapularis superior) passes along the root of the neck towards the scapula, giving off branches to the neighbouring muscles. The trunk passing through the notch in the superior costal of the scapula, takes the name of the suprascapular artery; it sends off many branches to the supraspinatus muscle, then descends under the acromion to the lower part of the scapula, where it communicates very largely and freely with the infra-scapular artery.

Observation. Sometimes the transverse artery of the shoulder is a branch of the superficial cervical artery. Sometimes it comes off as a distinct trunk from the axillary artery, and then the name of suprascapular is applied to the whole of it. In these cases the fourth branch of the thyro-ideal is small, and only reaches to the surface of the trapæzius, deltoid, &c.

The vertebral, which is an artery of great magnitude, arises from the upper part of the subclavian, behind the inferior cervical ganglion of the great sympathetic nerve; it ascends through the foramina of the vertebral processes of the cervical vertebrae, entering at the sixth, fifth, or fourth vertebra. In passing from the second to the first vertebra, it makes a great turn; then it again bends backwards along that groove of the atlas which is destined to receive it. Entering the skull at the foramen magnum, it ascends along the balaar process of the occiput, and under the medulla oblongata to meet the artery of the opposite side at an acute angle; by the union of the two trunks the balaar artery is formed. The vertebral artery, as it pases through the transverse processes, gives off some branches to the spinal marrow. While it is pasing through the occipital hole, it sends off the posterior meningeal artery, which supplies the dura mater on the occiput, and extends as far as the sinuoidal bone. The inferior artery of the cerebellum arises immediately before, or after the union of the vertebrae; it comes off near the origin of the par vagun and having distributed several branches to the inferior surface of the cerebellum, terminates in the fourth ventricle. The anterior and posterior spinal arteries are usually given off before the union of the vertebrae. They descend along the front and the back part of the medulla spinalis, and keep up their fine sinuosity to the bottom of it by means of frequent communications with branches from without. The balaar artery pases along the middle of the tuberculum annulare; its anterior margin, giving several small branches to its inferior surface. Then it divides into four branches, two for each side of the brain. The superior artery of the cerebellum bends round the crus cerebri, and is distributed to the upper part of the cerebellum; it also gives branches.
to the crust cerehi, thalam., tuberula quadrigemina, and pinal gland. The deep-seated artery of the brain is separated from the former branch by the nerve of the third pair. Ascending between the cerebellum and posterior lobe of the cerebrum, it sends off the communicating branch, which meeting and intercutting with a similar branch of the carotid, completes the circle of Willis. The root of the artery is distributed to the back of the brain.

The inferior intercostal artery goes off from the back of the subclavian, and descends over the heads of the first and second ribs. It gives small twigs to the esophagus; two branches to the spinal marrow; two others which penetrate to the muscles of the back; and two branches for the first and second intercostal spaces, which communicate with the inferior intercostal arteries.

These four branches are usually given off before the subclavian passes between the scaleni; the two following arise while it is passing, or immediately after it has passed.

The deep-seated cervical artery goes under the muscles of the neck, almost touching the vertebral. It is entirely distributed to the surrounding muscles, and reaches almost to the occiput.

The superficial cervical artery is hidden under the brachial nerves; its first branches go to the face nerves, and to the scaleni muscles; the root of the trunk goes to the muscles behind the neck, as the pectoris, complexus, trapezius, and levator scapula.

The artery, having left the scaleni muscles, recedes from the trunk of the body, and assumes the name of axillary; it bends obliquely downwards over the middle of the first and second ribs, and under the clavicle into the axilla. Emerging from under the clavicle, it is covered by the brachial nerves, by the axillary vein and glands; externally, it is protected by the pectoral muscles. It is situated in the axilla, between the pectoralis minor and subclavicular muscles; at the lower margin of the tendon of the latissimus dorsi, it changes its name for that of the humeral artery.

Branches of the Axillary Artery.

The first or upper thoracic artery arises near the upper margin of the pectoralis minor muscle, behind which it descends; its branches supply the serratus anterior, pectoral, and some of the intercostal muscles.

The long or second thoracic artery, which is sometimes a branch of the posterior circumflex, or infra-scapular arteries, passes also behind the pectoralis minor, far as the sixth rib. Its branches go to the axillary glands and mamma, also to the serratus, pectoralis minor, and intercostal muscles.

These two thoracic arteries incommunicate with the intercostals, and the internal mammary.

The thoracic artery of the shoulder (arteria thoracica humeraria) comes off near the second rib, and penetrating between the pectoralis major and deltoid, is distributed chiefly to the former muscle, and the neighbouring integuments.

The deep or fourth thoracic branch (arteria thoracica alaris), supplies the axillary glands, the pectoralis minor, and subcapularis.

Observation. The thoracic arteries are subject to considerable variety in number, size, and distribution.

The infra-scapular or subcapular artery, which is a very large trunk, comes off near the neck of the scapula. Its first branches go to the subcapularis, to the capsule of the shoulder joint, and to the muscles, which arise from the coracoid process. A very large muscular branch is distributed to the teres major and minor, the serratus, latissimus dorsi, subcapularis, &c. The principal part of the trunk turns over the inferior costa of the scapula, and ramifies on the dorso of the bone, supplying the infra-scapularis, and teres minor, and communicating with the suprascapular artery.

The posterior circumflex artery goes off between the teres major and subscapularis; it passes backwards between this, and under the long head of the triceps, and is reflected round the head of the humerus, being connected with the deltoid. Its branches go to the deltoid, and other muscles about the scapula, and communicate with the profunda humeri.

The anterior circumflex artery is a much more slender branch; it goes under the biceps and coracobrachialis, and terminates on the deltoid.

The brachial or humeral artery leaving the axilla, pursues its course along the middle of the biceps muscle; it passes over the brachialis internus, and advances gradually to the front of the arm. In this course the large median nerve lies in front of it. Arriving at the bend of the elbow, it runs under that production which the tendon of the biceps fends off to the falcia of the forearm, and is lodged deep in the hollow which is left between the two mallei of muscles on the forearm, where it divides into the radial and ulnar arteries. The median nerve still remains in front of the artery; the cephalic vein is situated considerableness on the outside of the artery; and the median vein crosses over it to join the cephalic.

Branches of the Brachial Artery.

Branches of little consequence go to the teres major, latissimus dorsi, triceps, coracobrachialis, biceps, and nerves of the arm.

The larger deep-seated artery of the shoulder (profunda humeri major or collateralis magna) arises high up in the arm, and is frequently given off by the inferior scapular, or posterior circumflex arteries. It ends backwards between the long and the external head of the triceps, giving many large branches to that muscle, and comes out at the back of the arm, where it divides into two branches; these communicate at the back of the elbow with the radial and ulnar recurrences.

The nutrient artery of the humerus comes off near the insertion of the coracobrachialis, and having distributed branches to the neighbouring muscles, enters the substance of the bone.

The smaller deep-seated branch, or branches, go to the outside of the brachialis internus, supinator radii longus, extensor carpi radiales, &c. and communicate with the recurrences of the fore-arm.

The great anastomosing branch (ramus anastomoticus magnus) comes off from the inside of the trunk, within a short distance of the joint, and proceeds towards the inner condyle; its branches communicate above with the profunda, below with the recurrences.

The two last-mentioned branches, with one or two more which descend along the triceps to communicate with the arteries of the fore-arm, are sometimes described under the name of collateralis minores.

The radial artery, which is smaller than the ulnar, seems to be given off as a branch from the ulnar; it passes along the surface of the pronator teres, and then goes on the inside of the supinator longus to the wrist. It bends under the extensor tendons of the thumb, and penetrates the abductor indicis to arrive in the palm of the hand. Here it passes along the heads of the metacarpal bones, and having formed the arcus profundus volae, communicates on the opposite side of the hand with a large branch of the ulnar.

Branches
Branches of the Radial Artery.

The recurrent branch of the radial artery is reflected towards the outer condyle, between the brachialis internus, and the radial extensors of the carpus; there it has numerous communications with the collateral arteries of the arm.

The superficial artery of the palm of the hand is given off just as the trunk begins to turn over the radius; it goes over the abductor pollicis, or through its fibres, to communicate with the ulnar, and thereby complete the superficial arch. This branch varies much in size; sometimes it is very small, and does not reach to the ulnar artery; sometimes it is so large, as to give off the branch to the outside of the thumb; or even to both sides of the thumb.

At the back of the hand, the radial gives off an artery or two to the back of the thumb, another to the back of the fore-finger, and a third to the back of the carpus (dorsalis carpi), which communicates with the interosseal, and sends small branches between the metacarpal bones.

After the radial artery has entered the palm of the hand, it sends off the great artery of the thumb, which runs along the side of the first phalanx of the thumb, and then divides into three branches. Two of these are for the two sides of the thumb, and the third for the radial side of the forefinger. The branches of the deep-seated arch are small, and supply the interosseous muscles, and come out at the back of the wrist and hand.

The ulnar artery goes under the pronator teres, flexor carpi radialis, flexor digitorum sublimis, and palmaris longus, and passes within the edge of the flexor carpi ulnaris to the wrist. There it is situated just within the pisiform bone, bends across the palm of the hand, over the flexor tendons, as to form the superficial arch of the palm of the hand, which is situated under the palmar fascia, and opposite to the middle of the metacarpal bones. It terminates at the opposite side of the palm by communicating with the superficial branch of the radial artery.

Branches of the Ulnar Artery.

The recurrent branch of the ulnar goes under the flexor muscles to the back of the inner condyle, where it communicates freely with the collateral arteries of the arm.

The interosseous artery comes off very soon from the ulnar; it immediately finds a large branch through the interosseous ligament to the back of the forearm; this branch gives off the interosseous recurrent, and then passes down the forearm to the wrist, supplying the extensor muscles. The trunk of the interosseous artery descends along the ligament to the pronator quadratus; there it perforates the interosseous ligament, and communicates with the other branch of the interosseous artery and with the dorsal branches of the radial and ulnar arteries.

An artery to the back of the hand (dorsalis manus), communicates with the interosseous artery.

The deep palmar branch goes off just below the pisiform bone; it passes under the flexor tendons, and communicating with the radial artery, completes the deep palmar arch.

The convex part of the superficial arch then produces three large digital arteries, which, passing between the metacarpal bones, and arriving at the root of the fingers, divide each into two branches, which go along the side of the fingers to their very apex, where they communicate.

Observation. The arteries of the forearm are subject to great varieties. The brachial sometimes divides long before it arrives at the elbow, even as high as the axilla, in some subjects. Then the course of these arteries is natural in other respects. Sometimes, however, where this high division takes place, the ulnar artery, instead of going under the muscules, which have been mentioned, goes over them and just under the skin. Sometimes the radial, ulnar, and interosseous arteries proceed straight into the palm of the hand, and are distributed to the fingers without forming any arches at all.

The aorta having formed its arch, passes gradually behind the lungs to the left side of the bodies of the vertebrae. It descends in a straight course along the back of the posterior mediastinum until it arrives at, and passes through, the crura of the diaphragm; this portion of the vessel is termed the thoracic aorta.

Branches of the Thoracic Aorta.

The common bronchial artery comes off high up from the front of the aorta; it divides into two branches, one for either lung.

The right and left bronchial arteries arise lower down; and often there is a fourth or inferior bronchial artery.

These arteries are destined for the nourishment of the substance of the lungs: they supply also the bronchial glands, and the roots of the great vessels, which come off from the heart. They are remarkable on account of their communications with the pulmonary artery.

The oesophageal arteries are about five or six in number; they run upon the surface of the oesophagus, and communicate below with the coronary artery of the stomach.

The lower intercostal arteries are nine or ten in number, according to the number of ribs, which are unfurnished by the intercostal branch of the subclavian artery. They arise from the back of the aorta, and follow the course of the lower or grooved edge of the ribs. The upper ones are the smallest, and ascend somewhat; the lower ones are nearly transfered in their course. The arteries of the right side are longer, as they have to pass over the bodies of the vertebrae. They all give off: 1. a branch which enters into the spinal marrow as the nerves pass out; 2. a larger branch, which goes to the muscles at the back of the spine; 3. an upper branch which coming off at the angle of the rib goes along the upper edge of the rib below. The continuation of the trunk communicates with the mammary and thoracic arteries above; with the epigastrium and lumbar arteries below.

The aorta, having passed through the crura of the diaphragm, takes the name of the abdominal aorta. It is still situated on the left side of the bodies of the vertebrae; it is separated from the vena cava by the left lobe of the liver and the crus of the diaphragm. It approaches gradually to the middle of the vertebral, and gets in company with the vena cava, a little above the kidneys. At the last lumbar vertebra, or at the arch between the fourth and fifth, it divides into the two common iliac arteries.

Branches of the Abdominal Aorta.

The right and left phrenic arteries are the first branches of the abdominal aorta; sometimes they arise from the iliac artery; sometimes a single trunk, either from the aorta, or from the celiac, produces both the right and left phrenic arteries; they cross over the crura of the diaphragm, and then bend round the central tendon, sending off branches to the fibres of the diaphragm in all directions: they give branches to the renal capsule and fat of the kidney.

The celiac is a large short trunk, coming off from the front of the aorta, while it is still between the crura of the diaphragm. It is surrounded by the lesser arch of the stomach; beneath it is the pancreas, and on the left side the lobulus Spigelii. After a course of a few lines, it divides into three branches; the coronary artery of the stomach, the hepatic, and the splenic arteries.

The coronary artery of the stomach is the central branch of the celiac; it mounts upwards towards the oesophagus, feeds
The renal or emulgent artery arises from the side of the aorta, between the superior and inferior mesenteric arteries. The left renal artery passes over the vein near the kidney; the right renal artery goes under the vena cava, and is covered by its corresponding vein. The artery divides into three or four branches, which enter at the notch of the kidney. The renal artery gives branches to the renal capsules to the fat of the kidney, and to the ureter.

The spermatic artery is a long slender vessel, arising from the front of the aorta. On the left side it frequently comes from the renal artery; it pursues a tortuous course, and gets into company with its vein upon the psoas muscle. In men, it goes through the abdominal ring at the back of the chord, and supplies the testes. It sends off branches to the fat of the kidney, and to the ureter.

The spermatic artery of females passes along the ligament of the uterus to the ovary. Its posterior branches supply the ovary; its anterior ones pass on with the Fallopian tube to the uterus, where it communicates with the uterine arteries.

The inferior mesenteric artery comes off low down from the left side of the aorta. It descends a little on the left side of the two bodies of the vertebrae, and sends off the left colic artery. This supplies the descending colon, and by communicating with the middle colic artery, forms the famous mesenteric arch. The continuation of the trunk under the name of the internal hemorrhoidal artery goes along the back of the rectum; its branches reach almost to the extremity of that intestine, and communicate with the middle and external hemorrhoidal arteries.

As the arteries of the renal capsule vary much in size and number, they may be divided into three classes: the upper capular arteries are branches of the phrenic; the middle ones generally arise from the side of the aorta, between the celiac and mesenteric arteries; the lower ones are from the renal arteries.

The adipous arteries are those which supply the renal fat; they arise above from the capular arteries; below from the renal and spermatic arteries, and from the aorta.

The ureteric are also derived from various sources: the upper ones are from the renal and spermatic arteries; the middle from the aorta or common iliac artery; and the lower ones from one of the vesical arteries.

The lumbar arteries are five in number, arising from the back of the aorta, at the intervals of the vertebrae, as the intercostal arteries do in the chest. They supply the muscles in the circumference of the body; they give branches to the spinal marrow, and others which penetrate to the muscles of the back; the last lumbar artery communicates with the ilolumbar artery.

The common iliac artery of the right side passes over the lower part of the vena cava; on the left side, it is situated exteriorly with respect to its vein; it supplies obliquely downwards and outwards, and divides over the sacro-ilac symphysis into the internal iliac, or hypogastric, and the external iliac arteries.

The middle faceral artery usually arises from the point of bifurcation of the aorta; it descends along the middle of the facrum to the coccyx, and communicates on both sides with the lateral faceral arteries.

The lateral iliac artery descends immediately into the pelvis. In the adult it is of the same size as the external artery, but in the fetus it is four or five times larger; and after having descended into the pelvis, becomes attached to the side of the bladder, and rises again to reach the umbilicus, under the name of the hypogastric artery. At this period, the arteries of the pelvis are small branches coming...
ART

coming from the lower or convex part of the hypogastric. Where the artery approaches the bladder in the adult, it is converted into a fibrous substance, which still remains perversus to a certain extent.

Branches of the Internal Iliac Artery.

The iliohumburary ascends between the psoas magnus and iliacus internus, towards the ecrura of the ilium. Its branches are distributed to the neighbouring muscles, and communicate with the lumbal branch artery.

The lateral facial arteries vary in number from one to three, four, or even five. They descend on the side of the salival, communicate with the middle facial artery, and send branches through the facial hole of the cuuda equina. The vesical arteries are three or four in number, arising from that part of the hypogastric which still remains perversus, as it approaches the bladder. One or more of these, which goes to the bottom of the bladder, and gives branches to the vesical rami, prolate, &c. in men, to the rectum and vagina in women, is distinguished by the name of the lower vesical artery.

The middle hemorrhoidal artery comes off between the pudendal and gluteal branches, passes along the front of the rectum, and communicates with the external arteries. It sends branches to the bottom of the bladder, &c. in men; and a large one (which sometimes comes off distinctly from the internal iliac) to the vagina in women.

The uterine artery comes off near the former; it sends a branch down to the vagina, then ascends along the side of the uterus, on which it communicates with the uterine artery.

The obturator artery, which frequently arises from the epigastric, passes along the side of the pelvis, at the upper edge of the obturator internus, accompanied by the nerve and vein of the same name, and goes through the passage which is left for it at the upper part of the thigh hole. Having quit the pelvis, it divides into an external and an internal branch, which are distributed to the obturator muscles, to the capsule of the hip, and to the origin of the triceps. They communicate with the internal circumflex branch of the profunda femoris.

The glutus or posteriil iliac artery is the largest branch of the internal iliac. It arises from the back part of the trunk, bends downwards and backwards, and quits the pelvis at the upper margin of the pyriformis muscle. It sends a large branch between the glutus maximus and medius. Another branch, more deeply seated, goes under the glutus medius, and sends an artery close to the dorsum of the ilium at the origin of the glutus minimus.

The ileohiumatic artery goes out of the pelvis at the lower margin of the pyriform muscle, together with the great ileohiumatic nerve; it is here covered by the glutus maximus, and descends towards the thigh; it sends off a coccygeal branch, which turns back between the fascio-ileohiumatic ligaments towards the coccyx. The other branches of this artery are distributed to the glutus maximus, and other muscles at the back of the thigh, and are remarkable on account of their numerous communications with the circumflex branches of the profunda.

The pudendal artery goes out of the pelvis, in company with the ileohiumatic; it is smaller, and situated farther from the facrum; it merely passes over the great fascio-ileohiumatic ligament, and enters the pelvis again at the small ileohiumatic hole. Then it goes along the inside of the tuberity and ramus of the ileum. It sometimes sends off small branches before it quits the pelvis to the rectum, prolate, &c. While it is passing over the fascio-ileohiumatic ligament, and the tuberity of the ileum, it gives off branches which communicate with the circumflex arteries; and the external hemorrhoidal arteries to the fat of the perineum, sphincter ani, &c. which communicate with the middle and internal hemorrhoidal arteries. At the ramus of the ileum the artery divides into, 1. The perineal artery, which ascends between the accelerator urinæ and erector muscles, and supplies the muscles, skin, and fat of the perineum. 2. The artery of the penis, which is the continuation of the trunk. At the lymphatics of the pubis it divides into, 1. The dorsal artery of the penis, which runs along the back of that organ as far as the glans, the root of which it encircles. 2. The deep-seated artery of the penis, which enters the corpus cavernosum of its own side, into the cells of which it opens, and gives branches to the spongy substance of the urethra. The vesicle, which is analogous to the artery of the penis of males, is termed the clitoridea in females. Its distribution to the clitoris is the same as that of the above-mentioned artery to the penis.

Observe. The branches of the internal iliac artery are constant in their definition, but vary much in the order and manner of their origin.

The external iliac artery passes along the inner edge of the psoas muscle, being situated on the outside of its vein. It is surrounded by the lymphatic vessels, which come up from the lower extremity, and by the glands, through which they pass. It descends under Poupart's ligament, still keeping to the inner edge of the psoas muscle, and there it takes the name of the femoral artery. Here the vein lies close on the inside of it, and the anterior crural nerve is situated on the outside, but at some distance from the artery.

Branches of the External Iliac Artery.

The epigastric artery arises from the inner side of the trunk, near Poupart's ligament; frequently indeed its origin is absolutely below the ligament. It is reflected upwards and inwards behind the spermatic chord; then crossing the upper part of the abdominal ring, it gets behind the rectus muscle, and ascends to the navel. The epigastric artery generally sends a pretty large branch down the spermatic chord, which communicates with the spermatic artery. The other branches of this artery are merely muscular ones; the trunk communicates at the upper part of the rectus abdominis with the internal mammary artery.

The circumflex artery of the ilium arises opposite to the epigastric; it turns back, and runs along the crista iliæ, between the attachments of the obliquus internus and transversalis abdominis muscles, as far as the back of the bone, where it communicates with the lumbar and iliohumburary arteries. Its branches are distributed to the neighbouring muscles.

The femoral artery is surrounded below Poupart's ligament by the inguinal glands, and much fat. After a course of an inch and a half to two inches, it divides into two branches of nearly equal magnitude. The branch which continues in the direction of the trunk retains the name of the femoral artery; while the other, which descends amongst the muscles of the thigh, is named the deep-seated artery of the thigh (arteria profunda femoris). The common trunk sends off some trivial branches to the integuments, lymphatic glands, and neighbouring muscles; two or three larger branches supply the skin and fat of the pudendal.

The profunda comes off from the back of the femoral artery; it passes backwards, and descends for a short space, then gets between the heads of the triceps muscle, and sends its branches through that muscle.

Branches of the Profunda.

The external circumflex artery, which is the first branch of the profunda, goes under the fariiures and rectus musc. etc.
cles, towards the root of the great trochanter. It sends off in its course numerous branches to the muscles along which it passes. Some of its branches communicate with the internal circumflex and perforating arteries at the back of the thigh. A large branch descends along the inside of the vastus intermus to the knee, and communicates with the superior articular, and with the great anatomic branches.

The internal circumflex artery comes from the opposite part of the trunk. It goes backward to the trochanter minor, and turning round the bone, appears between the quadratus femoris and triceps muscles. Its branches are distributed to the muscles on all sides; they communicate with the obturator, iliatic, and gluteal arteries.

The two perforating branches of the profunda (the second is the continuation of the trunk) pierce the triceps muscle, to which they give branches, and are distributed to the flexors of the leg. They communicate above with the circumflex arteries, and below with the articular arteries. The inferior perforating branch gives off the great nutrion artery of the thigh-bone.

The femoral artery passes from the front of the thigh gradually towards the ankle. It is at first covered by the lymphatic glands, then it goes under the fariorius, rectus, and arrives at the tendon of the triceps, through which it passes into the ham, and takes the name of the popliteal artery. During this course, the femoral artery sends off small branches to the glands, to the fariorius, rectus, and other muscles. The great anasomosing branch comes off as the trunk enters the tendon of the triceps muscle; it plunges into the substance of the vastus internus, from which it emerges at the knee to communicate with the articular arteries, and also with the descending branch of the external circumflex. Two branches go through the tendon of the triceps to the muscles at the back of the thigh; they are called by Murray the superior and inferior perforating branches of the femoral. They communicate with the perforating branches of the profunda.

The popliteal artery passes from the tendon of the triceps through the middle of that space which is termed the ham, and arrives at the upper extremity of the soleus muscle, where it divides into the anterior and posterior tibial arteries. In this course it lies between the flexor muscles, and almost close to the bone. It descends between the condyles of the thigh-bone and the heads of the gastrocnemius, in the contact with the capsule of the knee. It gives off small muscular branches to the flexor muscles, and other larger ones to the gastrocnemius and soleus. The articular branches of the popliteal are five in number: three of them come off above the joint, and are therefore called the superior articular arteries, the middle of these three is distributed to the back of the capsule; the other two bend round the former just above the external and internal condyles. The inferior articular arteries are two in number, one for the infide, the other for the outside of the joint. The four last-mentioned branches arrive in front of the knee, where they form a vascular net-work by their numerous communications with each other, and with the recurrent branch of the anterior tibial, the anasomosing branch of the femoral, and the descending branch of the external circumflex.

The anterior tibial artery comes off at the lower margin of the popliteal muscle, and immediately penetrates the interosseous ligament. It descends in the front of this ligament between the tibia and the extensor pollicis longus, becoming more and more superficial as it approaches the ankle. It pierces under the transverse ligament of the ankle in company with the extensor tendons, then goes between the extensor pollicis longus and the extensor digitorum pedis longus to the root of the first metatarsal bone, where it plunges into the sole of the foot, and terminates by a large communication with the external plantar artery.

**Branches of the Anterior Tibial Artery.**

The recurrent branch is given off immediately after the trunk has passed through the interosseous ligament. It goes through the tibialis anticus muscle to the front of the knees, where it communicates with the articular arteries.

Small muscular branches arise throughout the whole course of the artery along the leg.

The external and internal malleolar arteries supply the ankle joint and neighbouring part of the tarsi. The external malleolar artery communicates with both the anterior and posterior branches of the peroneal artery. The tarsal artery goes under the extensor digitorum brevis along the second phalanx of the toes. It gives small branches to the ankle-joint, external brevis, &c. It also sends off three arteries, which run along the intervals of the metatarsal bones to the roots of the toes, where they join the digit arteries at the point of bifurcation.

The metatarsal artery runs along the heads of the metatarsal bones, and varies in size according to the magnitude of the tarsal artery. Sometimes it is large, and produces all the branches which have been described as coming from the tarsal artery.

The artery of the back of the great toe comes off just before the anterior tibial descends into the sole of the foot; it runs between the first and second metatarsal bones, and is distributed to the back of the great toe and of the second toe.

The posterior tibial artery is situated under the soleus muscle, and between the flexor communis digitorum and the tibialis posterior. It descends to the lower extremity of the tibia in this situation; then becoming more superficial, it bends behind the inner ankle, and enters the sole of the foot between the abductor pollicis pedis and the concave surface of the os calcis; here it divides into the external and internal plantar arteries.

**Branches of the Posterior Tibial Artery.**

Large muscular branches to the soleus.

The nutritive artery of the tibia.

The peroneal or fibular artery, which varies much in size, descends between the tibialis posterior and flexor longus pollicis, giving branches to those muscles in its passage to the bottom of the leg, where it divides into an anterior and a posterior branch. The posterior branch descends in the direction of the trunk to the outside of the os calcis, where it communicates with the external plantar and external malleolar arteries. The anterior branch comes through the lower part of the interosseous ligament, and advancing to the ankle, communicates with the external malleolar artery.

Branches throughout the course of this artery to the neighbouring muscles.

Two large branches to the bottom of the os calcis.

The external plantar artery is the largest branch of the posterior tibial; it runs along the inside of the abductor minimi digitii till it reaches the fifth metatarsal bone; there it bends inwards to the first metatarsal bone, where it communicates with the tibialis anticus, and forms the plantar arch. This artery sends off many branches to the adjacent muscles, and to the bones of the tarsi. The convexity of the arch gives off four arteries, which pass between the metatarsal bones to the roots of the toes, where each of them divides into two; these are distributed along the sides of the toes. The arch also sends off three or four branches, which penetrate to the back of the foot.

The internal plantar artery keeps along the inside of the foot in the direction of the abductor pollicis; it terminates by
by communicating with those branches of the external plantar which supply the great toe.

**ARTHA** wounded. See **AURISMA**.

**ARTHA**, in **Geography**, a river of South Wales, which runs into the sea about ten miles south of Aberystwyth in Cardiganshire.

**ARTHEDON**, in **Ancient Geography**, an island of Asia Minor, upon the borders of the Troade. Pliny.

**ARThEL**, something cast into a court, in Wales, or its marches; whereby the court is letted or discontinued for the time. The calling of arthel is prohibited by 26 Hen. VIII. cap. 6.

Arthel is a British word, more correctly written **Ardeilw**, or **Arwithe**; and signifies to avouch; as if a man were taken with stolen goods in his hand, he was to be allowed a lawful arthel, or voucher, to clear him of the felony. This was part of the law of Hovel Dha, according to whose laws, every tenant, holding of any other than the prince, or the lord of the fee, paid a fine "pro defenso regis," which was called orion arthel.

**ARTHEMIS**, in **Zoology**, a genus of worms in the *Molusca* tribe established by Poli in his work on the shells of the two Sicilies. See **VERMES**.

**ARThES**, in **Geography**, a town of France, in the department of the lower Pyrenees, and chief place of a canton in the district of Orthes, five leagues north-west of Pau.

**ARTHRITICA**, in the *Materia Medica*, medicines fitted to cure the diseases of the joints, particularly the gout; but the term is so vague and of so indeterminate a meaning as to be altogether improper.

**ARTHRITIS**, formed from *ypos*, articulus, joint, in *Medicines*, a disease better known under the name of *gout*.

**ARTHROCACE, in Surgery**, a disease of the joints, or the extremities of bones, more commonly named *Spina Ventosa*, which fea. When this disorder afflicts children, it is called *Pedaarthrocace*. We do not recollect any author to have distinctly treated of this complaint before Rhaezes the Arabian physician, who has entered at large into the consideration of diseased joints.

**ARTHRODIA**, formed from *ypos*, articulus, and *ygos*, *recipio, I receive*, in *Anatomy*, a species of articulation, admitting of a very small degree of motion; as each bone composing the joint must have nearly a plain surface. Such is the articulation of the humerus with the scapula. See **Articulation**.

**ARTHRODYNA, in Surgery**, is a chronic rheumatic affection of the joints. This name was first imposed by Dr. Cullen, in his Synopsis Noologica Medicinae. See **Rheumatorr and White Swelling**.

**ARTHROPUSIS**, is a suppuration of the joints, or at least a strong tendency to form pus. In this case there is a deep-seated inflammation, obituously painful, sometimes throbbing, and frequently attended with feverish symptoms. The treatment is described under the articles, *Abscess, Spina Ventosa, White Swelling, Inflammation, and Rheumatism*.

**ARTHROSIS**, formed from *ypos*, articulus, in *Anatomy*, a juncture of two bones designed for motion; called also articulation.

**ARTHUR**, in *Biography* and *History*, the most remarkable name among the Britons. As a hero and a confammate warrior, he appears illustrious in our history; but as a being of romance, his splendor has dazzled the world. It has been generally inferred that the great achievements of this hero created those illitory actions and scenes depicted in the *Mabinogion*, or *Juvenile Tales*; and some authors, with such phantoms playing before their eyes, have denied existence to such a person altogether. But that there was a prince of this name, who often led the Britons successfully to battle against the Saxons, in the commencement of the sixth century, there ought not to be any doubts; for he is mentioned by contemporary writers, whose works are full extant; namely, Lllywarch, Merzin, and Taliesin; and he is likewise often recorded in the *Triads*, which are documents worthy of credit; but neither by these poets, nor in the *Triads*, is he in any respect exalted to that rank in which the world now beholds his name, nor extolled above other princes who held similar stations in the country.

About the year 516, or 517, Arthur was elected by the flates of Britain to exercise sovereign authority, as other princes had been chosen, in dangerous times; and he obtained that pre-eminence in consequence of his superior abilities and bravery, being until that time only a chieftain of the Silurian Britons. He continued to present a successful opposition to the increasing power of the Saxons, until a fatal disunion broke out between him and Medrod; a radical evil among the Britons, in consequence of their being divided into many small states; and which, about the year 540, kindled into a civil war; and Medrod joined his power with the Saxons, which ultimately produced the battle of Camlann, equally fatal to the British and the Saxon fides, and which brought diifurse ruin on the Britons.

Such was the career of Arthur, as exhibited by the bard and the *Triads*. The hero under the same name in the dramatic cases called *Mabinogion*, is totally of different features, and in fact is a distinct peripage altogether. The list is then a mythological character of times to remote as to be far beyond the scope of history; his attributes in the dramatic cases before mentioned point him out as such. Memorials of this being, and of several others connected with him, have been traditionally preferred in various and very distant parts of the world; and if we willake not, their memorials are written in the heavens, and some of the constellations bear their name. Arthur is the Great Bear, as the epithet literally implies; and perhaps this constellation being situated so near the north pole, and visibly describing a circle in a small space of the heavens, is the true origin of the famous round table.

By confounding the Arthur of history with that of mythology, the chroniclers of the middle ages have committed a monstrous anachronism; and thus have blended the real feats of the former with the allegorical attributes of the other; and this confusion is still increased by all the succeeding writers of romance.

There are some very extraordinary things related concerning the mythological Arthur, in the *Mabinogion*, and particularly in the story of the pursuit of Olwen; wherein we recognise the Indian Menu, exactly by name, and with similar attributes, acting as one of the agents of Arthur, to recover Olwen, the representative of the fecundity of nature.

To the above rational and credible account, for which the editor is indebted to an ingenious writer, it may not be improper to subjoin, for the gratification of the curious reader, some other particulars, transmitted by Geoffrey of Monmouth, and other histiorians, of more doubtful authenticity.

From them we learn, that Arthur was the son of Uther, the pendragon or dictator of the Britons, by an adulterous connection with Igerma, wife of Gurlois duke of Cornwall, favoured by the aid of Merlin's magical skill. Upon the death of Uther, in 516, Arthur, at the age of 15, or according
according to Buchanan, 18, years, ascended the throne. With a
competent army, which his extraordinary fame enabled
him speedily to raise, he routed Colgrim, the Saxon duke,
and all his forces, consisting of Saxons, Scots, and Picts,
who were committing horrid devastations in Britain. Hav-
ing pursued him to York, he was obliged, in consequeuce of
the favour accorded to Colgrim by Corde, king of the
Saxons, to raise the siege and to march to London. Afflicted
by the loss of his troops, persuaded by Jutacan, king of
Armenia or Britain, he marched to Lincoln, which
was besieged by the Saxons, whom he defeated; and be
then compelled the survivors to surrender, on condition of
being allowed to leave the kingdom. These men, after
having embarked, repented, and relapsed on the western
coast; and proceeding to lay siege to Bedou, or Bath,
Arthur was obliged to decline his intended pursuit of
the Scots and Picts, and to make forced marches for the
relief of the city. After a very obilinate and severe engagement,
which lasted two days, Arthur, having performed extra-
ordinary feats of valour, took their camp, and fled Colgrim,
and another of the principal leaders. He then hastily
returned to relieve his nephew Hoel, who was invested by the
Scots and Picts at Dumbriton in Scotland. Having
succeeded in this enterprise, he directed his course to York;
where he is said to have established the Christian worship
on the ruins of the Pagans, and to have married a lady called
Guanhumara, who, under the name of Guenever, became
the subject of various metrical romances. Fabulous history
reports, that he invaded and subdued Ireland, Iceland,
Gotland, and the Orkneys; and having finished these
exploits, governed his kingdom for 12 years with undis-
turbed tranquillity, and very extraordinary splendour.
At this time he instituted his famous order of knights of the
round table. Having also, as Fabre relates, conquered Nor-
way and Denmark, invaded France, and taken Paris, and in
nine years made himself master of the whole kingdom, the
provinces of which he distributed among his domestics, he
returned, and held a grand assembly of his tributary kings
and nobles at Caerleon in Monmouthshire, where he was
solemnly crowned. Whilk he was afterwards pursuing his
conquests, and marching for Rome, his nephew, Modred,
who in his absence had prevailed on his queen, Guanhumara,
to marry him, set up the standard of revolt, and called in to
his assistance the Saxons and other barbarians. Arthur
hastily returned, and three battles were fought between him
and Modred; in the last of which, Arthur, though vic-
torious, received so many wounds, that, retiring to the ile
of Avalon, he died, A.D. 542, and was buried in that
place. "Every nation," says Gibbon (Hist. vol. vi. p. 592.),
embraced and adorned the popular romance of Arthur and
the knights of the round table; their names were celebrated
in Greece and Italy."—"At length the light of science and
reason was rekindled; the talisman was broken; the vision-
ary fabric melted into air; and by a natural, though un\jut re\ere of the public opinion, the effe\ency of the present
age is inclined to question the existence of Arthur." Mr.
Whitaker (Hist. Manchester, vol. ii. p. 31-71.) has
framed an interesting, and even probable narrative of the
wars of Arthur; though it is impossible to allow the reality
of the round table. He supposes him to have been the
Artur, great man, or sovereign of the Silures, and to have
fought under the auspices of Ambrosius, the
pedragon of the Britons, who sent him to the relief of
the northern Britons, oppressed by the Saxons. After
great successes in those parts, he fought his twelfth battle
in the south of England, after he was elected to the pen-
dragonship against Cerdic the Saxon. Mr. W. believes in
the reality of his institution of a military order, the origin
of all others of a like kind on the continent of Europe.
He speaks in high terms of the glory of his reign, at length
futally terminated by the civil wars, which put an end to the

ARTICLE, or "Steward Bay," in Geography, lies on the
cost of New Jersey, in America, and is formed by the union
of Passaic and Hackensack rivers. ARTICLE v., in Articul.
ARTICENA, a country of Asia, which made part of the
kingdom of Parthia. PROEMY. ARTICHOKE, in Botany. See CYNARA.
ARTICHOKE, at Rufulum. See HELIANTHUS.
ARTICLE, Articulus, a little part or division of a
book, writing, or the like.

This form is also applied to the several clauses or condi-
tion of a contract, treaty of peace, or the like.

In this sense we say, articles of marriage, articles of capi-
tulation, preliminary articles, &c.

Articles of the clergy, Articuli clerici, are certain
flatures touching persons and causes ecclesiastical, made
under Edward II. and III.

The statute made in the reign of Edw. II. A.D. 1316,
was made for terminating the disputes between the temporal
and spiritual courts, about the limits of their respective jurisdic-
tion. As this statute was procured by the clergy at a
time when their influence was much needed, it was very
favourable to their flamable and exorbitant claims of exempt-
ion from civil authority. By the last chapter it is granted,
that when clerks confess before temporal judges their heinous
offences, as thefts, robbery, and murder, they cannot be
judged or condemned by those temporal judges upon their
own confession, without violating the privilege of the church;
and that the privilege of the church being demanded in
due form by the ordinary, shall not be denied. This statute
was actually pleaded, and admitted in favour of a bishop of
Hereford, A.D. 1324, under accusation of high treason.
The statue de clero, 25 Edw. III. 3. c. 4. provided, that
clerks convicr for treasons or felonies touching other per-
sons than the king himself, or his royal majesty, should have
the privilege of holy church.

Article of faith is by some defined a point of Christian
doctrine, which we are obliged to believe, as having been
revealed by God himself, and allowed and established as such
by the church.

The thirty-nine articles of the church of England
were founded, for the most part, upon a body of articles compiled
and published in the reign of Edward VI.

The articles of king Edward were 42 in number, and
framed by archbishop Cranmer and bishop Ridley; and after
having been submitted to the correction and amend-
ment of the other bishops and learned divines, they were re-
viewed by the archbishop, and then presented to the coun-
cll, where they received the royal sanction. These articles,
though not brought into parliament, nor agreed upon in
convocation, as the title seems to express, and as they ought
to have been, were announced as "Articles agreed upon by
the bishops, and other learned men in the convocation held
at London, in the year 1552, for the avoiding diversity of
opinions, and establishing consistent touching true religion."
In the reign of queen Elizabeth, they were reviewed by the
convocation, and the 42 articles were reduced to the presen-
t; the following articles were omitted: viz. Art. 30.
"The resurrection of the dead is not past already."
Art. 40. "The souls of men deceas'd do neither partake
with their bodies, nor sleep idly."
Art. 41. "Of the Millen-
Millenarians," Art. 42. "All men not to be saved at
first," one of the other articles underwent a new division,
two being joined into one, and in other parts one is divided
into two; but without any remarkable variation of doctrine.
It has been a subject of dispute, whether the first clause
of the 20th article, viz. "The church has power to decree
rites and ceremonies, and authority in controversies of
faith," was a part of the article which passed the synod
and was afterwards confirmed by parliament in 1571. It is
certain it did not make a part of king Edward's articles,
nor is it in the original MS. of the articles subscribed by
both houses of parliament with their own hands, and
preferved in Bennet college library. The dispute, however,
is of little consequence to the present subscribers, as this
clause made a part of the article confirmed by parliament in
1562. These articles, having passed the convocation, Jan.
31, 1562, were subscribed immediately by most of the
members of both houses of convocation; but they did not
pass into a law, and become a part of the establishment, till
five years after this time. In the year 1571, an act
was passed, confirming all the doctrinal articles agreed upon
in the synod of 1562; and enjoining subscription on all persons
ordained to be deacons or priests, and on all who held any
eclesiastical livings, as well as licensed preachers and curates.
13 Eliz. c. 12. It has been said (Neal's Hist. Puritans,
vol. i. p. 179, 410), that this act established only the doc-
trinal articles; too, as they are expressed, "which only
concern the confession of the true faith, and the doctrine
of the sacraments," and, therefore, that the articles of the
church, which relate to its discipline, were not designed to
be the terms of ministerial conformity. These articles were
ratified by parliament at the restoration of Charles II., in
1662; and subscription to them enjoined on the heads of
colleges, chancellors, officiols, and commissaries, and also on
schoolmasters, 13 and 14 Car. II. c. 4.

By 1 W. & M. H. 1. c. 18, commonly called the tolera-
tion act, diffenting teachers are to subscribe all these articles,
except the 34th, 35th and 36th, and part of the 20th; and
in the case of anabaptists, except also part of the 27th; or,
if they scruple subscribing the same, they shall make and
subscribe the declaration preferred by lat. 19 Geo. III.
c. 44. professing themselves to be Christians and believers,
and that they believe the scriptures to contain the revealed
will of God, and to be the rule of doctrine and practice;
otherwise they are exempted from the benefits of the act of
toleration. Diffenting schoolmasters are excluded from sub-
scription to the articles by the same act. See TOLERA-
tION.

Concerning these articles, very different opinions have
been entertained by those who subscribe them; and they
have also differed in their sentiments and views with regard
to the nature and extent of subscription. Some have inter-
preted them more laxly, and others more rigidly; and they
have not been agreed as to the strictness or latitude with
which they may be subscribed. For the reasons that have
been urged in favour of subscription, and against it, and the
manner in which it has been interpreted and understood,
see Subscription.

Articles, Lambeth, were nine articles on the subject
of predestination, perseverance, and the limitation of saving
grace, drawn up by archbishop Whitgift and other learned
divines, subscribed by them, and enjoined on the students
of the university of Cambridge, in consequence of a com-
plaint occasioned by a debate in that university, which
commenced with a sermon of a Mr. Barret, who attacked
the believers of predestination with great fervor. The
private, in his letter to the university, represents them not
as new decrees, but as an explication of certain points,
"corresponding to the doctrine professed by the church
of England, and already established by the laws of the
land." But as they had not the queen's sanction, who,
however, is said to have been fully persuaded of their truth,
he desired that they might not become a "public act," but
used privately and with discretion.

Articles, Statute of the six, or bloody statute, was an act
for abolishing diversity of opinion in certain articles con-
cerning the Christian religion; 31 Hen. VIII. c. 14. By this law,
the doctrine of the real presence, the communion in one
kind, the perpetual obligation of vows of chastity, the utility
of private masses, the celibacy of the clergy, and the necessity
of auricular confession, were established. The denial of the first
article subjected the person to death by fire, and to the
same forfeiture as in cases of treason; and admitted not
the privilege of abjuring; a severity unknown to the
inquisition itself. The denial of any other of the five arti-
cles, even though recanted, was punishable by the forfeiture
of goods and chattels, and imprisonment during the king's
pleasure; an oblation adherence to error, or a relapse, was
judged to be felony, and punishable with death. The
marriage of priests was subjected to the same punishment; their
commerce with women was, on the first offence, a forfeiture
and imprisonment, on the second, death. The abstaining
from confession, and from receiving the eucharist at the
accustomed times, subjected the person to fine and imprison-
ment during the king's pleasure; and if the criminal per-
ished after conviction, he was punished by death and for-
sue, as in cases of felony. The rigour of these articles
was somewhat abated by the 35th Hen. VIII. c. 5, in con-
sequence of the interference of Cranmer. By this statute
persons were not to be convicted but upon the oaths of 12
men; the prosecution was required to be within a year;
and a person who protested against them, was to be informed
against within 40 days. Nevertheless several were burnt at
this time for denying the doctrine of transubstantiation. Upon
the accession of Edw. VI. the statute of the six articles
was repealed.

Articles of War, in Military Language, denote certain
regulations for the better government of the army in the
kingdoms of Great Britain and Ireland, dominions beyond
the seas, and foreign parts dependent upon Great Britain.
These may be altered and enlarged at the king's pleasure.
In certain cases they extend to those that are not military
persons; as when by proclamation any place is put under
martial law or when people follow any camp or army for
the sake of merchandise, or serve in any menial capacity.
It is ordained, that the articles of war shall be read in the
circle of each regiment belonging to the British army every
month, or more frequently if the commanding officer thinks
proper. A recruit or soldier is not liable to be tried by a
military tribunal, unless it can be proved that the articles of
war have been duly read to him.

Articles of the Navy, are certain express rules and
orders directing the method of ordering seamen in the royal
fleet, and keeping up a regular discipline; first enacted by
the authority of parliament soon after the restoration, lat.
13 Car. II. H. 1. c. 9. but since new modelled and altered
by lat. 22 Geo. II. c. 23, amended by 19 Geo. III. c. 17.
In these articles of the navy almost every possible offence is
set down, and the punishment thereof annexed; in which
respect the seamen have much the advantage over their
brethren in the land service; whole articles of war are not
enacted by parliament, but framed from time to time at the
pleasure of the crown. Judge Blackstone figures, that
this distinction proceeded from the perpetual establishment
of the navy, which rendered a permanent law for their regulation expedient, and the temporary duration of the army, which subsisted only from year to year, and might therefore with less danger be subjected to discretionary government. He adds, "whatever was apprehended at the formation of the Mutiny Act, the regular renewal of our standing force at the entrance of every year, has made this distinction idle.

For if from experience past we may judge of future events, the army is now lastingly engrained into the British Constitution, with this singularly fortunate circumstance, that any branch of the legislature may annually put an end to its legal existence, by refusing to concur in its continuance."

**ART**

**ARTICLE of Death, articulus mortis,** the last pang or agony of a dying person. "The pope usually sends his benediction to the cardinals, &c., in articulo mortis."

**ARTICLE, in Arithmetic,** signifies the number 10, or any number juxta divisibile into ten parts; as 20, 30, 40, &c.

These are sometimes called decimals, and sometimes round numbers.

**ARTICLE, in Grammar,** denotes a particle used in most languages for the declining of nouns, and denoting the several cases and genders thereof.

The use of articles arises chiefly, that in languages which have no different terminations to express the different states and circumstances of nouns, there is something required to supply that office.

The Latins have no articles; but the Greeks, and most of the modern languages, have had recourse to them for fixing and ascertaining the vague signification of common and appellative names.

The Greeks have their ἄ, the eastern tongues their he emphaticum, from which, perhaps, the Greek article was derived, unless we derive the Greek ἀ, ἃ, ἂ, from the relative or, or both, by a kind of contraction very common in words much used, from the demonstrative ἀ. The Spaniards and the Italians have their il, lo, and la, which appear to be the Latin ille. The French their le, la, and les seemingly derived from either the Spanish or Italian. The Germans their der, das, dat. The English have also two articles, a and the; which being prefixed to substantives, apply their general signification to some particular things. See letter A.

Some grammarians make the article a distinct part of speech; others will have it a pronoun; and others a noun adjective. See Speech, and Pronoun.

**Articles, in the distribution of the ingenious Mr. Harris, belong to the specics of words which he denominates definitives; because, being associated with a noun, they serve to define, determine, or ascertain any particular object, so as to distinguish it from others of the classes to which it belongs, and, of course, to denote its individuality.**

Although there be a near relation between pronouns and articles, and it may be sometimes doubted concerning particular words to which classes they ought to be referred, yet they may be commonly distinguished by this rule: the genuine pronoun always stands by itself, assuming the power of a noun, and supplying its place; whereas the genuine article never stands by itself, but appears at all times associated to something else, requiring a noun for its support, as much as attributives or adjectives. Mr. Harris distinguishes articles into those chiefly and properly so called, and the pronominal articles, such as this, that, any, &c. The reafon and use of the former he illustrates in the following manner. When a certain object occurs, with which as an individual we are unacquainted, we refer it to its proper species, and call it dog, horse, lion, or the like. If none of these names suit it, we refer it to the genus, and call it animal. But the object which we are contemplating, is perhaps neither a species nor a genus, but an individual. Of what kind? known or unknown? seen now for the first time, or seen before, and now remembered? In this case we shall discover the use of the two articles a and the. A respects our primary perception, and denotes individuals as unknown. When an object passes by which I never saw before, I say, "There goes a beggar with a long beard." When the same man returns at some future time, I say: "There goes the beggar with the long beard." The article only is changed, the rest remains unaltered. The individual once vague, is now recognized as something known, and that merely by the efficacy of this
Articles are of great service in a language, as they contribute to the more neat and precise expressing of several properties and relations, which must otherwise be lost. Without articles, or some equivalent invention, men could not employ nouns to any of the purposes of life, or indeed communicate their thoughts at all. And hence one great disadvantage of the Latin above other languages which have articles, is that the article being either expressed, or left out, makes an alteration in the sense, which the Latins cannot distinguish. Thus, when the devil said to our Saviour, "Est tu filius Dei?" it may either be understood, "If thou art a Son of God," or, "If thou art the Son of God."—Scaliger, from the want of articles in the Latin, has concluded them useless, and bowed upon them opprobrious language, calling the article, "otium kequissime gentis instrumentum;" and the abbé Girard has degraded them to the humble reflection of "avant-coureurs," merely to announce the approach or entrance of a noun. Mr. Horne Took, "Divisions of Purley," has vindicated the honour of the article, and endeavoured to restore it to its primitive dignity. For this purpose he recurs to the reasonings of Mr. Locke, on the use and importance of general terms; and he observes, that it is the business of the article to reduce the generality of terms, and, upon occasion, to enable us to employ general terms for particulars. If, in combination with a general term, it is a subtiltute, yet it is a necessary subtiltute, which (he adds) is more than can be paid of abbreviations that have been advanced into distinct parts of speech, for they are not essential to the communication of our thoughts. The Italians even prefix articles to proper names, which do not naturally need any, because they of themselves signify things individually.—Thus they say, il Arigo, il Tasso, il Petrarcha.—Even the French join the article to the proper names of kingdoms, provinces, &c. as la Suede, la N. Mande.—And we likewise annex it to the names of certain mountains and rivers; as the Rhine, the Danube, the Alps, &c.

Fa. Buffier distinguishes a third kind of articles in French, which he calls intermediate or partitives, serving to denote part of the thing expressed by the subtiltutes they are added to: as, "des escavans out cru," "some learned men have supposed," &c.; I want "de la lumiere," "some light," &c. The use and distinction of the definite and indefinite articles le or la, and de or du, make one of the greatest difficulties in the French tongue, as being utterly arbitrary, and only to be acquired by practice.—We may add, that in the English, though the articles be so few, yet they are of such frequent use, that they easily discover any stranger from a natural Englishman.

ARTIFICIALIS, in Medicine, an epithet applied to a dicale which more immediately inteiles the artici, or joints. The morbus articularis is the same with the Greek αρθρίτις, and our gout.

ARTICULATE. Sounds are those which express the letters, syllables, &c. of any alphabet or language. Brutes cannot form articulate sounds, or they cannot articulate the sounds of their voice; excepting some few birds, as the parrot, phe, raven, storkling, &c.

ARTICULATED. Libell, libellus articulatus, that wherein the parts of a fact are set forth to the judge in distinct articles. This article is much the same with what is otherwise called libellus posiniouus.

ARTICULATED Leaf. See Leaf. ARTICULATED Radius, in Natural History. See Radius Articulatus.

ARTICULATION, &c., in Anatomy, the juncture or connection of two bones. Articulation is technically divided into diarthros, or moveable articulation; synarthros,
or immovable; and amphiarthrosis, which is defined to be a compound of both the others. The immovable connection of bones is said to be by Symphyses, Suture, Gomphosis, Schneiderian, Synarthroses, Synarthroses, or Synarthroses; for the explanation of which we refer to the separate articles. The movable articulations, which alone appear to deserve that term, are divided into Enarthroses, Ginglymus, and Arthrodia. When the spherical head of one bone is received into a corresponding cavity of another, a joint is formed, which admits of motion in every direction; this is Enarthrosis, which is called in English a ball and socket joint, and of which the hip joint is a good specimen. When the articular surface of one bone has a middle groove with lateral eminences, and the corresponding bone has a middle ridge with lateral depressions, a joint is formed which admits of motion backwards and forwards only, like a hinge; this is called ginglymus, and the elbow joint, as far as the ulna is concerned in its formation, or the second and third joints of the fingers and toes, exemplify this mechanism. Mr. Window divides ginglymus into the angular ginglymus, or that joint by which the first vertebra turns round upon the second; and he gives the same term to the articular connection of bones at different parts, as happens between the radius and ulna in the forearm. When two bones joined are a joint applied together by nearly plain surfaces, they may glide a little upon one another, but no extent of motion can take place. This is called arthrodia; and the junction of the collar bone to the acromion, and the metacarpal bones to the bones of the carpus, may be mentioned as specimens of this kind of articulation.

Articulation, in Botany, denotes the connection of parts that consist of joints or knaps, such as the pods of French honey-fuckles, which, when ripe, divide into as many parts as there are joints or knaps, and which usually find forth branches.

Articulation, in a general sense, is that form or character which the voice acquires, by means of the mouth and its several organs, the teeth, the tongue, the lips, &c. The voice by articulation is not made more loud or soft, which are its primary qualities, but it acquires in addition to these characters, certain others, which may co-exist with them. The emphatic of these new characters are those acquired by the voice, more or less, for the purpose of giving the voice a passage, and from the various configurations of these openings proceed VOWELS. There are other articulating forms which the mouth makes, not by mere openings, but by different contacts of its several parts; such, e.g. as it makes by the junction of the two lips, of the tongue with the teeth, of the tongue with the palate, and the like. These contacts are preceded or immediately followed by some opening of the mouth; and the articulations so produced are called CONSONANTS. There are other subordinate distinctions of these primary articulations, which are denoted in the language of grammarians, by the name of ELEMENT; because articulations of every other kind are derived from them and resolved into them. Under their smallest combination, they produce a SYLLABLE; syllables properly combined produce a WORD; words duly combined produce a SENTENCE; and sentences properly combined produce an ORATION or DISCOURSE. Thus it is, says Mr. Harris (Hermes p. 524.), that to principles apparently so trivial as about twenty that characterize sounds, we owe that variety of articulate voices which have been sufficient to explain the sentiments of so innumerable a multitude as all the present and past generations of men. See Dr. Hutton's paper on the subject of articulation, in Edinb. Trans. vol. ii. p. 7. See also CONSONANTS.

Articulation, in a more confined sense, is a branch or portion of Elocution; and in this sense a good articulation consists in giving every letter in a syllable its due proportion of sound, according to the most approved custom of pronouncing it; and in making such a distinction between the syllables of which words are composed, that the ear shall, without difficulty, acknowledge their number, and perceive at once to which syllable each letter belongs. Where these points are not observed, the articulation is proportionally defective. Exactness in sounding the words rightly, corresponds to propriety in spelling; and the articulation should be so clear and distinct, that the hearer may with ease keep pace with the speaker. Among the Greeks and Romans, who paid particular attention to speaking and regularly taught it, the slightest error in pronouncing was equally disgraceful in them, as false speaking is with us. A good articulation is the foundation of a good delivery, in the same manner as the sounding of the simple notes in music with exactness, is the foundation of good singing. As for the greater faults of articulation, such as flattering, hesitation, lipping, and inability to pronounce certain letters, they can never be cured by mere precept, but require the constant aid of a performer filled with the science of those faults, who by teaching each individual how to enliven the organs of speech rightly, and by shewing him the proper position of the tongue, lips, &c. may gradually bring him to a just articulation. Demoothing, it is said, when he first spake in public, could not pronounce the first letter of his art, "Rhetorick;" but by indefatigable pains he overcame the difficulty, and supplied this deficiency in his eloquence, even after he had arrived at the age of manhood. The first and most essential point in articulation is distinctness, and its opposite is the greatest fault. The chief source of indistinctness is too great precipitancy of speech. To this hasty delivery, which drops some letters, and pronounces others too faintly; which runs syllables into each other, and clutters words together, is owing that thick, mumbling, cluttering utterance, of which examples are too frequent. Demoothing had this fault; and this, it is not improbable, was the impediment or defect of speech, which he remedied by exercising himself in declaiming with pibbles in his mouth. For curing any imperfections in speech arising originally from too quick an utterance, the most effectual method will be to employ an hour every morning in reading aloud, in a manner much slower than is necessary; let a friend or some person attend, whose business it shall be to remind the reader, if he should quicken his pace and recur to his old habit of rapid utterance. These words should be marked which are passed over most hastily, and they should be repeatedly pronounced every morning slowly and distinctly. As in our language, words of more syllables than one have one syllable accented, and peculiarly distinguished from the rest, either by a smart percussion of the voice, or by dwelling longer upon it, the other syllables are often negligently articulated. In order to bring those, whose utterance is so rapid to a due medium, they should accustom themselves to pronounce the unaccented syllables more fully, and to dwell longer upon them. See Sheridan's Lectures on Elocution, p. 19—29.

Articulation, in reference to Grammar, is that part of it which treats of sounds and letters, and of their combinations, for the composing of syllables and words. Hence he who pronounces his words clearly and distinctly, is said to pronounce them articulately.

Articulation, in Vocal Music. This word, which belongs to every kind of elocution, as well as music, is too familiar to be called technical. Yet, as it is extremely important, and much neglected, it shall furnish an article.
The Roman artificers had their peculiar temples, where they assembled, and chose their own patron, to defend their canoes: they were exempted from all personal services. Taruntenus Patermus reckons thirty-two species of artificers, and Contantine thirty-five, who enjoyed this privilege. The artificers were incorporated into divers colleges or companies, each of which had their tutelar gods, to whom they offered their worship; and several of these, when they quitted their profession, hung up their tools, a votive offering to their gods. Artificers were held a degree below merchants, and argentarii, or money-changers, and their employment more forfend. Some deny, that in the earliest ages of the Roman state, artificers were ranked in the number of citizens; others, who affect their citizenship, allow that they were held in contempt, as being unfit for war, and so poor that they could scarce pay any taxes. For which reason they were not entered among the citizens, in the censor's books: the design of the census being only to fix what number of persons were yearly fit to bear arms, and to pay taxes towards the support of the state. It may be added that much of the business of artificers was done by slaves and foreigners, who left little for the Romans to mind but their husbandry and war. Dion. Hal. lib. ii. By means of the arts, the minds of men are engaged in inventions beneficial to the community; and thus prove the grand preservative against the barbarism and brutality which ever attend on an indolent and inactive stupidity.

By the English laws, a stranger, being an artificer in London, &c. shall not keep above two strangers servants; but he may have as many English servants and apprentices as he can get. 21 Hen. VIII. c. 16. And as to artificers in wool, iron, steel, brass, or other metal, &c. persons contracting with them to go out of the kingdom into any foreign country, are to be imprisoned three months, and fined in a sum not exceeding one hundred pounds. And such as going abroad, and not returning on warning given by our ambassadors, &c. shall be disfranchised from holding lands by descent or devise, from receiving any legacy, &c. and be deemed aliens. Stat. 5 Geo. I. 27. By 23 Geo. II. c. 13. § 1. penalty of 500l. and of imprisonment for twelve months, for the first offence; and for the second, of 1000l. and of imprisonment for two years, is also inflicted on persons feuding artificers to go abroad. By 14 Geo. III. c. 79, 15 Geo. III. c. 5, and 21 Geo. III. c. 37, heavy penalties are inflicted on masters of ships affilling in such seductions. See Manufacturers.

Ramazzini has a treatise on the diseases of artificers. Artificer by fire, a denomination sometimes given to chemists, and workers in metal. ARTIFICIAL, something made by art; not produced naturally, or in the common course of things. Artificial is also frequently used for fictitious. Thus we have artificial sal ammoniac, artificial borax, &c. Artificial fireworks are compositions of inflammable materials; chiefly used on solemn occasions, by way of rejoicing. Artificial Grasses, in Agriculture, are such grasses as are introduced into field husbandry, and cultivated either for the purpose of being made into hay, or for being fed off by cattle. Clover, lucerne, joint-joint, trefoi, ryegrass, and some others are of this nature. See Cattle.

The cultivation of artificial grasses has been practised in some districts of the kingdom for more than a century, while in others it has only been attended to within these few years, and there are still others that have but just begun to introduce these kinds of grasses. Wherever they have, however, been properly cultivated, so various and so manifest have been
found the advantages arising from them, that they form a very lucrative branch of husbandry, and are consequently grown in abundance in many parts of the kingdom. Those which, according to the author of the Synopsis of Husbandry, are most usually propagated and found to bring the most considerable profit to the farmer, are faihfoim or circine grass, clover, trefoil, hop-clover or non-fitch, and lucerne. One or other of these different species of griffes may indeed be beneficially cultivated on almost every soil, as where the poverty of the ground will not admit of growing either lucerne or clover, faihfoim or trefoil, from their requiring a little depth of soil, may turn out a weighty crop. Saintfoim, clover, and trefoil, are indeed now so universally raised from seed of English growth, that they have become in a manner naturalized to the soil, being scarcely any country in Europe where larger crops are grown than in this. Lucerne, though it be sometimes reserved for feed here, is most successfully raised from seeds of foreign growth. In respect to burnet, spruy, and timothy griffs, which are by some considered as artificial griffes, although their virtues have been highly celebrated by many, they have, perhaps, but seldom it is observed, been found to answer in the cultivation in any degree equal to the fangial commendation bestowed on them.

It is judiciously remarked by Mr. Kent, in the Agricultural Survey of Norfolk, that artificial griffes should always be chosen agreeably to the soil. Saintfoim should, says he, be introduced where there is a chalky, marly, or even a gritty bottom. White clover should be the principal griff, where land is designed to be laid for a continuance. Trefoil and burnet upon high and poor uplands, designed for sheep-walks, perennial damel, or what the farmers call rye-griffs, is, he thinks, proper upon light arable land, for though it is an exhaluer, it serves better than any other to brace the surface. A few acres of lucerne he likewise recommends to every farmer who has a piece of leamy tillage, and near his house.

And in the Survey of the County of Somerfet it is remarked, that on the free-brath and free-frome-griff soils faihfoim takes the lead; and that though the feed is very expensive, the quantity and quality of its produce, together with its durability, make an ample return of profit, particularly if hown when the land is clean. Next to faihfoim, rye-griffs, marl-griffs, and white Dutch clover, are in deferred repute, when the land is intended to remain some years in griffs; but when it is intended to be ploughed again in the course of a year or two, broad clover is preferred to all other artificial griffes. It is remarked, however, in the able Survey of Northumberland, that there few of the artificial griffes are ever grown alone, except red clover when intended to continue only one year, and even then a small portion of rye-griffs, as from one to three gallons per acre are generally found with it; and the writers suppose, with much propriety, as it not only comes early in the spring, but thickens the crop and facilitates making the clover into hay. When the land is intended to continue for three or more years in griffs, they are generally mixed in the proportion of eight or ten pounds of red clover, four pounds of white clover, and half a bushel of rye-griff seed per acre; to the above quantities are sometimes, it is observed, added three or four pounds of rib-griffs and hopmedick, as the foil fruits. See GRASS.

ARTIFICIAL LIGHTNING. See ELECTRICITY, and LIGHTNING.

ARTIFICIAL LINES on a factor or scale, are certain lines fo contrived, as to represent the logarithmic lines and tangents; which, by the help of the line of numbers, will solve all questions in trigonometry, navigation, &c. pretty exactly.

ARTIFICIAL Magnets. See Magnets.

ARTIFICIAL MUSICK, that which is composed according to the rules of art. There is no natural miusic but the wandering of birds, to which we are not applied; the melody of the avairy, or the notes of birds, to which the tones are too high, and the intervals too minute for our appreication. Rigorously speaking, all music is a work of art, particularly instrumental, in which the instrument itself is an artful contrivance for imitating vocal tones, and the hands of the performer must be guided by art. But the artifices of composition and performance are innumerable. In composition, fugues, canons, double counterpoint, ingenious and elaborate accomplishments, are included in artificial music; and in the performance upon instruments, the artifices of bowing on the violin, fingering on keyed instruments, double-tonguing on the German flute, &c. are only known and taught by great masters. The generating musical tones from glusses and other fabulances, not included in the three expedients for producing sounds by instruments, which the ancients as well as the moderns have confined to three several species, as strings, pipes, and percussion, is doubly entitled to the epithet artificial. The harmonies of a single string on the viola da gamba, have, perhaps, a better claim to the title of natural music, than any other sounds produced without human assistance.

ARTIFICIAL Pastures, in Agricultures, such pasture grounds as have been cultivated and trown down with plants of the artificial griffes kind, or such others as are capable of affording a large proportion of green food for the feeding of cattle and other animals. See Pasture.

ARTIGIS, in Ancient Geography, a town of Spain, in the country of the Turduli, supposed to be the prefect Albama, between Grenada and the sea.

ARTIGNI, Anthony GACHET, in Biography, a writer of literary history, was born at Vienna, and became censor of the archiepiscopal church of that city. His work, intitled, "Memoires d'Histoire de Critique et de la Litterature," published in seven volumes 12mo, at Paris, in 1749, manifests considerable talents for literary research and criticism. He died at Vienna in 1769, Nouv. Dict. Hist.

ARTIK-ABAD, in Geography, a town or district of Asiatic Turkey, in the government of Siwas, between the town of Siwas and that of Tocat or Tokai; abounding with grain and fruit.

ARTILLERY is originally a French word signifying archery. In a general sense, it denotes the offensive apparatus of war, particularly the missile kind; and in modern acceptation, is more immediately applied to fire-arms mounted on carriages, and ready for action, with their balls, bombs, grenades, &c. In a more extensive meaning, the term includes the powder, matchets, utensils of ordnance, the machines which facilitate their motion and transport them, the vehicles over which they traverse rivers, every thing necessary to them, and all that enters into the form of a train of artillery. The same word, fully farther extended in its meaning, likewise comprehends the men deflined for the service of the artillery, the people who provide the artillery with materials and implements when engaged, the cannoniers, the bombardiers, the officers of every rank, and engineers of every kind. By artillery is likewise understood the science which the officers of artillery are known to profess. See Engineering.

In the most ancient times, when war was made with quickness and implausibility, the use of artillery was unknown. Something like military engines seem hinted at in the book of Deuteronomy (chap. xx. v. 20.) but the earliest
The precise mention of artillery is in the second book of Chronicles (chap. xxvi. v. 15.), where we are told, that Uzziah, who began his reign 809 years before the Christian æra, "made in Jerusalem engines invented by cunning men, to be upon the towers and upon the bulwarks, to shoot arrows and great stones withal." This also is particularly mentioned by Josephus, who represents Uzziah's care of Jerusalem as toward the end of his reign.

The Greeks, who were defirs of appropriating to themselves every improvement of science they gathered from the East, would fain have been believed the inventors of artillery. But so far from being in possession of artillery, they had not in their early times, if we may judge from Homer's writings, one military engine that was calculated to shake a wall. The earliest instance of profane history is probably to be sought for in the siege of Motya, about 370 years before Christ, where Dionysius, having battered the fortifications with his rams, advanced to the walls, towers rolled upon wheels, whence he called the beleaguered with continual volleys of arrows and stones thrown from his catapults. (Anc. Univ. Hist. vol. vi. p. 401.) The next memorable instance that occurs is the siege of Rhodes by Demetrius Poliorcetes, where even Grecian ingenuity was exhausted in the invention and improvement of artillery. (Diod. Siculus, l. xx.) Another instance of notoriety occurs when Hannibal beleaguered Saguntum, 219 years before the Christian æra; and the Saguntines hindered his soldiers from using the battering-ram, by an incessant hurling of darts, stones, and other missile weapons. See the account in Livy (l. xxi. c. 7. edit. Fretilin), who has also supplied us (l. xxxvi. c. 45. 47.) with a curious inventory of the warlike engines which Scipio, eight years afterwards, found among the stores of Carthagians. There were no less than an hundred and twenty catapults of the larger size, two hundred and eighty-one of the smaller, of the greater balista twenty-three, of the leffer fifty-two; besides an innumerable quantity of scorpions of different sizes, arms, and missile weapons. Two years, however, previous to this, Marcellus had laid siege to Syracuse, a city proverbially fatal to the armies that attacked it. Archimedes was at that time resident in Syracuse; and at the earnest solicitation of Hiero, king of Sicily, exerted the powers of his mind in the invention of artillery and other warlike engines. Marcellus had brought with him an amazing engine called scirhica, upon eight galleys; which the mathematician destroyed by discharging huge stones of enormous weight upon it, while it was at a considerable distance from the walls. The chief instruments he used were balists, a sort of crow lowered by a lever, which hoisting the ships of the Romans by the prow, plunged them to the bottom of the sea; grapples; and scorpions. Archimedes, however, left no account of these military engines in writing; because he confided all attention to mechanics as mean and forlorn, placing his whole delight in those intellectual speculations which, without any relation to the necessities of life, have an intrinsic excellence springing from truth and demonstration only; and reckoning such inventions but among the amusements of geometry. See the life of Marcellus in Plutarch.

To multiply the enumeration of ancient sieges where artillery was used, would not only be tedious but endless. Every siege, it is probable, gave rise to some invention or improvement. Tactius indeed mentions an extraordinary instance (Hist. l. iii. c. 23. 29.) of an engine with which the fifteenth legion fought against the troops of Vespasian, at Cremona. It was a balista of an enormous size, which the Vitellians played off with dreadful execution; and discharged maffy stones of weight to crush whole ranks at once. Inevitable ruin, we are told, must have followed, if two soldiers had not signalized themselves by a brave exploit. Covering themselves with the shields of the enemy, which they found among the slain, they advanced unperceived to the battering engine, and cut the rope of the spring. At last, after a vigorous assault from Antonius, the Vitellians being no longer able to sustain the shock, and enraged at their disappointment, in a fit of despair, rolled down their battering-engine on the heads of the besiegers. Numbers were crushed by the fall of such a prodigious mass. It happened, however, that the machine drew after it a neighbouring tower, the parapet and part of the wall, affording the besiegers an easier access to the city. The continued use of these enormous engines must be remembered by every reader of history; as well as that the Romans had regular batteries both of ballistics and catapults.

The credit of introducing artillery into our own country must undoubtedly be given to the Normans, whom William of Malmsbury describes (l. iii. p. 57. col. 2.) as having a peculiar delight in war, and affixes to them an in all the arts of attacking their enemies, when their forces were insufficient. The Normans first introduced among their enemies the keep, placed upon a mount, whence they annoyed the surrounding enemy with their darts, stones, and other offensive weapons. (Strutt's Manners and Customs of the English, vol. i. p. 93.) Their method of attacking keeps seems generally to have been by means of towers; blockade was little practised; and the iron ram, which the Romans found so serviceable, was rendered in a great measure useless by the deep ditches which surrounded their fortifications. The principal machines which the Normans employed were of course of the projectile kind; and they were not only used in regular sieges, but occasionally contrived as to be used on ship-board. See Matt. Paris, p. 1091.

Machines for throwing stones occur so early as in the battle of Haltings (Will. Pictavien. p. 201.); and Robert de Brunne, in his wars against the Saracens, informs us, that when Richard the First set out against the Holy Land, he had in his barges and galleys mills turned by the wind which by force of the fall threw fire and stones.

The benefit which the English manner derived from the crusades, is a topic on which we shall have other opportunities of enlarging; but the anecdotes to the knowledge of our ancestors in the art of war were singularly confpicuous. From the Saracens they obtained a sort of wild-fire of so subtle a composition, that there was no method of extinguishing it but by smothering it with heaps of dust or vinegar. It was by this device that the Black Prince set fire to Remonentine; and it was often thrown in pots from the catapult.

The Greek and Roman writers afford us many instances of the superior force which the catapults and ballistics of the ancients could occasionally display; nor are parallel instances wanting in the annals of Britain. Camden informs us, that with the mangonels, trebuchets, and balistae, our forefathers used to cast forth mill-stones; and Holinshed (p. 239.) relates, that when Edward the First besieged Stirling castle, he caused certain engines of wood to be raised against it, which shot off stones of two and three hundred weight.

The catalogue of projectile machines in the eleventh and twelfth centuries, exclusive of the balista, catapulta, onager, and spiorion, was the mangonel, the trebuchet, the petracy, the robinet, the maticgrillon, the bricoll, the bugle or bible, the cipringal, the matatunda, the ribaudequin, engine a verge, and the war-wolf (Grote Milt, Hist. vol. i. p. 381.), which
whole form, construction, and particular history, will be desc-
duced with propriety from their magnitude, without hurting
the great effects which it was necessary on some occasions
they should produce. See Cannon, Gunnery, and
Projectiles.

Dr. Smith observes (Wealth of Nations, vol. iii. p. 70.),
that the great change introduced into the art of war by the
invention of fire-arms, has enhanced still further both the
expense of exercising and disciplining any particular number
of soldiers in time of peace, and that of employing them
in time of war. Both their arms and their ammunition
have become more expensive. A matchet is a more expensive
machine than a javelin or a bow and arrows; a cannon
or a mortar, than a balilla or a catapult. The powder
which is spent in a modern review, is lost irrecoverably,
and occasions a very considerable expense. The javelins
and arrows which were thrown or shot in an ancient one, could
casily be picked up again, and were besides of very little
value. The cannon and the mortar are not only much
dearer, but much heavier machines than the balilla or cat-
pulta, and require a greater expense, not only to prepare
them for the field, but to carry them to it. As the im-
portance of the modern artillery too, over that of the an-
tients, is very great, it has become much more difficult,
and consequently much more expensive to fortify a town
so as to defend it for even a few weeks, the attack of that su-
perior artillery. In modern times, many different causes con-
tribute to render the defence of society more expensive.
The unavoidable effects of the natural progress of improve-
ment have, in this respect, been a good deal enhanced
by a great revolution in the art of war, to which a mere acci-
dent, the invention of gunpowder, seems to have given
occasion.

Artillery-Park, the place in the rear of both lines in
the army for encamping the artillery, which is drawn up
in lines, of which one is formed by the guns; the ammun-
tion waggon makes two or three lines, sixty paces behind
the guns, and thirty distant from one another; the pon-
toons and tumbrels make the last line. The whole is sur-
rrounded with a rope, which forms the park; the gunners
and matrofes encamp on the flanks; and the bombardiers,
pon-toon-men, and artificers, in the rear. Of late when an
army has been upon the point of engaging, or in expecta-
tion of an attack, the artillery has been encamped in two
parks, upon both flanks.

Artillery Trail, or Train of, a certain number of
pieces of ordnance mounted on carriages, with all their
furniture, fit for marching.

Artillery Company, the, had its origin about 1585, when
London being warned with continual mutters, a number of
its gallant citizens who had served abroad with credit,
voluntarily exercised themselves, and trained others to the
ready use of war. The ground they used was at the north-
est extremity of the city, high Bishopegate, and had before
been occupied by the "fraternity of artillery," or gun-
ners of the Tower. Within two years there were near
three hundred merchants and others sufficiently skilful to
train common soldiers; and in 1588, some of them had
commisions in the camp at Tilbury; but their association
soon after fell to decay. (Ellis's History of Shoreditch,
p. 348.) From the company's register, the only book
they issued in the civil wars, it appears that the associ-
ation was revived in 1611, by warrant from the privy
council; and the volunteers soon amounted to six thou-
sand. Three years after this they made a general mutter,
when according to contemporary authority, the men were
better armed than disciplined. (See Nicholl's London
Artillerie, p. 104.) In 1622 they erected an armory,
toward which the chamber of London gave above 300l.; it was furnished with five hundred sets of arms of extraordinary beauty, which were all lost in the civil wars. Their captain, during a part of those affrighted times, was a Mr. Manby, who irrecoverably detained for his own pur-
poses, the arms, plate, money, books, and other goods of the company. The protector was in vain solicited to enforce their being restored. (Ellis's Hist. of Shored. p. 349.)
In 1640 they quitted their old field of discipline, and entered upon a plot of ground in Bunhill-fields, leaved to them by the city.
This company, at present, forms a regular battalion of infantry, consisting of a grenadier, light infantry, and hat divisons; together with the matro's division for the use of two field pieces, presented in the year 1780, by the city.
There is also kept up a division of archers; archery being the art cultivated by the company in days when the bow was an instrument of war. The command of the battalion is vested in officers who are annually elected. This municipal corps is authorized and privileged by many royal patents and warrants; and particularly by one of his present majesty, under the royal sign manual, wherein his royal highness the prince of Wales is declared captain-general. It consists of gentlemen of character and property, bound by a solemn declaration and obligation of attachment and fidelity to the king and constitution, and of readiness to join in supporting the civil authority, and defending the metropolis. It is regulated by a court of officers, consisting of a president, vice-president, treasurer, the field officers; the lord mayor, aldermen, and sheriffs for the time being, and twenty-four elective members. (See the company's address to the inhabitants of London.)
Artillery is also used for what we otherwise call pyrotechnia, or the art of fire-works, with the instruments and apparatus belonging to it.
Artinal, in Geography, one of the Pelew Islands in the Pacific ocean.
Artis, in Ancient Geography, a place of Aisia Minor, in Tonia.
Artisan. See Artist, and also Artificers, and Manufacturers.
Artisiga, in Ancient Geography, a village of Africa, in Mauritania-Carafiren; situated on the east coast, north-west of the mouth of the river Malva, about 27 miles west of Siga.
Artiscus, in Medicine, from ather, broad, to denote a trochee, but more particularly that prepared of vipers flesh, mixed up with bread, to be used in the composition of Venice treacle. These are more particularly called artificis theriaci, or ibericai trochees. They were formerly in great vogue, and brought with much parade from Venice; but Zeller discovered their vanity; since which time vipers powder has been generally substituted for them, in the preparation of the treacle.
Artison, in Natural History, a common name among the French for various kinds of insects that injure furniture, skins, stuffs, &c. such as the Dermelles, Mites, &c.
Artist, in a general sense, a person skilled in some art; or, according to Mr. Harris's definition, a person possessing an habitual power of becoming the cause of some effect, according to a figure of various and well-approved precepts. In this sense, we say, an excellent, a curious artist. The pre-eminence is disputed between ancient and modern artists, especially as to what relates to sculpture, painting, and the like. At Vicenza, we are told of a privilege granted to artists, like that of clergy in England; in virtue of this, criminals adjudged to death save their lives, if they can prove themselves the most excellent and comfronnable work-
men in any useful art. This benefit is allowed them in favorem artis, for the first offence, except for some particular crimes, of which forming is one. The exception is just, since here the greater the artist, the more dangerous the perfon. Evelyn's Difc. of Medals, ch. vii. p. 237, &c.
Artists are persons who practice those arts which must necessarily be combined with a considerable degree of science, distinguishing them from such as are properly artisans or mechanics. Artists are particularly those who study and effect what are termed the polite arts, i.e. painting, sculpture, and architecture, to which may be added engraving. An account of the most eminent artists, ancient and modern, will be found in this work alphabetically arranged, to which our readers are referred. It appears that all civilized nations in every age have produced artists, and that with a degree of excellence generally ascribable to their civilization and opulence. In every nation where the arts have flourished, the artists have made but rude effays, and by degrees they have been nurtured up to excellence, except in such influences where they have been transplanted, as from Greece to Rome. It is universally acknowledged respecting painting and architecture, that ancient Greece has produced the best artists in the world; their works which have escaped the ravages of time are the standing monuments of their fame, and are still considered as the models of perfection; there is however an uncertainty whether their painters were equally skilled with their statuaries. With some reason, many judicious persons have supposed they were not, while others contend, that so much excellence produced in one branch, must have contemporary artists who would excel in the other also. While we cannot doubt of the genius of the Grecian artists, and of their ability to produce works of excellence, yet it may not be allowed that this argument will be found to be so conclusive as it may at first appear, since Chines and Indian models are found in a more perfect state than either their drawings or paintings. Sir Joshua Reyn-
olds has given a hint upon this subject in his notes to Mr. Mau-
son's translation of Du Fresnoy, which may be consulted upon one side of the question; and Mr. Webbe, on the other, will not fail to interrel any reader who may be inclined to believe in favour of ancient painters. When the Goths overran Italy, the arts were destroyed; and, with Grecian architecture, painting, and sculpture, lay in one common grave forgotten, until they were revived under some of the twelfth and thirteenth centuries, which ought not to be esteemed as artists, but for the success which they have produced in the execution of which they have been corrected by the period after a short time after produced Michael Angelo, Raphael, Corregio, Titian, Algarde, Bernini, &c. painters, sculptors, and architects, to whose works the living artists are almost as much indebted as these illustrious characters were to the ancient monuments they dug from the ruins of old Rome. While painters continued to pursue their wretchedly dry and barbarously gothic method of design, prior to these enlightened artists, even then, the bronze gates of the baptistery of the church at Florence were produced; upon a sight of which, M. Angelo cried out with emotion, when he saw them, that they deferved to be the gates of paradise! Calls of these gates may be seen in the Royal Acad-
emy in London. This we notice to justify a remark which we have made, that painting does not always accompany with equal steps the efforts of sculpture.
An Englishman will observe with pleasure the progress which has lately been made, and is still making under the protection of our gracious sovereign, in this once barren land, by artists in painting, sculpture, and archi-
tecture.
Artist, artifex, in an academical sense, denotes a phi-
loater
ART

ARTIST is more peculiarly underfoot of a Chernill or alcymith. In which frame it is that Paracelsius and other adepts use the word.

ARTIZOOS, from άρτις, short, and γέν, life, is used by some ancient physicians for an infant short-lived, by reason of a difficult birth, whereby he was long detained in the paffage from the womb.

ARTOARTIA, in Ancient Geography, a town of India on this side of the Ganges. Ptolemy.

ARTOPRIGA, a town of Vindelicia, mentioned by Pliny, and supposed by some to be Altzburch in Bavaria, on the Danube; but according to Chelverius, to be Labanau, on the Saltzbach, below Laullien, in the archbishopric of Saltzburch.

F Fruitta apprano, fruit without seeds.
F Fruitt a feminiter, with seeds in the fruit.

Leaves gajfed. Forther, whole description of this tree appears to be more complete than that of any other writer, says it is the thickness of a man, and upwards of forty feet high; the trunk is upright, no wood soft, smooth, and yellowish, the inner bark white, composed of a net of filiform fibres, the outer bark smooth, but full of chinks, pale all, colour, with small tubercles thinly scattered over it. Wherever the tree is wounded, it pours out a glutinous milky liquor. The branches form an ample almost globular head; the lower ones, which are the longest, spring from the trunk ten or twelve feet above the ground, spreading almost horizontally, scattered, and in a sort of whirl; twigs ascending, bearing flowers and fruit at their ends. Leaves alternate, petioled, ovate, deeply divided above the middle into seven or nine lanceolate acute lobes, with rounded sinuses; they are otherwise quite entire, smooth on both sides, even, spreading, bright green, paler underneath, membranaceous, a foot and a half in length, eleven inches wide, veined, having a thick nerve to each lobe, diverging from the common rachis. The younger leaves, like all the more tender parts of the tree, are glutinous to the touch; petioles roundish, even, ascending, two inches in length; stipules in pairs, involving the younger leaves, lanceolate, acuminate, concave, entire, smooth within; hairy on the outside; deciduous; three inches long; peduncles at the ends of the twigs, and in the axils of the upper leaves, foliary, round, upright, having a few hairs, and two inches in length. The male flowers are among the upper leaves; and the female flowers at the ends of the twigs. The male ament is club-shaped, feathery, upright, a spn long, covered with innumerable small, feathery florets. The proper perianths is very small, two-valved; valves equal, oblong, blue, concave, closely adhering, flat, yellow-brown. These have no fruitlets. The female flowers have bilateral samarae, ovate-lanceolate, compressed, acuminate, upright, but at the tip, soft, a spn in length, at frill cloded, then deciduous, placed at the end of the peduncle; samarae globular, covered with many conuate germs, these are obconical,immered in the receptacle, somewhat convex at the top; styles scarcely any; stigma projecting points, withering; in some varieties these are bift, according to Thumberg. The fruit is a globular berry, smoothish, marked with hexagons on the surface, pale green, often nine inches in length, filled with a white, farinaceous, somewhat fibrous pulp, which, when the fruit is ripe, becomes juicy and yellow; it is fastened to a club-shaped, feathery receptacle, which is longitudinally fibrous, and a hand in length.

In captain Cook's voyage it is observed, that the bread-fruit tree is about the size of a middling oak; its leaves are frequently a foot and a half long, oblong, deeply fin-cuted like those of the fig-tree, which they resemble in consistence and colour, and in exuding a milky juice when broken. The fruit is the size and shape of a child's head, and the surface is reticulated not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small knife; the edible part lies between the skin and core; it is as white as snow, and of the consistence of new bread. It must be boiled before it is eaten, being first divided into three or four parts; its taste is acrid with a slight sweetness, somewhat resembling that of the crumb of wheaten bread mixed with Jerusalem artichoke. The fruit not being in feason all the year, there is a method of supplying this defect, by reducing it to four palte called malas; and besides this, cocoa-nuts, bananas, plantains, and a great variety of other fruits, come in aid of it.

This tree not only supplies food, but also clothing, for the bark is stripped off the trees, and formed into a kind of cloth. To procure the fruit for food cofts the Otaheiteans no trouble or labour but climbing a tree; which though it should not indeed shoo up spontaneously, yet, as captain Cook observes, "if a man plant ten trees in his life-time, he will as completely fulfill his duty to his own and future generations, as the native of our cold temperate climate can do by ploughing in the cold winter, and reaping in the summer's heat, as often as these fruitlets return; even after he has procured bread for his profert household, he should convert a surplus into money, and lay it up for his children.

But while the trees are once introduced in a favourable foil and climate, so far from being obliged to renew them by planting, it seems probable that the inhabitants will rather be under the necessity of preventing their progress; for young trees springs abundantly from the roots of the old ones, which run along near the surface. Accordingly they never plant the bread-fruit tree at Otaheite." The bread-fruit is distingushed into that which is distillate of seeds, and that in which seeds are found. The natives of Otaheite reckon at least eight varieties of trees which produce the former. The moll common of these is named uru or toro, bearing a globular, smooth, even fruit. The maira has an oval, smooth fruit, with the leaves more deeply cut. The patona has a fruit oblong and rough, with a scaly appearance. The tutuara has an oval fruit, with mamilary germs, muri-ated by the permanent style.—Probably, by extending the culture
ART
culture to distant countries, the varieties may be still further improved. The parts of fructification in those trees which bear fruit without flowers, are said to be defective; as the aman never expands, and the styles are also deficient. In the variety Ω, the fruit contains a considerable number of seeds, almost as large as chestnuts, oblong, somewhat angular, produced into a point at each end. They are farinaceous like the chestnut, and are eaten in some places by the savage inhabitants, either boiled, or roasted in embers. It will easily be supposed that this fruit, abounding lefs in pulp, and being both more fibrous and lefs juicy than that which has no seeds, must be much inferior as an article of food; and, accordingly, before the discovery of the South Sea islands, the bread-fruit had not acquired that degree of reputation which it is now found to deserve. It has been long known in many parts of the East Indies, but not being wanted there for food, and consequently not having received any degree of cultivation, it has continued nearly in its natural state, without receiving that improvement from the care of men, which probably necessitated first urged them to exercise. Accordingly, captain Cook remarked the great inferiority of the tree which he found at Batavia, to the *euros* of the South Sea islands.

This most useful tree is distributed very extensively over the East Indian continent and islands, as well as the innumerable islands of the South Seas. It was found by Dampier in the Ladrone islands: it is a native of Amboina, Banda, and other islands of the Molucca islands: Java and others of the Maldive islands: Timor, Balaia, and Madura, of Prince's island, &c. M. Somnerat conveyed some of the trees from the island of Luzon to the island of France. M. Poivre naturalized them both there and in the island of Bourbon; and they are cultivated both in Malabar and Coromandel. In the South Seas both varieties are still found in the Marian islands, in the New Hebrides, and Friendly islands; but most abundantly in the Society, Marquesas, and Sandwich islands. In Otaheite however, and some others, the evident superiority of the French variety for food, has enabled the other to be neglected, and it is consequently almost worn out. We are informed by captain King, that in the Sandwich islands the trees are planted and flourish with great luxuriance on rising grounds; that they are not indeed in such abundance, but that they produce double the quantity of fruit which they do on the rich plains of Otaheite; that the trees are nearly of the same height, but that the branches begin to unfit from the trunk much lower, and with greater luxuriance; and that the climate of these islands differs very little from that of the West Indian islands, which lie in the same latitude.—This reflection probably first suggested the idea of conveying this valuable tree to our islands in the West Indies. For this purpose, his majesty's ship the Bounty sailed for the South Seas, on the 23d of December 1787, under the command of lieutenant William Bligh. But a fatal mutiny prevented the accomplishment of this benevolent design. His majesty, however, not discouraged by the unfortunate event of this voyage, and fully impressed with the importance of securing to useful an article of food as the bread-fruit to our West Indian islands, determined, in the year 1791, to employ another ship for a second expedition on this service, and in order to secure the success of the voyage as much as possible, it was thought proper that two vessels should proceed together on this important business. Accordingly, a ship of two hundred tons, named the Providence, was engaged for the purpose, and the command of her given to Captain Bligh; and a small tender called the Affiant, commanded by lieutenant Nathaniel Portlock, Sir Joseph Banks, as in the former voyage, directed the equipment of the ship for this particular purpose. Two skillful gardeners were appointed to superintend the trees and plants, from their transplantation at Otaheite, to their delivery at Jamaica, and Captain Bligh set sail on the second of August 1791. He arrived at Teneriffe on the twenty-eighth, at St. Jago on the thirtieth of September, and at the cape of Good Hope on the fifth of November. He failed from thence on the nineteenth of December; arrived at Adventure's bay on the ninth of February 1792, and at Otaheite on the eighth or ninth of April. The binnacle of procuring and embarking the bread-fruit trees, &c. took up three months and nine days; though the natives of Otaheite gave all possible assistance to Captain Bligh and the gardeners. They failed on the eighteenth or nineteenth of July; arrived at Coupang in Timor on the second of October; at St. Helena on the seventeenth of December, and at St. Vincent's on the twenty-second of January 1793. Here they stayed seven days, to leave a part of their cargo, and on the fifth of February they arrived at Jamaica, and delivered the remainder. The number of plants taken on board at Otaheite, was 2634, in 1281 pots, tubs and cafes: and of these 1151 were bread-fruit trees. When they arrived at Coupang, 220 plants were dead, but the rest were in good order. Here they procured ninety-two pots of the fruits of that country. They arrived at St. Helena with 830 fine bread fruit-trees, besides other plants. Here they left some of them, with different fruits of Otaheite and Timor, besides mountain rice and other seeds; and from hence the East Indies may be supplied with them. On their arrival at St. Vincent's, they had 551 cafes, containing fix hundred and seventy-eight bread-fruit-trees, besides a great number of other fruits and plants to the number of 1245. Near half this cargo was deposited here under the care of Mr. Alexander Anderson, the superintendent of his majesty's botanic garden, for the use of the Windward Islands; and the remainder, intended for the Leeward Islands, was conveyed to Jamaica, and distributed as the governor and council of Jamaica pleased to direct. The exact number of bread-fruit trees brought to Jamaica was 352, out of which five only were reserved for the botanic garden at Kew. Though the principal object of this voyage was to procure the bread-fruit tree, yet it was not confined to this only, for the design was to furnish the West Indian isles with the most valuable productions of the South Seas and the East Indies. Accordingly, the gardeners were instructed to procure plants of sweet plantain called *mico*, the Otaheitean apple or *ever*, the root called *peau*, of which the islanders make a kind of pudding, and a species of yam much larger and better than any in the West Indies. They were also to obtain at Timor and other places in the East Indies such plants and fruits as are used for food or otherwise by the natives, as the *janja*, *mangofian*, *durion*, *jambon*, *nanca*, *tehampadin*, *bloking*, *jambolan*, *boutilharry*, *jafic*, *bleck*, long pepper, &c. together with some bushes of dry or mountain rice, which is cultivated without being overlooked with water; and they were to make themselves acquainted with the mode of managing it in order to communicate the same to the inhabitants of the West Indies. Captain Bligh had the satisfaction, before he quitted Jamaica, of seeing the trees which he had brought with so much success, in a most flourishing state; intimating that no doubt remained of their growing well and speedily producing fruit; an opinion which subsequent reports have confirmed. But though the fruit has been produced in great abundance, it is said not yet to have arrived at that high state of perfection in which it is described to be at Otaheite. Thunberg feets breads of the East Indian bread-fruit tree from Batavia.
to the botanic garden at Amsterdam, in 1775. In 1777, he sent some small living plants; and the year following, he brought with him to Europe a great number of plants, both of this and the following species. But the true feed-leaf, from the South Seas, was first introduced into the islands of St. Vincent and Jamaica, and into the botanic garden at Kew, by Captain Bligh, in 1793.

The bread-fruit, when perfectly ripe, is pulpy, sweetish, purerect, and in this state is thought to be too laxative; but when green it is farinaceous, and esteemed a very wholesome food, either baked under the coals, or roasted over them. The table is not unlike that of wheaten bread, but with more resemblance to that of Jerusalem artichokes or potatoes. It was mentioned before that a fort of cloth was made of the inner bark: to this we may add, that the wood is used in building boats and houses; the male catkins serve for tinder; the leaves for wrapping their food in, and for wiping their hands instead of towels; and the juice for making bird-lime, and as a cement for filling up the crotches of their vessels for holding water. Three trees are supposed to yield sufficient nourishment for one person.

In the Malay language the bread fruit is called _focem_, in Java _budu_, in Anamboi _sum or sam_, in Makasar _badak_, in Ternate _gono_, in Timiah _rimot_, the Dutch call it _focnuss_—boom, the Germans _bredbaum_. The French _firma_ or _fruit a pain_.

2. _A. integrifolia_, Indian Jack tree; leaves entire; _futum_ macaronpon, Thumbl. Phil. Trans. v. 69. p. 253. _Sitodion cauliflorum_, Gxtn. fruct. t. 345. _Succes derricussum_ namum, Rumphi. Amb. t. 30—31. _Tsacce-maram, f. Jacca_, Rheed. Mal. t. 26, 27, 28. The East Indian Jacca, or Jack-tree, is about the same size as the foregoing or perhaps larger. Branches alternate, spreading; the twigs hircute with long fluff hairs; leaves alternate, petiolate, ovate-oblong, blunt, obscurely serrate, undivided, nervled, bright-green, and very smooth on the upper surface, paler beneath, and hircute with fluff hairs, spreading, a span in length. The younger leaves are evidently toothen, but the teeth disappear. The foot-stalk is somewhat triangular, smooth, an inch in length; flowers as in the foregoing; flowers male and female distinct on the same stem or branch; peduncle either simple or branched, pendulous an inch thick, and a foot long; pedicles three, five, or more, the length and thickness of a finger. The fruit weighs thirty pounds and upwards; it has within it frequently from two to three hundred feeds, three or four times as big as almonds; they are ovate-oblong, blunt at one end, sharp at the other, and a little flattened on the sides. These two species of artocarpus cannot be distinguished with certainty either by the form of the leaves, or the situation of the fruit; for the leaves in this are sometimes lobed as on that; and the situation of the fruit varies with the age of this tree, being first borne on the branches and then on the trunk, and finally on the roots. The Jacka tree is a native of Malabar and the other parts of the East Indies. The fruit is ripe in December, and is then eaten, but is esteemed difficult of digestion; the unripe fruit is also used pickled, or cut into slices and boiled, or fried in palm-oil. The nuts are eaten roasted, and the skin which immediately covers them, is used instead of the areca nut in chewing betel. The wood of the tree serves for building. No leaves than thirty varieties of the fruit are enumerated in Malabar. It was introduced into the royal botanic garden, at Kew, in 1778, by Sir Edward Hughes knight of the bath.

Propagation and Culture. Those varieties which bear seeds may be propagated by them, sown in a pot of rich earth, and plunged in the bark-bed. Those which have no seed in the fruit may be increased from suckers, in which they abound very much, or by layers. In hot climates they succeed best in a rich soil; for though they will grow in an indifferent one, yet they by no means arrive at that magnitude, nor is the fruit so well-flavoured as when they are planted in a good one. In the East Indies they yield a fruit of the Jacca into the ground whole, and when the numerous seeds germinate and grow up, they tie the stems altogether with withes, and by degrees they form one stem, which will bear fruit in two or three years if not placed in too wet a situation. See Marty's Miller's Diet.

ARTOIS, in Geography, a province of France before the revolution, is one of the most fertile and most productive of grain and fruit in the whole kingdom. It was formerly one of the fourteen provinces of the Netherlands; but since the revolution it is not included in the department of _pic de Calais_, or _fruits de Calais_. The chief city is _Arras_. This province is about twenty-three leagues long, and twelve broad; and is bounded on the west and south by Picardy, on the north by Flanders, and on the east by Flandres and Cambresis. The name of _Artois_ is derived from the _Artobali_, who occupied this part of Gallia Belgica in the time of Caesar. From the dominion of the Romans it passed to that of the French kings, who possessed it in 865; in 1237 it was erected into a Comte by St. Louis, and given to his younger brother Robert I. It was surrendered by Charles VIII. the fon and successor of Louis XI. to Maximilian of Austria, by the treaty of Sculis, in 1492. The houses of Austria and of Spain possessed it in succession till the year 1648, when Louis XIV. obtained it by conquest from Philip IV. king of Spain; and from his time it has been subject to France. The peace of the Pyrenees, in 1659, secured it to him, with the exception of the towns of Aire and St. Omer, which, together with their respective territories, were reserved to Spain, but afterwards ceded to Louis XIV. in 1679, by the treaty of Nimeguen, confirmed by subsequent treaties, and particularly by that of Utrecht in 1713. Its commerce confids principally in grain, flax, hops, wool, and linen cloth.

ARTOLICA, in Ancient Geography, a town of the Salassi, in Gallia Cispadana, at the foot of the Alps, now called _Bielle_ by the inhabitants, a hamlet of Savoy, in the duchy of Aosta, at the foot of mount St. Bernard the Left.

ARTOMELI, from _pyto, bread_, and _pe, honey_, in Ancient Pharmacy, a kind of castor oil prepared of bread and honey, applied chiefly to the phlegm.

ARTON, in Geography, a town of France, in the department of the lower Loire, and chief place of a canton in the district of Paimbreuf, seventeen miles south-west of Nantes.

ARTONNE, a town of France, in the department of Puy de Dome, and chief place of a canton in the district of Riom, five leagues north of Clermont, and two and a half north of Riom.

ARTOTYRITES, or Artotyrite, in Ecclesiastical History, a branch of the ancient Montanists, who first appeared in the second century, chiefly in Galatia.

They use bread and cheese in the Eucharist, or perhaps bread baked with cheese.—Their reason was, that the first men offered to God not only the fruits of the earth but of their flocks too.

Hence, according to St. Augustine, came their name, which is composed of _pyto, bread_, and _pe, honey_.

The Artotyrites admitted women to the priesthood and episcopacy; and Epiphanius says, that it was common to see seven girls enter at once into their church, in white robes, with torches in their hand, where they bewailed with tears the miseries of human life.
ARTRO, in Geography, a river of North Wales, which runs into the sea near Llanddona in Merionethshire.

ARTUSI, Gio. Maria, of Bologna, in Biography, though he is ranked only among the minor writers on music, yet if his merit and importance are estimated by the celebrity and size of his volumes, certainly deserved the attention of students and collectors of musical works. In his "Arte del Contrapunto ridotta in tavole," published at Venice, 1586, he has admirably analysed and comprised the voluminous and diffused works of Zarino and other ancient writers on musical composition, into a compendium, in a manner almost as clear and geometrically as that in which M. d'Alambert has abridged the theoretical works of Rameau. In 1592, Artusi, who, like most of the musical writers of Italy, was an ecclesiastic, published a second part of his "Arte del Contrapunto," which is a useful and excellent supplement to his former compendium. And in 1602 and 1603, this intelligent writer published at Venice the first and second part of another work, "Delle Impropritzioni della moderna musica." Here the author gives a curious account of the state of instrumental music in his time: and in describing a grand concert that was made by the men of a convent at Ferrara, in 1598, on occasion of a double wedding between Philip III. king of Spain with Margaret of Austria, and the archbishop Albert with the Infanta Isabella, the king's sister, he enumerates the several instruments that were employed, and points out their excellencies and defects. Among these, though the violin is just mentioned, yet nothing is said of its properties, while the cornet, trumpet, viol, double-harp, lute, flute, and harpichord, are honoured with particular remarks both on their construction and use: but among these, the cornet, which has been supplanted in the favour of the public by the harpsichord, seems to have lost the highest in the author's estimation. The elder Doni, in his dialogue written about fifty years before, mentions the cornet more frequently than any other instrument: "Il divino Antonio da corrento perfettissimo—et M. Battista dell' Fondero con il suo corrento ancora; che lo fuma miracolamente." I have not been able, says Dr. Burney, to discover what instrument is to be understood in this dialogue, when Girolamo Parmabaco says, "Io fumerò il corrento a me!" and when it is said, "M. Gio. Vania o Buzi, in fumando di violone il tornacca, come egli fa miracolosamente," I am quite unable to guess what instrumental instrument makes the word "corrente," by a typographical error, has been printed for "violone." But to return to Artusi's remarks upon instruments: his hero on the cornet was Girolamo da Udine. In speaking of defects in the intonations of different instruments, I expected the violin would be celebrated for its superior perfection in that particular; but by the author's silence on that subject, I am convinced that it was either then but little used in concert, or was very ill played. Burney's Hist. Mus. vol. iii. p. 174.

ARTYMNEUS, in Ancient Geography, a town of Asia, in Lydia, where the Xanthians are said to have established a colony.

ARTZ, in Geography, a district of the island of Zealand, belonging to Denmark, in the prefecture of Kullandborg, which includes nine church...

ARTZBACH, a river of Germany, which runs into the Enz, four miles south of Reffingen, in the duchy of Swabia.

ARTZBERG, a town of Germany, in the archbishopric of Austria, near the Enz, twelve miles north-east of Steyr.

ARU, or ARURO, a small island in the Indian sea, between the island of Sumatra and the peninsula of Malaysia. See ARROD.

ARURO, in Ichthyology, a name by which the Russians designate a species of mackerel found in the seas about Kamtchatka: the natives call it kare.

ARUA, in Ancient Geography, a town of Spain, in the district of Hispall, now Auida, a citadel of Andalusia on the Betic or Guadalquivier, seven leagues south of Seville.

ARVA, in Geography, a town and castle of Hungary, the capital of a county which extends to Poland, between the frontiers of Slovakia and Silesia, fourteen miles north of Rosenberg.—Also, a river of Hungary, which runs into the Waag, eleven miles north of Arva.

ARVAD, in Ancient Geography. See ARVA.

ARVALES PRAETRE, in Roman Antiquities, were priests in ancient Rome, who officiated in the temples of the Salvaranes, offered every year to Ceres and Bacchus for the prosperity of the principal fruits of the earth, viz. the corn and wine.

They were instituted by Romulus, and were twelve in number; all of them peculiar of the first families; the founder himself having been of the body. They constituted a college called collegium praestitum.

The mark of their dignity was a gilded, composed of ears of corn tied with a white ribbon; thus, Pliny says, was the first crown in use at Rome.

According to Fulgentius, Acca Laurentian, Romulus's nurse, was the first founder of this order of priests; but, in feasts, had twelve sons, who used to walk before her in procession to the sacrifice; one of whom dying, Romulus, in favour of his nurse, promised to take his place; and hence, says he, came this sacrifice, the number twelve, and the name of brother.—Pliny (lib. xvii. cap. 2.) seems to indicate the same thing, when he mentions that Romulus instituted priests of this body, after the example of Acca Laurentia, his nurse.

ARCANUS, in Conchology, a species of the Murex genus, that inhabits New Guinea. It is a coarse and heavy shell, usually of a black or brownish colour, and encircled with rings; the aperture is angulated; the tail rather long, and spire pointed. The specific character is thus defined: tail patulous; spire crowned with spinas. Ol. This is the bacinarum arcanum of Rumphius.

ARVARI, in Ancient Geography, an ancient people of India, on this side of the Ganges.

ARVAS, a town of Asia, in Hircania. Q. Curtius.

ARVIA, in Geography, one of the Lyre islands in the West Indies, subject to the Dutch; it lies near the coast of Terra Firma, fourteen leagues west of Curacoa, is uninhabited, and produces little clay besides corn and wood. N. lat. 12° 39'. W. long. 67° 57'.

ARVIA, a town of Periia, in the province of Mecran, near the cape of the same name in the Indian ocean, thirty leagues east of Mecran.

ARUBIUM, or ARUBIUS, a town of Lower Media, on the Danube.

ARUBO, a river on the coast of Guinea, west of Ildefonso gulf.

ARUBOTH, or ARABOTH, in Ancient Geography, a town or country of Palestine, in the tribe of Judah.

ARUCCI NOVUS, a town situated on the confines of Ly- mitania and Batica, placed by Antonius thirty miles from Paxi Jukas; now Murua, a small town of Portugal, near the confines of the Ardila and Guadalquivier.

ARUCCI VETUS, a small town of the Turdetani, in Batica; now Aruda, a hamlet of Andalusia, on the confines of Portugal and Shaumardia, on the river Gamo, seven leagues to the east of Aruci Novus. A mountain in its vicinity called Arcucazus derives its name from it: now la Sierra d'Aruda.
ARUCIA, a town of Illyria, in the interior parts of Liburnia. Ptolemy. According to some, it is now *Brejna*; but according to others, *Ozybunia*, a citadel of Monchica.

ARUDIS, a town of Achaia, in Syria, situate on the Euphrates, south-east of Samosata. Ptolemy.

ARUDY, in Geography, a town of France, in the department of the Lower Pyrenees, and chief place of a canton in the district of Oloron, 16 miles south of Pau.

ARVE, a famous and violent river of Savoy, which rises from the Alps, in the county of Faucigny, and runs into the Rhine near Genay.

ARVEDORUM MONTES, in Ancient Geography, mountains of India, on this side of the Ganges. Ptolemy.

ARVENIS, in Entomology, a species of *Curculio* described by Mill. Zool. Dan. It is grey, with three lines on the thorax; wing-cases rufous, and faintly tesselated. *Arvenis*, a species of Cicada found in Denmark. It is yellow; front, abdomen beneath and disks black. Mill. Gmel. &c.

*Arvenis*, a species of *Philaena* (Nymph Linna.). The wings are brown, with a transverse yellow spot in the middle; margin brown. Gmel. Fab. &c.—*Nodius brunneus* of Wien. Schmett. This insect is of the middle size, and the under-side is brown; the larva is naked, brown, and spotted with white; the lateral line is bluish; head black, with two white lines.

*Arvenis*, a species of Vespa that inhabits Europe. It has four yellow bands on the abdomen, the third of which is interrupted. Lin. Fr. Sw. Schweff. &c.

ARVERNI, in Ancient Geography, a denomination given to one of the most powerful nations of Gaul, whose country, according to Strabo, was situated between the ocean, the Pyrenees, and the Rhine. They claimed affinity with the Romans, as the descendants of Antenor; to this purpose, Lucan says of them,

*Arvernique aui latio fe dicere fratres*  
Sanguine ab illeaco populi.*

And Pliny says, that after their conquest by the Romans, their ancient liberty was preferred to them on account of their bravery. When Caesar took possession of Gaul, it was divided into two factions, the Arverni, and the *Edui*; and it is said, that the complaints preferred at Rome by the *Edui* against the Arverni, were one of the causes which brought the arms of the Romans into Gaul, under the command of Fabius Maximus and Domitius Ahenobarbus. According to Steph. Byz. they were one of the most warlike nations among the Celts. Their country was comprised in Aquitania Prima, and their capital was "Augulfonum," now Clermont, in Auvergne. N. lat. 45° 42'. E. long. 3° 5'.

ARVERON, in Geography, a river which rises in a glacier of Montanvert, in the Alps, and runs into the Arve.

ARVICITO, a town of Italy, in the kingdom of Naples, on the salt coast of Calabria Ultra, four miles south of Stilo.

ARVICOLA, in Entomology, a species of *Scarabæus* (Melolontha Fab.) found in Russia, and greatly resembling *S. Horticola*. The shield of the head is reflected; body black and immaculate. Gmel. &c.—*Oeb*. It is hairy; and the thorax is tinged with blue.

ARVIEUX, LAURENT D', in Biography, was born of a family of rank at Mariéles, in 1635; and accompanied a relation to Seyde in 1653. In this place, and in other parts of Syria and Palatine, he resided 12 years, perfecting himself in the eastern languages, and extending his acquaintance with the history, manners, and politics of the Levant. Returning to France in 1665, he was despatched as an envoy to Tunis in 1669, for the purpose of negotiating a treaty. While he was successfully conducting this business, he procured the liberation of 380 French slaves, who, upon being restored to their country, offered him a purse of 620 piastres, which he declined accepting. At Constantinople, whither he was sent in 1672, he obtained every thing he asked; and surprised the Turks by holding all his conferences without an interpreter. He was afterwards, viz. in 1675, sent to Algiers, and obtained the freedom of 230 French slaves. In 1679, he was preferred to the consular at Aleppo, where he performed various services, which recommended him so much to pope Innocent XI. that he sent him a brief for the bishopric of Babylon, empowering him to appoint another person if he himself chose to decline it. Accordingly he nominated father Pidon to the office. In 1686, he returned to Mariéles, and principally devoted himself to literary pursuits. He wrote several memoirs on Modern History, and the affairs of the Levant; and he employed the last years of his life in the study of the scriptures in their original languages, aided by the learned commentaries and paraphrases. He died in 1702, aged 67. In 1717, M. De la Rocque printed, in 12mo., a Ms. which he had left unfinished, containing an account of a journey to the grand emir of the Arabs, with a description of the manners and customs of that people; and in 1724 there appeared, "Memoirs of the chevalier D'Arvieux," with an account of all his travels, &c. in 6 vol. 12mo., collected and arranged by father Labat, a Dominican. Moret. Gen. Biog.

ARVII, in Ancient Geography, a people of Gallia Lyonensis, mentioned by Ptolemy, who are supposed, by M. d'Avrille, to have occupied that part of Gaul which corresponds to part of Maine. Some vestiges of their ancient capital have been discovered in La Cité, on the river Erve, which runs into the Sarthe.

ARVII-Suppar, an entertainment made at funerals in the northern parts of England; and arvi/ bread is the bread delivered to the poor on such occasions. Arvi has also been used for the funeral rites themselves.

ARVRACUS, in Biography, a Britsh king, flourished according to Geoffrey of Monmouth, and other native writers, in the time of the emperor Claudius. Geoffrey's account is generally deemed fabulous; however, he says, that he was the son of Kymbeline; that upon the death of his father and brother, he headed the Britons, and gained a victory over Claudius; that upon Claudius's return to Rome, he became a powerful prince, and obtained independent authority; that upon the arrival of Vespasian, he made a compromise with him, and retained his dominions; and that, having governed the kingdom in peace, his life was protracted to a good old age; that he was loved and feared even by the Romans; and that he was buried at Gloucester, in a temple he had built and dedicated to the honour of the emperor Claudius. An old tradition reports, that, in the time of this king, Joseph of Arimathea came over to Britain, and planted the gospel in this country. Biog. Brit.

in threads or tendrils, in two rows, issuing from the middle of the spadix. Stam. filaments none; each anther fertile, four-cornered. * Female flowers on the lower part of the spadix, close to each other. Cultivated piele and spadix common to them with the males; perianth proper none. Cor. none. Pelt. germ each obovate; more le none; Pigma bearded. Per. berry globular, 3-5-fid, erect. Eff. Gen. Cham. Pf. the one-leaved, corded; spadix naked above, female below, pinnate in the middle. Species : * Without stems; leaves comp. 

1. A. crinitum, hairy leaved arum: "Leaves pedate, with the lateral segments involute; spadix hairy within: spadix ramentaceous above." 1 root leaves cut into seven parts, which are lanceolate, nerves, middle part largest; the five leaves are fagitate, or five-leaved, various; petals round, fărthest at bottom, fcape very short, round; spadix as in the common arum; spadix subcylindrical, a little shorter than the spathe; club many times longer than the other parts, having remote violet-coloured hairs festooned over it. The flower smells strong like carrion, by which flies are enticed to enter, but when they would retreat, the reverberated hairs prevent them, and they are there starved to death. It is a native of Minorca, and introduced in 1777, by Mr. Malcolm. It flowers in March. 2. A. dracunculus, long leaved arum or common dracunculus, "Leaves pedate, leaflets lanceolate, entire; lamina ovate, longer than the spadix;" this has a large tuberos fleshy root, which in the spring puts up a straight stalk about three feet high. Spotted like the belly of a snake; at the top it spreads out into leaves, which are cut into several narrow segments almost to the bottom; at the top of the stalk the flower is produced, which is in shape like the common arum, having a very long fcape of a dark purple colour, flanding over with a large fcape of the same colour, so that when it is in flower, it makes no unpleasing appearance, but the flower has fštong a fcent of carrion, that few persons can endure it. It is a native of the southern parts of Europe, flowering in June, and July. Cultivated by Gerard in 1596. 3. A. draconis, short fleshy arum, or green dracunculus, "Leaves pedate, leaflets lanceolate, entire, longer than the spadix, which is shorter than the spadix;" it rises about eight or nine inches high; leaves pedicled, upright, smaller than those of the common dracunculus; leaflets broad, lanceolate, commonly in threes; spadix awl-shaped, slender, longer than both fcape and leaves. It flowers with us in June, and grows in moister places in Virginia and New England, also in Japan and China. Cultivated by Mr. Miller in 1759. 4. A. serpatum, purple fowered arum, "Leaves pedate, leaflets suboval, entire, lamina lanceolate, longer than the spadix;" the native country of this species is not known. It flowers in March, and was introduced by Mr. Malcolm in 1774. 5. A. achor Phylum, five-leaved arum; "Leaves quinate"; it grows about a foot high, fubcalyciform, upright; leaflets lanceolate, entire, smooth. A native of the East Indies. 6. A. trilophium, three-leaved green-falked arum; "Leaves ternate, lamina lanceolate, acuminate, the length of the spadix;" it is subcalyciform, with the scape arising from the petiole; fcape fapes are male, others female, from the same root; the male fcape is erec, the female has the fcape inclined. The Brazilian plant has the side leaflets lobed outwards. The Virginia plant has them only gibbous, but the ftructure of the flower is the fame in both. This plant according to Loureiro differs in China from the foregoing, in having the leaflets distinct, not pedate. It flowers in June and July, and it appears from Evelyn's calendar to have been cultivated here, in 1664. 7. A. trifolium, three-leaved purple-falked arum.
ple; extending out of the spathe, turning upwards, the flower is held bisexual. It was brought from Ceylon in 1759, and flowered in the Chelsea garden. It is here in May and June. 16. A. juglandifolium, arrow-leaved arum, Jacq. Linn. 1793. See also Brown Jam. and Sloane's Jam. t. 15. t. 1760, t. 2. Linn. Coch. 353. "Leaves fagitate triangular; the angles divergent, acute;" upright from four to six feet high; leaves large, tough, green, held at the base, divergent, all the angles acute; footstalks round, spotted with red and black; spadix long, ovate, longer than the spadix, which is club-shaped. A native of the Spanish West Indies, China, and Cochinchina. Cultivated by Miller in 1731. In Jamaica it is a better smaller Indian arum, and cultivated there for medicinal purposes as the A. giganteum. 17. A. ursinum, common arum, Curt. Loc. pl. 1. 2. 17. Woods. t. 2. 25. Smith Flor. Brit. II. def. Withe. Light. & Germ. arum without spots. 2 Common spotted arum. 3. Indian arum. "Leaves hattate, entire; spadix club-shaped." It has a tuberous white root about the size of a large potato, growing underground, sending forth on every side a great number of fiddle shapes, propagating itself by lateral tubercles; leaves radical, from two to four, shining, veiny, frequently marked with dark purple or black spots, sometimes streaked with white, standing on sheathing triangular footstalks; spadix usually green, and often spotted like the leaves; spadix varies from a yellowish green, to a true purple; berries scarlet, in a naked cluster, each containing one or two seeds. It is common in most parts of Europe, and is the only species of the genus indigenous in Britain. It is usually found under hedges, flowering in May, and ripening its berries in the autumn. 18. A. virginicum, Virginian arum. "Leaves hattate-cordate, acute; angles obtuse." It grows wild in wet places in Virginia, Carolina, Pennsylvania, &c. The savages boil the spadix with the berries, and devour it as a great dainty. 19. A. prolifidulum, Apennine arum, ariflum. Turner. Bosc. Misc. 2. 61. t. 50. "Leaves hattate, spath the dyckinate, tobiron-fodiate." A native of the Apennines. Spathe shaped like a monk's cowl; leaves on very short footstalks. 20. A. ariflum, broad-leaved hooded arum, or friar's cowl. Hort. Cliff. 437. Sabb. Hort. 2. t. 79. "Leaves cordate-oblung, aperture of the spathe ovate; spath entire and bent inwards above, below not convolute;" about a foot and a half high; leaves firm-petioled, spath shorter than the leaves; spadix curved; berries red, one-seeded. A native of the north of Europe. Dr. Smolles observes, that the Italians call this plant il lume, from the striking resemblance of its flower, when revered, to a lamp with its wick. Cultivated by Gerard in 1596. 21. A. pilum, painted arum. "Leaves cordate, painted with coloured veins;" root-leaves three or four, petioled, painted on the upper surface with white veins; spath feathery, radical, united at the base, green, except at the top where it is purplish; spadix with an ovate-oblong, dark purple club; germa nobilis, green, anthers immediately above them; upper filamenta remote. See Supp. Plant. 410. 22. A. cornutum, Rumpl. Amb. 5. 312. t. 108. "Leaves ovate-oblung; spath febrabrum." A native of the East Indies. 23. A. tenaxfollum, grafs-leaved arum, or narrow-leaved friar's cowl. "Leaves lanceolate; spadix bristle-shaped, declinate." This species usually has five or six shining leaves resembing those of several other plants; spadix long, pointed, ribbed, while the spadix seven inches long, purple, with green points. It grows wild about Rome, Montpellier, also in Dalmatia and the Levant. We learn from Lobel that it was cultivated here in 1570. 24. A. canellifolium, Supp. Plant. 410. "Leaves lanceolate, veinless;" leaves few, two feet long, resembling those of canna; scape very short; spadix rather obtuse, red without. white within. In the spadix there is no space between the flaments and pistil. A native of Surman, on trees, parasitical. "Straw". 25. A. arborescens, tree-arum, Plum. Amer. 41. t. 51. g. & c. "Narly upright, leaves lanceolate ovate." It rises to the height of five or six feet, with a green jointed flake, as large as a walking-cane. Leaves placed irregularly at the top of the flake in a clump; they are oblong, of a light green colour, and sometimes punctured with holes, as in the aconitum perforatum. On the side of the flake, between the leaves, the flowers appear with a long spadix of a pale green colour, marked with white spots. The female flowers and flabices are ranged only on one side of the spadix, a circumstance which distinguishes it from all its congeners. It is a native of the Sugar Islands, and the warmer parts of America. Cultivated in 1759, by Miller. The whole plant abounds with an acrid juice, so that if applied to the tongue, this organ swells so much as to lose the power of articulation, and hence the name of dumb-cane. In this way it is said to have been used as a punishment for negroes. The juice is sometimes employed to allay the itch in promoting the granulation of sugar. 27. A. hederaesce, ivy-leaved arum, Jacq. Amer. t. 152. piet. t. 229. Miller's fig. 225. "Radicate; leaves cordate, oblong, acuminate; petioles round." A native of the West Indies. 28. A. lingulatum, tongue-leaved arum, Brown. Jam. 333. n. 12. Sloane's Jam. t. 77. t. 27. f. 2. 3. "Creeping; leaves cordate lanceolate; their footstalks edged with membranes." It readily climbs trees, and becomes more succulent and luxuriant towards the top. A native of the West Indies. 29. A. aurantium, ear-leaved arum, Brown. Jam. 351. n. 2. Sloan. 1. 169. "Radicate; leaves ternate; those on the side one-leaved." A climbing plant, sending out roots from the stems and branches; leaves large heart-shaped, having three lobes or ears; flowers included in a large spadix. A native of the West Indies. Cultivated on all the hills of Jamaica, climbing the trees, and is the only arum with compound leaves in that island. Cultivated by Miller in 1748. 30. A. indicum, Indian arum, Linn. Coch. 536. Rumpl. Amb. 6. t. 106. "Narly upright; leaves ovate; bifid at the base, rounded; spadices axillary;" stem five feet high, as thick as a man's arm; leaves very large, with many transverse parallel ribs, on subulate, erect, fimbriating footstalks; spathes axillary, small, acute, fimbriated, convolute; spadix tapering, erect; berries pale, small. A native of the East Indies. Cultivated in Cochinchina, where the spadix is boiled and eaten. 31. A. cucullatum, cowled arum, Linn. Cochinch. 356. "Upright; leaves petalate, cordate, with the ears cowled;" stem two feet high; leaves acuminate, on long round footstalks; spadix short, almost wholly covered with florets. A native of the suburbs of Canton. 32. A. spiralis, spiral arum, Retz. Obif. I. 30. n. 104. "Stemless; leaves lanceolate; spadix spiral phellid;" leaves acute, naked, with the footstalks dilated at the base, membranaceous, veined. A native of Tranquebar in the East Indies, discovered by König. This species ought to have been placed in the second division. It may here be observed, that in the arum, every pith and every anther is to be considered as a distinct floret, consequently it ought to be removed to the clafs monocaia; and this has been done by Schwcrber and Withering. Thunberg and Swartz place it in the clafs polyandra. We see no advantage however in removing it from the clafs gynandra, where it was left by the great author of the sexual system.
Medicinal qualities. Common arum is the only species of this genus included in the Materia Medica; and its use is confined to the root, which in a recent state is lachrymcent and extremely acrimonious, in so much that when cut into slices and applied to the skin, it has been found to blister the part; and upon being chewed, it excites an intolerable sensation of burning and pricking in the tongue, which continues for several hours. This acrimony, however, is gradually lost by drying, and may be so completely extinguished by the application of heat, as to leave the root a bland ferruginous aliment. Its medicinal efficacy, therefore, refutes wholly in the active volatile matter. It is a very powerful stimulant, and by promoting the secretions, may be properly employed in cachectic and chronic diseases, in rheumatic affections, and in various complaints of phlegmatic, torpid constitutions; but more especially in a weakened or relaxed state of the stomach, abounding with viscid mucus. If the root is given in powder, great care should be taken that it be young and newly dried, when it may be used in the dose of a scrofula or more twice a day; but in rheumatics and paralytic affections, requiring the full effects of this medicine, the root should be given in its recent state; and to cover the insufficient pungency it discovers on the tongue, Dr. Lewis advises us to administer it in the form of emulsion with gum arabic and spirits, increasing the dose from ten grains to upwards of a scrofula, three or four times a day; in this way, he says, "it generally occasioned a sensation of slight warmth about the stomach, and afterwards in the remotest parts, manifestly promoted perspiration, and frequently produced a plentiful sweat." As several obtrusive rheumatic pains were removed by this medicine, it is recommended to further trial. See Woody. Med. Bot. p. 75.

Propagation and Culture. Species 2. is very hardy, and will grow in any soil or situation; autumn is the proper time for transplanting it. 3. should have a moist, shady situation; it is with difficulty preferred in gardens. 6, 7, 8. are propagated by offsets; they will live in the open air, if planted in a sheltered situation, or if the surface of the ground be covered with tan. 9, 10, 11, 12, 13, 14, and 16. are to be propagated by offsets planted in pots, and plunged into a hot-bed, and after having acquired sufficient strength, kept upon shelves in a dry stove. 15. requires the tan-bed or bark-stove. Common arum ought to be transplanted soon after the seeds are ripe. 19, 20, 21. These multiply fast by offsets, and should have a shady situation. 25, 26, 27, 28, 29. are propagated by cutting off the shoots, into lengths of three or four joints, which must be laid to dry six weeks or more; for if the wounded part be not perfectly healed over before the cuttings are planted, they will rot and decay; they should be put in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tan, being careful that they have little wet till they have made good roots, when some of them may be placed in a dry stove, and others plunged in the tan-bed, in the bark-stove, where they will produce more flowers. They are tender plants, and must be constantly kept in the stove. See Martyr's Miller's Diet.

ARUM Ethiopticum. See CALLA.

ARUM Sardonicum. See DRACONIUM.

ARUMATIA, in Entomology, a name given by Marevanne, in his Natural History of Brazil, to the species of Mantis called Gigas by Linnaeus.

ARUN, in Ancient Geography, a village of Palestine, in the neighbourhood of Samaria.

ARUS, in Geography, a river of England, which runs into the sea at Little Hampton in Sussex, famous for its red mullets.

ARUNC. See ARUNCI.

ARUNC, in Entomology, a species of Cicada, described by Scopoli. This insect is entirely of a ferruginous color, with brown eyes.

ARUNCUS, in Zoology, a species of Rana or toad, that is larger than the common frog, but nearly of the same color. It inhabits Chili; and is described by Molina. All the feet of this kind are palmated, and the body warted. Dr. Shaw specifically defines it thus: R. corpore verucofo pedibus omnibus palmatis. Gmelin seems to think the palmated feet are a sufficient criterion by which it may be distinguished, "pedibus omnibus palmatis." Gmel.

ARUND, in Botany. See SPHILA.

ARUNDA, in Ancient Geography, a town of Spain, in Betic, situated on the Annus or Guadiana; now said to be Ronda, in the province of Granada, on the confines of Andalusia. N. lat. 36° 26'. W. long. 5° 49'.

ARUNDEL, THOMAS, in Biography, archbishop of Canterbury in the reigns of Richard II. Henry IV. and Henry V., was the second son of Robert Fitz-Alan, earl of Arundel and Warren; and at the age of twenty-one years, in 1374, promted from the archdeaconry of Taunton to the see of Ely, and embraced with the usual solemnities in 1375. While he held this see he almost rebuilt the episcopal palace in Holborn, and, besides other donations, presented it with a table of massive gold, enriched with precious stones, which he had bought of prince Edward for three hundred marks. Upon his translation to the archbishopric of York, in 1388, he expended a large sum in building an archiepiscopal palace, and in furnishing the church with several pieces of silver-gilt plate, and other ornamentals. After his advancement to the see of Canterbury, in 1396, he was a great benefactor to that church; for he built the southern tower and great part of the nave, and gave it a ring of five bells, called "Arundel's ring," several rich velments, a mitre enhaed with jewels, a silver-gilt crosier, a golden chalice for the high altar, and another to be used only on St. Thomas Becket's day. He held the office of lord high chancellor of England, with some interruptions, from the year 1386 to 1396; and in 1393, he removed the courts of justice from London to York: partly with a view of mortifying the pride and insolence of the inhabitants of London, and principally for the purpose of enroaching those of the latter city, over the diocese of which he presided: but after the experience of one or two terms, the courts returned to their first and more convenient station. Soon after his accension to the metropolitical see, he revived an old institution, by which the inhabitants of the several parishes of London were obliged to pay to their rector one half-penny in the pound out of the rent of their houses.

The interference of archbishop Arundel in the civil affairs of the kingdom, terminated in his imprisonment and exile. Have taken an active part in the first attempt that was made to deliver the nation from the oppression of Richard II. by obtaining a commission to the duke of Gloucester, his brother the earl of Arundel, and others, in which commission he himself was included, for governing the kingdom, he was impeached by the commons, sentenced to be hanged, and ordered to leave the kingdom within forty days, on pain of death. Pope Boniface IX. seizing this opportunity of extinguishing his displeasure against the king and parliament of England, gave Arundel a cordial reception at Rome, nominated him archbishop of St. Andrews, and promised him other preferments. The king's remonstrance, however, prevailed with his holiness to withhold the grant of the further favours which he had intended to confer on the exiled prelate. The dissatisfaction of the people of England with the
the government of Richard II. increasing, archbishop Arundel had an opportunity of returning to his country, and regaining his dignities. Whilist he was in Britain, in his way home, he was employed to solicit Henry duke of Lancaster, who had been banished by Richard, to return from France, and assume the crown; and having obtived the duke's snerules, the accesion of Henry IV. was accompanied with the restoration of Arundel to the metropolitan fee: and he had the pleasure of placing the crown on the head of his new master. At an early period of this reign, a design was formed of feizing the revenues of the church, in order to supply the exigencies of the public serviee. In a parliament held at Caenbury in 1421 or 1425, and called "Parlamentum Indoctum," this measure was proposed for execution. Arundel was present, remonstrated against the proposal, and urged that "the clergy were at least as serviceable to the king by their prayers, as the laity by their arms; and that the kingdom could not expect to prosper as long as the prayers of the church were depifed." His spirited exertions prevented, for the present, the further prosecution of this violent measure. The archbishop having thus rescued the temporalities of the church from depredation, manifested equal zeal in preserving inviolate its internal constitution. He exerted himself for restraining the progres of those new opinions, with regard both to doctrine and worship, which were disseminated by the Lollards or Wickhiffites; and as the university of Oxford was beginning to be infected with these opinions, he appointed visitors to examine and report the state of that seminary. He proceeded, in consequence of the information he received from the inquisitorial committee, delegated andfunctioned by his authority, to perecute, with an absurdity and cruelty which nothing but the ignorance and bigotry of the times can in any degree extenuate, those who were found chargeable with this new heresy. Upon the authority of the act for burning heretics, which passed in the reign of Henry IV. and which remained for a long time a disgrace to our statute books, a Lollard was condemned to the flames in 1413; and in the beginning of the reign of Henry V. Sir John Oldcastle, lord Cobham, a principal patron of the Lollards, was indicted by the priuate, convicted of the same, and sentenried to the flames. He had some time before attempted to procure an order from the pope to dig up the bones of Wickhiff, which was refused; and he actually procured a synodical condnction, which prohibited the translation of the scriptures into the vulgar tongue. It is said that whilst the archbishop was pronouncing sentence of excommunication and condemnation on lord Cobham, he was seized with an inflammation in his throat, which prevented his taking any further part, and soon terminated in his death, Feb. 20th, 1415. The death of the prelate, as to the time and manner of it, was attributed by the Lollards to the immediate interception of God: but however superstitious such judgments may be deemed in the present enlightened age, the intolerance and cruelty of the archbishop will be universally condemned, and they will entail just reproach on his name and character as long as any records of him remain. Biog. Brit.

ARUNDEL, in Geography, a corporation and borongh town of Englang, in the county of Suffie, seated on the river Arun, whence its name. It sends two members to parliament; the corporation consists of a mayor and twelve burgesses; it has two markets weekly, on Wednesday and Saturday, and is distant from London fifty-one miles. It has a harbour which admits vessels of one hundred tons burthen, and which was repaired in 1733. The castle, which stands on the north-east part of the town, was conferred by the empress Maud on William Ic Albano, as a recumbence for his defence of it against king Stephen. It descended to the Norfolk family in 1579, and the present duke has expended large sums in repairing and adorning it. This place belongs the peculiar privilege of conferring the title of earl on its politician without any patent or creation from the crown; and Arundel is the premier cardinal in England. N. lat. 50° 45'. W. long. 0° 26'.

ARUNDEL, a township of America, in York county and district of Maine, situate between cape Porpoise and Biddeford on the north-east, on the river Saco, twenty-one miles north-east from York, and ninety-six north-east from Boston. It contains 1458 inhabitants.

ARUNDELLIAN MARBLES, MARMORA ARUNDELIANA, or Oxford Marbles, called also Parian Chronicle, are supposed to be ancient stones, wherein is inscribed a chronicle of the city of Athens, engraven in capital letters in the island of Paros, one of the Cyclades, 264 years before Jesus Christ. They take their name from Thomas earl of Arundel, who procured them out of the East, or from Henry his grandson, who presented them to the university of Oxford.

These marbles, and other ancient relics, were purchased in Asia Minor, Greece, and the islands of the Archipelago, by Mr. William Petty, who was employed, in the year 1624, by Thomas earl of Arundel, in making such collections for him in the East. They were brought into England about the year 1627, and placed in the gardens belonging to Arundel house in London. Soon after their arrival, they excited very general curiosiuy among inquisitive and learned persons; and Sir Robert Cotton engaged Mr. Selden to explain the Greek inscriptions. Accordingly Selden and two of his friends, Patrick Young, or Patri- cus Junior, and Richard James, immediately undertook the business; and in the following year Selden published a small volume in 4to, under the title of "Marmora Arundeliana," containing about thirty-nine of the inscriptions, with annotations. During the civil wars, Arundel house was often defaced by its illiberal proprietors, and some of the marbles were defaced or broken, and others stolen or used for the ordinary purposes of architecture. The chronological marble, in particular, was broken and defaced; and the upper part containing thirty-one epochs, is said to have been used in repairing a chimney in Arundel house. In the year 1667, the Honourable Henry Howard, afterwards duke of Norfolk, the grandson of the first collector, presented these curious remains of antiquity to the university of Oxford; and as Mr. Selden's work was become scarce, bishop Fell engaged Dr. Pridius, dean of Norwich, to publish a new edition of the inscription, which was printed at Oxford in 1676, with additional notes and translations, under the title of "Marmora Oxoniensia, ex Arun- deliana, Seldeniana, et aliis confecta." In 1731, Mr. Mat- tair, favoured the public with a more comprehensive view of these marbles than either of his predecessors; and in 1763, Dr. Chandler published a new and improved copy of them, in which he corrected the mistakes of the former editors, and supplied the became in force of the inscriptions, particularly those of the Parian chronicle, by many ingenious conjectures. These marbles, in their perfect state, contained a chronological detail of the principal events of Greece during a period of 1318 years, extending from the commencement of the reign of Croesus in the year before Christ 1582, to the close of the archonate of Diosgenus in the year before Christ 264. But the chronicle of the last 90 years is lost, so that the part now remaining terminates with the archonship of Dio- timus, 354 years before Christ; and in this fragment the inscription
ARUNDINO, in Botany, Reed (supposed to be derived from arundo, because it soon becomes dry). Lin. g. 93. Schreb. 124. Jaff. 32. Clus. triandra digynia. Nat. Ord. Gramineae or Grasses. Gen. Char. Cal. glume one, or many-flowered, two-valved, crest: valves oblong, acuminate, awnless; one shorter. Cor. two-valved; valves the length of the calyx, oblong, acuminate; from their base arises a lamento, almost the length of the flower; stam. two, filaments, very small. Stamin. filaments three, capillary; anthers forked at both ends. Pile, gamopodium; file two, capillary, minute, villose; stigmas simple. Per. none; corolla adnate to the seed without gaping; seed sanguine, oblong, acuminate at both ends, furnished with long down (pappus) at the base. Ef. Gen. Char. Cal. two-valved; florets congregated, suffruticose.

Species. 1. A. lamba; bambu or bamboo-cane; A. bambus. Lour. Coccin. 56. A. arbor, Bauh. Pin. 18. -

ARUNDINACEA, in Conchology, a species of Sabella found in rivers in some parts of Europe. It is subconic, open at both ends, and composed of fragments of the bark of reeds placed on each other. Gmelin, &c.

ARUNDINACEAE, in Entomology, a species of Aranea that is found among reeds. The abdomen is sub-globose, and white spotted with pale brown. Linnaeus. Bl. Succ.

ARUNDINACUS, in Ornithology, a species of Turdus that inhabits reedy marshes of Europe, and is called La Ronchelle, or Roucarrle, by Buffon, Buffon, and other French writers. Ray and Willughby named it Junco, or greater reed sparrow; and Dr. Latham, the reed thrush. This bird is rather larger than the common lark; the colour is ferruginous brown; white with a fewaceous tinge beneath; quill feathers brown, reddish at the end. Gmelin, &c. Of this species Gmelin enumerates three varieties; viz. β, Turdus arundinaceus urupigio caudaque rufos; var. with rufous rump and tail. γ. Turdus arundinaceus supra fignitis nigri varius; var. varied above with black arrow-shaped spots. δ. Turdus arundinaceus minutus, supra e luteoscente virens, tetricricibus alarum ferruginis; var. small, above yellowish green, wing ferruginous. In the southern parts of Russia, and in Poland, this species, it is said, is very common. It makes its nest on the willy hillocks among reeds and rushes, or according to Cramer, suspends the nest between two or three reeds which are fastened together to support it. The female lays five or six eggs; and the male, it is likewise observed, is perpetually flitting while the female is sitting; and hence it has acquired the name of water nightingale.

ARUNDINETI, in Entomology, a species of Tipula described by Linnaeus and Fabricius. It is whitish; antennæ villose; eyes black. A native of Europe, and inhabits reedy marshes.

ARUNDINIS, a species of Phalæna (Novius linn.) that lives on the flanks of reeds. It is an European kind; the wings are cinereous with black dots, and marginal haloes of the same colour; and the wings beneath marked with a central brown spot. Fabricius, &c.

ARUNDINIS, a species of Arphe, that lives on the leaves of arundo epigea. The body is green; head and thorax brown, and covered with white dots. Fabricius, Gmelin, &c.

ARUNDINO, in Botany, Reed (supposed to be derived from arundo, because it soon becomes dry). Lin. g. 93. Schreb. 124. Jaff. 32. Clus. triandra digynia. Nat. Ord. Gramineae or Grasses. Gen. Char. Cal. glume one, or many-flowered, two-valved, crest: valves oblong, acuminate, awnless; one shorter. Cor. two-valved; valves the length of the calyx, oblong, acuminate; from their base arises a lamento, almost the length of the flower; stam. two, filaments, very small. Stamin. filaments three, capillary; anthers forked at both ends. Pile, gamopodium; file two, capillary, minute, villose; stigmas simple. Per. none; corolla adnate to the seed without gaping; seed sanguine, oblong, acuminate at both ends, furnished with long down (pappus) at the base. Ef. Gen. Char. Cal. two-valved; florets congregated, suffruticose.

Species. 1. A. lamba; bambu or bamboo-cane; A. bambus. Lour. Coccin. 56. A. arbor, Bauh. Pin. 18. -

to twenty feet in height, hard, almost woody, jointed or knotted, with diaphragms. Above each joint a leaf embracing the culm, with a yellow sheath, two feet long, and three inches broad. The top of the culm ends in a point, the leaves rolling in the form of a cone; panicle a foot and a half long, erect, many flowered. Number of flowers in the calyx variable, often two, but more commonly three. It is a native of the four of Europe, Siberia, Egypt, Cochinchina, &c. It was cultivated in 1658, in the Oxford botanic garden, and flowers here in July and August. The canes are brought to us from Spain and Portugal, for the use of weavers, and for making fishing-rods. There is a variety of A. donax, with striped leaves, noticed by Miller and others. 3. A. phragmites, common reed. Smith Flor. Brit. 144. Huds. 53. With 166. Relh. 51. Eng. Bot. 421. "Calixes five-flowered, panicle loose;" root perennial, creeping; culms annual, erect, simple, six feet high, round, jointed, leafy, smooth, white within; leaves lanceolate, acuminate, spreading, villous, rough at the edges, under-neath very smooth and glaucous; sheaths cylindric, villous, smooth; spikelets very short, hairy on both sides; panicle erect, diffused, much branched; glumes of the calyx very unequal, lanceolate, acute, the larger three-nerved; florets from four to six, surrounded at the base with a silky wool; interior glume ciliate, half the length of the exterior; seed covered with the inarticulate corolla. A variety of this species with variegated leaves is noticed by Relhan. It is common in ditches, standing waters, and on sides of rivers, flowering from July till September. The common reed is used for tethers in gardens, also as a foundation for plattier in eclusions, and for various other purposes. 4. A. epiygos, wood reed. Eng. Bot. 1. 147. Smith Flor. Brit. 142. A. calamagrostis, Huds. 54. Relh. 52. Lightf. 106. calamagrostis lanceolata, With. 122. gramen arundinaceum paniculatam, florid, majus, Smith. Calam. epiygos, Eng. Bot. 1. 147. Smith Flor. Brit. 142. 5. A. calamagrosa, a small reed, Eng. Bot. 423. Flor. Dan. 182. Smith Flor. Brit. 146. 182. A. epiygos, Huds. 54. Relh. 51. Calam. epiygos, With. 122. Cal. minor glumis rufus & viridans, With. 122. Huds. Relh. 51. Cal. epiygos, With. 122. "Calixes one-flowered, longer than the corolla; panicle erect, leaves lanceolate;" root creeping; culm nearly as high as the preceding, but weaker, and often branched at the base; leaves lanceolate acuminate, nervate, underneath glaucous and rough at the edges; sheaths smooth, inflated; spikelets lanceolate, many times divided, noded on both sides; panicle, erect, rough, spreading; flowers in clusters all on the same side, nodding; glumes of the calyx nearly equal, lanceolate, acute, nervous, rough on the keeled part; floret solitary, much shorter than the calyx, white, membranaceous, inserted in a spongy substance longer than the petals, often cloven at the apex; near the base, and from the back arises an awn, which is jointed, and nearly the length of the wool. We are told by Mr. Smith, that the wool and awn here noticed, were, from an error, not represented in the figure referred to in Eng. Bot. It grows in flooded ditches and wet meadows: and flowers in July. 5. A. calamagrosa, small reed, Eng. Bot. 423. Flor. Dan. 182. Smith Flor. Brit. 146. 182. A. epiygos, Huds. 54. Relh. 51. Calam. epiygos, With. 122. Cal. minor glumis rufus & viridans, With. 122. Huds. Relh. 51. Cal. epiygos, With. 122. "Calixes one-flowered, longer than the corolla; panicle erect, diffused; flowers scattered, erect; leaves linear." Smith. Root perennial, fibrous, scarcely creeping; culm erect, three or four feet high, round, very smooth, leafy, much flatter than the preceding, and sometimes branched; leaves linear, acute, narrow, somewhat involute, pale green underneath, rough above, sometimes hairy; sheaths long, close, inflated, almost smooth; spikelets lanceolate, often lacerated, decurrent, smooth on both sides; panicle very branching, diffused; flowers scattered, erect; glumes of the calyx of a chestnut or purple colour, nearly equal, lanceolate, acute, keeled, rough on the back, scarcely nervate; florets solitary, much shorter than the calyx, white, torn at the apex, included in wool longer than the petals, a small awn at the apex, between the divisions of the larger petal. It grows in grooves, hedges, and wet situations, flowering in July. 6. A. arenarius, low reed, Marram, Smith Flor. Brit. 148. Huds. 54. Mart. Flor. Ruph. 142. Dickf. II. S. Facs. 12. 5. Flor. Dan. 1. 917. Calamagrostis arenaria, With. 123. "Calixes one-flowered, longer than the corolla; panicle spicate; flowers erect, awnless; leaves rolled inwards, pungent." Root perennial, creeping, jointed, spreading itself to a great extent; culm about three feet high, stiff, round, smooth, articulated, leafy; leaves erect—petent, rigid, turning inwards, sharply pointed, glaucous, smooth on the under side, on the upper furrowed; sheaths nervous, smooth; panicle erect, spike-like, with short erect branches; flowers lanceolate, acute, compressed, keeled, obtusely three-nerved; florets solitary, rather shorter than the calyx; glumes lanceolate, unequal, nervous, with a rough keel, the outer broadened, crossed at the apex, and embracing the other; wool about one-third the length of the floret. Common on the sea-coasts, growing in the sand. By means of its extensive creeping roots, it is of great use in giving stability to driving lands which gather about it in hills or banks. It is planted about Wells in Norfolk to aid in repelling the sea; a purpose for which it seems peculiarly well adapted. 7. A. colorata, Canary reed-grass. Soland. in Ait. Hort. Kew. Smith Flor. Brit. 147. Phalaris arundinacea. Sp. Pl. Huds. Relh. Flor. Dan. 259. Cal. variegata. With. 124. "Gramen arundinaceum accrorum;" gluma notata, Linn. Syn. 405. Phalaris arundinacea gluma efferens. Linn. Syn. 405. Phalaris arundinacea; B. puctata. Sp. Pl. 80. "Calixes one-flowered, equal to the corolla; panicle erect, glomerate; flowers inclining to the same side, awnless; leaves flat." Root perennial, creeping, feathery, or turfy; culm erect, three to five feet high, round, leafy, epilated, smooth, furnished with many joints; leaves spreading, lanceolate, fringed, with a smooth margin on both sides, on the variety B. glaucous, in E. variegated; sheaths nervous, somewhat inflated, smooth; spikelets short, obtuse; panicle erect, branched, in lores, branches angular, rough; flowers rolled together, inclining to one side, variegated with white and purple; glumes of the calyx equal, compressed, keeled, three-nerved; florets solitary, the length of the calyx, lanceolate, rather compressed, awnless, furnished with two erectulous penciled substances at the base; glumes or valves hairy, equal in length, but the exterior broader than the other. It grows in flagrant waters, and on the banks of rivers. The variety E. cultivated in gardens, and called ribbon-grass, was also found wild near Cambridge by Mr. Relhan. The following are new species. 8. A. confus. Forti. Fl. Aul. n. 48. "Calixes one-flowered; panicle loose, from erect spreading; awn of the outer petal reflex, and very long." A native of New Zealand. 9. A. agrestis. Linn. Cochinch. 57. Arundaria phlomis. Rumph. Amb. I. 56. v. 7. 1. 4. "Flowers six-flamed; panicle spicate; spikelets allied; lower branches of the culm very spiky; calixes one-flowered." It grows to the height of thirty feet, and to the thickness of a man's arm. A native of Cochinchina, growing on mountains and dry desert places. 10. A. nitida. Linn. Cochinch. 57. arundinaria for. Rumph. Amb. I. 56. v. 7. 1. 4. "Flowers six-flamed, panicule erect, contracted; spikes long, imbricate; culm very even, unarmed; calixes one-flowered." This is rather higher and thicker plant than the A. agrestis. It is cultivated in Cochinchina, and being cut into long pieces, it is used for weaving into hats, coffers, baskers, and a variety of utensils, which are very elegant. 11. A. multiples. Linn. Cochinch. 58. Arundaria,
Abor, &c. Rumph. Amb. 1. c. 1. t. 1. "Flowers fix-fla-
mended: spikes intermingled; spikelets in whorls; culm divid-
ed; calyxes one-flowered." Culm perennial, twelve feet
high, with very long internodes; leaves linear-lanceolate.
A native of the northern provinces of Cochinchina. 12. A. bengalensis, Retz. Obs. 5. 20. n. 45. "Calyxes two-flowered,
panicle erect, with three flowered pedicels." Culms lofty,
thick, leafy; leaves two feet long. A native of Bengal.
13. A. pijfentoria. Lour. Cochinch. 55. "Calyces one-flower-
ed, spike terminating, culm branched, leaves minute." It
rises eight feet, with a perennial culm; knots approximating;
leaves lanceolate-linear. A native of Cochinchina. Being
plunged and tapering towards the end, it is well adapted for
one-flowered, spikelets in bundles, compound; spikelets linear;"
calm perenniel, eight feet high; knots distant; flowers
dioecious. A native of Cochinchina, in woods.

Propagation and Culture. The bamboo must be preferred
in a warm climate, and as the roots spread very wide, it
should be planted in a large tub, filled with rich earth;
this must be plunged into the hot-bed in the dark floor;
and must have plenty of water. When the tub decays,
the plant be permitted to root in the tan, it will grow to
a larger size; but then care must be taken, when the bed
is refixed with new tan, to leave a sufficient quantity
of the old tan about the roots. It may be propagated
by slips from the roots, taken off in the spring. 2. The
cultivated reed will bear the cold of our winters in the open
ground, provided it be planted in a soil not too wet; and
if the winter should prove very severe, a little mulch be
hid over the roots. The flem dies in autumn and a new
one rises the succeding spring, which will grow to ten or
twelve feet high during the summer, if properly supplied
with water in dry weather. It is very proper to be inter-
mixed with trees and shrubs, where it will have a pleasing
effect in adding to the variety. It is propagated by parting
the roots in the spring before they begin to shoot. It never
flowers in England. The variety with variegated leaves is
more tender, and must be sheltered in this country during
the winter. See Martyn's Miller's Dict.

ARUNDO. See Agrostis, Androphogon, Cench-
rus, Melica, Spinifex, and Zizania.
ARUNDO Florida et India. See Canna.
ARUNDO Rotang. See Calamus.
ARUNDO Saccharifera. See Saccharum.
ARUPINUM, Arufium, or Arufium, in Ancient
Geography, a town of Liburnia, being one of the four
which were occupied by the Japodes or Japydes, according
to Strabo.

ARURA, in Antiquity. See Arura.
ARURA, in Middle Age Writers, denotes a field ploughed
and sown.

ARUSINI CAMPI, in Ancient Geography, erroneously
written by Chucerius Taurufinii, plains in Lucania famous
for the last battle fought between Pyrrhus and the Romans.
Pyrrhus being at Tarentum, and hearing that the two
confils, Curius Dentatus and Cornelius Lentulus, had
divided their forces, the one invading Lucania, and the other
Sannium, divided a chosen detachment of his army into
bodies, and marched with his Epirots against Dentatus,
in hopes of surprizing him near Beneventum. The consul
prepared to meet him, repulsed his van-guard; and having
thus far succeeded, marched into the Arufian fields, and
drew up his army in a plain, which was wide enough for
his troops, but too narrow for the Epirot phalanx to act
with its full effect. However, the king's engeneers to try
his strength and skill induced him to engage, notwithstanding
this great disadvantage. Upon the first signal, the action
began, and as one of the king's wings gave way, victory
seemed to incline to the Romans. But the wing under
the king's immediate command repulsed the enemy,
and drove them to their intrenchments. Dentatus, perceiving
that this advantage was partly owing to the elephants,
commanded a corps de reserve, posted near the camp, to
advance, and to attack those animals with burning torches;
which so terrified them, that they turned about, broke into
the phalanx, and occasioned the utmost disorder. The
Romans, availing themselves of the confusion, charged with
such fury, that the enemy were entirely broken and defeated.
Upon this disaster, Pyrrhus retired to Tarentum, leaving
the Romans in full possession of his camp; which they so
much admired, that they made it a model which they followed
ever after. Pyrrhus, after this defeat, determined to leave
Italy, and prepared for setting sail for Epirus, where he
at length arrived with 8000 foot and 500 horse, regretting
that he had spent six years in Italy and Sicily to no pur-

ARUSIS, a town of Aisia, in the interior part of Media.

Ptolemy.

ARUSPICES, an order of priests among the Ancient
Romans, who foretold things to come, chiefly by inspecting
the entrails of beasts which were killed in sacrifice. They
also took their observations from the victims before they
were cut up; from the flame that used to rise while they
were burning, and from the flour, bran, frankincense,
wine, or water, used in the sacrifice. The word seems more
properly written baruspices; as being derived from barus,
which signifies the entrails of victims; and aspicer, to view
or consider; others derive aruspices, ab aris alpientis, from
their looking on the altar. These diviners were all at first
taken from Hetruria, where their art was in great repute;
but afterwards the senate ordered twelve of the sons of the
chief men of Rome to be sent into that country to acquaint
themselves with the rites and ceremonies of the Etruscan
religion, of which this science was the chief part; the
ceremony, however, of consulting the entrails of victims
was practiced among the Greeks before it was introduced
into Hetruria. An influence of it occurs at the battle of
Platea; and it was recurred to on other occasions among
the Athenians. But the Etruscans were perhaps the first
who reduced it to an art, and established the rites by which it
was conducted. The doctrine or discipline of the aruspices
was formed into a precise art. called aruspicia. Catu, who
was an augur, used to say, he wondered how one aruspex
could look at another without laughing in his face; by which
we learn what opinion he had of the folly of the aruspice.
Conflantius passed several laws against the aruspices; and
though he allowed the Pagans to consult them, he for-
bade their entering the houses of private persons, upon
pain of being burnt alive, and such as received them were
to forfeit their estates, and be banished for life. His inten-
tion was to prevent all private sacrifices and consultations,
and by one law he obliged those who consulted the ar-
uspices to send their answers to his secretary.

ARUSPICI LIBRI, a kind of sacred writings among the
ancient Hetrurians, wherein the laws and discipline of the
aruspices were described. They were also called rituales,
sometimes fulguroles libri, as directing how to take indica-
tions from thunder, lightning, &c.

ARVUM, in Ancient Agriculture, properly denoted ground
ploughed but not sown. Though the word is also some-
times extended to all arable or corn land, in contradistinc-
tion from pasture.

ARWACAS BAY, in Geography, lies on the east coast
of South America, and has the river Amona to the west. It has a good road for large ships, well sheltered from south and westerly winds, but exposed to the north.

ARWANGEN, a town and capital of Switzerland, in the canton of Berne, seated on the Aar, 12 miles east of Soleure.

ARX, in the *Ancient* Military Art, a town, fort, or castle, for the defence of a place. The arx in ancient Rome, was a distinct edifice from the Capitol, though some have confounded the two. According to Varro, the arx, properly speaking, was a place on the highest part of the Capitoline Mount, stronger and better fortified than the cella, with towers and pinnated walls; in which was also the temple of Jupiter Capitolinus. Struvi Syn. Ant. Rom. c. ix. p. 522.

Arx also denoted a consecrated place on the Palatine Mount, where the augurs publicly performed their office. Some will have the arx to have been the augural temple; but Varro expressly distinguishes between the two.

Arx was particularly used for a public place in Rome, for apart for the operations of the augurs. In this sense, arx amounts to the worse as in another called augural, and auguratorium, and in the camp augures. Out of this arx it was that *fausta* or heralds, gathered the drafts used in the ceremony of making leagues and treaties. Liv. i. c. 24.

ARYTENONEIDES CARTILAG, in *Anatomy*, a cartilage situated at the back part of the larynx. There are two cartilages which bear this name.

ARYTENOIDEUS MUSCULUS, is subservient to the motions of the above mentioned cartilages. For an account of both these articles, see *Larynx*.

ARYTHIMUS, or *Arhythmus*, formed from the privative *a*, and *rhythmus*, modulus or measure, in *Medicine*, is used by some for a linking or failure of the pulse, so that it cannot longer be felt: but it more properly denotes an irregularity, or want of due order and proportion of the pulse.

ARZAC, in *Geography*, a town of France, in the department of the Lower Pyrenees, and chief place of a canton in the district of Orthez, five leagues north of Pam.

ARZACHEL, or *Arzachel*, in *Biography*, a Spanish mathematician, lived in the tenth or eleventh century, and wrote a book on astronomy, entitled "Observations de Obligaments Zodiaca." Volinus.

ARZAMAS, in *Geography*. See *Arzamas*.

ARZANNO, a town of France, in the department of Finisterre, and chief place of a canton in the district of Quimperlé, five miles E. N. E. from Quimperlé.

ARZBERG, a town of Germany, in the circle of Frankonien, and principality of Barst, seven miles east of Wombach.

ARZENGAN, or *Arzengan*, a town of Afsic Turkey, in the province of Abdullah, eighty miles south of Erzerum. It was taken in 1422 by the Mogul Tartars.

ARZENI BAY lies on the coast of Barbary, in the Mediterranean, on the east side of Cape Ferrat or Farol, and extends to the north as far as Cape Dyry or Ivey. The town is at the south-west, in the bottom of the bay, and before it is good anchorage. It lies on the east side of the river which here falls into the bay.

ARZENZA, or *Chervesta*, a river of European Turkey, in Albania, discharges itself into the gulf of Venice, between Durazzo and Piro.

ARZES, in *Ancient Geography*, a town of the island of Cyprus, formerly a considerable city, and seat of a Greek bishop, but since the reduction of the island by the Turks, reduced to a village.

ARZES, a town of Afsia, situated towards the middle of the northern part of the lake Arissa.

ARZEW, in *Geography*, a sea-port of Africa, in the western province or province of Ten fan, twelve miles S.S.E. of Cape Ferrat. It is called by the Moors, the port of the "Besi Zeitan," after the name of the adjoining Kabyles, who were formerly a confederable community. Ptolomy places his "Decem portus" between Quiza and Arfemia, which, says Dr. Shaw, can be no other than this, provided Giza or Warnor is the ancient Quiza; as Arzew is, without doubt, the ancient Arfemia. Arzew is at the distance of three Roman miles from this port, as Ptolemy places his Arfemia. The country behind it is a rich champaign ground, but towards the sea there are steep rocks and precipices, which must have served for its defence in that direction. The water now used by the inhabitants lies lower than the sea, and of course is brackish. But for obtaining a supply of fresh water, the whole city was formerly built upon cemeteries, of which several still remain, and serve for dwellings to the inhabitants. Several ancient ruins of capitals, baths, and shafts of pillars, with sepulchral interments, are scattered over this place. Five miles from the sea-coast are the salt-pits of Arzew, which supply the neighbouring communities with salt. This commodity, as the pits are inexhaustible, would
would be a very valuable branch of trade under any other
government than that of the Turks. Shaw's Travels,
ARZILLA, a sea-port town of Africa, on the coast of
the Atlantic, in the empire of Morocco, built by the Romans
at the mouth of a river, situated five leagues from Tangiers,
and now inhabited by Moors and Jews, who carry on no
trade. It was formerly a Roman colony, afterwards fell
under the government of the Goths, and was next taken
by the Mahometans. It was taken and burned by the
English; after which it remained waste and uninhabited
for thirty years, but was rebuilt by the caliphs of Cordova.
In the year 1470, it was taken by Alphonso, king of Portugal,
called the African; and abandoned by the Portuguese about
the end of the sixteenth century. N. lat. 35° 30'. W. long.
5° 30'. Chierici's Morocco, vol. i. p. 22.
ARZUS, in Ancient Geography, a river of Thrace,
which ran into the Propontis at the latitude of about 42°.—Alfo,
A town of Thrace, called also Armus and Afflulus, situated be-
tween Opiorus and Sabuzepara, eighteen miles from the for-
mer, and twenty miles from the latter.
AS, among Antiquaries, sometimes signifies a particular
weight; in which sense the Roman as is the same with the
Roman libra, or pound. See Libra.
The word is by some derived from as, which, in the
Doric dialect, is used for a, one, q. d. an entire thing;
though others will have this money named as, quasi avo,
because made of brass.—Budeus has written nine books De afe,
& fpecies parrhias: "Of the as, and its parts." The
as had several divisions. See the table under As, an
integer. See also Weight.
As in some cases is the name of a Roman coin, which was made
of different materials and different weights, in different ages
of the commonwealth.
Under Numa Pompilius, according to Ennius in his
"Chronicon," the Roman money was either of wood, lea-
ther, or shells. In the time of Servius Tullius, who reigned
in Rome about 578 years before Christ, it was copper or bras,
and was called as, libra, bilbola, or pondo, because actually
weighing a pound, or twelve ounces. Mr. Pinkerton is of
opinion, that we may value the as liberis of ancient Rome at
about eight-pence English. This was called As gravis; and 
theas afeur were weighed, and not counted. The coinage of
Tullius seems to have been confined to the as, or piece of
bras, with the imprint of Janus on the one side, and the
pro of a ship on the other, because Janus arrived in
Italy by sea. Varro, however, informs us, that the first
coins of Tullius had the figure of a bull, or of other cattle
uppon them, like the Etruscan coins, of which they were
imitations; and hence it is said they were called pecuniae.
Theaes afeur with the figure of Janus and the pro of a ship
upon them, may be supposed, according to Mr. Pinkerton,
half to have appeared about 450 years before Christ; but, in
a short time, various subdivisions of the as were coined. The
as, in time, is commonly flamped with the head of Jupi-
ter laurated: the triens or third, with four ciphers, as being
originally of four ounces weight, has the head of Minerva,
the quadrans or quarter, marked with three ciphers, has the
head of Hercules wapt in a lion's skin; the sextans or sixth,
with two ciphers, is marked with the head of Mercury with
a cap and wings; and the uncia, having one cipher, is
marked with the head of Rome. All these coins appear to
have been cast in moulds, by a considerable number at a
time; afterwards the smaller divisions were fined, instead of
being cast; but the larger continued to be cast until the
as fell to two ounces. At this time, however, it was called
libra, and accounted a pound of copper; though larger de-
nominations of it were coined, such as the libella or double
as, triens and quadrans of three and four as, and even as
far as decies or ten as, marked X. The smaller parts of
the as fell to occur, owing to their small value; though
some are still found, such as the semis, triens, quadrans, sex-
tans, and uncia, coined in the times of Nero and Domitian.
Some coins occur which exceed the as liberis in weight;
and there are supposed to belong to the time of Tullius.
The Romans reckoned by as before they coined silver,
in the 48th year of the city, or 260 before Christ,
and afterwards they kept their accounts in folles.
Pliny says, that when the first Punic war had exhausted
the treasury, they reduced the as to two ounces. They then
obtained as many, and were enabled to pay their debts.
Mr. Pinkerton is of opinion, that Pliny, in ascertaining the
as continued of a pound weight till the end of the first
Punic war, is mistaken. Coins, that refute this assertion,
are still found; and he thinks it probable that the as
decreased gradually and slowly in weight, from a pound to
eleven ounces, then ten, nine, &c.; but neither the as
nor its parts were ever correctly fixed. In the second Punic
war, when the Romans were much pressed by Hannibal,
about the year of Rome 538, or 216 before Christ; Fabius
Maximus being dictator; the as were further reduced to
an ounce each; and the silver denominations were made to pass
for sixteen afeus, the quinarius for eight, and the sestertius
for four; and the republic gained upon the copper money one
half. This took place about thirty-six years after the former
reduction. The as liberis, with the face of Janus upon it, is
the form most generally occurring before it was reduced to
two ounces. Mr. Pinkerton supposes, that this continued
for at least a century, and a half after the coinage of Tullus,
till about 300 before Christ, in the year of Rome 454,
which and the 50th year of Rome, a gradual diminu-
tion of the as to two ounces must have taken place.
The following table exhibits, according to Mr. Pinkerton,
the dates of the Roman coinage. The liberis coined by
Tullius with the figures of oxen, &c. about 167 years after
the building of Rome, according to Sir Isaac Newton,
or about the year before Christ 460, or 587 according to Libri,
As liberis, with Janus and the pro of a ship 400
As of 10 ounces - - - - - 300
8 - - - - - 260
6 - - - - - 280
4 - - - - - 270
3 - - - - - 260
2, according to Pliny - - - - 250
1, according to the time - - - 214

Lastly, by the Papirian law, the as was reduced to half
an ounce: and it is generally thought that it reflected here all
the time of the commonwealth, and even till Vespasian's
reign. This law was called the Papirian as, because the law
just mentioned was passed in the year of Rome 559, or, ac-
cording to the Varronian computation, 191 before Christ,
by C. Papirius Carbo, then tribune of the people. Thus,
there were four different asaer in the time of the common-
wealth. The figure flamped on the as was at first a sheaf,
ox, or four, and from the time of the kings, a Janus with
two faces on one side, and the rogular or pro of a ship on
the reverse.
The triens and quadrans of copper had the figure of a
small vessel called ratio on the reverse. Thus Pliny: Nota
aria (i.e. afeus), sittit ex altera parte Janus geminus, ex altera rogular
cap. 3. Hence these pieces were sometimes called ratio.
After the Romans began to have an intercourse with
Greece, various elegant figures appear upon the parts of the
F 2
ASA

asa, though not on the as itself till after the time of Sylla. Towards the latter end of the republic, dupondii, or double-asa, were coined, together with the sextviri atri, which supplied the place of the quadrans, when the denarius began to be reckoned at sixteen asa; probably at the time when the latter was reduced to half an ounce. M. Paullus, in his "Metrologic," estimates the value of the asa from the foundation of Rome till the year 537, at 20 sols, or a livre; though it was sometimes 29 sols: from the year of Rome 537 to the year 545, at 3 French sols, its weight being two Roman ounces of copper: from 544 to 586, at 1 sol 1/2 deniers, its weight being one Roman ounce: from 586 to the reign of Claudius or of Nero, 1 sol 1/2 deniers: from the reign of Claudius or of Nero to that of Constantine, about 1 sol. See Coin, and Coinage.

As was also used to denote any integer, or whole.—Whence the English word acre.

Thus, as signified the whole inheritance; whence hero ex as, the heir to the whole estate.

So the fagrum, or Roman acre of land, being reckoned the integer, was called as, and divided, like it, into twelve uncia.

The as, and its parts or divisions, stand thus:

As, or Asa, in Mythology, a name given to a deity of the inhabitants of the north. Sperlingius fuggs that when the Alastis were driven from their country by Pompey, they retired into the northern regions; but as they were a delicate and polished people, they defiled the barbarous names of the north, and they were regarded among the rude inhabitants of these countries as superior to mortals, or as a species of divinities. Accustomed therefore to express any thing that was sublime and excellent by the terms Asa and Aser, they applied these appellations to their gods.

ASA, in Scripture Geography, a king of Judah, the son of Abijam, and succeeded him. 1 Mace. 3249, 2 Ch. 955. He was zealous in the establishment and maintenance of true religion, and active in demolishing altars created to idols, and in restraining and punishing such as were addicted to the infamous practices connected with idolatry, and restoring the worship of Jehovah. He obtained a decisive victory over Zerah, king of Ethiopia, in the plain of Zephatah or Zephakah near Mearkah. In his contest with Baasha, king of Israel, he called in the assistance of Benhadad, king of Syria, for which he was reproached by the prophet Hanani, whom he severely punished. He died A. M. 3590. B. C. 913, after having held the sceptre of Judah nearly forty-one years. 1 Kings xvi, 8, 2 Ch. xvi, 2 Chron. xiii, xvi.

ASA, in Geography, a river of Germany in the archduchy of Austria, which runs into the Danube two miles north of Eferding.

ASA, among Naturalists. The writers of the later ages have formed this word asa from the lafas of the ancients, and attributed it to a gum very different from that anciently known by the name they have thus corrupted. The asa of the ancients was an odorous and fragrant gum; and the asa of the after ages had lost little title to this epithet, that they distinguished it by one, expressing its being of an offensive or disgusting smell. The Arabian writers, according to this distinction, describe two kinds of asa, the one thinking, the other aromatic; and the modern Greeks approximated the name asa, or afer, to the thinking gum the Latins called by that name, but added a distinctive epithet to express its smell, and called it ferdhisharam.

ASA Osiris, in the Materia Medica, a name by which some authors have called the benjamin or benzoin of the shops. Dale.

ASA Fatidis, or ASA Fatidia. See Ferula.

ASABORUM Promontorium, in Ancient Geography, a promontory of Arabia, in the outskirts of the Persian gulf. Ptolemy.

ASABRA, in Geography, a river of Spain, which runs into the Aragon near Morillo.

ASAD, a town of Persia, in the province of Farsian, forty-seven leagues north-east of Sepirans.

ASAD-ABAD, a large and populous town of Persia, in the province of Trace-qui, on the frontiers of Ker- dilwan, twenty-two leagues N. N. E. of Anabad.

ASAE, in Ancient Geography, a people of Asa, in Sarmatia. Ptolemy.

ASAM, or ASAM, in Geography, a country of Asia; situate to the north-east of Bengal, and bounded on the north by Thibet, on the west by Hindoostan, on the south by the Bengah empire, or Ava. Its districts commence, where those of Bengal end, in N. lat. 26° and E. long. 91°. This country is divided into two parts by the river Brahmaputra, or Burmropoo, which flows from Khatra. The northern part is called Ut tacal, and the southern Dacchaucal: the former begins at Gowalhutty, the boundary of the Mogul possessions, and terminates in mountains inhabited by a tribe called Meeri Mechmi; and the latter extends from the village Sida to the hills of Sinagar. Asam is of an oblong figure; its length about 200 standard cols, and its breadth from the northern to the southern mountains about eight days journey. Several rivers flow from the southern mountains of Asam, and fall into the Burmrapoo; and the chief of these is the Dhonie. Between these rivers is an island well inhabited, and in an excellent state of tillage, containing a spacious and pleasant country that extends about fifty cols. The cultivated tract is bounded by a thick forest, which harbours elephants, and where those animals may be caught, as well as in four or five other forests of Asam. These animals are so numerous, that five or six hundred may be procured in a year. Across the Dhonie, on the side of Ghergong, which is the capital of the country, is a wide, agreeable, and level country, the face of which is marked with population and tillage, and presents every where delightful prospects of ploughed lands, harvests, gardens, and groves. This island lies in the part called Dacchimul. As the country is overflowed in the rainy seasons, a high and broad causeway has been raised for the convenience of travellers from Salagereh to Ghergong; each side of which is planted with bamboos, the branches of which meet and are intertwined, and thus afford a pleasant shade. Amongst the fruits which this country produces are mangoes, plantains, jack, oranges, citrons, limes, pine-apples, and pinnacles, a species of pineapple, which has such an excellent flavour, that every person who tastes it prefers it to the plum. There are also cocoanut trees, pepper-vines, arbor-trees, and the sad, or malabathorn, in great plenty. The sugar-cane excels in sweetness and fruitiness, and is of three colours, red, black, and white. There are ginger which is free from fibres, and betel vines. Such are the strength and fertility of the soil, that any seed that is sown, or slips that are planted, always thrive. The principal crop of the country consists in rice and mahl, which is a species of grain: wheat and barley are never found. The milks are excellent, and resemble...
resemble those of China; but they manufacture few more than are required for use. They embroider with flowers, and weave velvet and also tafftaud, a kind of silk, of which they make tents and kensars, or the walls that surround them. Salt is precious and scarce; but it is found at the bottom of some of the hills, of a bitter and purging quality; a better sort, extracted from the plantain-tree, is more common. The mountains, inhabited by a tribe called "Nana," produce plenty of excellent lignum aloes, which the natives annually import into Afam, and barter for salt and grain. These people are naked, and feed on dogs, cats, snakes, mice, rats, ants, and locusts. The hills of Camrup, Sida, and Luettigere, supply a fine species of lignum aloes, which links in water. Several of the mountains contain mule-deer.

The country of Uttarcar on the northern side of the Barampooter, is in the highest state of cultivation, and produces plenty of pepper and areca nuts: it even surpasses Dacchnel in population and tillage. The breed from the banks of the river to the foot of the mountains, where the climate is cold, and in which there is snow, is various; but it is not there less than fifteen nor greater than forty-five ftrs. The inhabitants of the mountains are strong, have a robust and respectable appearance, and are of the middling size. Their complexions, like those of the natives of all cold climates, are red and white; and they have also trees and fruits peculiar to frigid regions: several of the hills in the country of Dereng, on the side of Gowahtty, supply mulk, katans or mountain-cows, bozot and peree, which are two kinds of blanket, and two species of hores called goont and tanyans. Gold and silver are procured here, as also in the whole country of Afam, by washing the sand of the rivers. This, indeed, is one of the sources of revenue. It is supposed that 12,000, and some say 20,000 inhabitants, are employed in this occupation; and each of them pays a fixed revenue of a tola of gold to the rajah; a tola containing eighty reti-weights and eight retis being equal in weight to twenty-four barley corns or seven carats among jewellers. The people of Afam (says the writer whose account is here cited) are a base and unprincipled nation, and have no fixed religion. They follow no rule but that of their own inclinations, and make the approbation of their own vices mind the test of the propriety of their actions. They do not adopt any mode of worship practised either by Mahometans or Heathens; nOr do they concur with any of the known fields which prevail amongst mankind: unlike the pagans of Hindostan, they do not erect vihuals which have been draped by mahmnids, and they abstain from no flesh except human. They even eat animals that have died a natural death. It is not their custom to veil their women. The men have often four or five wives each, and publicly buy, sell, and change them. They shave their heads, beards, and whiskers, and reproach and admonish every person who neglects this ceremony. It has been asserted that their language has not the least affinity with that of Bengali; but others say, that young Brahmins often come from Afam to Nadiya for instruction, and that their vulgar dialect is understood by the Bengal teachers. Their strength and courage are apparent in their looks; but their ferocious manners and brutal tempers are also betrayed by their physiognomy. They are superior to most nations in corporeal force and hardy exertions. They are enterprizing, savage, fond of war, vindictive, treacherous, and deceitful. The virtues of compassion, kindness, friendship, quickness, truth, honour, good faith, and purity of morals, have been left out of their composition. Their dres consists of a cloth tied round their heads, another round their loins, and a sheet thrown upon their shoulders; but it is not customary to wear turbans, robes, drawers, or shoes. There are no buildings of brick or stone, or with walls of earth, except the gates of the city of Chergong, and some of their idolatrous temples. The habitations of the rich and poor are constructed of wood, bamboos, and straw. The rajah and his courtiers travel in flatly litters: but the opulent and respectable persons among his subjects are carried in lower vehicles, called dosalis. Afam produces neither horses, camels, nor asses; but those animals are sometimes brought thither from other countries. The brutal inhabitants, from a congenital impulse, are fond of feeding and keeping affies, and they buy and sell them at a high price; but they are much surprized at seeing a camel; and are so afraid of a horse, that if one trooper should attack 100 armed Afamians, they would all throw down their arms and fly, or if unable to escape, would surrender themselves prisoners. Yet if one of this detestable race should encounter two men of another nation on foot, he would defeat them.

The ancient inhabitants of this country, were divided into two tribes, the Afamians and the Cullumians. The latter excelled the former in all occupations except war and the conduct of hardy enterprises, in which the former are superior. A body guard of 60 or 70 Afamians, fierce as demons, of unshaken courage, and well provided with arms and warlike accouterments, always keep watch near the rajah's sitting and sleeping apartments: these are his loyal confidential troops and patrol. The martial weapons of this country are the musket, sword, spear, and arrow and bow of bamboo. In their forts and boats they have plenty of cannon, zebzen or swivels, and rammchegan, in the management of which they are very expert. Whenever any of the rajahs, magistrates or principal men die, they dig a large cave for the deceased, in which they inter his women, attendants, and servants, and some of the magnificent equipages and useful furniture which he possessed in his life time, such as elephants, gold and silver, badcafh or large fans, carpets, clothes, vihuals, lamps, with plenty of oil or a torch burning, for they consider these articles as flowers for a future state. They afterwards construct a strong roof over the cave upon thick timbers. The rajahs of this country have neither yielded submission and obedience, nor paid tribute and revenue to the most powerful monarch; but they have curbed the ambition, and checked the conquests of the most victorious princes of Hindostan. When an invading army has entered their territories, the Afamians have covered themselves in strong forts, and distanced the enemy by bratagens, surprises, and alarms, and by cutting off their provisions. If these means have failed, they have declined a battle in the field, but have carried the peasants into the mountains, burnt the grain, and left the country empty. But when the rainy season has set in upon the advancing enemy, they have watched their opportunity to make excursions, and vent their rage; and the famished invaders have either become their prisoners, or been put to death.

The preceeding account of the Afamians, who are probably superior in all respects to the Moguls, exhibits a specimen of the malignity and intolerance with which it was usual, in the reign of Aurengzebe, to treat all those whom the crafty, cruel, and avaricious emperor, was pleased to condemn as infidels and barbarians. It is extracted from "A description of Afam," written by Mohammed Cazin, and translated from the Persian by Henry Vanitart, Esq. Asiatic Researches, vol. ii. 1714-1835. It should be recollected, in justice to the people of Afam, that the author was an enemy, and a rigid Mahometan, resident at the
the court of Aurengzebe. The diet of the Afamele, though less refined than that of the Hindoes of Bengal, is by no means punitious; and their religion does not materially differ from that of Hindus, as might be proved by their coins, on which are inscribed the names of the Hindoo deities.

ASA, or ASACA, in Ancient Geography, a river of Africa, in Mauritania Tingitana.

ASAMON, a mountain of Palestine, in Galilee, over-against Scophri. Josephus.

ASCANARIA, a town of India, on this side of the Ganges. Ptolemy.

ASCANIA, a town of Germany. Ptolemy.

ASCAPHE, in Geography, a town of Asia, in the country of Diarbekire, situate on the Tigris, on the borders of Armenia.

ASCARO, a jurisdiction of South America, under the bishop of Cuenca, in Peru, fifty leagues from that city, in which are bred many cattle. In the north-east part of it there are some silver mines.

ASAPH, in Biography, a celebrated musician in the time of David, was the son of Busachias of the tribe of Levi. Asaph, and also his descendants, professed over the musical band in the service of the temple. Several of the psalms, as the 50th, the 73rd to the 83d, have the name of Asaph prefixed: but it is not certain, whether the words or the music were composed by him: with regard to them, which were written during the Babylonian captivity, they cannot in any respect be ascribed to him. Perhaps they were written or set to music by his descendants, who prefixed to them his name, or by some of that class of musicians of which the family of Asaph was the head. 1. Chron. vi. 39. 2. Chron. xxix. 35. xxx. 17. Nehem. xii. 46.

ASAPHE, St., in Geography, a city and bishop's see in Flinthire, which derived its name from St. Asaph. The diocese consists of part of Denbigh, Flint, Montgomery, and Merionethshire, and a small part of Shropshire; containing 121 parishes, and 131 church-chapels, most of which are under the patronage of the bishop. The see is valuable, and the patronage extensive. The town is seated on an eminence near the sea, at the termination of the vale of Clywydd. Although it is a denominating city, it is merely a village in extent. Its fine cathedral has been lately improved in its external decoration, and its palace has been rebuilt by the late bishop (Shipley); which being situated above the town, fronts the hill towards Holywell, commands a pleasant view.

ASAPHEIS, ασάφιος, from α, negative, and ο, open, in Hippocrates, in Proorh. & Coae. are such patients as do not utter their words in a clear manner. The defect is occasioned, as Galen says, Comm. 2. in Proorh. "either by some hurt which the organs of speech have contracted from a disorder of the nerves, or else by a d. britum."

ASAPHEIDA, in Ancient Geography, a town of Syria, in the Chalcidieic territory. Ptolemy.

ASAPHEL, or ASAPHE, an order of soldiers in the Turkish army, whom they always expose to the first shock of the enemy; to the end that the enemy being thus fatigued, and their swords blunted, the spathis and jambulites may fall on, and find an easy conquest.

The word is derived from the Turkish ṣaphe, which signifies sand, from whence they have formed ṣaphis, to range in line.

The aspides are said to be held of so little value, that they frequently serve as bridges for the cavalry to pass over in bad roads, and as stakes to fill up the ditches of places besieged. —The greatest part of them are natural Turks; they travel on foot, and have no pay but the plunder they can get from the enemy.

ASARACHA, or ASSARACA, in Botany. See Assarachum.

ASSARACHUM, or ASSARACHON, in Biography, son of Semnehoub, king of Syria, succeeded his father about 769 years before Christ, and having reigned 29 years in Nis- nevan, he became also king of Babylon, in the year 680 before Christ. He sent a colony of Babylonians and Cuthenians into Samaria; and his generals having taken captive king Maltom, sent him loaded with chains to Babylon. His reign terminated in the year 667 before Christ.

ASSARINA, in Botany. See Anthriscum, and Chelone.

ASSARO, in Geography, a town of Sicily, in the valley of Noto, eight miles south of Nicoea.

ASSAROTA, ἀσαροτα, from ἀ and σαρος, a spear, a kind of painted pavements, in use before the invention of mosaic work. The most celebrated was that at Pergamus, painted by Scexus, and exhibiting the appearance of crumps, as if the floor had not been swept after dinner, whence according to Pliny, the denomination. Perrault supposes they have been a black kind of pavements of a spongy matter. Plin. Nat. Hist. lib. xxxvi. cap. 25. Perrault ad Vitruv. lib. vi. cap. 5.

Species, 1. A. eurhoron, common asarabacca. Hudson. 265. With. 440. Smith Flor. Brit. 509. Med. Bot. t. 86. Flor. Dan. t. 623. "Leaves kidney-shaped, obtuse, in pairs, root perianth, creeping; stems short, simple, round, pubescent, one-flowered, and commonly two-leaved; leaves opposite, on long footstalks, reeniform, perfectly entire, somewhat downy; flower terminal, pitcher-shaped, of a dark purple colour, viscid, on a slender peduncle. It has been found in the north of England, in woods, particularly in Lancashire, but it is a very scarce plant in Britain. The time of its flowering is in May.

Medicinal
Medicinal Properties. The leaves and roots of afarabacca are strongly emetic and cathartic; the latter indeed has been observed to excite vomiting so invariably, that they have been proposed as a substitute for ipecacuanha. At present, however, this plant is seldom given internally, as the evacuations expected from its use, may be procured with more certainty and safety by various other medicines: it is now chiefly employed as an emetic or thermometric, and is found to be the most useful and convenient in the Materia Medica. For this purpose the leaves, being less acid than the roots, are preferred. A few grains sufficed up the nose several evenings produce a considerable watery discharge, which is sometimes continues for several days, by which it is observed, that those who take it, are often made worse, and that it is usually followed by a discharge, and some paralytic and foetal complaints, have been effectually relieved. See Wood's Med. Bot. p. 258. 2. A. canadensis, Canadian afarabacca. Mill. fig. 53. f. 6. "Leaves kidney-shaped, mucronate." The leaves of this are much larger than those of the preceding; their foot-flakes are also longer; in this species the leaves are pointed and hairy, and the flower greenish on the outside. A native of Canada, cultivated by Miller in 1731. It flowers from April to July.

3. A. virginicum, sweet-scented afarabacca. Lour. Cochinch. 292. Pluk. Alm. t. 78. f. 2. Mor. t. 7. f. 3. "Leaves heart-shaped, blunt, smooth, petiolated." The leaves of this are ovate and pointed on their upper surface, like those of the autumnal cyclamen. The flowers are shaped like the others, but much longer peduncles; and are of a dark purple. A native of Virginia and Carolina; also of several provinces in China. Both this and the second species were found in Japan by Thunberg. Cultivated by Miller in 1759.

Propagation and Culture. These plants delights in a moist shady situation, and may be increased by parting the roots in autumn. Much wet in winter will rot the Canadian species, and the last species will not bear too much fun. See Martyn's Dict. of

Asarum Hypopcella. See Cytinus.

Asa, a name given by the people of Guinea to a tree, the leaves of which being boiled in water, and held to the mouth, cure the tooth-ache. This tree in its form and manner of growing resembles the laurel; the leaves are very hard and stiff, and grow alternate on the flanks; they have short pedicles, and the branches are blackish and rugged, but they are variegated with small reddish spangles, or fleshy protuberances. Phil. Trans. No. 232.

Asaunly. in Geography, a town of Hindustan, in the circuit of Oudipour, eighteen miles south-west of Oudipour.

Asbamæa. in Ancient Geography, a fountain dedicated to Jupiter, near Tyana in Cappadocia. Philostratus, in his life of Apollonius, says, that the waters, though in a state of ebullition, were cold, and that they were pleasant and refreshing to those who observed their baths, but poisonous and fatal to liars and perjured persons. Jupiter had a temple near this fountain.

Asbeck, in Geography, a town of Germany, in the circle of Welfphalia, four miles south-east of Altain.

Asbestine, something incombustible, or that partakes of the nature and qualities of the hipo asbestos. Such as asbeine paper and cloth. See Asbestus.

Asbestine and Asbestrid of Kirwan, in Mineralogy. See Strahlestein.

Asbestinum, in Natural History, a species of Alcyonium, described by Petiver, Pallas. and others. It inhabits the American seas, is very porous, white, and roly within; the specific character is, item rather simple, round fib., with largih, oblong pores scattered on every part. Gelatin, &c. Petiver calls this kind Porus flongoides Americana, Gaz. t. 23. f. 2. 2.

Asbestos, a name given to plume-alum. See Asa.

Asbestus, in Chemistry, formed of the priv. s, and Aasno. to extinguish. Asa non mir. Fr. Asbestus immaturus of the old mineralogists. Gemmatur asebth. Germ. Tellur asbestus vulgaris. Werner. The most usual color of asbestus is black-green; sometimes mountain or olive-green, more rarely greenish or yellowish grey. It occurs in masses. Hexahedral prismatic crystals of asbestus are also mentioned as having been found at Griesebach near Pfaffau, and rhombohedral prisms of the same at Gemundt in Carinthia, and at Bagnères; according, however, to Remon and Linz, these are not crystals of asbestus, but of strahlestein. Internally it is shining, or little shining with a silky or waxy luster. Its fracture is parallel fibrous, either flat or curved, sometimes also plicated. It generally flies, when broken, into long splinterly fragments. It is trunclad at the edges; is tender, fixing into half-hard; is brittle, slightly elastic; somewhat unctuous to the touch. Sp. gr. according to Kirwan, 2.547.

Asbestos does not effervescence with acids; before the blowpipe it fuses without addition, but very difficultly, into a greyish black flag: at 160° of Wedgewood, it forms a grey porous porcelain, of sufficient hardness to give fire with a file.

The results of the analysis of this mineral are as yet but little satisfactory. Bergman analysed three specimens, from which it appears, that asbestus consists of 60.67 per cent. of oxide of silica, 13.16 carbonated magnesia, 6.12 carbonated lime, and a very variable proportion of alumine and iron. Wiegleb, on the other hand, found in the asbestus of Zoblitz 48.45 magnesia, 46.65 silica, 4.79 iron. It is fitly known, however, that the art of chemical analysis has been brought even to an approximation of certainty, and the causes of error are still so numerous, that, with the exception of Klaproth, Vanquelin, Chenevix, and perhaps a few others, hardly any authority is to be attached to the various chemists who have been engaged in this very important but most difficult branch of mineralogical science.

Asbestos is found in serpentine rock, and, in general, in the same situations as amianthus. It is sometimes mixed with indurated talc and magnetic iron.

Asbisi, in Geography, a small kingdom of Africa, in Guinea, on the gold coast.

Asbriot, in Geography, a town of Sweden, in South Gothland, six miles north of Wardberg.

Asburg, a town of Germany, in the circle of Welfphalia, and county of Meurs, two leagues east of Meurs, and fix west of Duiburg.

Asbystra, in Ancient Geography, a people of Africa, in Libya, placed by Herodotus above Cyrene. Euflathius places them near the temple of Jupiter Ammon, and the fountain of the fan.

Asca, in Geography, the name of a town of Arabia Felix.

Ascagne, Ascanius, in Zoology, a new species of Simia.
ASCANII, in Entomology, a species of CUCULIO, of a cylindrical shape, black, and blincith on the sides. Fabricius, Herbel, &c.—Obl. Curculio cylindricus of Herbst apud Fucell (Archives des Insectes). is considered by Gmelin as a variety (s) of this insect. Inhabits the south of Europe.

ASCANIIUS, in Geography, called also Iulus or Ius, the son of Aeneas by Creusa, the daughter of Priam; or, as others say, by Lavinia, accompanied his father in his flight and dangers, and succeeded him in the government of Lavinium, in the year before Christ 1177. He was called Acanthus from a river of that name in Phrygia, and Ius, changed into Iulus, from Ilum or Troy. Having defeated Mezentius, king of the Tuscans, who demanded of the Latins a tribute of all the wine produced in Latium, he made peace with him upon condition that the Tiber should be the boundary between the Latin and Hetrurian territories. When he found it expedient to resign Lavinium to Lavinia and his son Sylvius, he determined to build another city for the place of his residence, and the capital of his kingdom, which he called ALBA LONGA. Here he resided about 12 years, and, after a reign of about 38 years, died in this city in the year before Christ 1146. Dion. Hal. l. p. 45. &c. Livy, l. c. 3.

ASCANUS, in Entomology, a species of Papilio (Eq. Tra.). Above and beneath black, with a common white band; posterior wings clouded with red. Fabricius, &c. Inhabits Brazil.—The body of this insect is black, and the breast is spotted with red.

ASCANUS, in Ancient Geography, a river of Asia Minor, in Bithynia, according to Ptolemy, by which the lake ACTENIA or Acanthus discharged its waters into the sea. Phiny places it in a gulf near Eutheneum.—Also, a port of Asia, placed by Phiny near the city of Phocaes.—Also, a lake of Asia Minor, in Bithynia, now the lake of Itinus, near which Phiny places the city of Nicea.

ASCARA, in Geography, a town of Japan, in the province of Simooduke.

ASCARDIC, the capital of the country of Asia, called Little Thibet.

* Male flowers. Cal. amentum filiform; floccules scattered, sessile; Periant, a very short scale. Cor. none. Stam. filaments single, very short; anther oblong, spreading recurved, four-furrowed, large. * Female flowers in a different plant. Calyx as in the male. Cor. none. Pyl. germ globos; style none; stigma flat, three-lobed, growing to the germ. Per. drupe? Seed, single.

ASCARIS, in Natural History, is the generic name of those creatures belonging to the tribe of VERMES INFESSI, which have a round and elastic body, tapering towards each extremity; three protuberances at the head; tail obsolete; and the intestines spiral, milky white, and pellucid.

The knowledge of the ancients concerning these animals was apparently very limited; and they invariably confused the ascarids with other intestinal worms. To Redi much credit is due for directing his researches to this intricate subject; and though his discoveries are not of material moment, he was certainly the first among modern writers who endeavoured to improve upon that knowledge which the
the ancients had left us. He describes the acarides of the
eagle, the raven, the swan, and several other creatures, in his
work "De animaculis vivis que in corporibus animallium vivo-
rum repertiorum Observationes." Annal. 1738. Some further
observations were made by different persons after the time
of Redi, but many years intervened before any considerable
advances were made in this important branch of scientific
inquiry.

Although it is evident that several species of the acarides
were most clearly ascertained before the time of Linnaeus,
that celebrated naturalist has thought proper to infect only
two species of them in his Systema Naturae, which are A.
vermicularis and A. lumbricoidea. In the latter edition of
that work, Gmelin has availed himself of more recent discoveries,
and has augmented that number to seventy-eight: some
species have been even discovered by naturalists since the publica-
tion of that work, of which one or two is described by Dr.
Pulteney in the Transactiions of the Linnean Society of
London for the year 1830; and there can be no just reason
to doubt, that many other kinds of them exist in different
animals, which have hitherto escaped investigation.

Professor Pallas published an elaborate work on the acar-
ides and other internal vermes, intitled, "Thesis de infeti-
alis viventibus intra viventia." It was printed at Leyden in
1780, and deferentially acquired a very distinguished reputa-
tion. In this book the author has judiciously collated
every useful information the labours of his predecessors could
afford him, as well as his own experience and observa-
tions, and has given ample descriptions and accurate spe-
cific definitions, by which the kinds he describes may be
ascertained.

O. F. Muller has assiduously pursued the same inquiry,
and greatly extended our knowledge of these creatures.
The Royal society of Copenhagen also, aware of the vast
importance of this subject to the welfare of mankind, pro-
pounded a premium for the best dissertation on the origin,
genation, and best means of destroying the various kinds of
tenias, acarides, fuscida, and other pernicious vermes, about
the year 1780. This excited the diligence both of M. Bloch
and M. Goze, and to each of them a prize was assigned
as a reward for their labours. M. Bloch afterwards published
his dissertation in the German language, at Berlin, in 1782;
and in 1788, a translation of it into French appeared in
Strasburg, under the title of "Treatise de la generation
des vers des intestines et des vermines." That of
M. Goze was published in German with forty-four illustra-
tive plates, and is also a work of considerate merit and
utility.

Among the French naturalists of the present day M. La-
mareck’s "Sylléme des animaux sans vertébres," and
L'Histoire naturelle des vers," a sequel to D'Herelle's edirion
of Buffon, are much acclaimed. "In spite of the ob-
ervations of all the writers who have treated on the acar-
ides," says a modern French author, "it is to Lamarck
and Cuvier we are indebted for circumscribing the number
of species within the proper limits." M. Chabert, a man
of acknowledged skill in the veterinary art, has also written
on the internal vermes; as a naturalist, it seems he has
incurred some blame; his species may however be ascertained,
and what is of equal if not greater moment is the more
accuracy of arrangement and scientific definitions, he has
devoted to point out the bell means of extirpating
them.

From the observations of different writers it appears,
that the acarides are of the two sexes; and that the female
is oviparious and very prolific. All the species that are
truly acarides, live in the stomach of man or of animals; and
their origin, which it is of the utmost consequence to ascer-
tain, is ill all a matter of profound obscurity. The three
tubercles at the head have been mistaken by some for the
accompaniments of the vent, because there is obviously an
aperture or pore in the middle, but this is unquestionably
the mouth, and Brengier notices two little transverse open-
ings below, which he names ligamenta; and these, it is con-
jectured, are the organs of respiration.

It will be proper to observe, that besides the prodigious
number of acarides already ascertained, there is a nume-
rous host of similar internal enemies peculiar to different ani-
mal which do not possess the generic character of the ac-
aris, and are therefore arranged in the new genera micro-
cephalites, fioria, uncinaria, scolet, ligula, trilobato, ech-
olimbacchus, haraca, cecumilles, caryphylalus, lingualis, fas-
cidae, tania, &c. The species of acarides described by Gme-
lin are arranged in the following order:

Infesting Man, and the Mammalia.
Vermicularis, lumbricoidea; repertorionis, in the long-
ereat bat: Phoebe, biluda, canis, vicercalis, lupi, vulpis,
leonis, tigris, felis, cati, martis, bronchialis, renales, me-
phitidis, galonis, talpi, mus, hirci, vituli, equi, fuis,
apri.

Infesting Birds.
Arquile, albicille, butonies, milvi, subbutonies, herma-
aphrodisia, cornicis, coracis, cygni, anatis, fuligulas, lari,
cicones, tardo, papillodes, gallopavonis, galli, galline, pha-
flans, tetronias, colubres, alauda, turdi, turdi.

Infesting Reptiles.
Teudinis, lacerta, bufonias, pulmonalis, rubetra, trac-
chalis, rana, intestinalis, dysphoas, infons.

Infesting Fishes.
Anguilla, marina, blemius, rhombi, percae, globelis, la-
cutris, filuri, slariois, trutta, manane, acus, halicea, ar-
gentina, gobienios, raji, fiquis, lophii.

Infesting Worms.
Lumbrici.
In the sequel of this article we shall confine ourselves to
the two species of acarides that belong to the human body;
viz. the A. lumbricoidea and vermicularis, referring for their
scientific characters to their specific names.

The acarides of the first species generally infest the small in-
estines; sometimes they ascend through the duodenum into
the stomach, and creep out of the mouth and nostrils; they
frequent descend into the large intestines, except on the exhibi-
tion of medicines increasing the action of the intestines.
Sometimes they are very numerous. Dr. Hooper (to whose excellent
Paper in the Memoirs of the Medical Society of London we
are indebted for much of this detail) relates a case of a girl
seven years old who vomited per annum upwards of 200 in the
course of a week. Sometimes, however, they appear even fo-
litary. When recently excluded, they are transparent, and ap-
pear as if they had been sucking water tinged with blood;
this colour, however, soon disappears, and they become at
length of a light opaque yellow. After being evacuated, their
motion is feeble, and they soon die; sometimes when they
have been hastily evacuated, they will be very lively, and
by means of putting them into warm milk and water, they
will continue to for some time. Their motion is serpentine,
and in no respect resembles the motion of the lumbri-
cus terrestris, or earth-worm, which has the power of diminu-
ishing...
ing its length and extending itself again, while the length of the acairis humbricoides is never diminished; the head is always flat forward by the worm curving itself into circles, and suddenly extending its with considerable force to some distance.

It is said that the acairis humbricoides is not hermaphrodite. The worm here described is considered as the female. Dr. Hooper says he has examined a very considerable number, and has never met with any other appearances than those of the femal form. Dr. Hooper, in D. spesiosa. Cuticle.—The covering or external membrane of the worm, which may be considered as the cuticle, is very strong, chitinous, thin, smooth, and transparent, and easily separates from the parts underneath by maceration in water; under this we find the cutis or true skin, which is considerably thicker than the former, and retains marks of the muscles which it covers; it is also very strong, chitinous, and transparent. When the cutis is removed, the muscles, observable through the skin, present themselves; they do not entirely surround the worm as they at first appear, but are two distinct orders acting in opposition to each other, for the two longitudinal lines which extend from one extremity of the worm to the other, are each of them composed of two distinct tendons, separable from one another; these tendons serve for the attachment of the ventral muscles which cover the worm from the head to the tail. Upon carefully removing the serous muscles from the head to the depressed band, a number of minute vessels are to be seen (by means of a glass) filled with a transparent fluid which exudes on puncturing them. This cellular or parenchymatous apparatus closely embraces the intestinal canal from the head to the depressed band; but from thence to the tail there is merely a fibrous kind of cellular membrane. When the muscles are removed from the depressed band to the tail, an extremely delicate membrane appears, which as a peritoneum embraces the abdominal viscera, and lines the cavity of the abdomen, which cavity extends from the depressed band to the tail; it is divided with a transparent fluid, and contains the intestinal tube, and an apparatus supposed to be subervient to generation. The intestinal tube or canal begins from the mouth, and continues nearly half an inch in a parallel form, which Dr. Baille calls cephagian; it then becomes larger and transparent, increasing in size till it arrives to the beginning of the abdomen, closely embraced by the parenchymatous substance; it now obtains the dimensions of a crow quill, and passes straight, still enlarging, through the whole length of the worm to within an inch of a part of an inch, where it suddenly becomes narrow, and terminates in an anus. This canal is generally filled with a greenish coloured fluid of the confidence of nuxes. If a portion of this tube be macerated a few days in water, it exhibits distinct tubules, the external of which is a portion of the peritoneum; it is externally covered with filaments, which may be vessels of nutrition. The second veins is considered by some as peculiar to the female, and all agree it is for the purpose of generation; it begins about the middle of the worm, where the cavity of the abdomen commences by a slender tube which is continued from the punctiform aperture situated in the depressed band between the two longitudinal lines. This tube, which is termed the vagina, soon becomes larger, when it commences uterine, and divides into large cord, which for the space of four or five inches are of a uniform diameter, then suddenly diminish and appear like opaque threads, embracing in every direction the intestinal tube. Werner considers these as Fallopian tubes. This con-
AC

As of cuticle, cutis, and one set of annular muscles; there do not appear to be any longitudinal lines on its external surface. The cavity, containing the visera, begins at a very small distance from the head, and terminates where the tail commences, at which place is a very small opening, or the anus. The only visera in the male worm are oesophagus, stomach, and intestines: the oesophagus begins at the mouth, gradually enlarges for a small space, and terminates in the stomach; the stomach is a round bag, so that oesophagus and stomach together resemble a glass pebble which, according to Goëzé, connotes a distinguishing specific character. The stomach evacuates its contents into the intestinal canal, which continues through the worm more or less contracted and dilated to the anus: the contents of the stomach and intestines is always of a brown colour. The female has, besides these visera, an apparatus subserient to generation, which begins by a slender tube leading from the small punctiform opening situated nearly in the body of the worm; it soon becomes much larger, enters the intestinal tube in every direction, and fills up the cavity of the worm. This gy rated apparatus is not bifurcated as in the ascaris lumbricoides, nor has it the same filiform appendages; its end or fundus is as large as any other part; it appears under a high magnifier like a bladder distended with worms, for its young are seen distinctly moving about from one end to the other.

Symptoms of Worms. When these worms exist in any number, they produce more or less emaciation, paleness of the countenance, with sometimes flushing of the face, a blueish circle about the eyes, itching of the nose, desolation with staring and talking during sleep, thirst in the morning, nausea and disgust for food, though more frequently great appetite, fœtid breath, purging, stirring, and tenderness in the belly, especially about the navel; belly frequently much enlarged, flatulence, colic, sometimes at other times purging, weakness, languor, epileptic fits, and more or less symptomatic fever, pulse weak, and sometimes intermitting. These symptoms arise from the lumbricoides than the vermicularis; but where the latter are numerous, they will occasion nearly as violent symptoms; otherwise they are more known by their effects in and about the rectum and its neighbourhood, producing itching there more or less intolerable, with tendency, and even inflamed blisters. There are a number of other symptoms brought on by the existence of worms; these, however, are the principal and most decisive; but the heat and most satisfactory evidence is their being seen in the evacuations.

Cures. The indications for the cure of ascarides are of two kinds: first, the expulsion of them, their young, their ova, and the mucus containing them, from the bowels; and second, the correction of that weak state of the bowels, or other morbid dispositions of them, whatever they may be, which favour the production of them, and that mucus which becomes a nidus for their propagation. For although the only place in nature where these two species of infects are known to be generated, is the human intestines, during life, and therefore it might be reasonable to suppose, they might exist in them (not in great numbers) in a state of health, yet they are generally found in them when at least in a state of less vigour, as in infancy and age, or when weakened by any foreign means, among the causes of which (it may be proper to mention here) the dracitic purgatives, employed to get rid of them. These frequently weaken so much that the patient rather submits to the inconvenience of them, especially the ascaris vermicularis, than to the pernicious effects of vermifuges upon the digestive organs.

ASC

There is hardly a purgative, especially among the dracitic ones, which has not been employed for this purpose. These should be used with every precaution; and are hardly ever necessary for the expulsion of the ascarides. The lumbricoides is not very tenacious of life, and is easily destroyed and evacuated by means of cabomb, scirrurum or jalap, and other milder purgatives, in moderate doses, adapted to the strength of the patient. The purgative should be several times repeated, at short intervals, in order to remove fresh worms and ova as have been frequented by the fields of the intestines, or in the anus, from the action of the preceding dose. The same means are employed to remove the ascaris vermicularis, but not with the same success. This is much more necious of life, and as it is generally seent so far from the stomach, medicines administered by the mouth have little other effect upon it than as they evacuate the contents of the rectum in common with the other visera; but administered by glycerin, the relief they afford is very considerable, though not in all cases certain. A small quantity of dry, dissolved in some mucinuous fluid, and employed as a glicerin, is very powerful in this way, wished at the same time by medicine, to evacuate them from above. There are cases where no effectual remedy has been found to remove these troublesome vermin. We shall below transcribe the accurate history of a case of these worms, given by the late Dr. Hetherden in the first volume of the Medical Transactions, which will greatly illustrate this part of our subject.

The second indication of cure, the removal of that week and morbid state of the intestines which proves favourable to the generation of the ascaris, is by no means the least; and it is on this principle perhaps only that bitters have been ranked with worm medicines: it is hardly probable that infects always bred in bitternets, and which have been found in the ducums communis clochedochus, and even gall bladder, should be poisoned by bitters. Bitters, and tonics, as preparations of knee and other mineral and vegetable tonics, will be found nearly as useful as the medicines which simply expel them. The consideration of other remedies employed in the removal of worms, we must refer to the article TANIS.

Dr. Hetherden tells us, that being acquainted with an experienced and intelligent physician, who had from his infancy been troubled with ascarides, he defined to be informed by him what were the inconveniences which they had occasioned, and what was the success of the remedies which he had used; to which he replied, that according to his experience the peculiar symptoms of this species of worms are, a great uneasiness in the rectum, and an almost intolerable itching of the anus. We shall below transcribe the Dr. Hetherden's case, usually come on in an evening, and prevent sleep for several hours; they are attended with a heat, which is from times to considerable as to produce a swelling in the rectum, both internally and externally; and if these symptoms are not soon relieved, a tenesmus is brought on with a mucous discharge. Sometimes there is a gripping pain in the lower part of the abdomen, a little above the os pubis. If this pain be very severe, there follows a bloody mucus, in which there are often found ascarides alive. They were sometimes suspected of occasioning disturbed sleep, and some degree of headache. Purging and irritating eylerets were injected with very little success. One draught and a half of tobacco was infused in six ounces of boiling water, and the strained liquor being given as a eyleret occasioned a violent pain in the lower part of the abdomen, with flatness and a cold sweat. This injection, though retained only one minute, acted as a smart purg, but did little or no good. Lime water was also used.
a cliver, which brought on a colic, but had no good effect. Six grains of salt of steel were dissolved in six ounces of water, and injected. This cliver in a few minutes occasioned an acheing in the rectum, and a griping a little without purging, and excited a tenesmus. Some few aercrides were brought off with it, but all of them were alive. The

calendable occasioned by this cliver did not
date till some warm milk was thrown up. Wherever the
tenesmus or mucous fluids were thought worth taking notice
of, warm milk and oil generally gave immediate relief. If
purging was necessary, the leviest purgers, such as manna
with oil, were in this cafe made use of; rhubarb was found
too stimulating. But, in general, the most useful purger, and
which therefore was most usually taken, was cinnamar and
rhubarb, of each half a drachm: this powder seldom failed
to bring away a mucus as transparent as the white of an egg,
and in this many aercrides were moving about. The cinna-
bar frequently adhered to this mucus, which did not come
off in such large quantities, when a purge was taken without
the cinnabar. Calomel did no more than any other purger,
which operates brilfly, would have done; that is, it brought
away aercrides, with a great deal of mucus. Oil, given as
a cliver, has sometimes brought off these animalcula: the
oil swam on the surface of the mucus, and the aercrides were
alive moving in the mucus, which probably hindered the oil
from coming in contact with them and killing them. The
same mucus may reasonably be supposed to preserve these
worms unhurt, though surrounded with many other liquids,
the immediate touch of which would be fatal. If the aerc-
rides be taken out of their mucus, and exposed to the open
air, they become motionless, and seem to die in a very few
minutes.

The general health of this patient did not seem to have at
all suffered by the long continuance of his disorder, nor the
immediate inconveniences of the disorder itself to have
increased. It is perhaps universally true that this kind of
worm, though as difficult to be cured as any, is yet the least
dangerous of all. They have been known to accompany a
person through the whole of a long life, without any
reason to suspect that they have haitended its end. As
in this example there was no remarkable febrileness, indigestion,
pain of the stomatch, giudines, or itching of the nose,
possibly these symptoms, where they have happened
to be joined with the aercrides, did not properly belong
to them, but arose from other causes. There is indeed no
one sign of worms, but what in some patients will be want-
ing. From this case it further appears, that mucus or
flime is the proper nest of the aercrides, in which they live,
and perhaps the food by which they are nourished. It is
hard to satisfy ourselves by what instinct they find it out
in the human body, and by what means they get at it; but
it is observable in many other parts of nature as well
as here, that where there is a fit soil for the hatching
and growth of animals and vegetables, nature has taken
such proper care that their seed should find the way thither.
Worms are said to have been found in the intestines of
infants who have been born dead. Purges, by lessening this
flime, never fail to relieve the patients; and it is not un-
likely that the worms which are not forced away by this
quickened motion of the intestines may, for want of a pro-
per quantity of it, languish and at last die. Experience
furnishes no objections against supposing that the kind
of purge is of little moment in the cure of all other kind
of worms as well as of the aercrides, the worms being
always defended from the immediate action of medicines;
and that therefore those purges are the bell which act
briefly, and of which a frequent repetition can be most
easily borne. Purging waters are of this kind, and japy,
especially for children; two or more grains of which
mixed with sugar are easily taken, and may be daily
repeated.

ASCAROIDES, a species of Cucllilus found in the
flomach of the Sibillus glanses; it resembles the larva of the mufca, is about an inch in length, of a whitish
grey colour, and is gregarious. Guccie and Gmel. thus
define its specific character: head orbicular, and hooked on
each side; tail rounded, short, and pointed with two excreted
spicules.

ASCALACILIS, in Ancient Geography, a town of
Germany. Tietonm.

ASCALUM, a town of Venetia, north-west of Tavi-

nium.

ASCENDANT, in Astrology, denotes the horoscope;
or the ecliptic which rises upon the horizon, at the time
of the birth of any one. This is supposed to have an influence
on the person's life and fortune, by giving him a bent and
propensity to one thing more than another. In the celestial
theme this is called the first house, the angle of the eclip,
or oriental angle, and the significator of life.—Such a planet
ruled in his ascendant.—Jupiter was in his ascendant, &c.
Hence the word is also ufed in a moral fense, for a certain
superiority which one man has over another, from some un-
known cause.

ASCENDANT, in Genealogy, is understood of ances-
tors, or such relations as have gone before us; such are father,
greatfather, &c.—They are thus called in contradifition
to descendants, or the defending line. It is a canon
in law, that inheritances never lineally ascend. See In-
heritance. Marriage is always forbind between the
ascendants and descendants, in a direct line. See Mar-
riage.

ASCENDENS obliquus. See Obliquus.

ASCENDING, in Astronomy, is understood of those
stars or degrees of the heavens, &c. which are rising above
the horizon, in any parallel of the equator.

ASCENDING latitude, is the latitude of a planet when
going towards the north pole. See Latitude.

ASCENDING node, is that point of a planet's orbit,
in which it passes the celestial, to proceed northward.

ASCENDING nodes, among Astrologers, are those which
are upon their ascent, or rise from the nadir, or low-er point
of the heavens, to the zenith or higheft.

ASCENDING, in Anatomy, is applied to such vessels as
carry the briff blood upwards; thus part of the aorta, and
the inferior cava, have been termed the ascending aorta, and
ascending vena cava.

ASCENDING, in Botany, denotes growing firft horizon-
tally, and then bowed upwards; and the term in this fense is
applicable to leaves, to thalks, to items, as in fpirked speed-
well; or to thalms, as in all the speedwells.

ASCENDING Harmony, in Mufic, is modulating by 4ths;
deftcing harmony is acquired by the fife moving by
4ths.

ASCENSION, Ascendio, a rising or moving up-
ward.

ASCENSION, in Theology, is particularly ufed for that
miraculous elevation of our Saviour, when he mounted to
heaven in the fight of his apoffles. Acts i. 14, &c.

ASCENSION-Day, popularly called Holy Thursday, a fer-
tival of the church, held ten days before Whittunfte, in
memory of our Saviour's accention. The appointment of
this day for the fential of the accention is traced to the
Apostolical
Apocryphal Constitutions, l. v. c. 19. Its origin is not known; and hence some have been led to imagine, that it was received by tradition from the apostles.

Ascension, in Astronomy, is either right or oblique.

Ascension, right, of the sun, or of a star, is that degree of the equinoctial, accounted from the beginning of Aries, which rises with the sun, or star, in a right sphere. Or, right ascension is that degree and minute of the equinoctial, counted as before, which comes to the meridian with the sun, or star, or other point of the heavens. The reason of thus referring it to the meridian, is, because it is always at right angles to the equinoctial, whereas the horizon is only so in a right or direct sphere. The right ascension stands opposed to the right declension, and corresponds to the longitude of places on the earth. Two fixed stars, which have the same right ascension, i.e. which are at the same distance from the first point of Aries, or, which amounts to the same, are in the same meridian, rise at the same time in a right sphere, or with respect to people who live under the equator. If they be not in the same meridian, the difference between the times of their rising or coming to the meridian is the precise difference of their right ascension. In an oblique sphere, where the horizon cuts all the meridians obliquely, different points of the meridian never rise or set together; so that two stars, on the same meridian, never rise or set at the same time; and the more oblique the sphere, the greater is the interval of time between them. To find the right ascension of the sun, stars, &c. trigonometrically, say, for the sun, As radius is to the cofine of the sun's greatest declination, or obliquity of the ecliptic, so is the tangent of the sun's longitude to the tangent of the right ascension.

Let PESQ (Astronomy, Plate II., fig. 15.) represent the spherical colure, the centre of which is $\gamma$, and let the diameter EQ be the equator, and the diameter PO the equinoctial colure. Suppose the obliquity to be $\psi = 23^\circ$ 28'$; and the diameter $\angle \phi$ to be the ecliptic, in which take $\gamma \phi$ for the sun's longitude or distance from the point $\gamma = 43^\circ 16'$; and through PO & PS describe a circle of right ascension.

Then in the right-angled spherical triangle $\gamma \phi \beta$, we have

$$\text{Radius } = \frac{10.0000}{t. \text{ sun's long. } = 43^\circ 16'} = 9.97371$$

$$\text{As co-lat. ecl. } = 23^\circ 28' = 9.96525$$

$$\text{to t. right ascension } = 40^\circ 48' = 9.93622.$$  

While the sun is moving from $\gamma$ to $\phi$, or in the first quadrant of the ecliptic, the given longitude is the hypotenuse in the triangle $\gamma \phi \beta$, the declination $\beta$ is north, and $\gamma \beta$ is the right ascension. When the sun has past the follice $\phi$, and is descending towards $\phi$, or in the second quadrant, his longitude or distance from $\gamma$ being taken from 180$, the remainder $\phi$ becomes the hypotenuse, and the declination is still north; but the arc $\beta$ found for the right ascension is only the supplem, and must therefore be taken from 180$. The sun having past the point $\phi$, and descending towards $\phi$, in the third quadrant, its longitude, reckoned from $\gamma$, will be greater than 180'; in which case the excess above 180', or his distance from $\phi$, will be the hypotenuse $\phi \phi'$; the declination will be south, and the arc $\phi A$, found for the right ascension, must be added to 180' in order to obtain the right ascension estimated from $\gamma$. When the sun has past the follice $\phi$, and is ascending towards $\psi$, he is then in the fourth quadrant; therefore the longitude will be greater than 270', and must be taken from 360', for the hypotenuse $\psi \phi$. In this case the declination is south, and the right ascension, found by the above proportion, must be taken from 360', in order to have the right ascension from $\gamma$.

If the obliquity of the ecliptic, and the sun's declination were given, the proportion for the right ascension would be; radius to the cotangent of the obliquity of the ecliptic, as the tangent of the sun's declination to the sine of the right ascension.

The sun's right ascension in time is useful to the practical astronomer in regular observatories, who adjusts his clock by sidereal time. It serves also for converting apparent into sidereal time; as e.g. that of an eclipse of Jupiter's satellites, in order to know at what time it may be expected to happen by his clocks. For this purpose, the sun's right ascension at the preceding noon, together with the increase of right ascension from noon, must be added to the apparent time of the phenomenon set down in the ephemeris. The sun's right ascension in time serves also for computing the apparent time of a known star's passing the meridian; thus, subtract the sun's right ascension in time at noon from the star's right ascension in time, the remainder is the apparent time of the star's passing the meridian nearly; from which the proportional part of the daily increase of the sun's right ascension from this apparent time from noon being subtracted, leaves the correct time of the sun's passing the meridian. The sun's right ascension in time is also useful for computing the time of the moon and planets passing the meridian.

For finding the right ascension of a star, supposing its latitude and longitude, and also the obliquity of the ecliptic, to be given the method is as follows. Let PESQ, (fig. 16.) or the primitive circle, be the sidereal circle; EQ the equator, PS its poles, and $eb$ a parallel of latitude intersecting a circle of longitude $\beta A e$ in the place of a star. Suppose the latitude of the star to be $7^\circ$ N. and its longitude $\gamma 29^\circ 1'$, and the obliquity of the ecliptic $23^\circ 28'$. In the triangle $P A e$, we have $\psi A$ the distance of the poles of the equator and ecliptic, or the obliquity of the ecliptic $= 23^\circ 28'$, $\beta A$, or the complement of the latitude $= 82^\circ 41'$, and the contained angle $P A e = 60^\circ 59'$, or the longitude from the first point of $\psi$, and we are to find the angle $\beta A e$ or the right ascension. The proportion is as follows: rad.: cofine $\beta A e :: \tan \beta A e :: \tan M$. Take the difference between the side adjacent to the required angle and $M$, and call it $N$; then say, fine $N ::$ fine $M ::$ tangent $\beta A e ::$ tangent $\beta A e$. Or, first find the declination (see Declination), which is $17^\circ 45'$ N. Then say, $\text{co-declin. } = 17^\circ 45' :: 17^\circ 45' :: 17^\circ 45' ::$ tangent $\beta A e$. The right ascension and declination of a fixed star or planet, whose longitude and latitude, as well as (O) the obliquity of the ecliptic, are given, may be found by the following problem, communicated by Dr. Maskelyne to Dr. A. Mackay.

Tan. lat. — fine long. = tang. $A$, north or south, as latitude is. Call $O$ north in fix first figs, and south in fix last figs.

$$A + O = B.$$  

A less than $45^\circ$, co. ar. cof. $A +$ co. $B +$ tang. long. = $A +$ tang. long.

A more than $45^\circ$, tang. $A +$ co. ar. fine $A +$ cof. $B = +$ tang. long.

Tang. right ascension of the same kind as longitude; unless $B$ be more than $90^\circ$, when the quantity found of the same kind as longitude must be subtracted from 12 figs.

AR
ASC

A R (right ascension) nearer I11 and IX signs than 0 and VI signs, see AR + tang. B

Cos. Right ascension from σ or ε =

Ascent decl. x cos. lat. x cos. long. from σ or ε.

Mackay's Theory and Practice of finding the Longitude &c.

vol. i. p. 42.

For other methods of determining the right ascension of a fixed star by Mr. Flamstead, and Dr. Maskelyne, illustrated by examples, see Vince's Astronomy, vol. i. p. 391, &c.

The practical method of finding the right ascension of a body from that of a fixed star, by a clock adjusted to sidereal time, is this:—Let the clock begin its motion from 00:00:00 at the instant the first point of aries is on the meridian; then, when any star comes to the meridian, the clock would show the apparent right ascension of the star, the right ascension being calculated at the rate of 15° an hour; provided the clock was subject to no error, because it would then show at any time how far the first point of aries was from the meridian. But as the clock is liable to error, we must be able at any time to ascertain its error, or the difference between the right ascension shown by the clock and the right ascension of that point of the equator which is at that time on the meridian. To do this, we must, when a star whose apparent right ascension is known, passes the meridian, compare its apparent right ascension with the right ascension shown by the clock, and the difference will show the error of the clock. E.g. let the apparent right ascension of Aldebaran be 4° 23' 50" at the time when its transit over the meridian is observed by the clock; and suppose the time shown by the clock to be 4° 23' 52", then there is an error of 2" in the clock, as it gives the right ascension of the star 2" more than it ought. If the clock be compared with several stars, and the mean error taken, we shall have more accurately the error at the mean time of all the observations. These observations, being repeated every day, will give the rate of the clock's going, or show how much it gains or loses. The error of the clock, and the rate of its going, being thus ascertained, if the time of the transit of any body be observed, and the error of the clock at the time be applied, we shall have the right ascension of the body. This is the method by which the right ascension of the sun, moon, and planets are regularly found in observatories.

ASC

To find the right ascensions mechanically by the globe, see GLOBE.

The arch of right ascension that portion of the equator intercepted between the beginning of aries, and the point of the equator which is in the meridian; or, it is the number of degrees contained in it. This coincides with the right ascension itself.—The right ascension is the same in all parts of the globe.

We sometimes also say, the right ascension of a point of the ecliptic, or any other point of the heavens. The right ascension of the mid-heaven is often used by astronomers, particularly in calculating eclipses by the nonagmeal degree; and it denotes the right ascension of that point of the equator which is in the meridian, and is equal to the fun of the sun's right ascension and the hourly angle or true time reduced to degrees, or to the fun of the mean longitude of the sun and mean time.

ASCENSION, angle of right. See ANGLE.

ASCENSION, oblique, is an arch of the equator intercepted between the first point of aries, and that point of the equator which rises together with a star, &c. in an oblique sphere.

The oblique ascension is numbered from west to east; and is greater or less, according to the different obliquity of the sphere.

To find the oblique ascension of the sun by the globe, see GLOBE. See also ASCENSIONAL DIFFERENCE.

The arch of oblique ascension, is an arch of the horizon intercepted between the beginning of aries, and the point of the equator, which rises with a star or planet in an oblique sphere.—This coincides with the oblique ascension itself.

The oblique ascensions change according to the latitude of the places.

ASCENSION and DEFLECTION, REFRACTION of. See REFRACTION.

ASCENSION, Ile of, in Geography, one of the African islands situated in the Southern Atlantic ocean. S. lat. 7° 56' 30". W. long. 14° 22' 31". This dreary desolate island was first discovered in 1501, by J. de Nova Gallego, a Portuguese navigator, who called it "Isla de Nofia Senhora de Conceição," and it was seen a second time by Alfonso de Albuquerque, on his voyage to India in 1503. It was probably on Ascension-day when it received its present name. Capt. Cook stopped at this island in 1778; and he says that it is about ten miles in length, from north-west to south-east, and about five or six in breadth. Its surface is composed of barren hills and vallies, or a collection of rocks and hollows, without a shrub or plant for several miles, and exhibiting by the stones and ashes which abound in it, sufficient evidence that at some period or other it was a volcanic production. Mr. Forster, in his account of this island, says, that they could discern from the ship, near the centre of it, a broad white mountain of considerable elevation, on which there was some verdure, and from this circumstance it obtained the name of the "Green Mountain." When they landed on the beach, through a high surf, they found themselves amidst rocks, which consisted of minute shell-sand, chiefly of a frowzy white, deep and dry, and by the reflection of the sun intolerable to the eyes. In their progress, they ascended through heaps of black cavernous stone, which perfectly reflemed the common lavas of Vesuvius and Iceland. After a perpendicular ascent of about twelve or fifteen yards, they arrived at an extensive level plain, about fifty or eighty miles in circuit, at the different corners of which they observed large hills of a conical shape, and of a reddish colour, which were perfectly inflated. Between these hills the plain was covered with a great
great number of small hillocks, composed of lava similar to that which they found on the sea-shore, and the pieces of which found like glasses when struck against each other. Between the heaps of lava the soil was a black earth, and where the heaps did not appear, the whole was a red earth, so loose and composed of such minute particles, that the wind raised from it clouds of dust. These conic hills, filled of a different sort of lava, which was red and soft, and crumbled into earth. One of these hills stands directly in front of the bay, and has on its summit a wooden cross, whence the bay is said to take its name. The sides of the hill are very steep, but a path about 1 of a mile long winds to the summit. The plain on which they stood, they concluded to have been once the crater of a volcano, by the accumulation of whose cinders and pumice stones the conic hills had been gradually formed; the currents of lava, which were now distributed in many heaps, had, as they conjectured, been gradually buried in fresh cinders and ashes; and the waters, flowing from the interior mountain in the rainy season, had carried every thing before them, and thus filled up by degrees the cavity of the crater. The rocky black lava was the residence of numbers of men-of-war birds, and boobies, which sat on their eggs and allowed of a close approach. Here they found a New York looip, which came to the island to catch turtles, in order to sell them at the Windward Islands. The East India ships, it is said, touch at this island for the purpose of furnishing themselves with turtles, which are plentiful and very large. On a second visit to the island, Mr. Forster and his companions crossed the plain, and arrived at a prodigious current of lava, intersected by many channels from six to eight yards deep, which appeared to have been formed by torrents of water, but which they found dry, as the fun was in the northern hemisphere. In these gullies they perceived a small quantity of flow which was a black volcanic earth mixed with some whitish particles, which were gritty to the touch. This flow afforded sufficient nutriment to purplane, and a species of grafts, the “panicum fanguineum.” Having with difficulty climbed over this lava current, they came to the foot of the “Green mountain,” which was surrounded by a lava, that was covered with purplane, and a kind of new fern, “lontchis adfencionis,” on which several wild goats were feeding. This mountain is divided in its extremities by various clefts into several bodies, which run together towards the centre, and form one broad mass of great height. The whole appears to consist of a gritty topcaveous limelene, which has never been attacked by the volcano, but probably existed, as Mr. Forster refused, prior to its eruption: its sides are covered with a kind of grafts peculiar to the island, which Linnaeus has named “arilida adfencionis.” The goats which feed on it were very numerous, but being very shy, they fled with great velocity over tremendous precipices, where it was impossible to pursue them. This island, with a little trouble, says this writer, might in a short space of time be rendered fit for the residence of men. The introduction of furze, “alex Europaeus,” and some other plants which thrive well in a parched soil, and which are not likely to be attacked by rats or goats, would soon have the same effect as at St. Helena. The moisture attracted from the atmosphere by the high mountains in the centre of the island, would then not be evaporated by the heat of the sun, but gradually be collected into rivulets, and supply the whole island. A sot of grafts would everywhere cover the surface of the ground, and annually increase the liratum of the mould, till it could be planted with more useful vegetables. The outskirts of the island are represented to be beyond description dreary. It is said that, as this island is visited by the homeward-bound ships on account of its few-bows, fishes, turtle, and goats, there is in the crevice of a rock a place called by the sailors the “Poll Office,” where letters are deposited, first up in a well-corked bottle, for the ships that next visit the island. Mod. Un. Hist. vol. xi. p. 145.

ASCENSION, or Ascension. n is a small island about 120 leagues east from the coast of Brazil, N. lat. 26° 55′; W. long. 35° 40′. Some have supposed this island to be the same with the isle of Trinidad or Trinity. M. de Perouse, who wished to ascertain the existence of the island of Ascension, made search for it, and avers (see his voyage vol. i. p. 24.) that no such island exists from the meridian of Trinidad to about seven degrees west longitude, between the latitudes of 20° 15′, and 25° 50′. M. Le Peutre d’Agelet also suspected (Mem. Acad. Sc. Paris, for 1788) the French geographers have committed an error with regard to the isle of Trinity, which they have laid down in their maps of the African seas, but which he thinks is really the isle of Ascension, which, by some error of reckoning, occasioned probably by currents, has been twice laid down. But M. Dapres (Neptune Oriental, p. 10.) has placed the island of Ascension 100 leagues west of Trinidad, and fifteen miles to the southward. It appears also, that though the latitudes of these two islands were nearly the same, their longitudes were very imperfectly ascertained; and from the minute and very different plans which Dalrymple has given of these two islands and their appearance, it is presumed that they are not the same. La Perouze did not pursue his researches far enough, as the isle of Ascension is probably somewhat nearer the coast of Brazil than Dapres has placed it.

ASCENSION Bay, lies on the east side of the peninsula of Yucatan, in the bay of Honduras, having Amber bay on the north, and the northern point of Anibergreafe key on the south, which forms a passage into Havana bay, south from Ascension bay.—Albo, a bay in the north part of the gulf of Mexico, situate between cape Balize at the mouth of the Missipi, and the bay of Fresh-water on the west, in N. lat. 30°, and W. long. 92°.

ASCENSIONAL Difference, in Astronomy, is the difference between the right and oblique ascension of the same point on the surface of the sphere.

To find the ascensional difference trigonometrically, having the latitude of the place, and the sun’s declination given, say, as radius is to the tangent of the latitude, so is the tangent of the sun’s declination to the sine of the ascensional difference.

E. G. Let it be required to find the sun’s ascensional difference at London, lat. 51° 32′ N. on the 21st of June, being the longest day, when the sun’s declination 23° 28′ N.

Let the primitive circle PESQ (afron. Pl. II. fig. 17,) represent the meridian of the place, and the diameter HI the horizon; take RP from R, the north point; for the latitude = 51° 32′; draw the axis, or 6 o’clock hour circle, ES, and perpendicular to it draw the equator EQ; make E6, EQ, each = 23° 28′, the declination, and describe the parallel of declination mn, interfering the horizon in Q, the place of the sun at his rising or setting, and through this point describe the hour circle P′O′S.

In the spherical triangle γ AΩ, right-angled at A, the angle Q γ R, measured by the arc QK, is the colatitude; AΩ is the sun’s declination; and the required ascensional difference is γ A, which may be found by the proportion above stated; viz.

Rad.
This afcencional difference, 33° 7', converted into time, gives 2h 12' 28" for the time which the fun rises, and after the hour of fix, on the longest day. Hence it appears, that when the latitude and declination have the same name, the fun rises before, and after fix; but when they are of contrary names, the fun rises after, and after fix. And as the fun describes the parallel of declination in 24 hours, being at m when it is noon, and at m when it is midnight, the time in passing from m to o, or the time of rising being doubled, gives the length of the night; and the time of setting being doubled gives the length of the day. Consequently, 6° 4' 12' 28" = 8° 12' 28", will be the time of setting; and 5° 2' 12' 28" = 3° 47' 34", will be the time of rising; and 8° 12' 28" = 10° 24' 56", the length of the day; and 5° 2' 12' 28" = 2° 35' 4", the length of the night.

But when it is the shortest day at London, that is, when the sun has 23° 28' south declination, the lengths of the day and night will change places; the day being 7° 35' 4", and the night 16° 24' 56".

When the latitude and declination have the same name, the difference between the right ascension and the afcencional difference, is the oblique decretion; and their sum is the oblique decretion; but when they are of contrary names, the sum is the oblique decretion, and the difference is the oblique decretion.

The above solution is applicable to a star, as well as to the sun; but on account of the small change in the declination of the stars, the star's obclination in any latitude may be considered as having the same afcencional difference through the year. Hence it appears, that the diurnal difference of the star's rising, culminating, and setting in the same latitude, is nearly equal to the diurnal difference of the sun's right ascension. As the star's mean apparent daily motion is 50° 8' nearly, or in time 3° 56' 32", this will be the daily difference in the rising, culminating, and setting of any fixed star in the same latitude.

ASCENSIONIS, in Ichthyology, a species of Perca which inhabits the sea about Ascension island; it is reddish above, whitish beneath, and the tail is bifurcated. Obs. It. p. 388.

ASCERSONUM sometimes occurs, in our ancient writers, for a fiah or flacp.

ASCENT, in a general sense, the motion of a body tending upwards, or the continual rerese of a body from the earth. In this sense the word stands opposed to descent.

The Peripatetics attribute the spontaneous ascent of bodies, to a principle of levity inherent in them. The moderns deny any such thing as spontaneous levity, and shew, that whatever tends, does it in virtue of some external impulse or attraction. Thus it is that smoke, and other rare bodies, ascend in the atmosphere; and oil, light woods, &c. in water, not by any internal principle of levity, but by the superior gravity, or tendency downwards of the parts of the medium in which they are.

The ascent of light bodies in heavy mediums is produced after the same manner as the ascent of the lighter scale of a balance. It is not that such scale has an internal principle by which it immediately tends upwards; but it is impelled upwards by the preponderancy of the other scale, the excess of the weight of the one having the same effect by augmenting its impetus downwards, as so much real levity in the other; because the tendencies mutually oppose each other, and that action and reaction are always equal. See this farther illustrated under the articles Specific Gravity, and Fluid.

ASCENT OF BODIES ON INCLINED PLANES. See its doctrine and laws, under Inclined Plane.

ASCENT OF FLUIDS, is particularly understood of their rising above their own level, between the surfaces of nearly contiguous bodies, or in vessels filled with fluid, other, or the like porous substances. This effect happens as well in vacuo, as in the open air, and in crooked as well as straight tubes. Some liquids, as spirit of wine, and oil of turpentine, ascend with greater celerity than others; and some rise after a different manner from others. Mercury does not ascend at all, but rather subides. The phenomenon, with its causes, &c. in the inclination of capillary tubes, will be spoken of at large under Capillary Tube. Upon the same principle, two smooth polished places of glass, metal, stone, or other matter, being so disposed as to be almost contiguous, have the effect of several parallel capillary tubes; and the fluid rises in them accordingly: the same may be said of a vessel filled with fluid, &c. the divers little interfices of which form it were a kind of capillary tubes. So that the same principle accounts for the appearance in them all. And to the same may probably be ascribed the ascent of the sap in vegetables. Thus Sir I. Newton: "If a large pipe of glass be filled with lifted allies, well pressed together, and one end dipped into flagrant water, the fluid will ascend slowly in the allies, so as in the space of a week or fortnight to reach the height of thirty or forty inches above the flagrant water. This ascent is wholly owing to the action of those particles of the allies which are upon the surface of the elevated water; those within the water attracting as much downwards as upwards: it follows that the action of such particles is very strong; though being less dense and closer than those of the glass, theirs action is not equal to that of the glass, which keeps quicksilver suspended to the height of fifty or seventy inches, and therefore acts with a force which would keep water suspended to the height of about fifty feet. By the same principle, a sponge sucks in water; and the glands in the bodies of animals, according to their several natures and dispositions, imbibe various juices from the blood." Optics, p. 367.

If a drop of oil, water, or other fluid, be laid on a glass plane, perpendicular to the horizon, so as to stand without breaking, or running off; and another plane inclined to the former so as to meet a-top, be brought to touch the drop, then will the drop break, and ascend towards the touching end of the planes; and it will ascend the faster in proportion as it is higher, because the distance between the planes is confluently decreasing. After the same manner, the drop may be brought to any part of the planes, either upward, or downward, or sideway, by altering the angle of inclination. Lastly, if the same perpendicular planes be fo placed, as that two of their sides meet, and form a small angle, the other two only being kept apart by the interposition of some third body; and thus immersed in a fluid tinged with some colour; the fluid will ascend between the planes, and thus the highest where the planes are nearest; so as to form a curve line, which is found to be a just hyperbola, one of the asymptotes whereof is the line of the fluid, the other being a line drawn along the touching sides. The physical cause, in all these phenomena, is the same power of attraction.

ASCENT OF HYDROSTATICS (Pl. I. fig. 1.), and Cohesion.
ASCENT of vapour. See Evaporation, Cloud, and Vapour.

ASCENT, in Astronomy, &c. See Ascension.

ASCEND, in Logic, denotes a kind of argumentation, wherein we rise from particulars to universals. As when we say, this man is an animal, and that man is an animal, and the other man, &c. therefore, every man is an animal.

ASCESIS properly denotes exercise of the body. It is formed from the verb *ασκίνω*, used by the ancients in speaking of the sports and combats of the athlete.

ASCESIS is also used by philosophers, to denote an exercise conducive to virtue, or to the acquiring a greater degree of virtue. Budæus has a dissertation on this philosophical asceticism.

ASCETERIUM, in Ecclesiastical Writers, is frequently used for a monastery, or a place set apart for the exercises of virtue and religion. The word is formed from *ασκήσις* "exercise," or *ασκήσας*, one who performs exercise. Originally it signified a place where the athlete, or gladiators, performed their exercises.

ASCETIC, derived from *ασκίνω*, "I exercise," an ancient appellation given to such persons as, in the primitive times, devoted themselves more immediately to the exercises of piety and virtue, in a retired life; and, particularly, to prayer, abstinence, and mortification. Molière (Eccl. Hist. vol. i. p. 195) traces the origin of this word in the Christian church to the second century. He states that the ascetics owed their rise to certain Christian doctors, who maintained, that Christ had established a double rule of sanctity and virtue, for two different orders of Christians; the one was ordinary, and designed for persons in the active scenes of life: the other, extraordinary and more sublime, and intended for those who, in a sacred retreat, aspired after the glory of a celestial state. Accordingly, they distributed those moral doctrines which they had received either by tradition or writing into the two classes of precepts and counsels; the former being universally obligatory upon all orders of men, and the latter, relating to Christians of a more sublime rank, who proposed to themselves great and glorious ends, and breathed after an intimate communion with the Supreme Being. Persons of this latter description declared their resolution of obeying all the counsels of Christ, in order to their enjoying communion with God here; and also that, after the dissolution of their mortal bodies, they might ascend to him with the greater facility, and find nothing to retard their approach to the supreme centre of perfection and happiness. They looked upon themselves as prohibited the use of things which other Christians were allowed to enjoy, such as wine, flesh, marriage, and commerce. See Athenagoras Apol. pro Chr. c. 29. They thought it their indespensible duty to exterminate the body by watchings, abstinence, labour, and hunger. They sought felicity in solitary retreats, and in desert places, where, by severe and arduous efforts of sublime meditation, they raised the soul above all external objects and all sensual pleasures. Both men and women imposed upon themselves the most austerities discipline, which, though at first it was the fruit of pious intention, proved in the issue extremely detrimental to Christianity. These persons were called "ascetics, Ἀσκητοὶ Ἐκκλησίας, and philosophers; nor were they distinguished from other Christians merely by their appellation, but also by their garb. In this century, such as embraced this kind of austerities life, contented themselves with submitting to all these mortifications in private, without breaking ablunde their social bonds, or withdrawing themselves from intercourse with mankind. In the next century, and particularly in the reign of Constantine, these ascetics, who, as an elegant historian describes them, (Gibbon's Hist. vol. vi. p. 239.) "obeysed and abased the rigid precepts of the gospel, and were inspired by the savage enthusiasm which represents man as a criminal, and God as a tyrant," fled from a profane and degenerate world to perpetuate solitude, or religious society, and assumed the name of "Hermit," "Monk," and "Anachoret," expressive of their lonely retreat in a natural or artificial desert. The reasons which gave rise to this austerities sect are sufficiently obvious. One of the principal was, the ill-judged ambition of the Christians to resemble the Greeks and Romans, many of whose sages and philosophers distinguished themselves from the generality by their maxims, by their habit, and, indeed, by the whole plan of life and manners which they had formed to themselves, and by which they acquired a degree of esteem and authority. Of all these ancient philosophers, there were none whose sentiments and discipline were so well received by the ancient Christians, as those of the Platonic and Pythagorean, who preferred in their levies two rules of conduct, one for the sages who aspired to the sublime heights of virtue, and another for the people involved in the cares and agitation of an active life. As the opinions of some of these philosophers were adopted by the more learned among the Christians, they were naturally led to incorporate into the moral discipline which refoluted from them. Some of the religious fervors which they recurred were deduced from the genius and temper of the people by whom they were first practised. This moral discipline originated in Egypt, which abounded with persons of a melancholy complexion, and produced, in proportion to its extent, more gloomy spirits than any other part of the world. Here the Essenes and Therapeutae, those dimal and gloomy sects, principally dwelt, long before the coming of Christ, and also many of the ascetic tribe, who, led by a certain melancholy turn of mind, and a delusive notion of rendering themselves more acceptable to the Deity by their austerities, withdrew themselves from human society, and from all the innocent pleasures and comforts of life. From Egypt this four and unformable discipline paffed into Syria and the neighboring countries, which also abounded with persons of the same dimal constitution with that of the Egyptians; and from thence, in proces of time, its infection reached to the European nations. Hence sprung that train of austerities and superfluous rites, that yet, in many places, cast a veil over the beauty and simplicity of the Christian religion. Hence the celibacy of the prieyst order, the rigour of unprofitable penances and mortifications, the innumerable swarms of monks that withdrew their talents and labours from society, and who did this in the form of a perfect pursuit of a visionary art of perfection. Hence also proceeded the distinction between the theoretical and mystical life, and many other fancies of a familiar kind. The ascetics acquired the respect of the world, which they deplored; and the loudest applause was bestowed on this "divine philosophy," as it was called, which surpassed, without the aid of science or reason, the laborious virtues of the Grecian schools. When the monks came in fashion, the title of ascetic was bestowed upon them; especially upon such of them as lived in solitude. See Hermit, and Monks.

ASCETIC is also a title of several books of spiritual exercises; as, the Ascetic or devout treatises of St. Basil, archbishop of Caesarea in Cappadocia.

We also say the ascetic life, meaning the exercise of prayer, meditation, and mortification.

ASCETERIUM. See Secretary.

ASCETIC, in Ornithology, the name by which the Harrier is known. See Harrier.
ASC

Lanias Schach of Linnaeus, or Chineke Shrike, is called in
China, and under which it is described by Orbeck, Voy. p.
227. See Lanies Schach.

ASCHACI1, in Geography, a town of Germany, in the
circle of Franconia, and bishopric of Wurzburg, thirty-two
miles north of Wurzburg.

ASCHAFE, a small river of Germany, in the circle of
the Lower Rhine, which runs into the Mayne near Stock-
field.

ASCHAFFENBURG, a town of Germany, in the circle of
Franconia, situate about twenty-five miles from
Frankfort on an eminence near the Mayne. It belongs to
the elector of Mentz, who has a palace here, in which he
resides during the great part of the year, on account of
the fulness of the air, and the singular beauty of the situa-
tion. The country surrounding the town is uncommonly
fertile. At the distance of two miles towards the north-eaft
is seen the "Spallart," one of the largest forests in Europe,
forming a semicircle round part of this town, and sheltering
it from the bleak winds. This forest occupies a space of
fifty English miles in length, and the traveller through it
meets with only one small village consisting of four houfes,
in which he may have any accommodation. The road
through it is very good, and the elector of Mentz, to whom
the great part of the country belongs, keeps it free from
robbers, so that it may be passed any time of the day or
night, without any apprehenfion of offense. For the secu-
rity of passengers, a military establishment, consisting of a
company of hufars, is fixed at Alchaffenburg; and thence
are traversing the road at flated hours in order to prevent
the possibility of a robbery. N. lat. 49° 55'. E. long. 8°
52'.

ASCHAM, Roger, in Biography, an English scholar of
distinguished reputation, was born at Kirby-Wake, near
North-Alefter in Yorkshire, about the year 1515, of parents
who, having lived together for fifty-seven years, with un-
interrupted harmony, died at the same hour of the same
day. Having discovered very promising talents at an early age, he
was taken under the patronage of Sir Anthony Wingfield,
and after making considerable progress in classical literature
under the instruction of the domestic tutor of his sons, As-
cham was removed by his patron, in 1530, to St. John's col-
lege at Cambridge. Here he enjoyed peculiar advantages for
improvement under the tuition of two persons who were
eminent for literature at a period when the study of the
Greek and Roman classics was the object of particular at-
tention. Of these advantages he availed himself with fingu-
lar affiuity and emulation; and his proficiency was so con-
siderable, that he gained very distinguished reputation in the
university at a very early age. In order to perfect himself
in the Greek language, he taught it to others; and learning
very soon to discriminate with regard to the comparative ex-
cellence of different authors, he lost no time in the perusal of
mean or unfrofitable books. Upon the model of Cicero
and Cofar, whose works he diligently studied, he formed
his style; and among the philosophers, he selected Plato
and Aristotle; among the historians, Thucydides and Herodotus;
and among the orators, Demoliiones and Isocrates; and on
these two last authors he read lectures to his pupils, as he
also did on the most celebrated of the Greek poets. At
the age of eighteen, in 1534, he took his degree of bachelor
of arts, and soon after in the same year was elected fellow
of his college, though his attachment to the reformed reli-
gion raised some obstacles in the way of this appointment.
These honours were conferred by Aracham as inducements
through his continued and increasing application; and such was
his improvement, particularly in the Greek language, that
his lectures, both in the university and in his own college,
were received with universal applause. In the year 1536,
and at the age of twenty-one years, he was inaugurated
master of arts. Such was the proficiency of those who at-
tended his lectures, that one of them vizi William Grindal,
was, at his recommendation, appointed to be tutor in the
languages to the lady Elizabeth, an honour which it is pro-
bable he might have obtained for himself, if he had not de-
cided it from a preference of the monastic life to a fitation
at court. At this time Sir John Cheke attempted to intro-
duce a new mode of pronouncing Greek into the univer-
sity, which for some time was opposed by Ascham; but
upon mature and more deliberate examination, he approved
of it, and concurred in adopting and promoting it; and it
has since generally prevailed in the Schools of England.
The purity and elegance of his Latin style was held in such
evaluation, that he was constantly employed in writing the
public letters of the university. As a relaxation amidst his
fewer studies, he amused himself with the exercise of arch-
ery; and having thus given offence to some persons who
were envious of his superior merit, he wrote a small treatife
on the subject, intitled "Toxophilus," which was published in
1544. His design in writing this treatife was partly to
vindicate himself from the alperions of his enemies, and
partly to improve the English language, by introducing a
more natural, easy, and truly English diction, than that
which was used by the common writers of his age. The
author's views in whicie these respects were fully accom-
plished. This work, besides the purity and peripuiciy of its
style, abounds with learned allusions, with curious frag-
ments of English history, and with ingenious obervations
on life and manners. Ascham honestly confesses, that he
was actuated by another more selfish motive in the com-
petition and publication of this treatife. He wished to make
a tour into Italy, which was then the republic of letters,
and particularly the feat of Greek learning, and he was
desirous by dedicating his work to king Henry VIII., to ob-
tain his patronage and encouragement in the prosecution of
his plan. In this respect, his modest and laudable wish
was gratified; for in 1544, the king granted him a pension of
100. a year, equal according to Dr. Johnson, to more than
100l. at the present day. This pension, which was discon-
tinued after the king's death, was restored by Edward VI.,
and doubled by queen Mary. In the same year, Ascham
received the peculiar benefit as well as honour of an ap-
pointment to the office of Orator to the university; which
office, whilst he continued there, he occupied with great
credit.

He had also for some years received an annual gratuity
at an amount that is not ascertained, from Lee, archbishop
of York. At length, viz. in 1548, upon the death of his
pupil Grindal, he was called by the lady Elizabeth, to
whom he had already given lectures in writing, from his
college, to direct her studies. This charge he executed with
equal diligence and success; but after two years, a caufe of
disatisfaction occurred, and he returned from the service of
the princes to the university. Notwithstanding this circu-
stances, the prince's regard for him continued; for in the
same year, 1550, he was recalled to court, and appointed
secretary to Sir Richard Morelly, who was then going as am-
bassador to the court of Charles V. During this expedition,
which lasted three years, he had opportunities of convers-
ing with many learned men in various parts of Germany
which he visited, and made an excursion into Italy, where he
was much disgusted with the manners of the inhabitants,
particularly the Venetians. One of the fruits of this tour
was a curious tract, intitled, "A Report and Discourse of
the
the Affairs and State of Germany," &c. which contains valuable information and judicious reflections.

On the death of Edward VI. in 1553, Morpurse was recalled, and Afcham returned to his college, with no other support than his fellowship and salary as orator to the university, and the liberality of his friends. But by the interest of bishop Gardiner, who, though he knew him to be a protestant, did not defer him, he was appointed Latin secretary to queen Mary, with a salary of ten pounds a year, and permission to retain his college preferment. Afcham by his prudence, without any visible compliance that reproached his integrity, enjoyed the favour of the queen, and in the most perilous times, he maintained his integrity with Elizabeth; and he was partly indebted to the fidelity of his friendship with Cecil for his prosperity in the next reign. Indeed, his learning, and the facility with which he wrote Latin, made him necessary at court. In his capacity as Latin secretary, he is said to have written in three days forty-seven letters to persons of such rank that the lowest of them was a cardinal. Upon the accession of Elizabeth, Afcham was continued in his former employments with the same stipend. He had daily access to the queen, and read with some portions of works in the learned languages for some hours every day, and of her proficiency under such a master many proofs remain. Notwithstanding the benefit which the queen derived from his services, and the intimacy with which she honoured him by permitting him to play with her at draughts and chess, he obtained from her no other recompense than a pension of twenty pounds a year, and the prebend of Wiltwang in the church of York. This poor pension has been ascribed by some to the parsimony of the queen, and by others to her knowledge of the extravagance of Afcham. He has been charged, and not unjustly, with a profligacy, disgraceful to a man of letters and humanity, to cock-fighting. In his "Schoolmater," he intimated a design of writing a book "Of the Cockpit," which he reckons among the palamines fit for a gentleman. It is a subject, however, of regret, that whilst the queen did not think him unworthy of her patronage, she did not think proper to remunerate him for his services with a liberality more suitable to her high station. In the year 1563, a conversation occurred at Sir William Cecil's on the subject of education. Whilst the subject was much agitated, and different opinions were entertained, Sir Richard Sackville was so much prepossessed in favour of Afcham, by the arguments which he used for the mild treatment of boys, that he solicited his counsel and assistance with regard to the education of his son, and at the same time requested that he would write a treatise on the general subject of education. Thus was produced Afcham's excellent performance, intituled, "The Schoolmater," a work replete with erudition, and suggesting useful advice on the best method of teaching the classics. Afcham particularly recommends the method of "double translation," which merits adoption in schools. This treatise was published after the author's death by his widow, in 1571; and reprinted with notes, in 1580, at London, by Upton, in 1711. Afcham's last illness was occasioned by too tedious application to the composition of a poem, which he intended to present to the queen on the New Year's day of 1569. He died in his 53d year, December 25th, 1568. His death was generally lamented, and the queen expressed her concern by exclaiming, that "she would rather have lost 10,000 l. than her tutor Afcham." His epistles, which have been much commended for the elegance of their style, and also for the abundance of historical matter which they contain, were published in 1577, by Grant, and dedicated to queen Elizabeth; and his miscellaneous pieces have been since collected by Bennett into one volume, with a life by Dr. Johnson prefixed, and published in 1761, in 4to. Afcham is said to have been an elegant poet; but his verses are not to be found in the best edition of his works. One of his biographers, speaking of his works, says, "His Toxophilus was a good book for young men, his Schoolmater for old men, and his Epistles for all men." Mr. Wood ascribes another work to our author, intitled, "Apologia contra Millan," printed in 1577, 8vo.

It appears from the writings of Afcham, and those records of his that remain, that his temper was amiable; that he was kind to his friends, and grateful to his benefactors; that he was inclined to free inquiry on the subject of religion, but too much engaged in other pursuits to bestow much attention on this object; that he was, as a man, respectable; and that, as a scholar, he promoted correct taste and found learning; and by thus serving both his contemporaries and posterity, he deserved much more ample recompense than he received. He died poor, and left a widow and several orphans in defunct circumstances. His poverty has been ascribed to some of his attachment to dice and cock-fighting; and it is noticed by Buchanan in the following short epigram, said by some to display more of wit than friendship, which he confected to his memory:

"Afchamum extinctum patriae Graeco Canum
Et Latina vera cum pictate, dolent.
Principibus vivit carus, juicundus amicus,
Re modica, in moreis diuere fama nesquit."

Thus translated, and paraphrased:

"The Attic and the Latin muse deplore
The fate of Afcham, once their joy and pride;
His lays shall charm the lifting crowd no more;
Esteem'd by kings, lov'd by his friends, he died.
Fortune denied her favours,—juicer fame
Honour'd his worth, and spread abroad his name."

ASCHARIANS, or ASHARIANS, followers of Afchari, or Achari, one of the most celebrated doctors among the Mahometans, who died at Bagdad, about the year of the Hegira 329, or of Christ 940, and who was secretly buried, left the Hanbalites, by whom his opinions were reckoned impious, should tear up his remains from the grave. The Asharians were a branch of the Sefatiensis; and their opinions were, 1. That they allowed the attributes of God to be distinct from his essence, yet so as to forbid any comparison to be made between God and his creatures. 2. As to predetermination, they held that God hath one eternal will, which is applied to whatsoever he willeth, both of his own actions and those of men, so far as they are created by him, but not as they are acquired or gained by them; that he willeth both their good and evil, their profit and their hurt; and as he willeth and knoweth, he willeth concerning them that which he knoweth. They went so far as to say, that it may be agreeable to the will of God that man should be commanded what he is unable to perform. But while they allow man some power, they restrain it to such a power that cannot produce anything new; God, they say, orders his providence so, that he creates after or under, and together with, every created or new power, an action which is ready whenever a man wills it and sets about it; and this action is called "each," or acquirement, being, in respect to its creation, from God, but in respect to its being produced, employed, and acquired, from man. This is generally allowed the orthodox opinion, and has been variously explained. 3. As to mortal sin, the.

Afchari.
Afcharians taught, that if a believer, guilty of such a sin, die without repentance, his sentence is to be left to God, whether he pardon him out of his mercy, or whether the prophet intercede for him, or whether he punish him in proportion to his demerit, and afterwards, through his mercy, admit him into paradise; but that it is not to be suppos'd he will remain for ever in hell with the infidels, since it is declared, that whosoever shall have faith in his heart, but of the weight of an ant, shall be delivered from hell-fire. This is generally receiv'd as the orthodox doctrine in this point, and is diametrically opposite to that of the *Motuaites*. D'Herbelot's Bibl. Orient. Sale's Koran. Prel. Difc. p. 165.

ASCHEAUS, in Geography, a town of Germany, in the circle of Saubis, eight miles north of Ravenspur.

ASCHBARAT', a town of Turqueflan, in the country of the Geces or the other side of the river Sihan.

ASCHEMOR, or ASCHE-MOR, a town of Persia, in the province of Chorafan.

ASCHENBOURKA, or ASCHE-BOURKA, a town of Languedoc.

ASCHENFELDEN, in Geography, a town of Auff. in the province of Chorafan.

ASCHENHAGENSKOF, in Geography, a town of Siberia, on the confines of China, 530 miles S.S.W. of Seelingfink.

ASCHER, a district of the See of Aberg-Herred in the diocese of Christiania or Aberghusen, in Norway.

ASCHERSLEBEN, a town of Germany, in the circle of Lower Saxony, and principality of Halberstadt, seated on the Eine. It was once the capital of a country to which it gave name, and was one of the most ancient provinces of the house of Anhalt. The circle of Afchfereben, or Afcan comprehends the tract which was once the Afchferleben or Gaterleben lake, about two German miles long and half a mile broad; but being drained between the years 1703 and 1709, is now become good corn and pasture land.

ASCHE, Asch Cramer, Asch Gefer, &c., in Ichthyology, synonymous names of the fish called Grayling in England; and by Linnaeus *SALMO THYMALLUS*; which see.

ASCHOUR, in Geography, a river that passes by the town of Kafch in Turquellen, towards the north.

ASCHRAFF, in Ancient Geography, a city of Persia, in the province of Mazendran, near the Caspian sea, was once the favourite residence of Abbas the great, but now fallen into decay; the splendid palaces and gardens being sunk into a ruinous state, since the commotions that followed the death of Nadir Shah.

ASCHTITKAN, in Geography, a town of Asia, in Independent Tartary, sixteen leagues from Samarcand.

ASCHWOMSEE, a lake of Prussia, forty miles south-east of Konigberg.

ASCIA, in Antiquity, an instrument, suppos'd to be of the same kind, used in the fabric of the Roman tombs, and frequently reprehend'd on them.

The formula "sub aecia dedicatur," is frequently found inscrib'd on ancient tomb-stones. We also meet with "ro-gum aecia ne polito," among the antique laws of the Twelve Tables. These expressions, and the figure of the aecia, as seen on the tombs, have puzzled several antiquaries, who have formed very curious conjectures concerning it. F. Martin rejects all their opinions, and with considerable probability affirms, that the aecia was a hoe, or sort of pick-axe for digging up the ground, which is to this day called affadis, in Languedoc. This aecia, he pretends, was not an instrument of common use, but consecrated and employed only for digging of graves; and that it is the fame with what Sidonius Apollinaris calls *rurum funeris*, whereas the Gauls digged their graves. Lib. iii. ep. 12.

This, he thinks, appears plainly to be the signification of the word, from the Latin proverb, "ipse mihi aecia in crus impexi," which often happens to those who work with this instrument.

On this footing the famous law of the Twelve Tables, wherein the aecia is mentioned, and the explication of which has puzzled all our antiquaries, contains only a prohibition to dig graves with an instrument of iron or copper, such as the aecia. In reality it was a tradition observed by the remote antiquity, that no instrument made of those metals might be used in sepulture.

Dom. Martin has given a dissertation concerning the funeral monuments of the Romans, consecrated "sub aecia." La Relig. des Gauls, tom. ii. liv. 5.

Mabillon, in his explication of the formula "sub aecia dedicatur," &c. conjectures that the ancients, in dedicating their tombs to the sacred, made imprecaions against those who violated their sanctity; and such imprecaions he conceives, were exprest by the figure of the aecia, which bore a threatening aspect. Much to the same purpose is the opinion of Muratori, who apprehends that the formula "sub aecia," or the aecia itself placed upon the tombs, was a tacit but well-known supplication addressed by the person interred to the owner of the field in which the grave was dug, that the adjacent soil might be hoed, the briars removed, and the earth rendered light over the ashes of the deceased. Accordingly, "fit tibi terra levis," is part of an epitaph found on ancient monuments. The sentiments of Mabillon and Muratori have been illustrated and confirmed by Count Caylus. Moreover it appears, that the Romans annexed no imperious ideas to the formula "sub aecia dedicavit," as the first Christians made use of it on their monuments.

Ascia is also used, in Surgery, for a kind of bandage somewhat oblique or crooked; whose form and use are well described by Scultetus, in his Arm. Chirurg. p. 1. tab. 54. fig. 3.

ASCIBURGIIUM, in Ancient Geography, a citadel on the Rhine, mentioned by Tacitus, in which were a Roman camp and garrison; situated in a place corresponding with a small hamlet, now called Asbury, not far from Meurs, in the duchy of Cleves.

ASCIDIA, in Natural History, the name of a genus of Vermes that belong to the Mollosca tribe, the body of which is fixed, roundish, and apparently issuing from a sheath; the apertures two, generally placed near the summit, one below the other, Genl. &c. These creatures are more or less gelatinous, and have the power of contracting and dilating themselves at pleasure; some are furnished with a long stem, but most of them are fleshy. Gemlin enumerates the following species: papillofa, gelatinofa, intestinalis, quadridentata, rotifica, echnata, mentula, venosa, prunum, conchilega, parallelogramma, virginea, canina, patula, alpina, icabara, orichalica, corrugata, lepadiiformis, conplanata, tuberculium, villosa, clavata, pedunculata, mammillaris, globularis, plurica, gelatina, crysaltina, ocellentata, pattelliformis, pyura, aurantium, globularis: which see respectively.

ASCII, formed of the primitive ax, and ou, shadow, in Geography, are those inhabitants of the globe, who, at certain times of the year, have no shadow; such are the inhabitants of the torrid zone, because the sun is twice a year vertical to them, and they have then no shadow—To find on what days the people of any parallel are ax; see GLOBS.

ASCINDEO, in Botany, a name given by the people of Guinea to a shrub, which they use in medicine, boiling it in water.
ASCITA, in Ichthyology, a species of Silurus, that differs in several respects from other creatures of the same tribe, and is specifically described as having the dorsal fin slaty, and eighteen rays in the anal fin. This fish inhabits the Indian seas, and is figured both by Bloch, and in Diderot's edition of Buffon. The mode of generation, or manner in which the young are produced, is singular, for it is neither oviparous, nor viviparous, but, partaking of both, forms a distinctly connecting link between those two natural divisions of fishes: the eggs are not composed like those of most other creatures, but consist merely of a yolk, without white, and surrounded by a thin skin to which the embryo is attached by means of an umbilical vein on the outside, and by which it receives its proper nourishment till it is disengaged. Among other reasons it is affected that it cannot be viviparous, because it does not receive its nourishment from the parent by means of a placenta, but from the yolk of the egg to which it is affixed while it remains in the matrix; and that it cannot be oviparous because the eggs are not as usual deposited when completely formed, nor are the young contained within the egg, but only attached to the outside of it.

ASCITE, derived from axios, a bag, or bottle, in Antiquity, a feot or branch of Montanillos, who appeared in the second century.

The Ascite were so called, because they introduced a kind of Baccanals into their assemblies, who danced round a bag or skin blown up; saying, those were those new bottles filled with new wine, whereof Jesus Christ makes mention, Math. ix. 17. — They are sometimes also called Aesopdracitae.

ASCites, in Ancient Geography, a people of Asia, placed by Pliny and Ptolemy in Arabia Felix.

ASCITES, in Medicine (from axios, uuter, a fæculus or bladder), denotes a species of Dropsy which is seated in the abdomen. This disease is commonly divided into two kinds: viz. 1. When the water is contained within the peritoneum investing the general cavity of the lower belly; and 2. When the fluid is included within a bag, or cyst, in which case it is called an incysted dropy : but the description of this disease, and its appropriate treatment, will be found under the articles Dropsy, and Paracentesis or Tapping.

ASCITE, the operation for, in Surgery, is named Tapping, which see. This operation is likewise technically called Paracentesis. It consists in drawing off from the abdomen, by means of a trocar, the water or other fluid which is contained therein.

Species, 1. Aristium noromnaeia, Aublet Guian. t. 220. This is a tree furnished with alternate entire thick leaves. The flowers grow in loose spikes from the ends of the branches; they are alternate, subulate, and to each is a long bracte, with a claw to it, resembling the cowled bag of marigovia, to which genus this seems nearly allied. It is a native of Guiana.

ASCLEPIAD, in Antiquity, seats celebrated in various parts of Greece in honour of Aesclusus. They chiefly consisted of sylvae, and a contest between musician and poets. They were also called Megalaxaetia, or the great festivals of Aesclusus.

ASCLEPIAD, Asclepliades, a Greek or Latin verse of four feet, containing a foonsee, a choriambus, and two daicbys; or, which amounts to the same, a foonsee, two choriambuses, and a pyrrhichius.

Such are the verses: "Maccenas atavis edite regibus."
"Sublimi seriam sidera vertice."

ASCLEPIADA, in Entomology, a species of Chryso- mela discovered by Pallas in the vicinity of the rivers Volga and Irtin, in Siberia. It is of a dull blue, and glossy; antennae black; dots on the thorax scattered; or the wing-cases disposed in lines. Pallas, Gmelin, &c.

ASCLEPIADES, Artorius, in Biography, physician and friend to Caesar Octavianus, by whom advice the emperor left his camp the evening before the battle at Phalippi, by which his life was probably preferred, that part of the army being surprized and cut to pieces by Brutus. Artorius perished by ship-wreck soon after the battle at Actium, and the emperor caused a magnificent monument to be erected to his memory at Smyrna. He is said to have maintained, that the stomach is the part principally affected in the hydrophobia. Haller Bib. Med. Pract.

ASCLEPIADES, descendants of Aesclusus, so called; who were supposed to have preferred the tenets of their progenitor, and to have founded schools of medicine in various parts of Greece, which continued many ages. The most famous were those of Rhodes, Chios, and Cos, formed by different branches of the family. Hippocrates was derived from the latter branch: see article Hippocrates.

ASCLEPIADES, a celebrated physician, born at Prusa in Bithynia, flourished somewhat before the time of Pompey, and formed an intimacy with Licinius Cnæus the orator, and other personages of distinguished character. It is not known whence he took his name, as he was not of the family of Aesclusus. After completing his education, he went to Rome, where he commenced by teaching rhetoric; but not succeeding in that line, he applied himself to the study of medicine, in which he soon became famous; for, rejecting the doctrines of his predecessor in that art, he formed a new theory of diseases, and instituted new methods of curing them. He avoided all harsh and violent drugs, particularly vomiting and purging medicines, which he contended injured the stomach, and induced complaints more dangerous than those they were given to remove, and proscribed to cure diseases, ".into, cité, et jucunda."

Rome cum vixerat (Haller says) ad luxum et inofficiem Romanorum artem accomodavit. He was attached to the corporeal philosophy, and supposing that the free motion of the corpuscles in the vellis constituted health, and that disease ensued when they were restricted or checked in their motion by the straitness of the vellis. "Thus pains, ardent fevers, intermittents, &c. were occasioned (he said) by corpuscles impacted in the pores."

A doctrine full as intelligible, "as the vent of the humours obstructing the vellis," the favourite theory of one of the most celebrated teachers.
In 1753, he prohibited all food, and even drink to his patients, for three or more days, but when by this means, the violence of the fever was abated, he indulged them with animal food, and wine. When coffee, he used glycerin, which he frequently employed. In pleurisy, and in other complaints attended with violent cough, he preferred bleeding, but in chronic complaints, he depended principally on abstinence, exercise, baths, and frictions. Thence, he said, opened the pores, and gave free exit to the obstructed particles.

That he was in high repute in his time, we have the authority of Celsius, Caius Avredemus, Galen, and Scribonius Largus, from whose writings what is known of his opinions and practice is principally taken, as none of his works have been preserved. Mithridates, king of Pontus, invited him to his court; but his employment at Rome was too lucrative to permit him to accept the offer.

But besides the reputation he acquired by his practice, his fame was further increased by the number of pupils or disciples who attended his school, and who continued to follow his method long after his decease. Themison, one of his disciples, in part adopting, and in part deviating from his doctrine, formed a new sect, under the title of the Methodic, which in its turn became popular. Achesiades is said to have pledged his reputation on preferring his health, to have lived to a great age, and to have died at length in confinement of an ulcer. Le Clerc Histoire de la Medicine, Haller Bib. Med. Præc. who gives a detailed and particular account of his practice in a variety of diseases.

Asclepias, a Greek philosopher of the Eliac school, was born at Phìla, in Poloponous, and flourished about 250 years before Christ. He was the intimate friend and associate of Menedemus, whilst they both attended the school of Stilpo, and afterwards when they attended Plato's school at Elis. They were under a necessity of supporting themselves by the manual labour of masons. They left their country for the sake of enjoying the advantages of Plato's school at Athens, and gained a sufficiency by grinding in the night in one of the public prisons, that they might be able to spend the day in the academy. When the Athenian magistrates, upon inquiring into their mode of sufficiency, were informed of this circumstance, which manifested their ardent desire of knowledge, they approved their zeal, and presented them with 200 drachmas. In advanced life, Asclepiades lost his sight, but bore the affliction with cheerfulness. Athen. l.iv. c. 19. Ciceron Tusce. Dilp. i.v. c. 59. Dioq. Laert. vit. Mened. Brucker by Eischen, vol. 1. p. 197.

Asclepias, in Botany, swallower. (From Ἀσκληπιας, the god of medicine.) Lin. gen. 306. Schreb. 449. Jaff. 147. Gaertn. 1177. Class. pentadria digynia. Nat. Order. Conertae.—Apoeciae. Jaff. Gen. Char. Cal. pterianth five-cleft, sharp, very small, permanent. Con. monopetalous, flat, or reflex, five-parted; divisions ovate-acuminate, slightly bending with the fun; nectaries five, growing to the tube of the filaments, slyly, or cowled; a sharp horn protruding from the bottom, bending inwards. Stam. filaments five, collected into a tube, swelling at the base; anthers oblong, upright, two-celled, terminated by an inflex membrane lying on the stigma, having a reversed wing on each side; the pollen is collected into ten corporules, inflexible lanceolate, flat, hanging down into the cells of the anther by short threads, which are annexed by pairs to five carilaginous twin tubercles, each placed on the tip of the wings of the anthers, adhering to the angles of the stigma, between the anthers. Fls. germs two, oblong, acuminate; stigmas two, subulate; stigma common to both, large, thick, fire-cornered, covered at the top by the apexes of the anthers, umbilicate in the middle. Per. foliakes two, large, oblong, acuminate, swelling, one-celled, one-valved. Seeds, numerous, imbricate, crowned with down; receptacle membranaceou, free.

Ell. Gen. Char. Contorted; nectaries five, ovate, concave, putting forth a little horn. Species—

1. A. undulata, waved-leaved swallow-wort, apocynum africanum, lapathifolius, comm. Carr. t. 16. "Leaves sessile, oblong, lanceolate, waved, smooth." A native of the Cape of Good Hope. It was introduced into our gardens in 1783. Its flowers appear in July. 2. A. crispus, curled-leaved swallow-wort; apoc. creutum afric. &c. Herrn. par. 25. Comm. Carr. t. 17. "Leaves cordate, lanceolate, wavy, februous, opposite; umbel terminal." Its stem is pubescent, branching at the bottom; leaves subsessile, repand; one umbel of yellow flowers terminates the stem. Found at the Cape by Spreckens. Introduced into the Kew garden by Mr. Malfon in 1774. 3. A. pubescens, pubescent swallow-wort; apoc. afr. tuberufum, &c. Morr. Hist. 3. 612. Pluk. 139. f. 1. "Leaves ovate, veined, naked; stem harby; peduncles villose; the stem is harby, simple or little branched, very short villose; leaves on very short filo-alaks, villose, pointed, much veined, rather crowded; peduncles and umbels villose; flowers purple. A plant of the Cape of Good Hope." 4. A. puberula, twining swallow-wort, Rheed. Mal. 9. 21. t. 13. Rumpl. Amrb. 5. t. 175. f. 1. "Leaves ovate, entire, acuminate; stem arborous, twining; umbels erect; stem smooth; branches shining; leaves petiolate, ovate-subcordate, veined; umbels simple, on peduncles the length of the petiole; flowers greenish. A native of Malabar and Ceylon. 5. A. oblongum, allomatic swallow-wort. "Leaves petiolate, cordate-ovate, above smooth, entire; stem harby, twining, hirtute; umbels few-flowered." The whole plant is villose, except the upper surface of the leaves, which resemble those of lauter, heart-shaped at the base, pointed at the apex; umbels shorter than the leaves, often proliferous; flowers small. Found in the woods of Ceylon by Kcening. The root is esteemed in allomatic cafes. 6. A. gigantea, curved flowered gigantic swallow-wort, Brown. Jam. 182. 1. "Leaves obvate-ellong; petioles very short; segments of the corolla reflex, involute." It rises six or seven feet in height; leaves thick; flowers white; pods very large; nectaries without horns. Browne says, in Jamaica it is called auencula, or French ja- min. Cultivated at the royal garden, Hampton court, in 1690. It flowers from July till September. 7. A. viridus, Syrian swallow-wort. Hort. Cliff. 78. 8. A. exulata. Lin. Spec. 513. "Leaves oval, tomentose underneath; stem simple; umbels nodding," root creeping; stem strong, four feet high, on the sides of which, and near the top, the flowers appear, these are of a dingy purple, succeeded by large oval pods. A native of North America, and culturaed by Parkinson in 1629. In Canada, the French eat the tender shoots as asparagus. Poor people collect the cotton from the pods, with which they fill their beds. On account of the silkiness of this cotton, Parkinson calls the plant Virginian silk. 8. A. amoena, oval-leaved swallow-wort; apocynum, Dill. Eith. 31. t. 27. f. 30. "Leaves ovate, rather hairy underneath; stem simple; umbels nodding;" root creeping; stem strong, four feet high, on the sides of which, and near the top, the flowers appear, these are of a dingy purple, succeeded by large oval pods. A native of North America, and cultivated by Parkinson in 1629. In Canada, the French eat the tender shoots as asparagus. Poor people collect the cotton from the pods, with which they fill their beds. On account of the silkiness of this cotton, Parkinson calls the plant Virginian silk. 9. A. amoena, oval-leaved swallow-wort; apocynum, Dill. Eith. 31. t. 27. f. 30. "Leaves ovate, rather hairy underneath; stem simple; umbels nodding;" root creeping; stem strong, four feet high, on the sides of which, and near the top, the flowers appear, these are of a dingy purple, succeeded by large oval pods. A native of North America, and cultivated by Parkinson in 1629. In Canada, the French eat the tender shoots as asparagus. Poor people collect the cotton from the pods, with which they fill their beds. On account of the silkiness of this cotton, Parkinson calls the plant Virginian silk.
are straighter, longer, stiffer, more acute, and less excised than in the other species; the flowers are of a bright purple colour. Cultivated by Dr. Sherard, at Eltham, in 1732. A native of North America. 9. A. purpurascens, purple Virginian swallow-wort, Dill. Elth. 32. t. 28. f. 31. "Leaves ovate, villose underneath; stem simple; umbels erect; nectaries reflexuate;" stems many, as thick as the little finger, at bottom obtusely quadrangular; leaves on short stalks, from four to six inches long, with a purple midrib; flowers of a dusky herbaceous colour; horns of the nectaries horizontal. A native of North America. Cultivated by Dr. Sherard, in 1732. Linnaeus observes that this species is nearly related to A. Siliquaria. 10. A. carinata, variegated swallow-wort, apoc. americanum. Dill. Elth. 32. Pluck. Alm. 34. t. 77. f. 1. "Leaves ovate, wrinkled, naked; stem simple; umbels subsessile; pedicels tomentose." According to Miller, this resembles the foregoing only, but the leaves are rough, and the umbels of the flowers are more compact; they come out on the side of the stalk, are of an herbaceous colour, and not inclosed by pods in this country. A native of North America. We learn from Plunket, that this plant has been cultivated here in 1696. 11. A. cuneifolia, Cursesia swallow-wort, bladed isopacanuha, Brown. Jam. 183. 2. Apocynum. Dill. Elth. 33. t. 30. f. 33. "Leaves lanceolate, smooth, shining; stem simple; umbels erect, solitary, lateral." The flower is from one to two or three feet in height; leaves opposite, and decussate, petioled, acute, entire, smooth on both sides; flowers in umbels; umbellets terminal; involucre a few subulate leaves; pedicels one-flowered; corolla reflex; the flowers, according to Brown, are of a crimson colour in the low lands, but in the cooler island pastures they change to a white. This species so much resembles A. nivea, that Swartz doubts whether it be really distinct from it. Miller affirms that the roots have been sent to England for isopacanuha. The juice of the plant has been used as a vermifuge. It is a native of South America, the West Indian islands, and China. In 1692, it was cultivated in the royal garden at Hampton-court, where it flowered from June till September. 12. A. nivea, white or alabond leaved swallow-wort. Apocynum. Dill. Elth. 33. f. 32. Florn. Spec. 2. t. 30. "Leaves ovate-lanceolate, smooth; stem simple; umbels erect, lateral, solitary;" stems two feet high, bright, round, the size of a fawn's quill, dark green; leaves like those of common pericaria, deep green above, pale beneath, smooth, rather soft. The principal difference between this and the curcavifolia is in the flowers, which are green with white nectaries. A native of North America. Cultivated by Dr. Sherard in 1732. 13. A. intergata, bluish-coloured swallow-wort, Jacq. Hort. 2. t. 107. "Leaves lanceolate; stem divided at the top; umbels erect, twin." This puts several upright flanks, about two feet high; at the top of which are produced close umbels of purple flowers in Augt. A native of North America. Cultivated by Miller in 1731. 14. A. descendens, decumbens, swallow-wort. "Leaves villose, stem decumbent." The flanks are declivity, hairy, a foot and a half high; leaves narrow; umbels compact, at the extremity of the branches; flowers of a bright orange colour. A native of North America. 15. A. laifera, milky swallow-wort; "Leaves ovate; stem erect; umbels proliferous, very short." This is so like the vincetoxicum as scarcely to be distinguished from it; the leaves however are less cordate, the corymb compound, and scarcely longer than the pediels. A native of Ceylon. 16. A. vincetoxicum, official swallow-wort, Florn. Dan. 8.9. Woody. Med. Bot. Supp. B. A. Letea. Mill. Dict. "Leaves ovate, bearded at the base; flern erect; umbels proliferous;" root divided and fibrous; stems about two feet high, slender, woody, round, hairy; leaves cordate-ovate, acuminate, smooth, entire, on short footstalks; peduncles axillary, many-flowered; corolla white; follicles ovate-acuminate; seeds small, brown, included in cotton. It flowers during the months of June, July, and August. It is common in the northern parts of the continent. The medical virtues of the root are flated by Bergius to be ductive, sudiforme, emmenagoge, and alexipharmic. 17. A. nigra, black swallow-wort, Villars' Dauph. 487. "Leaves ovate, bearded at the base; flern twining a little at the top." This agrees with the official species in the shape of its roots, leaves, and flowers, but the flanks extend to a greater length, and at the upper part twist round other plants, &c. near them; the flowers are black. A native of the south of France. ** Leaves revolute at the sides. 18. A. arborescens, arboresect swallow-wort, apoc. frutice. &c. Berm. Afr. 21. t. 13. "Leaves ovate; stem pubescent, f. villose; stem simple, as thick as the finger, rough, with hairs; leaves opposite, on very short petioles, obulate, but with a minute smooth point; peduncles from the summit of the stem, umbellet, villose; corollas white. A native of the Cape of Good Hope. Cultivated by the dacha of Beaufort in 1714. It flowers in December. 19. A. fruticosus, thorny, or willow-leaved swallow-wort, A. glabra. Mill. Dict. n. 2. apoc. erucatum afric. &c. Mill. fig. 45. β A. crassifolia, Lin. Syn. ed. 13. "Leaves linear-lanceolate, stem thorny;" the nectaries are composite, without a claw, instead of which are two long reflex ears; follicles inflated, set with soft prickles. This is a native of the same place, and was cultivated in the same year, and by the same person, as the A. arborescens. 20. A. repandus, repand swallow-wort, apoc. erucatum afric. subfibrutum, &c. Herb. Par. 45. Comm. Rar. t. 17. "Leaves revolute, repand, hairy;" this is given on the authority of Richard. Its native country is unknown. 21. A. fibres, Siberian swallow-wort, Mur. Comm. Gott. 1779. t. 7. Gmel. Sib. 45. n. 21. "Leaves linear-lanceolate, opposite, or in threes, stem decumbent." This varies with alternate leaves. It is a native of Siberia, and cultivated in 1775, by Mr. J. Gordon. It flowers in July, 22. A. verticillata, verticillate swallow-wort, apoc. marianum, &c. Pluck. Mont. 17. t. 356. f. 4. "Leaves linear verticillate, stem erect;" flanks fider, upright; flowers small, white, in umbels at the top of the stems; leaves frequently four together. A native of North America. Cultivated by Miller in 1739. *** Leaves alternate. 23. A. rubra, red swallow-wort. "Leaves ovate, umbels many, from the same common pedicel." Stem upright, simple, annual; leaves acuminate; several umbels on a pedicel. A native of Virginia. 24. A. tuberosit, tuberosum swallow-wort, apoc. Nov. Angliae, &c. Herb. Lugd. t. 647. Dill. Elth. 33. t. 58. f. 34. "Leaves lanceolate; stem divaricate, hairy." Stems a foot high, hairy, round, dasky red; leaves alternate, except at the upper part of the stem, and where the branches arise; flowers of a bright orange colour; the tuberos roots are very large. A native of North America, flowering in Augt. Cultivated in 1690, in the royal garden at Hampton-court. *** 25. A. diffusa, narrow leaved swallow-wort. "Leaves dilatina; stem erect; umbels lateral, elongate, peduncled." This species was found at the cape of Good Hope, by Thunberg. 26. A. grandiflora, great flowering swallow-wort. "Leaves petiolate, oblong, hairy; stem simple, rough, erect; flowers axillary, peduncled." The flower of this is very large, coloured, and frilled like that of the fritillary
frilly. It also was found at the cape by Thunberg. 27. A. caroja, fliehy-leaved swallow-wort. "Leaves ovate, fliehy, very smooth;" leaves about four inches long, without veins; petals fliehy, half the length of the leaves; umbel simple, axillary, foliary; calyx minute; corolla scarcely half-five-cleft, flat. This differs much from the other species. A native of China. 28. A. lamens, climbing swallow-wort, Mill. Dict. n. 19. "Leaves oblong, lanceolate, suberhifate; stem thrumby, climbing; umbels lateral, compact." It climbs to the height of ten or twelve feet. At the joints are two opposite leaves, on short foot-stalks. Flowers of a sulphur colour, and appear in August. A native of Carthage. Cultivated by Miller in 1759. 29. A. proceru, all-flowered gigantic swallow-wort, Ait. Hort. Kew. A. gigantea, Jacq. Obi. 5. 17. t. 69. "Leaves obovate-oblong, petals very short; corollas subcampanulate." A native of Peru. Cultivated in 1714 by the duchess of Beaufort. It flowers from July till September. This ought to be placed before A. gigantea at 6. 33. A. purisfolia, small-flowered swallow-wort, Ait. Hort. Kew. t. 537. A native of Carolina and East Florida. Introduced by Dr. Litchfield in 1774. 31. A. tennata, a tall flax-flowered swallow-wort, Cavan. HISP. 42. t. 57. "Leaves scattered, fahulate, channelled; umbels laterall, many-flowered." A foot high; leaves narrower at the base, numerous; corolla white. We are ignorant of its native country. It has been cultivated in the royal garden at Madrid since 1788, and flows in autumn. 32. A. mexicana, Mexican swallow-wort, Cavan. HISP. 42. t. 58. "Leaves fix together in whols lanceolate; flowers unbemelled." Stems upright, smooth, a foot and a half high; leaves quite entire, with a short petiole; corolla white, deeply five-parted. A native of Mexico, and cultivated at the royal garden Madrid. 33. A. jucet, Lour. Cochinch. 170. "Stem creeping; leaves cordate, lanceolate; umbels axillary, in pairs," Stem herbaceous, twiving, flender, much branched at the top; leaves opposite, small, bearded at the base; flowers dully purple, small, with five car- shaped nectaries. A native of Cochinchina. 34. A. viminalis, Swartz. Prodr. 53. Brown. Jam. 183. 3. Sloane. 1. 207. t. 131. "Stem suffruticose, twining, filiform; leaves opposite, lanceolate, smooth; umbels lateral, many-flowered." Stalks flender, weak, spreading to the diameter of some yards. It has very few leaves, but many flowers disposed in large umbellate groups; it abounds with a milky juice. A native of Jamaica, in woods.

Propagation and Culture. In this numerous genus, only two species, viz. 16. and 17. are European; two or three are from South America; the rest are natives of North America, the East and West Indies, or Africa. Such as are inhabitants of North America, 7—10, 12, 13, 14. 22—24. are, as well as the European, hardy enough to bear the open air, and therefore are proper for large borders in pleasure grounds, and to mix with shrubs. The other species require the protection of the greenhouse or frame; all of them are tall perennials, flowering from June till August or September, mostly dying down to the root in autumn. They should have little water, especially in winter; they may be propagated by seeds where they can be obtained, or by cuttings; the hardy sorts may be increased by parting the roots. 1, 2, 3, 18—20, 25—27, 30, must have the shelter of a greenhouse in winter; 4, 5, 6, 14, 15, 28, 29, 31—34. can not live out in a frame. These must be raised from seeds sown in the spring on a hot-bed, and being transplanted into pots filled with rich earth, must be plunged into the sand-bed in the frame. After the second year, the 31th foot becomes naked, and does not produce many flowers, so that young plants ought to be reared to succeed them, especially as it produces plenty of seeds in England. All the Cape farts, 1, 2, 5, 6, may be propagated by seeds sown in April on a bed of light earth in the open air, and when the plants are three or four inches high, they should be each planted in a small pot filled with light earth, and shaded till they have taken new roots; then they may be placed with other exotic plants in a sheltered situation until October, when they may be removed into the green house or dry frame. They may also be increased by cuttings. The roots of the 8th and 22d should be planted in a warm border, and in winter covered with old tan. The 14th and 24th are propagated by seeds in pots placed in a moderate hot-bed, and gradually exposed to the open air as soon as the weather will permit. When they are of a proper strength, they may be planted in a warm border, and treated as other tender plants. See Martyn's Miller's Dict.

ASCLOSTERS, in Geography, a town of Sweden, in South Gothland, twelve miles south of Wardberg.

ASCOS, a town of Spain, in Catalonia, seated on the Ebro, ten leagues from Tortosa.

ASCODRUTE, in Antiquity, a feast in the second century, who rejected all use of symbols and sacraments; on this principle, that incorporeal things cannot be communicated by things corporeal, nor divine mysteries by any thing visible.

ASCOPHYSUS, in Middle Age Writers, denotes a bridge supported on bags made of leather or bullocks hides, Such bridges appear to have been in use among the ancients, and to have given the denomination to a tribe of Arabs, hence called Asita.

Hence also the appellation ofosonanii, given to pirates, by reason of their using bridges, or rather boats made of leather. Plin. Hist. Nat. lib. vi. c. 9. Du-Cange.

ASCOLI, in Geography, a town of Italy, in the eflate of the church, and marquisate of Ancona, seated on a mountain between the rivers Tronto and Caflirrino; twenty leagues south of Ancona, twelve north-east of Aquila, and thirty north-east of Rome. N. lat. 42° 50'. E. long. 15° 3'.

ASCOLI de SATRACOS, a town of Italy, in the kingdom of Naples, and province of Capitanata, the fee of a bishop. This town was almost destroyed by an earthquake in 1399. N. lat. 41° 8'. E. long. 15° 32.'

ASCOLIA, in Antiquity, a feast which the peasants of Aitica celebrated in honour of Bacchus.

They sacrificed a be-goat to him (as being the destroyer of vines); and of the victim's skin made a foot-ball, which they blew up, and anointed with some unctuous matter; or, as Potter thinks, they made a bottle of it, which they filled with oil and wine. The young people playing at this, and keeping themselves always on one foot, whilst the other was suspended in air, by their frequent falls gave occasion of diversion to the spectators. He that held the foot longest, and made the largest hops, was the conqueror. Hence the game called ascolia. Pitticus.

ASCOMARIH, in Ancient Geography, a people of Asia, in Sarmatia. Phiny.

ASCONA, in Geography, a town of Switzerland, lying on the Locarno lake, in which which is a college for the instruction of youth, founded in the sixteenth century.

ASCONIUS, PADIUS, in Biography, a Roman grammarian, was a native of Padua, and lived in the time of Augustus; the friend of Virgil, and the acquaintance of Quintilian and Livy. His notes on Cicero's orations are judicious, and still exist, though in a mutilated state. They were first published, with theof Luke's, in folio, at Venice, in 1477; and
and at Padua in 1493. They have been intermixed with those of other commentators, and may be found in Gronovius's edition of Cicero, published in 1640. Fabr. Bib. Lat. l. ii. c. 6.

ASCORA, in Geography, a province of the empire of Morocco. See ESCURA.

ASCORDUS, in Ancient Geography, a river of Greece, in Macedonia, one day's journey from Agrippa. Livy.

ASCOTANESE, a people of Asia, in Scythia, on this side of Imus. Ptolem.

ASCOTIA, in Geography, a town of Spain, in the province of Guipuscoa, on the river Urola, west of Tolosa, and two leagues east of Placentia.

ASCRA, in Ancient Geography, a town of Greece, in Eutonia, near mount Helicon. From its having been the place where Hecate was brought up, though he was born at Cumna in Eolis, it was called his country.

ASCRIPTII, or Adscripti, in Antiquity, those who entered their names in the colonies, and became coloni.

ASCRIPTITII, or Adscriptiti, a kind of villains, who, coming from abroad, settle in the lands of some new lord, whose subjects or servants they commence; being so annexed to the lands, that they may be transferred and sold with the same.

The aephritii are annexed to the land they hold, so that they cannot flir from it; besides that, whatever they acquire accedes to the benefit of the lord of the land. Du-Cange, and Calv. Lex. Jur.

ASCRIPTITI is sometimes also used in speaking of aliens or foreigners, newly admitted to the freedom of a city or country.

ASCRIPTITII was also used in the Military Laws, for the recruits appointed to supply the lobbies of the legions; called also Accessi.

ASCULUM APELUM, or Aeplum of Apulia, in Ancient Geography, now Afoil of Capitania, was situated in the Tranjan way which passed from Beneventum to Cananum, between Trivium to the west, and Cananum to the north-east. This place is famous as the scene of the first battle in which the Romans obtained success against the Epirus, under the command of Pyrrhus. Of this action, however, historians give a different account. Plutarch pretends that Pyrrhus gained a complete victory; whereas Eutropius affirms, that he was entirely defeated, and fled to Tarentum. Dionysius of Halicarnassus says, that the victory was doubtful, and claimed on both sides, and that Pyrrhus being congratulated upon his successes, replied, "Such another victory would undo me."

ASCULUM PILEUM, now Afoil of Ancusa, was the capital of the Piceni. It was a municipal town, and a Roman colony. Cicero (De Orat. c. 46) commends an orator, named "Butoecius Barrus," who was born in this city, and of whose discourses delivered at Asculum, some remained in his time.

ASCURA, a town of Asia, in the greater Armenia. Ptolem.

ASCURUS, a river of Colchis, according to Arrian.—Allo, a town of Africa, in Mauritania.

ASCUS, in Natural History, a word used by De Laet, as the name of that pouce or bag with which nature has supplied the animals of the Diadopli oder Opossum tribe, for the protection of their young; and in which they are contained in a state of imbecility, or time of danger. Later writers, as Linnæus, Gmelin, and others, call this abdominal pouce, or receptaculum, folliculatum; it is not the womb, as is vulgarly imagined, but a kind of skiny bag, situated under the belly, and in most species containing the teats of the animal.

ASCYRUM, in Botany, a genus of plants resembling St. John's wort (supposed from a, and espris, or espris, afferratus, not rough, a soft plant). Lin. g. 933. Schreb. 1225. Gaertn. 62. Juss. 254. Clas. polydendra polyandro. Nat. Ord. rotenace.—Hyrcanic, Jul. Gen. Char. Col. perianth four-leaved: the outer leaves opposite, very minute, linear; the inner heart-shaped, large, flat, erect, all permanent. Cor. petals four, oval; the outer opposite, very large; the inner less. Stams. filaments numerous, bristle-shaped, slightly united at the base in four parts; anthers roundish. Pill. germ oblong; style scarcely any; stigma simple. Per. capsule oblong; scorturate, one-celled, two-valved, inclosed by the larger leaves of the calyx. Seeds, numerous, small, roundish, fixed to the edge of the valves.

Eff. Gen. Char. Col. four-leaved; petals four; filaments many, in four divisions.

Species, 1. A. erus Aureus, common alyssum, or St. Andrew's cross. "Leaves ovate; stem round; panicle dichotomous." Stalks about six inches high, slender, dividing into two towards the top; from between the divisions of the branches leaves of small yellow flowers are produced; capsule small, pointed at the ends, compressed like a lens, obliquely two-lobed. A native of North America. Cultivated by Miller, in 1759. It flowers in July and August. 2. A. hypericoides. Brown, jam. 329. Swartz. Obs. 293. Hypericoides, &c. Plum. Gen. 51. t. 152. f. 1. "Leaves oblong; branches ascending." An elegant little shrub three feet high, full of leaves and branches. Branches dichotomous; twigs compressed and ascipital; leaves opposite, subfusiform, lanceolate, obtuse, entire, very finely perforated, smooth, at the base small glands; flowers terminating solitary, yellow; two leaflets of the calyx four times larger than the others. A native of South Carolina, Virginia, Maryland, and the cooler mountains of Jamaica. Cultivated by Miller, 3. A. villosum, "Leaves hirsute; stem fluff and straight." This grows about three feet high. The flowers are produced at the ends of the flalks, and are of the same shape and color as those of common St. John's wort. It grows wild in Virginia, and was cultivated by Miller in 1759.

Propagation and Culture. These are perennial plants, the stems decaying in the autumn. The first may be increased by laying down its branches; it loves a moist soil and shady situation. The second often barely produces seeds in England, but may be propagated by cuttings of the young shoots in May, planted in pots, and plunged in a moderate hot-bed, and afterwards transplanted into a warm border; but in severe winters they must be defended from the frosts by covering the roots with straw. The third may be increased by parting the roots in autumn, and planting them in a loamy soil. See Martin's Miller's Dict. of.

ASCYRUM. See Hypericum.

ASDRUBAL, in Biography, a name given to several of the Carthaginian generals. Adefrubal, the son-in-law of Hamilcar, the father of Hannibal, accompanied Hamilcar into Spain after the first Punic war; and on his death, was elected by the army his successor. Having made considerable conquests in Spain, he built a city called New Carthage, now Carthagena, in order to secure them. Hannibal served during three campaigns under him. His administration in Spain was prosperous for eight years; but it terminated with his assassination, which was effected by a Gaul, whose mother he had put to death. The assasins was so gratified with his revenge, that he feared in the midst of the tortures...
with which he was executed.—Asdrubal Barca was the son of Hamilcar and brother of Hamilcar. He commanded in Spain, while his brother was in Italy. After extirpating a rebellion of the natives, he was summoned to the assistance of his brother, but in his progress was completely defeated by the Romans. Asdrubal and the other Carthaginian generals maintained themselves with difficulty in Spain, and were frequently defeated by the two Scipios; but at length these two leaders were overpowered by the Carthaginians, and killed. Whilst he was advancing along the coast of the Adriatic to join his brother, and the existence of the Roman state was threatened by his numerous army, he was met at the river Metaurus, now Metauro, by the two confuses Livius and Claudius Nero with their united forces; and a bloody engagement ensued, which proved decisive, for Asdrubal was slain, and almost the whole of his army destroyed. Claudius Nero carried the head of Asdrubal to his station before Hannibal; and when it was thrown into the Carthaginian trenches, it was presented to Hamilcar, who recognizing his brother’s features, exclaimed “I perceive the fortune of Carthage,” and then retired, in the year before Christ 205, into the extremity of Italy.—As-

drubal, the son of Gisco, served in Spain with the former Asdrubal, and afterwards in Africa, against Scipio. He was father of the celebrated Sophonisba. —Another Asdrubal defended Carthage in its last siege by Scipio, and foreseeing its fate, surrendered himself to the Romans. When his wife, who was left behind him with her two children in the temple of Astarte, perceived that the temple was set on fire, she appeared on the walls magnificently adorned, with her two children; and having reproached and executed her husband for basely deserting her, she flung herself into the flames. See Car-
thage.

Asdynis, in Ancient Geography, an island of Egypt, according to Eudoxus, cited by Steph. Byz.

As, in Biography, a celebrated Jewish Rabbi, was born at Sora in Persia, and was chosen chief of the famous academy in that place in the fourteenth year of his age, which dignity he retained during sixty years, that is till the year 427, in which he died. As was the principal compiler of the Babylonish talmud. During his long residence at Sora, he published a collection of his decisions, which he divided into four parts: the first contained the rules and maxims of the Mishna, with the doubts and solutions relating to them; the second was chiefly occupied with the various questions of their doctors, and the sentiments of the Tha-
naim and Gezaraitis: the third comprehended the decisions and maxims published since Judah the faint: and the last recapitulated the texts of scripture relating to law-suits, with the comments of their learned men. This was the first division of the Babylonish talmud; but as As did not live to complete it, his disciples altered his method, and made several additions, which are thought to have rendered the work more obscure. See Talmud.

Asia, in Ancient Geography, a town of Arcadia, north-east of Megalopolis.

Aserrgur, in Geography, a town of Hindoosan, in the Candeh, fifteen miles from Burhampour, and eighty-five fouth of Indore.

Asiac, a town of Persia, in the province of Churzifan, thirty leagues south-west of 1pahan.

Asok, or Aserk, the name which the Turks give to the favourite sultaneis, who have brought forth sons. These are greatly distinguished above others in their apartments, attendants, pensions, and honours. They have sometimes shared the government. The sultana who first presents the emperor with a male child, is reckoned the chief favourite, is called buyuk ofeki, and ranks as a legitimate wife; though from the time of Bajazet I. the sultanas are forbid to marry by a public law, which Solymon II. violated in favour of Roxalana.

Aseina, in Entomology, a species of Phalama that is found in Germany. The wings are brownish, and with-
out spots. Fab. It belongs to the Bombyx family.

Aseina, in Atratomy, two fixed stars of the fourth magnitude, in the constellation Cancer.

Aseina, in Natural History, a species of Lenea described by Linnæus. Un. Sv. The body is lunate, and the thorax heart-shaped. Found on the gills of some fishes.

Aseus, in Entomology, the name of a tribe or genus of fishes adopted by Willughby, Ray, and other old writers on Natural History. Linnæus arranges the fishes of this kind in the GADUS genus; as for example: afflax major of Aldrovandus, is gadus anglis. Lin. (Haddock.) afflax spec-
ces of Ray, is gadus hispan Linn. (Bib.) afflax mollis minor of Willughby and Ray, is gadus minutus Linn. (Poor), &c. &c. See GADUS.

Aseus, in Entomology, a specific name of the common wood-loufe, or hog-loufe as it is called in England. It be-
longs to the ONISUS genus. It is of an oval shape; and has an obtuse tail, which is furnished with two simple styles. This well-knew creature delights in moist places, lurking under flones, in walls, in damps and rotten wood, &c. The young are contained in a four-valved receptacle under the abdomen of the female.

Aseus, in Conchology, a species of Chiton, found in the North seas, most frequently adhering to mythus medusa-
. The shell consists of eight valves, is very black, convex above, with a yellowish dorsal spot on each valve. Chemnitz, Gmel. &c.

Aseus, a species of Cypraea, very common about the Madeira islands. It is white, with three broad bands. Linn. This shell is called Aseus also by Rumphius and Argenville. The shape is oblong; and the brown bands are bordered with yellow, or sometimes reddish.

Asemus, or oxynus, from a negative, and ovum, a sign, is an epithet applied to events that fall out contrary to all appearance, and without any manifest cause.

Asepta, in Medicine, oxynus, from a negative, and ovum, to purify; signifies any thing unpurified, or uncon-
coted.

Asele, Ase-Lapmark, or Angermanland Lapmark, in Geography, a province of Lapland, lying near the Angermanland river, borders on Angermanland towards the east, on Umea-Lapmark towards the north, and joins to the mountains on the west, and to Jamtland on the south. In length it is about thirty Swedish miles. In the reign of Charles XI. about the year 1673, measures were taken for improving the population of this country. In this Lapmark lies the parish of Akele, about eight or nine Swedish miles long; of which the southern part is inhabited by Swedish peasants. This district is not capable of much improvement, and few parts of it have been cultivated. Barley is the only grain that is grown, and when the crop fails, the inhabitants are reduced to the necessity of mixing the bark of fir-trees dried and pulverized with their barley-meal, and of this mixture to make their bread. They chiefly fubtitute by breeding of cattle and fihing. The coun-
try is infested by a kind of fmitid grats, which are very troublesome, against which they secure themselves by be-
fineing their faces with an ointment of tar and grease, and which they drive from the houfes by fmoke. Service is performed in a wooden church, built by queen Chriftina in 1648, once on every other Sunday; and the Lapps meet once a fortnight, on Friday evening, and continue till Sunday evening in their huts erected near the church, and the penfants in the houfes built by them for the fame purpofe. At the fair which is held every year at Xenac near Afele church, the Lapps fell the flieh and skins of reindeer, furs, workings, fowls, &c.; and the Lapland penfants carry butter, cheeffe, dried fish, fowls and fome fort of furs, to the fame market.

ASENELLUS, GAUFR., of Cremona, in Biography, born toward the end of the sixteenth century, taught anatomy at Paris with great reputation. In 1622, while pre- fecting his studies, he discovered "carn magis quam conclu- bius," Douglas fays, the lacteals running across the mefenfery, in a dog that had been opened alive foon after eating a plentiful meal. He defecribes thefe veins as pafling from the intelfines to the liver, not knowing their real courfe, and viljaking the lymphatics of that vifeus for them. He faw their valves, preventing the regurgitation of the chyle. The lacteals, he candidly obferves, had been mentioned by fome of the earliest medical writers, but not defcribed, or their functions stated, and as none of the modern relofors of anatomy noticed them, the defcovery is properly attributed to him. Caifer Hoffman ridiculed the invention of them; and our great countryman, Harvey, fuppoled them to be only defined to convey the lymph.

Aelleius miftook a collection of glands in the mefenfery for the pancreas, and defcribed the pancreas as a new discovered gland, which, with his error in describing the courfe of the lacteals, threw much obscurity on his defcovery. He died fome time in the year 1626, and was buried at St. Peter's at Milan, aged, as appears by the infcription on his tomb, only forty-five years. The year following, his friends, Alex- ander Padinus and Senator Septulius, publifhed, from a manu- script that had been prepared by the author, "De lacl- tus fui lae&íc venus, quarto fummarum mefuriometorum gener, novo invente, difcoverto, cum figuris elegantiffimas Medicolan, 1627, 4to. It was re-publifhed at Bafle 1628, at Leyden 1648, and afterwards among the works of Spigelius and Margeto, in folio. Haller Bib. Anat. Eloy Dict. Hist.

ASENA, in Ancient Geography, a town of Spain, in the territory of the Carpetani.

ASEN, a people of India, whose capital was Bucephala. Pline.

ASER, in Geography, a town of Asa, in the Arabian Ira, fixuated on the Tigris, eight miles well-north-west of Bafilon.

ASES, in Ancient Geography, a Sceythian people, who inhabited the vicinity of the Cimmerian Bophorus.

ASFACA, in Geography, a town of Perfa, in the pro- vince of Mecran, 52 leagues north-west of Mecran.

ASFELD LA VILLE, a town of France, in the de- partment of the Ardennes, and chief place of a canton in the diuft of Rethel, thirteen miles north of Rheims.

ASFUS, or ASFOUN, a town of Egypt, four miles north of Erment. This is the fite of one of the cities called Aphroditopolis.

ASFUR, in Ethnology, a species of Chaetodon, found on the coafts of Arabia. It is black, with a yellow trans- verfe hinar-wedged band. Fork. Fn. Arab. The fame author defcribes a variety of this fish, of a blafhe colour, with oblique bands, blotches, and fine lines of violet. Length five inches; body oval, covered with rhombic scales, difpoled in a quineuxus order, and finely dentated; a fpine on the gill-cover half an inch in length; lateral line curved; dorfl and anal fin faleated; tail rounded, fulvous, and edged with black.

ASGILL, in Ancient Geography, an island fittuated in the Pericn gulf, on the coast of Arabia Felix. Pliny.

ASGILL, JOHN, in Biography, an English barrifer of injuger character, was born about the middle of the 17th century, and educated at Lincoln's Inn, under Mr. Eyre, a very eminent lawyer. He political talents and fingular vein of humour were manifefted in two pamphlets, which were printed in 1689, and which attracted public notice: the ftrife was intitled, "Several Afftrions proved in order to create another Species of Money than Gold and Silver;" and the fefond, "An Essay on a Register for Titles of lands." These were followed, in 1700, by another whimsi- cal and enthalutical treatife, intitled "An Argument, proving, that, according to the coovenant of eternal life, re- vealed in the fcriptures, man may be tralated from hence, without paffing through death, although the human nature of Chriffi himself could not be thus tralated, till he had paff- ed through death." This publication excited a general clamour againft the author as an infidel and a blafphemor. Before this time he had removed into Ireland, and purfued the practice of the law with fo much success, that he was enabled to purchase an eflate, and to obtain a fect in the Irish parliament; but this publication occafioned his expulfion from the houfe, as a perfon whose blafphemors writings rendered him unworthy of repreffing a Chriffian people. On his return to England, he obtained a return to the Bri- tish parliament, in 1705, for the borough of Biammer in Suffolk, and held his fect for two years. But his want of oeconomy involved him in debts which he was unable to dif- charge, and during the interval of privilege, he was arrefted and committed to the Fleet prifon. On the opening of the next fefion of parliament, in 1707, he was demanded by the feigeant at arms, released from cuftody, and refumed his feat. However, his embariffed circumftances, and the confideration of his being a privileged debtor, created a prejudice againft him in the houfe, and a committee was ap- pointed to examine his offensive publication; in order to ju- tify the propofed meafure of his expulfion. This committee reported that his book contained feveral blafphemous ex- prifions, and that it fecm'd to be intended for exposine the fcriptures; and though Asgill made a spirited defence, and folemny profeffed, that he publifhed his treatife under a firm belief of the truth of the fcriptures as well as of his own argument, he was expulfed. In confequence of this mea- sure, as his debts increafed, he was thrown by his creditors into the King's bench prifon, where he remained thirty years; furnifhing himfelf with amufement and occasional supplies, by writing pamphlets, chiefly political, againft the pre- tender, and by prifing in the way of his profeflion. Notwithfanding his misfortunes, and the conffuftions of his own indifferenion, he retained great vivacity of spirits, and peculiar powers of entertaining converfation, till his death, which happened within the rules of the King's bench, in 1738, at the age as fome fay of 80, or according to others 100 years. Aigill feems to have been a visionary and enthufi- afth, rather than an infidel or blafphemor; and his eccen- tricities rendered him more the object of contempt or pity, than perfection and punishment. Bia& Brit.

ASH, Common, Flowering, and Mannia, in Botany. See

ASH, Mountain. See SORBUS.

Ash-Balls, are formed of the ashes produced by a flow incineration of the green plants of fern, which contain a

considerable
confiderable portion of alkali, and are used in making lye for the scouring of linen. See Felt.

Ash Tree, in Planting, a tree of the deciduous kind, of which there are several species cultivated either for the sake of variety, or for the purpose of ornamenting pleasure grounds, &c.; but the kind which deserves attention here, is the common ash, so well known as a timber tree as to need no description. See Praxineus.

The ash tree will thrive in barren soils, and in the bleakest and most exposed situations; but it grows to the greatest advantage on such lands as have a tolerable depth of soil, and in which water is not liable to stagnate. It is found to be of so hardy a nature, as to withstand the effects of the sea-winds; it may therefore be planted on the coasts, where but few other kinds of trees are found to prosper. When planted on the sides of ditches, or in moist meadow lands, from the spreading of its roots it has been found to render the ground more firm and dry. From this, as well as other causes, it is, however, highly prejudicial when planted on arable land; it ought therefore to be chiefly planted on the waste nooks and corners of fields, or perhaps, on improveable swampy lands, and on the springy sides of hills, as it would not only render them useful as plantations, but, from the spreading of its roots make them more firm and dry.

This sort of tree propagates itself plentifully by means of seeds, which being scattered in autumn in places where cattle do not come, plenty of plants come up in the spring. Where any person is desirous of raising a quantity of these trees expeditiously, the seeds should be sown as soon as they are ripe, and the plants will then come up in the following spring; but if the seeds be kept out of the ground till spring, they will not come up till the second year. The ground should be kept clean all the summer where they are sown, and not disturbed, lest the seeds be turned out of the ground, or buried too deep to grow. When the plants are come up they must be kept perfectly clean from weeds during the summer months, and if they make good progresse in the seed-bed, they will be fit to transplant by the following autumn; some ground should therefore be prepared to receive them, and as soon as their leaves begin to fall, they should be transplanted. In removing the plants, care should be taken not to break or tear off their roots; to prevent which, they should be taken up with a spade, and not drawn up, as is frequently practised; for as many of the plants which rife first from seed will outstrip the others in their growth, it is a frequent practice to draw out the largest, and leave the others to grow a year longer before they are transplanted; and to avoid hurting those that are left, the others are drawn out by hand, and consequently many of their roots torn off or broken. It is therefore much the better way to take all up, little or big, together, and transplant them out, placing the large ones together in rows, and the small ones by themselves. The rows should be three feet asunder, and the plants a foot and a half distant in the rows. In this nursery they should remain two years, by which time they will be strong enough to plant out when they are to remain; as the younger they are planted out the better they will grow, so that where they are designed for use they should be planted very young, and the ground where they are raised should not be better than that where they are to grow. For when plants are raised in good land, and afterwards planted into worse, they very rarely thrive well; on which account it is much the best method to make the nursery upon a part of the same land where the trees are designed to be planted, and then a sufficient number of trees may be left standing upon the ground, which will generally outstrip those which are removed, and grow to a larger size.

Where planters reside in the neighbourhood of ash-trees, they may supply themselves with plenty of self-fowmed plants, provided cattle are not suffered to graze on the land; and where the seeds fall in hedge-rows and are protected by bulrushes, the plants mostly come up and thrive well; in such hedge-rows the trees are permitted to grow till they have destroyed the hedge; for there is scarcely any tree so hurtful to all kinds of vegetables as the ash, as it robs every plant of its nourishment within the reach of its roots; it should therefore never be suffered to grow in hedge-rows, as the hedges are not only killed, but corn, or whatever is sown near them, greatly impoverished. If a plantation of this kind of trees be rightly managed, it will turn greatly to the advantage of the owner; for by the underwood which will be fit to cut every eight or ten years, there will be a continual income more than sufficient to pay the rent of the ground and all other charges, and if a flock will be preferred for timber, which, in a few years, may be worth forty or fifty flizations, or perhaps much more per acre. In the fifth volume of the Bath papers, Mr. South observes, that the growth of ash, in soils adapted to its nature, is little inferior to that of elm or beech; but that there is no timber whatsoever that differs more in its value than this does, according to its situation. The productions of dry and healthy grounds will prove acceptable to most purchasers; those of woods are generally clean in the shaft, and more valuable than the former. The nearer the ground the tougher is the timber; the shaft therefore is coveted, the brittle branch is rejected; the buyers of this timber accepting the shaft and its continuation, or hell bough; the reet, be they ever so large, go with the top. When this sort of timber is raised in damp meadows or morinh feet, it becomes light, spongious, brittle, and of small value in comparison of that on dry and healthy spots. In meadows these trees will attain a size which cannot be expected in moors and bogs; for when the roots reach the peat, the bark grows moly, and the top decays: how long it lasts may be productive of poles in such situations, remains to be determined; but experience determines that ash thus planted will never become timber of any value, as the roots must perish before the tree arrives to perfection. If ash-trees get disheveled, though in appearance they should be flourishing, on being felled, the roots will be frequently found decayed, and the stems at bottom a complete hellow; they ought not therefore, in point of profit, to be suffered to stand. These trees, when they stand among firs and larches if planted close, will grow too tall and fliender, but thrive well when planted alone. They are frequently known to have thriven for at least ninety years, as may be seen by their ring. But in the fiftieth year, as well as the half, the growth has been observed slow. It is remarkeol by Mr. Marulln, in his Rural Economy of the Midland Counties, that in the intermediate years, the different thicknesses of the rings in different years were striking. This kind of timber is generally esteemed next in value to that of the oak, and in some places even nearly equal to it. It is of great value to the coachmaker, the wheelwright, and cartwright, for ploughs, axletrees, fellies of wheels, harrows, ladders, and other implements of husbandry; and also to the shipbuilder, for oar-blocks for pulleys, and many other purposes.

The best season for selling this sort of timber is from November to February; for if it be done either too early in the autumn, or too early in the spring, the wood will be subject
subject to be infested with worms and other insects; but for lopping of pollards, the sping is preferable for all sort of woods.

Great attention has lately been paid to the planting of this useful timber tree in different parts of the kingdom. According to the transactions of the Society of Arts, near Great Finborough in Suffolk, Mr. Wollaston has planted twenty acres; and at Butshill near Durham, Mr. White has covered thirty-five acres; in Kent a still larger extent of land has been planted by Mr. Day of Frintonbury; and at Buckfast, near Farringdon, Berkshire, Edward Loveden Loveden, esquire, is said to have planted thirty-three thousand on a few acres of land. Mr. Smith, in Staffordshire, five thousand have been set by Mr. Sneyd of Belmont; and in Welfordland, the bishop of Landaff has planted eleven acres with twenty thousand. In Scotland likewise, something has been done in the cultivation of ash timber; in Cromarty, forty-two thousand have been planted by Mr. Rose; and fifty-seven thousand by the earl of Fife, in the county of Murray.

The ashes resulting from the combusting of this kind of wood, are found to contain good potash in a larger proportion than most other kinds of green wood.

Ash-Wood. See Egoedium.

ASHA, in Geography, a town of Germany, in the archduchy of Austria, four miles north of Eiferning.

ASHAJA-TUSLA. See SOLI.

ASHAN, in Scripture Geography, a city in the tribe of Judah (Joshua xvi. 42): but, perhaps, afterwards rendered to Simeon. (Josh. xix. 7.) According to Eusebius, Beth-Alphon was 16 miles west from Jerusalem.

ASHAU, in Geography, a river of Germany, in the circle of Lower Saxony, which runs into the Lech, near Zell.

ASHBOURN, a town of England, in the county of Derby, on the east side of the river Dove; its weekly market is on Saturday; distant north-west 159 miles from London. N. lat. 53° 5'. W. long. 1° 35'.

ASHBURNHAM, formerly Dorchester-Canada, a town of America, in Worcester County, in Massachusetts, 30 miles north of Worcester, and 54 from Boston, was incorporated in 1765, and contains 951 inhabitants. In this township is a white sand, which is thought to be fit for making fine glafs.

ASHBURTON, an ancient borough town of England, in the county of Devon, which sends two members to parliament; it lies in a valley, with hills to the north and south. It is one of the four flannah towns of Devonshire; and has in its neighbourhood mines of tin and copper. It has two weekly markets, one on Tuesday, chiefly for woollen yarns, for the accommodation of the farge manufacture which is carried on in the town; and one on Saturday, for provisions. This town gives the title of baron to the family of Dunning. It is distant west-north-west from Exeter 19 miles, and 1914 west from London. N. lat. 50° 30'. W. long. 3° 10'.

ASHBY, a township of America, in Middlesex county, Massachusetts, fifty miles north-west from Boston; containing 751 inhabitants.

ASHBY de la Zouch, a town of England, in the county of Leicestershire, near the borders of Derbyshire; the principal trade of the town depends upon the making of malt; its market is on Saturday. The decayed castle, which was formerly the property of the family of de la Zouch, now belongs to the earl of Huntingdon. It is distant 17 miles north-west from Leicestershire, and 1144 north from London. N. lat. 52° 40'. W. long. 1° 20'.

ASHCUTNEY, or Ascucutney, a mountain of America, in Vermont, situate partly in the townships of Windsor and Weathersfield, and opposite Claremont, on Sugar-river, in the state of New Hampshire. It is 2531 feet above the sea, and 1732 feet above high water in Connecticut river, which runs by its eastern side.

ASHDOD, in Ancient Geography. See Azotus.

ASHDOTH-PISGAH, a city in the tribe of Reuben, so called from פֹּסִגַּה, well-cultivated plains, and situated in the fertile plains at the foot of mount Pisgah, or at the springs of Pisgah; whence its name.

ASHKENAGUR, a province of India, corresponding with the country of the Affasani, in which Alexander warred, on the west of the Indus, situate at or near the confluence of the Penje-koreh and Sewad rivers, and two marches from Bijore. The present Sewad is part of the ancient province Ashenagur. Kennel's Memoirs, p. 149.

ASHER, the son of Jacob, by Zilpah, gave denomination to one of the twelve tribes which was settled on the north-west of the province of Lower Galilee, in a very fertile country producing abundance of corn, wine, and oil, of the best kinds, with Phoenicia west, mount Libanus north, mount Carmel and the tribe of Issachar south, and Zebulun and Naphtali east. It contained some considerable cities near the sea, but no sea-port of any note. This tribe never possessed the whole extent of district affign'd to it, which was to reach to Libanus, Syria, and Phoenicia.

ASHER, a city of Palestine between Scythem and Shechem.—Allo, according to Eusebius, a large town between Azot and Aculon.

ASHES, in Chemistry. This is a term of general import, which is applied to the pulverulent residue left after the combustion of any substance whatever. In this sense, the combustion of metallic bodies has been said to yield metallic ashes, but to these the terms calc and oxide have been substituted; and it is only vegetable and animal matters that are now said to afford ashes after burning.

To confine vegetable or animal substance to ashes, the free access of air is requisite, more particularly with the latter. Vegetable Ashes. When a vegetable is set on fire, a vast quantity of aqueous vapour first escapes, together with the component parts of most of the vegetable principles, such as the native juices, the acids, the sugar, the oil, &c. which latter either burn with flame or are driven off in a dense smoke. The more solid carbonaceous part requires a longer continuance of heat, and a free access of air for its complete combustion; but when this is effected, a certain portion of white or grey ashes remain behind, consisting of the fixed fatty, the earthy, and the metallic ingredients. In general, it is found (as would be expected) that the watery, succulent, and herbaceous plants, yield a less quantity of ashes than the hard and woody parts of vegetables; but there are numerous exceptions to this rule, as the hardness of texture is more determined by the quantity of carbonaceous matter. A very violent heat either melts the ashes into a flag or foria, or disintegrates their fatty ingredient, and leaves only the earthy and metallic; so that a certain management of the fire is requisite in order to procure the greatest possible quantity of ashes from vegetable matter.

From the fatty ingredient are procured those very important articles in chemistry and manufacture, the fixed alkalies, both vegetable and mineral; the former distinguished according to its species and purity by the terms soap ashes, pearl-ashes, pot-ash of commerce, salt of tartar, or salt of woody ashes; the latter by the terms natron, barilia, kelp, and soda.
ASH

As the combustion of vegetables, when carried on in the large ways, is always directed to the object of procuring the alkaline salts, and as this subject includes a variety of interesting observations, and the particulars of the analysis of ashes, we shall refer the whole of this article to those above mentioned, and especially to that of CARBONATE OF POTASS AND OF SODA.

We may add, however, that though vegetable ashes are composed of fixed earths and alkalies combined with acids, and of some metallic oxides, especially those of iron and manganese, almost every possible variety of combination and proportional quantity of ingredients is to be met with, according to the nature of the plant, the composition of the soil, the season of the year, climate, and the like. In general, chemical analysis has detected the following substances in vegetable ashes: silica, magnesia, lime, potash, soda; the sulphuric, carbonic, phosphoric, and muriatic acids; and the oxides of iron and manganese. The most usual dates of combination of these ingredients are, the sulphates of potash, soda, lime, and magnesia; the muriates and carbonates of the same, and the phosphates of lime. It is still a question, which of the saline ingredients represent the actual state of the vegetable juices, and which of them are formed by the procès of combustion; the acid of the carbonates may with great probability be supposed to arise from the latter cause.

When the saline part of vegetable ashes has been separated by lixiviation, the light earth that remains, probably still mixed with a portion of sulphate of lime, is sometimes employed, after being well washed, for the formation of the large CUPELS used in the refining of silver.

The ancient alchemists paid considerable attention to the ashes of different plants; and some of the Rosicrucian school of deceived and deceiving impostors, pretended to be able, by a species of palingenesis or re-production, to exhibit in the ashes of a plant a complete miniature representation of the gradual growth and maturity of the individual vegetable.

Animal Ashes. A very few words will be requisite on this subject taken separately. Animal matter is much more difficult of complete combustion than vegetable; the volatile part of each is driven off by heat without much difficulty, but the coal of animal substance is of very difficult incineration, often requiring a very long continued and violent fire. This is probably owing in part to the greater quantity of oxide of iron which, uniting with the carboaceous matter by the affinity of heat, forms a carburet of iron that burns with extreme difficulty. The saline and earthy parts almost peculiar to animal ashes are the phosphat of soda, phosphat of ammonium, and phosphat of lime, and often the carbonates of soda and lime. The proportion of carbyl felt in bones, horn, and the harder parts of animals, is generally full one half the weight of the substance when fresh from the body; in bone it is almost entirely phosphat of lime, mixed however with a small portion of sulphate and carbonat of lime; in shell the carbyl part is principally carbonat of lime.

For further particulars concerning animal ashes we must refer the reader to the individual articles of animal matter; such as BLOOD, BONE, HARTSHORN, SHELL, and to the above-mentioned earthy and alkaline salts.

The only animal ashes employed to any extent in the arts are the lixiviated ashes from bones, which when mixed up in water, and cast in proper moulds, form the CUPELS that are employed in ASSAYING and REFINING of gold and silver. The finer and whiter ash of calcined horn is employed to a small extent in medicine, under the term CORNU CERVICALE, or calcined hartshorn.

ASHES, in Agriculture, the earthy or other particles of combustible substances after they have been burnt in the fire. The beneficial effects of such matters, as manures, may probably, in a great measure, arise from the portion of alkaline saline matter which they contain, which by its action on, and combination with the materials that are present in soils, may render them more fertile and proper for the nutrition of plants. Considerable utility may also be derived from their operating mechanically, and in that way lessening the tenacity and stiffness of the heavier kinds of soils, and likewise by their absorbent powers in lands of the more moist kind. Ashes are of different sorts, as bleacher's ashes, coal ashes, peat ashes, pot ashes, seafores' ashes, turf ashes, wood ashes.

The first sort consists principally of the hard undissolved parts of potash, kelp, weed-earth, and barilla. Laid on land alone, they are too stimulating; they ought therefore, perhaps, never to be used but in union with earth, or earth and dung. It is said, however, they answer well with blood, garbage, and putrid animal substances. They are generally laid upon follow for wheat. The greatest advantage derived from them is upon clays or deep loams. Upon ruddy grounds, one or more yards, these will prove particularly good, in destroying the coarse plants that infest them.

The second sort, or coal ashes, probably from their containing a portion of calcareous matter, are found to be highly beneficial on stiff and four lands; for which purpose they are successfully used in the neighbourhood of many great cities, where coal is much burnt for fuel. They also open the texture of clayey grounds, and correct their tenacity, and other bad qualities. The gardeners and farmers about London know their value, and make a very profitable use of them, particularly in bringing into order those grounds which have been dug up for brick-earth. Mr. Bradley some years ago, indeed, blamed the people of Staffordshire, and the countries adjoining, where there are coal-pits, for not improving their heavy grounds from them, by manuring them with coal ashes, which might be easily burnt out of the waste coals of such pits; and suggested "that wherever there are plenty of coal-pits, there can be no want of good profitable land." Mortimer held the same opinion, esteeming sea-coal ashes as the best manure of any for cold lands, as well as the most lifting and fitted to kill worms and flugs. And Worley looked upon them as an excellent compost, when mixed with horse-dung; remarking, that they have great effects in removing moss and nathes in moist grounds. Ashes of this kind are employed in different proportions, in different places, according to the particular circumstances of the crop, and the land on which they are applied. It is observed by Mr. Farey, in the Annals of Agriculture, that about Dunstable they are used at the rate of from fifty to sixty bushels to the acre, for a complete dressing; and that they succed, well fown on clover, in March or April, on dry chalky lands. They have also much effect on sward-land, when applied during the winter or spring; but they are never used on wheat. It is likewise further remarked by the same writer, that in very dry seasons they do little service, except on cold swarms, which they invariably improve; and that on light land they require rain, after being sown or spread over the land, in order to promote their operation.

The ashes formed from peat, are found, from long experience, to be a very good manure. The author of Modern Agriculture remarks, that in many parts of the kingdom peat-earth cut and dried in the course of the summer, is the only fuel; and that the peat dug from the mosses that are so firm as to bear cattle to tread on them, is the best both
both for fuel, and afterwards for manure. The ashes of the
fward, or what is pared from the surface of heaths and com-
mons by the cottagers in many parts, as about Bedford,
are, he says, of little value, when compared to those above
mentioned. It is probable that Berkshire is the only distric-
t of Great Britain, where peat ashes, without the mixture of
any other sub stance, are at present generally used as manure.
The ashes of peat, dug from extensive meadows in that county,
have been proved, by the experience of fifty or seventy years,
to be a most excellent manure, when used as a top dressing
on almost all kinds of crops ; as oats, wheat, barley, turnips, clo-
ver, fainfain, meadows, pastures, &c. The quantity generally
used is about twenty quarters, more or less, as the condition of
the land seems to require; and the price about three-
pence or four-pence a quarter. To such an extent is this
mode of manuring carried on in that county, that the pro-
pietors often receive two or three hundred pounds of the
acre for the liberty of cutting and carrying off peat to the
depth of five or six feet. It would be absurd to suppose,
says he, that the peat ashes of Berkshire are superior, as
manure, to those in every other part of the island; and as
their effects in that country, when applied to the soil, have
been conspicuous for a great number of years, it is certainly
a circumstance meriting the attention of those who reside
where peat is the only fuel, to ascertain whether peat ashes in
such districts do not possess all the fertilizing qualities of
those in Berkshire. The experiment is easily made; all that
is necessary being to keep the ashes dry, and under cover
during winter; and to sprinkle them with the hand over the
crops in spring, at the rate that has been just mentioned.
Lord Dunfcaird, in his Treatise on the Connection of
Agriculture with Chemistry, however, remarks, that the
ashes procured from peat in the neighbourhood of Reading,
in Berkshire, seem to possess a fertilizing power infinitely
greater than ashes obtained from moss other peat. They
certainly, he believes, contain no alkaline salts; and in an
hasty analysis made some years since, no saline matter, says
he, is recollected to have been got from them, but a small
proportion of Epilom salt. Had these ashes, however, been
analyzed with more care, and when newly made, they prob-
ably would, he thinks, have been found to contain a kepar
of lime, a salt which is soluble in water; whilst gypsum, to
which it reverts on exposure to the air, is insoluble. To
this kepar, therefore, says he, may the fertilizing power of
these ashes most probably be attributed. And the writer of
the Survey of the County of Middlesex suggests, that as
the hills on each side of the meadows which produce the
Newbury peat ashes, consist of chalk easily digested by
heavy rains, which washes it off the ridges, down the fur-
rows, ditches, and dreamlets, to the low grounds, where,
mixing with the floods, it is floated over the meadows, and
deposited with the peat, consequently the peat of that
district differs from that of moss other, by the quantity of
chalk which it contains; and that when dug, dried, and
burnt, the fire reduces the chalk to lime, and the rest to
ashes. Hence Newbury ashes are a mixture of lime and vege-
table ashes; and it is very probable, he thinks, that any
common peat-ashes, or the ashes of rough grazed land, of
turf, heath, furze, ling, wood, &c. produced by the opera-
tion of paring and burning, being mixed with chalk-lime in
due proportion, would be equally fertilizing as those
noted ashes. It has indeed been long since observed by Mil-
ler, that these ashes are generally bettered by being mixed
with lime before they are put on the land. These ashes are
produced from land that is black and crumbly at top, under
which lies the peat to the depth of several feet. They do
not burn the peat in the field by choice, because the peat
is burnt for ashes, when it cannot be dried for sale; and then
it is burnt in large heaps, with a smoothing fire, as is likewise
the superficial black earth, or moor foil, together with
the refuse of the peat; the ashes of these are laid up in
round or long heaps, rising at top like the ridge of a house,
in order to throw off the rain and keep them dry till they
are cold. Sometimes they are laid under dry fields or in houses
to save them from wet, which they cannot be wholly pro-
tected from by laying them up in ridges exposed to the
weather, into which the rain penetrates for some inches deep; but
these ashes are never so good manure as those that are kept dry.
Near the surface of the peat earth there is sometimes a bed of
whitish earth called marrn, which is a composition of
earth and very small shells of the periwinkle kind; this
is also burnt to ashes for manure, and the quantity of it in
some places is so great, that the ashes are of a whitish colour,
while those from the peat or moorish earth are reddish.
The white are esteemed to be as good manure as the red;
and being a kind of shell-marl, would make good manure
without being burnt; as indeed they rarely are thoroughly,
though they seldom lay them upon land till they have pulled
the fire, or are mixed with the ashes of the peat-earth.
The ashes of the peat fold for fuel, and burnt in chimneys,
are much stronger manure than the ashes burnt in the field;
and if care be taken to keep them dry, are foid for nearly
double the sum of the field ashes. Mr. Pacy states, in the
Annals of Agriculture, that he has found field ashes to
improve the chalky soils about Dunstable; but on the wet
lands, or cold swaors, and hot sandy lands, they did little
good. They may be employed on the same kinds of crops,
and in the same way as coal ashes, and also on the wheat
or oats about April. But Mr. Middleton says, that he has tried
the Newbury peat-ashes on wheat, turnips, meadows,
in various quantities to the acre, without producing
any sensible effect. In Norfolk, ashes are not in estimation
as manure; even those of the heath are in some degree
neglected. But the meadows and fens abound with peat-
bogs, which in some places would be considered as ineffi-
cient sources of manure; and the peat-earth in such
meadows, when burnt, would no doubt afford an ample
supply of ashes. In many places, much advantage has been
supposed to arise from the practice of mixing lime with
peat-ashes before they are applied to the ground.

The refuse, or ashes, remaining after the burning of differ-
ent green vegetable matters from which the alkaline salt
called pot-ash has been extracted, is a kind of ashes which
has been found of great service to moor forts of land; but as
they have been in a great measure deprived of their saline
property, it is necessary to lay them on much thicker than
any other fort of ashes. Mr. Bradley affirms that a buffer and
a half of these may be used in the room of a buffer of fresh
ashes; and that they should always be mixed with some
other light ingredient which may be used in any quantity
when laid on very stiff land; but if the land be not over
still, they may be laid on it with less mixture. As in places
far removed from the means of improvement, a substitute
for common manures, that is of easy carriage, and can be had
at a moderate expense, must be valuable, pot-ash may be
employed; for, from experiments that have been made, it ap-
ppears that two hundred pounds of it are sufficient for an acre
of strong land. For lighter soils much less is required, if
laid on by itself; on these, however, a compot of this and
train or refuse oil incorporated with mould, will be the best
way of employing it. Upon strong clays and deep loams
however, it ought always to be applied by itself. When
the expense of carriage is considered, this will often be
found a cheaper manure than lime; and in one respect it
is superior, for the union of pot-ash with all the different acids forms a neutral salt which is in some degree useful in vegetation; whereas when lime meets with vitriolic acid, it is almost entirely lost to the purposes of agriculture. A considerable part of what is used in manufactures (glass excepted) may be useful as a manure, after the processes of the different manufactures have been served; particularly in bleaching, the alkali of which will be found improved in consequence of the moulage or oil which it has imbied from the cloth or other matters.

The foapers' ashes are a composition of wood ashes and lime, remaining after the soap-makers have drawn off their lye. These are in general a very valuable manure; but there is great difference in the quality and effects of them. Tho' from wood ashes the weakest fort, as, wood ashes being very light and spongy, their farts are soon dissolved and extracted by the lye; so that there remains but a very flight portion of salt in the ashes. But when the soap-boilers make use of kelp instead of wood ashes, the kelp, from its being of a harder nature than wood-ashes, is not so easily separated and dissolved by the lye; consequently, much more of the saline matter remains in the ashes. The soap-boilers also make use of another kind of potash called barilla, which is imported from Spain and other places in large lumps, and which is much harder than common pot-ash, and though they break this fort very small, and sometimes fix them or lift it; much more salt remains than when pot-ash is employed; so that the ashes from barilla are for the most part stronger than any other; and if the same quantity of them were laid upon land as is commonly the case with wood ashes, they would burn and destroy the crop. Farmers should therefore use soap-boilers' ashes with caution, till they know their qualities and strength. Wood ashes and pot ashes are used in various places for making soap; but in and near London, very little of any thing but barilla is employed. The ashes from the barilla are a strong rich manure, and sold at five shillings per cart-load. They are not now however so good as they were formerly, the soap-makers having found means to extract more of their salt from them; as they also take the salt from the lye which was formerly rather superior to the ashes as a manure, and to be had for nothing, being all thrown away as udefies. This excellent manure was first used by the Flemings with great success. Two loads of these ashes are sufficient for an acre of arable land. They should be laid on the ground when the weather is inclined to be moist, in order that the rain may more easily dissolve and wash them in. As foapers' ashes principally consist of lime, which is used by soap-makers to deprive the alkaline farts of their fixed air, the addition of lime to the ashes is unnecessary. They are used to most advantage when made into composts with earth and well-fermented dung in the proportion of two loads of dung to one of earth; the ashes being then added in the quantity of one load to ten of this mixture, turning and incorporating the whole completely. The quantity necessary for strong clays or deep loams is ten cart loads to an acre. If the dung has been well fermented, perhaps the most profitable way of using this compost may be as a top-dressing harrowed in with the grain, taking care, however, that the caustic quality of the ashes be properly blunted by sufficient mixture of dung and earth, or rich earth only. These ashes, when beat small, may be made into a rich compost with refuse oil and earth, and used as a top-dressing for young crops. They will destroy flugs and vermin of every description, and are therefore highly valuable on lands where the early wheat is injured by the worm. Laid upon grass lands in the end of autumn, this manure, it is said, produces a deep verdure during the winter, and an early vigorous vegetation in the spring; it is therefore particularly calculated for cold wet paiture lands.

In respect to turf ashes, produced by burning turf or the peat Hud of the surface of heathy, moorish, and other lands, their utility as a manure, perhaps, chiefly depends upon the proportion of alkaline saline matter which they contain, and which is produced by the burning of the fresh vegetable substances of turf, and the combination of vital air or oxygen, with the clayey part of the soil during the processes of combustion, as well as by the mechanical action of such substances on the tenacious earthy matters of the soils. According to the Rev. Mr. Comber, the ashes in the moors of Yorkshire, are carried out daily, or once in two or three days to the dung-hill; and the farmer takes the opportunity of his first leisure towards the end of the year, to carry them out to his meadow lands on which he lays them thicker or thinner as he has more or less land which he apprehends to want them, and more or less of them. The fire rains wash them in, and the next summer never fails to shew their good effects. It would however be probably a much better practice to apply them to the land in the early spring when the weather is rather wet, and not to leave them to be washed away by the heavy rains and lands-floods during the winter months. They would also be much more efficacious if kept in shreds, or other suitable places, instead of being carried out to the dung-hill, where the rains must diffuse and carry away their most nutrient properties; as these ashes are much finer or more pulverized than those of coal, they may ininate themselves more into the soil, but they are probably not so lasting in their effects. Of the truth of this a remarkable instance is mentioned.—A field, whereof the soil was a poor gravel, that had a crop of the broad or red clover growing upon it, was dressed, one side of it with peat ashes, and the other side with turf ashes. The farmer laid upon this field all the ashes he had of these two sorts, and the middle of the field had no dressing. The clover in the middle part not dressed was a very poor crop, the plants being short, yellow, and flunted; the side dressed with turf ashes was much better than the middle; the plants being taller, of a better colour, and promised to be double the crop of the undressed part; but that side dressed with peat ashes produced a crop that appeared to be as much superior to the part dressed with the turf ashes, as this last was superior to the middle that had no dressing at all. The ashes were sown upon the clover by hand, and the improvement made upon the clover was so great, that the call of the lower's hand was extremely plain next to the middle, and appeared like an indenture; and the vigour of the plants there was so much greater than the undressed plants, that the extent of the peat ashes might be plainly distinguished almost to an inch. This observation was however made in the beginning of summer, before the clover had arrived to its full growth. See Pareing, and Burning.

Ashes produced from wood and moss green vegetable products contain a considerable quantity of fixed alkaline salt, blended with the earthy particles; but none or very little can be produced by the combustion of dead or decayed vegetable matters. It is from the ashes of the former kinds of vegetable matter that the alkaline salts called potash and pearl-ashes are commonly extracted. It seems also probable, from the observations of the Earl of Dundonald, that the effects produced upon land by the application of the ashes of fresh vegetable products, arise from the vegetable alkaline salt which they contain, which, by its action on what he terms the oxygenated or inert mould or earth of the soil, renders it soluble, and more suitable for the nutrition of plants.
plants. As the saline matters contained in these substances are liable to be lixiviated and carried away by moisture, they should always be kept dry and free from water, either by means of sheds or other conveniences. It has been long ago observed by Mortimer, that one load of dry ashes will go as far as two not kept so; but though rain-water diminishes their salts, so the moistening them with chamfer-ley or soap-uds will add greatly to their strength. Two loads of these ashes will manure an acre of land, better than six loads of those that are exposed to the rain, and that are not ordered so, which is the common allowance for an acre, though some lands require more, and some less. That the ashes of any sort of vegetables are very advantageous to land, is what is experienced in many parts of England, by the improvement that is made by burning of furze, and stubble, straw, heath, furze, flage, bean-flakes, &c. Mr. Young, in the first volume of the Annals of Agriculture, approves of charcoal ashes, in preference to powdered charcoal itself. And wood ashes mixed with mud (he says) are superior to ashes alone, and four times better than mud alone, as a manure. In the second volume of the fame useful work, he adds, that wood ashes appear to be a molten powerful manure. In a neighboring aboundning with vitriolic acid (he says), they more than neutralize that salt; they furnish, besides, the food of plants. In neutralizing it, the fixed vegetable alkali they contain forms with the acid a vitriolated tartar, which is beneficial to vegetation. From the alkaline matter contained in ashes, and its known operation on earthly substances, they may probably be used to great advantage in combination with good mould or earthy materials, and dung, in the proportion of one load of ashes to ten of the compost; and thus may be applied to tillage-lands as well as those under grafs, in their simple state; but in the former they would seem to be the more proper, when conjunction with other matters, such as have been mentioned above. They may, when employed in the unmixed way, be fown upon the surface, and harrowed in with the crop to which they are used. But in whatever way they are made use of, they should be spread out as equally as possible on the land. Moat grafs-lands are improved by their application, but more especially those that are wet, and given to the production of wild forre, rushes, or other coarse plants of the fame kind. When used in the way of compost on tillage-lands, they are generally laid on at the rate of about ten or twelve loads to the acre, but on pature or grafs-lands, the quantity applied varies very considerably, as from one hundred to one hundred and sixty bushels. These substances have been found highly useful, when sown on the green wheat and clover crops in the spring, and also when harrowed in with turnip seeds, or sown over the young plants which they first appear, as by this practice the ravages of the fly are said to be greatly lessened in many cases. See Manure.

Ashes, Volcanic. See Volcano.

Ashfeld, in Geography, a township of America, in Hampshire county, Massachusets, about 15 miles northward of Northampton, and 117 miles from Boston; containing 1450 inhabitants.

Ashford, a town of England, in the county of Kent, seated on the river Stour. It has a monthly market for cattle on the first Tuesday, and a weekly market on Saturday for corn &c. It is distant 45 miles E.S.E from London. N. lat. 51° 15'. E. long. 0° 45'.

Ashford, a township of America, in Windham county, Connecticut, incorporated in 1710; distant about 38 miles north-east from Hartford, and 76 south-west from Boston.

Ashford, New, a township of America, in Berkshire Vol. III.
fear, their belly being nearly close to the ground, advancing a few steps at a time, and then pausing. They have some-thing very mild, feeble, and timid in their deportment, are gentle, and easily tamed: though when roughly handled at the first, they bite very fiercely.

This animal is found plentifully on mount Libanus: I have seen them also among the rocks at the Pharan promontorium, or Cape Mahomet, which divides the Ebanitic from the Heropeletic gulf, or gulf of Suez. In all places they seem to be the same; if there is any difference, it is in favor of the size and formes which those in the mountain of the sun seem to enjoy above the others. What is this food I cannot determine with any degree of certainty; when in mypossession he ate bread and milk, and seemed to be rather a moderate than a voracious feeder. I suppose he lives on grain, fruit, and roots. He seemed too timid and backward in his own nature to feed upon living food, or catch it by hunting.

The total length of this animal, as he fits, from the point of his nose to the extremity of his body, is seventeen inches and a quarter: the length of his foott, from the extremity of the nose to the occiput, is three inches and three eighths; his upper jaw is longer than his under; his nose stretches half an inch beyond his chin. The aperture of the mouth, when he keeps it close, in profile, is little more than an inch. The circumference of his foott around both his jaws is three inches and three eighths; and round his head just above his ears, eight inches and five eighths; the circumference of his neck is eight inches and a half, and its length one inch and a half. He seems more willing to turn his body altogether, than his neck alone. The circumference of his body, measured behind his fore-legs, is nine inches and three quarters; and that of his body, where greatest, eleven inches and three eighths; the length of his fore-leg and toe is three inches and a half; the length of his hind thigh is three inches and one eighths, and the length of his hind leg to the toe, taken together, is two feet two inches; the length of the fore-foot is one inch and three eighths; the length of the middle toe fix lines, and its breadth fix lines also. The distance between the point of the nose and the first corner of the eye is one inch and five eighths; and the length of his eye from one angle to the other four lines. The difference from the fore angle of his eye to the root of his car is one inch and three lines; and the opening of his eye two lines and a half. His upper lip is covered with a pencil of strong hairs for mufcloses; the length of which is three inches and five eighths, and those of his eye-brows are two inches and two eighths. He has no tail, and gives at first sight the idea of a rat rather than of any other creature. His colour is a grey mixed with a reddish brown, perfectly like the wild or common rabbit. His belly is white from the point of the lower jaw to where his tail would begin if he had one. All over his body he has scattered hairs, strong, and polished like his mufcloses; there are for the most part two inches, and a quarter in length; his ears are round, not pointed: he makes no noise that ever I heard; but certainly chews the cud. [Dr. Shaw observes, that this particular of the atinkoko seems very doubtful, and may probably be owing to the peculiar motions of the mouth resembling those of the hare, which has also been suppofed by slow to the Ass and Gen. Zool.]. To discover this was the principal reason of my keeping him alive: those with whom he is acquainted he follows with great affility. The arrival of any living creature, even of a bird, makes him seek for a hiding-place; and I shut him up in a cage with a small chicken, after omitting to feed him a whole day; the next morning the chicken was unhurt, though the atinkoko came to me with great signs of having suffered with hunger. I likewise made a second experiment, by inclining two smaller birds with him for the space of several weeks; neither were they hurt, though both of them fed without impediment of the meat that was thrown into his cage; and the smallest of these, a titmice, seemed to be advancing in a sort of familiarity with him, though I never saw it venture to perch upon him, yet it would eat frequently, and at the same time, of the food upon which the atinkoko was feeding; and in this colluded chiefly the familiarity I speak of, for the atinkoko himself never shewed any alteration in the place of the bird, but treated it with a kind of absolute indifference. The cage indeed was large, and the birds having a perch to fit upon in the upper part of it, they did not annoy one another.

In Amhara, this animal is called atinkoko, which, I apprehend, is derived from the singularity of those long hermecous hairs, which, like small thorns, grow about his back, and which, in Amhara, are called atkho. In Arabia and Syria, he is called Israel's sheep, or Gannim Israel, for what reason I know not, unless it is chiefly from his frequenting the rocks of Horeb and Sinai, where the children of Israel made their forty years pergrination; perhaps this name obtains only among the Arabian; I apprehend he is known by that of Spahian in the Hebrew, and is the animal erroneously called by our translators currnis, the rabbit or coney. [Bruce Append.]

M. Schreber, who names this animal Hixon fricicus, gives it this specific character: H. plantis tridactylus, ungubus subequarebus. (Feet tridactyle, with all the claws nearly equal.) To this Dr. Shaw, in his Zoology, adds, that it is rufous-grey, and white beneath. Gmelin also has Hixon fricicus, pedibus unguiculatis. See Hyrax Sy- ricus.

ASHLAR, a term used among Builders, by which they mean common or free stones, as they came out of the quarry, and of different lengths and thickneses.

ASHLEP, in Agriculture, a term sometimes applied to swopers' ashes or wath. See Soppor. ASHES.

ASHLING, among Builders, signifies quartering, to lath to, in garrets, about 2¾, or 3 feet high, perpendicular to the floor, up to the under side of the rafters.

ASHLEY, in Geography, a river of North America, which runs into the sea on the south-west side of Charlestown, in South Carolina.

ASHMOLE, Elias, in Biography, an eminent antiquarian of the 17th century, was born at Litchfield in 1617; and at the age of sixteen was received into the family of his kinsman James Paget, esq. a baron of the exchequer, where he studied the law and other branches of knowledge. Having married in 1638, he settled in London as an attorney; but on the commencement of the civil war, his wife being dead, he entered into the king's service, and was employed in the department of the Ordnance, first at Oxford, and afterwards at Worcester. At Oxford he became a student of Brazen-nofe college, and directed his attention to mathematics, natural philosophy, and astronomy. From the fund of the latter important and useful science he devoted it to that of alhology, to which he seems to have been much attached. In 1646, he was admitted into the society of free and accepted masons, and his election into this society was conflu-ented by him as a distinguishing era of his life. His valuable collections very much contributed to the illustration of its history in this kingdom. Upon the surrender of Wor- cester to the parliament in this year, he withdrew first to Chelshire, and afterwards came to London, where he formed
ASH, intimate acquaintance with the alchemists of that period, Moore, Lilly, and Booker. In 1647, he retired to Englefield in Berkshire, and applied to the study of botany. Here he became acquainted with a rich widow, whom he married in 1649, and then removed with her to London, where his house was a place of resort for all the proficient in the curious and occult sciences. Having acquired from an adept in Berkshire a taste for alchemy, he published, under a forged name, a treatise by the famous Dr. Dee; and another by an anonymous author, on this subject; and with great labour and expense he made a collection of the MSS. works of English chemists, which he published in 1652, under the title of "Theatrum Chymicum Britannicum," in 4to. Having brought to a favourable termination some legal disputes occasioned by his wealthy marriage, he devoted himself with singular affability to the study of antiquity and the perusal of records; and relinquishing hermetic philosophy with a preface to a treatise on the philosophers' stone, which he edited, he began to make collections for the work which conducted much more to his literary reputation than any of his astrological and chemical pursuits, and this was his "History of the Order of the Garter." As he was fond of the study of botany, he chose for the place of his residence the house of John Tradescant, a scientific gardener of Lambeth; and became possessor of the collection of rarities that had been made by Tradescant and his father, and which was conveyed to Mr. Ashmole by a deed of gift in 1659. On the restoration, Ashmole was particularly noticed, on account both of his loyalty and learning, by the king, who appointed him Windsor herald, and committed to him the description of the royal medals. He was also made a commissioner, and afterwards comptroller of the exchequer; he was called to the bar in the Middle Temple, admitted a fellow of the Royal Society that had been recently established; presented, by the university of Oxford, with the degree of doctor of physic; and promoted to other offices, both honourable and lucrative. Upon the death of his second wife, he married the daughter of his friend Sir W. Dugdale. In 1672, he presented to the king his book "On the Order of the Garter," intitled "The Institutions, Laws, and Ceremonies of the Most Noble Order of the Garter, collected and digested into one body," and printed at London in folio, in 1672. In 1679, he resigned his office of Windsor herald, and declined accepting that of garter king at Arms, on two vacancies which occurred. His valuable library, which he had been thirty-three years in collecting, and also his cabinet containing of nine thousand coins, and many curious antiquities, were destroyed by a fire, which happened in the chambers adjoining his own in the Middle Temple; but his MSS. and gold medals were preferred at Lambeth. When the university of Oxford had finished an edifice for a museum, in 1683, Mr. Ashmole sent thither his Tradescant collection of rarities, with the additions which he had made to it; and afterwards added to this donation, his books and MSS. Thus commenced the "Museum Ashmoleanum," now subsisting at Oxford. Mr. Ashmole, having attained the 76th year of his age, died in 1692, and was buried in the church of Great Lambeth. Some few of his numerous MSS. chiefly on antiquities, have been published since his death; and also "A Diary of his Life" written by himself. His rank in literature and philosophy may be estimated by the brief account that has now been given of his researches and pursuits. Whilr a sober judgment will hesitate in admitting the extravagant panegyric of the "Biographia Britannica," which records him as "one of the greatest men in the last century," he will be allowed to have possessed, in a high degree, industry, perseverance, curiosity, and exactness; and "Anthony Wood," says one of his biographers (see Aikin's Gen. Biogr.), "in his quaint language, has perhaps not ill characterized him, as—the greatest virtuoso or curioso that was ever known or read of, in England, before his time." Biog. Brit.

ASHMOT, in Geography, the principal harbour in Isle Madame, which is dependant on Cape Breton.

ASHMOUNEIN, probably, says Bruce (Trav. vol. i. p. 91.), the ancient Latopolis, a large town of Egypt, which gives name to the province. See ACHMOUNAI.

ASHMUN-TANAH, a town of Egypt, on a canal, between the Nile and the lake of Temenis, twelve miles east of Manfreda, and twenty south of Damietta.

A-SHORE, in Nautical Language, a term signifying on the shore, as opposed to A-BOARD. It also means A-GROUND.

ASH-PIT, is the lower part of any air-furnace, which serves to receive the ashes of the fuel as it is consumed, and in general to supply the air necessary for the combustion. See FURNACE.

ASHUELOT, or ASHWILLET, in Geography, a small river of America, having many branches, whose most remote source is at the north end of the Sunapee mountains, in New Hampshire. It runs south-westerly through part of Cheshire county; below Wincheste, its course is west by north, and it discharges itself into Connecticut river at Hinsdale.

ASHUR, in Ancient Geography and History, the second son of Shem, occupied at the dispersion the country called after his name, and by the Greeks Asphrya, at present Curdistan, or the country of the Kurds. Pezron supposes that he was driven out of Shinaar by Nimrod, the grandson of Ham; but however this be, it seems to have been Ashur, (Gen x. 11.), and not Nimrod, who went out of Shinaar into Asphrya, and built Nineveh, and other cities; and thus Perizonius maintains, that the text ought to be understood. See ASBYRIA.

ASH WEDNESDAY, the first day of Lent, supposed to have been so called from a custom in the church of sprinkling ashes on that day on the heads of penitents then admitted to penance.

ASIA, in Geography, one of the four grand divisions of the earth, and the second in order, that, though inhabited. It is separated from Europe by the Mediterranean, the Archipelago, the Euxine, the Palsus Meotides or sea of Azof, the Dan, and the Dvina; from Africa by the Red sea and the isthmus of Suez. On the other side it is surrounded by the Great South sea. It does not join to America. Its principal parts are, Arabia, Asiatic Turkey, Persia, India, Tartary, Asiatic Russia, China, Japan, the Kingdom
kingdom of Ava, that of Siam, the island of Ceylon, and the Sunda islands, whereof the chief are Sumatra, Borneo, Java, Celebes, the Moluccas, the Philippines, and the Maldives. Aria, according to Mr. Pinkerton, extends, in length, from the Hellepont to what is called the East cape; that is, from about the twenty-sixth degree of longitude east from London, into the other hemisphere near 190 degrees of east longitude, or 170 degrees west from London; being no less than 164 degrees, or (taking the degree at a medial latitude) more than 6750 geographical miles. From the southern cape of Malacca, to the Severovolotki-noi cape, the north-eastern cape, now called the cape of Taimura, which breaks the ice of the Arctic Ocean, the breadth extends, from about the second degree of northern latitude, to about the seventy-seventh, or nearly 3500 geographical miles. If, for the sake of a rude and merely comparative calculation, one-sixth part be added for the difference between the natural and geographical mile, the length of Aria in British miles would be about 7583, and the breadth 5250. — Under their proper heads, will be found the names of the places it contains, and such general accounts of them as the limits to which we are confined on this subject will allow.

For ascertaining the real length of the continent of Aria, there was no guide as to its southern and eastern part, even beyond the Ganges, except from the accounts that were obtained from the time that the navigations began in the sixteenth century, and their disagreements with the arbitrary alterations that had been made. A long period elapsed before it was possible to settle the position of that portion of Aria, still susceptible of much correction, notwithstanding the observations of the Jesuits at Pekin, the most accurate of any extent. We shall content ourselves then with relating the result of the latest observations of the academy of sciences at St. Petersburg, of the latitude and longitude of the following places in the north of Aria.

Unalakh, by the general map of Russia, lies in 58° of latitude from Ferro, 223° of longitude; and from Greenwich, 205° 25'. The same place, according to the chart of Krenitzin and Levathes, is in 53° 30' latitude, longitude from Ferro 205° 30', from Greenwich 187° 55'; the longitude from Ferro to Greenwich being computed at 17° 34' 45''.

If the ancients had so flight a knowledge of the southern countries of Aria on the other side the Ganges, we ought not to be surprised if they had been able to hand down to us concerning the hyperborean regions, coasts, and seas, or the northern extremities, should be considerably more so; and it must have been merely by chance that Pliny obtained some slight knowledge of Cape Tabin and of the island Tazzata; as we have learnt a few uncertain notices about those vast lakes towards the west of America, from savages taken prisoners, and others, and from vague report, with which we are obliged to be satisfied for want of better information. It was impossible to acquire any more authentic, except by means of the Russians, with whom, till the seventeenth century, we were scarcely any more acquainted than with the savage inmates of those northern coasts. Nay, it had not been for the Russian, Anika Stroganof, who formed speculations for profiting by the lucrative commerce which the Samoyedes carried on at Mosco, in peltries brought from countries beyond them, Siberia, properly so called, would have remained a great while longer unknown to the Russians themselves. Thus, as a thirst for riches had been the chief motive that excited the Spaniards to the discovery of America, and attracted the attention of other maritime nations to that quarter, so the fame greediness of gain occasioned the discovery and conquest of northern Aria, a country till then unknown to the Europeans. The first foundation of this conquest was laid by the celebrated Yermak Timafeyev, at the head of a band of adventurers, left civilized, though not so inhuman, as the conquerors of America. By the accession of this vast territory, now known by the name of Siberia, the Russians have acquired an extent of empire, never before attained by any other people. (Tooke's View of the Russian empire, vol. i. p. 303.) It was however owing to Anika Stroganof and his comrades, that this conquest was undertaken, who also showed the way to subjugate, by degrees, farther distant nations. The Russians themselves became known to the Europeans, through the voyages undertaken by the latter. The English and Dutch obtained some intimation of them while in quest of a north-east passage; they learnt of the Samoyedes that the little sea froze over in winter, but the great sea was never frozen; that they went thither to fish between the mouths of the Pafida and the Yenisey; that opposite to the east and north point of Nova Zemla, was another, making a great salient angle, from which the coast afterwards declined towards the east and south-east, nearly to the hot countries. Here we see to what a small matter was confined the knowledge at that time obtained of the southern part of Aria, and the only materials from which they could lay down their charts. They were puzzled how to reconcile these statements, and the more, as the coast between the Pafida and the easternmost point of its cape was unknown to them. Some knowledge of it by land had indeed been obtained; and even the coasts of the sea to the westward of it, as far as its mouth, are filled with smimows, or winter-huts, consequently peopled; but those situated beyond that little river were so indubitably known to them, that they thought it best to mark them down in an indeterminate manner.

They reasoned thus: Cape Tabin must form a suis terre, the extremity of Aria towards the north. There is a sea that washes all those shores; and we are assured there is another that divides Aria from America; these two seas therefore must join, and at that place form an angle, which will prove to be this Tabin; having an island to the westward which they laid down as lying at the mouth of a river. This notion, notwithstanding the numerous discoveries that might have destroyed it, has always fulfilled, under one form or another, to the very times in which we live. Some, building on the report of the Samoyedes, marked the coast from the cape to the Taimura, as declining gradually towards the south-east. Others, willing to reconcile one with the other, laid down this declension only to the Lena, at its mouth, having got intelligence of some islands there; accordingly they carried the coast north-eastwards, for the sake of preserving this Tabin. On learning that the Russians and others regarded Svetoi-noi as the most advanced promontory, they gave its name, or Promontorium Sacrum, to the pretended Tabin. Afterwards, being informed that this Svetoi-noi laid to the east of the Lena, they marked it accordingly, and hence were more firmly persuaded, that the islands at the mouth of that river were those of Tazzata; while on the other hand, they perfumed the idea of a cape in a terra, which they left unfilled under the names of Tabin (which we shall continue
to use while speaking of it in this sense), Svetoi-nof, Caput Sacrum, Timuikhi-nof, Thalak-kholoi-nof, &c.

Strahlenberg notices this cape in a striking manner; and the navigators of the eighteenth century, likewise, even so early as Linschoten and his contemporaries, were persuaded that it was no other than that prominent angle towards the Taimura; indeed it is the most advanced cape of all that coast, lying beyond the 77° 15' or 78° 25', and therefore the finis terra towards the north. But Strahlenberg at the same time points out the site of Tazzata, which he proves to be Novaya Zemla, since the ancient Scythians and their successors began with the northern nations of Europe, by the river Taz, whence they detromated the great gulf to which we give the name of Oby, the gulf of Taz, and from which Novaya Zemla, situate over against it, was called Tazzata. This is so natural, and can be the less doubted of, as that island has always been reputed as lying to the west of cape Tabin, near the mouth of a river. Whence Strahlenberg concludes, that those geographers who mark it more to the east are greatly mistaken, "huc upiam Tazzata insula a Finio ponitur."

After the conquest of Siberia, some Russians fell upon the same reflections as Anika Stroganoff and his companions had done concerning the wealth that might be drawn from these oriental parts by the articles of petrify, on going direct to obtain them, either by the chace or by commerce; several companies were accordingly formed of people who were then, and are still known by the name of Promuih-lemiye.

They considered that the method of making the greatest profit possible would be by going to sea coastwise, and trafficking with these unknown tribes, who being ignorant of the value of their peltries, would give them for a low price. In this they were not deceived: and, notwithstanding the great risk they ran, as their vessels were small and heavy; as they were no less mindful of the art of constructing than in managing them; as in not venturing far from shore, they were in jeopardy every moment of founding among the ice; yet the thrill of these was too strong to prevent them from being deterred from their projects; and the government was well satisfied with them, as they furnished it with the means of rendering all these people tributary.

They began their courses from Yakoutsk about the year 1676; proceeding in this manner step by step, they every year almost, discovered some new river, some new cape, the Yana, the Indigirka, the Alaera, the Kovyma. No sooner were they come to the last of these rivers, than their curiosity was excited to know what other dreams might be beyond it, in the two-fold view of rendering the nations bordering on them tributary to the empire, and of procuring the expected capture of fables for their own enrolment. The first voyage from the river Kovyma was undertaken in 1646, by a free company of these Promuihleni, under the conduct of a certain Iacae Ignatiev, a native of Melen. They found the sea full of ice; between the ice, however, and the main land was an open passage, along which they proceeded twice 24 hours; when, coming to an inlet between the rocks and the shore, they ran into it. These 48 hours make seven degrees and a half, and the bay they entered lies in 72 deg. Here they met with people of the Thukhthi nation, with whom they began to trade in the manner customary with uncivilized people; spreading their commodities on the shore, of which the Thukhthi took what they pleased, and deposited in their place walrus-teeth, and articles made of that species of ivory. None of the mariners would venture on shore to the Thukhthi, particularly as they had nobody on board who could serve as interpreter. Contenting themselves therefore with having made this first discovery, they returned to the river Kovyma.

The accounts brought home by these people of the walrus-teeth, induced some other Promuiheten some years afterwards to undertake a second voyage. To this end Fedor Alexeyef, a native of Kolomogor, associated himself with a Moleo merchant of the Geffima emn, a vassal of Alexey Uffof, and were immediately considered as the chief of the enterprise. He thought it, however, expedient to ask of the commandant at Kovyma, one of his kozaks to look after the concerns of the crown during the voyage, who appointed one Simeon Ivanof for Deputy, to attend him, with proper instructions. Four kotches, a species of boats, failed at the fame time in June 1647, from the river Kovyma. Some loose informations having been obtained of a river Anadir, or as it was then pronounced, Anandir, the borders of which were inhabited by numerous tribes of strange people, it was calculated that this river must fall into the Frozen ocean; one of the objects therefore of the present voyage was to discover its mouth. However, in this, as well as all the rest, they completely failed; the sea, even in summer, being too full of ice to permit them a free navigation.

Nevertheless, the passion for discoveries for augmenting the revenues of the crown and the wealth of private individuals was so great, that no thoughts were entertained of giving them up. Indeed the number of adventurers seemed rather to increase, both among the Kozaks and the Promuiheten, to that the following year four jetts were fitted out in the same design; what became of four of these vessels the accounts received make no mention. Of the three others, Simeon Dehnof and Gerail Anadkinof were commanders on the part of the Kozaks, and Fedor Alexeyef the principal of the Promuiheten. Previous to their departure a quarrel broke out between the two former, arising from the jealousy of Dehnof, that Ankadinof should share in the honour as well as in the profits to accrue from the future discoveries. The crew of each vessel might consist of about thirty persons; at least that was the number of Ankadinof's people.

It is to be lamented that the accounts of Dehnof, the original source of Mr. Miller was lucky enough to find among the archives of Yakoutsk, should say so little, and even nothing at all concerning the fate of four of these kotches; nothing of what happened to him and his companions on board the other three till they came to the Great Cape; nothing about the ice, because, doubtless, says Mr. Miller, there was none; and as Dehnof remarks in another place, the sea is not every year navigable.

The relation begins at this cape. His words are: "This cape is entirely different from that which projects near the river Thukotha, westward from the Kovyma. It is situated between the north and north-east, forming a semicircle towards the Anadyr. On the Russian or western side, the Thukotha have raised by the side of a river a number of whalebones in the form of a tower (according to other reports they are the tusks of the walrus). Opposite to the promontory (it is not mentioned on which side) are two islands, whereon were seen people of the nation of Thukotha, distinguished by wearing pieces of the teeth of the walrus, inserted in their upper lip. It is possible, with a very good wind, to stretch from the promontory as far as the river Anadyr in three times 24 hours; and it would require no longer time to do it by land, as the Anadyr discharges itself into a bay." On this promontory it was
that Ankudinof's kotsch perished; the people however were saved, and put on board the other two kotsches. Shortly afterwards they were separated, and never again got sight of each other. Deblinof, after being driven about by wind and weather till October, suffered shipwreck, as far as can be collected from circumstances, confirmably to the south of the river Anadyr, somewhere on the river Olona. What became of Fedor Alexieff and his ship's company we shall mention presently.

Deblinof, with his followers, five and twenty in number, now set out in search of the Anadyr, which they did not discover till after they had wandered about, for want of a guide, the tedious space of ten weeks. The region where they came up to the Anadyr was not far from its mouth, a country entirely void of inhabitants, and destitute of forests; circumstances that naturally threw them into the extremity of distress, as perceiving no means of obtaining subsistence. Wild animals were not to be expected, as they usually haunt the woods; and they had no implements for fishing. In this perplexity, twelve of the company went up the course of the river; but after a devious journey of twenty days, failed finding no trances of mankind, they turned about to regain the station where Deblinof and the rest were waiting for them; which, however, on account of hunger and fatigue, only a few of them reached.

After undergoing incredible hardships, Deblinof, in the summer of 1649, with the small remains of his people, went up the Anadyr by water, till he came to a people called Anadyl; and there he founded the Anadyrkaloi oltrog, which was followed by other buildings. Deblinof observed a great sand-bank lying at the mouth of the Anadyr, advancing on the northern side far into the sea, the extent of a vast number of morhbes and other amphibious animals. This circumstance was too flattering to be neglected. Accordingly, he began to fell timber, in 1653; for the confirmation of a kotsche to be employed in conveying the tribute to Yakutsk by sea; but was obliged to desist from his purpose from the want of other materials, and because he learnt that the sea about Tlukotlki-nofs was not every year equally free from ice.

In 1654, he made another expedition to the korga, or sand-bank, for the purpose of collecting morhbe-teeth. He now associated with him a Kazak named Yutko Seliverstof, who had accompanied Mikhail Stadikin on his voyage of discovery in the Frozen Ocean, and was sent from Yakutsk to collect these teeth for the benefit of the crown. In his instructions mention is made of a river Shendon, falling into the bay at Penlinsk, as well as of the Anadyr; and he was ordered to levy a tribute on the inhabitants dwelling about both these rivers; as what Deblinof had been doing was not as yet known at Yakutsk. On this occasion new difficulties arose. Seliverstof arrogated to himself the discovery of the korga, as having failed to that place with Stadukin, in 1649. Deblinof, however, proved that he had not even reached the great Tlukotlki-nofs, which he affirmed to be formed of nothing but bare rocks, as was but too well known to him, since Ankudinof's vessel had been wrecked upon them. He farther alleged, that this was by no means the true promontory that appeared under the appellation of Stukoj-nofs. The two islands lying opposite the Tlukotlki-nofs, belonging to the mouth of the Anadyr were at a great distance from them.

Deblinof, while surveying the sea-coast, learnt of the Kories of the fate of the two Ankudinofs, Fedot and Germ, as well as of Fedor Alexieff.

In 1659, other expeditions were again undertaken; but, from the foregoing impediments, though they met with much loss, they were not able to do much damage. They began by exploring the Bering Strait in the ship of St. Peter, that they might return from such voyages for a longer time; and it was not till the reign of Peter the Great that these enterprises were resumed. It is well known that his commanders were so wise to secure their aims only with ideas and grand projects; that being principally desirous to establish an extensive commerce by means of navigation, he began by opening to himself the navigation of the Baltic by the foundation of St. Petersburg; Archangel already existed on the shore of the White Sea; he thought himself secure in the navigation of the Euxine by the possession of Azof, and that of the Calpian by Astrakhan, which he succeeded in bringing to effect. He now conceived that it might not be impossible for him to participate in the lucrative commerce of the Indies, of Japan, of China, and of America, by establishing factories at the extremity of Asia, in the proximity of those countries. The Dutch East India company declining to attempt the discovery of the north-east passage, the tsar adopted the project, as well as that of subjecting the countries adjacent to the objects of his commerce, beginning by Kamchatka, of which some obscure information had been obtained.

Thither, in 1696, he sent Vladimir Atlafil, as commandant of the Kazaks at Anadyrkaloi-oltrog, a settlement that had been retained as a result of its first erection by Deblinof, as before related, who was naturally supposed to have acquired an extensive knowledge of all the neighbouring countries. He accordingly dispatched sixteen Kazaks of Yakutsk, to render the Kazaks in the river Opuka tributary; Morolko, their chief, acquiesced well of his commission, and even took a Kamchatade oltrog. Atlafil, profiting by this advantage, put himself at the head of sixty Kazaks, and as many Yukagirs, and led them to the river Kamchatka, and the surrounding districts. In his judicial declaration, he relates, among other things, before he concludes the recital of his progress to Kamchatka; that, between the Koryma and Anadyr is a double cape, which some have called Shalakii-koi cape and Anadyrko cape. Of the latter he affirms, that it can never be doubled in vessels of the ordinary construction, because on the western or northern side are always vast pieces of floating ice (stationary and solid in winter); and that the other side of the sea of the Anadyrko cape is at all times free from ice. That, though he himself was not perfectly at the height of these capes, yet he learnt from the Tlhuktis, who dwell about the mouth of the Anadyr, that over against this cape is a large island inhabited by people who come to them in winter over the ice, and bring them bad fables.

To avoid proximity, we omit the remainder of his account, only observing, that Mr. Müller feems rather to depart from his usual candour in regard to this narrative, which he acknowledges to be really Atlafil's, but qualifies that it does not exactly tally with a letter of his in 1700, nor with his judicial deposition in 1701. In order to have given validity to his doubts, he should have communicated these pieces among the great number with which he has enriched his valuable collection. This he has not done. As far as the tsar, who was an excellent judge of mankind, was to be well satisfied with him, that he made him colonel of the Kazaks at Yakutsk, this circumstance ought to have its proper weight with us.

Parties were repeatedly sent against the Tlhuktis, without success;
out being able to subdue them. In 1711, the Yakutsk-Kozak Peter Iljin fin Popof, the promyshlennik Yegor Vasiliev
fin Teldin, and the newly baptized Ivan Vasiliev fin Turel
kin, made a vigorous attempt to compel those who dwelt on
the other side of the bay, and of the cape or noes, to pay
the tribute; which they as feriously refused. They, how-
ever, obtained from them a great number of particulars
concerning the situation of the surrounding countries; and,
among others, that opposite, whether to the Kowma or to
the Amandy they could not sufficiently comprehend, is situate
a spacious island, to which the Thluikhi give the name of
the great land, the inhabitants whereof pierce their cheeks,
and pafs large pieces of teeth through the orifice; not
having the same language with the Thluikhi, who have
been at war with them from time immemorial. Popof saw
few of them, who were prisoners to the Thluikhi; and he
remarked that these pieces were shofk of the walruses. He
learnt that in former they pafs over to this island in baidars
in one day, and in winter likewise in one day in fledge on
the ice.

On the promontory or land of this cape no other ani-
imals than wolves and foxes are seen, since there are no fo-
rels; whereas on the other land are all sorts of animals that
furnish the finer sorts of furs. The inhabitants keep numer-
ous herds of rein-deer. The country produces cedars, firs,
pines, larches, and other trees. Popof suppos'd that the number
of the Thluikhi at the cape might amount to two thou-
sand men, and that of the islanders to triple that sum;
that, from the Amandy-Kofof-objog they go by land to the
noes, along the rock Matkol, which runs out from a great
gulf.

At the time of which we are speaking, there being yet
no implements for navigation at Okhotk, and the use of
the compass not being known there till the year 1714, by
the express command of the great czar Peter I., the governor
Prince Gagarin appilied both these defets. Probably the
governor at first imagined that the purpofes of discovery
might be efecuted without these helps; for the first order
relating to the discovery of a passage by fea to Kamfhatka,
dated the 17th of February 1713, directed to the voivode
Yeltihn, contains not a word about the conftruction of ves-
fels, nor of people expert in the art of navigation; ac-
cordingly, nothing farther appears than that the dvoranin Ivan
Sokolov, who was charged with the buifines at Yakutsk,
arriving with twelve kofoos at Okhotk in the autumn of
that year, committed a great many blunders, and was
brought back to Yakutsk in cuifold. It was now found nece-
nary, that the governor fould immediately send some
able flemens and fhip-carpenters. By thefe, who arrived at
Yakutsk the 23rd of May 1714, and were fent off to Ok-
hotk the 30 of July, under the command of a Kofo named
Kolmas Sokoloff, with about twenty Kofoos, the long-wifhed
for discovery was made.

One of the fropers, by birth a Dutchman, a native of Hoorn,
(Strangebnem calls him a Swedish corporal, who had formerly
been a ship-carpenter. But Bucbf himfelf fays, that he had
erved in various places many years as a farpent, and at laft in the
Swildh cavalry, and fo came to be taken prisoner at Vyborg,
in the year 1763,) named Henry Bucbf, was ill living at
Yakutsk in 1736, when Mr. Muller made fome stay there;
and, in answer to his inquiries, learnt of him the following
particulars. After they were come to Okhotk, the car-
penters built a vesfel of the fame kind with the Ruffian
ladders, in which they used formerly to go from Archangel
to Melenc, Puffozerof and Nova Zentha. These labours oc-
cupied the whole of the year 1715. The vesfel was very
flour and substantial. It was eight fathom and a half in
length, and in breadth three fathom. When loaded, it drew
three fect and a half of water. All things neccffary for the
voyage being ready, the firit expedition was undertaken in
June 1716. They coated north-eaifwards, as far as the
region of the river Ola. It was intended to pursue the
fame coourf farther; but a contrary wind drove the vesfel,
as it were againft the will of the navigators, across the seas
to Kamfhatka. What they firit defired, as they after-
wards informed, was a promontory, fkarting northwards
from the mouth of the river Tigil. The coaf teemed steep
and rocky, therefore they would not venture on fhore, defe-
tute as they were of any pilot or guide. Proceeding, how-
ever, to keep the fea, a contrary wind arose, which drove
the vesfel back upon the Okhotfsian fhoare. The wind after-
wards coming favourable, the navigators talked about,
and came exactly back to the Tigil, where they now call anchor.
Some of the people went on foare in fearch of human beings,
but found only empty huts. The Kamfhadales had per-
ceived the vesfel approaching, and had flid for fear into the
forefts and mountains. Our mariners therefore again fet
fail, paffed the Tigil, and in the space of a day reached the
fream Chariuflofa, having two small iflands lying in its vi-
cinity. The former, being the largelt, is at the distance of
five verfts from the main land; the other, confiding only
of barren rocks, a little farther. Leaving the Chariuflofa,
they froid out to fea the whole night, and the next morn-
fing found themselves in with the land at the river Ithia.
Here they fent fome of the crew on foare; who, finding
however neither people nor habitations, prefently returned.
Continuing to fall along the coaf, they came up with the
river Krufogrova, into which they would have run, but
miiffed the inlet; luckily, however, a bay opening to the
fouth of the river being found convenient, in it they dropped
their anchor. A detachment of them, while exploring the
country, met with a Kamfhadale girl picking up edifie
roots in the fields. She directed them to fome huts, where
ult at that time a party of Kozaks had put up for the pur-
pofe of collecting the tribute. Thefe, on being fent to,
came and ferved them as guides and interpreters. The vesfel
was brought to the mouth of the river Komzakova, which
they found a good birth to moor in for the winter. Here
they had not been many days when a whole was thrown
ashore by the fea: in the body of the fish was flicking a
harpoon of European manufacture, marked with Roman
letters. If I could have furnifhed, continues Mr. Muller,
that the farior who related to me this fact, had known of
the like accident that happened to the fhip-wrecked Dut-
chmen on the coaf of Korea, in 1653, (Wifon, ed. 2. p. 45.
Voyage au Nord, tom. ix. p. 102.) I might have been led
to fuppofe, that he perhaps was amusing me with a tale
that had no other foundation than what he borrowed from
the former. This, however, was not the cafe. For he was
a completely illiterate man, could neither read nor write,
and scarcely knew that there was such a place as Kaika in
the world; confequently the fact is only the more confirmed
by two examples. The commander Sokoloff, during the win-
ter, made a journey to Niffnei Kamfhabaloi olrfog, whence
he returned to the fhip in spring, and at the beginning of
May 1717, put againft to fea. The fea, however, was so
full of ice, that on the fourth day from their departure they
were completely jammed in between some fields of it, where
they were obliged to remain fixed upwards of six weeks,
before they could proceed on the voyage. In the mean
time they were in great want of provisions. Happily they
reached the Okhotfsian fhoare, between the river Ola and
Talmidolrfog, where they remained at anchor a few days;
and about the middle of July returned to Okhotk. From
this
this time a navigation has been uninterruptedly kept up be-
tween Okhotkk and Kamchatka.

While all this was transacting, governor prince Gagarin,
in the year 1716, dispatched colonel Jacob Ageefin Yel-
thin, formerly voivode at Yakutsk, with a considerable
party of officers and people, to the same regions, with or-
ders to make diligent inquiries concerning Kamchatka,
and chiefly such as related to the object in question.
Kokschenski mentions, that ships from Japan came to the faith of
the Kurilii islands, Shokoki, for ores or minerals, which they
carried back to their island. This, however, seems to be
not quite correct, as differing widely from all the other ac-
counts, which say, that the Japanese (probably when
driven about by adverse winds and storms) used never to
proceed farther than Matmai. Nor had any subsequent
information confirmed what he advances. This therefore
was one of the principal matters into which the colonel
was instructed by the governor to inquire; he was likewise to
proceed from Tihukotkoi-nof to the opposite islands, and
thence to the mainland. By his instructions also he was to
gain accurate information about the islands of Shantar;
to attempt to fettle a regular traffic with the Japanese, and
whatever else he could effect in consequence of his own ob-
servations: nothing, however, of importance ensued from
it. The governor had given the colonel, a Swedish lieu-
teutenant named Ambtborn Holmy, who was to controul the
vedtchshpper for the several enterprises at Okhotski.
this man pretended that there was no timber to be found at
that place fit for the purpose. (Seealso Strahlenberg, p. 17.)

Disputes arose now between the colonel and the voivode
of Yakuts, Ivan Vasiliev sin Rakitin, which likewise probably
threw great impediments in the way of this expedition; and
the disgrace of prince Gagarin happening soon after, the whole
business came to nothing. The only benefit accruing from it
was a voyage got on foot by Yelthin, in the year 1718,
to the Shantary islands, and performed by the sin boyaridki
Prokofey Philcieef. This person was still living when Mr.
Muller was at Yakutsk, and from whom he learnt the fol-
lowing particulars of his voyage.

Philkief was provided with able seamen, the better to
ensure success; when they were out at sea, the colonel de-
clared to him that they were resolved to visit not only the
Shantary, but all the other islands lying in those seas, as
far as the Kurilii; which done, they would winter on the
largest of the Shantary islands, by way of eminence is
denominated Shantar. This not being agreeable to Phil-
kief, he caufed himself, with a couple of Kozaks, to be
put on shore at the mouth of the river Tugur. The reft
accomplished their design, pafted the winter on the island of
Shantar, and had a rich capture of fables. Having negligi-
gently, however, left a fire they had being, the flames
cought the trees, fo that the whole forest of the island was
in a blaze, by which they also loft their fables. The next
summer they returned to the continent, where, intending
to fift along the coast between the Tugur and the Amoor,
the greater part of them were flain by the Giliaks. They
computed the isle of Shantar to be from south to north
about twenty verfs, and three or four verfs in breadth,
without any mountain upon it. How then were these
islands to be seen from the mouth of the river Ud? This
therefore seems to confirm Philkief's affertion, that they ar
fntuate in the proximity of the Tugur, and that it re-
quires eight days to pasl from the Ud to the Tugur, in lod-
kas or small craft. If we admit the situation of the coasts
to be as they appear upon the maps, namely, as stretching
direcly fouth from Okhotk to the Amoor, then the diffi-
culty is much increafed; becaufc in that cafe there must be
several promontories projecting fo far as to conceal thefe
islands from the view. But various reasons may be found
for believing that the coasts from Okhotk to the river Ud
runs south-eflewards, and from the Ud to the Amoor
south-eflewards. If fo, as it is highly probable it will here
after be found, then the Shantary islands may lie in such
a manner as to follow one another in succession northwards
from the river Tugur. There may be more of them than
we imagine, since the number of them is by no means af-
certained. In that cafe, the neareft may unquestionably be
difcerned from the river Ud.

In 1718, a tribe of Tihukthiis came voluntarily to fur-
render themselves at the Amadirkoi oitrog, declaring that
they inhabited the promontory between the Amadyr and
the Koyma; that they were in number about 3500 men;
that this promontory was covered with rocks and moun-
tains, but that the flat country consisted of turfl-land; that
opposite to the cape was seen an ille of moderate dimensions,
the inhabitants whereof bore a resemblance to the Tihuk-
thiis, but spoke a different language; that from the point they
could go over to the ille in half a day; that beyond it was
a large continent which might be seen from the island in fair
weather; that its inhabitants likewise resembled the Tihuk-
thiis, but had a different dialect, numerous forests, 
&e. (giving
an exact description of the great ille mentioned above)
that with their baidars, or boats. by coasting the pro-
montory, they could make the voyage from the bottom of
the bay of Amadyr, to the extreme point of the promontory,
in three weeks, and often in lefl time.

Peter the Great, desirous of obtaining a more accurate
knowledge of these parts and paflages; and unable to in-
duce the Dutch East India Company to take up the matter,
resolved himself to prosecute the design with vigour. Ac-
ccordingly, in 1727, he sent two geodesils, or geometers,
and Kamchakta. Of what they executed or discovered nothing
ever came to the ears of the public. It is only known,
that on their return, the tzar gave them a very gracious re-
ception; whiere it may be presumed, that they acquitted
themlelves of their trulf to his satisfaction.

In short, the tzar being resolved to satisfy his curiosity
by cauing these latitudes to be explored, and above all to
be certified whether Afla was contiguous to America on
the north-eaferen side, towards Tihukthiis, close on the
north side it undoubtedly was not; he made choice of
Vitus Bering, an expert Dutch mariner, for that purpoee,
who he became jointed Spangberg and Thiknof. Peter had this business so much at heart, that though con-
fined to his bed by the ilife that put an end to his life,
he conversed with Bering, and even drew up with his own
hand a set of instructions for his guidance, which paper
was delivered to him five days after the demise of that
great monarch.

He set sail the 14th of July 1728, from the river of
Kamchakta, and steered north-eaferwards, following the
land so as to lend fo great a distance, which Bering came up with on the 10th of August,
and gave it the name of Saint Lawrence.

On the 15th of the fame month, in 67° 18'. lat. per-
ceiving that as the Tihukthii had said, the coast bent towards
the west, and no longer to the north, it is said that he drew
this
this false consequence, that he had reached the extremity of the north-eaft of Asia; that the coast thenceforward taking a western direction, it was impossible there could be a junction of Asia with America; and that he had ful-
filled his commiffion. Mr. Miller adds, that he was mi-
taken, since he was only then at Spridzakan, whence the coast indeed turns to the west, forming a large gulf; but that, in the attempt to reach this land and naviga-
or gulf as the great Thukthutkii-nafs. On his paflage back, the 20th of Auguf, forty Thukthutkii approached his ship in four haid-
ders, and informed him that their countrymen frequently went to the Koyyna by land, with merchandise, but never by water.

Afanafy Shelafak, colonel of the Yakutkii Kozaks, having made several propoftals to the Senate to render the obfinate Thukthutkii tributary, it will be neceffary to lay something of his expedition as being of some confequence to the history of navigation. Shelafak was refolved to reduce not only the Thukthutkii, but likewise the Korilks who dwell on the Siberian eafth of the Penfchnian sea, and likewise inhabit both fhores of the northern part of Kam-
tjatka, and were frequently in a state of rebellion, to obedi-
ence. He purpofed to visit the country lying opposite to 
Thuktsttijoi-nafs, and fubjeé the inhabitants to the Russian authority. It was part of his plan likewise to make an at-
tempt to difcover the pretended land in the Frozen ocean; 
and, latterly, before his return, to explore the Shantarain and Kurily islands. The elocution, with which he accom-
pounded the delivery of his project, gained him universal ap-
probation, and high and low became inteéted in the success of his enterprise, all conceiving it extremely probable that great public benefit might accrue from it. Accordingly he was appointed commander of a particular expedition. The admiral of St. Petersburg was to put this plan into execution, and name Jacob Hens, with an aflifant Ivan Fedorof, a goodefiff Michael Gvofdef, a minerologist named Herchelof, and ten failors. At Ekatarinburg, he was supplied with feld-
pieces and mortars, with all proper appurtenances. At 
Tobohif, a captain of the Siberian regiment of dragoons, 
Dmitri Pavluzki, was ordered to join him, with four hun-
dred Kozaks, under their united command; and they were farther empowered to increase their strength from all the garnitrons, oflrogs, and fimoivies, in the territory of Yakutkii, wherever they fhould come, at their difcretion.

These preparations being made, Shelafak fet out from 
St. Petersburg for Siberia in the month of June 1727. At 
Tobohif he tarried till the 28th of November, pafted the 
winter in the upper regions of the Lena, and reached Yakutkii in the ifummer of 1728. Here a violent quarrel arose be-
tween Shelafak and Pavluzki, which probably ocdeoned them to part, though they profecuted their ferval purpoftes to 
the fame end. Shelafak, in 1729, repaired to Okhotkii, and there took to his ufe the veffels with which captain 
Beering had lately returned from Kamthtka. Having dif-
patched his kinman the fin boyarikoi Ivan Shelafakoff, on the ifirt of September, in one of them, the Gabriel, to go to 
the river Ud and thence to Kamthtka, for the purpoft of 
examining and defcribing all the iflands he might meet with on that voyage; he failed in the other veffel, the Fortuna, for 
Taviikoi oflrog, but had the misfortune to fuffer ship-
wright, and to fee the greater part of his people perifh in the 
billows, with great difficulty faving himfelf and four other 
perifons from birting他们的 fate. The 30th of Sep-
tember, he fent from Taviikoi oflrog a kozak, Ivan Ola-
fief, in company with an elder of the Koriaks, forwards 
along the coaft, with orders to proceed to the river Pe-
ffhina, and by kind words and fair promises to purfue the 
refatory Korilks dwelling in that trauh, to submit to the 
Russian government. He ifelf folowed, at the commence-
ment of December, with the reft of his men, took up Ofaf-
fief by the way, and arrived within two days journey from 
the Penfchnia, where he fell in with a prodigious hoft of 
Thukthutkii on their march to make war upon the Korilks. 

Though the number of Shelafak’s followers, Ola-

This happened the 14th of March 1733, near the ifream Ve-
gath, which falls into the Penfchnian gulf between the 
riors and Penfchima.

Three days prior to this difbluent expedition, Shelafak had 
fent an order to Taviikoi oflrog, directing the Kozak 
Trypho Krviftef to proceed in one of the veffels to Bol-
feretzkoi oflrog, from thence doubling the southern point of 
Kamtjatka, to fall on towards Nachni Kamthtjatki oflrog, 
to continue his voyage in the fame ship to the river 
Anadyr, and invite the inhabitants of the vaft trauh of 
which country lying opposite to pay tribute to Russia. In this 
difbluent he recommended Krvifkef to take with him the 
geoedefift Gvofdef, in cafe he were inclined to go, and 
treat him with all posifible kindness. Concerning what came 
of it no accounts are extant. Only thus much is known, 
oberves Mr. Miller, that the geoedefift Gvofdef was ac-
ualy, in the year 1732, between the 65th and 66th degrees of 
latitude, at a fhort diflance from the country of the 
Thukthutkii, on an unknown shore ifituating over againi the faid 
country; that he even found people there, with whom, how-
ever, he was unable to converse with an interpreter.

During these tranfactions, the fin boyarikoi Ivan She-

defk was failing on board the Gabriel to Kamthtka, and 
and on the 19th of September 1729, arrived at Balfheretzki.

For though his inftructions were to proceed firft to the river 
Ud, he was prevented from doing fo by violent adverfe 
storms. The following ifummer, however, he made the 
voyage to the Ud, touched at Udki oflrog, where he found 
people who had been fent thither by colonel Shelafakoff, and 
built a veffel; but that not being fit for his purpoft, he 
returned to Kamthtka, having been both on his pafl-
gage outwards, and on his way back, ferval iflands, and 
at laft made again the port of Okhotkii.

While Shelafak was on his paflage back to Okhotkii, 
Jacob Hens the pilot, received a disbluent from captain Pav-
luzki, who had come direcdy from Yakutkii, by the common 
inland road, to Nachni Kovytmof Simovie, or oflrog, iform-
ing him that he had heard, by way of Anadyrski oflrog, of the death of the Kozak colonel Shelafakoff; but 
that this would caufe no impediment to the progres of the 
expedition: at the fame time ordering the pilot Hens to go, 
with one of the veffels which captain Beering had left at 
Okhotkii, round by Kamthtka to Anadirek, whether like-
wife captain Pavluzki would proceed without delay.

In purfance of this order, Hens went on board the Gabriel, 
and failed for Kamthtka. On the 26th of July 1734, he 
arrived at the mouth of the river Kamthtka, intending 
to pursue his voyage to the Anadyr, when a report was 
brought to him, that the fame day a rebellious crew of 
Kamtzales were come to Nachni Kamthtjatki oflrog, 
where after murdering moft of the Ruffians, they had fi-
sed fire to the dwellings of the inhabitants. The few re-
mainitg Ruffians took refuge on board the veffel, and Hens 
ent a party of his people on shore to reduce the Kamthtjales.
to obedience; in which they succeeded; but the event effectually stopped the navigation of the river Anadyr.

In the mean time, captain Pavluzki had arrived, the 3d of September 1730, at Anadyrskoi oftrog. From this place in the ensuing summer he marched upon an expedition against the refractory Thukhkti. Pavluzki opened his campaign the twelfth of March 1731, his force consisting of 215 Ruffians, 160 Koriaks, and 60 Yukagirs. He took the road across the sources of the rivers Ubona, Belg, and Tichern, which fall into the Anadyr, advancing directly north toward the Frozen ocean, and leaving the head of the Anadyr to the left. Of the other rivers which he crossed nothing is known, as there was nobody to inform him of them, or tell their names. After a course of two months, in which they could not proceed above ten versts a day, and that only by reeling at times, Pavluzki came to the Frozen ocean, at a place where a considerable river dehembogues into it, but the name of which he could not learn. He now proceeded fourteen days eastward along the coast, moly over the ice, without observing any mouths of rivers, as they were oftentimes obliged to keep out on the ice at a distance from land.

At length they perceived a great troop of Thukhkti advancing towards them, apparently intending to come to an engagement with them. Pavluzki, by an interpreter, summoned them to surrender to Ruffia: which, on their peremptorily refusing to obey, he immediately attacked them, and had the good fortune to give them a total defeat. This happened on the 7th of June.

After reeling one week, Pavluzki continued his march, and at the latter end of June came to two rivers that discharge themselves into the Frozen ocean, at the distance of a day's journey analyzer. On the bank of the latter of these rivers, on the 30th of June, a second battle was fought, which terminated as happily as the former.

They now lay still for three days, then proceeded to Thukhkti-koi-nofs, resolving to go right across it to the Anadyrkian sea, when a third time they saw advancing towards them a numerous army of Thukhkti, collected together from both coasts. Here on the fourteenth of July was fought the third battle, in which the flauter on the enemy's side, was greater than the advantage on that of the Ruffians; as, notwithstanding their defeat, the Thukhkti would bearken to no terms of submission or tribute. Among the spoil were found many articles that had belonged to the Kozak colonel Sheltakof, and were left in the engagement that happened near the stream Yegartn. That affair therefore was thus amply revenged; especially as in all the three battles, not more than three Ruffians, one Yukagir, and five Koriaks, were left on the field. It was affirmed, that among the killed of the enemy in the last encounter, one was found who had a hole in the upper lip on each side of the mouth, in which pieces of the walrus's tooth were inserted.

Pavluzki now marched triumphantly across Thukhkti-koi-nofs, in which he had to climb over the summits of huge mountains, and at the end of ten days happily reached the other coast. Here he sent off some of his people by water in landarks: but remained himself, with the greater part of his followers on shore, and kept along the coast, which there stretches south-eastward, so that every evening he received reports from the landarks. On the seventh day they came up to the mouth of a river, and twelve days after, to that of another, from which, at the distance of about ten versts, a point of land rising far out into the sea, which at first is mountainous, but terminates in a plain extending as far as the eye can see. This point is probably the fame that obliged captain Bering to put back. One of the mountains is by the inhabitants of Anadyrskoi oftrog called Serdzekamen.

Pavluzki hence turned in land, and returned to Anadyrskoi the twenty-first of October, by the same way that he went out.

Mr. Müller speaks of the ardent zeal which M. Kerilof, at that time secretary of the senate, manifested for the success of these discoveries in 1732.

Having related what information has been obtained from the Ruffians, and particularly from the indefatigable Mr. Müller, we shall now proceed to deliver, as briefly as possible, what we gather from other authors, more ancient.

Pere Ayril was informed by a vaivode, that the people dwelling about the Koryma frequently went to the shores of the Frozen ocean to purifie the mouths, for the sake of their teeth. Mr. Witlen in his celebrated for his persevering diligence, from about 1670 to 1692, in the discovery of these unknown countries, says, that "the great projecting point, which he calls cape Tahan, extends near to America; that about fifty or thereabouts men, coming from the Lena, a little before 1692, put out to sea in the Frozen ocean; and, having turned to the right, came to the point against which the fields of ice driving from the north strike with their whole force, &c. It was therefore not possible for them to double this cape, nor to perceive its extremity from the mountains of the north-east of that point of Asia, which is not extremely wide in that place: they remarked that the sea was free from ice on the other side, that is, the southern; whence it may be inferred that the land of that point extends so far to the north-call, that the floating ice, coming down from the north, cannot pass on the southern side."

M. Buache, from whom this passage is taken (Consider. Geograph. p. 105, 160.) corroborates and illustrates the account thus: "The first pieces of ice (he says) coming from the north, float at the island between the cape and America, and on the shallows which connect it to the two continents; these large flakes, accumulating on one another, form a sort of bridge; and it is only then, that the others which afterwards come down from the north, are unable to pass to the south, &c. On this point (continues M. Witlen) are found men who wear little flanes and pieces of bone pierced in their cheeks, and seem to have a strong affinity with the North Americans."

Kampefer, in 1683, sparing no pains that might any way lead to the knowledge of the northern regions, was informed by several persons, that the Greater Tartary was joined by an illusus, composed of lofty mountains, to a neighbouring continent, which they supposed to be America. He was shown the first maps of the Ruffian empire, laid down some years before, without degrees of longitude. On them appeared several considerable capes on the eastern shores of Siberia; one of them, too large for being comprised within the border of the map, which was cut in wood, was abruptly shortened by it. This is the point spoken of by M. Witlen; but at that time, it is said to have been thought more near to Ruffia than it really is.

Ibrandt Iedes, from informations carefully taken in 1693 and 1694, speaks of Kamthskatka, as of a town, which, with the surrounding country, was inhabited by the Xuuli and Kerilkì (Thukhkti and Koriaks); says, that the cape of ice is a tongue of land projecting into the sea, where it is intersected by several arms of water, which form gulfs and ilises above Kamthskatka; the sea has an entrance frequented by the fishermen; here are the towns Anadyrskoi and Sabatka (on the map, and according to others Sabatia), inhabited by the two nations above-mentioned. The inhabitants of Yakutsk go to eastwards. abatia, Anadyr, Kamthskatka, &c. in quest of the narval.

The Swedish officer, who was a prisoner in Siberia from 1709.
I and am certain hour, and a variety minutes, him order the I should multitude and gitude, and inflan lying to the north-east of Svetoi nos, and that this ice is the north-west of America. Strahlenberg mentions nothing farther in his work than the facts already related, excepting that the Yukagirs are a people settled near the Frozen ocean, between the mouth of the Lena and Cape Tabin. It has been found, that in the part of the continent of America of which some knowledge has been obtained, opposite the cape, there is a large river, wasting down its current number of great trees, &c.

From all these, and various other documents and data, M. Engel endeavours to establish some important facts; such as, that the position of this pretended cape Tabin owes its origin to the desire of fixing that of Pliny spoken of above; and this motive having fulfilled till within a few years past, or at least the idea of a finis terre towards the north-east, it has been preferred, and some cape or other was to be found for that purpose. That the largest of all, that which extends farthest into the sea; and the most formidable, according to all accounts, is the double cape, called Seduzekamen, or heart of stone, north of the Anadyr, which may in some years, at least, without difficulty be doubled; since it is not owing to its proximity to the pole, but to the occasional conjunction of vast bodies of ice, that renders it at such times impracticable.

M. Gmelin says: "There are even traces of a man, who in a small boat, not much bigger than a fisherman's canoe, doubled the Shalaginskoye cape, and made the voyage from the Kovyma to Kamchatka." It may be added, adds M. Engel, whether I am so credulous as to believe it: No: if I should grant what he means by that cape, since this man must have failed, according to the arbitrary distances laid down in the charts, five or six hundred leagues. But if according to my fyltem, we banish cape Tabin into its proper nonentity, diminish the extent of the coasts, approximate the rivers, especially the Kovyma (for the supposed declination of the coast, and the greater proximity of the Indigirka and the Kovyma, are confirmed by various arguments); by doubling the Serdzekamen, as the scele and real cape Shalaginski, them would be by no means impossible, in one of those years, when, as M. Müller allows, there are no mafles of ice in its environs.

The authorities wherein M. Müller and the Russian geographers fix the longitude of the eastern extremity of Asia beyond the two hundredth degree from the first meridian of Ferro, or 150° 15' from Paris, are derived from the observations of Jupiter's satellites, taken by Krallinikof, at Kamchatka and in several parts of Siberia; as also from the expeditions, both by land and sea, of the Russians towards Thuktokoi-nos.

M. Engel disputes the accuracy of these observations, and deducts no less than twenty-nine degrees from the longitude of Kamchatka as fixed by the Russians. M. de Vaugondy, however, fees no sufficient reasons for so extraordinary a sublation; and contents himseif with curtailing the continent of Asia of no more than eleven degrees of longitude. M. Busche differs from the opinions both of Engel and Vaugondy; defending the fyltem of the Russian geographers on the authority of tables drawn up by M. Maraldi.

It is certain that Krallinikof compared his statements with correspondent observations made at Petersburg, and the results were; on comparing an observation of an eclipse of the first satellite of Jupiter, taken at Okhotsk, Jan. 17, 1743, with an observation of an eclipse of the same satellite taken at Petersburg, Jan. 15, of the same year, the difference of longitude between Petersburg and Okhotsk appeared to be 7 hours, 31 minutes, 39 seconds; from a comparison of two subsequent similar observations, the difference of longitude was found to be 7 hours, 31 minutes, 33 seconds; the proportional mean whereof, rejecting the half second, is 7 hours, 31 minutes, 31 seconds, the true difference between the meridians of Petersburg and Okhotsk according to these observations. Adding the longitudinal difference between Petersburg and Paris, which is 1 hour, 52 minutes, 25 seconds, we get the longitude of Okhotsk from Paris, 7 hours, 25 minutes, 56 seconds, differing only 26 seconds from the result of M. Maraldi. (See Nov. Comm. Petropol. tom. iii. p. 470.) So likewise the longitude of Bolheretik, from correspondent observations taken there, and at St. Petersburg, appears to be 10 hours, 20 minutes, 22 seconds, differing from Maraldi about 2 minutes, 5 seconds. (Id. ib. p. 469.)

But the longitude of the haven of Peterpavlovsky, calculated in like manner to the correspondent observations, disagrees with the longitude as computed by Maraldi no more than 20 seconds. (Ibid.) Besides, the results deduced from correspondent observations of the eclipses of Jupiter's satellites taken at Bolheretik, and at the haven of Peter and Paul, by Krallinikof, and at Pekin by the Jesuit missionaries, evince by their near agreement the care and attention with which the observations must have been conducted; whence there is great reason to suppose, that the spurious of inaccuracy imputed to Krallinikof are with the sacrifice of a jull foundation. (Oberv. Alfron. eccl. Sat. Jovis, &c. Nov. Comm. Petropol. tom. iii. p. 452, & seq. Oberv. Alfron. Pekini facie. Ant. Hallerlinc. Curante Max. Hell. Vindibone, 1768.)

For supporting, however, in some fort, these spurious, M. Vaugondy pretends, that the time-pieces and other instruments ulyed by Krallinikof at Kamchatka, were greatly damaged by the length of the journey; and that the person who was sent to repair them was not expert in his business. But this opinion seems to have been too hastily adopted; for, though Krallinikof does indeed allow that his time-piece sometimes flopt, and that too when he wanted to ascertain the true time of the observation; and farther admits, that consequently the observations taken by him under these disadvantages, when he was unable to correct them by former or subsequent observations of the sun or stars, are not to be relied on, and which he has therefore disfigured by an alteration; there are nevertheless many others not liable to any objections of this nature; and the observations alluded to above fall under this description. (See Nov. Comment. Petrop. tom. iii. p. 444.) However, the testimony of the late professor Mühlauer, who was in these parts with Krallinikof, as to the sufficiency of the instruments entirely removes that objection.

The best way of trying the accuracy of the Russian geographers in settling the longitude of Kamchatka, will be by comparing it with that of Yakutsk, which has been clearly established by a variety of observations taken at different times and by different persons. If therefore any error be in placing Kamchatka so far to the east, it is in the longitude between Yakutsk and Bolheretik.

Now, Krallinikof, on his return from Kamchatka, observed at Yakutsk several eclipses of Jupiter's satellites, from which it appears, on comparing them with calculations of the same eclipses made by M. Wargentin for the meridian of Paris, that the mean of the result is 8 hours, 29 minutes, 5 seconds. The observations of M. Ilenieff, taken at Yakutsk
kutk in 1769, whither he had been sent to observe the
transit of Venus, received the sanction of the imperial
xiv. pars iii. p. 268—321.) The longitude given by him to
Yakutsk is 8 hours, 29 minutes, 34 seconds, a sufficiently
accurate agreement with the longitude resulting from the
observations of Krafilinof.

The longitude therefore of Yakutsk from Paris being 8
hours, 29 minutes, 5 seconds, or 122° 16' 55"; and of Bol-
sheretsk 10 hours, 17 minutes, 17 seconds, or 155° 19' 15";
the longitudinal difference of these two places, from astro-
nomical observations, is 1 hour, 28 minutes, 8 seconds, or
27° 3' 0".
The latitude of Bolsheretsk is 52° 55' 3", and that of Yakutsk 62° 1° 55' 0"; then the difference of their
longitude being from the foregoing statement 27° 3' 0", the
direct distance between the places measured on a great circle
of the earth will appear by trigonometry to be 10° 57', or
about 1773 versts, reckoning 104\frac{2}{3} versts to a degree. This
distance consists partly of sea and partly of land; and a
constant intercourse is kept up between the two places, by
means of Okhtutk, which stands in the intermediate space.
The distance by sea from Bolsheretsk to Okhtutk is estimated
by nautical reckonings to be 1254 versts, and the distance
by land from Okhtutk to Yakutsk is 927, making together
2181 versts. The direct distance deduced by trigonometry,
supposing the difference of longitude between Bolsheretsk
and Yakutsk to be 27° 3', is 1773, falling short of 2181 by
408; a difference naturally to be expected, on considering
that neither journeys by land, nor voyages by sea, are ever
performed precisely on a great circle of the globe, which is
the shortest line between any two places.

Such being the agreement between the distance thus
estimated, and that deduced by calculation, admitting the
difference of longitude between Yakutsk and Bolsheretsk
to be 27° 3', it seems highly improbable that there should be
an error of many degrees in the astronomical determi-
nation.

Since then the longitude between Ferro and St. Peterburg
is confessedly 48° 3'; that between St. Peterburg and Ya-
kutsk 65° 21'; and, as the difference in longitude between
Yakutsk and Bolsheretsk cannot be materially less than 27°
3'; it follows, that the longitude of Bolsheretsk from Ferro
cannot be much short of 174° 24'. How then are we to
find room for so considerable an error as 29 degrees, which,
according to M. Engel, or even of 11', which, according to
M. Vaugondy, is chargeable on the Russian geographers in
determining the longitude of Kamthakia?

From the isle of Ferro the longitude of
Yakutsk is - - 14° 0' 0"
Okhotk - - 160 7 0
Bolsheretsk - - 174 13 0
Peter and Paul - - 176 10 0

As no astronomical observations have been made farther
to the east than the haven of Peter and Paul, it is impossible
to ascertain with precision the longitude of the north-eastern
promontory of Asia. It is nevertheless apparent, from
Beering's and Syned's earlier voyages towards Thukotko-
nofs, as well as from other expeditions to those parts by
land and sea, that the coast of Asia, in lat. 64°, stretches at
least 23° 2' 36" from port Peter and Paul, or to about 200°
longitude from the isle of Ferro. But the accuracy of
Krafilinof's observations at the harbour of Peter and Paul
has since been confirmed by captain Cook, who places that
harbour in lat. 53° 1' 7" long. 158° 36' from Greenwich;
Krafilinof stating it to lie in lat. 53° 38' 4", long. 176°
10' from Ferro, or 158° 35' from Greenwich. The differ-
ence therefore is only twenty-two seconds in the latitude,
It has been objected to Defnse's narrative, that Cook and Clerke were in two successive years prevented by the ice from pursuing forward into the Frozen ocean; but in reply to this it should be observed, that Defnse failed in a small vessel, more easily worked than the English ships; and that the year in which he paifed round is represented as more than usually free from ice. The feafon in which Defnse doubled the great Siberian promontory, probably was more favourable to navigation in the Frozen sea, than the time of year adopted by the English. For, though he failed on the frift of July, or June 20, O.S. yet he appears to have arrived in the southern foon till towards the end of September. Shortly after Ankudinoff's ship-wreck on Thukotkoi nefs, Defnse mentions that he landed on the frift of October, or September 20, O.S., and skirmifhed with the Thukotki. Consequently, from the length of the interval between the day of his departure from the mouth of the Kovyma to his entrance on the Eastern ocean, it may reasonably be inferred that he was waiting for an opportunity of getting through the ice, which he at length effected. Whereas Cook quitted that dreary region on the 29th of August; and Clerke fo early as the month of July. The middle and the latter end of September are generally esteemed the most proper periods for navigating the Frozen ocean.

The fole aim of Defnse being to fail from the Kovyma to the Anadyr, it was not incompatible with his plan to continue on the coast, and to persevere in expecting a favourable occasion for efectuating his purpose, without expofing himfelf to thofe difficulties and dangers which feem from more diftant quarters mult necifarily experience. Whereas the grand deign of the English navigators being to feconf the practicability of a north-eaem paffage, and having incoHerently determined that important question in the negative, they accomplished the primary object of their expedition. They could not therefore, confidently with their views and inftructions, by delaylng their departure from thofe frozen regions, expose themfelves to the hazard of being hemmed in by the ice, merely for the fake of evincing the possibility of getting round to the Kovyma.

These circumftances feem to prove that Defnse actually performed this voyage; yet as he neither made any aeronautical observations, nor traced a chart of the coast, his expedition, though it decided the long controversy concerning the separation of the two continents, contributed, however, nothing towards an accurate knowledge of the north-eaem extremity of Asia, for which we are indebted to capt. Cook alone. (See Coxe's Russian Discoveries.)

In the year 1785, capt. Billings, an Englishman in the Russian fervice, was fent by Catharine II. on a voyage of discovery into these parts; and the results of his obfervations are found to agree with thofe of captain Cook, placing the caflern extremity of Asia in lat. 66° 6'. and elferting its longitude at 109° 22' from Greenwich.

The population of Asia, says Mr. Pinkerton, is by all authors allowed to be wholly primitive and original; if we except that of the Thukthki, who by the Russian travellers and Mr. Tooke are fuppofed to have paifed from the oppofite coast of America. A few colonies have migrated from Russia to the northern parts, as far as the sea of Kamfahtka; and well-known European fettlements are in Hicoflan and the illes to the fouth-call; but the firt ferior attempts to fettle in the interior of the country, the recent fettlement at Port Jackson. With thefe and other trifling exceptions, Asia prefents a prodigious original population, as may be judged from the following table, which will be found more cleaf than any prolix difquisition on the subjeft.

**Linnian Table of the Nations and Languages in Asia.**

Of the three several appellatives, the frift denotesordo, the fecd genus, the third species.

1. Allyrians.—Allyrians, Arabians, Egyptians.—Chaldce, Hebrew, &c.
2. Scythians.—Persians, Scythians intra and extra Imaum, &c. Armenians.—(The Parth and Zend are cognate with the Gothic, Greek, Latin, according to Sir William Jones. Indian Diflert. vol. i. p. 266. The Pehlavi is Allyrian or Chaldce.)
3. Sarmats.—Medes and Parthians.—Georgians and Circsaffians.
4. Seres and Indi.—Hindoos, northern and southern, &c.
5. Sino.—Chinese and Japanese.—These have a Tartar form and face; they are probably highly-civilized Tatars, Mongoles or Mandshurs.
6. Samoyedes, Oltiaks, Yurals, &c.
7. Yakutes.—Yukagirs. (Expelled Tatars, according to Tooke and Leflps.)
8. Koriaks.—Thukthki. (From the oppofite coast of America. Tooke's Ruffia. The Yukagirs are a tribe of the Yakutes, around Yukutki, and both are expelled Tatars. Tooke's View, ii. 80. Leflps, ii. 312.)
9. Kamthadales.—Kurillans. (These resemble the Japanif.)
10. Mandshures or Tungufes.—Lamutes. (Ruling people in China.)
11. Mongoles.—Kalmucks.—Soongares, Tungufes, Burats, &c.
12. Tatars or Huns.—Turks, Khasares, Uzes, and Siberians.—Nogays, Bukhirs, Kirghifcizaki, or Kirghifs, Kaiizaks, Tchelwets.

After the deftrution of Attila's swarms, and the effcers of unfortunate inroads, the Huns became fubject to the Mongoles, who under Zingis or Chingis Khan, Timur, &c. combined the fupreme nation in Asia. The great fshare of population which Europe has received from Asia will appear from the following brief statement.

**Primitive Inhabitants.**

1. Celts.—Irifh, Welch, Armoricans.—Erfe, Manks, Cornith.
2. Fins (chief god Tummta).—Finlanders, Edihonians, Laplanders, Hungarians, Permians or Birmians, Livonians, Votians and Cheremifles, Vogues and Oltiaks.
3. Scythians or Goths (Odins).—Icelanders, Norwevians, Sweden, Danes, Germans, Englifh.—Swifs, Frifins, Flemith, Dutch.
4. Sarmats or Slavons (Perune).—Poles, Ruffians, Kajizaks.—Huri, Vendi, Lettes.

The inhabitants of France, Italy, and Spain, are also of Aftatic origin; and speak corrupted Roman, which, like the Greek, is a polifhed dialect of the Gothic, according to Sir William Jones, and other able antiquaries. The Huri, Vendi, and Lettes, used mixed and imperfect dialects of the Scalian.

Besides these numerous original nations, the Malays and Aftatie infidlers constitute another large and diftinct class of mankind, with a peculiar speech, in the fouth of the extensive continent of Asia.
It appears that not above one quarter of Asia was known to the ancients; and this knowledge was little increased till Marco Polo, whose travels became well known in Europe in the fourteenth century, established a memorable epoch in geography, by calling to China, and delineating the extent of that country, the islands of Japan, and a faint intelligence of other regions, illustrated and confirmed by recent accounts. The wide conquests of the famous Thanghish-khan, commonly called Zingis, in the beginning of the thirteenth century, first opened the discovery of the distant parts of Asia; the Mongols, whose sovereignty he was, being situated to the east of the Hans, who had before diffused terror over Europe. The primitive seat of the Mongols was in the mountains which give source to the river Oxus; and at a short distance to the south-west was Kara-kum, the first capital of the Mongol empire. The victories of Zingis extended from Cathay, or the northern part of China, to the river Indus; and his successors protected them over Russia, while they made inroads as far as Hungary and Germany.

The power of the Mongols, thus widely diffused, naturally excited an attention, never stimulated by a number of petty barbaric tribes; and at the same time facilitated the progress of the traveller, who, as in Africa at present, had been formerly impeded by the enmities of diminutive potentates. By force of arms the Mongols also first opened the oblique recesses of Siberia. Sheibani khan, in the year 1242, led a horde of fifteen thousand families into those northern regions; and his descendants reigned in the Tobolkoy above three centuries, till the Russian conquest. (Gibbon, xi. 474.)

Two European travellers, Carpani and Rubraquis, being commissioned to inspect the power and resources of the new empire of the Mongols, the latter found at Kara-kum a Parthian goldsmith employed in the service of the khan; and by Carpin's relation it appears, that from their brethren in Siberia, the Mongoles had received some intelligence concerning the Samoyedes.

Thus the discovery of Asia, which had lain nearly dormant since the time of Ptolemy, began to revive in the thirteenth century. Yet after the publication of Marco Polo's travels, little was done for two centuries; and the authenticity of his accounts even began to be questioned. From the map of the world by Andrea Bianco, the Venetian, 1440, it sufficiently appears that the discoveries of Polo had, even in his native country, been rather diminished than increased. (See Formacleoni, Itagin fulla nautica antica de Vencziani, Ven. 1753; 8vo.) See also the description of Asia by pope Pius II. who appears not even to have seen the travels of Polo. One man indeed of great mental powers, was impressed with their veracity, and in consequence accomplished a memorable enterprise. This was Chrifloval Colon, or as we call him, Christopher Columbus; who, led by the relation of Polo, conceived, that as Asia extended so far to the east, its shores might be reached by a short navigation from the western extremity of Europe. In this erroneous idea, when that great man discovered the islands now called the West Indies, he thought that he had arrived at the Zipango of Polo, or Japan; and thus the name of India was at first bellowed upon those new regions.

After the discovery of America and the cape of Good Hope, the maritime parts and islands of Asia were successively disclosed. Yet the recent voyages of the Russian navigators, of our immortal Cook, and of the unfortunate La Péronne, evince that much remained to be done. Concerning the interior of Siberia, scarcely any solid information was had till Peter the Great, after the battle of Pul- tava, sent many Swedish prisoners into that region; and Strahlenberg, one of the officers, published an account of Siberia; which though extremely inaccurate and defective, opened the way to further intelligence. The knowledge thus obtained was greatly improved and augmented by the well-known journeys of Pallada and the other academicians. Our acquaintance with Asia is still however far from being perfect, especially as regards to Daoria and other regions near the confines of the Russian and Chinese empires; not to mention central Asia in general, Thibet and some more southern tracts; nor had even the geography of Hindostan been treated with tolerable accuracy, till major Rennell published his excellent map and memoir.

The religions of Asia are various; and the climate admits of every variety, from the equator to the Arctic sea.

Though Asia cannot vie with Europe in the advantages of inland seas, yet, in addition to a share of the Mediterranean, it possesses the Red sea (the Arabian sea), and the gulf of Persia, the bays of Bengal and Nautkin, with other gulfs, which diversify the coasts much more than those of Africa or America, and have doubtless contributed greatly to the civilization of this celebrated quarter of the globe.

The Red sea, or the Arabian gulf of antiquity, constitutes the grand natural division between Asia and Africa; but its advantages have been chiefly felt by the latter, which is entirely delimitate of other inland seas; Egypt and Abyssinia, two of the most civilized countries in that division, having derived great benefits from that famous gulf, which, from the straits of Babelmandel to Suez, extends about 21° or 1470 British miles; terminating, not in two equal branches, as delineated in old maps, but in an extensive western branch, while the eastern extends little beyond the parallel of mount Sinj. The Perisan gulf is another noted inland sea, about half the length of the former, being the grand receptacle of those celebrated rivers the Euphrates and the Tigre.

The other gulfs do not afford such strong features of what are properly termed inland seas. But the vast extent of Asia contains seas totally detached, and of a different description from any that occur in Europe or other quarters of the world. Such is the Euxine, and likewise the Caspian, which extends about ten degrees, or 700 miles in length, and from 100 to 200 in breadth. Strabo and Pliny idly supposed this sea to be a gulf, extending from the northern ocean; though Herodotus, many centuries before, had delivered fuller notions of it. The Caspian, however, seems, at some remote period, to have spread farther to the north, where the defects are still sandy and saline, and present the same thalls that are found in the Caspian; yet that chain of mountains which branches from the west of the Urals to the north of Orenburg, and reaches to the Volga, must in all ages have retarded the northern bounds of the Caspian. To the east, this remarkable sea, in the opinion of most geographers, extended, in times not very distant, to the Aral. This sea, or lake Aral, a hundred miles to the eastward of the Caspian, is about 200 miles in length, and about 70 miles in breadth; receiving the river anciently called Iaxartes, more recently the Sirr or Shishon, and the river Gihon, the Oxus of antiquity; both streams of considerable course, flowing from the mountains Belar Tag or Imaus. The Aral sea being surrounded with sandy defects, has been little explored; but it is salt like the Caspian, having many small saline lakes in its vicinity.

Another remarkable detached sea is the Baikal in Siberia, or Asiatie Russia, extending from about the fifty-fifth to the sixty-fifth degree of north latitude, being about 350 British miles in length, though its greatest breadth is not above 35. The water is fresh and pellicid, yet of a green or sea tinge, commonly
commonly frozen in the latter end of December, and clear of ice in May.

Puffing by the other Asiatic seas of inferior note, a few observations may be offered on the remarkable Strait that divides Asia from America. This Strait, which, as we have already seen, was discovered by Beering, and afterwards by Cook, is about thirteen leagues or near forty miles in breadth. Beering actually sailed this Strait in 1728, probably in the usual fog of the climate, without discovering land to the east; but our great navigator gave the name of that Danish adventurer to these Straits, when he afterwards explored them with his usual accuracy. On the Asiatic shore is the Eath-cape; and on the American that is called Prince of Wales. The depth of water in the Strait is from twelve to thirty fathoms. To the north of these Straits the Asiatic shore tends rapidly to the west, while the American proceeds nearly in a northern direction, till, at the distance of about four or five degrees, the continents are joined by solid and impenetrable banks of ice.

In the Asiatic seas are numerous shoals or sand-banks; but few of them have been described as conducive to human industry.

The chief rivers of Asia are the Kianaku and Hoang Ho, the Lena, the Yenisey, and the Obby, dreams which rival in the length of their course any others on the globe. Next in consequence are the Amour, and the Makong of Laos, if the course be rightly delineated, the Samoan or Buriram-pooter, and the Ganges; compared with all which the Euphrates and Indus are but moderate streams.

The Asiatic mountains are reputed not to equal the European in height. The Uralian chain forms one of the boundaries of Europe; and the Alatan ridge may be classed among the most extensive of the globe, reaching from about the seventieth to the hundred and fortieth degree of longitude east from London, or about 5000 miles, thus rivalling in length the Andes of South America. But, as chains of mountains rarely receive uniform appellations, except from nations highly civilized, the Uralian chain, beyond the sources of the Yenisey, is called the mountains of Sayanik, and from the south of the sea Baikal, the Yablomoy mountains, branches whereof extend even to the country of the Thukthi, or extreme boundaries of Asia. The chain of Alak may perhaps be regarded as a part of the Alatan, branching to the south; while the Taurus, now known by various names in different countries, was by the ancients considered as a range of great length, reaching from cape Keldoni, on the west of the gulf of Satalia, through Armenia, even to India: this last chain, however, has not impressed modern travellers with the same idea of its extent. To the south of the Alatan range extends the elevated desert Goby or Sham, running in a parallel direction from east to west; and the high region of Thibet may be included in this central prominence of Asia. Other considerable ranges of mountains are: Bokh, Kiang-yew, Behar, those of Thibet, the eastern and western Gaus of Hindoostan, and the Caucaean chain between the Euxine and the Caspian.

The Asiatic governments are almost universally despotic; and the very idea of a commonwealth seems utterly unknown to that quarter of the world. The mildst systems are perhaps those found in Arabia. (See Pinkerton's Modern Geography, vol. ii.)

Asia, Proper, in Ancient Geography. Much perplexity has arisen among authors by the diverse acceptations of the term Asia; so as to render it extremely difficult for their readers to know what region was distinctly understood by that appellation; nor is it easy to reconcile the apparent incongruity between the scarred and profane writers as to the provinces comprised under this denomination. The ancient geographers divided the vast continent that was known to the Greeks and Romans under the word Asia, first into the Greek named, and named Asia. The latter, commonly termed Asia Minor, comprised a great number of provinces; but that which included Phrygia, Myph, Caria, and Lydia, was denominated Asia Proper, or Asia properly so called. Cicero (Orat. pro Flacco), enumerating the regions contained in Asia Proper, makes no mention of Eolica or Iolia, though undoubtedly a district of it, as being comprised partly in Lydia and partly in Myph. Lydia, beside the inland country commonly known by that name, contained also Ionia, lying on the sea side, between the rivers Hermus and Meander; and Eolica, extending from Hermus to the river Caicus (Ptol. lib. v. cap. 2.), or to the promontory Lectum (Strabo, lib. xii. p. 393.), the ancient boundary between Tras and the sea-coast of the greater Myph. Accordingly, Asia Proper comprehended Phrygia, Myph, Lydia, Caria, Eolica, and Ionia. This tract was bounded, according to Ptolemys, on the north by Bithynia and Paus, extending from Galatia to Proponis; on the east by Galatia, Pamphilia, and Lycia; on the south by part of Lyph and the Rhodian sea; on the west by the Hellespont, by the Egean, Scarian, and Myrtoan seas. It lies between the three-fifths and forty-first degree of north latitude, and extends in longitude from 55° to 62°.

As Asia Proper is but a part of Asia Minor, the Lydian Asia is only a part of Asia Proper. Asia, in this acceptation, comprehends Lyph, Eolica, and Ionia; and is that Asia whereof mention is made in the Acts, and the Apocryphal. Aristotle tells us that Smyrna was at first poiseled by the Lydians (Arisot. lib. de poetaica add. Plutarch in lib. de vita & poeti Homeri); and Scylax Coridonensis reckons it among the cities of Lyph, as also Epeus, Sardis, Philadelphia, and Thyatira, are reckoned by Ptolemys among the cities of Lyph, as is Laodicea by Stephanus. (Steph. de Urbir.)

That in ancient times Lyphia was called Maonia, and the Lydians Mazonians, is manifest from Herodotus, Diodorus Siculus, Dionyius Afer, Strabo, Pliny, Stephanus, and others; and that Maonia was called Asia, is no less plain from Callinus, who flourished before Archilochus, from Demetrius Scelpus, contemporary with Crates, and Aristarchus the grammarians, from Eupides, Suidas, the great etymologist, &c.; may, that Lyphia was formerly called Asia is expressly affirmed by the ancient scholiast Apollonius Rhodos. From whence Lyphia borrowed the name of Asia is altogether uncertain; some deriving it from a city of Lyphia, seated on mount Tmolus; others from one Asia, king of Lyphia, who according to the Lydians, communicated his name to the whole continent. But, be that as it may, it is certain that Lyphia has a better claim to the name of Asia than any other part of that continent.

Asia, in Modern Geography, falls into the following divisions: Tartary, China, India, Persia, Turkey in Asia. Tartary is divided into Chinese, Independent, and Russian; Chinese Tartary contains the country of the Mandu, and that of the Manigola Tartars; Independent Tartary contains the dominions of the khan of the Chelots or Kalmucks, Turkicchan, the country of the Ulfe Tartars, the Daghetchup, Circassia, and the tribes inhabiting mount Caucasus; Russian Tartary contains the governments of Altaihans and Kazan, and Siberia. China is divided into the northern provinces of Pecheli or Pekin, Changhi, Xeni, Hwun Canton, from east to west, and the southern provinces of Naskirs, Cheki, Kiang, Fokien, Huqiang, Quantong, Quangfu, Queicheu, Yunnan, Suchuen, from east to west. India is divided
divided into the states of the Great Mogul, comprising the
kingdoms of Delhi, Agra, Guzarate, Bengal; the peninsula
of India beyond the Ganges, comprising the kingdoms of
Vidapoor, Golconda, to the north; Bissagar, Malabar, in the
middle towards the south; the peninsula of India within the
Ganges, comprising the kingdoms of Pegu, Tonkeen, Co-
chin-china; Siam, containing Martaban, Siam, Malacca,
from north to south. Perin is divided into the northern provinces
of Shirvan, Kilan, Khorasan, from west to east; the middle
provinces of Erakatz, Sabulun, Shirvan, from west to
east; the southern provinces of Kirishian, Fars, Kirman,
Makran, from west to east. Turkey in Asia is divided into
Natolia or Assyolia, comprising the provinces of Natolia
Proper, Armenia, from north-west to east; Karmania, Ala-
dolia, from south-west to east. Syria, comprehending the
provinces of Syria Proper, Phcenicia, Palæstina, from north
to south. Arabia, containing the provinces of Berbara or
Arabia Deferta, Baragab or Arabia Petraea, Hezran or
Assyria Felix, comprising Hagar, Theama, Hadratun, Se-
cer, Oman, Bahrains, Yuhanna, from north to south; the
provinces of the Euphrates, viz. Darbek, containing Dar-
bec Proper, Erzerun, Yerrack, from north to south; Turko-
mania, containing Turcomania Proper, the Kirishian, from
west to east; Georgia, containing Mingrelia, Gurgillan, from
west to east. The islands of Japan; Japan, the island of Xicoco
or Tucocin, Bongo, &c., the island of Niphon, &c., from
north-east to south-west. The Philippine islands; Luzon or Lu-
conia, among which is Manila, Tandare, Mindanam, &c.,
from north to south. The Molucca islands; Ternate, the
isle of Gillo, Celebes, isle of Geran, Amboyna, &c., from
north west to east. The Ladrones; Guan, Tinian, Pagon, &c.,
from south to north. The Bonda islands; Borneo, Sumatra,
under the equator, Java, &c., south of the two former. The
Maldive islands, the principal whereof is Male. The
number of these is very considerable, but all of them are small.
The island of Ceylon, in which are seven kingdoms, the most
considerable being that of Candi.

Asia, in Ancient Geography, the name of an island of
Ethiopia. Steph. Byz.—A port of the Jews and Phenici-
ans, on the Red sea. Eufebius.—A lake of Asia, near the
Caifer. Virgil. En. I. v. 800.—A town of Asia Mi-
nor, in Lydia, situate near mount Tmolus. Suidas.—A
hurgh or town of Asia, in Sufiana. Ptolomay.—A moun-
tain of Pelopennecus, in Laocina. Paufanias.

Asia, Proconsular, so called because it was governed by
a proconsul, comprehended, according to Augustus's dis-
tribution of the provinces of the Roman empire, Lydia, Io-
ma, Caria, Myfia, Phrygia, and the proconsular Hellepont.
In the time of Cæsarius the Great, the proconsular Asia
was much abridged, and a distinction was introduced between
this and the Asiatic diocese; the former being governed by
the proconsul of Asia, and the latter by the vicarius or lieu-
tenant of Asia. The proconsular Asia seems, by the de-
scription given of it by Eunapius (in Vit. Maxim.), to have
been much the same with the Lydia Asia, which
comprehended Lydia, Asia, and Ionia, and which is the
Asia mentioned in Asia, ch. xvi., and including the seven
churches of the book of Revelations, ch. ii. and iii.
This Lydia Asia was only a part of Asia Proper, or Asia pro-
per so called, which according to Cicero (in Orat. pro
Flacco) consisted of four regions, viz. Phrygia, Myfia, Ca-
ria, and Lydia. In the reign of Thodocius the elder, who
succeeded Valens, the confular Hellepont was taken from
the vicarius of Asia, and added to the proconsular Asia; but
under Arcadius, the proconsular Asia was abridged of all
the inland part of Lydia. However, the southern part of
Lydia, lying between the Maeander, and Caifer, and the
maritime provinces from Ephesus to Aflus, and the prono-
tary Lectorum, were left to the proconsular Asia.

Asia, in Geography, an island on the coast of Peru, sita-
ute at the distance of seven leagues from Cucotte on the
south-east, and Chiles on the north-west. It is a white
island under the shore, about half a league in circuit. S. lat.
1° 6'.

Asia, in Mythology, was one of the nymphs called
Oceanides; and according to Diodorus, the wife of Jupet-
us. ASIARCHA, in Antiquity, the superintendent of the
p. 161.
The ariarch differed from the Galatarcha, Syriarcha, &c.,
Some will have the ariarch to have been persons of rank,
chosen in the way of honour, to procure the celebration of
the solemn games at their own expense.

As the ariarchs united the magnificence and priesthood,
they were entrusted with the care of the temples and sacred
edifices; and the expense of the office being considerable,
they were selected from persons of great wealth and reputa-
tion. In the election of these officers, assemblies were con-
voked in all the towns of Asia at the commencement of the
Asiatic year, or about the autumnal equinox. From each of
these a deputy was sent to the general assembly of the
nation; and of ten persons who were returned to the pro-
consul, he appointed one to the office of ariarch. The
attributes of the ariarch were a crown of gold, with a toga
ornamented with gold and purple. This officer existed for
some time under the Christian emperors, although they had
abolished the sacred games and temples. To these officers
there is a reference in Acts, xix. 31. And as they were per-
fons of opulence and dignity, they acted with civility and
kindness towards the apostle Paul, in finding a message
from the theatre to apprise him of the temper of the peo-
ple, and to diffuse him from coming thither.

ASIANO, in Geography, a town of Italy, in the princi-
pality of Piedmont and lordship of Vercelli, four miles south
of Vercelli.

ASIANTE, a country of Africa, eastward of the Gold
Coast, situated about N. lat. 5° 35', and the fame longitude
with London.

ASIATIC, in a general sense, denotes any person or
thing that bears relation to Asia.

ASIATIC, in Biography, is a surname given to L. Scipio,
the brother of Scipio Africanus, after his defeat of Antio-
chus king of Syria.

ASIATIC diocese, in Geography, a part of Asia, which
comprehended eight provinces that were governed by the
vicarius, or lieutenant of Asia, viz. Lydia, Caria, Phrygia
Salutaris, Phrygia Pacatiana, Pamphylia, Lyca, Lycaonia,
and Paphisa. Sometimes it is taken in a more strict sense,
as different from the provinces of Asia. And the provinces
under the jurisdiction of the proconsul; and sometimes in a
more extensive sense, as comprehending also the procon-
sular Asia.

ASIATIC Society, in the History of Literary Establisments.
See SOCIETY.

ASIATIC Style, in Rhetoric. See Style.

ASIATICA, in Entomology, a species of Chrysmoelea,
found in Siberia. The form is oval; colour brassy-green,

ASIATICA, an Asiatic species of Blatta, described by
Profeffor Pallis, It. 3. p. 253. It is of a grey colour, and
oblong form; the wings and wing-cases are longer
than the body, and narrow or pointed at the end. Gmel.
&c.

ASIATICA, a species of Sphex, found in the island of
8
Antigua,
ASI

Abtigu. The abdomen is black, with a yellow lunar mark on the first segment. Fabricius.

Asiatica, in Ornithology, a bird of the Mysterea genus, or fabiru. This is of a large size, white colour, with a black head through the eyes; lower part of the back, quill, and tail feathers black. Ind. Or. The bill of this bird is duckly, and the legs pale red. It is a native of the East Indies, and feeds on insects.

Asiatica, a species of Emberiza, found in the East Indies, where it is called Gaur. We know very little of this bird; it is of a small size, being about four inches and a half in length. Bill pale rose colour, head, neck, back, breast, and belly cinereous, palest beneath; wings and tail brown with paler edges; legs pale blue. Lath. In the Ind. Orn. it is descriibed specifically as being of a cinereous colour; wings and tail brown.

Asiatica, a species of Cirtitia, or creeper, that inhabits India. It is about four inches in length, and briefly described in the Linnean system. The body is yellow and have a brown spot on the inner side of the wing, a black bill, and legs of the same colour. Lath. Ind. Orn.

Asiaticus, a new species of Falco, described by Dr. Latham in the Supplement to his Synopsis of Birds. The length is twenty-one inches; and though smaller, it resembles the common buzzard. The bill is blue-black; breast cream colour, dashed down the shafts with dusky black; belly, thighs, and vent white; quills grey, barred with black; on the secondaries a bar of the same. In his Ind. Orn. this bird is thus specifically described: legs half-dowwny and yellow; body brown above, beneath white; breast streaked, tail-feathers silver grey, with five obsolete bands on the exterior ones. Inhabits China, and is called in England the Asiatic falcon.

Asiaticus, a species of Caprimulgus, described by Dr. Latham, Sup. Gen. Syn. under the name of Bombay Goat-flicker. It is pale ash colour clouded with black, and ferruginous breast faciated with ash-colour; a blackish streak on the crown of the head, a pale one on each side of the jaw, and a pale spot on the throat; length eight inches and a half. Inhabits India. In addition to the foregoing specific character, it may be observed that the plumage of this bird is an elegant mixture of ash colour and brown, and that between the legs it is of a pale rusius; quills dusky, barred with rusius; four of the greater quills have a spot of white on the inner web; tail marked in the same manner as the quills, except the two middle ones, which are mottled like the back, and the two outer ones have the ends white for about an inch; the middle toe is greatly pectinated.

Asiaticus, a species of Trogon, in Latham's Ind. Orn. unnoticed by Gmelin. It is green; forehead, crown, and back of the neck red; throat blue, with a red spot; quill and tail feathers black. The length of this bird is nine inches; the red on the forehead is bounded by a white line, and on the crown and neck is bounded below by a white line, and on the sides by a black one; legs green. Inhabits India.

ASIDÆANS. See CHASIDÆANS.

ASIGRAMMA, in Ancient Geography, a town of India, seated on the Ganges. Ptolemy.

VOL. III.

ASI GRUM, in Botany. See HYPERICUM.

Asi, in Ancient Geography, a tribe or horde of Scythian Nomades, who came from the country beyond the Jaxartes, and deprived the Greeks of Bactria. Strabo, i. xi. p. 779.

ASILIFORMIS, in Entomology, a species of Sphinx, the wings of which are deeply scalloped and dentated; anterior ones cinereous, with a dark band and black dot upon it; posterior pair red, with a black margin. Inhabits India. Fabricius.

Asiliformis, a species of Musca (Symphus Fabr.) that inhabits Germany. The thorax is hairy and yellowish; abdomen black; first and second segment whitish. Fabricius, Gmelin, &c.

ASILUS, a genus of deeply-insect of the Linnean system, the character of which is that the mouth is furnished with a horny, projecting, straight, bivalve, sucking trunk that is gibbous at the base; and the antennae filiform. These are the wasp flies of some writers; they prey chiefly on insects, but are very troublesome to cattle.

The species described by Gmelin are numerous: viz. grofus, maurus, algerius, barbarus, concinna, crenatus, ephippium, alyamus, faberi, ha bitans, gibbosus, ater, diadema, cinereus, flavus, violaceus, gilvus, punctatus, marginatus, plumbeus, cayenius, tuctanus, germanicus, rubipes, macros, margellus, annullus, fylalus, cingulatus, nigripennis, forcipatus, tipuloides, cinereus, lineatus, cyanus, oedolanicus, morio, stagnans, conopoides, linearis, uliciformis, villatus, pubescens, frigatus, albifrons, albius, nigerrinus, and pedagogius; which see respectively. Allus has the body entirely brown, and inhabits Africa. Fab. & Gmel. Alus is a native of North America, is cinereus, and has the three last segments of the abdomen white. Linn. Gmel. Allus inhabits Europe; the colour is cinereus, with three black lines on the thorax; legs black; flanks tawseous. Schrank. Seopel describes a variety in which the legs are entirely black.

Asilus, a species of Onisicus, that inhabits the European ocean. The abdomen is covered with two scales; and the tail is semioval. Linn. F. Suec. Fabr. &c. This is pediculus marinus of Rondel.

ASINARA, in Geography, a small island in the Mediterranean near the north-west coast of Sardinia, about ten leagues in circumference, is fertile and populous. The mountains abound with wild boars, deer, buffaloes, and falcons. N. lat. 4° 5'. E. long. 8° 30'.

ASINARIA, in Antiquity, cities of the Syracusans, instituted in commemoration of the victory gained by them over Nicias and Demolhenses, the Athenian generals, near the river Afiniarus, now Falanera, from which they took their name.

ASINARI, in Ecclesiastical History, an appellation given by way of reproach to the Christians, as well as Jews, from a mistaken opinion, among heathens, that they worshipped an as. The appellation was originally given to the Jews, and only became applied to the Christians: the Jews were charged with keeping a golden as's head in the sanctuary of the temple, to which on certain occasions they paid adoration; in memory of a herd of asses, which, in their passing through the wilderness, shewed Moses the way, under a diffusing water of life, to the spring. Tacit. Hist. lib. v.

Some had even the impolicy to represent Christ with an as's ears, and one foot hoofed, holding a book, with the inscription Deus Christianorum saeculis. Cnites de Honell. Discipl. lib. c. g. "See ASINUS."

ASINATA, in Entomology, a species of Phalena M (Geometrica),
I like to travel to Spain, amidst a peculiar geography, not without white men and aboriginal races. According to Pliny and Oppian, among the fancied writings are frequent allusions to them. They uniformly attracted the notice of travellers in Asia and Africa; and professor Pallis in particular has treated on them with his accustomed accuracy. The appearance both of the wild and tame asses in those parts of the world is altogether striking. "It was with difficulty," says Adanson, when speaking of the asses of Senegal, "that I could recognize this animal, to different did it appear from those of Europe; the hair was fine, and of a bright mouse colour; and the black line that crosses the back and shoulders had a good effect. There were the asses brought by the Moors from the interior of the country." From the beard it appears, that in a natural state, the ass has a soft woolly mane; a foreead greatly arched; and ears long, erect, and pointed, in particular in which it differs most obviously from the domesticated kind, which has the ears flouiching, and the forhead flat. The former stands also higher on its limbs, and the legs are more slender in proportion.

The colour of the hair is white or silvery grey; the upper part of the face, the sides of the neck, and body, inclining to a straw colour; and the hind part of the thighs the same; the forepart divided from the flank by a white line, which extends quite round from the rump to the tail; the belly and legs are also white along the very top of the back. From the mane quite to the tail, runs a stripe of bafy waved hairs of a coffee-colour, broadest about the hind part, and growing narrower towards the tail; another of the same colour crosses it at the shoulders, and forming a similar mark to that by which the tame ass is distinguished. This is peculiar to the male, and is bounded on each side by a line of white. Its winter coat is very fine, soft, and silky, much undulated, and not unlike that of the camel; glossy to the touch, and the flaxen colour more vivid than in the summer. In its summer coat there are certain shaded rays that mark the sides of the neck, pointing downwards. These animals inhabit the dry and mountainous parts of the deserts of Great Tartary, but not higher than lat. 48°. They are migratory, and arrive in vast troops to feed during the summer, in the tracts to the east and north of lake Aral. About autumn they collect in herds of hundreds, and even thousands, and direct their course towards the north of India to enjoy a warm retreat during winter. But they more usually retire to Persia, where they are found in the mountains of Caucasus, and where part of them remain during the whole year. According to Barbagli, they penetrate even into the southern parts of India to the mountains of Malabar and Ceylon. The Kirghizas and Arabs hunt them, or take them in flocks for the sake of their flesh. At first when the animal is killed, the meat is hot and unpalatable; but if kept two days after it is boiled, it becomes excellent. The flesh of wild asses is it well known, was esteemed an article of food among the ancient Romans.

The wild ass feeds chiefly on the soft sylva or bitter plants of the desert, as the kali, atrepex, chenopodium, &c., and also prefers the salted and most brackish water to that which is fresh. Of this the hunters are aware, and usually station...
fation themselves near the ponds to which they retort to drink. Their manners greatly resemble those of the wild horse. They assemble in troops under the conduct of a leader, or centinel; and are extremely shy and vigilant. They will however stop in the midst of their course, and even suffer the approach of man at that instant, and then dart off with the utmost rapidity. They have been at all times celebrated for their swiftness. Their voice resembles that of the common as, but is shriller.

The Periakis catch these animals alive for the sake of domesticating them, or improving the breed of tame as: they think, for this purpose, pits of a convenient size and depth, which they half fill with plants, both as a temptation to the creature, and to break its fall. The breed of as in such high esteem in the eait, is produced by crossing the tame kind with the as reclaimed from a state of wildness. These animals were anciently found in the Holy Land, Syria, Arabia, and Lycia; but they rarely occur in those parts at this time; and seem to be almost entirely confined to Tartary, some parts of India, and Africa.

It is said that neither as nor horses were found in America, although the climate of South America is perfectly adapted for them. Those which the Spaniards transported from Europe, and left in various parts of the New Continent have greatly multiplied, and are found in troops in a state of nature at this period.

The excellencies and defects of the common or domestic as have amply engaged the lively pens of several defective writers on the history of animals; and of none with more happy effect than those of the eloquent Buffon, and the ingenious abbé la Pluche: of the latter we shall speak hereafter; the former after entering minutely into a comparison between the horse and the as, and endeavouring to prove that the two species are distinct (a fact which cannot well be doubted), concludes in a style of language so beautiful, so animated, and so calculated to enforce the tenor of his preceding arguments, that we cannot refrain inferring some few extracts from it.

"The as is then an as," says Buffon, "and not a horse degenerated, a horse ith a naked tail. The as is neither a stranger, an intruder, nor a ballad; he has, like other animals, his family, his species, and his rank; his blood is pure and untainted, and although his race is less noble, yet it is equally good, equally ancient, with that of the horse. Why then is there so much contempt for an animal so good, so patient, so quiet, and so useful? Do men despise, even among animals, those which serve them best, and at the smallest expense? We educate the horse, take care of, instruct, and exercise him, whilst the as is abandoned to the power of the lowest servant, or the tricks of children; so that instead of improving, it must lose by his education, and if he had not a fund of good qualities, he would certainly lose them by the manner in which he is treated. He is the sport of the ruffians, who best his him with flaves, abuse him, overload him, and work him beyond his strength. We do not consider that the as would be in himself, and, with respect to us, the most beautiful, best formed, and most distinguished of animals, if there were no horses in the world; he, however, holds the second, instead of the first rank, and it is from that only that he appears to be of so much value. It is comparison alone degrades him; we look at, and give our opinions, not of himself, but comparatively with the horse.

We forget that he is an as, that he has all the qualities of his nature, and that he is not judged to be fixed, and only think of the figure and qualities of the horse, which are wanting in him, and which he ought not to have.

"He is naturally as humble, patient, and quiet, as the horse is proud, ardent, and impetuous; he suffers with constancy, and perhaps with courage, classification and blows; he is moderate both as to the quantity and quality of his food; he is contented with the hardest and most disagreeable herbs, which the horse, or other animals, will leave with disdain; he is very delicate with respect to his water, for he will drink none but the clearest, and from rivulets which he is acquainted with; he drinks as moderately as he eats, and does not put his nose in the water through fear, as some say, of the shadow of his ears: as care is not taken to comb him, he frequently rolls on the grass, thistles, and in the dust; without regarding his road, he lies down and rolls as often as he can, and seemingly to reproach his master for the little care he takes of him; for he never wallows in the mud or in the water; he even fears to wet his feet, and will turn out of his road to avoid it; his legs are also drier and cleaner than those of the horse; he is susceptible of education, and some have been seen sufficiently disciplined for a public show."

"When young, they are sprightly, hand-some, light, and even graceful; but they soon lose those qualities, either from age or bad treatment, and become slow, stubborn, and headstrong. The as is ardent in nothing but love; or rather when under the influence of that passion, he is so furious that nothing can restrain him: he has been known to exhaust himself by excessive indulgence, and die some moments afterwards. As he loves with a kind of madness, he has also the strong attachment to his progeny. Pliny assures us, that when they separate the mother from her young, he will go through fire to recover it. The as is also strongly attached to his master, notwithstanding he is usually ill-treated; he will feed him at a distance, and distinguish him from all other men. He also knows the places where he has lived, and the ways which he has frequented. His eyes are good, and his smell acute, especially with regard to females; his ears are also excellent, which has contributed to his being numbered among timid animals, which it is pretend have all long ears, and the hearing extremely delicate. When he is overloaded, he shows it by lowering his head, and bending down his ears: when greatly abused, he opens his mouth, and draws back his lips in a most disagreeable manner, which gives him an air of disaffection. If his eyes are covered, he remains motionless; and when he is laid down, and his head so fixed, that one eye rests on the ground, and the other being covered with a piece of wood, he will remain in that situation without endeavouring to get up. He walks, trots, and gallops like the horse, but all his motions are smaller and much slower. He can however run with tolerable swiftness, but he can hold it only for a small space, and whatever pace he utters, if hard pressed, he is soon fatigued."

"The horse neighs, but the as brays; which he does by a long, disagreeable, and discordant cry, by alternative discord of sharps and flats. He seldom cries but when he is pressed by love or appetite. The as has her voice clearer and more shrill."

"I confess" says the abbé la Pluche "that the as is not matter of very shining qualities; but then he enjoys those which are very solid. If we refer to other animals for distinguished services, this at least furnishes us with such as are most necessary. His voice is not altogether melodious, nor his air majestic, nor his manner very lively; but then a fine voice has very little merit with people of folly. With him the want of a noble air hath its compensation in a mild and modest countenance, and instead of the boisterous and irregular qualities of the horse, which
which are frequently more incommodious than agreeable, the behaviour of the afs is entirely simple and unaffected; no supcierious and self-sufficient air. He marches with an uniform pace, and though he is not extraordinarily swift, he pursues his journey for a long time, and without interruption. He finishes his work in silence, serves you with a steady perseverance, and discovers no dettention in his proceedings, which is certainly a considerable accomplishment in a domestic animal. His marts require no preparation, for he is perfectly well contented with the first thistle that presents itself in his way. He does not pretend that any thing is due to him, and never appears froward or dissatisfied: he thankfully accepts whatever is offered him: he hath an elegant relish for the best things, and very civilly contents himself with the most indifferent. If he happens to be forgotten, or is stiffened a little too far from his fodder, he interests his master, in the most pathetic language he can utter, to be so good as to supply his necessaries. It is very well that he should live, and he employs all his rhetoric with that view. When he has finished his exploits, he patiently waits the arrival of a little bran, or a few withered leaves; and the moment he dispatches his meal, he returns to his burthen, and marches on, without a murmur or reply.

His occupations have a tinge of the meanest of those who fit him to work; but the judgments that are formed, both of the afs and his master, are equally partial. The employments of a judge, a man of confluence, and an officer of the revenue, have an important air, and their habit imposes on the spectators; on the contrary, the labour of the peasant has a mean and contemptible appearance, because his dreefs is poor, and his condition despicable. But we really make a false estimate of these particulars. It is the labour of the peasant which is most valuable, and alone remunerative. Of what importance is it to us when a manager of the revenue glitters from head to foot with gold; we have no advantage from his labours. I confess, judges and advocates are, in some measure, necessary; but they are made so by our folly and misuse of them; for they would be no longer wanted, could we conduct ourselves in a rational manner. But, on the other hand, we could on no account, and in no fashion or condition of life, be without the peasant and the artisan. These people may be considered as the souls and nerves of the community, and the support of our life. It is from them we are constantly deriving some accommodations for our wants. Our houses, our habits, our furniture, and our sufficiency, rise out of their labours. Now what would become of your vine-dressers, gardeners, masons, and the generality of country people, that is to say of two thirds of all mankind, if they were destitute of either men or horses to convey the commodities and materials they employ and manufacture? The afs is perpetually at their service: he carries fruit, herbs, coal, wood, bricks, tiles, phaftier, lime, and straw. The most abject offices are his ordinary lot, and it is a singular advantage to this multitude of workmen, as well as ourselves, to find a gentle, strong, and indefatigable animal, who, without either ex pense or pride, replenishes our cities and villages with all sorts of commodities. A short comparison will complete the illustration of his services, and in some measure raife them out of their obscurity. The horse very much refembles those nations who are fond of glass and hurry; who are perpetually finging and dancing, and extremely fublime to fat out their extremities, and mix gaiety in all their actions. They are admirable on some distinguished and decisive occasions; but their fire frequently degenerates into romantic enthusiasm; they fall into wild transport: they exhaust themselves, and lose the most favourable conjunctures for want of management and moderation. The afs, on the contrary, resembles those people who are naturally heavy and pacific, whose underhandings and capacity are limited to husbandry or commerce, and who proceed in the same track without difcomposure, and complete, with a passive air, whatever they have once undertaken.

Of all animals that are covered with hair, it is believed the afs is the least subject to vermin; and the authors of the Encyclopedia Britannica have even ventured to say, that it is never troubled with lice. This opinion is altogether erroneous, and the most unaccountable, since a slight acquaintance with the anatomical writings of Redi, of Linnaeus, Fabricius, and several others, might have convinced them that it is not only infested with lice, but even with a species peculiar to itself, and for that very reason named asini, or hofs of the afs. Pediculus asini, Red. Exp. 21. Pediculus asini, Linn. Pediculus asini, capite porrecto obtusfo abdonce ovato fulco friato, Fabr. &c. The skin of the afs is extremely hard and very chafie, and is used for various purposes: such as to cover drums, make shoes, or parchment. It is of the skin of this animal that the orientals make the fagri, or, as we call it, flagreen.

At two years and a half old, the first middle incisive teeth fall out, and the others on each side foon follow; they are renewed at the same time, and in the same order as those of the horfe. The age of the afs is also known by his teeth in the same manner. From the age of two years and a half the afs is capable of procreating its kind, and the female will earlier. The females are in heat in May and June, which, when pregnant, soon goes off. In the tenth month, milk is found in her dugs, and the derives forth in the twelfth, and very rarely has more than one foal. Seven days after she is capable of again receiving the male. At the end of five or six months the foal may be weaned; and it is even necessary, if the mother be again pregnant. The foal of the afs should be chosen from the largest and strongest of its species; he must at least be three years old, but should not exceed ten; his legs should be long, his body plump, head long and light; eyes brisk, nostrils and cheek large, neck long, loins fleety, ribs broad, stump flat, tail short, hair flying, foot to the touch, and of a deep grey.

The afs, like the horfe, is three or four years in growing, and lives also like him twenty-five or thirty years; it is said the female lives longer than the male; but perhaps this happens from their being more pregnant, and at those times having some care taken of them, instead of which the males are contented worn out with fatigue and blows. They leap less than the horfe, and do not lie down to sleep, except when they are exceedingly tired. The male afs also has much less than the oal; the older he is, the more ardent he appears; and, in general, the health of this animal is much better than that of the horfe; he is less delicate, and not nearly so subject to maladies.

There are among afses, as among horses, different races, though they are much less known, because they have not been taken the same care of, or followed with the same attention. Travellers inform us, that there are two sorts of afses in Persia, one of which, being slow and heavy, are used for burdens; and the other is kept like horses for the saddle. The latter have smooth hair, carry their head well, and are much quicker in their motion; but when they ride on them they fit nearer the buttocks than when on horseback. They are drest like horses, and like them are taught to amble; and they cleave their nostrils to give them more room for breathing. According to Dr. Kussel, there are two forts in Syria, one of which are like ours, and the other
very large, with remarkable long ears; but both kinds are employed for the purpose of carrying burdens.

The wild mule, the equus from the species equus, in Gmelin's arrangement, under the name assigned to it by Pallas; and will be noticed hereafter in the article H诣MUS. The common mule, engendered between the male as and mare, is much cultivated in Spain, and is little inferior in size to its female parent.

The as was one of the unclean animals under the Jewish law, as it did not chew the cud; and it prohibited coupling an as with an ox for draught; Lev. xi. 7. The Jews were accursed by the Pagans of worshipping the head of an as. See ASINAS.

The author of this calumny seems to have been Appion the grammianian; for he affirmed (Josephus, contra Appion l. iii.) that the Jews kept the head of an as in the sanctuary; and that it was discovered there when Antiochus Epiphanes took the temple, and entered into the most holy place. Suidas also says (in Damonico and in fide) that Damocritus, or Democritus, the historian, averred, that the Jews adored the head of an as, made of gold, and sacrificed a man to it every three or every seven years, after having first cut him in pieces. Plutarch (Sympol. l. iv. c. 5.) and Tacitus (Hist. l. V.) seem to have been imposed upon by this slander. They believed that the Hebrews adored an as, from gratitude for the discovery of a fountain by one of these animals, at a time when they were exceedingly fatigued and perished with thirst in the wilderness. The same absurd idolatrous wordship was imputed by the heathens to the Christians. Thus Cæcilius (apud Minut.) says, "Audio Chriosianos turfumime pecudis amini caput consecratur inepta nescio quam perfusione venerant." To the same purpose Tertullian tells us (Apolog. c. 16.), that some enemies to the Christians exposed to public view a picture, representing a person with a book in his hand, drested in a long robe, with an as's ears, and one foot like that of an as, upon which was inscribed, "The God of the Chriosians has an as's head." Learned Christsmen have attempted to investigate the origin of this calumny. The report of the Jews worshipping an as might originally have been derived from Egypt; to this country it is traced by Tanaquil Faber, who delineates it from the temple in Egypt called Onion, derived, as it is supposed, from Oo, an as. To this purpose it may be added, that the Alexandrians hated the Jews, and were much addicted to raillery and defamation. And they might have been informed, that the temple Eionion, at Hebron, was named from Onias, the high-priest of the Jews, who built it in the reign of Ptolemy Philometer and Cleopatra. A. M. 3834, ante Christ. 195. Joseph. l. xiii. c. 6. Bochart is of opinion (De Animal. Sac. l. ii. c. 18.), that the error took its rise from a passage of scripture, "The mouth of the Lord hath spoken it," in the Hebrew טו ב, or י, or י. Hence, as pio, in the Egyptian language, signifies an as, the Alexandrian Egyptians, hearing the Jews often pronouncing the word pio, might believe that they called on their god, and thence infer that they adored an as. Omitting other conjectures, we shall add, that M. Le Moine supposes, that the golden urn containing the manna, which was preferred in the sanctuary, was taken for the head of an as, and that the omer, or aroh, of manna, might have been confounded with the Hebrew banor, which signifies an as. Calmet.

Asinus Pificus, in Ichthyology, a name given by some old writers, to the common haddock. It was also called onos. Willughby, &c.

Asio, in Ornithology, a species of Strix or owl, described by Linnaeus, the body of which is brown above, and white beneath; and the wings marked with five white dots. This is the petit seu de la caroline of Buffon, little owl of Cateby, red owl of Pou. Arch. Zool. and red-eared owl of Latham.

Its native place is North America.

Cateby says it is about the size of a jackdaw. The bill and iris are of a fawn colour; tail brown; edge of the balsard wing whitish; on the quills a few white spots; legs covered to the toes with light brown feathers; toes brown. Buffon seemed to imagine this bird might be only a variety of the long-eared and American owls, both of which he deemed the same species.

Asio, is also a name given by Aldrovandus to the Italian long-eared owl, and synonymous with otus: also five otus. Aldr. Ray applied the same name to the long-eared owl or horn-owl of Willughby and Albin, and Strix otus of Linnaeus.

Asiongaber. See Eizongaber.

Asiofie, in Ancient Geography, a people of Asis, in Scythia, on this side of Imais. Ptolemy.

Asiref, in Geography, a town of Persia, on the south of the Caspian sea, in the province of Taberitain, eleven leagues east of Ferabad.

Asiasarath, in Ancient Geography, a town of Africa, in Mauritania Caesariens, between the rivers Guls and Amphagus. Ptolemy.

Asisia, a town of Liburnia, the Asselis or Afforia of Pley, now in ruins. The traces of ancient magnificence discernible at Podgrize, the seat of Assia, are numerous. Among the Liburnian cities which attended the congress or diet of Scardona, Pley mentions the free Assians, who created their own magistrates, and were governed by their own municipal laws, and who were of course more opulent and powerful than their neighbours. The walls of this city appear to have measured in circumference 3600 Roman feet, and to have been constructed with Dalmatian marble, some pieces of which are of large dimensions, and brought from a considerable distance.

Asilum, or Assisi, now Affi, a town of Italy, in Umbria, was a Roman municipium, and situated to the east of Arna. Pliny mentions the Aflantis. See Assis.

Asitchou Aghassieh, in Ornithology, the name by which some species of geeseak is known in Hudson's Bay; and which Dr. Latham supposes to be the white-winged croft-bill of his General Synopsis.

Asitia, in Medicine, a lots of appetite, from us, privative, and ac, food. A symptom which occurs in numerous difeases.

Asius, in Entomology, a species of Papilio. (Ep. Tro.) that inhabits South America. The wings are tailed, black, with a common white band; base and tip of the posterior pair beneath spotted with red. Fabricius.

Ask, in Geography, a river of Japan.

Asker, in Zoology, a name used in some parts of England for the water-newt or es.

Asker-Mokrem, in Geography, a town of Assia, on the eastern bank of the Tigris, in the Arabic Irae; called also Sermenri.

Askersund, a town of Sweden, in the province of Norcia, on the Wetter sea, five miles from Orbo.

Askeyton, a market, and, till the nation, borough town of the county of Limerick, in Ireland, seated on the small river Decl, near its junction with the Shannon; famous for its castle built by the earl of Desmond, and for one of the most beautiful and perfect abbeys in Ireland. Distance from Dublin 1164 miles. Long. 8° 54' W. Lat. 52° 34' 30" N.
ASKRIG, a town of England, in the north riding of Yorkshire, beautifully situated on the banks of the river Ure, at the upper extremity of Wensleydale. It has a weekly market on Thursday; distant 247 miles north from London.

ASLA, a river of Spain on the northern coast, which falls into a bay in the bay of Biscay, where it forms a good harbour, to the east of Cape Pinos.

ASLANI, in Commerce, a name given to the Dutch dollar, current in most parts of the Levant. The word is also written corrup.tly, oflendi. It is originally Turkish, and signifies a loan, which is the figure flapped on it. The Arabs take the figure of a lion for a dog, called it al拜加/f. The allani is silver, but of a base alloy, and oftentimes counterfeited. It is current for 115 or 120 apers. See Asper.

ASLAPATH, in Geography, a town and district of Aria, in Armenia, near Naickivan, on the banks of the Aras. It is inhabited by Armenians; and the women are said to be so beautiful, that the king of Persia supplies his seraglio from this place.

ASLING, or Jesse, a town of Germany, in Carinola, sixteen miles S. S. W. of Chigengurt. In this town, which is not far from the river Sau, is dug a fine marble; and near it are lead furnaces, and other works, in which considerable quantities of iron and lead are smelted.

ASMER, a small town of Hindostan, in the states of the Mogul, south-west of Agra, and in the extremity of the province of Bandoo, called also Asmer.

ASMEROEA, a mountain of Aria, in the country of the Seres, inhabited by a people called Affurians, who are divided through the province of Cataja, a part of Tartary. — Allo, a town of Aria, in the same country, according to Ptolemy.

ASMODAI, in Mythology, the name given by the Jews to the prince of demons; and, according to R. Ellis, the same with Sammael.

ASMONOAE, in Ancient History, the name given to the Maccabees, the descendants of Matthias, who, according to Josephus, was the grandson of Aemoneus; though others derive the appellation from Mount Aemavor, placed by Josephus in the midst of Galilee, near Sephoris; and others again consider it merely as a title of honour given to Matthias and his descendants, alleging that chas будем фью from Hebrew, princes. However this be, the family of the Aemoneans became very illustrious in the latter period of the Hebrew commonwealth, and possessed the supreme authority and the high-priesthood from the commencement of the government of Judas Maccabenus to Herod the Great, during a period of 129 years, or 126 years according to Josephus, who reckons from the time in which Judas was established in the government by his peace with Antiochus Epiphanes, three years after he first assumed it. It was the practice of the Aemonean princes to impose their religion upon all the countries which they conquered, leaving to the vassals such other choice but either to become Jews, or else to have their dwellings demolished, and to seek new habitations.

ASMURA, or Asmura, in Ancient Geography, a town of Aria, in the interior of Hyrcania. N. lat. 35° 30'.

ASNUM, in Geography. See Essk.

ASNAUS, in Ancient Geography, a mountain of Europe, in Macedonia, between which and Oeropus was a valley, in which flowed the river Oeas.

ASVEN, in Geography, a lake of Sweden, in the province of Smoland, about North lat. 56° 36'. East longitude 14° 48'.

ASNID, a town of Aria, in the kingdom of Candahar, 23 leagues north of Salas.

ASNIFES, a town of France, in the department of the Upper Vienne, and chief place of a canton in the district of Bellac, 10 miles north-west of Bellac.

ASO, a town of Japan, in the province of Smoodfuke.

ASODES, in Medicine, a term applied to fevers accompanied with anxiety and oppression about the stomach and precardia. It is derived from ουρε, which, in its primary sense, means a boiling of food; but which is used by Hippocrates, and other ancient physicians, to denote great unctuities and reflexions, whether with or without mucus. It is sometimes written affodes.

ASOLA, in Geography, a town of Italy, in the territory of Brescia, on the river Chiuse; which was formerly a fortified place, belonging to the republic of Venice.

ASOLO, a town of Italy, in the district of Treviso, situate on a mountain at the source of the river Minova; small, but well-peopled. N. lat. 45° 49'. E. long. 12° 2'.

ASONA, a river of Italy, in the marquisate of Ancona; which rises in the Appennines, on the frontiers of Umbria, and runs into the Adriatic sea, ten miles south-east of Fermo.

ASOPH. See Azor.

ASOPIA, in Ancient Geography, a country of Telephonius, in Sicily. Strabo.

ASOPUS, a town of Laconia, in which was a temple of Minerva Cyparissus, south-east of Cypriffis. At the distance of twelve fadis was a temple of Eleutharios, surmounted by a statue of Poseidon, the friend of the people. The citadel is now standing, and called by the sailors Cafler Rampano.—Allo, a river of Beostra, which had its source in mount Citheron, north-west of Plataea; and passing east by north of this city, discharged itself into that part of the sea which separated the isle of Euboea from the continent over against Ecretia. now called Apos.—Allo, a river of Sicily, which rises in the south-west of Arcadia, near Mount Cyllene, near the city of Icynan, and discharged itself into the gulf of Corinth.—Allo, a river of Greece, in Thesaly, which had two sources in that part of mount Oeta that was contiguous to mount Pinus, and running eastward, emptied itself into the Gulf of the Amaliac gulf, north of Thermopyilla.—Allo, a river of Asia Minor, which watered the town of Indicae upon the Louc, Phys.

ASOTUS, in Ichthyology, a species of Silurus found in Aria. It has a single dorsal fin, and four cirri at the mouth, two on the upper and two on the lower jaw. The teeth of this kind are numerous; the dorsal fin is studded with thorns; the uppermost pectoral fin is serrated; and the anal fin is long, and connected with the tail.

ASOUKAS, in Geography, a town of Persia, in the province of Farshil, twenty-three leagues north of Shiraz.

ASP, or Aspis, in Zoology, a species of Coluber, described by Linnaeus, as having 146 plates on the belly, and 46 scales on the tail. Dr. Shaw has some doubt concerning the Linncean alpis, but concludes it is the serpent described under the name of alpis by the count de Cepede, who informs us that it is a native of France, and particularly of the northern provinces of that country. The length is about three feet; the head rather large, and covered with small carinated scales; the scales of the body smaller, but of a similar structure. In the structure of its fangs it resembles the viper, and is said to be equally poisonous. M. Latreille.
is not willing to allow this to be the real Coluber aspis of Linnaeus.

In addition to the specific character of the coluber aspis (taken from the number of abdominal plates, and scales of the tail), Gmelin observes, that the nose is terminated by an erect watt; the body robust, with figured flakes, which are alternately confluent, and the under side, red-blue dotted with yellow. Dr. Shaw calls his coluber aspis, the refuent viper, with roundish, alternate, dark, dorsal spots, subconfluent towards the tail; and states the number of abdominal scuta to be 155, subcylindrical scales 37.

The true aspis of the ancients seems to be entirely uncertain. It is very frequently mentioned by ancient writers, but in each case a different and minute manner that it is impossible to ascertain the species with precision. With the aspis is said the high-spirited princes Cleopatra effected her death, rather than infamy herself, as a captive to grace the triumphal cory of her conqueror Augustus into Rome. This trait of her own in that distinguished character is contested. The indications of Cleopatra's having occasioned her death by means of an aspis, were only two almost inexpressible punctures observed in her arm; and it is asserted by Plutarch, that it is unknown of what death she died.

Brown places the popular report of her death in this manner among his vulgar errors. Others are of a different opinion. Some have imagined it was the Egyptian viper, described by Haffelquin, which Cleopatra made use of on that occasion. Mr. Bruce is led to conclude, from various circumstances, that it might be the ceraeas, celer ceraeas of Linnaeus.

"I apprehend," says Mr. Bruce, in speaking of the ceraeas, "this to be the aspis which Cleopatra employed to procure her death. Alexandria plentifully supplied by water, null then have had fruits of all kinds in its gardens; the basket of figs must have come from thence, and the aspis or ceraeas that was hid in them, from the adjoining desert, where they are plenty to this day; for to the wellward in Egypt, where the Nile overflows, there is no sort of serpents whatever that ever I saw, nor, as I have before said, is there any other of the mortal kind that I know in those parts of Africa adjoining to Egypt, except the ceraeas. It should seem very natural for any one, who, from motives of delicacy, has resolved to put a period to his existence, especially women and weak persons, unaccustomed to handle arms, to seek the gentlest method to free themselves from the load of life now become insupportable."

"It is not to be doubted," adds Mr. Bruce still farther, "but that a woman, high-spirited like Cleopatra, was also above the momentary differences in feeling; and had the way in which she died not been ordinary and usual, the certainly would not have applied herself to the invention of a new one. We are therefore to look upon her dying by the bite of the ceraeas, as only following the manner of death which she had been accustomed by those who intended to die without torment. Galen, speaking of the aspis in the great city of Alexandria, says, I have seen how speedily thry (the aspis) occasioned death. Whenever a person is condemned to die, whom they wish to end quickly and without torment, they put the viper to his breast, and suffering him there to creep a little, the man is presently killed."

Lord Bacon makes the aspis the least painful of all the infringements of death; he supposes its poison to have an affinity to opium, but to be less disagreeable in its operation; which does not so well agree with the description of the symptoms given by Dioscorides and others. Immediately after the bite, the light becomes dim, a sensible tumour arises, and a moderate pain is felt in the Rach. Mathi-
ner, keel bina, conformable with the wings; Stare, filaments ten, united into a leaflet, gaping longitudinally at the top, ascending, anthers oblong; Plt. germ ovate, style simple, ascending, stigma sharp; Pet. legume ovate, awnless; seed, generally two, kidney-shaped.

Note. This genus is singular in having several leaves from the same bud, in a shrubby plant.

Species, 1. A. spinosa, thorny sphenatherus. Gentitella, &c. BRENN. Cent. t. 25. Thk. Thyt. t. 237. f. 6. "Leaves fascicled, linear, naked, surrounding a Scymnese spine." Flowers laterally; calyx longer than the leaves; legume small, ovate at the base, triangular, upwards drawn to a point, compressed like a lens, containing two seeds, one compressed kidney-shaped, the other globular. 2. A. verrucosa, warted A. "Leaves fascicled, filiform; buds warty, naked, tomentose." A shrub two feet high, with large buds or war; leaves finely, smooth, sharpish, an inch long; flowers lateral, shorter than the leaves; subfelted; calyx pubescent; banner villose. 3. A. calyptrata, headed A. Thk. Phyt. t. 307. f. 6. Scb. Muf. t. 23. f. 6. "Leaves fascicled, linear, sharp, flowers headed, breasts naked." Leaves pubescent; flowers covered with furginous down; segments of the calyx subulate; keel of the flower arched and the length of the banner. 4. A. glomerata, glomerate A. "Leaves fascicled, linear, sharp, villose, tomentous inwards, flowers headed, divisions of the calyx ovate, corollas smooth." This differs from the third, in having its leaves bent inwards, the calyces ovate, and the corollas smooth. 5. A. affrutes, flarry A. Plnt. Muf. 88. t. 413. f. 3. Scb. Muf. t. 24. f. 6. "Leaves fascicled, fabulate, mucronate, smooth, but villose, flowers scattered." This has the appearance of juniper; it branches very much, and the twigs are covered with hoary down, and laden with a profusion of flowers.

6. A. chenopodia, genita africana lutea, &c. HEIN. Afr. 11. Chamaelirix. BRENN. Cent. t. 23. t. 11. Scb. Muf. t. 23. f. 64. "Leaves fascicled, fabulate, mucronate, rough with hairs, flowers headed, very hispicate." A shrub about three feet high, with slender branches terminated by the flowers, which are yellow, collected in woolly heads; the leaves are prickly like those of juniper. Cultivated in 1759, by Miller.

7. A. albesc, white A. "Leaves fascicled, fabulate, fiky, spreading at top, branches of flowers feathered." Shrubby, upright, and covered with brown bark, which is full of chinks; leaves in fives, sharp, spreading at the tip, of a fiky whitens; flowers terminating in bunches, tomentose, small of a fiky white; calyx pubescent. Introduced here in 1774, by Mr. Maffon. It flowers in July. 8. A. thyrsiflora, thyme-leaved A. Gen. minima, &c. PLNT. Muf. 88. t. 413. f. 1. "Leaves fascicled, fabulate, unarmed, smooth, very short; flowers alternate." This is a very small shrub; the leaves are crowded together and shining, resembling thyme of. 9. A. eirens, heath-leaved A. Gen. acth, non spinosa, &c. PLNT. Muf. 88. t. 413. f. 6; "Leaves fascicled, linear, unarmed, hispicate, flowers alternate, calyxes linear." A small shrub very much branched, pubescent, or extremely hispicate; leaves minute; flowers lateral, scarcely longer than the leaves; banner villose. 10. A. nigra, black A. "Leaves fascicled, linear, rather obtuse, flowers headed, pilose, pubescent." A branching shrub, three feet high; buds and twigs pubescent; leaves minute, and become black on drying; flowers terminating, pubescent, bractes in pairs, narrow. 11. A. carnea, flaky A. "Leaves fascicled, almost common obtuse, calyxes subpubescent, hairs, corollas smooth." About the height of the tenth species; branches naked, determinate; leaves subcyllindric, flaky, bent in, smooth, four or seven together; flowers yellow, terminal, unbellled; calyx bell-shaped; bractes three, ovate, lanceolate. 12. A. eilalis, "Leaves fascicled, filiform, februous, flowers terminal sessile, banners pubescent." Stem shrubby, two feet high, branching determinately, somewhat hairy, with naked war; leaves roundish, sharp, erect, rough beneath, and when young, ciliate; flowers three or five, with a yellow corolla, and an ash-coloured banner. 13. A. geoffrayi, broom-like A. "Leaves fascicled, filiform, pollinated, calyxes subfascicled, peduncles, which as well as the corollas are smooth." Shrubby, nine feet high, branching with a reticulate base, and white villose buds; leaves roundish, half an inch long; flowers three or four, terminal, peduncles; calyxes smooth, with short teeth; bracts two, minute; corollas yellow; style protuding. 14. A. hispina, porcupine A. "Leaves fascicled, filiform, rigid, flaky, flaky, flowers lateral, sessile, solitary, corollas villose." This shrub differs much from the other species by its leaves resembling flaky whiskies. 15. A. galiiodes, "Leaves fascicled, linear, pollinated; peduncles two-flowered, elongate, leafy at the end. Stem two feet high, decumbent, branching, smooth; war of the buds small, remote, tomentose; leaves like those of Arapagus acute; teeth of the calyx the length of the corolla, which is smooth, yellow; legume ovate, lanceolate, smooth. 16. A. reticulata, filiform, very small; branches fascicled, very spreading; flowers solitary, terminal. 17. A. uniflorus, one-flowered A. Gen. æthiop. glabra, &c. PLNT. Muf. 88. t. 414. f. 7. "Leaves fascicled, linear, unarmed, smooth; liplices sharp, permanent; flowers solitary, divisions of the calyxes boat-shaped." Branches alternate, crowded, tomentose; flowers one or two, terminal, pubescent, keel of the corolla tomentose. 18. A. arvensis, Gen. &c. PLNT. Muf. 88. t. 414. f. 5. Scb. Thof. t. 38. t. 23. f. 6. "Leaves fascicled, bristle-shaped, unarmed, hispicate, flowers headed." Leaves hairy, beset with tubercles, and rough on both sides; banner hairy outwards. 19. A. ophioglossus, "Leaves fascicled, fettaceous, rather hairy; calyxes kaf-shaped, the length of the corolla, solitary." A shrub much branched, with small pubescent war where the leaves fall off; leaves pointed, thinly scattered with hairs; flowers solitary, fettaceous. 20. A. ceratoc, flaky A. "Leaves fascicled, lanceolate, flaky; peduncles two flowered, terminal, banner armed naked." This resembles the preceding, but the leaves are flat, and none of them in heads; flowers large, fomol. 21. A. canescens, hoary A. "Leaves fascicled, subulate, tomentose, flaky, flowers lateral; banners pubescent." An erect, flaky, hoary shrub, with alternate branches; leaves harsh; flowers fomol, at the sides of the branches; calyx bell-shaped, with pubescent teeth, shorter than the body of it; bractes two, short, fettaceous; corolla yellow; banner hoary. 22. A. heterophylla, various-leaved A. "Leaves of the branches fascicled, of the branchlets ternate, linear, hairy, spikes terminal; calyx and corolla villose." Lower leaves in bunches, upper, ternate; spikes long, flowers yellow. This and all the foregoing species, are natives of the Cape of Good Hope. 23. A. indica, fomol-flowered A. PLNT. Alm. 225. t. 201. fig. 2. (called Lotus, &c.) "Leaves quinate, fettaceous one-flowered." A fender shrub with alternate branches; leaves alternate; leaflets oblong, obtuse, blunted, smooth, broader towards the end; peduncles axillary, much longer than the leaves, but shorter than the legumes; flowers of a pale red colour, and appear in May. A native of the East Indies, and in 1759, cultivated by Miller. 24. A. critters, evergreen A. "Leaves trine, wedge-shaped, smooth, lateral ones shorter; filipes obolate, flowers headed." About four feet high, with very flexible branches; leaves
leaves many, small, narrow, oblong, fleshy, evergreen, reflex at the edge, with a hard point, sometimes curled at the base; peduncles axillary; flowers of a pleasant smell, in two rows, yellow, very small;艰苦, yellow, containing a single round compressed thinning seed. A native of the Cape.

27. A. pilosa, hairy A. "Leaves in threes, linear villose; heads terminal, very hairy; corollas pubefcent." Stems shrubby simple, a little hairy; leaves spreading, fesh, acute, pubefcent; head of flowers protected by bractes and calyces, which have white hairs. A native of the Cape. 28. A. rubrifolius. "Leaves three lanceolate, equal subpubefcent; leaves none, heads terminal." This shrub has a bifurcate ftem; the leaves are fimple, rather fesh, the upper ones somewhat hairy; heads solitary, fesh, oblong; three bractes under each calyx. It has the appearance of a lotus or anthyllus. Cape.

29. A. leucata, leafleaved A. "Leaves tern linear, villose; flowers in branches of five; calyxes feshy; ftems puberulous round." Stem fubherbaceous, decumbent, round, flexible, pubefcent; branches alternate; leaves feshy, on very fhort petioles; flowers terminal, fimple, no bractes; corolla smooth, yellow. Cape. 30. A. argentea, filvery A. Cytfus. &c. Phuk. Mant. 63. t. 345. f. 2. "Leaves fimple linear feshy; simple fimple mucronate; flowers fettered tomentoife; shrubby, four feet high; flowers fometimes in spikes, purplfe, downy. Cultivated by Miller in 1759. A native of the Cape. 31. A. callosa, callous A. Phuk. Mant. 63. t. 345. f. 4. "Leaves fimple fubfulate equal; fimple froundish, callous; flowers fimple, fheep." An underfhrub, having the branches covered with round callus, occasioned by the falling of leaves, which are feshy, with a callous base like thoae of juniper; spikes feshy; bractes one-leaved; flowers yellow, feshy. Cape. 32. A. orientalis, Levant A. "Leaves fleshy, lanceolate, pubefcent; flowers in branches of five; calyces pubefcent; ftems erect, angular." Stems a foot high; leaves feshy, refembling thoae of ox; corolla yellow; the fize of thoae of juncus; lamens conuate. Found in the Levant by Turner. 33. A. mucronata. "Leaves fleshy, polifhed, branches acuminate; flowers in racemes." Stem fheep; branches remote, tapering to a pout; leaves lanceolate, on fhort petioles; racemes terminate, erect, on very fhort pedicles. Cape. 34. A. pinnata, pinnate-leaved A. "Leaves pinnate-quinate obovate; peduncles headed; leaflets five, close, a little hairy, tomentoiffe, underfheath, on fhort petioles; leaves rather tomentoife. It reemblies A. qnultifolia, n. 25. Cape. 35. A. pedunculata, small-leaved A. I.'Herit. Ang. t. 26. "Leaves fheafed, fubfulate, fheep; peduncles fhimifer, twice the length of the leaf." Found at the Cape by Maffon, and introduced into the Kew garden in 1775. It flowers in June. 36. A. candida, fair A. "Leaves fimple and fheafed, fimpie, fheep; flowers fublateral, banner naked." This was also found at the Cape by Maffon and introduced in 1774. 37. A. arborea, tree A. Lour. Cochinch. 431. "Leaves pinnate-quinate; racemes terminating." This is a middle-fized tree with a straight trunk, and weak re clinning branches; leaves feshy, entire, feshy; fowers white, small, banner obcordate, broaden, ascending; wings oblong, equal to the banner; lamens allconcave.

Vol. III.

Propagation and Culture. Few of these shrubs have hitherto been cultivated in Europe. They are to be propagated by seeds which must be obtained from the country where they grow spontaneously, and should be sown in pots filled with light earth as soon as they arrive: if this happens in the autumn, the pots should be plunged into an old tan-bed whole heat is spent, where they may remain till spring, when they should be removed into a temperate hot-bed, which will bring up the plants. But when the seeds arrive in the spring, the pots in which the seeds are sown should be then plunged into a moderate hot-bed; and in warm weather the glasses must be shaded during the hot part of the day, and the plants frequently refreshed with water. Those seeds that are sown in the spring, seldom grow the same year; therefore, in the autumn, the pots should be put into an old tan-bed as above directed, and the following spring put into a hot-bed. When the plants become strong enough to remove, they should each be planted in a separate small pot filled with light earth and plunged into a moderate hot-bed to promote their rooting again, and as soon as they are established in the pots, they should gradually be removed to the open air, into which they are to be transplanted in the summer, and remain in a sheltered situation till autumn, when they must be placed in the green-houfe, allowing them very little water during the winter. See Martyn's Miller's Diet.

Aspalathus. See Robinia and Spartium. Aspalathus Ebena. See Amerinum.

Aspalax, in Zoology, an animal mentioned by Aristotle, as being blind. The Romans and some moderns translating the term aspala, mole, and knowing that this animal is not blind, have thought themselves warranted in denying the assertion of Aristotle. Olivier, however, has not long since brought from the Levant an animal actually blind, with its skin not so much as pierced in the place of the eyes. This animal lives under ground, and has all the characters attributed by Aristotle to the aspalax. It is known to zoologists under the name of mus typhlus, and nemrini.

Aspalax, a species of Mus, called by Pennant and later English naturalists the Daurian rat; Linnæus names it Mus muscula; and Pallas, Schreber, Gmelin, &c. specifically describe it as having a short tail, cuneate or wedged foreteeth, no ears, and claws of the forefeet elongated. It is a native of the Altna mountains, and of the country beyond the lake Baikal; like some other subterranean or ground rats, it burrows with its fiont and fects, raises numerous hillocks of earth in its progress, and feeds on bulbous roots. In respect of size, it varies considerably, being from five to eight inches and a half or more in length.

Dr. Shaw observes that this species in form and manners of life agrees with the mus typhlus, or blind rat; but is in general of a smaller size and of a yellowish fesh colour, and in some specimens a whith fline or longitudinal fline appears on the top of the head; the upper forefeet are naked, but the lower are covered with a movable lip; there is no appearance of external ears, and the eyes are extremely small and deeply fteenth; the head is flat and fheep; the body fhort and somewhat depreffed; the limbs very frong, especially the fore-feet, the fets of which are large, naked, and well adapted for burrowing into the ground, having five toes, the three middle of which are furnished with long and frong fightly curled claws; the hind feets are also naked, and have five toes with small claws; the tail is very fhort. Gen. Zool.

Aspaluka, in Ancient Geography, a valley of the Pyrenees, now the valley of Apsa, in which was the Gabarus, or Gave.
ASPANEUS, a forest of Asia Minor, in the Troas, being a part of the forest of Ida, Strabo.

ASPANG, in Geography, a town of Germany, in the archduchy of Austria, seventeen miles south of Eben-ebich.

ASPARAGI, in Entomology, a species of Curvispina (Linn.), with a red thorax marked with two dots of black; wing-cases yellow, with a cruciform mark, and four spots of black. Geoffroy calls it le criocére porte croix de l'appendice: it is attelabus asparagus of Scopoli; lema asparagus of Fab. Ent. Syll. Supp.; cryptoccephalus asparagus of Gmelin; and achenia asparagus of Marih. Ent. Brit. This милевичуер intruder into the kitchen garden, is but too well known by its depredations in the larva flate upon the beds of asparagus; it is a little grub of a blackish-brown colour, that feeds exclusively on these plants; and if neglected, will in the course of a few days leave nothing but the naked stalks of the asparagus remaining in those beds where they can once take up their residence. Donov. Brit. Inf. &c.

ASPARAGUS, in Botany (ασπαραγος; a young shoot, before its leaves unfold). Lin. g. 424. Schreb. 573. Gært. 16. Juf. 41. Chrys. hexandria monogyna. Nat. Ord. forrängece. Gen. Char. Cal. none. Cor. petals six, cohering by the claws, oblong, erected into a tube, three alternately interior, permanent. Stam. filaments six, filiform, inferted into the petals, erect, shorter than the corolla; anthers roundish. Py. gurn, turbinate, three-cornered; style very short; stigma, a prominent point. Pet. berry globular, umbilicated with a point, three-celled. Seed, two, round, angular on the inside, smooth. Of. According to Dr. Smith, there are three filiguma; the flower appears as if it were monopetalous. Eff. Gen. Char. Cor. six-parted, erect, equal. Cal. none; style very short; stigma three; berry superior, three-celled; seeds two, externally convex. Smith.

Species. 1. A. officinalis, common asparagus or sperage, Hudf. 145. With. 340. Smith Brit. 369. Eng. Bot. 339. Flor. Dan. 805. " Stem herbaceous, round, erect, leaves falcatus; flupules uniform, subfoliary." It grows wild in maritime places in the south of England, abundantly on the pebbly beach opposite the ferry going from Weymouth to Portland island. A variety 2. viz. A. maritimus crassifoio, (Dill in Ray's Synop.) has been found in Anglesea. Root perennial, creeping, with very long, thick, simple fibres; stem erect, occasionally procumbent, round, firm, and bearing alternate leaves (or flupules without leaves blow) in the upper part, branching in a paniled alternate manner: leaves in tufts, very narrow, and briskly, but flexible; flupules solitary, membraneous, triangular, acute, the upper ones ovate and jagged; flowers from the axilile of the branches on capillary simple flilaks, drooping, white, none of the segments inflexed, in some the flumen, in others the ptilium occasionally abortive; style deeply three-cleft; berry red. It flowers in August. The above is a description of the plant in its wild state in which its flumes are usually about the size of a goose's quill, yet this is now well known to be the origin of our luxuriant garden asparagus, for the cultivation of which ample instructions are subjoined.

2. A. declinatus, long-leaved A. " Stem unarmed, round; branches declined; leaves falcatus." This resembles the common asparagi, but it is higher, has more and much longer leaves; flupules solitary, lanceolate-subulate, with a membraneous point at the base downwards; leaves seven or ten in a bunch, filiform, spreading. A native of the Cape. Introduced in 1787, by Mr. Maffin. 3. A. falcatus, fiddle-leaved A. Burm. Flor. Zeyl. 36. t. 13. f. 2. "Prickles solitary, recurved; branches round; leaves en-

form, falcated." A native of Ceylon. 4. A. retroflectus, arch-leaved A. " Prickles solitary, branches round, recurved, and retroflect; leaves falcatus, falcated." Its branches are round dichotomous, warded at the divisions with a minute nodding prickle. The flumks are shrubby, crooked, irregular, eight or ten feet high; leaves long, narrow, in clusters like those of the larch. A native of the Cape. Cultivated by Miller in 1759. The leaves prefer their verdure all the year. 5. A. euboreicus. " Prickles solitary, recurved; branches angular; leaves lanceolate-linear." This is nearly allied to A. falcatus, but the leaves are smaller, and about seven in a bunch. The flupules put forth a recurved spine. A native of the Cape. 6. A. acutius, flender-flaked A. "Prickles solitary; stem erect; branches filiform; leaves falcated, falcatus." It sends up many weak shoots in cluters, and armed with sharp spines at the fides and ends of the shoots; leaves in small clusters, and continuing green all the year. 7. A. altus, white A. "Prickles solitary; branches angular, flexuose; leaves falcated, triquetrous, awnlike, deciduous." Stems shrubby, covered with white bark, armed with thorns, three or four feet high, furnished with many branches, bearing short narrow leaves. These continue green all the winter, if mereed from the frost. A native of Spain and Portugal; cultivated here in 1646. 8. A. acutifolius, acutely-leaved A. " Stem unarmed, angular, shrubby; leaves needle-shaped, rather rigid, perennial, mucronate, equal." It has white, crooked, shrubby flumes, four or five feet high, without spines; leaves like those of larch, but short, and end in prickles. It resembles A. aphyllus, from which it differs in usually having seven leaves together, which are much smaller. A native of Spain and the Levant. Cultivated by Miller in 1739. 9. A. hovidius, thorny A. "Leaflets, shrubby, pentagonal; prickles four-cornered, compressed, flat." The spines are about the length of the finger. A native of Spain. 10. A. aphyllus, prickly A. " Stem unarmed, angular, shrubby; leaves subulate, fiatet, unequal, diverging. Stems weak, irregular, furnished with flfl, short spines instead of leaves; flowers small, of an herbaceous colour; berries very large, and black when ripe. A native of the south of Europe. Cultivated here in 1640. 11. A. cephalis, cape A. "Spines in fours; branches aggregate, round; leaves falcatus." Pluk. Alm. t. 78. f. 3. Root tuberous; items crustiferi, filiform, flexuose; branchlets from the axilile of the spines, filiform, loioe, unarmed, deciduous; leaflets falcatus, acute, short. A native of the Cape. Cultivated in the royal garden Hampton-court, in 1691. 12. A. fortofusa, linear-leaved A. "Leaves filiform, linear-lanceolate; stem flexuose; prickles recurved." It rife five or six feet high; and its shoots are fo closely befet with short crooked spines that it is difficult to touch the branches. The roots, which are long and filiform, are eaten with broth or milk by the inhabitants of Ceylon, who are very fond of them. Cultivated in 1713, by the duches of Beaufort. 13. A. verticillaris, whorl-leaved A. "Leaves verticillate." Found by Townsefort in the Levant.

ASPARAGUS, in Gardening, comprehends one of the most valuable edible vegetables of the kitchen garden; it has erect, herbaceous stalks, three or four feet in height, and very fine briskly leaves; it is a perennial fibrous rooted vegetable, the roots being of many years duration, but the top or flumes annual. The plants being raised from seed, after having acquired a period of three or four years growth, produce proper sized asparagus, of which the same roots furnish an annual supply for many years, continuing to rise in perfection for fix or eight weeks in the summer season, the
the shoots afterwards run up to stalks and flowers, and perfect feeds in autumn.

But besides the crop raised in the summer season, it may also be obtained in perfection during the winter, early in the spring, by the aid of hot-beds, in the manner explained below.

Propagation of the Plants. It is observed by the authors of the Universal Gardener, that the propagation of this plant is by seed only, which may be easily obtained from seed-shops. It should be sown in February, or any time in March, in a four feet wide bed of rich earth, either broad cast on the surface, and directly raked in, or in drills longways six inches asunder, the ground being afterwards raked. In six weeks or thereabouts, the plants will generally appear; they should be kept clean from weeds all the summer, and in winter a little short flable litter spread on the ground to defend the crowns of the roots from frosts; and in the spring following they will be fit for transplanting where they are finally to remain, and in two or three years afterwards, as has been just observed, they will produce asparagus fit to gather.

Asparagus is always three years at least from the time of sowing the seed before the plants obtain strength enough to produce shoots of due size for the table; that is, one year in the feed-bed, and two after being transplanted, though it is sometimes three or four years after planting before they produce good full-sized shoots. But the fame bed or plantation will continue producing good asparagus ten or twelve years, and even endure fifteen or twenty years; however, at that age the shoots are generally small, and the whole annual produce inconsiderable; a new plantation should therefore be made every eight, ten, or twelve years, as may be judged necessary. When new plantations of asparagus are required to be raised in the quickest manner for use, it should be done by purchasing ready-raised year-old plants of the nurseriesmen or kitchen gardeners, as in this way a year may be gained.

The best season of the year to make a plantation of these plants is in March, in common light ground, or at the latest, the first or second week in April; but in cold moist soils, from about the twentieth of March to the fifteenth of April.

In regard to soil and situation, the plants succeed tolerably well in any that is light and mellow, and that is sufficiently rich; but it is eligible to allow them a spot that is rich and light in one of the open quarters of the garden, that is exposed to the free air and full sun, as this is of much importance. Dung must be added six or eight inches thick at least; the ground is then to be trenched one or two feet deep, as may be necessary, burying the dung regularly in each trench, observing that where the trench is but one spade depth, the dung be buried well in the bottom; but if two spades depth, between the first and second spad, or about ten or twelve inches below the surface. Where the trenching is performed in winter, or any considerable time before the planting season, it is proper to throw the ground into ridges to meliorate and improve by the weather into better preparation for planting, as well as for the benefit of the young plants. When the time of planting arrives, it is to be levelled down, which will be a further improvement. See Trenching and Ridding of Ground.

The space of ground necessary to plant for private use is generally from about four or five to twenty rod, according to the extent of the family; and the proper quantity of plants to a rod, exclusive of the alleys, is about 250; one year old plants are to be preferred to such as are older, as those of that age will establish themselves sooner and more effectually than older roots. The plants at the time of being put into the beds, confining usually of only roots, are at the proper time to be taken up from the feed-bed with a dung-fork as entire as possible, and the strongest forked out for use, but not trimmed, only such parts as are broken or bruised being cut off.

In planting, they are to be placed in rows a foot asunder, and formed into beds, each bed to consist of four rows ranging lengthways of them, and planted in drills, or in small narrow trenches, as explained below, allowing three feet and a half interval between every four rows, two feet of which to be afterwards allotted for an alley between the beds, and the rest to be annexed to the beds, which, as well as the alleys, must be regularly laid out in their proper dimensions, four feet and an half for the beds, and two feet for each alley between bed and bed. Or they may be at first marked out and formed into beds and alleys regularly and of their respective dimensions; the beds four feet and a half, and the alleys trodden out between the different beds two feet wide; then four spaces a foot asunder marked out for four rows lengthways of each bed, the two outside rows of each nine inches from the edge; stretch a line tight along the length of the bed in the first outside row, and with the spade held in an erect position, the back being towards the line, cut out a small neat trench along close to the line about six inches deep, forming the side next the line upright, turning out the earth evenly to lie close along the edge of the trench, ready to earth in the roots as planted; this being done, proceed to planting the row, placing the plants in the trench close against the upright side ten or twelve inches asunder, with the crowns upright about two inches below the surface, spreading the roots both ways, and drawing a little earth up to the sides of each plant as they are put in, jut so as to fix them in their places till the whole of the row is planted; then directly rake the excavated earth into the trench over the roots and crowns of the plants evenly; which done, move the line a foot further for the next row, and cut out another trench as above, and plant it in the same manner, directly earthing over the plants as in the first row; and thus proceeding regularly with the rest till the whole is completed. Having finished the planting in either of the above methods, the bed and alleys bed either be lined out now regularly, or deferred until the winter and spring dressing, or, where the beds, &c. are formed previous to the planting, it may be eligible to line them neatly in their proper dimensions as soon as planted, making the edges of the beds and alleys straight, and the alleys level and even. In the other method, either forming the beds and alleys now or afterwards, as hinted above; observing that of the wide intervals of three feet and an half between the beds, two feet only are to be allowed for alleys, the other eighteen inches must be added to the beds, which will make each bed four feet and a half wide, nine inches on each side wider than the outside rows; and noting that in either method, if the beds, &c. are formed as soon as planted, the alleys at this time are only to be trodden out gently the proper width, without cutting out any of the earth upon the beds, so as to stand in the alleys, and lightly to rake the bed even, drawing off any large floes and lumpy clods, so as to leave a smooth surface.

In performing the above, if you have occasion to make the mott of every part of the ground, a thin crop of onions may be drawn the first year on the same plot as soon as the asparagus is planted; but in this case, sow the seed moderately thin, taking it in generally with a light and even hand, so as not to displace any of the asparagus plants.

The asparagus being planted in this manner, it requires the following culture.—The shoots mostly appear above ground.
ground the beginning of May, commonly not much bigger than their seed; all such must be permitted to run wholly to stalk. During summer, they must be kept clean from weeds by small hoeing or hand weeding them three or four times in the course of that season; and if there be a crop of onions, thin them in the usual way, cutting out all such as grow immediately close about the asparagus plants. In October, when the asparagus stalks decay, cut them down, and clear off all weeds from the beds into the alleys, and then dig the alleys two feet wide, burying the weeds therein, and spread some of the earth over the beds. See Winter Dressing.

This is all that is necessary to be done until March, at which time the beds should be deeply hoed and raked smooth, permitting all the shoots to run as in the first summer; and in October, cut down the decayed shoot as before, and land up the beds: in the spring following, being the second after planting, lightly fork-dig the beds, and rake them level. See Spring Dressing. In this spring, the shoots rise of some tolerable substance, begin the first gathering of the largest plants in the first fortnight; but do not prolific any general gathering till the third year. See Caring Produce.

**Winter Dressing, or landing up the Beds.**—From about the middle of October to the latter end of November, is the time to give the asparagus beds their winter dressing. This consists in cutting down the decayed stalks of the plants annually at the above time, and clearing the bed from weeds, digging the alleys, and spreading some of the earth upon the top of the beds, which is called landing up the beds. It is done in the following manner.—The decayed stalks, or haulm, are cut down with a knife close or within an inch or two of the ground; then with a sharp hoe cut up all weeds, drawing them off at the same time into the alleys to be buried; after this, proceed to line out the alleys, stretching the line along the edges of the beds about nine inches from each outward row of plants, the flakes that are to be placed at the corners of the beds, or otherwise the rumps of the flakes, will be a guide; then with a spade chop the ground along by the direction of the line, by which you will form each bed four feet wide, and the alleys two feet. The alleys are then to be dug one spade deep, and a good portion of the earth spread over each bed two or three inches thick. As you proceed in digging, let the weeds driven off the beds be trimmed into the bottom, and buried a due depth, referring to land the beds all a regular thickness, so as to make them about six or eight inches higher than the level of the alleys, forming the edge of each bed full and straight. This work must be repeated every autumn. It may be supposed by some that annual landing of the beds, they may in several years be considerately raised; but by the spring forking and raking, together with the repeated hoeings and clearing off weeds in summer and at the time of preparing for landing up in autumn, a considerable part of the earth is annually drawn off again into the alleys.

After thus performing the winter dressing of the beds, a row or two of cabbage plants may be planted in each alley, as a place of shelter during winter, by which they will be forwarded for early spring coleworts; or a row of mazayan dwarf or other beans may be planted in November or December in the warmest side of each alley, for an early crop; or occasionally, where ground is scarce, some of the beds might be occupied during winter by planting a crop of cabbage lettuce on it for spring use, which being all gathered, or transplanted into other places, by the beginning of April, are superseded to do little harm. It must, however, be done with great care, and such crops not suffered to remain long, otherwise they may injure the asparagus plants in a high degree.

**Spring Dressing the Beds.**—The spring dressing consists in forking digging the beds annually at that season to a moderate depth, to loosen the soil, that the buds may freely advance and swell to their due size. The forking for performing this work is any time in March, but not later than the first or second week in April, because many of the buds will then be formed, and, in forward seasons, begin to advance in growth.

This work is mostly performed with a short flat three-pronged fork. In the first spring dressing after planting, it is proper to loosen the surface only with a hoe, two or three inches deep, and then rake the beds smooth. But the general spring dressing is to be annually performed by fork-digging all such beds as have been planted more than one year, three or four inches deep, with the asparagus fork; being careful to loosen all the earth as deep as the surface of the roots; having regard however not to wound the crowns of them; and afterwards all the beds should be neatly raked, to break clods, clear off flounces, and form a level smooth surface, drawing off all rough earth, &c., into the alleys, which afterwards also rake up in a neat order.

**Manuring the Beds.**—There should be enriched with an addition of good rotten dung, once every two or three years at farthest, the benefit of which will be evident in the quantity, as well as the size and quality of the produce; the season of applying this manure is at the time of winter dressing or landing up the beds. The dung for this purpose should be perfectly well rotted, as the dung of old cucumber and melon beds, or any other of similar quality, which should be applied after the stalks and weeds are cleared off; spread two or three inches thick over the surface of each bed, and a double portion in the alleys; the beds being then lightly fork-digged to bury it; after this, dig the alleys in the usual way, and spread a portion of the earth evenly over the beds. In this way, the winter rains may wash the enriching quality of the manure into the beds and the roots, from the vegetation of the spring.

**Gathering Produce.**—As asparagus plants sometimes, in very rich ground, afford tolerable large buds the second year, here and there, one of the largest that happens to appear the first week or fortnight may be cut, afterwards permitting the whole to run to stalk; but in the third year, a more general gathering may be practiced, and continue a month or two longer. The crocks or beds in the fourth year the general produce will rise to its utmost perfection. Then and every succeeding year, gather all the buds arising from every plant during the season of cutting. The proper size of the asparagus for use, is when the shoots are about two or three inches above the surface of the earth, while the heads remain compact and plump. The principal season of cutting them, is from the latter end of April, or beginning of May, according to the forwardness of the season, till the middle or latter end of June. They might, however, be obtained a month or two longer in the season, by continuing to cut all the buds, according as they attain proper size; but this would be a very wrong practice, as the roots would thereby continue feeding up a fresh supply, till they in a manner exhaust their vegetable food, as would be apparent by the insignificantness of the future crop, and short duration of the plants. The principal gatherings should therefore be terminated generally towards the latter end of June, especially as by that time there will be plenty of young peats to be used as a sublimate in its place at table.

In cutting the asparagus for use, it is necessary to be furnished with a flat narrow-pointed knife, the blade six or eight inches long, toothed on the edge like a saw, which is
to be slipped down close to each separate bud, in order to cut it off planting, three or four inches within the ground; being careful not to injure any of the younger buds rising in succession, as there are generally several from the same root, advancing in different stages of growth.  

Forcing Asparagus.—As asparagus is frequently required in winter, and early in spring, another method must be practiced for obtaining it in these seasons. This is by means of planting the roots in substantial hot-beds, covered with frames and glaases. When it is intended to have a constant succession of asparagus during the winter and spring, a new hot-bed must be made, and planted with fresh plants every three or four weeks. As these roots when forced in hot-beds do not continue to yield any tolerable produce longer than that period of time, when they will in a manner be quite exhausted, and are not fit for that or any other purpose afterwards; therefore, for this purpose, a fresh quantity of plants must be in readiness for every new hot-bed. These are raised in the natural ground to a proper age: they must be three or four years old, the plants being raised from seed, as directed for the natural ground asparagus, and when they are one year old, transplanted into beds of rich earth, as directed for the natural plantations, in rows a foot asunder; but they need not to be more than nine inches distant in each row, forming them in beds of six rows in each, with only two feet alleys, just to go in to clean off weeds, &c. as the beds need not be broken up in winter, as in the natural asparagus; but when the plants have had two summers' growth, they will, in good ground, be fit for forcing, though they are in greater perfection if permitted to stand three years. During this time they remain in the natural ground, none, or very few, buds should be gathered, the whole being permitted to stand each summer. It is also necessary, when intended to force asparagus annually, that some seed should be sown every spring, and a due quantity of plants transplanted as before directed, so as to have three different pieces of ground always employed at the same time with plants for the above purpose; that is one piece with seedlings in the seed-beds, the other two with transplanted plants, one to be of a year's growth before the other; by which practice, after the three first years, an annual succession of plants fit for forcing may be procured. But where it is inconvenient to wait the raising of the plants in this manner, they may be furnished by most of the kitchen gardeners in the neighbourhood of great towns, when where raised to proper growth for this purpose, they commonly fall by meausurement of the ground they grow upon, generally from six to ten shillings per rod, according to the age and size of the plants, and fulness of the crop.

Mr. Nicol, in his Forcing Gardener, observes, that plants for this use should not be older than seven or eight years, nor younger than four years, and that they should be covered with litter or straw, in order to have access to them during frosts. The necessary quantity of plants for hot-beds is (he says) considerable, since about as many as grow upon three rods of ground, are requisite for a bed intended for a common three-light garden frame. The common allowance of the London gardeners is about one rod to a light; for the plants are to be placed as close as they can possibly stand to one another, to the amount of five, six, or seven hundred, or more according to their size, in a three-light frame, otherwise a bed would not supply a quantity adequate to the expense and trouble necessary in the culture of these plants in hot-beds. For, from a bed of the above dimensions, we commonly expect about three hundred large buds or ware, besides spire, weekly, and in the whole, about eight or nine hundred good asparagus, and near as many small ones, in three weeks, in which period of time, the roots will have exhausted their strength, and produce very little more. Therefore, in raising or procuring plants for the above purposes, the quantity must be proportioned to the number of lights you intend working, and the succession of asparagus required. The season for beginning the above work, is according to the time the asparagus is required for use; as for instance, if root would have good asparagus at Christmas, it is proper to make the hot-bed in the first or second week in November, and so on in proportion to any other time in winter or spring it is desired to have it fit to gather. The rule is this: if a constant succession is required from about Christmas to the time when the natural asparagus come in, a new hot-bed should be made every three weeks or a month from the beginning of November until that of March: but some begin about the latter end of September, in order to obtain asparagus about the second week in November. The proper materials for this sort of hot-bed are, according to the authors of the Dictionary of Gardening, a sufficient quantity of horse stable dung, turf and full of heat; for one or more three light frames, two feet and an half or a yard high; also some to line the sides of the bed, when the heat declines, a quantity of good kitchen garden earth, and one or two three light garden frames to place over the beds, and some large garden mats to cover occasionally in nights and bad weather; the dung being previously prepared as directed under the article Hot-Bed. The best situations for the hot-beds are some of the warmest and most sheltered compartments of the kitchen garden, or the melon or cucumber ground if there be room; though the London gardeners, when they make a considerable extent of asparagus hot-beds, often form them in or near some of the large quarters of the kitchen garden, where the soil is rich and light, for the convenience of having plenty of good proper earth at hand for earthing the beds, banking up the outside plants, and moulding at top, &c. The exposure should be open to the full southern sun, and well defended from the northern winds. The beds may be made either wholly on level ground, or occasionally in a hollow trench, four or five feet wide and six or eight inches deep, or if intended to make them in any of the quarters of the kitchen garden, a trench might be formed as above, in which to make the beds for the sake of the earth being laid ready for earthing the beds and plants, and to save the trouble of bringing it from a distance, especially for beds of considerable length; but otherwise they may be made, as has been just seen, entirely on even ground in the most convenient situations. As to the general dimensions of the beds, they must be in proportion to the width and length of the intended frames, or rather a little wider and longer, to allow from three or four to five or six inches clear on each side and end, whereon to bank up some earth against the outside roots, &c. and they should be about a yard high, earthed at top about six inches thick for the reception of the plants, before the frames are put on, keeping them within the compass of them upright and as close as they can stand, as directed below. The clear space of a few inches on each outside end is, as suggested above, to receive a small bank of earth against the outside roots, both to defend them from the weather, and for the support of the frame; the latter of which, on account of the first violent heat, is not put on till some time after planting the roots: these, as soon as planted and banked up on the outsides, are earthed over the crowns of the plants an inch deep, which should be increased to five or six inches when the buds appear through the first earings, at which time as the heat of the bed will be moderate; the frame and glaases should be placed on. See General Culture.
The author of the Scotch Forcing Gardener, however, suggests, that the forcing of asparagus in flued pits, is by far the most eligible method; such pits may answer several other purposes; besides the grace is of a much better colour and higher flavour than that produced on a dung hot-bed. Such a pit as is represented at § 4, in Plate I (GARDENING), will completely answer the intentions of the cultivator. As it frequently occurs in large families, where much labour is kept, that this elegant is wanted in a hurry, the convenience of a pit will be found to be a great relief in this respect; as it is much easier (by aid of flues) to forward or protract the growth of the plants here, than in a common hot-bed; on the one hand, if the plants are advancing too rapidly, you are, it is observed, under the necessity of cooling the bed in a certain degree; and on the other, if they are not advancing so fast as you would have, you are under the necessity of applying linings, which is attended with trouble and loss of time. The author says, that a pit twenty-five or thirty feet long, and six wide, and which one fire can perfectly command, is sufficient to force asparagus to serve a large family from November to May, in a constant and regular succession; after which it may be advantageously employed in raising a late crop of melons or cucumbers, or in striking young pine-apple plants, &c. The trifling consumption of fuel, even where it is most valuable, ought not, he thinks, to deter any who require asparagus, French beans, fallada, &c. at an early season, from building so useful a compartment in the forcing garden. If, continues he, a scrupulous attention is paid to the design in general, particularly to the construction of the fire-places and flues, it will give more satisfaction to the gardener than any other hot-bed whatever, and in the end be a saving to the proprietors. In the construction of this kind of hot-bed, the flues by no means, the flue runs along the front, the bottom of which is about the ground level, and as the outer wall of the flue is only a brick in bed, it is obvious that early cellery, carrots, lecutines, radishes, cauliflowers, &c. &c. found on a well-prepared border about two feet broad, immediately adjoining the breast of the pit, would reap advantage from the flue. At the time of any operation within the pit, a board or plank, supported by bricks, &c. would defend the border from injury. The pit is about four feet in the back and three in the front, deeper than the bottom of the flues; which great depth is made on the supposition that it may be frequently used for pine-apple plants; but where it is used for asparagus alone, half the depth would be sufficient. It is immaterial whether the pit is entirely filled with tan or not; the author frequently used three-fourths of flable dung, prepared in the same manner as for a hot-bed, with equal success; but has always found that dung is worse to manage than the tan, as it is more liable to heat violently; besides, from the nature of the building, there is not a possibility of drawing off the rank heat, as in a hot-bed; for which reason, if dung is to be used, it ought to be sweated in a more careful manner. It is added, that a very small degree of bottom heat is sufficient for the purpose; and that if the pit has been previously employed with young pines, it will require no preparation whatever for asparagus roots, excepting to level and put a few inches of very rotten tan upon the surface. But if melons were the last thing the pit produced, it will be necessary to flur up the bed about two feet deep, and add a little new tan or dung; then level the surface with old rotten tan, as before. In either case the surface should be levelled in a sloping manner to the sun, about six inches above the bottom of the flues, allowing so much for the tan settling; the roots are then to be placed in and covered, as directed for the common hot-bed. If the pits are from twenty to thirty feet long, one half will be sufficient for a time; and, to keep a constant succession, the other half may be filled in about fifteen or twenty days, which will begin to come up before the first is all used; after which, once a month or five weeks, according to the size of the pit and consumption of the family, may be sufficient, till it be fit for cutting in the open ground. It is recommended that no fires be made if the thermometer stands as high as forty-eight to fifty degrees; but, if necessary, covered with mats at night; also to admit plenty of air through the day, if the weather will permit. When it is necessary to make fires, it should be done with caution; a small one made in the evening will serve the whole night, and it will be unnecessary to make any in the morning, unless it be a great storm. He has, however, sometimes found it convenient to make a small fire in the morning, that he might have it in his power to admit air, and at the same time keep up a proper degree of heat. It is added, that warmth will here be required in a more plentiful degree than recommended for hot-beds; but due observation of the state of the tan and the health of the beds should always determine the warmth that may be necessary. In filling the first end of the pit a second time with fresh roots, it will be unnecessary to flur up the tan, &c. and perhaps it may be so even at the third filling; but by keeping a thermometer plunged in the bed, or watch-flicks, you will be best enabled to judge: at all events, there will be no necessity for adding fresh materials, as he has always found that trenching the bed to the depth of two feet or so has answered the purpose for the whole season. If dung or oak leaves are used, the bed should be turfed; and at least a foot of very rotten tan or light mould laid on before the roots are placed in. This precaution is unnecessary, he says, when tan alone is used; for which reason, the first should not exceed more than an eighth part of new tan ought to be trenched in.

Method of making the Beds, planting the Roots, and Culture. When the first method is followed in the situation and exposure above described, it is advised by the authors of the Universal Gardener, to mark out the place of the hot-bed, of the proper width and length proportionally to that of the intended frame or frames, whether one, two, or more; and if a trench is intended, to dig out the cavity, only one moderate spit deep, and the width as above; then wheel in the dung, and with it form the bed of the proper width and length, either on level ground or in a trench, as just directed, raising it regularly of the same dimensions, about a yard high, especially in winter; but for the final spring beds, two feet and a half depth of dung may be sufficient, working the whole upright and firm in the usual manner.

Mr. Nicol, however, recommends that a sufficient quantity of flable dung be shaken up to heat and sweeten, and that after it has lain six or eight days, it be turned over and shaken well up again, in which state it may lie four or five days more; by which time it will be ready for building the bed; this must be done in the common way, to the height of four feet in the back and three in front, and about a foot larger than the frame all round; it is then to be well levelled, the whole covered with figures of turf, cut so as to join again exactly, which are to be laid the green side down, and smoothed well with the back of the fpade; then place the frame thereon, which should be thirty inches deep in the back, and twenty in front, in which dry well-reduced old tan should be laid to the thickness of six or eight inches; which also level, and gently smooth with the fpade. Where old tan cannot be procured, he advises a light sandy earth, with a fourth part of good vegetable mould. The bed will begin to heat in twenty-four hours, and must then have air admitted to pass off any fream that may arise, which

...
will however in general be inconsiderable; the only reason of the surface is to prevent the steam, which, if carefully done, will have the desired effect. Yet, it sometimes happens, that there will be a little, especially if the dung did not undergo a proper fermentation; but until the grass begins to appear, it is of no great consequence if there is a little steam in the frame, nor provided there is not much steam, whether it has any air admitted or not. But, from the moment the buds begin to peep through, the greatest attention must be paid to prevent steam, which is sure to give the grass a disagreeable flavour and bad colour. In order to prevent the grass from drawing up weak, a large portion of air must be admitted every day, if the weather be not stormy; and a little air should be let in at night; while the bed has a rank heat in it, Fahrenheit's thermometer should not stand above 50° at any time, unless in sunshine, and then not above 60°. By the above rule, it will easily be seen, whether mowing at night is necessary, and to what extent, but it must be attended to, till it entirely disappears.

When the beds are formed in the first method, they are advised in the Dictionary of Gardening to be directly earthed at top for the reception of the plants, with finely broken earth six inches thick, to the full width and length of the beds, the surface being raked level and smooth. Then immediately to proceed to place the roots, for no time must be lost in asparagus hot-beds, in waiting for the temperature of the heat; previously to planting the roots, mark out on the surface of the beds the exact width and length of the frame, so as to have a clear space on each outside of a few inches width, to receive the banking of earth against the outside roots, &c., as before mentioned; then begin at one end, and raise a small ridge of earth cross-ways upon the surface, five or six inches high, against which lay the first row of roots, then having the roots which are not to be trimmed, place the first course cloe against the ridge and entirely upon the surface of the beds, with the crown upright, and as close to one another as you can possibly place them, either wholly upon the top of the earth, or only draw a little to the lower ends of the roots, or infert the ends a little into the earth, though they are often planted without either drawing any earth about the fibres, or inferting them therein; and when one course or row is thus placed, lay another against these in the same manner; and so proceed, laying them one against another, every way as you can possibly crowd them, from one end of the bed to another, being careful to place all the crowns of such an equal height, that the whole may form as it were a level surface, keeping the whole rather within the measure of the frame, so they will unavoidably swell out a little on each side. If more frames than one are intended for the same bed, then, at the termination of the length of each frame, raise a cross ridge of earth, as at first, about six inches in height; so proceed laying the roots as before; and when all the roots are thus placed the whole length of the bed, directly bank up some earth on each side and end as above hinted, against the outside roots, raising it an inch higher than the crowns; then cover the crowns all over evenly with finely broken light earth an inch deep, which finishes the work until the buds appear; for the roots must not till then be earthed deeper, nor the frame and glasses placed upon the beds till the violent heat has subsided, because they would confine the burning steam, and occasion the bed to heat too vehemently to the destruction of the plants.

In forming the above beds, they sometimes, where necessary, to the saving of dung, are only made the exact width of the frame, so as to secure the outside roots; but for the support of the frame, raise a bank of earth quite from the ground, six inches broad at bottom, drawing it in gradually to the top, banking it close against the sides of the beds; and that of the outside roots, raising it an inch higher than the crowns at bottom of them, so earthing them all over the top an inch deep as before observed; which method of banking quite from the ground may also prove effectual in preserving the temperature of the bed, by defending the dung from driving rains, snow, and piercing winds. As soon as the beds are made and planted in either of the above methods, in order to judge of the temperature of the heat, it is proper to thrust some sharp-pointed sticks, too feet long, down between the roots into the dung of the bed, and by drawing these up daily, and feeling the lower part, you will be able to judge of the degree of heat, whether too violent or weak, which is to be regulated accordingly.

The beds being made and planted, the roots will soon after send forth fresh fibres into the earth, and even in time into the very dung, and the buds of the asparagus begin to appear in a fortnight or three weeks; but till that period, as the heat will probably be very strong, the bed is to remain unframed and uncovered, except being occasionally defended at top; or at least, if the frames are placed on the beds, the glasses not fully put on, only using them occasionally if very inclement weather should happen at that time, just to protect the bed and crowns of the plants from excessive wet or rigorous frost; or the bed may be occasionally defended with long litter or garden mats from violent rains, snow, and severe frosty weather; observing, however, to use only occasional covering just to preserve the heat of the bed and the crowns of the plants till the buds begin to appear, and the heat becomes quite moderate, as at this period too much covering would increase the heat to a violent degree, and scourch or fumaceul the roots, which, in strong beds, must be particularly guarded against. The temperature of heat must therefore be every day examined by the trying-flick; and if it is found to be so slight that you judge the roots are in danger of scourching, the remedy is to bore with a large rake-handle, &c., the sides of the bed quite through in several places, both in the dung, andbetwixt the top of the dung and the earth, that the rank steam and burning quality may evaporate at the holes; at the same time the free air may have access; and in two or three days the bed will be reduced to a moderate temperature. On the other hand, it should likewise be observed, that if the bed in a week or two after being made does not heat kindly, or seems rather to decline, it may be proper to lay dry or warm flake-litter round the sides and over the top, which will forward and revive the heat more effectually. When the asparagus begin to appear, they are then to have their final earthing of four or five inches depth of additional mould all over the crowns of the roots, and the frame and glasses put on. At this period prepare some light, rich, finely-broken earth, sufficient to mould them the above depth; at the same time in order to secure the outides of the said final earthing, it is proper to form a sort of wreathing or embalment round the top of the edges of the bed four or five inches high, which is done either with a thick straw-band, or by raising the outside banking an additional four or five inches; either of which, as just observed, is necessary not only to secure the sides and ends of the said final top covering of earth, but also to support the frames when finally placed on the beds.

The beds being now finally earthed and framed, and the heat become moderate, the glasses or lights are to be kept constantly upon the frames, which in the night should be covered.
Asp<br>

Asp is a plant that grows in moist, sandy, or gravelly soils, often found in the wild. It is known for its yellow or white flowers, which are followed by small black berries. The plant is also known for its ability to thrive in coastal areas. In the wild, it is often found growing in the sand dunes of the Mediterranean coast. It is a hardy plant that can withstand salt spray and wind, making it a popular choice for coastal landscaping. Asp is also known for its medicinal properties, such as its ability to treat respiratory problems and skin infections. It is often used in herbal remedies and is also popular in aromatherapy. Asp is a versatile plant that can be used in a variety of ways, from landscaping to medicinal purposes. It is a hardy and resilient plant that can thrive in a variety of conditions, making it a great addition to any garden.
we suppose) of bearing living children, or of undergoing the pains of labour, without manifest danger of their lives. There have never been wanting persons professing to be able to procure abortion, with perfect safety to the women; but either these have been the vain hopes of impudent pretenders, or the art has been long lost, no drug or composition now known possessing such powers. See the article Abortion in this work. It is not known who this Aspasia was, or in what age she lived. Le Clerc Hist. de Med.

ASPASIA, in Eumenology, a species of Papilio, in the family Helicinius. It inhabits Tranquebar: the wings are black, with transparent flakes and spots; and the posterior ones yellow at the base. Fabricius, 6c.

ASPASIAE, in Ancient Geography, a people of Asia, placed by Polybius between the Ouxus and the Tanaus; probably the same with the Aspasiaires of Strabo, and the Aspasia of Ptolemy.

ASPASTICUM, in Ecclesiastical Writers, a place or apartment adjoining to the ancient churches, wherein the bishop and presbyters sat, to receive the fulsations of the persons who came to visit them, direct their blessings, or consult them on business.

This is also called apsaticum, diacunicum, receptucium, metatorium, or meditorium, and salutatorium; in English, meeting-rooms.

ASPATHIS, in Ancient Geography, a town of India, on this side of the Gangetic Ptolemy.

ASPE, in Geography, a town of Spain, in Valencia, situated on the Eida, four leagues west of Alicant.

ASPE, a valley of Berne, in Switzerland, between the Pyrenees and the town of Oleron. The river of Oleron passes through this valley, and is called the Gave of Aspe.

ASPE VIEJO, a town of Spain, in Valencya, three leagues and a half west of Alicant.

ASPECT, in Astronomy, is used for the situation of the stars, or planets, in respect of each other; or, in Astrology, it denotes a certain configuration, and mutual relation between the planets, arising from their situations in the zodiac, whereby their powers are supposed to be mutually either increased or diminished, as they happen to agree or disagree in their active or passive qualities. Though such configurations may be varied and combined a thousand ways, yet only a few of them are considered. Hence Wollius more accurately defines aspect to be the meeting of luminous rays emitted from two planets to the earth, either situated in the same right line, or including an angle which is one or more aliquot parts of four right angles.

The doctrine of aspects was introduced by the astrologers as the foundation of their predictions. Hence, Kepler defines aspect an angle formed by the rays of two planets meeting on the earth, able to excite some natural power or influence.

The ancients reckoned five aspects, viz., contrication, when the planets are in the same sign and degree, or have the same longitude, denoted by the character $\circ$; opposition, where they are in opposite points of the circle, or at the distance from one another of 180 degrees, exprest by $\varnothing$; triune, when they are distant one-third of the circle, or 120 degrees, denoted by $\Delta$; quadrature, or quartile, when they are distant $\frac{1}{4}$th of the circle, or 90 degrees, marked by $\varphi$; and sextile, when their distance is the sixth part of a circle, or 60 degrees, denoted by $\alpha$.

Conjunction, and opposition, are the two extremes of the aspects; the first being the beginning, and the second the highest or ultimate term. The aspects are divided, with regard to their supposed influences, into benign, malign, and indifferent.

The quadrature aspect and opposition are reputed malign, or unfriendly; triune and sextile, benign or friendly; and conjunction, an indifferent aspect.

To the five ancient aspects, the modern writers have added several more; as sextile, containing the tenth part of a circle; tridecile, three-tenths; quintile, a fifth part of the circle; and biquintile, four-tenths, or two fifths.---Kepler adds others, as he tells us, from meteorological observations; as the semiseptile, containing the twelfth part of the circle; and quinconx, containing five-twelfths.

Lately, to the astrological physicians we owe, sextile, containing one-eighth; and tridecile, containing three-eighths.

The angle intercepted between two planets in the aspect of conjunction is 0; in the semi-septile aspect, 30°; in decile, 36°; in octile, 45°; in sextile, 60°; in quintile, 72°; in quartile, 90°; in tridecile, 108°; in tridecile, 120°; in biquintile, 144°; in quinconx, 150°; in opposition, 180°.

These angles, or intervals, are reckoned on the secondary circles, or according to the longitudes of the planets; so that the aspects are the same, whether a planet be in the ecliptic, or out of it.

The aspects are also divided into parile and platic.

Aspects, Parile, are when the planets are just so many degrees distant, as is above expressed. These alone are the proper aspects.

Aspects, Platic, are when the planets do not regard each other from these very degrees; but the one exceeds as much as the other falls short.---So that if the one does not cast its rays immediately on the body of the other, but only on its orb or sphere of light.

Aspect, Double, is used in painting, where a single figure is so contrived, as to represent two or more different objects, either by changing the position of the eye, or by means of angular glances.---Influences heretofore, fee under the articles Asamorphosis, Cataeoticus, Cistula, and Mirror.

Aspect, in Gardening, is used for what we otherwise call esprière.

Aspect, in Military Language, is applied to a country and to an army thus; a country is said to have a military aspect, when its general situation presents appropriate obstacles or facilities for an army's acting on the offensive or defensive.

An army is said to hold a menacing aspect, when by advanced movements or positions, it gives the opposing army reason for apprehending offensive operations. An army is said to have an imposing aspect, when it appears stronger than it really is; and this aspect is assumed for the purpose of deceiving an enemy, and serves as a kind of feint in war.

ASPLAN-TREE, in Planting, a species of the poplar, having small roundish leaves with an angular indentation, and smooth surfaces on both sides. According to Marshall, the leaves of this tree stand upon long, flat, slender footstalks, which render them liable to the shaken by the leath wind; whereas it has been called the trembling poplar or aspen tree. This tree will grow on most kinds of soil, but may be cultivated to the greatest advantage on such as are inclined to be moist, without having much stagnant surface water. In such situations, they will sometimes grow to a considerable size. They may be raised in the same way and with equal facility as the common poplar. The wood of the aspen tree is light, porous, and open; consequently of little value.
timber. From its lightness, it might however probably be used to advantage for the purpose of common field-gates, hurdles, and other similar uses. In Mr. Marshall's treatise on Farming, it is represented as wholly unfit for being set in such grounds as are intended to be kept for pleasure, on account of the great number of suckers that are annually thrown up by it. See Populus.

ASPENDII, in Ancient Geography, a people of Pamphylia, who inhabited the town of Aspendus. They fortified their town in order to dispute the payment of the tribute which they had promised to Alexander; but he marched against them, and compelled them to submit; and afterwards double the tribute which he had at first demanded.

ASPENDUS, a town of Pamphylia, situated upon the Eurymedon, at the distance of 6o stadia from the sea, according to Strabo, who says that it was well-peopled, and that it had been founded by a colony from Argos. In M. D'Anville's map, it is placed between Perga and Sida.

ASPER, or Spiritus Asper, in Grammar, denotes a character, or accent, in form of a ē; placed over certain letters, in the Greek tongue, to show they are to be strongly aspirated, and that the breath is here to supply the place of an enlarged sound. Asper is translated, thus, HEKATON. Nevertheless, the ancient Greeks did not judge it necessary always to express this aspiration upon their monograms. Thus upon a medal of the Tyrians we find IEPEC. Hence it is very doubtful, whether this aspiration was in common use in the time of the apostles; and it becomes much more doubtful, when we consider, that the most ancient versions so frequently confound asper with aspero, that both words seem to have been written without an aspiration. Martin's Michaelis, vol. ii. p. 522. See Aspere.

ASPER, or Aspers, in Commerce, signifies a small Turkish silver coin, wherein most of the grand signoir's revenues are paid.

The asper may be estimated at 6 deniers (one farthing).

—The only impression it bears is that of the prince's name on whom it was struck. —The pay of the janizaries is only distributed every three months, and has a progressive increase from 3 aspers to 99; and 99 aspers are equivalent to 491 fions, or about two-thillings and three farthings. But from an estimate made of the respective currency, the course of exchange reduces it to 39 fions 6 deniers (1s. 7d. 1½); though this calculation is much above the intrinsic value of this coin.

ASPER, in Conchology, a species of Murex described by Martin (Conch. 4. t. 150.) The shell is plaited longitudinally, and ribbed transversely; spine rather prominent; aperture oval; and the lip crenulated. This kind is reddish; whorls about five or six; and the ribs acute. Gmelin. In the Gmelian System Nature, there is also another species of Murex under the same name, which is a native of Guinea; the whorls of the spine are inflated transversely, flattened, and curved; and the tail (or beak) ascending. The colour is milky white, with rows of brown dots; solid, with from twelve to fourteen furrows; aperture rather oval; and a single slit on the pilar lip. Gmelin.

The first species belongs to the section Candidior, cauda flavula chaula recta elongata, tella inermi (or murices, with fabulate, fivartight, elongated, and closed beak, and shell unarmed); and the second to turriti fulbulati, cauda brevillima (murices tapering, fabulate, and furnished with a very short beak).

ASPER, a species of Trochus, figured by Chemnitz, the native place of which is unknown. The shell is oblong; whorls broader, with many rows of tubercles, fulcated and flattened transversely; pillar-lip dentated; aperture turrit. This kind is of the middle size, cincereus, or tesselaceus; lip plaited and rugose within.

ASPER, in Entomology, a species of Cerameyx (Scnecerus Fab.), a native of Italy, and figured by Sulzer. It is black, rough, thorax armed with two spines; wing-caves tuberculated in the middle. Sulzer, &c.

ASPER, a species of Scaraebus found in Europe; the head and thorax are grooved transversely; wing-caves: tuberculate. Fabricius, &c.

ASPER, a species of Cancer found on the British coasts. The thorax is heart-shaped, spinosus; two spines on the probosces; legs and arms spinous.

ASPER, in Ichthyology, a species of Perci. It is furred with yellowish, and has thirteen rays in the second dorsal fin. Jonston, Ray, and others, call this asper pificus; and asper pificus, gobionis similis.

ASPERA ARTERIA, in Anatomy. See Arteria Aspera.

ASPERA, in Conchology, a species of Tellina, about an inch and three quarters in length, and three inches in breadth. This shell is pointed at one end, yellowish within, and externally radiated, and rough, with transverse flake. Gmelin. Country unknown.

ASPERANA, in Entomology, a species of Phalaena (Torric), found in the vicinity of Hamburg, and other parts of Europe. The anterior wings are white at the base, brown at the tip, and rough. This insect belongs to the Tetrica section in the Linnaean and Gmelian arrangements; in that of Fabricius in the section Pyralis.

ASPERELLA, an European species of Phalaena, of the Tineida tribe. The anterior wings are whitish, emarginate at the tip, with two common black spots. This is phalana tinea alia albius; macula communis fucea, apicibus nigro punctatis retibus of Linn. F. S. V.

ASPEREN, in Geography, a small town in Holland in the country of Gorkum or Arkel, seated on the Linge, two leagues north-east from Gorkum, and five south from Utrecht.

ASPERGELLOUS, in Botany, the name given by Micheli to that genus of mollusks called by Dillenius and others, abyssus.

ASPERGILLUM, in Antiquity, a long bristled made of horse-hair, fixed to a handle, wherewith the lulfral water was sprinkled on the people, in lustrations and purifications. Horrey Brit. Rom. lib. ii. cap. 1.

This is also denominated aspergile, and aspersorium. The ancients, instead of a bristle, made use of branches of laurel and olive. It is also used in Ecclesiastical Writers, to denote the instrument in Roman churches, wherewith holy water is sprinkled.

ASPERIFOLIOUS, in Botany, one of the divisions or classes of plants in the Fragmenta Methodi Naturalis of Linnaeus; so denominated, because they are usually rough-leaved. According to Mr. Ray, these plants make a distinct genus, the characters of which are, that the leaves stand alternately, or without any certain order, on the stalks: the flowers are monopetalous, but they have the margin cut into five divisions, sometimes deep, sometimes shallow; and the upper spike or top of the plant is often curved back, something like a scorpion's tail.
In the place of each flower, there usually succeed four seeds; Mr. Ray supposes the cerasphie the only plant of this genus that has less than four seeds at the base of each flower; this indeed hath been granted.

To the class of herbae aperipolos, referred in the Linnaean system to the monopetalous tetraspermosa distinction, under the class of pentandria and order of monogynia, belong the pulmonaria, cyngnosophium, borago, anchusa, echium, heliotropium, lithospermum, cerasphie, heliotropium, myosotis, symphytum, onosma, asperugo, lycopersic, porana, tournefortia, and mefferciodia.

They all possess the same general virtues, and are accounted gustatory and glaucous.

ASPÆRITY, implies the inequality or roughness of the surface of any body; by which some parts of it are so much more prominent than the rest, as to hinder the hand, &c. from passing over it with ease and freedom.

Asperity, or roughness, stands opposed to smoothness, evenness, politure, &c.—From the asperity of the surfaces of contiguous bodies arises friction.

According to the relations of Vermausen, the blind man is famous for distinguishing colours by the touch, it should appear, that every colour has its particular degree and kind of asperity. He makes black the roughest, as it is the darkest of colours: but the others are not smoother in proportion as they are lighter; i.e. the roughest do not always reflect the light first: for, according to him, yellow is two degrees rougher than blue, and as much smoother than green. See Colours.

ASPÆRÆNÁA, in Entomology, a species of Phalaena, of the geometra family, described by Linæus. The wings are whitish; anterior margin subfuscous. Inhabit Europe. M. L. L. Gmel. &c.

ASPÆROSÆ, in Geography, a town of European Turkey, which is a bishop's see, seated on the north-east of the Archipelago, and not far from the island of Tasso, opposite to the northern point of which is a cape of this name. N. lat. 40° 58'. E. long. 24° 20'.

ASPÆRÆMUS, in Conchology, a species of Murex. The shell is brown, varied with yellow and white, and ribbed; whors oblique, with a tuberculated margin; a brown band in the middle, and another of white; tail short, dilated, and ascending; length about two inches. Gmelin, &c.

ASPÆRÆ, is a species of Helix that inhabits Italy. The shell is subperforate, rather globous, pale yellow, with four rufous bands interrupted with white spots; lip white. Müll. Gmel. This kind is from an inch to an inch and a half in diameter; fusiforme, with minute impressed dots; rarely white; whors four, and the aperture elongated. The synonyms, quoted by Gmelin, are very doubtful, if not incorrect.

ASPÆRÆ, in Natural History, a species of Ascidia, described by Müller, Zool. Dan. As a native of the Norwegian sea. This is rather compressed, and somewhat rough, white, bag spotted with red. Adheres to sea-weeds; heart-shaped; skin pellucid, and smooth within; bag yellowish.

ASPÆRÆ, in Heraldry, a term sometimes used instead of flourished or flourished.

ASPÆRÆSÆ, formed of the Latinaspergere, to sprinkle; of ad, to, and spargere, I scatter, the act of sprinkling with water, or some other fluid.

Some contend for baptism by aspersæ, others by immersion.

ASPÆRÆSCHIRCH, in Geography, a town of Germany, in the archduchy of Austria, five miles to the south-call of Pervinca.
Richard. 3. *A. turbinata*, broad-leaved woodroof; *leaves four in a whorl, ovate-lanceolate; flowers in terminal bunches.* Root perennial, woody; stems a foot high, branched; leaves hairy, nerv'd; peduncles one or two; bracteoles. A native of the mountains of Switzerland and Italy, flowering in June. It was cultivated by Miller in 1739. 4. *A. cornifolia*, thick-leaved woodroof; *leaves four in a whorl, oblong-lateral, revolute, bluish, pubescent.* Stem alternately branching; leaves: the length of the internodes, the whorls on the branches more remote, and leaves narrower, unequal; flowers few, in upright terminal branches, pubescent on the outside. A native of Crete and the Levant. A drawing of the flower is introduced here by Mr. Thouin, in 1755. 5. *A. calabria*, Calabrian woodroof, L'Herit. flrps. nov. 4. 67. t. 32. "Leaves four in a whorl, oblong, obtuse, firm, and even." An underbush, a cubit high, decumbent, fiedt. Leaves lanceolate, one-nerved; there is a short thorn upper side of the leaves, half embracing the stem; flowers three or four, in terminating corymb; bracts two-leaved, acute, spreading a little below the guins. A native of Syria. The faetid smell of this sufficiently distinguishes it from the other species. 6. *A. pita*, narrow-leaved woodroof; *leaves linear, the lower six, the middle four, in a whorl; stem pubescent; flowers generally trifid.* Stem branching, procumbent, three feet in length; leaves resembling those of wild thyme; peduncles from the axil of the leaves, forming little umbels; flowers white; seeds smooth. The roots are used in Gotland for dying wool of a red colour. A native of Sweden, Germany, Swiceland, &c. Cultivated by Mr. James Gordon in 1750. 7. *A. pyrenica*, Pyrenean woodroof; *leaves four in a whorl, lanceolate-linear; stem erect; flowers generally trifid.* Root perennial; stems six or seven inches high; leaves keeled, acute, fuscous; lower ones shorter, more obtuse, lanceolate; upper and floral leaves opposite, broader; flowers red. A native of the Pyrenees, and about Beul. 8. *A. ranken*, fimbriatus-wort, or small woodroof. Huds. 65. With 186. Smith Brit. 172. Eng. Bot. 55. Rubecula vulg. &c. Ray Syn. 225. "Leaves four in a whorl, linear; the upper ones very unequal; flowers all quadrifid; fruit smooth." Root perennial, fibrous; lower leaves in fours, on the branches obivate; upper leaves linear, and those near the top very unequal, so that the intermediate pair seems diminished into flippules; umbels terminal; corollas of a fifth colour, marked with red lines, fragrant; fruit fuscous. It grows in England on warm banks, affecting a calcareous soil. 9. *A. nitida*, awn-flowered woodroof; *leaves linear, rather fimbriate; lower ones four in a whorl; flowers subternate.* Stem upright; leaves pale, yellowish, placed parallel, divisions bluntly acute. A native of the south of Europe. 10. *A. levigata*, shinng woodroof; galium rotundifolium, Jacq. Auct. 1. 158. t. 94. "Leaves four in a whorl, elliptic, nerv'des, smoothish; peduncles divaricate, trichotomous; seeds roselinh." Stem simple, smooth, spreading; leaves subpetioled, obtuse; flowering branches horizontal, bidentate two, small, lanceolate; flowers white, usually in threes. 11. *A. asphalites*, flat-leaved woodroof, Allion Ped. t. 77. "Leaves flat in a whorl, linear; flowers umbelleted, terminal, subfimbriate." Root perennial; stems generally simple; leaves acuminate, flat, erect; umbels accompanied with ten or twelve leaves; corollas purple, white within; segments a little revolute; seeds shaggy, compressed. It grows on the heights of rocks near Tunis. Propagation and Culture. All these plants being perennial, except the second, may be increased by the roots as well as by the seeds. The first will prosper under the shade of shrubs in wilderens quarters. The fifth must have the protection of a green-houfe, and does not continue many years; but may be increased both by seeds and cuttings. The eighth growing naturally in chalk, and most of the others being natives of rocks, must have a dry open situation. Martyn's Miller's Dict. ASPEIURUM, in Conchology, a species of Buchium, about an inch and a half in length. It is figured by Liller, but its habitat is unknown. The whorls of the spire are ribbed, and flattened transversely; the first is gibbous, and the tail (or beak) rather prominent. Gudin, &c. ASPET in Geography, a town of France, in the department of the Upper Garonne, and chief place of a canton in the district of St. Gaudens; two leagues south-east of St. Gaudens. ASPEYTLIA, a town of Spain, in the province of Gui- pucoza, seven leagues from St. Sebllian. ASPHALITES, in Anatomy, the fifth vertebra of the loins. It is thus called, because conceived as the support of the whole spine of the loins; from the privative and σφάλας, a supplant. ASPHALITTE LAKE, in Geography, a lake of Pa- lestine, so called from the great quantity of bitumen, called asphaltum, which it produces. It has also been called the Dead Sea, from a supposition that no fishes will live in it, and that birds, which have attempted to fly over it, have been suffocated. From its situation, it has been denominated the East Sea; and distinguished by other appellations, as the Salt Sea, the Sea of Sodom, the Sea of the Desert, and the Sea of the Plains, by the sacred writings. Its origin has been ascribed to the submersion of the vale of Siddim, where once flood, according to common report, the three cities which perished, in the miraculous conflagration, with those of Sodom and Gomorrah. These cities have, on account of their number, been called Pentapolis. Strabo, however, on the authority of an ancient and received tradition, reckoned thirteen of these cities, of which Sodom was the capital; and he adds, that they were overthrown by a violent earthquake occasioned by subterraneous fire, that threw up this great and sulphurous lake, in which all those cities were swallowed up. Job plus likewise witnesses us, that in the overthrow of Sodom, this vale became the lake Asphaltites. It has been said, that the ruins of these cities are still to be seen in clear weather; and we likewise read of apples that grew about it, fair without, but bitter to the taste and filled with alets; which added to the deadly nature of its water and smoke, afforded another evidence of the divine indignation. Some of the circumstances that have been recited concerning this lake, and which have long obtained credit, have been contradicted by the testimony of more modern travellers. Although it was long thought that nothing would sink in the waters of this lake, and that no animal could live in it, yet Dr. Popecock affirms us that much as their specific gravity is augmented by the salt with which they are impregnated, several persons, and among others this writer himself, have and dived in this lake, and birds have flown over it without injury. It is possible, indeed, that the specific gravity of the water of this lake may have been diminished since the experiments made by Vepaian, and recited by Linny (N. H. 1. v. c. 15.), because great quantities of the bitumen have been collected and removed, and this lake has been supplied with copious streams of fresh water. Mr. Kirwan says (Analysis of Mil- tern Waters, p. 144.), that the heavy water of which he spoke was met with any account is that of this lake. Lavater found it 1.253, and that it contained 44.4 per cent. of fine-line matter, of which 6.25 parts were common salt, and

38.15
38.15 were murinated lime and murinated magnesia. See Mem. Paris, 1778, p. 63. From these falls the water derives its bitter taste; and the bitumen which floats upon the surface of this lake, and which arises from its borders or its bottom, does not contribute to it any quality. As to the fall which produces, the Arabs furnish themselves with large quantities by digging pits about the shore of the lake, filling them with water, and leaving them to be crystallized by the sun. As to the bitumen which gave name to this lake, it is said to have thrown up great quantities of it, and that it is much used by the Egyptians and the inhabitants of other countries for the purpose of embalming dead bodies. Indeed Josephus affirms us, that it ascended in mazzes as big as an ox without its head, and even of a larger size. Mr. Maundrell says (Journey, p. 84.), that there was no bitumen in the place where he happened to be; but that it is gathered near the mountains on both sides in great plenty. Pococke, however, (Travels, p. 56.), observed it to float on the surface of the water, and after windy weather to be found on the shore, where the Arabs gather it for the purpose of applying it to the fame use with common pitch; and Dr. Shaw (Travels, p. 347.) informs us, that he was assured that the bitumen is raised at certain times from the bottom of the lake in large hemispheres, which, as soon as they touch the surface, and are acted upon by the external air, built at once with great smoke and noise like the pulsus fulminans of the chemists, and dispersed themselves into a thousand pieces. This, he adds, only happens near the shore; for in greater depths, the eruptions are supposed to discover themselves in such columns of smoke as are now and then observed to arise from the lake. This bitumen is described as resembling our black pitch, and not to be distinguished from it except by its fulgurative and hectic smell, occasioned either by friction or by setting it on fire. Some perfumes have confounded it with a blackish combustible stone thrown on the shore, and sometimes called "Mofa's stone," which held in the flame of a candle, will burn long, and emit a smoke and intolerable stench. Whilst its weight is much diminished, it retains its bulk, and becomes of a whitish colour. Dr. Pococke observes, that these stones are found about two or three leagues from the shore; and he supposes, that a fragment of this kind of stone under the lake is probably one part of the matter that feeds the subterraneous fire, and causes the ebullition of the bitumen. Mr. Maundrell informs us, that he saw several birds flying about and over this sea without any visible harm; and he supposes that the tradition which reports, that no animals can live in these waters is false, as he observed among the pebbles on the shore two or three shells of fish resembling oyster shells, which were cast up by the waves. He surveyed the waters with attention, in order, if possible, to discern the ruins of the absorbed cities, but he failed in his attempts to discover them; he was told, however, by two aged perfons, not destitute of understanding or probity, that they had once actually seen one of these ruins near the shore, and the waters being shallow, they went to it, and found there several pillars and other fragments of buildings. As for the apples of Sodom, Mr. Maundrell neither saw nor heard of any; nor was any tree to be seen near the lake from which such kind of fruit might be expected. A late traveller, Mr. Volney (Travels in Egypt and Syria, vol. i. p. 310.) says, that this lake contains neither animal nor vegetable life. No verdure is perceived on its banks, nor are birds to be found in its waters; but it is not true, adds this writer, that its exhalations are pestiferous so as to destroy birds flying over it. It is very common to see swallows thinning its surface, and dipping for the water necessary to build their nests. The real cause which deprives it of vegetables and animals, is the extreme saltiness of the water, which very much exceeds that of the sea; the soil around it, intermixed with this salt, produce no plants, and the air itself, loaded with it by evaporation, and receiving the sulphurous and bituminous vapours, cannot be favourable to vegetation; and hence proceeds the deadly aspect which reigns around this lake. The origin of this mineral (says Mr. Volney) may be easily discovered: for on the south-west shore are many of fossil salt, which are situated in the sides of the mountains extending along that border, and which have, for time immemorial, supplied the neighbouring Arabs, and even the city of Jerusalem. On this shore are also found fragments of sulphur and bitumen, which the Arabs convert into a trifling article of commerce. There is also found a sort of stone, which, with friction, emits a noxious smell, burns like bitumen, receives a polish like white alabaster, and is used for the paving of court yards. At intervals there may be also seen unshapen blocks, which prejudice has mistaken for mutilated statues, and which pass with ignorant and superstitious pilgrims for monuments of the adventure of Lot's wife. Mr. Maundrell was informed that on the west side of the sea is a small promontory, near which flooded the monument of Lot's metamorphosed wife, part of which, as he was told, is visible at this day. But he had neither faith enough in the report of his informer, nor sufficient leisure for examining the truth of this fabulous relation. One remarkable property of this lake remains to be mentioned; and this is, that though it receives the Jordan, the brooks of Jabok, Kibon, Arnon, and other springs, which roll down from the adjacent mountains, yet it never overflows; this circumstance has led some naturalists to imagine that there is a subterraneous communication between this lake and the Mediterranean, or the Red Sea. But no proof of this kind has been discovered; nor, indeed, is it necessary to recur to any hypothesis of this kind; since it has been demonstrated by accurate calculation, that evaporation is more than sufficient to carry off the waters with which the lake is supplied. This evaporation is, in fact, very considerable, and frequently becomes sensible to the eye by the fogs with which the lake is covered at the rising of the sun, and which are afterwards dispersed by the heat. This lake is included on the east and west by very high mountains; on the north it is bounded by the plain of Jericho, on which side it receives the waters of Jordan; on the south it is open and extends beyond the reach of the eye. Josephus (Antiq. l. viii. c. 2. De Bell. l. iv. c. 14.) affirms this lake, the length of 580 furlongs, from the mouth of Jordan, to the town of Siger or Zohar on the opposite shore, or about twenty-two leagues; and a breadth of about 150 furlongs, or five leagues; but Mr. Maundrell (ibid supr. p. 84.) says, that it is twenty-four leagues long, and six or seven broad.

ASPHALTUM, in Minera, 376, denotes kind of bituminous stone, found near the ancient Babylon, and lately in the province of Neufchâtel; which, mixed with other matters, make an excellent cement, incorruptible by air, and impervious to water; this was supposed to be the mortar so much celebrated among the ancients, wherewith the walls of Babylon, and the temple of Jerusalem were cemented.

It yields an oil which defends from water, worms, &c. much better than the ordinary composition; and which is also of good service for the cleaning and healing of ulcers. See Mineral Plants.

ASPHLAX, in Artem. Geography, a nation of the island of Cythera, Steph. Byz.

ASP

Gen. Char. Cal. none; corolla one-petalled, fix-petalled; divisions lanceolate, flat, spreading; nectary, fix very small valves, converging into a globe, inserted into the base of the corolla. Stam. filaments fix, subulate, inserted into the valves of the nectary, bow; alternate shorter; anthers oblong, incumbent, rising. Pfl. germ round within the nectary: fylle fabulate, in the same situation with the lamens; stigma truncate. Per. capsule globular, flathy, three-lobed, three-celled. Seeds, several, triangular, gibbous on one side.

Species. 1. A. latius; yellow aphodel, or king's-spear, Jacq. Hort. t. 32. t. 77. "Stem leafy, leaves three-rib'd, flutitated." Root composed of flathy long thick tubers: flals round, fimple, about three feet high, and wholly covered with long triangular boat-shaped leaves. The upper part of the flalk is crowned with yellow fhar shapped flowers, which open in facection, about the beginning of June. Peduncles one-flowered, arising from the axilles of the bractes, which are membraneous, fmal, white. The corolla has a fweet flamm, and is fuch deeply holed as to fec to be monopetalous, and the divisions or petals are alernately narrower. It is a native of Sicily. 2. A. ramus; brachend aphodel. Villar's Dauph. 2. 265. Murray in Com. Gott. 1776. 37. t. 5. A. albus. Mill. Dict. n. 3. "Stem naked, leaves eniform, keeft, foomooth." Root composed of many tubers and fifbres; leaves long, flexible, fharp at the edges, growing in irregular clusters from the crown of the root; falks three feet high, fending off faked branches, from the upper part of which arife many flar shaped flowers, which are white, with a longitudinal purple line along the outside of each seginent. A native of the south of Europe. 3. A. fubflatus; onion-leaved aphodel. Gardn. Fruit. 1. 68. Goun. Hort. 174. "Stem naked, leaves fliff, fabulate, flutitated, fubfibfulhoic;" annual; roots conflit of many flifly yellow fifbres; leaves in a large cluster from the crown of the root, convex on their under fide, flat above and hollow. Flower flalks fife immediately from the root, and grow to the height of two feet, dividing towards the top into three or four branches, which are adorned with white flarry flowers, having purple lines on the outside; there come out in July and August, and their feds ripen in October. A native of the south of France, Spain, and the island of Crete. Scopoli has defcribed and figured another species, which he named aphodelus libanus; it has yellow pendulous flowers, freaked with five brownish lines, and has farron-coloured filaments. It was found in Itflia by Mygind. See Flor. Carn. n. 411. t. 12.

The three former species were cultivated by Gerard in 1596.

Propagation and Culture. The flirt species multiples very falf by roots, and will foon overfread a large border, if fuffered to remain undifturbed. The fcond does not increafe very readily by roots, nor fhould it be often transplant- fed, for that will weaken it; therefore the belt way is to propagate it by feds. These aphodels are pretty ornaments in a garden, and requiring very little trouble to culti- vate, are rendered more acceptable. They may be propagated by feds which fhould be foon after they are ripe, on a warm border of light fresh earth: in the fpring the plants will appear, when they are to be carefully cleared from weeds, and in dry weather frequently watered, by which means the plants will be in a proper flate to be transplant- fded the Michalmas following. A bed must then be prepared in the flower nurfery of fresh earth, into which you fhould plant the roots, at about six inches dilance, and fo deep that the top of the roots may be three or four inches under the surface of the bed; and some old tan or dung preated over the bed to keep out the froft. In this bed they are to remain one year, by which time the roots having acquired ftrong enough to produce flowers the following year, they fhould in autumn, when their leaves are decayed, be carefully taken up and transplant- fded into the flower garden, obferving to place them in the middle of the borders among other hardy kinds of flowers, where being properly intermixed, they will make an agreeable variety, and continue a long time in flower. The third fort is an annual, and can only be propagated by feds which fhould be fown in autumn, and not removed till they have put out four or five leaves, when they are to be transplant-fded into the places where they are to remain. If the feds of this plant are permitted to fcatter, they will come up without care, and those which are not removed will be the ftrongeft, and produce a greater number of flowers. See Martyr's Miller's Diét.

ASPICIA, in Medicine, a term which, in its literal fence, fignifies a want of palliation, being derived from a privative, and εἴς, εἰς, πάλιν. It is used to denote apparent death. Such fupffufions of the vital actions are referred by Cullen to apoplexy and syncope; but in the fystem of Sau- vages they confitute a diftinct genus, under the above name. The laft-mentioned nofologist has been too minute in his fubdivision of this, as well as of many other difeafes. The following appear to us to be the only legitimate species; viz. A. jafenifcras, apparent death from drowning; which fee. A. jafenifcras, apparent death from hanging; which fee. A. conglofcras, apparent death from exposure to extreme froid. This we fhall notice here, as the moft convenient place. In the northern latitudes, frequent fffiaces occur, during the winter feaon, of perons being frozen to death. Before this event takes place, they are fefed with a general numbness, and an irreffible propenfity to fleep, followed by fuppor, and infenfibility. In this ap- parently lifelefs flate they fìke for several hours, or even days, according to the infenfivity of the cold, and the previous condition of the body. They are, however, yet recover- able by proper treatment; which confists in taking off the perons's clothes, and rubbing the body all over with fnow, or dashing cold water upon it. The froid fhould be con- fìttued for many hours, until figns of life appear; when the patient fhould be wiped dry, and put into a cold bed, in a room without fire: he fhould have but few clothes upon him at first. When the power of swallowing is retorted, a fmall quantity of white water and water (two parts of water to one of wine) fhould be given in a tepid flate; but on no account any spirituous liquors, fuch as brandy, rum, &c. Afterwards he may have tea, with a large proportion of milk, increafing the quantity of nourishment gradually. He fhould avoid a heated room for a day or two, as well as all strong drinks and fleftioned food; orfetherife a fever, or dangerous local inflammati ons, will be excited. Travellers or others who are about to be exposed to extreme degrees of cold, fhould be cautioned againft the ufe of spirituous liquors, and every effort fhould be exerted by their companions to prevent them from falling afleep. For the treatment of partial injuries from fice, fee the article Frost-bitten. A. a carbone (A. carbonica, as we would term it), fuffocation from the fumes of charcoal, from the gas thrown out by fermenting liquors, &c. (i.e. fuffocation from the carbonic acid gas.) See Suffocation. A. a nephetidte (A. azotea), fuffocation from foul air or azotic gas. See Suffocation. A. nephe- tocras, apparent death of new-born infants. See Mid- wifery.

ASPIA, in Ancient Geography, a river of Italy, in Picen- num, north-call of Axumnum.

ASPIC, Fr. in Artillery, a piece of ordnance, weighing 4250 lb., and carrying a 12 lb. shot.
ASPIC, in Botany, a plant which grows in plenty in Languedoc, in Provence, and especially on the mountain of St. Baume, in France. It is a kind of lavender, nearly like what grows in our gardens; both with regard to the figure and colour of its leaves and flowers. The botanists call it *Lavandula mas*, or *lavea nardii, pseud耐ardus*, &c.

ASPIC, Oil of. See Oil of Spike.

ASPIDO, in Geography, a river of Italy, in the marquise of Ancona: it rises near Polverigro, and runs into the Mufon, a little above its mouth in the Adriatic sea.

ASPIDOPHORE, in Ichthyology, the name of a new genus of fishles in Lacépède’s arrangement. This genus is composed of two species of *Cottus*, in the Linnean system called *cataphractus* and *japonicus*, the former of which M. Lacépède names *Aphthophore armis*, and the latter *Pisophoros fissa*. See *Cottus*.

ASPI, in Ancient Geography, a powerful people of India, whom Alexander defeated in a pitched battle near the river Euphrates. He had previously crossed this river, as well as the Choe; and after the battle he passed through the territory of the Guri, and crossed the river Gurus, supposed by major Kennell to be the Kamb or Cabul river. This ingenious geographer conjectures, that the nations of the Alpi, Teveri, and Arafaci were inferior divisions of the modern Cabul, and situated between the rivers of Ghizni and Cabul, at the height of Ijab and Dukkah. Mem. P. 172.

ASPING, in Zoology, a name given by the inhabitants of Smoland to a venomous small snake, not more than six inches long, found in Oleri and Willow-holts, the bite of which is frequently fatal, and which is much dreaded by the Smolanders. It is the *Coluber Chersia* of Linnaeus, with 150 abdominal fena, and 34 subcaudal scales.

ASPIRAN, in Geography, a town of France, in the department of Journet, and chief place of a canton in the district of Lodove, two leagues north of Pezenas.

ASPIRATE, ASPIRATION, in Grammar, a character used to denote an aspiration.

The aspirate, by the Greeks called *spiritus aspirer*, and marked over their vowels, seems to be of a very different nature from the letters; but is nevertheless a true letter, as well as the reil, and a real consonant.—By letters we do not mean the characters of the alphabet, which are changeable according to the languages and the people, and among the same people, according to time and custom; and even according to the fancy of particular persons. Thus, fome, for instance, write the aspirates, or letters aspirated; which by others are omitted; though both the one and the other pronounce alike; as in *buona*, *buonini*, an Italian word frequently written *buomo*, *buonani*. But by letters we mean articulate sounds, marked by them, and formed by the organs of speech, viz. the throat, mouth, tongue, palate, teeth, &c.

These sounds are of two kinds, the one simple, and the other compound, or modified. *Simple sounds* are those pronounced by a single motion of the organ, such as the vowels. *Compound sounds* are those simple sounds modified by a motion of the organ, superadded to the motion necessary to pronounce the simple sound; of which kind are the consonants.

Now an aspirate is an effect or consequence of a motion made by some of the organs of speech; and therefore it must either be a vowel or a consonant. The former it cannot be, as not being a simple sound, or a sound that may be pronounced by itself. It must therefore be a modificative, or consonant; and in effect it has all the properties of one.

For, 1st. It results from a motion of the organ, which of itself produces no sound. Thus the *spiritus* of the Greeks, our *b*, aspirate, as well as that of the French, and other people, has no more found of itself, than *h*, *s*, *d*, &c; and the same thing may be observed of the *alph*, *beta*, and *epsilon*, of the Eastern languages.

2dly. On the contrary, our *b*, the *spiritus* of the Greeks, and the other aspirates just mentioned, are pronounced with all the vowels, in the same manner as consonants are. They modify those vowels, and are effects of a motion of the organ superadded to the motion necessary to form the vowel. Thus, to pronounce *ba*, two motions of the organ are required, as well as for *ba*, or *ca*, &c; one for *a*, which itself is a sound; the other for *b*, which yields no sound, no more than *h*; but adds something to *a* which modifies it, and makes that *ba* is not mere *a* nor *ba*, nor *ca*, &c; and this must hold still more sensibly in the stronger aspirates, as those of the oriental tongues *t*, *t*, *t*, *t*, &c. in all which there are evidently two motions, the one to express the vowel, and the other to modify it: now this being the nature and effence of a consonant, it follows, that let them be denoted in what manner they will, whether as our *b*, as the orientals do, i.e. by proper characters in the course of the words themselves; or, as the Greeks do some of theirs, by a sign of aspiration placed over the vowel, it matters not. The aspirate is no less a consonant in *w* than in *w*, in *h* than in *w*; and so of others.

The third and last reason urged by some, is, that the Eastern languages, which, according to them, do not express the vowels, do yet express the aspirates. This kind of argument seems, however, to be grounded on a mistake; since it is more than probable, that the *t*, *t*, of those languages, should be ranked among the vowels, and were to used.

Add, that the aspirate is frequently changed into a consonant, and expressed by a consonant. Thus of *t*, made *t*, of *t*, *t*, of *t*, *t*, *t*, &c. of the Hebrew *t*, *t*, and hence *t*, *t*, *t*, &c. Nay even in the same language, Hesiod, speaking of Hercules’s buckler, uses *f* for *t*, making no difference between *t* and an aspirate.

Hence it follows, that aspirates are real consonants; and that we ought not to exclude the *b* in our language, out of the number of letters.

Other grammarians contend, that the *b* is founded only by a strong emission of the breath, without any conformation of the organs of speech, and consequently is no letter. See H.

ASPIRATION, the act of aspirating, i.e. of pronouncing any syllable, or word, strongly, with a good deal of breath, and vehemence.

This we do, for instance, in those words which have the letter *b* before them; as *barangue*, *hock*, *Holland*, &c. whereas the like syllables are founded much more slowly and easily without the *b*; as in *ear*, *cat*, &c. See H.

ASPIS, in Ancient Geography, a town of Spain, north-west of Ilicis and very near it on the same river.—Also, a town of Africa Propria, in 33° 20’ N. lat. according to Ptolemy.—Another town of the same country, about 30° 20’ N. lat. according to Ptolemy. Strabo places it in the Greater Syrtis, and says it is the belt port of that coast.—Also, a hill or territory of Africa, in the promontory of Taphitis, according to Strabo. —Also, a town of the CARTHAGINIANs, called *Chypa*. A’dAnville thinks this to be the same with the former; but Ptolemy distinguishes them. —Also, an island of Africa upon the coast of Asia Minor, between Tenedos and Tars. It was called, according to Strabo, Arconneus. —Also, a promontory of Ethiopia, near Egypt.—An island in the vicinity
vicinity of the Cyclades.—Alloa, a town of Aïa, in Macedonia, founded by Philip, the father of Pericles. Steph. Byz.

Asphaste, a town of Aïa, in the country of the Siatae. Ptolem.—Allo, a river of Aïa in the same country.

Aspis, in botany, a species of Cyprinus, that inhabits the fresh water streams in most of the northern parts of Europe. Linnaeus in his Fauna Suecia, describes it specifically as having fifteen rays in the anal fin, and the lower jaw longer than the upper one, and recurved. It grows to the weight of twelve pounds; is blackish above, and bluish-white on the sides; feeds on vegetables, worms, and little fish; spawns in March; fleshy white, soft, fat, and well tailed. This is Cyprinus rapax ovatus subcom- prehens carullseus, &c. of Leef.; leucites argenteus, &c. Klein; and r rape of Gelm.

Aspledon, in ancient Geography, a town of Beotia, north-east of Orchomene, from which it was separated by the small river More.

Asplenium, in Botany, spleenwort (said to be derived from α and πες, because it was supposed to dry upon the spleen). Linn. 1. 1178. Schreb. 1651. Lingua cervina, trichomanes Tournef. Chuf., cryptogama filices. Generie Clar. Fructifications disposed in right lines along the under disk of the frond.

* Frond simple.*

Species, 1. A. rhizophyllum, root-leaved spleenwort. Phyllitis Pluk. Alm. 154. f. 105. f. 3. Morr. Hill. 3. 557. f. 14. t. 1. f. 4. "Fronds cordate-enform undivided, top folioform, rooting." Root fibrous; fronds triangular acuminate, point long linear; at the base hollowed, cared, on long footstalk; fructifications irregularly dispersed over the whole disk of the leaf in oblong spots; the ends of the fronds bent down to the ground, and there striking root. A native of North America. Introduced here by Mr. Bartram in 1764. 2. A. hemionitis, mule's-tongue spleenwort. Lour. Cochin. 677. "Fronds simple, cordate-elliptic, five-lobed, entire; flipes smooth and even." It rifes about six inches in height, and nearly resembles N° 3. (hart's-tongue), but the longitudinal diameter of the frond scarcely exceeds the transverse one; the flipes are slender and in tufts; the lobes of the fronds are sublinear, unequal; fructifications in oblique lines. A native of the south of Europe.

Introduced here in 1779. 3. A. foedoperidium, hart's-tongue spleenwort, Hud. 452. With. 3. 51. Lightf. 665. Curt. Lond. 1. 67. Bolton Fl. 18. t. 1. Woodv. Med. Bot. f. 272. The variates are 1. phyllitis crispa. Bauh. Hill. 9. P. f. Lingua cervina maxima, undulato folio auriculato per biform. Pluk. phyt. 2. Lingua cervina, multi- fido folio. Bauh. pin. 1. P. f. Lingua cervina minor crispa, fol. multiforme, ramuloso, Pluk. phyt. "Fronds simple, cordate-elliptic, quite entire; flipes bifurcate." Root black, hard, fleshy, furnished with numerous fibres; flipes and lower part of the mid-rib covered with ciliate scales; fronds from five inches to a foot long, and from an inch to two inches broad, lanceolate, rounded, and hollowed at the base, of a firm tough texture, and of a shining green on the upper side, and more or less waved at the edges; fructifications in parallel lines; these are at first covered with a pulvillus involucrum, which burrs when the capsules swell; they then appear globular and brown, and each is surrounded with a jointed elastics ring, by which the seeds when ripe are forced out of the capule and dispersed to a considerable distance. It grows commonly on old walls, rocks, and in shady lanes. This plant, like some others of the same genus, was formerly used to strengthen the venae, restrain haemorrhages, and alvine fluxes, expel gravel, and open obstructions of the liver and spleen; but its medicinal qualities are now little valued. It is one of those termed the five capillary herbs. 4. A. nidae, bird's-nest spleenwort; "Fronds simple, lanceolate, quite entire, smooth." Leaves two feet long, broad, thick, smooth, flarked; fructifications in parallel lines, extending one-third of the breadth of the leaf. It roots into the tops of trees; the leaves come out in a circle, and form a kind of umbel, in the middle of which birds make their nests. A native of Java and the Society Isls. 5. A. ferratum, ferrate-leaved spleenwort. Phyllitis, &c. Sloan. Jan. t. 72. n. 5. "Fronds simple, lanceolate, ferrate, tubificid." Root composed of brown fibres, which feed forth eight or nine fronds about three inches long, gradually broader near the end, which is formed into a blunt point. A native of woods in the inlands parts of Jamaica. 6. A. glaucescens, ferratulate-leaved spleenwort. Brown Jam. 92. "Fronds simple, orbate-lanceolate, subternate, leaf pedunculate," The fronds rise from a thick fibrous root to the height of ten or twelve inches, with an even margin and a smooth edge. A native of Jamaica. 7. A. lanceatum, lanceolate spleenwort. Thum. Japon. 33. "Fronds simple, elliptic, entire, smooth; flipes round, scaly." Stipe leathery, decumbent; lines of fructifications near the edge of the leaf, which is lanceolate. A native of Jamaica. 8. A. hirsutum, double-leaved spleenwort, Lingua cervina, &c. Plum. fil. 116. t. 153. "Fronds pinnate; leaflets lanceolate, subfusiform, connate." Fronds all double, or composed of two equal similar leaflets, united at the base by a common membrane; the common peduncle forks a very little above the base, and forms the mid rib. A native of South America.

** Frond pinna.***

9. A. teterata, common spleenwort, Hud. 452. Lightf. 661. Bolton Fl. 20. t. 1.2. "Fronds pinnae; lobes alternate, con fluent, obtuse." Fronds many, from three to six inches long; fronds of the third, short, broad, roundish, entire, about twenty pairs in a frond. This grows in similar situations to those mentioned of A. foedoperidium. 10. A. ovatifolium, blunt-leaved spleenwort, adiantum alis in若い, Pet. fil. 117. t. 2. f. 4. "Fronds subpinnae; pinnae obtuse, ininate, decurrent, alternate." A native of South America.

** Frond pinnae.***

11. A. nodosum, knotted-thalke spleenwort. Brown Jam. 93. Lour. Cochin. 678. Sloane Jam. 1. 85. t. 41. f. 1. "Fronds pinnae; pinnae opposite, lanceolate, entire." Above a foot and a half high, upright, smooth; pinnae long, oblong, frilled; fructifications in oblique, straight, parallel lines. A native of the West Indies and Cochinchine. 12. A. fulvescens, willow-leaved spleenwort. Luchitius, &c. Plum. Amer. 4. t. 6. Pet. fil. 116. t. 3. f. 1. Sloane Jam. 1. 78. 24. "Fronds pinnae; pinnae decipitate-lanceolate, crenate from the base upwards, angular." A foot high or more; pinnae alternate; middle pinnae largest, serrate at the edges. A native of Jamaica and the Antilles. 13. A. trichomanes, common maiden hair. Hud. 452. With. 3. 52. Bolton 22. t. 1.3. Woodv. Med. Bot. 204. Eng. Bot. 576. "Fronds about five or six inches long, lanceolate; flipes and rachis smooth, glossy, blackish, purple; pinnae fifteen or twenty pairs, the loweol most remote, of an irregular ovate form, largest below; terminal line oblique to the mid-rib, three, four, or five in number. It grows in the crevices of rocks and walls, and in shady places among stones. The leaves have been used in disorders of the breast proceeding from an acrimony of the fluids, and also to promote the expectation.
ASP

exsanguination of tough phlegm, and to open obstructions of the viscera. They are usually directed in infection or dejection, with the addition of a little liquorice. A syrup prepared from what is common in our shops, both as made here and imported from abroad; this latter has an admixture of orange-flower water. A little of these syrups, mixed with water, makes a very pleasant draught. 14. A. virile, green spleenwort. Hudson. 453. With 3. 52. Lightf. 653. Bolton Filt. 24. t. 14. Trich. colla viridis, &c. Rai Syn. 119. 2. Trich. ful. eleganter incis. Tournef. Inf. 539. t. 350. f. l. c. 5. Fronds pinnate; pinnas roundish, crenate, truncate at the base. Fronds eighteen or twenty pairs; leaflets sometimes alternate, rhomboidal, or trapizezium-shaped. It is found on rocks in mountainous situations in the north of England.

Froonds numerous, linear lanceolate, a foot high, often twisted; leaflets numerous, rather alternate, falcate; line of fructification fingle. The younger Linnaeus has confounded this plant with A. refeculum. A native of the Cape. 21. A. rota muraria, wall-rue, text-wort, white spleenwort. Hudson. 453. With 3. 53. Bolt. Filt. 28. t. 16. Eng. Bot. 150. "Fronds alternately decomposed; leaflets wedge-shaped crenate." Fronds three or four inches high, furnished at the end with two, or more commonly three alternate pinnas; they are broad, broad, and somewhat a rhomboidal figure; fructifications appear in two or three white dots on each side of the nerve. It grows on ledges of rocks and rocks. 22. A. altenfollium, alternate-leaved spleenwort. Jacc. Mifc. 2. 51. t. 5. f. 2. "Fronds simply pinnate; leaflets alternate, wedge-shaped, gash ferrate." Linnaeus regarded this as a variety of the preceding species, from which it differs in having the leaves more fimbriate, black at the base, with one or two short divisions only, having three leaves lobed and two-lobed; the other leaves are foliar: in the lower part of the leaf are two or three lines of a longish form. A native of Switzerland and Austria. 23. A. lapidarium nigra, black maidenhair. Hudson. 454. With Bolt. 30. "Fronds subtriangular, leaflets alternate, pinnas lanceolate, gash-ferrate." Fronds eight or nine inches high, their outline triangular; fronds glossy, black, or very dark red; pinnas alternately pinnate. It grows on ledges of rocks and old walls, and among thorns and shady places. 24. A. lanceolatum, lanceolate spleenwort. Eng. Bot. 250. Hudson. 454. With 3. 54. A. trichomanes ramusum. Lith. Sp. Plant. "Fronds doubly pinnate, lanceolate; pinnas obovate, crenate; root crowned with tufts of long narrow dark scales." Fronds in size and habit somewhat like pol. fragile; pinnas lanceolate, lobed above; pinnule and lobes obvate, veiny, sharply crenate or toothed. Found on the great rocks at Tunbridge, and in Fawai one of the Azores. by Porter. 25. A. margination, margined spleenwort. Pet. Filt. 168. t. 12. f. 2. Plam. 88. t. 168. "Fronds pinnate; pinnas opposite, ciliate-lanceolate, submarginate, entire." A native of South America. 26. A. jepunsum, falcate-ferrate spleenwort. Pet. Filt. 112. t. 5. f. 2. Plam. Filt. 86. t. 153. "Fronds pinnate; pinnas acuminate, gash ferrate." A native of South America. 27. A. ginteri, falcate fringed spleenwort. Phil. Filt. 15. t. 19. 19. "Fronds pinnate; pinnas pinnatifid, obtuse, crenate, the terminal one cinnate. A native of South America. 28. A. trifrons, divided spleenwort. Brown. Jam. 94. Shorr. Jamb. 73. t. 33. f. 2. "Fronds pinnate; pinnas trapezium-shaped, tridented, crenate, crenate at the base. From fourteen to eighteen inches high; pile black, simple; leaves pointed, and appearing as if torn at the margin. A native of Jamaica. 29. A. japonicum, Japonese spleenwort. Thum. Jap. 134. "Fronds pinnate, pinnas acute, gash-pinnatifid, serrate; pile falcate. Stipe compressed, furrowed, falcate at bottom, two feet high; pinnas opposite, ciliate, lanceolate. Lines of fructification approximating. A native of Japan. 30. A. ref. falcata, half-leaved spleenwort. Smith ic. inf. 3. 72. "Fronds pinnate; pinnas trapizeum-shaped, acuminate, gash-ferrate." Frond lanceolate, a foot high; leaflets numerous, alternate, subfalcate, an inch long, entire at the base, and along the hinder edge, and appearing as if cut off at the nerve in front, and at the tip, unequally gash-crenate, veined; lines of fructification two or three. Found by Commeron in the isle of Bourbon. 31. A. bulbifera, bulbous-rooted spleenwort. Lour. Coch. 679. "Fronds pinnate; pinnas lanceolate, slightly crenate; root bulbous." A foot high, diffuse; fronds fimbriate, thick, tuberced, recurving; leaflets smooth; fructification in oblique parallel lines. A native of the mountains of Gochnia, where the roots are eaten.

The following eight species are from Swartz.

ASP

Swartz 130. "Fronds tripinnatifid; pinnae somewhat wedge-shaped, pinnales crose, toothed at the tip. 39. A. cicutanum. Swartz 130. "Frond tripinate, very smooth, the upper one pinnatifid, leaflets lanceolate, entire." The last leaf species are natives of Jamaica.

The following species are from Forlir, and are all Natives of New Zealand.

Propagation and Culture. Whoever is deficient of cultivating any of these trees, must have walls or rocks or heaps of stones to set the hardy species in, or pots may be filled with loamy unduged earth, or sand gravel and lime rubbish for that purpose, placing them in the shade. In the winter, the trees have been raised from seed; but all the forms may be increased by parting the roots. Some of the foreign species must be placed under a common frame in winter; and it is evident that such as are natives of the West Indies and other hot climates, require the protection of a stove.

ASPOLEM. See ACROSICHUM, and MENISCIUM.

ASPOE, in Geography, a small island in Sweden, in the Baltic, two miles south-west of Calferton.

ASPQNA, in Ancient Geography, a municipal town of Asia Minor, in Galatia, in the road from Ancyra to Celfarea, according to Antoine’s itinerary.

ASPQRENUM, a district of Asia Minor, near Pergamus; which, according to Strabo, was baren and rocky, and in which was a temple dedicated to the mother of the gods, called Aphorene.

ASPOTAGOEN MOUNTAIN, in Geography, a high land in America, that lies on the promontory which separates Mahone from Margaret’s bay, on the coast of Nova Scotia. This land, which is seen at a diatance, is that which is generally made by the tides from Europe and the West Indies to Halifax. Its extremity is about 300 feet above the level of the sea.

ASPA, a town in Italy, in the territory of the church, upon the river Aja, between Tivoli and Terni. It was formerly in the district of the Sabines, and called Calpernia, and Capirola.

ASREDO, in Ichthyology, a species of Sillurus that inhabits the rivers in America. This kind has a single dorsal fin, with five rays, and has eight cirri. Gilmar. The back is ciliated, and the tail forked. Klein names it Bara-bus.

ASPRELLA, in Botany. See LEERSIA.

ASPREMON, in Geography, a town of France, in the department of the Meuse, and chief place of a canton in the district of St. Michiel, four miles south-eat of St. Michiel.

ASPREN LEVAYNES, a town of France, in the department of the Higher Alps, and chief place of a canton in the district of Serres, fifteen miles west of Gap.

ASSPR, a river of European Turkey, which runs into the sea, twenty-eight miles west of Lepanto.

ASSPRONISI, formerly Automatic, a small island of the Archipelago, which, by some convulsion at a former period was separated from Thera, now Santorin. This separation is said to have happened 237 years before the Christian era. The coast of the gulf between these two islands, composed of these rocks, black, calcined, and towering upwards of 300 feet above the level of the sea, appears to be the edge of an enormous crater, the bottom of which has never been fathomed. Asspronisi is rent internally, and covered with pumice stone; whence it has obtained the name of the White Island, which it now bears. Solimani’s Travels in Greece, &c. p. 188. Olivier’s Travels in the Ottoman empire, p. 169.

ASSPROTI, a small town of European Turkey, in Livadia, upon the gulf of Lepanto.

ASSPOTAMO, a river of the southern part of Greece, has its source in Mount Mezzovo, and discharges itself into the Ionian sea.

ASSPROPIA, in Ancient Geography, a town of Africa Propria. Ptolem. ASSPUNITANI, a people of Asia, near the Palus Meotis. Strabo. ASPURGIANI, a barbarous nation about the Bosphorus. Strabo. ASS, Afinus, in Zoology. See ASINUS. ASS’s Mill. See MILK. ASS Bus, in Geography, lies on the south coast of the island of Newfoundland.

ASS, Cucumber. See MAMORDICA. ASS, Feast of the, in Eckes’s History, a festival which was celebrated in several churches of France, during the dark ages, in commemoration of the Virgin Mary’s flight into Egypt. On this occasion a young girl richly dressed, with a child in her arms, was set upon an asf richly caparisoned. The asf was led to the altar in solemn procession, and high masses was said with great pomp. The asf was taught to kneel at proper places: a hymn no less childish than impious was sung in his praise; and when the ceremony was ended, the priest, instead of the usual words with which he dismissed the people, brayed three times like an asf; and the people, instead of their usual repique, “We blest the Lord,” brayed three times in the same manner. This was an act of devotion performed by the mufflers of religion, and by the authority of the church. However, as this practice did not prevail universally in the catholic church, its absurdity contributed at last to abolish it. Du-Cange, Vec. Feltum.

ASSA, in Geography, a town of European Turkey, in the island of Cephalonia, sixteen miles N.N.W. of Cephalonia.

ASSABA, in Botany, the name given by the people of Guinea to a shrub which they are very fond of for its medicinal virtue; they boil it in water, and rub it on a bula, and it proves a cure. Phil. Trans. N. 232.

ASSABENIS, in Ancient Geography, an episcopal see of Africa, in Numidia.

ASSABET, in Geography, a river of America, which rises in Grafton, Worcester county, Massachusetts, and runs north-east into Merrimack river.

ASSACANI, or ASSACENI, in Ancient Geography, a people of India, who inhabited a country situated between Baxira, now Bijuco, and Pucellatiss, corresponding to the present Puckholl. The government of the country, when Alexander
Alexander invaded it, was possessed by a woman, as Plutarch, Curtius, and Justin agree: she was, as they say, the wife of Ahascenus, and, according to the latter, her name was Cleopha. The Ahasceni, when they were attacked by Alexander, had, according to Arrian, (l. iv. c. 24, 25) 20,000 horses, 30,000 foot, and 30 elephants, ready to take the field. Their capital was Malsanga, called by Curtius Mazaga, by Strabo Magoga, and by Diodorus Maffana, which Alexander took by assault, though he was wounded on the occasion, and repeatedly repulsed; and he then proceeded to summon Bazira, the capital of the next adjoining territory. After the capture of the rock Aornus, Alexander made a second expedition into the country of the Ahasceni, in order to get possession of some elephants which were so fierce that they might not fall into his hands. These elephants were at last found in the pastures near the Indus, and sent off by land to the grand army. The country of the Ahasceni, afterwards called Ahasnagar, answers, says major Kennell, (Mem. p. 173.) to the present Seward or Sowand; or at least Seward was one of the divisions of Ahasnagar. See Ahasnagar, and Seward.

ASSACH, or ASSATH, in Antiquity, a kind of purgation, anciently used in Wales, by the oaths of three hundred men. It was abrogated by 1 Hen. V. c. 6.

ASSACH, in Zoology, the name by which some Arabic writers call the lion.

ASSA-DULCIS. See Asa-Dulcis.

ASSAFA, ASSAFENSIS, in Ancient Geography, an episcopal see of Africa, in Mauritania Sitifensis.

ASSA-FETIDA, or ASSA-FETIDA, in Pharmacy, (Tauffriz's Drecx, Germ. (Devil's Dung.)

This curious and valuable article of the Materia Medica is a gum resin procured from the root of a large umbelliferous plant, growing in the mountains of several provinces in Peræa, and on the borders of the Peræan gulf, and called in the language of the country kingfish. For the botanical description of this plant, see Ferula Affa-Fetida.

The affa-fetida is brought over in masses of various size and form, of a yellow brown, or bluish colour, intermixed with roundish pieces white in the inside, which are the affa-fetida in tears, and the purest.

The taste of this gum is bitterish, acid or biting, and very permanent on the tongue; when chewed, it becomes plastic, and soon dissolves in the saliva into a white milky liquid. Assafetida is principally distinguished as its name imports) by its exquisitely strong fetid smell, somewhat resembling that of garlic; which is extremely diffusible and permanent. The odour, however, is not of a sickening or very oppressive quality, and so readily can the organs be accustomed to it, that this gum makes a favourite feconizing for food in many countries of the East.

By chemical analysis, assafetida is found to consist of an essential oil, a resin, and a gummy substance, so that it is with great propriety reckoned among the gum resins. Trommsdorf obtained about fifteen or sixteen grains of essential oil from an ounce of the gum, which in one experiment swam upon the water with which it was distilled, and in another partly sank to the bottom. The remaining gum yielded 1 08 grains of resin, and 292 grains of gum. The analyses of Neuman and Carlebuer exhibit the same ingredients, but in different proportions. Both spirit and water distilled off this gum resin are strongly impregnated with its ungrateful odour. If assafetida be digested with warm water, the liquor presently whitens, and by long standing the whole is reduced into a soft pulp mass of a dirty yellow, owing to the solution of the gummy part. By trituration with water, this gum is entirely dissolved into a milky liquor which remains uniformly turbid for a considerable time. It is partly soluble in expressed oil, but scarcely so in the effential oils.

The following curious and authentic account of the method of collecting the assafetida is given from ocular testimony by Kämper, who visited the country in the year 1697. The plant which yields this valuable gum resin (and called in Peræa kingfish) is found abundantly on the mountains around Heraut, the capital town of the province of Chorasan, and in the province of Laar, which extends from the river Cuur to the town of Congo on the Peræan gulf. Beyond this, on the Arabian fide, the plant is said to lose much of its strong odour and acid quality, so that goats browse upon it with great delight and advantage. The richer the soil, the more valuable is the gum. The principal harvest of this substanee is made on the mountains around the small town of Dísguam, in the province of Laar.

The root of the kingfish grows for many years increasing in size, till sooner or later it lends forth the flowering umbelliferous stem, after which, on the succeeding year, the whole plant perishes. The crop of gum thereon is procured from the root before the time of flowering. When the root is four or five years old, the thickest parts of it, and of considerable length; it seldom yields any gum before this age, and the older it is, the greater is the quantity of product. The root is heavy, smooth externally, when growing in a rich soil; but scaly in a sandy one. It is often found bifurcated or further divided at about a foot below the surface. The upper part, which rises above the soil, is thickly beset with short fibres standing up like hairs. The kind of the root is easily separable when fresh, the substance within is smooth and moist, consisting of a tough fibrous part, including a pulpy cellular portion, full of an oily white juice, of a most intensely fetid smell, which when exposed to the air becomes first clammy and yellow, and at last hardens into the gum assafetida. The intensity of the smell is the test of the goodness of the gum, and the odor of the fresh juice or recent gum is beyond all comparison more fetid than that of the gum as it is received by us. Hence in the gathering season, the whole town of Dísguam smells of it; a single ship is exclusively devoted to transporting the bulk of this commodity to the ports in the Peræan gulf; and in carrying smaller parcels they are tied to the top of the mast to prevent their infecting every thing on board. In a short time, however, this intensity of smell goes off.

The whole gathering of the assafetida is performed by the inhabitants of Dísguam in four different journeys to the mountains. The demand for the article in foreign countries being first ascertained to be sufficient to indemnify the trouble of collecting, the gatherers divide into companies of four or five each, and proceed to the mountains about the middle of April, when the leaves of the plant are turned yellow and decaying, a sign that the root is in a proper state to yield the juice. The first operation is to remove the foil for a hound's breadth from the plant, and to strip off the leaves and the hair-like leaves, leaving the root perfectly bare and smooth, which is again earthed round and covered with a bundle of its own or any other leaves at hand, to screen it from the sun. These bundles of leaves are confined by a large stone, left the wind should blow them off; for without this precaution, the heat of the sun would destroy the roots in a day's time, and the juice would be spoiled. Each party of four or five men take to themselves about two thousand plants, and when several
myriads of roots are thus prepared, the whole company return home.

In about forty days, or towards the end of May, the parties return to the mountain, arriving there at day break. The implements they employ are a sharp knife for cutting the root, a broad and flat iron scoop for scraping off the dried juice, a small pan fastened to the thigh for receiving the contents of the scoop, and a double basket suspended at each end of a pole which is slung across the shoulders in order to carry the whole crop when they return home. They now uncover the root, remove the earth to a little depth from the top, and with the knife they cut off a small transferve slice. The root, in which the juice that has been collecting for forty days, has been made to flagrant by the previous operation of stripping off the boughs, now bleeds copiously; and it is immediately again covered with the umbrella of leaves as before, taking care that these do not actually touch the surface of the root and rub off the juice. On the ensuing day it is sufficiently concreted to be scraped off, after which another very thin slice is cut off from the surface of the root, which bleeds afresh, and is allowed time to concretize as before. This process is performed on half the roots on alternate days, that the employment of the gatherers may be more uniformly divided. After this collection has been twice made from each root, a third slice is cut off, the root is covered with its umbrella, and the whole company leave the mountain bringing home their first harvest, which to each party of five or six men is about fifty pounds weight of afaesfetida. This first gum is reckoned of rather inferior strength to the subsequent crop, and is called 

In about ten days the company again return to the mountain, making their third excursion, and they find on the top of each cut root a quantity of very fine and pure afaesfetida, which having bled time to concretize very slowly, is esteemed the best and most powerful, and is called Pipsas, and sells at a much higher price than the Sär. This latter, however, appears chiefly to owe its inferiority to a quantity of earth with which the gatherers adulterate it while yet in a very soft and semifluid state, whereas the Pipsas being concreted into a hard gum is not liable to this abuse. After this latter is collected, two more successive incisions are made, the juice is scraped off as before, the root is again cut and covered over, and the company return home.

The fourth and half excursion is made after an interval only of three days, for the root, which is exhausted by so many repeated bleedings, is now on the point of perishing. The Pipsas, or first croping, is again collected, and the root will bear about two or three more incisions, after which it is quite exhausted, and is left to die by the heat of the sun, which happens in a single day. Each root of the four-year-old plants will bear ten or eleven successive cuttings, but the large roots of twenty years standing or upwards, such as are sometimes found in the less accessible parts of the mountains, will yield the gum much oftener, though not with such ease, that the harvest from these is not limited till about the end of December. It is not quite ascertained whether the ancients were acquainted with this gum reja. Some authors have supposed it to be the 

A plant, however, was so different from that given by 

In many parts of Arabia and Persia it forms an important article of the Materia Medica, and is employed largely as a condiment for food. In its native country, the common people resort to it as a sovereign remedy for dropsy, flatulent and colicky pains in the bowels, and even as an external application to wounds. In the above disorders, its strongly stimulant and antispasmodic power renders it peculiarly valuable, but the factor which transpires from the bodies and evacuations of those that use it is so excessive, as to be almost intolerable even to the organs of the natives. The Banian Indians, who not using animal food, have always recourse to the strongest and most acrid condiments, employ afaesfetida liberally in their cooking, and even rub their mouth with it before meals to stimulate their appetite.

Another use common to this, as to all other stimulating and heating substances in the East, is to excite the venereal appetite.

With us, afaesfetida is considered as a most powerful nerve, antispasmodic, carminative, and antichymic, though the potency of its odour, in which probably consists a large proportion of its medical virtue, prevents its use in a variety of cases in which it might prove highly beneficial. It is of the greatest service in hypochondriac affections, in which the state of the bowels is always torpid, and digestion liable to be deranged. For the true typhoid, a Clyster of two drams of afaesfetida dissolved in water, thrown up once or twice a day, is an excellent remedy. Dr. Millar has introduced the use of this gum with great effect against the spasmodic asthma, and the spasmodic state of hooping cough. The dose of the solution, even to children, should be large; and it is worthy of remark, that the difficult excited by so strongly afaesfetida a remedy is much sooner surmounted than might at first be imagined, nor, when it is in the stomach, does it ever excite colic. The flatulent colic attending lytic affections is much relieved by this gum, exhibited either by the mouth or in gyllers. On account of its heating quality, it should be avoided when general fever is present. The vermifuge property of this gum appears to be very considerable. Kämpfer relates, that the leaves and stalk of the fresh plant in Peria, are laid in the channels through which the water runs for irrigating gardens, and that fruit-trees and plants are thus preserved from all kinds of vermin. Probably its penetrating odour much incommodes these animals; and it has long been known both in the East and in Europe as a very powerful aetherthetic, especially when combined with the stronger purgatives, or given in the form of gyller, and followed by them.

Hufeland has employed this gum internally as a very good remedy in venereal exfoliosis, and carries of the bone; after the constitution has received as much mercury as it will bear. Afaesfetida enters into some of the compound plasters for external application, and in this combination is reckoned to be stimulant and refolvent.

The pharmaceutical preparations of afaesfetida in actual use, are the following:

Lac Afaesfetida (P. Lond.); a milky solution of two drams of the gum in half a pint of water, formed by the assistance of triturating.

Tinctura Afaesfetida (P. Lond.); made by adding two ounces of afaesfetida to a pint of rectified spirit of wine. The fame in the Edinburgh Pharmacopoeia, but a quarter of a pint more of the spirit is used.
Rectified spirit is employed, for the dilute or proof spirit, though it dilutes none of the gum, makes a turbid solution; whereas the mixture with the former spirit is quite clear. It may be given in doses of from ten to fifty drops. The tinctura Furtuniv of the former Pharmacopoeia, now diluted, was made with wood foot, aaffact[a], andproof spirit; but the foot is properly omitted, as it does not appear to add to the virtue of the medicine, and needlessly increases its nauseous odour.

Spiritus Ammonis furtuniv (P. Lond. and Ed.), prepared by distilling the spirit of ammonia with aaffact[a], whereby it is strongly impregnated with the peculiar odour.

Pilule Gallini composita (P. Lond.), composed of several heating and gravulent gums, viz. galbanum, opoponax, myrrh, fagacanum, and aaffact[a]. The proportion of the latter is one-ninth of the whole.

Pilule Afe-jeftulice composita, formerly Pilule gummosae (P. Ed.), composed of aaffact[a], myrrh, and galbanum, of each one ounce, and one drachm of oil of amber.

Empiroytrum Af-ejeftulice, formerly Empiroytrum anhydricum (P. Ed.), composed of lithege platter and aaffact[a], of each two parts, and of yellow wax, and strained galbanum, of each one part.

The smalln of aaffact[a], and along with it its peculiar virtues, are liable to be lost and injured by long and careless keeping, but a considerable latitude may be allowed in the doing, without much danger of rilk or injury to the patient.

ASSAIL, in Geography, a town of Japan, in the province of Oomi or Orii.

ASSAI, in Italian, is an adverb of augmentation generally in the imperative degree, which is added to another verbal term to increase its force: as Princo aaffari, Algo aaffari, very quick; Large aaffari, very few.

ASSAILANT, one that aaffaults or lets upon another. See Assault.

ASSAM, in Geography. See Assam.

ASSAN, a town of Aia, in the province of Diarbekir, forty miles from Diarbek.

ASSANCale, a strongly fortified town of Armenia, on the river Aras, surrounded with walls, and guarded by towers and a garrisoned citadel, in the road to Erzerum, and a short day's journey from it. It has hot-baths that are much frequented.

ASSANUS, in Ancient Geography, now Iser, a river of Africa, in Mauritania Cæsariensis, which by its junction with other rivers formed the ancient Sig, or present Tafna.

ASSAPOOR, in Natural History, a name given by the people of the East India to a peculiar species of flathe, which they used in medicine, reducing it to powder, and stewing this on burning coals, that the flesh perfon may receive the fumes of it. It is principally used for children, when they are disordered by taking cold. The smell of it while burning is very offensive.

ASSAR, in Geography, a river of Abyssinia, which is the southern boundary of Aroos, as Kelii is the northern. This is the largest river which Mr. Bruce saw, except the Nile; it was about 150 yards broad, and two feet deep, running over a bed of large stones, though generally through a flat country; its course is rapid, and after much rain it is scarcely passable, owing to the height of its source in the mountains of the Agows. Its course where Mr. B. forded it, was from south to north; but it soon turned to the north-east, and, after flowing five or six miles, joined the Nile. Below the ford is a cataract above twenty feet high, and eighty broad. The whole river falls in an undivided sheet of water with incredible violence and noise; but below this cataract it becomes much narrower, till it loses itself in the Nile. Bruce's Trav. vol. iii. p. 502.

ASSARA, in Ancient Geography, a river of Africa in Mauritania Cæsariensis, Ptolemy.—Allo, a place of Aias, in the department of Melopotamia. —Allo, a river of Asia, which discharges itself into the Mediterranean, in the gulf west of the great promontory, Ptolemy.

ASSARABACCA. See Assarabacca.

ASSAR ACE, in Ancient Geography, a people of Africa, in the interior Libya, placed by Ptolemy east of mount Arunga.

ASSARIUM denotes a small copper coin, being a part or diminutive of the a.

The word is used by Suidas indifferently with sps, and sps, to denote a small piece of money; in which he is followed by Cujacius, who defines sps, sps, by minimus ari nummus.

The aaffarium, or imperial a, was worth one half-penny English. This division of the a began to be called aaffarium as soon as its fize was reduced to half an ounce, and it was then always struck on copper. Its fize regularly corresponded to that of the dupondius, and declined till at the clofe of the reign of Gallicius, it became what is called small brâs, and weighed only about the eighth part of an ounce. In the time of Diocletian, it was about the twentieth part of an ounce; and in that of Justinian, it was the fame with sps, sps, or the smallest coin excepting the sps, sps. The Greek aaffarium kept pace with the Roman. Pinkerton's Eff. on Medals, vol. i. p. 121.

We find mention of the aaffarium in the gospel of St. Matthew, chap. x. ver. 29.

ASSARLI, in Geography, a town of European Turkey, in the province of Romania, forty-four miles E. S. E. from Filippopoli.

ASSARON, an ancient Jewish measure of capacity, equal to the tenth part of the ephah. Exod. xvi. 16.

The aaffarium is the name with what is more frequently called omer, or gomer.

Josephus calls it sps; in the Hebrew it is alfo written aaffhr, Calmet and Arthusnot.

ASSART, ASSARTUM, (derived either from aaffartir Fr. to make plain, or as Spelman supposes fromavgart, pulled up by the roots, for it is sometimes written aaffart), in Latin, an offence committed in the forest, by pulling up by the roots, woods which serve as thickenets and covert for the deer, and making them plain as arable land. This is the greatest trepifs that can be committed in the forest, being more than a waife. For whereas waife of the forest is but the fellowing and cutting the covert, which may grow again; aaffart is a total extirpation. What we call aaffartum, is else where termed deflocaatio.

ASSART was alfo used for a parcel of land aaffarted. See Essart.

ASSART- rents were thofe formerly paid to the crown for forest-lands aaffarted. Stat. 22. Car. ii. c. 6. See Rent.

ASSAS, in Ichthyology, a fpecies of Balistes that inhabits the Red Sea. The body is margined with brown spots; and a triple row of black ones on the tail. Forik. Arab. Length about six inches, brown, belly, white, vent black surrounded by a fulvous ring. The flesh of this kind is eatable but insipid.

ASSASSINS, in Ancient Geography and History, the name of a people of Phoenicia, who inhabited the mountains of Libanus, to the north-east of the city of Tyre, and who pretended to derive their origin from the family of the Arfacidæ.
Arfacidæ, the founders of the Parthian empire. To a corrup-
tion of Arfacidæ into Assailsins some have ascribed the
tymology of the appellation by which they were distingui-
shed; whilst others suppose it to have been formed from
Isháfin, in reference to the poniard, which was their cu-
tomary weapon. It is said that they were a sect of Maho-
metans, who arose in the year 891, when Carmat, or Karmat,
a pretended prophet in Arabia, drew after him many follow-
ers. He failed, and laboured with his hands, and prayed fifty
times a day. He promised to re-establish the family of
Ali, and to dethrone the caliphs. He released his disciples
from the most troublesome observances of their religion,
permitting them to drink wine and to eat any kind of food.
By this indulgence, joined to the hopes of plunder, he col-
lected a great army, and ravaged the dominions of the
caliphs. This Carmat had a series of successors, of whom the
most famous was Abu-Thahir or Abd-Adher. Their
Carmatians, or Karmathians, being enfeebled, kept their
religion concealed, mixed themselves with the Mahometans,
and were dispersed over various parts of the eal. About
the year 1090, they were settled in Persia; where Hacen, or
Al-Hafan their chief, receiving a threatening message from
the sultan, commanded one of his subjects, in the presence
of the messenger, to fling himself from the top of a tower,
and another to kill himself, which they infamously performed.
Upon which Hacen said to the messenger, "Tell your
master that I have 70,000 men ready to do as much." In
Persia and Syria, they were denounced Ismaelians; and
among the hills to the south of the Calpian, these odious
factories maintained their power for nearly two centuries.
Their prince, or Imam, exalted his lieutenant to lead and
govern the colony of Mount Libanus, fo famous and fo forfe-
itable in the history of the crusades. They had acquired
or founded ten castles in the hills above Tortos, and poifef-
scd several cities about Tyre. As these crusaders had not
feffed themselves of the belf part of Al Jbel, in the Persian
Irak, under the conduct of Al Hafan Ebn Masbah, or Al
Hafan Sabah, as he is sometimes called, the commencement
of the dynasty of the Ismaelians is generally placed
at this period, or the year of the Hegira 483, A.D. 1090.
The style or title adopted by these princes was "Sheikh Al
Jbel," that is, the prince of Al Jbel; or "the chief of the
mountainous country;" the province of Al Jbel being such a
country, and from this circumstance deriving its modern
name, "Kuhellan or Choufilian?" the words "Sheikh
al Jbel" may likewise be properly rendered "the senior,
or old man of the mountain," and hence the chief or prince
of the Assailsins has obtained the appellation of "the old
man of the mountain," amongst the writers of the history of
the Holy Wars. Al Hafan Ebn Masbah and his descendants
reigned in Al Jbel 171 years, till the whole race of them
was destroyed by the Tartar Hulaku, or Holagou Khan,
the grandson of Zingis, or Jenghis Khan, who abolished
the caliphate by the destruction of Bagdad, in the year of the
Hegira 656, A.D. 1258. Gibbon says that the Ismaelians of
Syria were extirpated by the Mamalouses about the year 1280.
Not a vetige is left of these enemies of mankind, whose
draggers have been felt both in the east and the west, except
the term assailsin, which, in the most odious sense, has been
adopted in the languages of Europe. With the fanaticism
of the Koran, the Ismaelians had blended the Indian trans-
migration, and the visions of their own prophets; and it
was their delight to devote these fohus and bodies in blind
cadence to the vicar of God. Such was the ascendency
which their prince had acquired over his debased and fan-
tactical subjects, that they paid the most implicit deference to
his commands; exalted assailsin meritorious, when
fanctified by his mandate; courted danger, and even certain
death, in the execution of his orders; and fancied, that
when they sacrificed their lives for his sake, the highest joys
of paradise were the inducible reward of their devoted obe-
dience. It was the custom of this prince, when he imagined
himself injured, to dispatch secretly some of his subjects
against the aggressor, to charge them with the execution of
his revenge, to instruct them in every art of disguising their
purpose; and no precaution was sufficient to guard any
man, however powerful, against the attempts of these subtle
and determined ruffians. The greatest monarchs flowd in
awe of this prince of the assailsins; and in 1192, Conrade,
marquis of Montferrat, a zealous crusader, fell a sacrifice to
his resentment. The prince determined to avenge the death
of some of his people who had been murdered by the inha-
bbitants of Tyre, then under the government of this noble-
man, employed two of his subjects for the execution of his
purpose. Those men intimated themselves in disguise
among Conrade's guards, and openly, in the streets of
Sidon, wounded him mortally; and when they were feized
and put to the most cruel tortures, they triumphed amidst
their agonies, and rejoiced that they had been defined by
heaven to suffer in a caufe so just and meritorious. The
prince of the Assailsins himself avowed the action in a formal
narrative which he sent to Europe. In 1173, a prince of the
Assailsins in Phœnícia, sent a deputy to the king of
Jerulalem, declaring himself and his people inclined to re-
ceive the Christian religion; but the knights temples affa-
linted the deputy on his return home, and the king was
unable to chastise or restrain them. In 1213, Louis of Ba-
varia was murdered by the Assailsins. The followers of these
Assailsins were condemned by the council of Lyons, under
Innocent IV., in 1231. Hunt's Hist. vol. ii. p. 178. Gibb-
Assailsins, a denomination which distinguished a faction that sprang from the followers of Judas of Galilee,
in the Jewish war that preceded and succeeded the destruc-
tion of Jerusalem. The head of this faction was Eleazar,
the grandson of Judas the Gaulonite. For their fate at the
siege of Massada, which terminated the Jewish war, see MA-
SSADS. As those who had previously escaped, some fled
to Alexandria, where they were at first kindly received by
their brethren; but as they excited sedition and tumult,
they were delivered up to the Romans, and 600 of them
put to death. An order was also issued for shutting up the
Jewish temple at Alexandria, and the worship of it was dis-
continued. See GAVOLONITES, and SÉALOTS.
Assailsins, in Law, a person who kills another with the
advantage either of an inequality in the weapons, or by
means of the situation of the place, or by attacking him at
unawares. For the etymology of the term, see the pre-
ceding article.
There was a certain law of nations, an opinion received
in all the republics of Greece and Italy, whereby he that
assailsin an usurper of the supreme power, was declared
a virtuous man. At Rome, especially after the expulsion
of the kings, the law was formal and solemn, and influenc-
es of it admitted. The commonwealth armed the hand of any
citizen, and created him magistrate for that moment. Confid.
for les Caud. de la Grand. des Rom. chap. xi. p. 121.
Assailsins' Bay, in Geography, lies on the south-east
coast of New Zealand, in the south Pacific ocean.
Assault, formed of the Latin afflire, to roof, the
preparing or derriving foods, or medicaments, in their own
juices, by an external heat, without addition of any foreign
moilure. Assault, in respect of culinary matters, is more
frequently
frequently called roasting; and in pharmacy, utlron, or torrefaction.

ASSAULT, in the Art of War, signifies a general attack made by a besieging army, to become masters of an intrenched camp, fort, or fortresses. In the latter case it is particularly understood to take place without the advantage of any works to screen the assailants from the fire of the garrison.

Anciently, siege-tactics were yet in their infancy, and the art of besieging places bore comparatively no proportion to that of defence, we rarely meet with instances of walled towns entered by assault. A close blockade was generally the measure referred to, and the garrison were slowly dis- tressed, and the patience of the besiegers exhausted, by circum- valuations supported for years. The sieges of Azotus by the Egyptians, of Nineveh by the Medes and Babylonians, and of Babylon by Darius Hyrrapex, where treachery alone prevented a resistance equally tedious with that of the two former places, are evidences of the almost insuperable difficulties attending the reduction of strong holds in earlier days.

The Greeks, previously to the era of Alexander, had very imperfect notions of assaulting towns. The Carthaginians first demonstrated the possibility of shortening sieges by a summary expedient of reiterated and furious attacks. Thus they became masters, in the fifth century B.C., of Himera and Schnos in Sicily; and, nearly two hundred years after, of Saguntum in Spain. The cruelties they executed against the unfortunate inhabitants were afterwards amply retaliated upon themselves by the Romans. That warlike nation was employed for ages in almost con- tinual wars before they practised this method of attack. Surprize, not an open and vigorous assault, made them masters of Veii. In the first Punic war, Lilybæum for years baffled their utmost efforts, though they had then united to their own system of tactics, whatever was most new and valuable in that of the Greeks. The storming of New Carthage by Scipio is one of the first and most memorable examples of a successful assault in the Roman annals. To what perfection they afterwards carried this branch of military science, the capture of Athens by Sylla, of Avaricum by Caesar, and of Cremone and Rome itself by the armies of Verpaian, are melancholy witnesses. In the dark period of the decline of the empire, the barbarians who successively invaded it only carried on their operations against fortified places by continued assaults, which were commonly successful, nor were the superior tactics of the Romans then capable of refuting their fury.

Alike impetuous and irresistible, the Mogul destroyers, who, under Jengis Khan and his successors, defoliated the fairest regions of Asia, mocked the ordinary rules of war. A place which had once refused capitulation, never experienced a repetition of the offer. Assault succeeded to assault with astonishing rapidity, and no reprieve was allowed the devoted garrison, till weakened beyond the power of further resistance, they were employed, with the innocent inhabitants, and the place itself, in one common destruction.

With the Europeans of the middle ages, the science of attack lost much of its former superiority; and the castle of a petty-baron frequently baffled the endeavours of the most powerful monarch.

The invention of gunpowder offered new advantages to the art of besieging; but general assaults have become infinitely more dangerous against ramparts mounted with artillery. Even after the requisite breach is made, it is absolutely necessary to destroy the works whose fire, on either side, flank and protect the point of attack. Before therefore a fort is attempted, the besieging general should ascertain that his troops are exposed to no other fire than the garrison are able to maintain from the front of the breach itself.

Owing to the fancied advantages a regular garrison were supposed to possess behind good fortifications, the rules of war formerly required a governor to sustain three assaults before he surrendered. But such rigid notions have been by degrees disregarded. Few commanders chuse, by maintaining a fortress to the last extremity, to expose their troops to an uncleav'd slaughter, or the inhabitants to the murder and pillage inevitably the attendants of a storm. At Glogau, carried by the Prussians in 1741, and Bergen op Zoom, by the French in 1747, success was more the effect of a couple of men than a regular assault.

The Turks, however, materially differ from us on this head. It is with them a maxim of religion, never to surrender to Christians a place where they have once possessed a mosque. They, therefore, hold out to the last. Severe punishment has, indeed, attended this obscurity, Bender, Oezkowak, and Innell, are memorable for the undistinguished slaughters exercised by Russian ferocity, and have crowned with bloody laurels the names of Panin, of Potemkin, and of Suwarow. The capture of Warsaw, in 1794, is a fresh instance of the summary methods observed by the latter general in attacking towns, and of the lamentable consequences of ineffectual resistance to a barbarous and unforgiving enemy.

During the late war, an ineffectual cannonade and bombardment have been chiefly substituted by besiegers to the system of assault. Pavia indeed, with some smaller places in Italy, suffered, in 1765, all the horrors of an assault, from the French army, under general Buonaparte. The year 1799 also furnishes four remarkable instances: 1. The assault of Naples (January 22), by general Championet, to which the railroads of the Lazzaroni madly exposed themselves, but memorable for the daring and desperate, though unsuccessful resistance, maintained by them against regular troops. 2. The storming of Jaffa by Buonaparte (Feb.), the garrison of which place, 3,500 strong, was nearly extirpated, presents a fleeting and frightful picture of Turkish obstinacy. 3. That of Acre (May 8), where the French, after having penetrated within the town, were eventually repulsed with great loss, is the more worthy of notice, from its having effectually checked the adventurous progress of Buonaparte on the side of Syria. 4. The assault of Zurich (Sept. 24) by the republican army of Helvetia, and which may with more propriety be denominated a battle, displays too much ingenuity in the complicated movements directed by general Maffena, all of which were inseparably connected with the main point of attack, such precision, firmness, and bravery in the execution, and such importance in the consequences, as to demand a separate relation elsewhere. It will here be sufficient to observe, that the Russian camp before Zurich was forced, the town itself carried sword in hand, and that this event gave to decided a superiority to Maffena, as to be immediately followed by a precipitate retreat of the allied forces from Switzerland.

Affailants, as such, acquire a very considerable superiority over those they attack. This superiority, says an excellent writer on tactics, may be derived from two causes; the first a physical one, viz. the size of brasses, peculiar to assailants, cannot but astonish and intimidate an enemy who sees that no difficulty can stop them; the second is, that the assailants can command as much time as they please, to take their measures for overcoming all obstacles that can be thrown in
in their way. Mante’s Translation of Milcroy’s Tactics, vol. i. p. 186, &c.

ASSAULT, Affidavit, or Affidavit, in Law, an offer or attempt to hurt the person of another.

Or, it is a violent injury offered to a man’s person, of a larger extent than battery, because it may be committed by only offering to give a blow, without touching him, as if one lifts up his cane, or his fist, in a threatening manner, at another; or strikes at him, but misses him; this as an assault described by Finch (l. 202.) to be an unlawful setting upon one’s person. But no words whatever, he says, to provoke, can amount to an assault, notwithstanding many eminent opinions of the contrary. 1 Hawk. P. C. 62. § 1.

Assault does not always imply a blow; for, in trespass for assault and battery, a man may be found guilty of the assault, and exculpated of the battery. 1 Hawk. P. C. 263. But every battery includes an assault.

For an assault, the offender is subject both to an action at the suit of the party, in which he shall render damages; and also to an indictment at the suit of the king, in which he shall be fixed according to the heinousness of the offence. 1 Hawk. 263.

The assaulting of a person with offensive weapons, with a design to rob (though no robbery ensues), is punished with transportation for seven years. 7 Geo. I. c. 21. Assaulting in the street or highway, with intent to spoil people’s chattis, and spoiling them, is felony and transportation, by 6 Geo. I. c. 23. 5 & 6. 11. And the assault of a privy councillor in the execution of his office, is felony without benefit of clergy, by 9 Ann. c. 16. Assaulting or threatening a councillor at law, or attorney employed in a cause against a man, or a juror giving verdict against him, or an adversary for fixing him, &c. is punishable on an indictment, by fine and imprisonment, for the contempt. 1 Hawk. 58.

There are other assaults to which particular punishments are annexed: thus, at 5 Hen. IV. c. 6, and 11 Hen. VI. c. 11. render assaults on members of parliament more than usually penal, upon non-surrender on proclamation. Stat. 9 Edw. II. l. 1. c. 3. gives a double criminal process against those who assault clergymen, indictment for the temporal offence, and process in the ecclesiastical court for the spiritual one. By Stat. 5 Eliz. c. 4. servants assaulting their master, mistresses, or overerce, may be imprisoned twelve months, on conviction before two justices. By Stat. 9 Ann. c. 14. § 8. to assault, beat, or challenge another, on account of money won by gaming, incurs forfeiture of goods, and two years imprisonment by Stat. 9 Geo. I. c. 22. to assault another by wilfully shooting at him, is felony without clergy. By Stat. 12 Geo. I. c. 34. assaulting a master woolsomber or weaver, &c. for not complying with the demands of workmen, is felony, and transportation for seven years. In many cases a man may qualify an assault: the defendant may justify a miller’s man, i.e. a workman in his service, in defence of his person or goods; or of his wife, father, mother, or master, or for the maintenance of justice. Brad. 9 E. 4. 55 H. VI. c. 51. There are also other cases in which assault may be justified as, of an officer redirected in arreasing a man by warrant, of a parent reasonably chastising his child, or a master his servant, or a schoolmaster his scholar, or a gader his prisoner, or even a husband his wife for reasonable and proper caule, &c.

Hawk. P. C. 258.

ASSAY, Essay, or Say, in Metallurgy, the proof or trial of the goodness, purity, value, &c. of metals, and metalline substances.

In ancient statutes, this is called touch; and those who had the care of it, keepers of the touch. Under Henry VI. divers cities were appointed to have touch for wrought silver plate. 2 Hen. VI. c. 14. By this one might imagine they had no better method of assaying than the simple one, by the touch-flone; but the caule is far otherwise. In the time of Henry II. the bishop of Salisbury, then treasurer, confiding that though the money paid into the king’s exchequer for his crown-rents, did answer number all, pander, it might nevertheless be mixed with copper or brass; whereas a constitution was made, called the trial by combustion: which differs little or nothing from the present method of assaying silver. See a description of it in the Black Book in the Exchequer, written by Gervase of Tilbury, c. xx. The trial is also there called affutum, and the officer who made it is named sufior. Vid. Lownd. Eff. Amend. Silv. Coin. p. 5. & 155.

The method still in use of assaying gold and silver, was first established by an act of the English parliament, in 1554. Anderdon’s Com. vol. i. p. 187.

ASSAY, or Effay. Effayer Fr. Prohiriien Germ. The term assay in its most extended signification, means a species of analysis applied to metallic ores or alloys, the object of which is to ascertain the quantity and proportion of only one of the ingredients of the mass. Hence it differs from analysis in general, as this takes notice of all the ingredients: thus, in the assay of copper ores, the sole object is to know the proportion of pure metallic copper which a given weight of the ore can be made to yield; disregarding all the other component parts, such as the sulphur, iron, flux, &c. or rather confounding them together under the general term impurities. The same mode of inquiry takes place in the assay of a mixture of gold, or gold and silver, with copper, lead, tin, or any other of the inferior metals, the whole attention being directed to the proportion of fine, or of gold and silver contained in the alloy. For the various methods of conducting the assays, the reader is referred to the several metals; in all which articles the second section is devoted to the assay and analysis of the metals treated of. Gold and silver, from their superior commercial value, from their being the universal medium of exchange throughout the civilized world, and from their being the materials of the most costly and splendid utensils, ornaments, and articles of furniture, have demanded and obtained a greater accuracy in their assay than any of the other metallic bodies. The method of conducting it has been the subject of various legislative regulations, has from time immemorial been entrusted to a distinct craft or profession, and has more than any other process engaged the attention of some of the most able and accurate chemists of the present as well as of former ages. For these reasons, under the articles Gold and Silver, we shall enter at length into the consideration of this important subject. It was at first our intention to have introduced in this place all the matters relative to the art of the assayer, but by such an arrangement, much unnecessarily repetition would have been required of information that properly belongs to the articles Assay, Balance, Copper, Culpulation, Coin, Assayer’s Furnace, &c.

Assay-Master, an officer, under certain corporations, entrusted with the care of making true touch, or assay, of the gold and silver brought to him; and giving a just report of the goodness or badness thereof.

Such is the assayer-master of the mint in the Tower, called also assayer of the king.

The assayer-master of the goldsmiths’ company is a sort of assist-warden, called also a touch-warden, appointed to survey, assay, and mark all the silver-wark, &c. committed to him.—There are also assayer-masters, appointed by statute, at York, Exeter, Bristol, Chelten, Norwich, Newcaselle, 2 and
and Birmingham, for affaying wrought plate. The assayer is to retain eight grains of every pound troy of silver brought to him; four whereof are to be put in the box, or box of deal, to be re-assayed the next year; and the other four, if allowed him for his waste and spillings, 12 and 13 W. III. c. 4. 1 Ann. c. 9.

Note. The number of penny-weights set down in the assayer's report, is to be accounted as per pound, or so much in every pound of twelve ounces troy. For every twenty penny-weight, or ounce troy, the silver is found by the assayer to be worse than standard, or flerling, five per cent is to be deducted; because every ounce will cost so much to reduce it to standard goodness, or to change it for flerling.

In gold, for every carat it is set down to be worse than standard, you must account that in the ounce troy it is found by so many times 3. s. 8 d. And for every grain it is set down worse, you must account it worse by so many times 1 t. 6 d. in the ounce troy. And for every half grain 5 d. ½, for so much it will cost to make it of standard goodness, &c. Touchstone of Gold and Silver Ware, &c. p. 41, &c.

ASSAY-Balance, a balance used in the operation of assaying. See Balance.

ASSAY of Weights and Measures, signifies the trial or examination of common weights and measures, by the Clerk of the market.

ASSELEBERA, in Geography, a town of France, in the department of the Mayenne, and chief place of a canton in the district of Evron, one league from Evron.

ASSE LA BOIS, a town of France, in the department of the Sarthe, and chief place of a canton in the district of Parnay le Vicomte, eight miles S.S.W. of Alençon.

ASSECOMA, in Ancient Geography, a place of Spain, between Pina and Brevia. Itin. Anton.

ASSECTATOR, in Entomology, a species of Insect that inhabits Europe. It is black; abdomen falcate, with three rufous spots on each side; posterior flanks yellow and black. Fabrices.

ASSED-ABAD, in Geography, a small town of Persia, towards Amadan.

ASSELEN, a town of Germany, in the circle of Weilphalia, nine miles S.E. of Paderborn.

ASSELO, a town of Persia, in the province of Farisian, on the north coast of the Persian gulf, 47 leagues south of Shiras.

ASSELYN, John, in Biography, a painter, was born in Holland about the year 1610, and after receiving his education under Isaiah Vanden-Velde, a battle-painter, at the Hague, travelled into France and Italy. He studied at Rome, and particularly imitated the manner of Dambocio. His hands and fingers were crooked, and from this circumstance he was denominated by the Flemish students "Crabate." After improving his time during his residence at Rome, he passed through Lyons on his return, and there married the daughter of a merchant at Antwerp, whom he brought with him to Amsterdam in 1645. His countrymen received him with applause, and from him the Dutch painters first acquired the idea of imitating the natural manner of colouring landscapes, for which Claude Lorrain has been so much admired; and abandoning the bome style, with the prevalent blue and green tints of Paul Bril and Bruegel. Asselyn was in great reputation at Amsterdam, and his paintings, consisting of history pieces, battles, and landscapes exhibiting antiques, and also men and animals, were purchased at a high price; they were disfigured by their corrections, and admirable brilliancy of colouring; and a set of 24 of his landscapes and ruins has been engraved by Perelle. Asselyn died at Amsterdam in 1650. D'Argenville, Vies des Peintres. Gen. Biog.

ASSEM, or GREAT ARDAH, in Geography, a town of Africa, on the Silver coast, the capital of the kingdom of Ardaah. It was formerly the residence of the kings of Ardaah, and five or six leagues in circuit. The ocrets are very wide, and each house surrounded by its own rampart, as a security against fire. The walls are of mud, but high and thick, and also compact as if they were formed of stone and lime. The gates are defended by deep ditches in the inside, which are crossed by draw-bridges, and near each gate is a guard-room for the convenience of the officers and soldiers. The river Euphrates compiles one half of the city. The buildings are of clay, covered with straw, and the ocrets are kept in good order. The people are numerous, and the women are richly dressed. In the conquest of the kingdom of Ardaah by the king of Dahomay, in 1724, this city suffered very much. It is situated 16 leagues from the sea, and to the north-east of Little Ardaah.

ASSEMBLE, the joining, or uniting, of several things together; or, the things themselves to be joined or united. The assembly of two bones for motion, is called Articulation. Carpenters and joiners have various kinds and forms of assemblage; as, with mortises and tenons, with dove-tails, &c. See Dove-tail, Mortise, &c. The Europeans admire the Carpentry of some Indians, where the assemblage is made without either nails or pins. Herrera.

ASSEMBLE is also used in a more general sense, for a collection of several things, so disposed together, as that the whole has an agreeable effect. It is with difficulty as with bodies, which owe their chief excellency to the just assemblage and proportion of their members.

ASSEMBLY, formed of adjutant; compounded of ad, to, and simul, together; a meeting of several persons in the same place, and with the same common design. Assemblies of the clergy are called convocations, synods, and councils of the clergy; though that annual one of the kirk of Scotland retains the name general assembly, &c. The assemblies of judges, &c. are called courts, &c. The assemblies of the Roman people were called comitia. The assembly of a preacher, &c. is his audience. The academies have their assemblies, or days of assembly.

Under the Gothic governments, the supreme legislative power was lodged in an assembly of the states of the kingdom, held annually for the like purposes as our parliament. See Parliament.

ASSEMBLY, General, in Ecclesiastical History, is an assembly possessing the highest authority in the church of Scotland, and consisting of a certain number of ministers and ruling elders delegated from each presbytery, and of commissioners from the universities and royal boroughs. A presbytery, composed of fewer than 12 parishes, sends two ministers and one ruling elder to this assembly; if it contain between 12 and 18 ministers, it sends three of these, and one ruling elder; if it contain between 18 and 24 ministers, it sends four ministers and two ruling elders; and of 24 ministers, when the presbytery consists of so many, it sends five with two ruling elders. Every royal borough elects one ruling elder, and Edinburgh two; and their election must be attested by the kirk-fielion of their respective boroughs. Every university sends one commissioner from its own body. The commissioners are chosen annually, six weeks before the meeting of the assembly; and the ruling elders are often men of the first eminence in the kingdom for rank and talents.
talents. In this assembly, which meets once a year, the king
prefides by his commissioner, who is always a nobleman;
but he has no voice in their deliberations. Appeals are
brought from all the other ecclesiastical courts in Scotland
to the general assembly; and in questions purely religious,
no appeal lies from its determinations. The first general
assembly of the church of Scotland was held in the year
1563; but it bore, says Mr. Robertson (Hist. Scot. vol. i.
p. 251.), all the marks of an infant and unformed society.
The members were few, and of no considerable rank; and
and, of course, a convention so feeble and irregular, could
possess no great authority; and confessors of their own
weakness, the members put an end to their debates, without
venturing upon any decision of much importance. By
degrees, however, it acquired dignity, authority, and per-
manence.

Assembly, General, of the Jewish Rabbits. See AGEDA.

Assembly of Divines, is the name given to an association
of ministers and others, summoned by an ordinance of par-
liament, in the year 1643, to meet at Westminster, "for
settling the government and liturgy of the church of Eng-
lund, and for vindicating and clearing the said church from
false aspersions and interpretations." This assembly con-
ferred on 121 divines, and 30 hymen, "celebrated in their party,"
says Mr. Hume, "for piety and learning." The several
parties in this assembly were composed of Presbyterian,
Erastians, and Independents. By their advice, alterations
were made in the thirty-nine articles, the first fifteen of
which employed their committee for ten weeks; and these
alterations chiefly respected the doctrinal articles, and were
designed to render their sense more express and determinate
in favour of Calvinism. It was of still greater importance,
that they utterly abolished the liturgy, and, in its stead,
established a new directory for worship, by which, suitably
to the spirit of the puritans, the utmost liberty, both
in praying and preaching, was indulged to the public
teachers. They also agreed in introducing and enforcing
the solemn league and covenant, by which episcopacy was
abjured; and a national engagement, attended with every
circumstance that could render a promised face and obliga-
tory, was entered into with the Scots, never to suffer its
re-admission. All these measures, says Mr. Hume, showed
little spirit of accommodation in the parliament; and the
king's commissioners were not surprized to find the establish-
ment of presbyters, and the directory positively demanded,
together with the subscription of the covenant, both by the
king and kingdom. This assembly published till Feb. 22.
1643, about three weeks after the king's death, having sat
five years, six months, and twenty-two days, in which they
had 1163 sittings. They were afterwards changed into a
committee for the examination of such ministers as pre-
fented themselves for ordination or induction into living,
and met once a week, till March 25, 1652, when the long
parliament being turned out of the house by Oliver Crom-
well, they broke up without any formal dissolution. The
works of the assembly, besides some letters to foreign
churches, and occasional admonition, were, 1. "Their
humble advice to the parliament, for ordination of ministers,
and settling the presbyterian government." 2. "A di-
"A larger and shorter catechism." 5. "A review of
some of the thirty-nine articles." 6. "When polemics,"
says Mr. Neal, "shall impartially review this assembly of
divines, and consider the times in which they lived,
they will have a just vexation for their memory; for
though their sentiments in divinity were in many instances
too narrow and contracted, yet, with all their faults, amongst
which their perfecting zeal for religion was not the least,
they were certainly men of real piety and virtue, who meant
well, and had the interest of religion at heart, and most of
them professed as such learning, as any of their contempo-
raries. Mr. Baxter, Mr. Gataker, Greenhill, Armstrong, Twigg, bishop Reynolds, Wallis, &c. will always meet with esteem from the learned world; and
had they not grasped at coercive power or jurisdiction over
the consciences of men, their characters would have been
unblamed." Lord Clarendon (vol. i. p. 550.) allows,
"that about twenty of them were revered and worthy
persons, and episcopal in their judgments; but as to the re-
mainder, they were but pretenders to divinity; some were
infamous in their lives and conversations; and most of them
of very mean parts and learning, if not of scaberdous igno-
rance, and of no other reputation than of malice to the
church of England." Mr. Ezechiel confesses, that his
lordship has, perhaps with too much severity, said,
that some of these divines were infamous in their lives and
characters; but Mr. Baxter, who knew most of them, says,
"they were men of eminent learning, godliness, ministtrial
abilities, and fidelity; and being not worthy to be one of
them myself," says he, "I may more fully speak the
truth, which I know, even in the face of malice and envy,
that as far as I am able to judge by the information of
history, and by any other evidences, the Christian world,
like the days of the apostles, had never a synod of more
excellent divines than this synod, and the synod of Dort.
"The divine right," says Mr. Neal, "of the presbyterian
government, filled them into heats, and then divided
them; engaging them first with the parliament, and then
with the Independents and Erastians. Their opposing a
toleration, raised them a great many enemies, and caused
a feclusion in their own body; for after they had carried the
question of "divine right," the Independents and Ersa-
tians defected them, after which they found it very difficult
to muster as many as would make a house. Had the parlia-
ment dissolved them at this juncture, they had separated
with honour; but they dwindled by degrees, and the
bifincs of the church was translated to the provincial af-
vol ii. p. 35. & c. p. 335. 416.

Assemblies of the campus Martis, or Militis, of the field
of Mars, or Mars; see Field of Mars. &c.—Rebellious
assembly; see REBELLIOUS.—Unlawful assembly; see
UNLAWFUL.

Assembly is particularly used in the beau-monde, for
a rated and general meeting of the polite persons of both
sexes, for the sake of conversation, dancing, and play.

Assembly is also used in the Military Art, for the
second beat of the drum, being that before the march. On
hearing this, the soldiers strike their tents, roll them up,
and then stand to their arms. The third beating is called
the march, as the first is called the general.

ASEMON, AZMON, or IFESMON, in Ancient Geography,
a city in the wilderness of Moen, south of the tribe of Judah.
1 Sam. xxiii. 21. Joh. xvii. 4. Alfo, an encampment of
Israel in the defert. Azmon was the nearest city to Egypt,
forth. Numb. xxxiii. 29, xxxiv. 4, 5.

ASENA, in Geography. See ESSÉ.

ASSENEDE, a town of Flanders, one mile south-west
of Sas de Gent.

ASSENEPOWALS, a lake of America, westward of
Christianas lake, through which its waters run into Albany
river, in New South Wales.

ASSENHEIM, a town of Germany, in the circle of the
Upper Rhine, and county of Solms Rodelheim, at the
conflux
ASS

confines of the Wetter and Nidda, eleven miles north-east of Frankfort on the Main. N. lat. 50° 11'. E. long. 8° 50'.

ASSENS, a sea-port town of Denmark, situated on the west coast of the island of Funen, with a good harbour on the Little Belt, chiefly inhabited by fishermen. The passage from hence, across the Little Belt, to Arros found, in the duchy of Sleswick, is nine miles. N. lat. 55° 21'. E. long. 9° 54'.

ASSENSU, fin., Capitulis, in Lawe. See SINE, &c.

ASSENSIU, Regio. See REGIO.

ASSENSU Patris, Dowser ex. See DOWSER.

ASSENT, ASSENSU, an agreement or acquiescence of the mind to something proposed or affirmed. —Thus, to assent to any proposition, is to allow it to be true, or to perceive its truth.

Assent is distinguished, like faith, into implicit, or blind; and explicit, or seeing, &c. — Others distinguish it into actual and habitual.

Assent, actual, is a determination of the mind, arising from the perception of the truth of any proposition.

Assent, habitual, consists in certain habits of believing or acquiescing, in the mind by repeated acts.

To this belongs faith, which is an assent arising from the authority of the person who speaks. — Such also is opinion, which is defined an assent of the mind, cum formidini opponit, &c.

Father Malebranche lays it down as an axiom, or principle of method, never to allow any thing for truth, from which we can forbear our assent without some direct reproof of our own reason.

Mr. Hume, in his Treatise of Human Nature (vol. i. p. 172, &c.), has given us a new theory of assent or belief in general; a theory, which suits very well with his hypothesis of ideas, and seems to be a natural consequence of it, and which at the same time reconciles all the belief that we find in human nature to perfect scepticism. According to this writer, "an opinion or belief may be most accurately defined, a lively idea related to or associated with a present impression." Upon this notion of belief a great part of his theory is formed; and hence he deduces what he calls his hypothesis, "that belief is more properly an act of the sensitive than of the cognitive part of our nature." Dr. Reid has justly observed, in his examination of this theory (Ess. on the Intellectual Powers of Man, p. 553.), that the belief of a proposition is an operation of the mind, of which every man is conscious, and what it is he understands perfectly, though, on account of its finitude, he cannot give a logical definition of it. If he compares it with the strength or vivacity of his ideas, or with any modification of ideas, they are so far from appearing to be one and the same, that they have not the least similitude. That a strong belief and a weak belief differ only in degree, we may easily comprehend; but that belief and no belief should differ only in degree, no man can admit who understands what he speaks; for this in reality is to say, that something and nothing differ only in degree, or that nothing is a degree of something. Every proposition that may be the object of belief, has a contrary proposition that may be the object of a contrary belief. The ideas of both, according to Mr. Hume, are the same, and differ only in degrees of vivacity: that is, contraries differ only in degree; and for pleasure may be a degree of pain, and hatred a degree of love. Such are the absurdities that follow from this doctrine; but it is needless to trace them, as none of them can be more absurd than the doctrine itself. Mr. Hume, in the third volume of his "Treatise of Human Nature," sensible that his theory of belief is very objectionable, seems in some measure to retract it; but he still appears to be of opinion, that belief is only a modification of the idea, though vivacity is not a proper term by which to express that modification. He therefore adopts some analogous phrases to explain that modification; such as "apprehending the idea more strongly, or taking farther hold of it." But this is merely a change of terms which have no precise difference; and whatever modification of the idea he makes belief to be, whether in vivacity or in a stronger apprehension of it, the hypothesis, which makes perception, memory, and imagination to be different degrees of that modification, is chargeable with the same absurdities already mentioned.

Dr. Hartley's theory on this subject, though not very intelligibly expressed, is not very different from that of Mr. Hume; and it is liable to similar objections. "Assent and differ," says this writer (Observations on Man, p. 191. ed. 4to. 1791.), "whatever their precise and particular nature may be, must come under the notion of ideas, being only those very complex internal feelings, which adhere by association to such clusters of words as are called propositions in general, or affirmations and negations in particular." Accordingly, he distinguishes assent, and of course its opposite, differ, into two kinds, rational and practical. Rational assent to any proposition may be defined a readiness to affirm it to be true, proceeding from a close acquaintance of the ideas suggested by the proposition with the idea, or internal feeling, belonging to the word truth; or of the terms of the proposition with the word truth. Rational differ is the opposite to this. This assent, he adds, might be called verbal; but as every person supposes himself always to have sufficient reason for such readiness to affirm or deny, he prefers the term rational. Practical assent is an assent to act in such manner as the frequent vivid recurrence of the rational assent, disposes us to act; and practical differ the contrary. Practical assent is therefore the natural and necessary consequence of rational, when sufficiently impressed. For his mode of investigating the causes of both kinds of assent, and of accounting for them on the principles of association, we must refer to his workEntire.

For a further account of this subject, with regard to the reasons or principles upon which assent is founded, and the various measures and degrees of it, see Demonstration, Evidence, Faith, Judgment, Knowledge, Probability, and Testimony. See also AXIOMS, MAXIMS, and PRINCIPLES.

Assent Royal, See ROYAL.

ASSER, or ASERIUS MENEVSENIS, in Biography, an English divine of the ninth century, was a native of St. David's in Wales, where he assumed the monastic habit among the Benedictines. According to Dr. Cave, he was a relation, and Heane says, nephew, to Asserius, archbishop of St. David's. Having made a considerable progress in learning under John Scotus Erigena, he was invited to court by king Alfred, and amongst other preferments, obtained the bishopric of Sherborne. Dr. Cave informs us, that Alfred, by his advice, founded the university of Oxford; but the time of its establishment has been a subject of dispute. After wrote "The Life of Alfred," first published by archbishop Parker in the old Saxon character in his edition of Waltham's History, printed at London, in folio, in 1574; and republished in a collection of English historians by Camden, at Frankfurt, in folio, in 1602; and again by Mr. Wife, at Oxford, in 1640. In 1722. Nicholson, in his "Historical Dictionary," observes, that Alfred's Life, by Asserius, reaches no farther than the 45th year of his age, coinciding with his computation with the year.
year of our Lord 893; and therefore the continuation to the king's death must have been supplied by later authors. This work has been ascribed by Hearne to the archbishop of Chersones. Another work, under the title of "Affricus's Annals," has been ascribed to him, and was published by Dr. Gale in his "Decem Scriptorum," &c." at Oxford, in 1691, folio; but it has been doubted whether the name of Affricus has not been ascribed to an anonymous collection of unquestionable authenticity, though the real author was not certainly known. Tho "Annals," it has been alleged, extend to the year 914, whereas Affric died in 909, and there is no trace of any appendix to the work. Dr. Gale ascribes it to Affric, and his notion is favoured by its inscribing chiefly upon the fortunes of king Alfred. Affricus has the reputation of a faithful historian. Some other works have been ascribed to him; and some have said that he was the translator of "Boethius de Confaloniate," and not king Alfred, commonly reputed as such. Affric died, according to Godwin and Hearne, in 883; but according to Du-Pin, Cave, Olden, and Oudin, in 899. Cave's H. L. vol. ii. p. 66. Gen. Dic. ASSENTA, in Geography, a town of European Turkey, in Macedonia, upon the river Vera, near Salonichi.

ASSERA, among the Turks. See Assis.

ASSERADOES, in Geography, a small island near the west coast of North America, at the mouth of the bay Realejo, in the province of Nicaragua.

ASSERIDA, in Botany, a name given by the people of Guinies to a kind of shrub, the leaves of which being chewed are a cure for the colic, to which that people are very subject. Phil. Trans. N. 252.

ASSERIGO, in Geography, a town of Italy, in the kingdom of Naples and province of Abruzzo ultra, seven miles north west of Sulmona.

ASSERITION, in the Language of the Schools, a proposition which a person advances, and which he avows to be true, and is ready to maintain in public.

ASSES, Order of, Afnorum Ordo, in Ecclesiastical History, a denomination given to the Mathurins or Trinitarians, because they were anciently obliged, in travelling, to ride on asses, not horses. This obligation was set aside by a new rule given by the order by pope Clement, in 1657. Du-Cange.

ASSES, in Geography, a people of Africa, in Guinen, on the Gold Coast, in the interior part of the country, to the west of Rio de Volta.

ASSESSMENTS, in Law, denote taxes levied on the inhabitants of a parish or district for some special purpose, or on those of the country for the support of government. The term "affets" is derived by Johnstone from the Italian "affetti," to make an equilibrium or balance, and signifies to charge with a certain sum. In the beginning of the civil wars between Charles I. and his parliament, the latter having no other sufficient revenue to support themselves and their measures, introduced the practice of laying weekly and monthly affements of a specific sum upon the several counties of the kingdom, to be levied by a pound rate on lands and personal effects; which were occasionally continued during the whole usurpation, sometimes at the rate of £20,000l. a month, sometimes at inferior rates. After the restoration, the ancient method of granting subsidises, instead of such monthly affements, was twice, and twice only, renewed; viz. in 1663, when four subsidiues were granted by the temporality, and four by the clergy; and in 1670, when £20,000l. was raised by way of subsidy, which was the last time of raising supplies in that way. For the monthly affements being now established by custom, being raised by commissioners named by parliament, and producing a more certain revenue; from that time forwards we hear no more of subsidises, but occasional affements were granted as the national emergencies required. These periodical affements, the subsidises which preceded them, and the more ancient feutage, hydage, and taille, were to all intents and purposes a land-tax, and the affements were sometimes expressly so called. See Land-tax, and Subsidy.

ASSESSMENT, in a Military Service, signifies a certain rate which is paid by the county-treasurer to the receiver-general of the land-tax, to indemnify any place for not having raised the militia, which sum is to be paid by the receiver-general into the exchequer. The sum to be affessed is four pounds for each man, where no annual certificate of the state of the militia has been transmitted to the clerk of the peace: if not paid before June yearly, it may be levied on the parish officers. Such affement, where there is no county rate, is to be raised in the same manner with the poor's rate.

ASSESSOR, formed of ad, to, and fide, if, an inferior or subordinate officer of justice, chiefly appointed to afford the ordinary judge with his opinion and advice. In this sense, the masters in chancery are assessors of the lord chancellor. There are two kinds of assessors in the imperial chamber, ordinary and extraordinary.—The ordinary are now in number forty-one, whereof five are elected by the emperor, viz. three counts or barons, and two justices, or civil lawyers. The electors appoint ten, the six circles eighteen, &c. They act in quality of councilors of the chamber, and have salaries accordingly. Asseessor is also used for a person who affesses or lays affements of taxes and other public duties.

In this sense, assessors, among us, are inhabitants of a town or village elected by the community to assist or settle the taxes and other impositions of the year, to fix the proportion which each person is to bear, according to his estate, and to see the collection made. These are also called in our law assessors. By the flat, 16 & 17 Car. II, two inhabitants in every parish were made assessors for the royal aid.

ASSESSUS, in Ancient Geography, a town of the Mlefians, in which was a temple of Minerva Affensis, which was burned by the flames which were driven thither by the wind. Herodot. i. i. c. 19.

ASSES (Fr. affets, i.e. faithful, enough), in Law, signify goods enough to discharge that burden which is cast upon the executor or heir, in satisfying the debts and legacies of the testator or ancestor. Bro. tit. Affect. Affets are real or personal; where a man hath lands in fee-simple, and dies feigned thereof, the lands which come to his heir are affets real; and where he dies possessed of any personal estate, the goods which come to the executor are affets personal. Affets are also divided into affets per defcent, and affets inter maines; affets by descent is where a person is bound in an obligation, and dies feigned of lands which depend to the heir, the land shall be affets, and the heir shall be charged as far as the land to him defended will extend: affets inter maines is when a man indebted makes executors, and leaves them sufficient to pay his debts and legacies; or where some commodity or profit ariseth to them in right of the testator, which are called affets in their hands. Terms de Ley, 56, 57.

As to affets by descent, it is to be observed, that by the common law, if the heir had sold or aliened the lands which were affets before the obligation of his ancestor was put in suit, he was to be discharged, and the debt was left; but by flat. 3 W. & M. c. 14, made perpetual by 6 WILL. III. c. 14, the heir is made liable to the value of the land by him sold, in action of debt brought against him by the obligeer, who shall recover to the value of the said land, as if the debt was the proper debt of the heir; but the land which is sold or aliened:
aliened bond side before the action brought, shall not be liable to execution upon a judgment recovered against the heir in any such action. And by fl. 25 Car. II. c. 3. § 10, lands of estates that shall be affìts by defect, and by the same fl. § 12, estates pur antre vic shall be affìts in the hands of the heir, if they come to him by reason of a special occupancy; and where there is no special occupant, they shall go to the executors and administrators of the party that had them by virtue of the grant, and shall be affìts in their hands. When a man binds himself and his heirs in a bond, and dies leaving issue two sons, if the eldest son enters on the lands by defect as heir to the father, and die without issue; and then the youngest son enters, he shall be charged with affìts as heir to the father. Dyce, 568. Lands which come to the heir by purchase shall not be affìts. 1 Danv. Abr. 577. A reversion in an estate for life or years shall be affìts, and a reversion expectant upon the determination of an estate for life is affìts, and ought to be pleaded specially by the heir. An advenlion is affìts, but not a presentation to a church actually void, which may not be held. Co. Lit. 374. Lands by defect in ancient demeine will be affìts in debt; but a copyhold estate descending to an heir is not affìts; nor is any right to an estate affìts, without positìon. Danv. 577. An annuity is no affìts, for it is only a chief in advenlion. Equity of redemption of an estate mortgaged, and a term for years to attend the inheritance, are affìts.

Leaves are affìts to pay debts, notwithstanding the affìt of the executor to the devise of them. 1 Lill. Abr. 99. Affìts in the hands of one executor, are affìts in the hands of others; and if an executor hath goods of the testator in any part of the world, he shall be charged in respect of them. 6 Rep. 47. In actions against executors, the jury must find the value of the affìts; for the plaintiff shall recover only according to the value of the affìts found. 1 Red. Rep. 58. A special judgment against affìts only shall have relation to, and bind the lands from the time of filing the original writ or bill. Carth. Rep. 245.

ASSEVERATION, an earnest affirmation, or avouching.

ASHETON, WILLIAM, in Biography, an English episcopal divine, was born at Middleton in Lancashire, in 1641, and educated at Brazen-nose college in the university of Oxford. Distinguished by his application and proficiency in various parts of learning, he became a fellow of that college in 1663, and in 1673 was honoured with the degree of doctor in divinity. Besides other preferments to which he was advanced, he was presented to the rectory of Beckenham in Kent, in 1676. He was conscientiously and zealously attached to the church in which he officiated, and faithful and exemplary in the discharge of the duties of his profession. Whilst he was an upright and able advocate for the established religion, he was no less affianced in inculcating, from the precepts as well as from the pulpits, the indispensable obligations of morality and practical religion. In the present age, however, his "Treatise against Toleration," and his "Possibility of Apparitions," written in defence of them, will not be regarded as evidences of the liberality of his spirit, and the soundness of his judgment. The former, under the title of "Toleration disapproved and condemned, &c." was published at Oxford, in 1670, 4to. ; and his book intituled, "Cafes of Scandal and Persecution, &c." to the fame purpose, was published at London, in 1674; and his "Possibility of Apparitions" was occasioned by the story of Mrs. Veale, who died at Dover, and was found to have appeared to her friend Mrs. Bargrave at Canterbury, and published in 1706. This story has been since prefixed to "Deline

court on Death." In 1685, Dr. Asheton, who was a zealous advocate for monarchy, wrote "The Royal Apology," in defence of the doctrine of absolute submission to kings; and after the revolution, he wrote a piece in defence of king William and queen Mary, intitled, "A reasonable Vindication of their present Majesties," in which he declared to the public the reasons which induced him to swear allegiance to them. He also wrote several tracts against popery, and in vindication of the Trinity, and various pieces of a practical nature. Dr. Asheton claims peculiar commendation and respect as the first projector of the scheme for providing a maintenance for clergymen's widows and others, by a jointure payable out of the mercenaries' company. To this scheme he devoted much attention, and after contending with many difficulties and discouragements, he had the pleasure of succeeding. An "Account of the Kife, Progress, and Advantages of the Proposal, &c." was printed in 1713. The plan, however, was not founded on a sufficient acquaintance with the doctrine of annuities; and the society of course failed in making good its proposals. Asheton having employed his time and talents in promoting the interests of truth, according to his views of it, and the cause of virtue and humanity, died at Beckenham, in 1711, in the 70th year of his age. Gen. Dict. Biog.-Br.

ASSIDEANS, or rather HASIDEANS, in Antiquity, a sect among the Jews; thus called from the Hebrew حضى, hasidim, merciful, righteous. 1 Mac. ii. 42. vii. 16. Ecclesiastus, xliv. 10.

Dr. Prideaux lays (Comm. p. ii. book iii. vol. iii. p. 257.), that after the stetting of the Jewish church in Judea, on the return from the Babylonish captivity, there were two forts of men among the members of it; the one contented themselves with the written law of Moses, and were called Zadikim, or the righteous; and the others superadded to the law the constitutions and traditions of the Elders, and other religious observances, which they voluntarily regarded by way of supererogation, and being considered as posseffing a degree of holiness superior to that of the others, they were denominated Cylinderans, or the pious. From the former were derived the sects of the Samaritans, Sadducees, and Karaites; and from the latter, the Pharisees, and Eilleens. These Affidans, who were men of great value as well as eminently zealous for the law, joined Mattathias and his company in the fastnesses of the mountains, as soon as Antiochus was returned to Antioch, and determined to fight with him for the law of their god and the liberties of their country.

ASSIDENT, SIGN, Signum Affidend, in Medicine, a symptom which usually attends a disease, but not always. Thus a dry rough tongue, thirst, and watching, are affident sign in an ardent fever. In this sense, affidents differ from pathogonomics, which are inferable from the disease.

ASSIDUUS, or ASSIDUUS, among the Romans, denoted a rich or wealthy person.

The word in this sense is derived from attis, affis, q. d. a maned man.

Hence we meet with affidius: foruries, affidii fiducciffores, answering to what the French now call city freethers or seculars, caution bourgeoise.

When Servius Tullius divided the Roman people into five classes, according as they were affieded or taxed to the public, the richer sort who contributed most, were denominated affidius; and as these were the chief people of busineses who attended all the public concerns: those who are diligent in attendances came to be denominated affidii.

ASSIDUI was also used for volunteers, or those who served in the army at their own expense.

ASSIENTO,
ASSIENTO, or ASSIEN[I], in matters of Commerce, a contract or convention between the king of Spain and other powers for furnishing the Spanish dominions in America with negro slaves.

The term is originally Spanish, and signifies a bargain; accordingly the first assiento was a treaty or contract made with the French Guinea company whereby they were put in possession of this privilege, in consideration of a certain duty which they were to pay to the king of Spain’s farms, for every negro thus furnished.

The Spaniards, having almost destroyed the natural inhabitants of Spanish America, have been many years, and still are obliged to perform the work of their mines, and other laborious business, by negroes, of whom they could scarce ever obtain the number they have wanted: and it is certain, if they were fully supplied, they would get yearly above twice the silver perhaps they now do, or have done for many years past. It must be confessed, they have used variety of measures to obtain them. The Genoese undertook to supply them at a concerted price between them; for which end they formed a company called the assiento, who had their factors at Jamaica, Curacoa, and Brazil; but by their ill management made nothing of this contract; nor did their successors the Portuguese. After them it fell into the hands of the French, who made so much of it, that they were enabled, by a computation made from the registers of Spain, to import into the French dominions, no less than 202,400,000 of pieces of eight. Yet they at length overbalanced the market, and became sufferers towards the conclusion.

By the treaty of Utrecht, Philip V. being declared king of Spain by the allies, it was one of the articles of the peace between England and France, that the assiento contract should be transferred to the English. Accordingly a new instrument was signed in May 1713, to last thirty years; and the furnishing of negroes to Spanish America was committed to the South-sea Company, just then erected; though the first convention for this purpose was made in or about the year 1689.

In virtue whereof they were yearly to furnish 4800 negroes; for which they were to pay at the same rate as the French, with this condition, that during the first twenty-five years, only half the duty shall be paid for such as they shall import beyond the stated number.

The last article gives them a farther privilege not enjoyed by the French; which is, that the English assentees shall be allowed, every year, to send to the Spanish America a ship of five hundred tons, laden with the same commodities as the Spaniards usually carry thither; with a licence to sell the same concurrently with them, at the fairs of Porto Bello, Carthagena, and Vera Cruz. This additional article was supposed as advantageous to the company, as the whole contract besides being granted contrary to the usual Spanish policy, which has ever solicitously preferred the commerce of their America to themselves.

Some new articles were afterwards added to the ancient assiento; as, that the English should send their regifter-ship yearly, even though the Spanish fota and galleons did not go; and that, for the first ten years, the said ship might be of 650 tons.

Finally, as the South-sea company had on the whole been losers by their trade, and at the time of the treaty of Aix-la Chapelle, in 1748, they had only four years more of their assiento term remaining (the war between Spain and England having commenced in 1739, and interrupted the continuance of it), which Spain was determined not to renew, at half not on any promising terms; for these and other reasons, it was concluded by the British court to instruct her minister at Madrid, to obtain the bell equivalent that could be procured for the remaining short time of the company’s assiento contract.

By the treaty of Madrid, concluded on the 9th of October 1759, it was agreed that his Britannique majesty should yield to his Catholic majesty his right to the enjoyment of the assiento of negroes, and of the annual ship, during the four years stipulated by the treaty of Aix-la-Chapelle; and in consideration of a compensation of 100,000l. being to be paid by his Catholic majesty to the South-sea company within three months, his Britannique majesty agreed to surrender to him all that might be due to that company for balance of accounts, or in any manner arising from the said assiento; thus all claims, in consequence of this contract, were finally abolished, and a period was put to all the foreign commerce of the South-sea company.

In consequence of the assiento conveyed to Great Britain by Philip V., British factories were established at Carthagena, Panama, Vera Cruz, Buenos Ayres, and other Spanish settlements. The veil with which Spain had before this time covered the state and transactions of her colonies, was removed. The agents of a rival nation, residing in the towns of most extensive trade, and of chief resort, had the best opportunities of becoming acquainted with the interior condition of the American provinces, of observing their fated and occasional wants, and of knowing what commodities might be imported into them with the greatest advantage. In consequence of information so authentic and expedient, the merchants of Jamaica, and other English colonies who traded to the Spanish main, were enabled to afford and proportion their cargoes so exactly to the demands of the merchants, that the contraband commerce was carried on with a facility, and to an extent, unknown in any former period. Besides, the agents of the British South-sea company, under cover of the importation which they were authorized to make by the ship annually sent to Porto Bello, poured in their commodities on the Spanish continent, without limitation or restraint. Instead of a ship of 500 tons as stipulated in the treaty, they usually employed one which exceeded 900 tons in burden. She was accompanied by two or three smaller vessels, which, coaling in some neighbouring creek, supplied her clandestinely with fresh hakes of goods, to replace such as were sold. The inspectors of the fair, and officers of the revenue gained by exorbitant premiums, conviced at the fraud. The company itself, however, sustained a considerable loss by the assiento trade; whilst many of its servants acquired immense fortunes. Thus, partly by the operations of the company, and partly by the activity of private interlopers, almost the whole trade of Spanish America was ingrossed by foreigners. The immense commerce of the galleons, formerly the pride of Spain, and the envy of other nations, sunk to nothing; and the squadron itself reduced from 15000 to 2000 tons served hardly any purpose, about the year 1737, but to fetch home the royal revenue arising from the fifth, or silver. In order to prevent these encroachments, Spain flotated ships of force, under the appellation of “Guardia Colas,” on the coasts of those provinces which were most frequented by interlopers. The captains of these guardia colas, by several unprofitable acts of violence, precipitated Great Britain into a war with Spain; in consequence of which the latter obtained a final release from the assiento, as we have above related, and was left at liberty to regulate the commerce of her colonies, without being restrained by any engagement with a foreign power. *Anderson’s Commerce*, vol. iii. p. 378. *Robertson’s Hist. Amer.* vol. iii. p. 378, &c.
ASS

ASSIENTO, in Geography, a country of Africa, on the Gold Coast, bordered on the north by the unknown regions, on the east by Achem, and on the south by Akanni or Little Achan. Assiento is imperfectly known, as its inhabitants maintain little or no correspondence with the maritime negroes. It is said, however, to be rich in gold, which the Achanne sometimes bring to the coast. Its situation, near the source of the River Scull, is very advantageous for trade, if the natives were more disposed for commerce, and better acquainted with their own interest.

ASSIGN, To, in Common Law, hath various significations: one general, viz. to set over a right to another, or to point a deputy; &c.; another special, viz. to set forth a point out, as to a leaife, assign false judgment, waife, &c. In assigning of error, it must be when the error is committed; in false judgment, wherein the judgment is unjust; in waife, wherein especially the waife is committed. Judices are also said to assign to take affies. Stat. 11. Hen. VI. c. 2.

ASSIGNABLE Magnitude, in Geometry, is used for any finite magnitude that can be expressed or denoted, and Assignable Ratio, for any expressible ratio.

ASSIGNEE, or Assign, in Law, a person to whom a thing is appointed, or assigned by the act of the party, or the operation of law, to be occupied, paid, or done.

An assignee differs from a deputy in this, that the assignee poiffesses or enjoys a thing in his own right; and a deputy acts in right of another.

Assignee may be so either by deed or by law.
Assignee by Deed is when a leaife of a term, &c. falls and assigns the estate to another: the other is his assignee by deed.

Assignee by Law, is he whom the law makes, without any appointment of the person. Thus, an executor is assigned by law to the tefator, who dies poiffesst of a lease made to him and his assignz.

Assignees under a commiion of bankruptcy, are persons to whom the bankrupt's estate is assigned, for the benefit of the creditors: they are chosen at one of the three meetings appointed by the commissioners, and published in the Gazette, by the major part in value of the creditors who shall then have proved their debts; but they may be originally appointed by the commissioners, and afterwards approved or rejected by the creditors: and no creditor shall be admitted to vote in the choice of assignees, whose debt does not amount to ten pounds. By virtue of the statutes 1 Jac. I. c. 15. 21 Jac. I. c. 15, all the personal effects and effects of the bankrupt are considered as vested by the act of bankruptcy in the future assignees of his commissioners, whether they be goods in actual possession, or debts, contracts, and other choses in action; and when the assignees are chosen or approved by the creditors, the commissioners are to assign every thing over to them; and the property of every part of the estate is thereby as fully vested in them, as it was in the bankrupt himself, and they have the same remedies to recover it. 12 Mod. 324.

The assignees may pursue any legal method of recovering the property vested in them, by their own authority: but cannot commence a suit in equity, nor compound any debts owing to the bankrupt, nor refer any matters to arbitration, without the consent of the creditors, or a major part of them in value, obtained at a Gazette meeting.

The assignees must, after four, and within twelve months after the commiion illued, give one and twenty days notice to the creditors of a meeting for a Dividend, and within eighteen months, a second and final dividend shall be made, unless all the effects were exhausted by the full.

ASSIGNING. See Assign.

ASSIGNMENT, the act of assigning or transferring the interest or property a man has in any thing; or of appointing or setting over a right to another. Assignments may be made of lands in fee, for life or years; of an annuity, rent-charge, judgment, statute, &c. as to lands, they are usually of leases and estates for years: and an assignment differs from a lease only in this; that by a lease one grants an interest less than his own, referring to himself a reversion; whereas in assignments he part with the whole property, and the assignee stands to all intents and purposes in the place of the assignor.

No estate of freehold or term of years shall be assigned, but by deed in writing signed by the party, except by operation of law. Stat. 29 Car. II. cap. 3. If lease for years assign all his term in his lease to another, he cannot refer the rent in the assignment; for he hath no interest in the thing by reason of which the rent referred should be paid; and where there is no reversion, there can be no diffire: but debt may lie on it as on a contract. 1 Litt. Abr. 99. If the executor of a leaife assigns the term, debt will not lie against him for rent incurred after the assignment; because there is neither privity of contract nor estiate between the leffor and executor; but if the lefso himself assign his lease, the privity of contract remains between him and the lefso; although the privity of estate is gone by the assignment, and he shall be chargable during his life; but after his death, the privity of contract is likewise determined. 3 Rep. 14. 24. Although a leaife make an assignment of his term, yet debt is against him by the lefso or his heir (not having accepted rent from the assignee); but where a leaife assigns his term, and the lefso his reversion, the privity is determined, and debt doth not lie for the reversioner against the first leaife. Meor 472. If an assignment is made by an assignee, the first assignee is not liable for the rent; for if he be accepted by the lefso, the admission of one assignee is the admission of twenty. Comp. Attorn. 491.

Where a tenant for years assign his estate, no consideration is necessary; for the tenant being subject to payment of rent, &c. it is sufficient to sell an estate in the assignee; in other cases, some consideration must be paid. 1 Mod. 262. The words required in assignments are, grant, affiine, and set over, which may amount to a grant, feufoin, lease, release, confirmation, &c. 1 Inft. 501. In these deeds the assignee is to covenant to fave harmless from former grants, &c. that he is owner of the land, and has power to assign; that the assignee shall quietly enjoy, and to make further assurance; and the assignee covenants to pay the rent, and perform the covenants, &c.

The Stat. 32 Hen. VIII. c. 34. gives the assignee of a reversion (after notice of such assignment), the same remedies against the particular tenant, by entry or action, for waife or other forfeitures, non-payment of rent, and non-performance of covenants, covenants, and agreements, as the assignee himself might have had; and makes him equally liable on the other hand, for acts agreed to be performed by the assignee, except in the case of warranty. A bond, being a chose in action, cannot be assigned over to fo as to enable the assignee to sue in his own name; and therefore, the form of assigning a chose in action is in the nature of a declaration of trust, and an agreement to permit the assignee to make use of the name of the assignee, in order to recover the possession. Accordingly, when in common acceptance a debt or bond is said to be assigned over, it must still be in the name of the original creditor; the person, to whom it is transferred, being rather an attorney than an assignee. But the king is an exception to this general rule;
for he might always either grant or receive a *chafe* in action by assignment; and our courts of equity, considering that in a commercial country almost all personal property must necessarily lie in contract, will protect the assignment of a *chafe* in action, as much as the law will that of a *chafe* in possession. 3 P. Wms. 199. In equity, therefore, a bond is assignable for a valuable consideration, paid and the assignee alone becomes entitled to the money, so that if the obligor, after notice of the assignment, pays the money to the assignee, he will be compelled to pay it over again.

2 Vern. 295.

Several things are assignable by acts of parliament, which seem not to be assignable in their own nature; such as promissory notes and bills of exchange, by Stat. 3 & 4 Ann. c. 9; bail-bonds by the sheriff, by 4 & 5 Ann. c. 16; a judge's certificate for taking and protecting a felon to conviction, by 10 & 11 W. 3. c. 23. and a bankrupt's effects, by the several statutes of bankruptcy.

The *assignment of dower* is the setting out of a woman's marriage-portion by the king. By the old law, grounded on the feudal exactions, a woman could not be endowed without a fine paid to the lord; neither could she marry again without his license; but she could contract herself, and fo convey part of the feud, to the lord's enemy. Mirr. c. 1. § 3. This license the lords took care to be well paid for; and as it seems, would sometimes force the dowager to a second marriage, in order to gain the fine. But, to remedy these oppressions, it was provided, first by the charter of Henry I. and afterwards by Magna Charta (cap. 71.), that the widow should pay nothing for her marriage, nor be restrained to marry again, if she chose to live without a husband; but should not, however, marry against the consent of the lord; and farther, that nothing should be taken for assignment of the widow's dower, but that she should remain in her husband's capital manhon-house for forty days after his death, during which time, called the widow's "quarantine," her dower should be assigned. The particular lands to be held in dower, must be assigned by the heir of the husband, or his guardian; Co. Litt. 34. 35. not only for the sake of notoriety, but also to entitle the lord of the fee to demand his services of the heir, in respect of the lands so held. For the heir by this entry becomes tenant thereof to the lord, and the widow is immediate tenant to the heir, by a kind of subinfeudation or under-tenancy, completed by this infeudition or assignment, which tenure may be created, notwithstanding the statute of *quia emptores*, because the heir parts not with the fee simple, but only with an estate for life. If the heir or his guardian do not assign her dower within the time of quarantine, or do assign it unfairly, she has her remedy at law, and the sheriff is appointed to assign it. Co. Litt. 34. 35. Or, if the heir, being under age, or his guardian assign more than the ought to have, it may be afterwards remedied by writ of *admeasurement of dower*. Bl. Com. vol. II. 135. &c.

The assignment of the lands is for the life of the woman; and if lands are assigned to a woman for years, in recompence of dower, this is no bar of dower. 2 Danv. Abr. 168. When other land is assigned, that is no part of the lands in which the woman claims dower, that assignment will not be good or binding; and there must be certainty in the which is assigned; otherwise, though it be by agreement, it may be void. 4 Rep. 2. 1 Inft. 34. If a wife accept and enter upon less land than the third of the whole, on the sheriff's assignment, she is barred to demand more. Moor. 679. But if a wife is entitled to dower of the lands of her first husband, and her second husband accepts this dower less than her third part, the may, after his death, refuse the same, and have her full third part. Fitz. Dower, 121. By proviso of law, the wife may take a third part of the husband's lands, and hold them discharged. 2 Danv. 672. The sheriff may also assign a rent out of the land in lieu of dower; and her acceptance of it will bar dower out of the same land, but not of other lands. 2 And. 31. Dyer. None can assign dower but those who have a frehold, or against whom a writ of dower lies; and therefore a tenant by statute-merchant, statute-flaple, or elegit, or leesse for years, cannot assign dower; for none of these have an estate large enough to enowr the plaintiff's demand. Park. 403. 404. Co. Litt. 35. Bro. 63. 94. 1 Ral. Abr. 681. 6 Co. 57. If the heir within age assign to the wife more land in dower than she ought to have, he himself shall have a writ of *admeasurement of dower* at full age by the common law. F. N. B. 148. 332. Co. Litt. 39 a. 2 Inft. 367. 7 H. II. c. 4. 13 Edw. I. c. 7 & 8. If the heir within age, before the guardian enters, assigns too much in dower, the guardian shall have a writ of *admeasurement*, by Stat. 2 W. II. c. 7. 2 Inft. 317. If a wife after assignment of dower improves the lands, so that they then become of greater value than the other two parts, no writ of *admeasurement* lies, &c. F. N. B. 149. 2 Inft. 368. 5 W. 12.

Assignment, Newel. See Novel.

ASSIMILATION, compounded of ad, to, and similia, like, the act of assimilating; an act whereby a thing is rendered similar, and like to another.

Assimilation, Assimilatio, in *Physic*, is properly a motion whereby bodies convert other duly digested bodies into a nature like, or homogenous to their own. Influences of this assimilation we see in flame, which converts the oily or other particles of fuel into its own fiery and luminous nature. The like also appears in air, smoke, and spirits of all kinds.

The like we see in vegetables, where the watery juices imbied from the earth, being farther prepared and digested in the vessels of the plant, become of a vegetable nature, and augment the wood, leaves, fruit, &c.

So also, in animal bodies, we see the food assimilated or changed into animal substance, by digestion, chyliciation, and the other operations necessary to nutrition.

ASSIMILATOR, in *Entomology*, a species of *Ichneumon*, found in North America. The general colour is scarlet; anterior part of the thorax black; wings brown; base and band yellowish, with a saugineous dot. Swede- rus New: Act. Stockl. &c.

ASSIMILIS, a species of *Brentus*, a native of New Zealand, and first described by Fabricius in his *Species Insectorum*, under the name of *Curculio assimilis*. It is of a cylindrical form, with the apex of the back globorous and black; and the wing-cases somewhat frizzled with ferruginous. Fab. Gmel. &c.—Ohf. The snout is shorter than the body; antennae brown, black at the tip; thorax black, and caniculated; wing-cases pointed, and marked with four or five dots.

Assimilis, a species of *Gryllus* (*Acheta* section). The wings are tailed, and longer than the wing-cases; abdomen with two hyphes, which are cleft at the end.

Assimilis, a species of *Sphex*, that inhabits Tranquebar. It is black; antennae, tail, and legs rufous; wings blue, white at the base and tip. Fabr. Mant. Inf.

Assimilis, a species of *Oniscus*, found in the European seas. It is oval; the tail obtuse and unarmed; body cinereous. Fabricius. This is *aesculopus marinus vulgi brevior*.
ASS

vior et lator of Ray; and it is conjectured is the same kind as Pallas calls onicus globator.

Assimilis, a species of Oniscus, called by Pallas onicus globator; and by Ray aequalis marinus vulgari brevior et lator. It inhabits the European seas; is oval, cinceres, with an obtuse, unarmed tail.

ASSIN, in Geography. See ISSIN.

Assinibo, or Red river, sometimes called Affinibois, and Affinibois, a river in the north-west part of North America, which disembogues on the south-west side of the lake Winnipeg, in N lat. 50° 20'. W. long. 96° 30'. It alternately receives the two denominations of Assinibo and Red river, from its dividing at the distance of about thirty miles from the lake into two large branches. The eastern branch, called the Red river, runs in a southerly direction to near the head waters of the Missisipi. On this river are two trading establishments. The country, on either side, is but partially supplied with wood, and consists of plains covered with herds of the buffalo and elk, especially on the western side. On the eastern side are lakes and rivers, and the whole country is well wooded, level, and abounding with beaver, bears, moose-deer, fallow-deer, &c. &c. The inhabitants, who are considered as the Algonquin tribe, are not very numerous, and are considered as the natives of Lake Superior. This country is also inhabited by the Nadowais, who are the natural enemies of the former; and the head of the water being in the war-line, they are in a state of continual hostility. Although the Algonquins are equally brave, they are generally outnumbered by the others; and, therefore, if they venture out of the woods, which form their only protection, they will probably be soon extirpated.

There is not; it is said, a finer country in the world, for the residence of uncivilized man, than that which occupies the space between this river and Lake Superior. It abounds in every thing necessary to the wants and comfort of such people. Fish, venison, fowl, and wild rice, are very plentiful; and their subsistence demands that exercise which is essential to health and vigour. This country was formerly very populous: but the aggregate of its inhabitants does not now exceed 300 warriors; and the widows appear to be more numerous than the men. The racoon is a native of this country, but is seldom found to the northward of it.

The other branch of the river is called after the tribe of the Nadowais, who are denominated Affiniboins, and who are the principal inhabitants of its environs. It runs from the N.W. and in lat. 51° 25', and W. long. 103° 20', rises in the same mountains with the river Dauphin. The country between this and the Red river is almost a continual plain to the Missisipi. The soil is sand and gravel, with a slight mixture of earth, and produces a short grass. Trees are very rare, and insufficient, except in particular spots, for building houses, and supplying fuel-wood for the trading establishments, of which there are four principal ones. Both these rivers are navigable for canoes to their sources, without a fall; though in some parts there are rapids, caused by occasional beds of limetone and gravel; but the bottom in general is sandy.

The Affinibois, and some of the Fall, or big-hulled Indians, are the principal inhabitants of this country, and border on the river, occupying the central part of it; that next lake Winnipeg, and about its source, being the Iation of the Algonquins and Knillencaux, who have made choice of it in preference to their own country. They do not exceed 500 families. They are not beaver-hunters, which accounts for their allowing the division just mentioned, as the lower and upper parts of this river have these animals, which are not found in the intermediate district. They confine themselves to hunting the buffalo, and trapping wolves, which cover the country. What they do not want of the former, for raisin or food, they sometimes make into pemican, or pounded meat, while they melt the fat, and prepare the skins in their hair, for winter use. The wolves they never eat; but produce a tallow from their fat, and prepare their skins; all which they exchange for arms or ammunition, gun, tobacco, knives, and various edibles, with those who go to traffic in their country. These Nadowais, or Affiniboins, called also Store Indians, who inhabit the plains on and about the source and banks of the Saskatchewan and Assinibois rivers, are supposed to have migrated from the southward, being detached tribes from the Nadowais, who inhabit the western side of the Missisipi, and lower part of the Missisipi, and their progress is north-west. Mackenzie's Voyages from Montreal, &c. Intro. p. 63; &c. p. 407.

ASSINOIS, a nation of Indians, inhabiting the forests of Canada.

ASSIRATUM, in Antiquity, a bloody drouth, whereewith treaties were ratified. It was made of wine and blood, called by the ancient Romans, affis.

ASSIS, in Physiography, either denotes opium, or a powder made of hemp-seed, which being formed into holes about the bigness of chafins, is swallowed by the Egyptians, who are hereby intoxicated, and become ecatic, and full of the most agreeable visions.

This is also called by the Turks afferar.

ASSISA, or Assisie. See the articles Assise, and Tullage.

Assisa, cadere, to fall from the affisa, in Law, is to be nonuiat. Fleta, l. iv. c. 15. Bracton, l. ii. c. 7.

Assisa cadit in juratum, is where the thing in controversy is so doubtful, that it must necessarily be tried by a Juri. Fleta, l. iv. c. 15.

Assisa capi in modum affisa, is when the defendant pleads directly to the affisa, without taking any exception to the count, declaration, or Bill. Stane, 1. iv. c. 15.

Assisa continua, is a Bill directed to the justices, to take an affisa for the continuance of the cause, where certain records alleged cannot in time be procured by the party. Reg. Orig. 217.

Assisa nonuuii, is an affisa of Nusance. See the article.

Assisa panis & cerevisiae, denotes the power or privilege of affinging and adjusting the weight and measure of bread and beer.

Assisa judiciui, in Law, signifies a judgment of the court, given either against the plaintiff or defendant, for default.

Assisa proponenda, is a Bill directed to the justices of affisa, for the slay of proceedings, on account of the king's business wherein the party is employed. Reg. Orig. 208.

Assise, or Assise, affisa, in Law, a fitting of judges or justices, for the hearing or determining of causes. The word is French, affisa, or affisa, fated; formed of the Latin affisa, to fit together, which is compounded of ad, to, and fido, i fit.

Such is the etymology of the word affisa, given by sir Edward Coke; so that it signifies, originally, the jury who try the cause, and sit together for that purpose. By a figure, it is now made to signify the court or jurisdiction, which comprises this jury together by a commission of affisa, or "ad affisas capiendam" wherein the judicial affinements held by the king's commission in every county, as well to take these writs of affisa, as to try causes at "Nisi Prius," are termed in common speech, the affisa.

ASSIS,
ASS, Clerk of. See Clerk.

Assise, or Assises, was anciently used for certain extraordinary sittings of superior judges, in the inferior courts depending on their jurisdiction, to inquire whether the subordinate judges and officers did their duty; to receive the complaints preferred against them; and to cognize appeals of cases from them. These are also called mercular affises.

Assise was also a court or assembly, composed of several great persons of the realm; held occasionally in the king's palace, for the final decision of all affairs of importance.

This is more usually called, among our writers, placa nulla poation, or curia general. Yet there is some difference between affises and placiæ.—The vicounts or sheriffs, who originally were only lieutenants of the comites, or counts, and rendered justice in their place, held two kinds of courts, the one ordinary, held every day, and called placiæ; the other extraordinary, called affises, or placiæ general; at which the count himself assailed, for the dispatch of the more weighty affairs. Hence the term assise came to be extended to all grand days of judgment, at which the trials and pleadings were to be solemn and extraordinary.

The modern constitution of assises is different from that above-mentioned.—Our assise may be defined a court, place, or time, where and when writs and processses, either civil or criminal, or both, are considered, dispatched, decided, &c., by judges and jury.

In this sense we have two kinds of assises; general and special.

Assises, or Assizes, general, are those held by the judges twice a year, in their several circuits.

The nature of the assises is explained by lord Bacon, who observes, that all the counties of the kingdom are divided into six circuits; to each of which two learned men, assigned by the king's commissio, sit twice a year, except London and Middlesex, where courts of nisi prius are held in and after every term, before the chief or other judge of the several superior courts; and except the four northern counties, where the assises are held only once a year. These are called justices, or judges of affise, and have several commissions by which they sit: viz.

1. A commission of oyer and terminer, directed to them, and many others of the best account in their respective circuits.

In this commission, the judges of affise, or serjeants at law, are only of the quorum; so that without them there can be no proceeding. This commission, which is the largest they have, gives them power to transact matters relating to treasons, murders, felonies, and other misdemeanors. See Oyer and Terminer.

2. The second is of gaol-delivery, which is only to the judges themselves, and the clerk of the affise associate.—By this commission, they have concern with every prisoner in gaol, for every offence whatsoever. See Gaol-Delivery.

3. The third is of affises directed to themselves and the clerk of the affise, to take writs of possession, called also affises, in the several counties; that is, to take the verdicts of a peculiar species of jury, called an affise, and summoned for the trial of landed disputes. These writs were formerly frequent; but now men's possessions are sooner recovered by ejectments, &c.

4. The fourth is to take the nisi prius, directed to the justices, and the clerks of affises; whence they are also called justices of nisi prius. See Nisi Prius.

5. The fifth is a commission of peace, in every county of their circuit; and all the justices of the peace, having no lawful impediment, are bound to be present at the affises, to attend the judges.

The sheriff of every shire is also to attend in person, or by a sufficient deputy allowed by the judges, who may fine him if he fail.

These commissions are constantly accompanied by writs of affias, in pursuance of the statutes 27 Edw. I. c. 4. 12 Edw. II. c. 3, by which certain persons (usually the clerk of the affise and his subordinate officers) are directed to appoint themselves with the judges and serjeants, and they are required to admit the said persons into their society, in order to take the affises, &c. that a sufficient supply of commissioners may never be wanting. But to prevent the delay of justice by the absence of any of them, there is also prefixed of course a writ of "si non onus," directing, that if all cannot be present, any two of them (a justice or serjeant being one) may proceed to execute the commission.

There is a commision of the peace, oyer and terminer, and gaol-delivery of Newgate, held eight times in every year, for the city of London and county of Middlesex, at justice-hall in the Old Bailey, where the lord mayor is chief judge. In Wales there are but two circuits, North and South Wales; for each of which the king appoints two persons learned in the law to be judges. Stat. 18 Eliz. c. 8.

This excellent constitution of judges, circuits, and affises, was begun in the time of Henry II., though somewhat different from what it is now. The grand affise, or trial by jury, instituted by Henry II., as an alternative instead of judicial combats, is particularly described by Gualvin, who was probably the adviser of the measure.

For this purpose a writ, De magna affisa eligenda, was directed to the sheriffs, to return four knights, who were to elect twelve others to be joined with them; all these together formed the grand affise, ordained to try the matter of right.

The judges of affise came into use in the room of the ancient justices in eye, justitiarri in teneore; who were regularly established, if not first appointed, by the parliament of Northampton, A.D. 1176, 22 Hen. II. with a delegated power from the king's great court; and they afterwards made their circuit round the kingdom once in seven years, for the purpose of trying causes. They were afterwards directed by Magna Charta, c. 12, to be sent into every county once a year. Blackstone's Com. vol. iii. See Justices of Affise.

Assise Special, is a particular commision granted to certain persons, to take cognizance of some one or two causes, as a diffidens, or the like. This was very frequently practiced among our ancestors. Bracton, h. iii. c. 12.

Assise is also used for a writ directed to the sheriff, for the recovery of possession of things immovable, whereof a man's self, or anciliaries, have been dispossessed.

Juttletton, and others, suppose these writs of affise, in which the sheriff is ordered to summon a jury or affise, to have given the denomination to the affises, or courts so called; and they assign several reasons of the name of the writ: as,

1. Because such suits settle the possession and right, in him that obtains by them. 2. Because originally they were executed at a certain time and place appointed; for by the Norman law, the time and place must be known forty days before the judges sit; and by our law there must be fifteen days preparation, except they be tried in the flanding courts at Westminster. But it is more natural to suppose the writs denominated from the courts; and that they were called affises, because anciently tried at special courts of affises, set and appointed for that purpose. Though of latter days, these
these are dispatched at the general affifes, along with the commissiion ofoyer and terminer, &c.

This writ of affise is said to have been invented by Glanvil, chief justice to Henry 11; and if so, it seems to owe its introduction to the parliament held at Northampton, in the twenty-second year of that prince's reign; when judges in oyer were appointed to go round the kingdom, in order to take these affises: and the affises themselves (particu larly those of mort d'ancstor and novel d'secif) were clearly pointed out and described. As a writ of entry is a real action, which disproves the title of the tenant, by shewing the unlawful commencement of his possession, so an affise is a real action, which proves the title of the demandant, merely by shewing his or his ancestor's possession; and these two remedies are in all other respects to totally alike, that a judgment on recovery in one is a bar against the other; so that when a man's possession is once established by either of these pleasatory actions, it can never be disturbed by the fame antagoni, in any other of them.

This remedy by writ of affise was called by flat. Wilm. 2. 13 Edw. I. c. 24. feffion remedium, in comparison with that by a writ of entry; as it did not admit of many dilatory pleas and proceedings, to which other real actions are subject; and it is only applicable to two species of injury by ouer, viz. abatement, and a recent or novel d'secif.

Assise of Mort d'Ancestor, or death of one's ancestor, is a writ that lies when father or mother, brother or sister, uncle or aunt, nephew or niece, dies seised of lands, tenements, rents, &c. held in fee simple; and after their death, a stranger abates. It is good as well against the abator, as against any other in possession; but it lies not against brothers or sisters, &c. where there is privy of blood between the person prosecuting and them. Co. Litt. 242. It must also be brought within the time limited by the statute of limitations, in fifty years; or the right may be lost by negligence.

This writ directs the sheriff to summons a jury or affise, who shall view the land in question, and recognize whether such ancestor were seised thereof on the day of his death, and whether the demandant be the next heir; soon after which, the judges come down by the king's commissiion to take the recognition of affise; when, if these points be found in the affirmative, the law immediately transfers the possession from the tenant to the demandant. F. N. B. 195. Finch. L. 290. If the abatement happened on the death of one's grandfather or grandmother, then an affise of mort d'ancestor no longer lies, but a writ of "aile," or "de aevus," if on the death of the great grandfather or great grandmother, then a writ of "fiefde," or "de proveo," but if it mounts one degree higher, to the "frifade," or grandfather's grandfather; or if the abatement happened upon the death of any collateral relation, other than those before mentioned, the writ is called a writ of "rejagnis," or "de confanques," Finch. L. 266, 267. And the same points shall be inquired of in all these actions "ancestrel," as in an affise of mort d'ancestor, as they are of the same nature (flat. Wilm. 2. 13 Edw. I. c. 20.) though they differ in this point of form, that these affise writs (like all other writs of "precept") expressly affect a title in the demandant (viz. the feisin of the ancestor at his death, and his own right of inheritance); the affise affects nothing directly, but only prays an inquiry whether these points be so. 2 Inst. 399. There is also another affise writ, denominated a "super exit," to establish an equal division of the land in question, where, on the death of an ancestor, who has several heirs, one enters, and holds the others out of possession. F. N. B. 197. Finch. L. 293. But a man is not allowed to have any of these actions ancestrael for an abatement consequent on the death of any collateral relation, beyond the fourth degree (Hale on F. N. B. 271.), though in the final act he may proceed in infinitum. It was always held to be law (Bradon. l. 4. c. 13. 3. F. N. B. 160.), that where lands were devisable in a man's will by the custom of the place, there an affise of mort d'ancestor did not lie. For where lands were so devisable, the right of possession could never be determined by a proeis, merely inquiring concerning the feisin of the ancestor, and the heirship of the demandant. Hence it is only the right of possession as to the land, which the statute of wills, 32 Hen. VIII. c. 1. made all socage lands devisable, an affise of mort d'ancestor no longer could be brought of lands held in socage (1 Leon. 267); and that now, since the statute 12 Car. II. c. 24, which converts all tenures, a few only excepted, into free and common socage, no affise of mort d'ancestor can be brought of any lands in the kingdom; but that, in case of abatement, recourse must be properly had to the writs of entry. Bl. Com. vol. iii. p. 187.

These writs, however, are now almost obsolete, being in a great measure superseded by the action of ejectment, which answers almost all the purposes of real actions, some very peculiar cases excepted.

Assise of New d'Secif is an action of the same nature with the "office of mort d'ancestor," as in this the demandant's possession must be shewn. But in other points it is different, particularly as it requites a complaint by the demandant of the d'secif committed in terms of direct averment; whereupon the sheriff is commanded to recifie the land, and all the chattels thereon, and keep the fame in his custody till the arrival of the justices of affise (which, in fact, hath been usually omitted); and in the mean time to summon a jury to view the premises, and make acquaintance of the affise before the justices. F. N. B. 177. At which time the tenant may plead either the general d'secis, "null tortis," or "null d'secifis," or any special plea. And if, upon the general plea, the recognizors find an actual feisin in the demandant, and his subseffion d'secific by the present tenant, he shall have judgment to recover his feisin, and damages for the injury sustained.

This is called "nouel d'secifis," because the justices in eyre went their circuits from seven years to seven years; and no affise was allowed before them, which commenced before the last circuit, called an ancient affise; and that which was upon a d'secif since the last circuit, an affise of new or recent d'secif. Co. Litt. 153. b.

This remedy lies where a tenant in fee-simple, fee-tail, or for term of life, is put out and d'secified of his lands or tenements, rents, common of pellure, common way, or of an office of profit, toll, &c. Glanv. l. 10. Reg. Orig. 197. Affise lies for tithes, by flat. 32 Hen. VIII. c. 7. Cro. Eliz. 559; but not for an annuity, pension, &c.

For preventing vexations and vexatious d'secifs, it is enacted by the statute of Merton, 20 Hen. III. c. 3, that if a perfon d'd'hisfe be recovered feisin of the land again by affise of novel d'secifis, and be again d'secified of the same tenements by the same d'd'hisfe, he shall have a writ of "re-d'secifis," and if he recover therein, the re-d'secifor shall be imprisoned.

And by the statute of Mailberge, 52 Hen. VIII. c. 8, shall also pay a fine to the king; to which the statute Wilm. 2. 13 Edw. I. c. 26 hath superadded double damages to the party aggrieved.

In like manner, by the statute of Merton, when any blind or tenements are recovered by affise of "mort d'ancestor," or other jury, or jury judgment of the court, if the party be afterwards d'secified by the same person against whom judgment was obtained, he shall have a writ

ASSIS, Certificate of, in Law, a writ granted by flat. Well. 2. c. 23. to a party aggrieved, by a verdict or judgment given against him in an aff individually, since he had something to plead, as a record or reekape, which could not have been pleaded by his behalf, or when the affile was taken against himself by default, to have the deed tried, and the record brought in before the juries, and the former jury summoned to appear before them at a certain day and place, for a further examination and trial of the matter. This, in reality, was not mere nor less than a second trial of the same cause by the same jury. Brahms, 1. 4. tr. 5. c. 6. § 2.

ASSISTMENT, See ASSISTANCE.

ASSISTMENT, or ASSISTMENT, in Law of Scotland, is a compensation for a man slain.

Affiliation is the fame with what, in the English Law, is called Mem. Bote.

ASSIUS LAPS, in Physiolog. See LAPS Affius.

ASSO, in Ancient Geography, a town of Hifpania Tarraconensis, in the country of the Dallitani. Trogus.

ASSOCIATE, compound of affis, and ficius, companion, an adjunct, partner, or member.

ASSOCIATION, or ASSOCIATION, the act of associating, or forming a society or company.

Association is properly a contract or treaty of partnership, whereby two or more persons unite together, either for their mutual assistance, or for the joint carrying on of an affair; or even for a more commodious manner of life.

In a military sense, it denotes any number of men embossed in arms for mutual defence in their districts, and for preferring the public tranquillity against foreign and domestic enemies.

The cloofe of all associations is that made by the band of covenant, See Society.

ASSOCIATION of Ideas, is where two or more ideas conjoined, and immediately follow or succeed one another in the mind, so that one shall almost infallibly produce the other; whether there be any natural relation between them or not. Or, it is that principle or faculty by which two or more sensations, ideas, or motions, are so united together, that any one impressed alone shall excite all the rest.

Where there is a real affinity or connection in ideas, it is the excellence of the mind to be able to collect, compare, and arrange them in order, in its inquiries: but where there is none, nor any cause to be assigned for their accompanying each other, but what is owing to mere accident or habit, this unnatural association becomes a great imperfection, and is generally speaking, a main cause of error or wrong deductions in reasoning. Thus, the idea of goblins and sprites has really no more affinity with darkness than with light; and yet let a foolish maid inculcate these ideas often on the mind of a child, and raise them there together, it is possible he shall never be able to separate them again so long as he lives, but darkness shall ever bring with it those frightful ideas. Let custom, from the very childhood, have joined the idea of figure and shape to the idea of God, and what absurdities will that mind lie liable to about the Deity?

Such wrong combinations of ideas, Mr. Locke shews, are a great cause of the irreconcilable opposition between the different fields of philosophy and religion: for we cannot imagine, that all who hold tenets different from, and sometimes even contradictory to one another, should wilfully and knowingly impose upon themselves, and, refuse truth offered by plain reason: but some loose and independent ideas are by education, custom, and the constant din of their party, so coupled in their minds, that they always appear there together: these they can no more separate in their thoughts, than if they were but one idea, and they operate as if they were so. This gives fene to jargon, demonstration to absurdities, consistency to nonsense, and is the foundation of the greatest, and almost of all, the errors in the world.

Mr. Hume observes (Essays, vol. ii. p. 73.), that there is a principle of connection between the different thoughts or ideas of the mind; and that, in their appearances to the memory or imagination, they introduce each other with a certain degree of method and regularity. Of this connection he alleges evidence from our more serious thinking or discourse, from our wilder and most wandering reveries, and even our dreams, and from our looelt and most remote contemplation. Among different languages also, words expressive of ideas the most compound, nearly correspond to each other: and hence it is inferred, that the simple ideas comprehended in the compound ones are bound together by some universal principle, which has an equal influence on all mankind. This writer affirms the association or connection of ideas to three principles: viz. "resemblance," "contiguity" in time or place, and "cause" or "effect." These, he says (p. 54.), are the only bonds that unite our thoughts.
thoughts together, and beget that regular train of reflection or discourse, which, in a greater or less degree, takes place among all mankind. Although it should be allowed, that these are real principles of association or connection in our ideas, it may be urged that ideas succeed one other without resemblance or contiguity as to time and place, and without the mutual correspondence or relation of cause and effect; and that there are other associations besides those of ideas, which are associated with passions and emotions, and passions and emotions are associated together. A particular idea is associated together with a proper name; and often with the general name of the species; general conceptions, or mixed modes, as they are denominated by Mr. Locke, are associated with signs both audible and visible, and signs are associated with one another. Virtue, as it conforms in action and intention, does not resemble the found virtue, is not contiguous to it in time or place, and is neither its cause nor its effect; nor can it be imagined that the arbitrary signs of various objects should have any natural relation to one another. But if there were no other principles of association besides those of Mr. Hume, the author himself has not shown how they account for the phenomena.

Dr. Hartley, whatever may be thought of his general system, has attempted to form a mechanical theory of the human mind and its various operations by means of "association." The principle or law of association seems to have been first noticed by Mr. Locke; but he applies it to the solution of very few phenomena. Mr. Gay, in "A Dissertation upon Virtue," prefixed to "Law's translation of King's Origin of Evil," deduces the moral feelings from association; and Dr. Hartley traces all, or at least most of the other phenomena of mind to the same cause. This law of association extends to "Sensation, to Ideas, and to Muscular Motion;" which see respectively.

Accordingly he distinguishes it into synchronous and successive; and ascribes our simple and complex ideas to the influence of this principle or habit. Particular sensations result from previous vibrations conveyed through the nerves to the medullary substance of the brain; and these are so intimately associated together, that any one of them, when impressed alone, shall be able to excite in the mind the ideas of all the rest. Thus we derive the ideas of natural bodies from the association of the several sensible qualities with the names that express them, and with each other. The sight of part of a large building suggests the idea of the rest instantaneously, by a synchronous association of the parts; and the sound of the words, which begin a familiar sentence, brings back remembrance of the remaining parts in order by successive association. Dr. Hartley maintains that simple ideas run into complex ideas by association; and apprehends that by purifying and perfecting this doctrine, we may form time or other be enabled to analyze those complex ideas that are commonly called the ideas of reflection, or intellectual ideas, into their several component parts, i.e. into the simple ideas of sensation of which they consist; and that this doctrine may be of considerable use in the art of logic, and in explaining the various phenomena of the human mind. For a further exposition of Dr. Hartley's doctrine of association, the philosophical principles upon which it depends, and the mode of its application, the reader must be referred to his "Observations on Man," vol i. or part i. passim; and also to Priestley's "Abridgment of Hartley," s. t. Stewart's "Elements of the Philosophy of the Human Mind," 4to. 1792. ch. v.; Darwin's Zoology, vol i. § 5—10.

A late writer observes, that the doctrine of association is to be very carefully distinguished from the theory of vibrations, being established upon independent evidence and undeniable facts. This therefore, he adds, must stand, though the other should be regarded only as a plausible hypothesis, delusive of satisfactory proof. It was to prevent the confusion of the nature and evidence of association and vibration, says this writer, that Dr. Priestley published his edition of Hartley's work, from which the present work is entirely excluded. Belphius' Elements of the Philosophy of the Mind, and of Moral Philosophy, etc. 1801. P. 54. See also Ether, Idea, Memory, Sensation, Vibration, and Vibrations.

Association, in Law, is a writ or patent sent by the king, either of his own motion, or at the suit of a party plaintiff, to the justices of assize, to have other persons associated to them, in order to take the affize.

Upon this patent of association, the king sends his writ to the justices of the affize, thereby commanding them to admit such as are sent.

The clerk of the affize is usually associate of course; in other cases some learned seigneurs at law are appointed. See Assize.

Association of Parliament. In the reign of King William III. the parliament entered into a solemn association to defend his majesty's person and government against all plots and conspiracies: and all persons having offices civil or military were enjoined to subscribe the association to stand by King William, on pain of forfeitures and penalties, &c. by stat. 7, and 8 W. III. c. 27.

Association, Peathers Tavern, consisted of a number of clergymen, and of gentlemen in the professions of civil law and physic, who, willing to be exempted from the obligation of subscribing the thirty-nine articles of religion, applied in the year 1772, by petition to parliament for this purpose. Their society was so called, from the place where they met. The object at which they aimed was to be permitted to hold their preferments, upon condition of merely subscribing to the holy scriptures, agreeably to the grand Protestant principle; which is, that every thing necessary to salvation is fully contained in these scriptures, and that they are the sole rule of faith and manners. The request, however, was not thought to comport with the nature of a civil establishment in religion; and principally on this ground, it was strenuously opposed by many distinguished members of parliament, and as strenuously defended by some of the first persons in the house of commons. After a long and interesting debate, the admission of the petition was rejected by a large majority. It was the general opinion, that those who propose to reap the benefits of the established church, ought to comply with the terms on which they are offered.

Association, Protestant, took its rise from an act passed in 1778, for relieving his majesty's subjects, professing the Roman religion, from certain penalties and disabilities imposed upon them in the eleventh and twelfth years of the reign of King William III. The act was passed unanimously; nor did it at first appear to excite any great alarm among persons of any clafs. The papists, as they now thought the government inclined to be more indulgent to them than it had formerly been, began to take somewhat greater liberties in the exercise of their religion than they had been accustomed. By degrees, a number of persons in London, and in some other parts of the kingdom, began to express great apprehensions of the increase of popery, and to exclaim against the late act, by which they thought it was countenanced and supported. Meetings of these zealous persons were held from time to time in London; and they formed themselves into a body under the
ASS

the title of the “Protestant Association,” and at length
Lord George Gordon became their president. The object
of their association was to procure a repeal of the late act in
favour of the papists. The persons who attended these
meetings were, many of them, honest and well-intentioned
people, who had a just aversion to popery, but who did not
duly consider that, an intolerant spirit was at least as conser-
vable in a protestant as in a papist. In a little while, how-
ever, their number, confounding of persons in the lower ranks
of life, became very considerable. A petition to parliament
was framed, for a repeal of the late act, and the utmost pains
were employed to procure subscriptions to it. The number
of subscribers is said to have amounted to 120,000 persons.
In order to give weight to their petition, it was determined
that it should be attended by great numbers of the petitioners
in person; and a public advertisement was issued for that
purpose, signed by Lord George Gordon. Accordingly
it is supposed that at least 50,000 persons assembled on the
second of June in St. George’s Fields, and proceeded in
great order to the house of commons, where their petition
was presented by their president. Several members of both
houses of parliament were greatly inflamed and ill-treated by
the populace, and in the evening a mob assembled which
destroyed two Romish chapels. The metropolis, for sev-
eral subsequent days, became an unexampled scene of alarm,
terror, and devastation; and for some time the magistrates
in general manifested little activity. At length, when the
rioters were making a formidable attack upon all property,
and every man’s personal security was endangered, the
military interposed, and, after considerable exertions, restored
the capital of the kingdom to order and tranquillity, after
a devastation that had continued for six days, and not with-
out the loss of many lives. The number of persons killed
and wounded by the military in the suppression of these
riots, is said to have amounted to 458 persons. It would
be unjust, however, to impute to the protestant association,
as the first agents in this business thought proper to flyle
themselves, the whole of the mischief that ensued, or to
impute to them what we may foretell the calamities to which
they gave occasion. Yet it must be allowed, that these unhappy
people owed their origin to their bigotry and delusion; and
that the members of that association manifested a spirit the
very reverse of that which distinguishes real and enlightened
protestants, and very disgraceful to the national character.
It has been asserted, that no member of the protestant associ-
ation was executed or tried for any share in the riots; and it
is most probable, that those who engaged in this diabolical
business from religious bigotry, would have the discretion
to retire before the law executed, and before the intervention
of the military. Several of the rioters were afterwards appreh-
sended, tried, and executed. Lord George Gordon was
committed to the Tower on the tenth of June, arraigned on
the twenty-fifth of January, 1781; and on the fifth of
February, tried under a charge of constructive treason, and
acquitted.

ASSOILE, in Our Ancient Law-Books, signifies to ab-
solve, deliver, or set free from an excommunication. See
A bsolution.

ASSOKO, in Geography, a town of Africa, the capital of
Issi, in an island of the same name, formed by the river
Issi; which is the ordinary residence of the king and his
attendants.

ASSOM. See Assem.

ASSONANCE, in Rhetoric and Poetry, a term used
when the words of a phrase, or verse, have the same sound
or termination, and yet make no proper rhyme.

These are usually vicious in English; the Romans some-
times used them with elegance: “Mili-ment comparavint,
exercise ordinavint, aciem luftravit.”

The Latins call it familiaris definitio; and the Greeks
translato.

ASSONANT Rhymes, is a term particularly applied
to a kind of verses common among the Spaniards, where
a resemblance of sound serves instead of a natural rhyme.

Thus “tiger, cubierta, tierra, mefio,” may answer each other
in a kind of affonant rhyme, because they have each an e
in the penultimte syllable, and an a in the last.

ASSONGSONG, in Geography. See Island of

ASSONIA, in Botany, a genus of plants, fo named in
honour of Ignatius de Affo, a Spanish botanist. Lin. gen.
121. Clafte, monadelphus subfandus. Nat. Ord. columna-
outer three-leaved, unilateral, deciduous; inner one-leaved,
five-parted, fully lanceolate, acute, reflex. Cor. petals five,
roundish, narrowed at the base, spreading, withering, affixed
to the pitcher of the flowers. Stems. Flaments fifteen, fili-
form, upright, shorter than the corolla, joined at the base
in the form of a pitcher; anthers oblong, subfagittate, erect;
five linear-lanceolate, somewhat erect, coloured, petal-formed
flaps between the flaments, proceeding from the pitcher.
Pitch, germ roundish, five-furrowed; style simple, longer
than the flaments, permanent; stigma five, recurved. Per.
capsule subglobose, or turbinate, five-celled; cells separable,
bivalve. Seed, solitary or in pairs, subovate. Obs. aflonia
with the outer perianth one-leaved, three-toothed, and
with five styles, does not seem separable from Dombeya cav.
with the outer perianth three-leaved, and a single style, any
more than the hibiscus tilacuss from the other hibiscus;
or the one styled fidda, from the red; especially as Dombeya
ovata cav. has the style divided almost to the base.

We have therefore followed Schreber and Martin in uniting
Dombeya with aflonia.

Species. 1. A. populnea. Cavan. Diff. t. 120. 1, 124, f. 1.
“Leaves cordate, ovate-acuminate; flowcrs corysted.”
A small tree resembling hibiscus populneus. The French
call it bois de fenteur bleu ou galeux, because the wood is
sweet-scented, and blue in the centre, and when old it be-
comes very hard. Leaves alternately feathered, large, entire,
and often obliquely or angularly small, or feveral as scarcely to be
observed; petals small, oblong, obtusely five-angled, stiff, white,
afterwards ferrugineous. A native of the coast of
Bourbon, in allied woods. 2. A. palma, Dombeya palma, Cavan. l.c.
“Leaves cordate, palmate, smoothish, lobes
seven, acute, ferrate-crenate; flowers corysted.” Stem
arboresous; leaves alternate, on long footstalks; lobes oblong-
acuminate; iliples lanceolate, tomentose, deciduous; flowers
in solitary peduncules, at the ends of the branches, tomentose;
corolla an inch and a half wide, changing from white to a
phurpul colour, and lally ferrugineous. A native of the
isle of Bourbon, where it is called by the natives mahot-tantian.
3. A. acutangula. Cavan. l.c. “Leaves cordate, roundish,
three-cupped, crenate; flowers racemose.” Stem arboresous;
leaves alternate, of the length of the footstalks, seven-nerved,
and commonly with an angular tooth between the base and
lateral divisions; racemes solitary, axillary; calyxes extremely
long; tomentose; corolla as that of A. palmata (2); but veined
and coraceous; fruit pear-shaped. A native of the
isle of Bourbon. 4. A. angulata, Dombeya angulata. Cavan. l.c.
“Leaves cordate, roundish, angular at top, ferrate-toothed
To mentose; umbels numerous; common peduncles shorter
than the petiole.” Arboresous; branches tomentose; leaves
with three angles at the tip, seven-nerved; iliples embracing
the
the stem; umbels axillary, solitary; fruit globular, with two seeds in each cell. A native of the Isle of Bourbon. 5. A. tilagyphi, Dombeya tilagaphi. Cav. L. c. "Leaves cordate, rounded, crenate; flowers raceme-corymbed, arborescent." All the shrub very tomentose; leaves shaped like those of the common lisetree, seven-nerved, tomentose; peduncle axillary, solitary, divided at the end into opposite horizontal racemes. A native of the island of Bourbon. 6. A. tomentosa, Dombeya tomentosa. Cav. L. c. "Leaves cordate, rounded, crenate, tomentose, with almost circular veins; flowers unised." Stem arborescent; branches the whole tree very tomentose; stigmas coriaceous, broad-ovate, acuminate, ciliate, half-blister clasping; common peduncle very long, forked at the top, and terminated by two umbels; petals roundish, fimbriated. A native of Madagascar. 7. A. punctata, Dombeya punctata. Cav. L. c. "Leaves ovate-lanceolate, long, quite entire, tomentose underneath, rugged with dots on the upper surface." Trunk about the thickness of the human leg or thigh, covered with dark-brown bark; branches alternate, tomentose; leaves three or four inches long (sometimes cruculate or minute), rounded at the base; flowers on a long axillary common peduncle, umbelised, white, but becoming ferruginous by age; pedicellis twenty or thirty, one-flowered. A native of the island of Bourbon. 8. A. decandra, Dombeya decandra. Cav. L. c. "Leaves ovate-acuminate, repand-crenate, smooth; stamens five, two-anthered; flowers small, unised." Stem arborescent, with a brown furrowed bark; leaves alternate, scattered, four times as long as the pedicels; the outer calyx-conflis of three very small bristles; corolla in 5 or 6 lines in diameter; filaments ten, five barren, five fertile; germ five or more, one each in each cell of the fruit. A native of Madagascar. 9. A. umbellata, Dombeya umbellata. Cav. L. c. "Leaves cordate, ovato-oblong, acuminate, repand-linear; flowers umbelisised, globular." A tree entirely smooth, with a brown bark; leaves longer than the pedicels, either repand about the edge, or oblootely and broadly crenate; common peduncles solitary, axillary, on the tops of the branches red-dish, very smooth, terminated by a single foliaceous umbel. A native of the island of Bourbon, where ropes are made of the bark. 10. A. ovata, Dombeya ovata. Cav. L. c. "Leaves ovate, toothed, five-nerved, tomentose; flake very small." Stem shrubby, branched, covered with a ferruginous nap; leaves alternate, white underneath, rugged on the upper surface, double the length of the pedicels; stigmas capillary, crenate; pedicels forked at the top, with a corymb at each division; corolla small; petals narrow, roundish at the end, or fimbriated; their claws are permanent, and deeply ferruginous. Fruit globular, five-cornered, within the segments of the calyx. A native of the island of Bourbon. 11. A. ferruginea, Dombeya ferruginea. Cav. L. c. "Leaves ovato-oblong, seven-nerved, ferruginous beneath; petals, pedicles, and calyxes tomentose." Stem arborescent, from eight to ten feet high; branches covered with a rufous nap; leaves on the extreme twigs, scattered alternately, acuminate, tooth-furrowed, crenate on the under surface; pedicels double the length of the pedicels, forked at the top, with a many-flowered corymb on each division. This, perhaps, may be a variety of the A. ovata; the leaves, however, are much broader at the base, acuminate, seven-nerved, and very much toothed; wheras in that they are finitely ovate, five-nerved, and the teeth are divergent. A native of the island of Mauritius, and first discovered by Comberon in 1769.

Propagation and Culture. See Hibiscus and Pentapeses. Assonias, or Dombeya Pheneica. See Pentapeses. Assorus, in Ancient Geography, a town of Macedonia, in Mygdonia. Potokery. Also, a town of Sicily, seated on a hill to the left of the river Chryus. Died. Sic. Assos, or Assos, a sea-port town of Asia Minor, in the Troad, fortified both by art and nature, according to Strabo. Aés, xx. 13. Assos, or AsaS, is now a sea-port of Asiatic Turkey, in Natalia, on a gulf of the Ician sea, to which it gives name, four leagues s. e. from Troad, and eleven leagues west of Adamnit. N. lat. 35° 38'. E. long. 26° 1'. Assos, Assos, or Asas, a small town of Crete. Assouan, near the ancient Syene, a poor village on the east side of the Nile, with a small fort commanded by an agn of the janizaries. N. lat. 24° 4'. E. long. 33° 30'. This place is called by the Arabs Assouan, which signifies enlightened, in allusion as Bruce supposed, to the circumstance of the well mentioned by Pliny (H. N. i. ii. 52.)-enlightened within the fune's being directly over it in June. Bruce's Travels, vol. i. p. 158. See Syene. Assrumina, in Botany, the name given by the people of Guineal to the shrub whose leaves they use as a cure for the long worms which are found in their flesh in those parts of the world; they only bruise the leaves, and apply as much of the mps to the part where the worm is, and they are cured at once, without the pain and hazard of drawing it out. Phil. Trans. No. 232. Assulatus, in Natural History, a species of Echitis. The shell is facetted, the facets united by transverse lines. Klein, p. 15. 26. Eldorado tefubata of Klein, p. 27. is supposed to be a variety of this kind. Assumpsit, in Law, denotes a voluntary promise by which a man affirms and takes upon him to perform, or to pay any thing to another. This term comprehends all verbal promises made upon consideration, and is variously expressed by the civilians, according to the nature of the promise: sometimes by promissum; sometimes by promissum et fidelitatis, or confitutum. If the promise be to do any explicit act, it is an express contract, as much as any covenant; and the breach of it is an equal injury. However, the remedy is not exactly the same. Since, instead of an act of covenant, there only lies an action upon the cafe, for which it is called the affumpit or undertaking of the defendant; the failure of performing which is the wrong or injury done to the plaintiff, the damages of which the jury are to estimate and settle. As if a builder promises, undertake, or affirms to build, that he will build and cover his house within a time limited, and fails to do it; Cans has an action on the cafe against the builder for this breach of his express promise, undertaking, or affumpit; and shall recover a pecuniary satisfaction for the injury fullained by such delay. So also in case of a debt by simple contract, if the debtor promises to pay it and does not, this breach of promise entitles the creditor to his action on the cafe, instead of being driven to an action of debt, 4 Rep. 92. Thus likewise a promissory note, or note of hand not under seal, to pay money at a day certain, is an express affumpit; and the payee at common law, or by cullum and act of parliament the indorser, may recover the value of the note in damages, if it remains unpaid. Action on the cafe or affumpit lies, for not making a good estate of land sold, according to promise; not paying money upon a bargain and sale, according to agreement; not delivering goods promised on demand; this is by express affumpit.
ASS

affumptio. When one becomes legally indebted to another for goods sold, the law implies a promise that he will pay the debt; and if it be not paid, indebJation affumptio lies: and the same lies for goods sold and delivered to a stranger "ad requisitionem" of the defendant; the price being agreed upon and proved: 1 Danv. Abr. 26, 27. If a tenant, being in arrear for rent, settles an account of arrears with his landlord, and promises to pay him the sum in arrear, an affumptio lies on this promise. 1 Rol. Abr. 9. If a man and woman, being unmarried, mutually promise to marry each other, and afterwards the man marries another woman, by which he renders himself incapable of performing his contract, an affumptio lies, in which the woman shall recover damages. Carter, 233. There are, however, five cases, specified by the statute of frauds and pari juries, 29 Car. II. c. 3, in which no verbal promise will be sufficient ground of action, without some note or memorandum in writing, signed by the party who is to become chargeable. 1. Where an executor or administrator promises to answer damages out of his own estate. 2. Where a man undertakes to answer for the debt, default, or miscarriage of another. 3. Where any agreement is made, upon consideration of marriage. 4. Where any contract or sale is made of lands, tenements, or hereditaments, or any intervel therein. 5. Where there is any agreement that is not to be performed within a year from the time of its being made. In all these cases a mere verbal affumptio is void. The consideration is the ground of the common action on the case; and no such action lies against a man for a promise, where there is no consideration why he should make the promise.

Besides ex profi contracts, there are others implied by law: and these are such as reason and justice dictate, and which, therefore, the law presumes that every man has contracted to perform: and, upon this presumption, to become answerable to such persons as suffer by his non-performance. Of this nature are, first, such as are necessarily implied by the fundamental constitution of government, to which every man is a contracting party. Thus it is that every person is bound and hath virtually agreed to pay such particular sums of money, as are charged on him by the sentence, or affixed by the interpretation of the law. By the same principle of an implied original contract to submit to the rules of the community of which we are members, a forfeiture imposed by the bye laws and private ordinances of a corporation upon any that belong to the body, or an amercement in a court-leet or court-baron upon any of the tutors to the court, create a debt in the eye of the law; and such forfeiture or amercement, unpaid, works an injury to the party or parties entitled to receive it, for which the remedy is by action of debt. The same reason may with equal justice be applied to all penal statutes, or such acts of parliament that inflict a forfeiture for transgressing the provisions enacted by them. A second class of implied contracts are such as arise from natural reason, and the just construction of law; and this class extends to all presumptive undertakings or affumptios, which, though never perhaps actually made, yet constantly arise from this general implication and intention of the courts of judicature, that every man hath engaged to perform what his duty or justice requires. Thus, if I employ a person to transact any business for me, or to perform any work, the law implies that I undertook or assumed to pay him so much as his labour deserved. If I neglect to make him amends, he has a remedy by an action on the case upon this implied affumptio. The valuation of his trouble is submitted to the judgment of a jury, who will affix such a sum in damages as they think he really merited. This is called an affumptio on a "quantum meruit." There is also an implied affumptio, on a "quantum solvitor," similar to the former; where one takes upon goods or wares of a tradesman, without expressly agreeing for the price. Here the law concludes, that both parties did intentionally agree, that the real value of the goods should be paid; and an action on the case may be brought accordingly, if the vendee refuses to pay that value. Another species of implied affumptios is when one has had and receivd money belonging to another, without any valuable consideration given, on the receiver's part; for the law construes this to be money had and received for the use of the owner only; and implies that the perdon to receiving promised and undertook to account for it to the true proprietor. And if he unjustly detains it, an action on the case lies against him for the breach of such implied promise, and undertaking; and he will be made to repair the owner in damages, equivalent to what he has detained in violation of such promise. This is applicable to almost every case where the defendant has received money, which "ex suo et boso" he ought to refund. 1 Burr. 1012. Moreover, when a perdon has laid out and expended his own money for the use of another at his requell, the law implies a promise of repayment, and an action will lie on this affumptio. Carth. 446. 2 Keb. 99. Also, upon a listed account between two merchants, or other persons, the law implies that he against whom the balance appears has engaged to pay it to the other; though there be no actual promise. From this implication, actions on the case are frequently brought, declaring that the plaintiff and defendant had settled their accounts together; "in faciis comptis," which gives name to this species of affumptio, and that the defendant engaged to pay the plaintiff the balance, but has since neglected to so it. The last class of contracts, implied by reason and construction of law, arises upon the supposition, that any one who undertakes any office, employment, trust, or duty, contracts with those who employ or entrust him to perform it with integrity, diligence, and skill; and, if by his wanting either of these qualities, any injury accrues to individuals, they have their remedy in damages by a special action on the case. If a sheriff does not execute a writ sent to him, or wilfully makes a false return, the party aggrieved shall in both cases have an action on the case for damages, to be assailed by a jury. Moor, 431. 2 Rep. 99. If a sheriff or gaoler suffers a prisoner, taken upon forfeiture, or during the pendency of a suit, to escape, he is liable to an action on the case; but if, after judgment, a debtor charged in execution for a certain sum be permitted to escape, a gaoler or sheriff is compellable by action of debt for a sum liquidated and ascertained, to satisfy the creditor his whole demand. Rat. Weitn. 2. 13 Edw. I. c. 11. and 1 Ric. II. c. 12. 2 Inst. 382. An advocate or attorney betraying the cause of their client, or, being retained, neglecting to appear at the trial, by which the cause miscarries, are liable to an action on the case, for a repayment to their injured client. Finch L. 188. There is also in law a promise, implied without consideration, known under the name of inkeeper, to secure the goods of his guest; with a common carrier or stage-carrier, to be answerable for the goods he carries; with a common carrier, that he does a horse well, without laming him; with a common tailor, or other workman, that he performs his buisness in a workman-like manner; in which if they fail, an action on the case lies for the recovery of damages for such breach of their general undertaking. 11 Rep. 54. 1 Saund. 324. If an inkeeper, or other victualler, hangs out a sign, and openes his house for travellers, it is an implied engagement to entertain all persons who travel that way; and upon this universal affumptio an action on the case will be against him.

ASS & ASSURANCE
If the odds against its failing being two to one, that is, if it may be expected that some one of three lives, at the age of the given life, will fail in the year, the value of the assurance will be a third of the first value, reckoning the same interest, or 31. 14s. 1d. If the odds be nineteen to one, or if it may be expected that some one out of twenty lives, at the age of the given life, will fail in a year, the value of the assurance will be a twentieth part of the first value, or 4l. 15s. 3d. If the odds be forty-nine to one, or only one out of fifty such lives as the given life can be expected to fail in the year, the value of the assurance will be a fiftieth part of the first value; that is, it will be 1l. 18s. 1d. Now the odds of three to one are, according to the Northampton Table of Observations (see Mortality), the odds that a life aged 62 will not drop in a year. The odds of 19 to 1 are the odds, according to the same table, that a life aged 65 will not drop in a year; and the odds of 49 to 1 are the odds that a life aged 39 will not drop in a year. It follows, therefore, that the value of the assurance of 100l. for a year on a life aged 62 is 31l. 14s. 1d.; on a life aged 65, 4l. 15s. 3d.; on a life aged 39, 1l. 18s. 1d., reckoning interest at 5 per cent. If interest be reckoned at 5 per cent, these values will be 32l. 7s. 6d.; 4l. 17s. 2d.; 1l. 18s. 1d. The assurances most commonly practiced are those on single lives, either for a given term, or during their whole continuance. When a life is assured for a given term or number of years, the value may be paid either in one single present payment, or in annual payments, to be continued till the failure of the life, should that happen within the term; or if not, till the determination of the term.

The method of finding these values cannot be easily understood by those who are unacquainted with the doctrine of life-annuities, as it has been taught by mathematicians; but the following observations may be of use to give some general idea of the subject. Let us suppose that a person aged 30 years wants to assure 100l. on his life for 27 years, or till he is 60 years of age, and that he chooses to advance the proper compensation for it in a fixed annual payment, the first to be made immediately, and the following payments to be continued till either the term ends, or his life drops. The value of the assurance for the first year, is by what has been already shewn, 1l. 18s. 1d., reckoning interest at 5 per cent. The value of the assurance for the last year of the term, supposing him to have lived to the beginning of it, or to have completed 65, is likewise, by what has been already shewn, 4l. 15s. 3d., reckoning all along at the same interest. If, therefore, the value of the assurance for the whole 27 years is to be one constant sum paid at the beginning of every year, that sum, it is obvious, ought to be greater than the first, and less than the last; or a sum which is some mean between 1l. 18s. 1d. and 4l. 15s. 3d. The rule for finding this mean in all cases is the following.

"From the value of an annuity certain for the given term, found by Tab. III. under the article Annuities, subtract the value of the life for the given term, found by the method explained under the article Life Annuities, and refer the remainder. Multiply the value of 1l. due at the end of the given term (found by Tab. I. under the article Annuities), by the perpetuity (see Remark II.), and also by the probability (see Mortality), that the given life shall fail in the given term. This product being added to the referred remainder, let the total be multiplied by the sum to be assured, and afterwards divided by the perpetuity increased by unity, then let this quotient be referred. Find next the value of an annuity on the given life for one year less than the given term, and the referred quotient being divided by this last value, increased by unity, will give the required value of the assurance in a fixed annual payment, till either the life fails, or the term ends."

Example.

Let the term be 27 years, the life aged 39, the sum 100l., and the interest 5 per cent.

Solution.

The value of the life of a person whose age is 39, for 27 years, is (reckoning interest at 5 per cent., and by the Northampton Table of Life Annuities) 11,019. This value subtracted from 14,643 (the value of an annuity certain for 27 years, see Tab. III. Annuities), leaves 3,452, the remainder to be referred. The value of 1l. to be received at the end of 27 years is 267.85, by Tab. II. under the article Annuities. The probability that the life of a person aged 30 shall fail in 27 years, is, by the Northampton Table, (see Mortality) 24 1/8; and the perpetuity is 20. These numbers multiplied by one another, and 3,452 added to the product, make 6,686, which multiplied into 100l. the given sum, and divided by 21, the perpetuity increased by unity, gives 31,276 for the quotient to be referred.

The value of an annuity on a life of 39 for 26 years, is 11,019. Dividing therefore 31,276 (the referred quotient) by 12,019, or the value of the above annuity, with unity added to it, we have 2,621, or 2 l. 12s., which is the required value, in fixed annual payments, of the assurance of 100l. on the given life for 27 years, reckoning interest at 5 per cent.

The value of the same assurance in one present payment is the quotient referred above, or 31l. 5s. 6d.; in other words, it is the value of an annuity of 2 l. 12s. for 26 years on a life of 39; the first payment of which is to be made immediately, and the remaining ones at the beginning of each year; or, it is the fund arising in the foregoing operation before the division by the value of the life for the term of 26 years.

If the assurance is to be made for the whole possible duration of the life, the method of finding the value will be more simple, and the rule for this purpose is as follows. From the perpetuity subtract the value of the given life, and multiply the remainder by the given fund, and this last product divided by the perpetuity, increased by unity, will give the value in a single present payment. And this payment, divided by the value of the life, will give the value of the assurance in annual payments during the continuance of the life."

Example.

Let the age of the life be, as in the last example, 39; the sum to be ascertained for its whole duration 100l.; and the rate of interest 5 per cent. The value of the life, according to the Northampton Table (see Life Annuities), is 11,079. The value of the life subtracted from 20 (the perpetuity) is 8,021, which multiplied by 100, the given fund, and divided by 21, the perpetuity increased by unity, gives 38,195 l. or 381 4s. for the value in a single payment of the assurance of 100l. for the whole duration of a life aged 39, reckoning interest at 5 per cent. And this payment divided by 11,079 is 3.488 l. or 3 l. 3s. 9d. the value of the same assurance in annual payments during the continuance of the life.

Remark I.

If the value of the assurance is defined in annual payments, the first of which, instead of being made at the end of the year as the preceding rule supposes, is to be made immediately, the value in a single payment (found as directed above) must be divided by the value of the life increased by unity; that
that is, in the present instance, by 12.979, which will make
the required value of the assurance 1294.1, instead of 3188.1
or 2118.410.1, instead of 31.389 d.
The reason of adding unity to the values of lives taken
from the tables is, that in all the tables the values of annui-
ties on lives are given on the supposition that the first
payment is not to be made till the end of a year. If therefore
the first yearly payment is to be made immediately, the
value must exceed that in the tables by one year's pur-
chase.

REMARK II.
The perpetuity means the value of the reversion of an
estate, which is found by dividing 100 l. by its interest for
a year. For example, if the rate of interest be 5l. per
cent. 100 l. divided by 5 gives 20 for the perpetuity; if
the rate of interest be 4l. 21/3, or 3 per cent. 100 l. divided
by 4, 35 or 3, will give 25, 28.571, or 33.333 for the
perpetuity.

REMARK III.
If instead of a gross sum, an estate or a perpetual annuity is
to be assured during the whole duration of a life, the value in
a single payment will be "the value of the life subtracted
from the perpetuity, and the remainder multiplied by the
annuity, or by the rent of the estate." And the value in
annual payments beginning immediately will be "the single
payment divided by the value of the life increased by unity.
"—Universally, it ought to be remembered that the assurance
of an estate or annuity after any given life or lives, is
worth as much more than the assurance of a corresponding
sum, as 100 l. increased by its interest for a year is greater
than 100 l.—Thus the present values, in single and annaual
payments of the assurance of an estate of 5 l. per ann. for
ever, and of a 100 l. in money on the whole duration, or
on any part of an assigned life, are to one another (interest
being at 5 per cent.) as 105 to 100. The reason of the differ-
ence is, that the algebraical calculations, by which these values are determined, suppose that the gross sum and the first yearly payment of the annuity are to be received at the same time after the extinction of the lives. It is easy
to see, that this is a circumstance which must make the
latter of more value.

This specimen is sufficient to explain the general nature
and principles of assurances on single lives, and to teach
in all cases the method of finding the values of such
 assurances. To those who wish to be further informed on
this subject, it may not be improper to add the following
mathematical demonstrations of the rules which have been
given above. Let a be the number of persons living at
the age of any given life A; let a', a'2, a" etc. be the number
of persons who have died in the 1st, 2d, 3d, 4th, 
year after the age of A; let r be 1 l. increased by its interest for
a year, and S the sum to be assured. The probability that A
dies in the 1st year is \( \frac{a}{a} \), the value therefore of the
assurance in that year is \( \frac{S.a}{ar} \). The probability that A dies
in the 2d, after having survived the 1st year, is \( \frac{a'}{a} \), and

\[
\text{consequently the value of the assurance in the 2d year is } \frac{S.a'}{ar}.
\]

In like manner, the value of the assurance in the 3d, 4th, 5th,

\[ \ldots \text{--- n-th year, supposing m to denote the number of persons} \]

\[ \text{who have died in the m-th or last year, is } \frac{S.a''}{ar^2}, \frac{S.a'}{ar^3}, \frac{S.a}{ar^4}, \ldots \]

\[ \text{--- and } \frac{S.m}{ar^n} \text{ respectively. The whole value, therefore, of} \]

the assurance for n years is \( S \times \frac{a}{ar} + \frac{a'}{ar} + \frac{a''}{ar} + \ldots + \frac{m}{ar^n} \).

But the series \( \frac{a}{ar} + \frac{a'}{ar} + \frac{a''}{ar} + \ldots \) &c. is \( \frac{1}{r} - \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \frac{a-a^4}{ar^4} + \ldots \)

\[ = \frac{1}{r} + \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \frac{a-a^4}{ar^4} + \ldots \]

\[ = \frac{1}{r} - \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \frac{a-a^4}{ar^4} + \ldots \]

\[ = \frac{1}{r} + \frac{a-a}{ar} \] (supposing l to be the number of per-
sons who have died in the \( n-1 \) th year). The series \( \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \ldots \)

\[ \text{is known to express the value of an annuity on the life of } A \text{ for } n \text{ years, and the se-
ries } \frac{1}{r} + \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \ldots \]

\[ = \frac{1}{r} + \frac{a-a}{ar} \text{ to express the value of an} \]

annuity certain for \( n \) years. Call the first of these series \( A \), and the second \( N \); then will the whole of the above
series be \( N-A = \frac{N}{r} + A + \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \ldots \)

\[ = \frac{N}{r} - A + \frac{a-a}{ar} + \frac{a-a^2}{ar^2} + \frac{a-a^3}{ar^3} + \ldots \]

\[ = \frac{N}{r} + \frac{a-a}{ar} \text{, and the value of the assurance of } S \text{ for } n \text{ years will} \]

\[ \text{be } \frac{S}{r} \times \frac{N}{r} - A + \frac{a-a}{ar} \text{, agreeable to the rule given} \]

above.

If the assurance be for the whole continuance of life, the
fraction \( \frac{m}{ar^n} \) vanishes, \( N \) becomes equal to the perpetuity,
and \( A \) to the value of an annuity for the whole life of \( A \),
so that in this case the expression becomes simply \( \frac{S}{r} \times \frac{N}{r} + \frac{a-a}{ar} \),

\[ = \frac{S}{r} - A \] which is the rule given in words for finding the
value of an assurance on the whole possible duration of the
life of \( A \).

If the assurance be that of an estate or a perpetual annuity,
the value of each payment of such annuity depending on the
failure of the life of \( A \) in one, two, three, &c. years to \( n \)
years will be \( \frac{1}{r} - \frac{a-a'}{ar} - \frac{a-a''}{ar^2} - \frac{a-a'''}{ar^3} - \ldots \)

\[ = \frac{1}{r} - \frac{a-a}{ar} + \frac{a-a'}{ar^2} + \frac{a-a''}{ar^3} + \ldots \]

\[ = \frac{1}{r} - \frac{a-a}{ar} \text{, and the value of the} \]

reversion after \( n \) years, depending on the contingency of
\( A \) having died in the mean time, will be \( \frac{m}{ar^n} \); the whole
value, therefore, of the assurance will be \( N-A + \frac{m}{ar^n} \)
multiplied into the annuity; or simply \( p-A \) multiplied into
such annuity, if the assurance is to be continued during the
whole duration of \( A \)'s life. For the more ample dis-
cussion of this subject, the reader is referred to Mr. Simp-
son's "Select Exercises," Dr. Price's "Treatise on Reversion-
ary Payments," and Mr. Morgan's "Doctrine of An-
nuities and Assurances" stated and explained.

Assurances may be made on any number of joint lives, or on
the longevity of any lives. Rules for finding the values of such
assurances...
assurances are given in the books just referred to. There are further assurances on survivories; by which is meant an obligation for the value received, to pay a given sum or annuity, should a given life cease to survive any other given life or lives. The method of finding these values is given under the article Survivory.

All these different kinds of assurances are of the greatest use; and the offices for making them are a particular advantage to the public. The principal of these offices in England are, the Amicable Society, incorporated for a perpetual assurance; the Society for Equitable Assurances on Lives and Survivorships; the Royal Exchange Assurance; the Westminster and the Pelican Life-Offices.

The Amicable Society requires an annual payment of 5l. from every member payable quarterly during life. The whole annual income hence arising is equally divided among the representatives of such members as die every year; and this renders the dividends among the claimants in different years more or less according to the number of members who have happened to die in those years. But this society engages that the dividends shall not be less than 130l. to each claimant, though they may be more. None are admitted whose ages are greater than 45, or less than 12; nor is there any difference of contribution allowed on account of difference of age. This society has subsisted ever since 1726, and its credit and usefulness are well-established. Its plan, however, is liable to several objections. First, it is evident that regulating the dividends among the representatives by the number of members who die every year, is not equitable; because it makes the benefit which is accruing from the assurance, to depend, not on the value of the contribution, but on a contingency; that is, on the number of members who have happened to die in the year. Secondly, its requiring the same payments from all persons under 45, is also not equitable, for the payment of a person admitted at 12 ought not to be more than half the payment of a person admitted at 45. Thirdly, by limiting the sums assured on one and the same life to 450l. it is ill adapted to make a competent provision for the families of its members; nor can it be of any service to persons whose age exceeds 35 years; a period of life which, it has been found from experience that many, if not most persons, have exceeded before they have been able to provide for the support of their families. The life of a man has been too often made by so means fitted to the circumstances of persons who want to make assurances on their lives for only one year, or for a short term of years. Thus, the true value of the assurance of 130l. for five years on the life of a person whose age is 35, may be found by the first rule to be nearly three guineas per annum, supposing interest at 3 per cent. and the probabilities of the duration of human life as they are given in the Northampton Table of Observations. But such an assurance could not be made in this society without an annual payment of 5l.

Neither is the plan of this society at all adapted to the circumstances of persons who want to make assurances on particular survivories. For example, a person possessing of an estate or fabley, which must be lost with his life, has a person dependent upon him, for whom he desires to secure a sum of money payable at his death. He desires this only as a security against the danger of his dying first. In these circumstances he enters into this society; and by an annual payment of 5l. entitles his nominee at his death 150l.

In a few years, perhaps, his nominee happens to die, and the object of his Assurance having thus ceased, he determines to give up the advantage arising from his former payments and to withdraw from the society. The right method in this case would have been to have taken from such a person the true value of the sum assured on the supposition of non-payment, provided he should survive. Had this been done, he would have paid for the assurance (supposing interest at 3 per cent. his age 30, the age of his nominee also 30, and the values of lives as given by Dr. Price from the Northampton Table) 5l. 6s. 8d. in annual payments, to begin immediately and to be continued during the joint duration of his own life and the life of his nominee.

None of these objections, however, are applicable to the other offices just mentioned. In all of them assurances may be made for any term and at any age between eight and sixty-seven years, either at single or annual premiums, proportioned to the age of the person assured, and to the risk or hazard attending the assurance. The business transacted in these offices is very extensive, and so far as relates to the premiums they require, is founded on strict calculation. These premiums, which are now indiscriminately adopted by all of them, were originally computed in the year 1761 for the use of the Equitable Society,—an institution so entirely guided by computation in all its practice, that in ascertaining its profits at fixed periods, and distributing them among its members, it has never failed to proceed on the same sure principles, and by this means to render itself one of the greatest public benefits to this country. In consequence of its immense capital, and the very wide extent of its business, it certainly far exceeds any other office of the same kind; and therefore by giving an account of its rise and progress, a proper idea will be obtained of the nature of life-assurances, as well as of the important benefits which are derived from them.

This society was established in the year 1762, in consequence of proposals which had been made, and lectures recommending such a design, which had been read by Mr. Thomas Simpson; and the premiums then adopted for its practice were computed by Mr. James Dodson, the author of the Mathematical Repository. It assures any sums or reversionary annuities on any life or lives, for any number of years, as well as for the whole continuance of the lives, and in any manner that may be best adapted to the views of the persons assured; that is, either by making the assured sums payable certainly at the failure of any given lives, or on condition of survivvory; and also, either by taking the price of the assurance in one present payment, or in annual payments during any single or joint lives, or any terms less than the whole possible duration of the lives. Any persons, for instance, who depend on incomes which may be lost when they die, or who are only tenants for life in estates may, by affuring an equivalent on their own lives, guard their families or representatives against the losses which would accrue by their death. Hence, clergymen, councellors, persons holding any places of profit, traders, and others who have families whose fulness depends on the continuance of their lives, may be enabled to make provision for their families after their decease. All persons likewise who enjoy annuities for the lives of others, may here secure themselves against the losses they would suffer, should they survive the persons on whose lives the annuities depend, by making assurances which would entitle them to any sums payable on condition their survivory should take place. Any person entitled to an estate, annuity, legacy, or office after another person provided he survives, may here secure an equivalent for his family at his decease, provided he does not survive. Husband may in this society secure annuities for their wives, provided they should leave them widows. Parents, by affuring the lives of their children, when infants, till they attain a given age, may secure for them, should they live to that age, such sums as may be necessary to put them out to apprenticeships, or to make capitals or fortunes for them, with which to let out in businesses, or to marry. Any persons, apprehensive of being left without support in old age, when incapable
incapable of labour, may purchase an annuity to commence at any future year of his life and to continue during the remainder of his life, and he may do this at a small expense if he is young, and willing to wait for the commencement of his annuity, till he is fifty-five or sixty years of age. In short there are no kinds of assurance on lives or survivorships which this society does not make. In doing this, while it proceeds on mathematical principles in computing its premiums, it takes advantage of making these computations at so low an interest as 3 per cent. in order to gain such a profit as shall enable it to bear the expenses of management, and render it a permanent benefit to the public. In the infancy of the institution also, it adopted tables of the values and probabilities of lives in London, where, as in all great towns, the rate of human mortality is much greater than it is among mankind in general. But after an experience of twenty years, it found that tables giving higher probabilities of life might be safely used, and therefore it made choice of those more correct tables which were published by Dr. Price from observations at Northampton; and it appears, from comparing the decrements of life in the society with those in the table just mentioned, that, during a term of thirty-four years, the ratio of mortality in the former is to that in the latter between the ages of 10 and 20 as 1 to 2,

20 and 30 as 1 to 2
30 and 40 as 3 to 5
40 and 50 as 5 to 7
50 and 60 as 7 to 9
60 and 70 as 9 to 10
80 and 90 as 9 to 10,

or that in all ages between 10 and 80, fewer deaths have happened in the society than should have happened according to the tables from which its premiums have been computed in the proportion of two to three. In consequence of this and of other still less equivocal proofs of its prosperity, the society has been enabled since its first establishment not only to reduce its premiums above one half, but to make such additions to the claims in the years 1782, 1786, 1791, 1793, 1795, and 1800, as amount at present to the sums specified below:

For every 100, an addition over and above the sum assured of

These are advantages peculiar to this society, and therefore it is no wonder that its business should in far surper that of every other institution of the same kind. But in the midst of its prosperity the society has hitherto proceeded with the utmost prudence and caution. Aware of the danger of being led astray by the dazzling appearance of a large capital, necessarily increased by an influx of new members, it has provided by a special law, that, as on former occasions, so in future, no distribution of its stock shall ever be made without a previous investigation of its finances; that this investigation shall take place once in ten years; that the distribution shall never exceed two-thirds of the surplus stock of the society; and that no such distribution shall be adopted at all without the concurrence of two-thirds of its members, attending at three successive general courts. As far as human prudence and foresight can provide against danger, these precautions are likely to secure the society, and to increase its usefulness. But there is one danger against which no laws can guard it: we mean the danger of employing ignorant persons to conduct the management of its affairs. It must be manifest from the preceding account of this society, that none but skilful mathematicians are qualified for this business; and it is to be hoped that on any future vacancies, no other regard will be had in filling them up, than to the ability and integrity of the candidates. The melancholy experience of other societies for the benefit of age, for the benefit of widows, &c. which were established about thirty years ago, and which have long since ended in disappointment and ruin, should serve to guard this society against the attempts of ignorance, as much as the present prosperous state of its affairs should incite it to persevere in that wise and temperate course which has displayed so much prudence and skill in the management of its affairs, and raised it so high in the opinion of the public.

The following are the rates of assurance on single lives in this society, and also very nearly in the Royal Exchange and other offices, where those premiums have been adopted with little or no variation.

**Assurance, Royal Exchange, is a corporation or company established by an Act 6 Geo. 1. c. 18:; and, by their charter, executed June 22, 1720, empowered to assure ships and goods at sea, or going to sea, and to lend money on bottomry; and to raise for this purpose a capital of £50,000; on condition, that, upon three years' notice being given by parliament, at any time within thirty-one years from the date of the charter, and repayment of the sum of £50,000, which the company had agreed to pay to government, the corporation should cease. In the following year they obtained another charter, dated the 25th April 1721, by which they were authorised to assure lives, and also to assure houses and goods from fire, and were empowered to raise a further capital of £50,000 making, with the former sum, two millions. It was also enacted, that, in consequence of the company having paid into the Exchequer £1,250,000, and having covenanted to pay the farther sum of £38,750, within three months, they should be released from payment of the remainder of the £300,000. The whole capital of 2,000,000£ was subscribed, but it was thought necessary to call for the payment of only 500,000£; which, after paying the 150,000 to government, had been found sufficient for carrying on the extensive concerns of the company. A new branch was added to their business, by an act, obtained in 1793, enabling them to grant annuities on lives, either immediate or in reversion; and, in 1801, the company obtained an act for affording vessels and their cargoes on canals and inland navigations, in which act the London Assurance company are likewise included. The dividend to the proprietors, which has gradually increased from 3 to 7½ per cent., becomes due at Christmas and Midsummer, and is usually paid about the 15th January and July. [At Midsummer 1802, an exceptional dividend was made in fowl, being 10½ five per cents, 1797, for every 1000. of the company's flock.] The transfer-days are Tuesdays and Thursdays, between the hours of eleven and one. The dividends are paid on Mondays, Wednesdays, Fridays, and Saturdays, from ten to two.

N.B. The foregoing Annuities are receivable in Quarterly Payments.
The person making the assurance is to declare the place and date of birth of the person whose life is to be assured; whether he has had the small-pox; whether subject to the gout; and whether in the army or navy.

The life assured to appear at the office, or to one of the company's agents, or pay 10s. per cent. on assurances for one year, 15s. per cent. for more than one year, and the first payment not exceeding four years, 20s. per cent. if for more than seven years, only.

One quarter per cent. additional, will be taken on the first payment as admission-money.

Fifteen days are allowed for payment of the annual premiums after they respectively become due, but if the same remain unpaid more than the said fifteen days, and not exceeding three calendar months, a fine of ten shillings per cent. must be paid, and a warrant given of the health of the life assured.

Conditions of Assurance made by Persons on their own Lives.

The assurance to be void if the person whose life is assured shall depart beyond the limits of Europe, shall die upon the seas (except in his majesty's packets plying between Great Britain and Ireland); or shall enter into or engage in any military or naval service whatever, without the previous consent of the company; or shall die by suicide, duelling, or the hand of justice; or shall not, be, at the time the assurance is made, in good health.

Conditions of Assurance made by Persons on the Lives of others.

The assurance to be void if the person whose life is assured shall depart beyond the limits of Europe, shall die upon the seas (except in his majesty's packets plying between Great Britain and Ireland); or shall enter into or engage in any military or naval service whatever, without the previous consent of the company; or shall not, be, at the time the assurance is made, in good health.—Any person making an assurance on the life of another, must be interred therein, agreeable to act 14 Geo. III. c. 48, which prohibits wagering, or speculative insurances.

N.B. Assurances on the lives of persons engaged in the army or navy, or going beyond the limits of Europe, may be made by special agreement.

Assurance, London. The charters of this company were granted at the same time with those of the Royal Exchange Assurance, for the same purposes, and upon similar conditions; one of which is, that no person poaching flock in either company can purchase flock in the other, under penalty of forfeiting the share so purchased. The principal difference in the business of the two offices is, that the London assurance confine themselves to sea and fire assurances, very seldom affurining lives, and not being empowered to grant annuities. Their flock is 1,000,000, divided into shares of 25l. each, on which 12l. 10s. has been paid in, making the whole sum paid in 500,000l. The dividend has been raised to 18s. per share per annum, and becomes due at Lady-day and Michaelmas. The transfer-days are Tuesdays and Thursdays, from eleven to three o'clock. The dividends are paid on Mondays, Wednesdays, and Fridays, from eleven to three.

Assurance, Collateral, in Law. See Collateral Assurance.

Assurances, Common, of the kingdom, express the legal evidences of the conveyance or transfer of property; by which every man's estate is assured to him, and all controversies, doubts, and difficulties, are either prevented or removed. These common assurances are of four kinds: 1. By matter in pais, or deed; which is an assurance transferred between two or more private persons in pais, in the country; that is, according to the old common law, upon the very spot to be transferred. See Davis, 2. by matter of record, or an assurance transferred only in the king's public courts of record. See Register. 3. By special covenants, obtaining in some particular places, and relating only to some particular species of property. See Custom. These three assurances are such as take effect during the life of the party conveying or affurining. 4. The fourth takes no effect till after his death; and that is by devise, contained in his last will and testament. See Devise, and Will. 11th Com. vol. ii. p. 351.

ASSURGENT Lowers, in Botany, denotes such as are first bent down, and then rise erect towards the apex. This term scarcely differs from adicenoid or incurvus, and seems peculiarly proper for describing the change which takes place in the position of the leaves of mimosa, and other creeping plants.

Assurgent, in Heraldry, a term used for a man or beast rising out of the sea.

Assuror, a merchant or other person, who affurnes, or makes out a policy of assurance for a ship, house, life, or the like. Assurers are not answerable for what damages arise through the negligence, or other fault of the master or seamen; or even those which arise from any vice or defect in the thing assured. See Insurance.

Assuritani, or Assurians, in Ecclesiastical History, a branch of Donatists in the middle of the fourth century. The Assuritans, or Assurians, or rather the fan to be inferior to the father; they repudiated their converts from the catholics, and affecled that the church is not composed of good and bad, but of the good alone.

Assurus, or Assuras, now Kisser, in Ancient Geography, a town of Africa, situate in the inland country of the ancient Bizæum, to the west of Adrumetum, and south-east of Sica Vecerina.

Assy, in Geography, a town of France, in the department of the Oise, and chief place of a canton in the district of Crepisy, eight miles south of Crepisy.

Assyiani, in Ancient Geography, an ancient town of the Tauric Chersonesus.

Assyria, a kingdom of Asia, of the extent, origin, and duration of which very different accounts have been given by ancient writers. Cicéras and Diodorus Siculus affirm, that the Assyrian monarchy, under Ninus and Semiramis, comprehended the greater part of the known world; but, if this had been the case, it is not likely that Homer and Herodotus would have omitted a fact so remarkable. The sacred records intimate, that none of the ancient states or kingdoms were of considerable extent; for neither Cædersonor, nor any of the neighbouring princes, were tributary or subject to Assyria; and we find nothing, says Playfair, of the greatness or power of this kingdom in the history of the Judges, and succeeding kings of Israel, though the latter kingdom was oppressed and enfealed by many different powers in that period. It is therefore highly probable, that Assyria was originally of small extent. According to Ptolemy, this country was bounded on the north by part of Armenia and mount Niphates; on the west by the Tigris; on the south by Susiana; and on the east by part of Media, and the mountains Choatra and Zagros. The country within these limits is called, by some of the ancients, Adiabene, and by others Aturia or Atysia. It is divided, by Ptolemy, into the following provinces or districts; viz. Calachene or Calacian, Arrachfutis, Adiabene, Arbelaia, Apollonias, Sittacene, and Chalonitis. Among the rivers of Assyria we may reckon the Tigris, the Lycus, the Caprus, and the Gorgus.
CORUS. Of the origin, revolutions, and termination of Assyria, properly so called, and distinguished from the grand monarchy which afterwards bore this appellation, the following account is given by Mr. Playfair, as the most probable. The founder of it was Ashur, the second son of Shem, who departed from Shinar, upon the dispersion of Nimrod, at the head of a large body of adventurers, and laid the foundations of Nineveh, where he resided, and erected a new kingdom, called Assyria after his name. See Ashur. Gen. x. 11. These events happened not long after Nimrod had established the Chaldean monarchy, and fixed his residence at Babylon; but it does not appear that Nimrod reigned in Assyria. The kingdom of Assyria and Babylon were originally distinct and separate (Micah, v. 6); and in this state they remained until Ninus conquered Babylon, and made it a part of the Assyrian empire. Ninus, the successor of Ashur (Gen. x. 11. Diod. Sicul. l. 1.), feized on Chaldaea after the death of Nimrod, and united the kingdoms of Assyria and Babylon. This great prince is said to have subdued Aila, Peria, Media, Egypt, &c. If he did so, the effects of his conquests were of no large duration; for, in the days of Abraham, the Chaldeans do not find that any of the neighbouring kingdoms were subject to Assyria. Ninus was succeeded by Semiramis, a princess bold, enterprising, and fortunate; of whose adventures and exploits many fabulous relations have been recorded. Playfair is of opinion, that there were two princesses of this name who flourished at different periods: one, the comfort of Ninus, and another, who lived five generations before Nitoeres, queen of Nebuchadnezzar. Euseb. Chron. p. 58. Herod. B. i. c. 134. See Semiramis. Of the successors of Ninus and Semiramis nothing certain is recorded. The last of the ancient Assyrian kings was Sardanapalus, who was besieged in his capital by Arbaces, governor of Media, in concurrence with the Babylonians. These united forces defeated the Assyrian army, demolished the capital, and became masters of the empire. E. C. 821. See Arbaces, and Sardanapalus. Such is the subsistence of the account given by Ctesias, and after him by several ancient Greek and Latin writers; and particularly by Diodorus Siculus. These writers have referred the commencement of the Assyrian empire to about sixty or seventy years after Noah's flood; but concerning its beginning, as well as its duration, ancient writers have given very different accounts. Africanus and Eutropius suppose that Ninus, the second Assyrian king, began to reign 309 years after the flood, and 43 years before the birth of Abraham. Berossus, the Chaldean historian, dates the foundation of the empire from the building of the tower of Babel, about 131 years after the flood. Callidius admits an interval of more than four centuries between these two remarkable events. Usher extends this interval to 1085 years; and Jackson reduces it to 551. As to the period of the duration of this empire, Ctesias, Diodorus, and others, make it 1500 years; Justin, 1200; Caflor, 1250; Synesius, 1400; Scaliger, 1500; Eutropius, 1250; Vellianus Paterculus, 1207; Herodotus, 520; and Appian makes the whole duration of the Assyrian, Median, and Persian empires, not to exceed 900 years. In Blair's Tables the commencement of the Assyrian empire is assigned to the year before Christ, 2059, and its termination to the year before Christ 820; so that its whole duration comprehends 1239 years. Goguet refers the conquest of Babylon by Ninus, king of Assyria, and the consequent union of the Babylonian throne with that of Nineveh, to the 50th year after the flood, or the 175th year B.C. In settling this date, he places the foundation of the kingdom of Babylon by Nimrod, about the year 150 after the flood. This kingdom, as most chronologers allow, had subsisted 440 years; under two distinct dynasties or families, at the time of Babylon's being taken by the Assyrians. The first of these dynasties, whose kings were Chaldeans, possessed the throne 225 years; and the second, originally from Arabia, reigned 215 years; and the total is 440 years. If to these years we add 150 years from the flood to the foundation of Babylon by Nimrod, the capture of Babylon will fall in the 590th year after the flood, and consequently in the 175th year B.C. After the capture of Babylon, the two monarchies formed one state, under the name of the Assyrian empire. From this time the kingdom of Babylon was no more than a province of the Assyrian empire, to the time in which the revolt of the Medes gave the Babylonians an opportunity of striking off the Assyrian yoke, about 770 B.C. As most of these computations are primarily borrowed from Ctesias, it may not be improper to inquire how far his testimony is credible. Aristeotle, who was almost his contemporary, declares him to be unworthy of credit; and his history of India excites him to be a fabulous writer. Although he gives us the names of the Assyrian kings from Belus and his son Ninus to Sardanapalus, the last king of Assyria, the greater number of his names is derived from different nationalities, Persian, Egyptian, and other names; and except in two or three instances, they have no affinity with the names of the Assyrians mentioned in scripture. The true empire of the Assyrians, described in scripture, whose kings were Pul, Tiglath-pileser, &c. he does not mention, though much nearer to his own times; and this circumstance shews that he was ignorant of the antiquities of the Assyrians. After the death of Sardanapalus, says Mr. Playfair, the Assyrian empire was divided into three kingdoms; viz. the Median, Assyrian, and Babylonian. Arbaces retained the supreme authority, and nominatd governors in Assyria and Babylon, who were honoured with the title of kings, while they remained subject and tributary to the Persian monarchs. Bela, he says, a Chaldean priest, who affiled Arbaces in the conquest of Sardanapalus, received the government of Babylon as the reward of his services; and Phul was entrusted with that of Assyria. The Assyrian governor gradually enlarged the boundaries of his kingdom, and was succeeded by Tiglath-pileser, Salmanasar, and Sennacherib, who asserted and maintained their independence. After the death of Assar-haddon, the brother and successor of Sennacherib, the kingdom of Assyria was split, and annexed to the kingdoms of Media and Babylon. Several tributary princes afterwards reigned in Nineveh; but we know no more of the kings of Assyria, after the first monarchy, than those of Babylon. Cyaxares, king of Media, avouched Nebuchadnezzar, king of Babylon, in the siege of Nineveh, which they took and destroyed B.C. 606. The history of Assyria, deduced from scripture, and acknowledged as the only authentic one by far Isaac Newton and many others, ascribes the foundation of the monarchy to Pul or Phul, about the second year of Menahem, king of Israel, twenty-four years before the era of Nabonassar, 1579 years after the flood, and according to Blair 769, or according to Newton 790, years before Christ. Menahem having taken forcible possession of the throne of Israel by the murder of Shallum (2 Kings, xvi. 10), was attacked by Pul, but prevented the hostilities meditated against him, by presenting the invader with a thousand talents of silver. Pul, thus gratified, took the kingdom of Israel under his protection, returned to his own country, after having received voluntary homage from several nations in his march, as he had done from Israel, and became the founder of a great empire. As it was in the days of Pul that the Assyrians began to afflict the inhabitants of Paluine (2 Kings, xvi. 9, and 1 Chron.
i Chron. v. 26.), this was the time, according to Sir Isaac Newton, when the Assyrian empire arose. Thus he interprets the words “since the time of the kings of Assyria” (Nehem. ix. 32.); i.e. since the time of the kingdom of Assyria, or since the rise of that empire. But though this was the period in which the Assyrians afflicted Israel, it is not so evident that the time of the kings of Assyria must necessarily be understood of the rise of the Assyrian empire. However Newton thusreasons; and observes, “that Pul and his suc-
cessors afflicted Israel, and conquered the nations round about them; and upon the ruin of many small and
indifferent kingdoms erected their empire, conquering the Medes, as well as other nations.” It is further argued that God by the
prophet Amos, in the reign of Jeroboam, about ten or twenty years before the reign of Pul (2 Kings ch. vii. 13. 14.), threatened to raise up a nation against Israel; and that as Pul reigned presently after the prophecy of Amos, and was the first upon
record who began to fulfill it, he may be justly reckoned the first conqueror and founder of this empire. See 1 Chron.
v. 26. Pul was succeeded on the throne of Assyria by his
elder son Tiglath-pileser; and at the same time he left Baby-
lon to his younger son Nabonassar, B. C. 747. Of the con-
quists of this second king of Assyria against the kings of
Israel and Syria, when he took Damascus and captivated the
Syrians, we have an account in 2 Kings, xxv. 37.
xvi. 5. 9. 1 Chron. v. 26. Amos, i. 5. Josaph. Ant. i. c. 13.,
by which the prophecy of Amos was fulfilled, and from
which it appears that the empire of the Assyrians was now
become great and powerful. The next king of Assyria
was Shalmanezer or Shalmanassar, who succeeded Tiglath-
pileser, B. C. 729, and invaded Phcenicia, took the city of
Samaria, and B. C. 721 carried the ten tribes into captivity,
placing them in Chalach and Chabor, by the river Gazon,
and in the cities of the Medes. Jos. Ant. i. c. 14. 2 Kings,
xvii. 6. Shalmanezer was succeeded by Sennacherib, B. C.
719; and in the year B. C. 714 he was put to flight, with
great slaughter, by the Egyptians and Egyptians. In
the year B. C. 711, the Medes revolted from the Assyrians; Sen-
nacherib was slain; and he was succeeded by his son Ebin-
Haddon, Affer-hadon, Afordan, Affaradin, or Sarchedon,
by which names he is called by different writers. He began
his reign at Nineveh in the year of Nabonassar 42; and in
the year 68 extended it over Babylon. He then carried
the remainder of the Samaritans into captivity, and peopled
Samaria with captives brought from several parts of his
kingdom, and in the year of Nabonassar 77 or 78, he seems
to have put an end to the reign of the Ethiopians over Egypt. “In the reign of Sennacherib and Affer-Hadon,” says Sir J. Newton, “the Assyrian empire seems arrived at its
greatness; being united under one monarch, and containing
Assyria, Media, Apollonitania, Susiana, Chaldea, Mopet-
tamia, Cilicia, Syria, Phcenicia, Egypt, Ethiopia, and part
of Arabia; and reaching eastward into Lylymais, and Pare-
tecene, a province of the Medes, and if Chalach and Chabor
be Colchis and Iberia, as some think, and as may seem prob-
able from the circumicion used by those nations till the days of
Herodotus (i. i. c. 104.), we are also to add these two
provinces, with the two Armenias, Pontus, and Cappadocia,
as far as to the river Halys. For Herodotus (i. i. c. 72.
I. vii. c. 63.) tells us, that the people of Cappadocia, as far
as to that river, were called Syriacs by the Greeks, both
before and after the days of Cyrus; and that the Assyrians
were also called Syriacs by the Greeks.” Affer-Hadon was
succeeded in the year B. C. 668, by Saosdichinus. At this
time Manasseh was allowed to return home and fortify Jeru-
salem; and the Egyptians also, after the Assyrians had
raffed Egypt and Ethiopia three years (I. xii. 23. 4.), were

fet at liberty. Saosdichinus, after a reign of twenty years,
was succeeded at Babylon, and probably at Nineveh also, by
Chyniladon, in the year B. C. 647. This Chyniladon is sup-
pended by Newton to be the Nabuchodonosor mentioned in
the book of Judih (i. 1.15.), who made war upon Arphaxad
king of the Medes, and though defeated by his auxiliaries
of Cilicia, Damascus, Syria, Phcenicia, Mesab, Amnon, and
Egypt, routed the army of the Medes, and flew Arphaxad.
This Arphaxad is supposed to be either Deioches, or
his son Phnaez, mentioned by Herodotus (i. i. c. 102.) Soon
after the death of Phraezes in the year B. C. 655, the
Scythians invaded the Meses and Persians; and in 625,
Nabopolasfar, the commander of the forces of Chyniladon
in Chaldia, revolted from him, and became king of Babylon.
Chyniladon was either then, or soon after, succeeded at
Nineveh by the last king of Assyria, called Sarac by Poly-
hilor. The authors of the Universal History suppose Saos-
dichinus to have been the Nabuchodonosor of Scripture,
and Chyniladon or Chyniladon to have been the Sarac of Poly-
hilor. At length Nebuchadnezzar, the son of Nabopolas-
far, married Aniyite, the daughter of Atlyages king of
the Medes, andifter Cyaxares; and by this marriage the two
families having contracted affinity, they conspired against
the Assyrians. Nabopolasfar being old, and Atlyages dead,
their foes Nebuchadnezzar and Cyaxares led the armies of
the two nations against Nineveh; flew Sarac, destroyed
the city, and shared the kingdom of the Assyrians. This
victory the Jews refer to the Chaldeans; the Greeks, to
the Medes: Tobit (xv. 15.), Polyhilar (apud Eunób., in
Chron.), Josephus (i. x. c. 2. § 2. p. 435.), and Cte
das (apud Diod. Sic. ii. c. 24. p. 725) to both. With this victory
commenced the great successes of Nebuchadnezzar and
Cyaxares, and it laid the foundation of the two collateral
empires of the Babylonians and Medes, which were branches
of the Assyrian empire; and hence the time of the fall of
the Assyrian empire is determined, the conquerors being then in
their youth. In the reign of Josiah, when Zephanaiah proph-
phesied, Nineveh and the kingdom of Assyria were fading,
and their fall was predicted by that prophet, Zeph. i. 2. and
ii. 13. And in the end of his reign, Pharaoh Necho king of
Egypt, the successor of Pharnaces, went up against the
king of Assyria to the river Euphrates, to fight against Car-
 permission or active human intervention.

8
ass

succession of Tiglath-pileser, in the first year of Nabonassar, or 747 B.C.; that of Salmanasar, in 727 B.C.; that of Semmeserib in 712 B.C.; that of Ellabandos or Affaradus, in 709 B.C.; and the union of Assyria and Babylonia under Affaradus in 662 B.C.; and upon the separation of Assyria and Babylon in 667 B.C. he makes Saladinshun King of Babylon, who then commenced his reign, and was succeeded in 657 B.C. by Chyshidanaus; and the king of Assyria, who commenced his reign in 657, he calls Ninus II. and his successor, in 641, Nabuchodonosor; and the last king of Assyria, Sarac or Saradanapalus, whose reign commenced in the year 624 B.C.; and the union of Assyria and Media he refers to the sixteenth year of this king, and the twelfth of Cyzaexes King of Media, or the sixteenth year B.C.; in which year Nineveh was taken and destroyed by the united armies of Cyzaexes and Nabopolasar.

The government, laws, religion, learning, customs, &c. of the ancient Assyrians, nothing absolutely certain is recorded. Their kingdom was at first small, and subdivided for several ages under hereditary chiefs; and their government was very simple. Afterwards when they rose to the sublimity of empire, their government seems to have been truly despotic, and the empire to have been hereditary. Their laws were probably few, and depended upon the arbitrary will of the prince. To Ninus we may ascribe the division of the Assyrian empire into provinces and governments, for we find (Diod. Sic. l. i.) that this institution was fully established in the reigns of Semiramis and her successors. In this empire the people were distributed into a certain number of tribes (Herodot. l. i. Strabo, l. xvi.); and their occupations or professions were hereditary. The Assyrians had several distinct courts, and several tribunals for the regulation of public affairs. Of councils there were three, which were created by the body of the people, and who governed the state in conjunction with the sovereign. The first consisted of officers who had retired from military employments; the second of the nobility; and the third of the old men. The sovereigns also had three tribunals, whose province it was to watch over the conduct of the people. The first was employed in disposing of the young women in marriage, and in punishing adultery: the second took cognizance of theft; and the third of all acts of violence. Strabo, l. xvi. As to their religion, they were idolaters, and had their idols and temples. In customs, arts, and learning, they differed but little, if at all, from the Babylonians. The Assyrians are said to have had one practice, with respect to marriage, that is worthy of attention. All the young girls, who were marriageable, were assembled in one place, and a public crier put them up to sale one after another. The money which was received for those that were handsome and fetched a high price, was bellowed as a portion with those whose persons were more plain and homely. When the most beautiful were disposed of, the more ordinary were offered with a certain sum, and allotted to those who were willing to take them with the smallest portion. In this manner all the young women were provided with husbands. This ingenious and politic method of facilitating and promoting marriage, was also practised by several other nations. If at any time it happened that the parties could not agree, the man was obliged to refund the money which he had received. It was likewise very expressly forbidden to use women ill, or carry them into any foreign country. Herodotus informs us, that this wife institution was abolished towards the end of the Assyrian monarchy. Herodot. l. i. Strabo, l. xvi. The Assyrians have been competitors with the Egyptians for the honour of having invented alphabetic writing. It appears from the few remains now extant of the writing of these ancient nations, that their letters had a great affinity with each other. They much resembled one another in shape; and they ranged them in the same manner, from right to left. Playfair's Chronology, p. 67-70. Newton's Chron. iii. apd Oper. by Halley, i. &c. p. 193—214. Anc. Hist. vol. iii. p. 325—327. Goguic's Orig. of Languages, &c. vol. i. p. 41.

ASSYRIAN LETTERS. 

LITERAE ASSYRIAE, a denomination given by several Rabinns and Talmudists to the characters of the present Hebrew alphabet, as supposing them to have been borrowed from the Assyrians during the Jewish captivity in Babylon. Montfaucon.

ASTA, now Asia, in Ancient Geography, a town of Liguria, or Piedmont, which was a Roman colony, upon a river of the same name, not far from the Tanarus. The fortifications of this place afforded a temporary shelter to the emperor Honorius, when he was pursued by the Goths, A. D. 459; and he was relieved from the danger of a successful siege, and the indignity of a capitulation to the Barbarians, by the favourable arrival of Stilicho, who cut his way through the Gothic camp under the walls of Asia, and thus revived the hopes and vindicated the honour of Rome. See Asti.—Also, a town of Spain, in Bética, south of Nebeiana, upon the left arm of the Betic, which discharged itself into the bay of Gades.

ASTA, in Geography, a town of the United Netherlands, in the duchy of Guelderland, four miles south-east of Culemburg.—Also, a river of Spain, which empties itself into the bay of Bilcay, at Villa Viciosa.

ASTABAT, a town of Armenia, thirty-three leagues south-east of Erivan.

ASTABATEN, in Ancient Geography, a people of Asia, in Hyrcania. Ptol. 

ASTABORAS, a river of Abyssinia, forming, as Pliny has said, the left channel of Atbara; or as the Greeks have called it, the iland or peninsula of Meroë; as Aethus forms the right channel. Allaboras, is the name given by the natives to the Tacazze, or the Sirs of the ancients. It joins the Nile in N. lat. 17° 47'. See Atbara, Meroë, and Tacazze.

ASTACAMPRON, a promontory of Asia, in the Indian sea, to the left of the gulf of Baryza. Arrian.

ASTACANA, a town of Asia, in Baaria, called Asoca by Ammianus Marcellinus. Ptolomy.

ASTACANI, a name given by some to the Assacani.

ASTACAPRA, a town of India, on this side of the Ganges, situated between the mouths of the Indus. Ptolomy.

ASTACUM, a country of Asia, in Pontus, which took its name from the river Asaces which traversed it.

ASTACENUM ASTARAUM, Marsida, a gulf of Spain in Bética. Ptolomy.

ASTACENUS SINUS, a gulf of the Proponent, on which was situated the town of Nicomedia.

ASTACHAR, in Geography, formerly Asacara, a town of Peria, near Bendifir and the ruins of Persepolis. It is now a village, having however a caravansera, mosque, and the ruins of a palace.

ASTACICUS, a town of Africa, in Mauritania. Ptolomy.

ASTACILIS, TESSALAS, a place of the interior country of Africa, in Mauritania Cattariens, which was a Roman station, situated in the mountains south of Portus Magnus. Ptolomy.

ASTACUS, in Entomology, a species of Cancer, with a smooth thorax; proboscis toothed along the sides; and a single tooth on each side at the base. This is the common claw-fish, that inhabits rivers, and lodges itself in holes.
which it forms in the banks. Very frequent in many countries of Europe.

Astacus is also the name of a genus in the Fabrician system, formed of these species of the Limnean Caerii, that have four pedunculate antennae, the two front-ones of which are long and falciculate, and the posterior ones confluent. Among these the lobster and craw-fish are included.

ASTACEI, in Ancient Geography, a town of Asa, in Bithynia, situated upon the Aetnae gulf, according to Strabo. The city was built by the Megarians and Athenians, and destroyed by Lycurgus, and its inhabitants transported to Nicomedia, by whom it was founded or re-established. Some have said that Nicomedia was built on the ruins of Astacus. Also, a town of Greece, in Arcadia.

ASTE, a people of Europe, in Thrace. Steph. Byz.

ASTEGENI, a people of Arabia Felix. Prolem.

ASTAGON, in Geography, a town of Africa, in Monomogari, on the confines of Zanguebar.

ASTAMAR, ACTAMAR, or ASAMAS, a large lake, with a fortified town of the same name, in Armenia. N. lat. 36° 30'. E. long. 44° 34'.

ASTAN, a river of Arabia, in Lathia, which is probably the stream in Naged mentioned by D'Anville, and is represented by Nichuria as only a wali or brook which runs after rains.

ASTANDA, called also Astalin, in Antiquity, a royal courier or meffenger, the fame with Angusus.

King Darius of Persia is said by Plutarch, in his book on the fortune of Alexander, to have formerly been an atand. See Astana, in Ancient Geography, a town of Asia, in Aria. Prolem.

ASTAPA, Estapa la Vieja, a town of Spain, in Baetica, south-west of Singili. It is distinguished by the records of its vigorous defence against Marins and the Romans, in the year of Rom. 546. When they were no longer able to refit the besiegers, they kindled a fire into which they threw all their effects, and rushed with their women and children into the midst of their enemies, by whom they were vanquished and slain; but no trophy of victory remained for their conquerors.

ASTAPEI, a people of Africa, placed by Steph. Byz. in Libya.

ASTAPUS, a river of Abydusia, which with the Astabaros formed the peninsula of Meroe. This river, known now by the name of the "White River," is represented by Diodorus Siculus as proceeding from large lakes to the southward, and having thrown itself into the Nile, makes with it the right hand channel inclosing Meroe in Atbara. See Astabaros and Meroe.

ASTARA, in Geography, a town of Persia, in Chilian, on the Caspian sea.

ASTARABAT, a town of Persia, in Segelitan, 150 miles north of Zareng, and 220 W. N. W. of Candahar.

ASTARAC, a small territory of France, situated in the late province of Gascony, about eight leagues square, of which the capital is Mirande.

ASTARTH, in Ancient Geography, a town of Palaeldine, in Batusan, or Bafian. This was a strong city belonging to the half tribe of Mafaiich, on the other side of Jordan. It was granted to the Levites of the family of Gerbon, according to Joshua.

ASTAROTH-CARNAIM, another town of Palaeldine, south-west of the former, and distant from it nine miles, between Adra and Abila. It is supposed to have derived its name from Astaroth, called Astaroth, the deity of the Phcenicians, and Carnaim, signifying horns or a crescent, with which she was represented.

Astaroth, in Mythology, an idol of the Philistines, which the Jews destroyed at the command of Samuel. It was also the name of a deity of the Sidonians, which was worshipped by Solomon in his idolatrous days. See Astaroth.

ASTARTA, in Ancient Geography, an island of Ethiopia. Steph. Byz.

ASTARTE, a deity of the Assyrians, under which appellation they worshipped the moon, and from them that species of idolatry extended to the Phcenicians, Carthaginians, and other ancient nations. Adonis, who was an Assyrian by descent, is said to have married Astarte; and after their death they were elevated to the rank of gods: and as it was the opinion of ancient times, that the souls of distinguished personages after their death inhabited the stars, it has been imagined that those of Adonis and Astarte made choice of the sun and moon for their respective residence; and hence their worship and that of their luminaries was the fame. Astarte was called in Hebrew Astaroth or Astaroth; which appellation some have erroneously ascribed to her having been represented in the form of a sheep. Others have conjectured, from the etymology of the word Astaroth, which signifies "flocks of sheep or goats," that in ancient times, when men were chiefly addicted to pastoral life, and peculiarly delighted in this occupation, the most approved monuments of excellence and beauty were deduced from hence; and this has been supposed to have been the reason of the name Astaroth or Astarte. Astarte was usually represented, like Isis, with cow's horns on her head, and for the same reason, namely, for exhibiting the moon's increase and decrease; as she was consecrated into that planet, and adored under the denomination of the "queen of heaven." Her principal worship was established at Hierapolis in Syria, where she had a magnificent temple, and more than 300 priests employed at her altar.

Cicero, and alfo Suidas, suppose that the Astarte of the Phcenicians was one of the four Venuses, whom the Roman orator enumerates. Beger and Bochart add, that she was Venus armed, or the goddess of war; and Paufanias, on whose authority they rely, says, that the Cythereans, who adored her under this form and appellation, had received this worship from the Phcenicians. Astarte, according to Lucian, was the moon; and Juno among the Carthaginians, according to St. Augustin, who, as Bochart imagines, had derived their opinion from Horace, l. ii. od. 1. and Virgil Aen. l. i. 15. This goddess was represented by her votaries in different nations, under a variety of forms and attributes. The Sidonians represented her under the figure of a hen who covered her chickens with her wings. The Astarte, mentioned by Cicero, was exhibited in Phcenicia with a quiver and arrows. In her temple on mount Libanus, where she was nursing her loft Adonis, her head was veiled, and relit on her left hand, and floods of tears flowed down her cheeks. Among the Assyrians, she was sometimes termed a goddess, and sometimes a god, on account of the ambiguity of gender in the oriental languages, and because the Hebrews knew no distinction of sex in the gods. The mythological writers, in general, have thought that Astarte is, under different names, the Venus or Mylitta of the Assyrians, the Mithra of the Persians, the Isis of the Egyptians, the Io and Venus Urania of the Greeks, the great goddess of the Syrians, the Derceto of Afcalon, and probably Diana &c. When the black conical flame, which was thought to have fallen from heaven at Emesa, and under the form of the sun was worshipped in that place, and
and under the appellation of Elagabalus, was brought to Rome by the emperor who assumed this name, and fixed in a magnificent temple raised on the Palatine mount, this imperial fanatic made choice of Astarte, under which name the moon was adored by the Africans, for his comfort. According to his image, with the rich offerings of her temple as a marriage portion, was transported with solemn pomp from Carthage to Rome; and the day of these mystic nuptials was a general festal in the capital, and throughout the empire. Antiquities have fupposed that she is exhibited as a half-naked female, &c. on the medals of Berytus and Ceasarea; in a chariot, &c. on a medal of Elagabalus at Sidon; and on the medals of Carthage, in the form of a female seated on a lion, with a thunderbolt in her hand. Propitiating was practised by the female worshippers of Astarte at Byblus, in Phoenicia, in Babylon, and in Carthage.

ASTASANA, in Ancient Geography, a town of Asia, in Aria. Potemly.

ASTATI, in Ecclesiastical History, the followers of one Sergius, in the ninth century, who renewed the errors of the Manichees.

The word is derived from the privative α and λεγει, βα, to stand, and signifies any thing unstable and inconsistent. They prevailed much under the emperor Nicephorus, but his successor, Michael Europatides, curbed them with very severe laws.

ASTHICKCUNIPI, in Geography, a large lake in New Britain, abounding with whales, and fupposed to communicate with the Northern sea.

ASTEIM, in Rhetoric, a genteel way of irony, or homodie way of deriding another. Such is that of Virgil:

"Qui Davium non oedit, amit tua carmina Maxi."

ASTEIXIS, in Ancient Geography, a mountain of Africa, part of mount Atlas, to the south of Mauritania Cefaricins.

ASTELEDE, a town of Asia Minor in Lydia. Steph. Byz.

ASTELEPHUS, a river of Colchis which ran into the Euxine sea. Arrian.

ASTEREL, MARY, in Biography, the daughter of a merchant at Newcastle-upon-Tyne, was born in the year 1688, and instructed by her uncle, who was a clergyman, in logic, mathematics, and philosophy, as well as in the Latin and French languages. At twenty years of age she removed to London, and devoted the principal part of her time to study. In order to excite emulation and a desire of improvement among her sex, she published "A Serious Proposal to the Ladies, wherein a method is offered for the improvement of their minds," printed in 1720. At London in 1697. Her proposal, which was the establishment of a seminary for female education, excited so much attention, that a lady, supposing to be the queen, formed a design of giving 10,000l. towards erecting a kind of college for the education of the female sex, and as an asylum to such ladies as might wish to retire from the world; but bishop Burnet discouraged the liberal intention, by alleging, that such an institution would too much reframe a nunny. Mrs. Aftell’s "Reflections on Marriage," written in consequence of a matrimonial disappointment, were published in 1700 and 1705. Mrs. Aftell was orthodox in her religious creed, and in her politics an advocate for the doctrine of non resistance. Besides some controversial pieces, such as "Moderation truly flavoured," "A Fair Way with the Bif. fenters," "An Impartial Inquiry into the Causes of the Rebellion," and "A Vindication of the Royal Martyr," all printed in 1460. in 1704; the also distinguished herself by a more elaborate performance, published in 1705, and intitled, "The Christian Religion as professed by a Daughter of the Church of England," in which she had the resolution to attack Locke and Tillotson. The close of her life was embittered by the anguish of a cancer in her breast, and the bore amputation with fortitude. She died in the year 1731. Her manners were amiable, and her principles right; and though she attracted notice at the time in which she lived, neither her natural talents nor literary attainments would command attention among the females of the present day. Grudging the waste of time occupied by trifling visitors, and yet libelous of elevating footholds to her servants according to the refinement of modern practice, the fufed to accotch such intruders on their approach, and jealously lay to them, "Mrs. Aftell is not at home." Ballard's Mem. of British Ladies. Biog. Brit.

ASTENAS, in Ancient Geography, a town of Spain in Bética. Strabo.

ASTENOUS, in Etnology, a species of Papilio (Eq. Abti.) that inhabits the Cape of Good Hope. The wings are black both above and beneath; a radiated white spot on the anterior pair; dill of the posterior ones yellow. Fabricius. This is papilio ponticus of Cramer; and papilio minor of the famed author is suppos’d to be a variety (2) of this species.

Species 1. A. tetricifolius, yew-leaved starwort. "Under-shrubby; leaves decurrent, lobulate, channelled, ciliato; flowers terminal." Stem scarce a foot high; leaves alternate, crowded, linear, revolute; flowers sessile, or subpedunculated, solitary. 2. A. rufescens, reflected starwort. "Shrubby; leaves ovate, subimbricate, recurved, ferrate-ciliato; flowers terminal." Stem profusorous; leaves crowded, sessile, little, smooth, lower ones ferrate, upper ciliato; flowers solitary, sessile, ray blood-red. 3. A. crinitus. * Subshrubby; leaves ovato-oblong, acute, tomentose under-neath; calyxes terminated in a hair. Branches with fewdivisions; leaves sessile, exquisitely pointed, rough about the edges; peduncles terminal, leafy, one-flowered; ray of the flower blue. 4. A. fruticosus, shrubby starwort. "Shrubby; leaves linear, dotted; peduncles one-flowered; naked." Stems three feet high; branches woody, furnished with clusters of narrow leaves like those of the larch tree; flowers solitary, upon long slender peduncles; they are of a pale blue colour, and appear in March. Leaves narrow, acute, approximating. Cultivated in 1759 by Mr. Miller. This and the preceding species grow wild at the cape of Good Hope.

* Hor.
Herbaceous, entire-leaved, peduncles naked.

5. *A. temnus*, bristle-leaved starwort. Curt. Bot. Mag. 53. "Leaves filiform, prickly-acute; calyxes hemispherical, with equal leaflets." Stem annual, seven inches high; leaves scattered, linear, muricately underflor; flowers peduncled, solitary, terminal; disk of the corolla yellow, ray blue, often rolled back. A native of the Cape. Introduced here by Maiton in 1774. 6. *A. alpinus*, great blue mountain starwort, Curt. Mag. 199. "Leaves subfriatulose, rough with hairs, entire; stems simple, one-flowered." With us it rises to near a foot in height; at the top of each flower is one large blue flower; stem-leaves two, seldom three, the lower alternate, ciliately petiolar next the root, on the stem fleshy, lanceolate. It flowers in June. A native of the Alps and Pyrenees. Cultivated by Miller in 1759.

9. *A. Amellus*, Italian starwort, Jacq. Auct. 5. 435. "Leaves oblong-lanceolate, entire, scabrous; branches corymbed; calyces imbricate, subfibrarose; leaflets obtuse, the inner inmembranaceous, coloured at the end." Stems numerous, branching at the top into eight or ten peduncles, each terminated by a single large flower having blue rays, with a yellow disk. A native of the south of Europe. Cultivated by Gerard in 1596.

10. *A. divaricatus*, divaricate starwort. "Branches divaricate; leaves ovate, serrate; floral leaves quite entire, rather obtuse, semiclasp." Stems rough, about two feet high, dividing towards the top into many forked branches; flowers grow almost in an umbel. A native of Virginia.

**Herbaceous, entire-leaved, peduncles scabrous.**

11. *A. hirspfitius*, hirspfit-leaved starwort. "Leaves linear-lanceolate, drawn to a point at the base, entire, stiff; branchlets corymbed, fagitate; leaflets frequently linear, imbricate; calyces imbricate." Stem a foot high; eight purple florets in the ray; disk elevated, greentish; ilamens telfaceous; piliuf yellow. A native of North America. Cultivated in 1760 by Miller. 12. *A. dumosus*, bushy-starwort. "Leaves linear, entire, smooth, those on the branchlets very short; branches panicked; calyces cylindrical, closely imbricate." Stem two feet high, much branched; branchlets filiform; stem-leaves narrow-lanceolate, on the branches linear; flowers small, very white, disk yellow. Cultivated in Chelsea garden in 1725. 13. *A. vir- colis*, heath-leaved starwort. "Leaves linear, entire, very smooth, those of the branchlets fimbriated, approximating, those of the stem elongated; calyces subfibrarose; leaflets acute, stem fimbriate." Stalks fleshy, three feet high; branches numerous, forming a thick bush, and terminated by single flowers. Cultivated by Miller in 1758. 14. *A. tenufigulis*, fine-leaved starwort. "Leaves subfimbriate, quite entire; peduncles leafy." Stems five feet high, slender, angular, smooth, with few branches; leaves alternate, roughish; flowers terminal, solitary, small, white; peduncles with four subfimbriate leaflets fimbriated over them. 15. *A. lineariflouis*, fimbriate-leaved starwort. "Leaves linear, entire, mucronate, scabrous, stiff, upper ones lax, remote; calyces imbricate; branches fagitate." Stems purplish; leaves very rough, sharp, keeled, scabrous; peduncles alternate; flowers few, terminal, solitary. Cultivated here in 1712. 16. *A. knififolius*, fimbriate-leaved starwort. "Leaves linear, entire, roughish; branches corymbed, fagitate with small leaflets; calyxes imbricate; rays about equal to the disk." Leaves lanceolate, gradually narrowing to the end; peduncles with many small fimbriate scales; stems strong, from two to three feet high, with many branches, terminated by one blue flower. Cultivated in 1759 by Miller. These species are natives of North America. 17. *A. nvis*, "Leaves lanceolate-linear, stiff, entire, flat; flowers corymbed fagitate; peduncles leafy." Much branched; leaves very narrow; flowers of a pale bluish colour, in large clusters at the top of the plant. A native of the south of Europe. 18. *A. concordus*. "Leaves ovate, sessile, quite entire; stem scabious; racemose terminal." Four feet high; flowers of a pale blue colour; the whole plant tomentose; raceme scabious, with very short peduncles. A native of Virginia. 19. *A. rigida*, stiff-leaved starwort. "Leaves linear, alternate; flowers terminal, solitary." Leaves small, fimbriate, many; stem woody, almost simple, terminated by one specious flower; floecles of the ray purple, long. A native of Virginia. 20. *A. novi angliae*, New England starwort. "Leaves lanceolate, entire, corymbose, fimbriate, hairy; calyces longer than the disk, hoarf; leaflets linear-lanceolate, nearly equal; stem hispid." Stems many, five feet high, brown, terminated by large purple violet flowers, growing in a loose panicle, and appear in August; peduncles very short. A native of New England and Virginia. Cultivated in 1731 by Miller. There is a variety, with numerous panicked branches. 21. *A. nodulosa*, waved starwort. "Leaves fimbriate, hairy waved, lower corollid; petioles winged, dilated at the base; branchlets virgate; calyces imbricate; stem hispid." Stems two or three feet high; leaves broad, heart-shaped at bottom; flowers on loose spikes, of a pale blue colour, inclining to white; leaves on the peduncles minute, ovate. A native of North America. Cultivated in 1699, by J. Bo- bart. 22. *A. grandifloris*, Catesby's starwort, Mill. fig. 1282. "Leaves fimbriate-clasping, linear, entire, hispid, ciliolate; those of the branches and calyx reflexed." Stems three or four feet high, fimbriate, reddish, hairy; leaves of the branches small, lanceolate, rough, about the size of those on common flax; branches each terminated by one large blue flower. Mr. Catesby, in 1720, brought this plant from Virginia.

**Herbaceous, leaves ferrate, peduncles smooth.**

AST

obtuse; stem almost naked; siliform, a little branching; peduncles naked. Stem green, hairy, erect; leaves like those of daily; filiform, flenter, white. A native of Virginia.

Herbaceous, leaves alternate, peduncles scaly.

27. A. indicus, Indian starwort. "Leaves ovate-oblong, serrate; floral leaves oval-lanceolate, quite entire; branches one-flowered." Stem herbaceous, round, fluted, branched, two feet high; lower leaves oblong, remotely and acutely serrate; upper lanceolate, entire, gradually diminishing towards the top; flowers solitary. A native of Japan and China. 28. A. lactis, smooth after. "Leaves filiform, entire, shining; root-leaves subferrate; branches simple, bearing about one flower; calyxes imbricate, peduncles leafy, subdivided; leaflets somewhat wedge-shaped; acute, thickened at the end; stem smooth." Ray blue. A native of North America. Cultivated in 1758 by Miller. 29. A. mutabilis, variable starwort. "Leaves almost filiform, lanceolate, serrate, glossy, drawn to a point below; branches virgate; calyxes rather leafy; leaf; stem smooth." Leaves of the peduncles and calyx squarrose and recurved; ray a deep purple; disk frilly yellow, afterwards purple. Cultivated by Miller in 1751. 30. A. paniculatus, Trajectant's starwort. "Leaves lanceolate, ferrate, febrile, smooth; middle branches virgate; calyxes closely imbricate; stem round, smooth." Radical leaves four inches long like those of willow; stems round, smooth, woody, brownish; ray varies from white to purple, confuting of twenty florets. A native of Virginia. Cultivated in 1751 by Miller. There are two varieties, viz. the dwarf and tall starwort. 31. A. Novi Belgii, New Holland starwort. "Leaves almost filiform-lanceolate, lanceolate, smooth, but februous about the edge, the lower ferrate; branches subdivided; calyxes loosely imbricate, leaflets linear-lanceolate; stem round, smooth." Stem four feet high, having broad leaves at the bottom, diminishing gradually to the top; disk of the corolla yellow; ray pale blue, revolute. It is very like A. mutabilis. Its flowers appear in the latter end of August. A native of N. America. Cultivated in 1759 by Miller. 32. A. taraxacum, late-flowering starwort. "Leaves febrile, lanceolate, drawn to a point at the base, serrate, smooth; calyxes lax, leaflets lanceolate-linear, subequal, smooth." Stems two feet high, februously branching, fimbriate, smooth; leaves large, smooth, rather frilly, ferrate at the middle, and having a pachycentic flax; flowers like those of the foregoing. It differs from the diligent in having the branches more disarticulate, and a knot or joint at the base. A native of N. America, introduced here in 1775 by Mr. Crees. 33. A. minor, small white-flowered starwort. "Leaves febrile, lanceolate, sub serrate, smooth; calyxes imbricate, leaflets acute; disk equal to the rays." Stem a foot and a half high, thick, green, leafpanicle than the rest; stems leaves a little ferrate, nodding, thse of the branches lanceolate; ray white, very small, poor, disk small, convex, pale, with dark yellow styles. A native of N. America. Introduced here in 1756 by Monf. Thoinin. 34. A. macrophyllus, broad-leaved blue starwort. "Leaves ferrate, oblong; the upper ovate, febrile, thse on the stem cordate, petiolate; upper petioles winged." Peduncles crowded at the top, often trifid. A native of N. America. Cultivated in 1759 by Miller. 35. A. chinensis, China after or starwort. "Leaves ovate, angular, toothed, petiolate; calyxes expanding, leafy, terminal." Height from eighteen inches to two feet, putting out long bending branches from top to bottom; leaves next the ground, and at the origin of the branches resemble those of common goosefoot (chenopodium), thse on the branches are much smaller, and the upper ones narrow and very entire. The flowers are large and handsome of any of this genus. Dift yellow, floccules of the ray broad and long. Dillenius and Miller affirm, that this species came originally to Europe from China; Linneus doubts of this. Besides the common varieties, white, blue, purple, and red, both single and double, there is now another in the gardens, with variegated blue and white flowers. 36. A. totarius, Tartarian starwort. "Root leaves lanceolate-ovate, ferrate, februous; stem few-flowered." Radical leaves large, running into pedites; stem rough, scarcely twice as long as the radical leaves; flowers large, five or eight in number; the peduncle has two alternate flender entire branches; ray of the corolla blue. A native of Siberia. 37. A. hispidus, flaggy starwort. "Lowst leaves oblong, crenate, februous, stem leaves lanceolate, entire, ciliate, stem februous." Stem erect, hispid, branching, a foot high; lower leaves obtuse, remotely notched; flowers terminal, solitary; ray white; down ferrufugious. 38. A. floer, rugged starwort. "Leaves oblong, ferrate, februous, peduncles panicled." Stem herbaceous, a foot high, at top branched in panicles; leaves alternate, petiolate, pointed, above green, rough, with white cilia, underneath pale, veined, smooth; flowers in terminal panicled branches. Both the above are natives of Japan.

Species recently by Mr. Miller, &c.

39. A. glaber, peach-leaved starwort. "Leaves oblong-lanceolate, acute, ferrate, stem branching, flowers terminal, calyxes linear, erect." Five feet high, bearing large, pale blue flowers. A native of N. America. 40. A. ferris, late-flowering blue starwort, or Michælmas daily. "Leaves oblong, acute, broader at the base, half ferrate, stem branching, flowers terminal, and for the most part solitary." Stems numerous, three feet high; branches lateral, bearing large pale blue flowers. Brought from Virginia, by Tradecant. 41. A. procera, early starwort. "Leaves oblong, acute, februous, sharply toothed, half ferrate, stem hairy, flowers coriaceous, calyx hairy, erect." Stems a foot and a half high; flowers large, blue, expanding in July. A native of the Alps and Pyrenees. 42. A. rhustissus, lottsy starwort. See puneecus (2) n. 24. 43. A. rampanthus, branching starwort. "Leaves linear-lanceolate, villif; stem very branching, spreading; flowers placed regularly one above another; peduncles leafy." Stems fnder, purplish, about three feet high; branches numerous spreading; flowers small, pale purple, appearing in November. A native of N. America. 44. A. umbellatus, umbelled starwort. "Leaves lanceolate, drawn to a point at the base, entire, februous about the edge, branches coriaceous, infatigable." Stems few feet high, channelled; ray of the flower white. A native of N. America, flowering in July and August. Cultivated by Miller in 1759. 45. A. novoglus, three-nerved starwort. "Leaves linear-lanceolate, acute, serrate; stem simple, flowers terminal in a kind of umbel." This much resembles the umbellatus, but the leaves are narrower, whiter on the under side, and have three longitudinal veins. The flowers are also larger and white. Sent from Pennsylvania to P. Collinson, esq. who gave it to Miller. 46. A. paniculatus, panicked starwort. "Lower leaves ovate, half-ferrate clapping at the base; upper leaves lanceolate, small; stem panicked, branches one-flowered, peduncles leafy." About four feet high; branches erect, forming a loose spike of large blue flowers. A native of N. America. 47. A. latifolius. "Leaves linear-lanceolate, smooth, three-nerved, flowers coriaceous, terminal." Stems a foot and a half high, terminated by peduncles on every side, each fulling one pale blue flower. A native of Canada. 48. A. procumbens, procumbent starwort. Mill. Fig. t. 57. -
AST

f. 2. "Leaves ovate, toothed; stem procumbent; peduncles naked, axillary, one flowered." Stems round, inclining to the ground, about four or five inches long, delilute of leaves, each supporting one flower of the shape and fize of the common dally, of a whitish purple colour. Discouered by Dr. Holdowl, about Vera Cruz in America. Perhaps some of these may not be distinct from the foregoing ones, as there are certainly many species recited by authors which have not yet taken their proper place in the system, and require a very sagacious botanist to arrange them. In Gordon's Catalogue we find the following notes not noticed by Linnæus: 1. A. alehentus, virgatus, falkifolius, purpurus, auleatus, repens, coribosus. 39. A. boksericus, For. 

Species of After, from Alston's Hort. Kew.

51. A. cymbaria, cymbalaria-leaved fawort. "Shrubby, leaves ovate, finnate, rough, with hairs, calyxes imbricate, hairy." Found at the Cape, by Maffon. Introduced here in 1786. It flowers most of the summer. 52. A. renuvalis, wood fawort. "Leaves linear-lanceolate, drawn to a point at the bafe, somewhat fcarious; branches fiffiform, one-flowered; calyxes lax imbricate, leaflets acute." A foot high, ray of the corolla blue, <i>dik</i> white. It floers in Augt. A native of Nova Scotia. Introduced in 1778, by W. Malcolm. 53. A. paludofus, marsh fawort. "Leaves linear, flem clafping, entire, smooth, fcarious at the edge; peduncales almost naked, caIyxes fquarrose." Leaves three to four inches long, remote, ray blue, large, <i>dik</i> yellow. A native of the fwnaps of Carolina. Introduced by Mr. Fairbain, in 1784. It puts out flowers in September and October. 54. A. patens, spreading, hairy-falked, fawort. "Leaves oblong, entire, acute, cordate, almost leaf-clafping, fcarious, branches spreading, elongated, few-flowered, caIyxes imbricate, fubquarrose, <i>flem</i> rough with hairs." Three feet high; branches remote, pubefcent; leaves bent obliquely at the fable; ray pale blue, <i>dik</i> tawny. A native of Virginia, flowering in September. Introduced about 1773, by G. Aufrere, efq. 55. A. felolus, leafy fawort. "Leaves lanceolate-linear, entire, smooth; those on the branches spreading very much; calyxes imbricate, leaflets acute, <i>flem</i> pubefcent." A native of N. America. Cultivated by Dr. Sherard in 1732. It flowers in October. 56. A. multiflorus, small-fawort. "Leaves linear, entire, smoothfih; branches one-rankfed; calyxes imbricate, fquarrose, fcales somewhat leafy, acute; <i>flem</i> pubefcent." Stems unequal to support the abundance of its flowers; leaves rough, the veins form rhomboids; fcales of the calyx minute, relief; flowering branches and peduncles covered with leafy scales; ray white, small. A native of North America. Cultivated by Dr. Sherard in 1732. F. October. There is an early and a late flowering variety of this species. 57. A. falkifolius, willow-leaved fawort. "Leaves linear-lanceolate, quite entire, smooth; calyxes imbricate, lax; <i>flem</i> glossy. Stem five or six feet high, leaflets of the calyx acute, expanding at the end; ray of a bluefih fclour." A native of N. America. Cultivated in 1760, by Miller. 58. A. flbruus, Labrador fawort. "Leaves lanceolate, almost leaf-clafping, quite entire, smooth, fcarious about the edge; calyxes lax, leaflets equal." Stem two feet high, cipid; ray blue. A native of N. America. Introduced here in 1776, by Meff. Gordon and Co. F. in July and August. 59. A. juniceus, slender-falked fawort. "Leaves lanceolate-linear, fettle, smooth, the lowest subferrate, those of the branches lanceolate; branches virgate; calyxes imbricate; flem smoothfih." Four feet high, leaflets of the calyx acute, spreading at the end; ray fightly fclor-coloured; <i>dik</i> elevated, pale yellow. A native of N. America. Cultivated in 1758, by Miller. F. in October. 60. A. pendulvs, pendulous fawort. "Leaves elliptic-lanceolate, ferrate, smooth, those of the branches rather remote; branches very much divaricatfed, <i>flem</i> pubefcent." Ray of the flower white; <i>dik</i> yellow, changing to furgognitive. A native of North America. Cultivated in 1758 by Miller. F. October. 61. A. difjufus, diffinte fawort. "Leaves elliptic-lanceolate, ferrate, smooth, those on the stem linear-lanceolate, elongated; branches spreading; calyxes imbricate; <i>flem</i> pubefcent." Above five feet high, weak; calyx cylindrical, with numerous acute leaflets; <i>dik</i> white shorter than the calyx, <i>dik</i> reddifh. A native of North America. Cultivated in 1758 by Miller. F. October. 62. A. crempofus, coriybosed fawort. "Leaves coriaceous, f #####
the roots, so as to be troublesome, and the seeds of some are blown about and come up like weeds. The Italian fiar
wort (5) has not been so much cultivated in England since the great variety of American species has been introduced, though it is by no means inferior to the best of them. It is propagated by parting the roots soon after the plant is out of flower. The roots should not be removed oftener than every third year. Cateby's fiar-wort (22) not multi-
plying fast by its roots, may be propagated in plenty by cuttings from the young shoots in May, which, if planted in light earth and shaded from the sun, will flower the same year. When the annual fiar-wort (25) is once introduced, the seeds will scatter, and the plants come up without care. The China after (35) being an annual plant, is propagated by seeds, which must be sown in the spring on a warm border, or rather upon a gentle hot-bed, just to bring up the plants; for they should be enured to the open air as soon as possible; when the plants are three inches high, they should be taken up and planted in a bed of rich earth, at six inches distance every way, observing to shade them from the sun till they have taken new root; and if the season is dry, they must be often refreshed with water. In this bed they may remain a month or five weeks, by which time they will be strong enough to transplant into the borders of the flower garden, where they are designed to remain; or into pots to adorn court-yards, &c. The plants should be taken up carefully with large balls of earth at their roots; after they are planted, and the earth closed about their roots, there should be some water given them to settle the earth. If the ground be rich, these plants will flower in August, and form the greatest ornament in the flower garden in autumn. They ripen in the beginning of October, and should be gathered when they are perfectly dry. Procumbent fiar-wort (48) being a native of a warm climate, will not live in the open air in England. The seeds must be sown in a hot bed; and the plants will require a stone to preclude them during the winter. See Martyn's Miller's Dict.

ASTER. See ARCTOTIS, ARNICA, BUCHNHELLM, CARPESTIUM, CHRYSANTHEMUM, CHERYSOMA, Cine-
BARIA, CONYZA, ERIGERON, GERTAIA, IILEA, SENE-
CIO, SOLIDAGO, Tussilago.

ASTER, in Mineralogy, a denomination given to a species of Samian earth.

ASTER, in Natural History, a species of Hydras in Ge-
lin's Syll. Nat. This is the smash after of Ellis, and in-
habits the American seas. The stem is thick, flabby, subcylindrical, smooth, trunaced, and radiated with ten-
tacle.

ASTER is also a denomination, in the Ancient Pharmacy, given to a kind of medicine, invented by Andromachus, against delusions, and divers other pains.

ASTERIA is the name of a gem, usually called the
cat's eye, or obsida cetti. It has only two colours, a pale brown and a white; the brown seeming the ground, and the white playing about it, as the fire color in the opal. It is considerably hard, and will take a fine polish, but is usually worn with its native shape and smoothness.

It is found in the East and West Indies, and in Europe. The island of Borneo affords some very fine ones, but they are usually small; they are very common in the sands of rivers of New Spain; and in Bohemia they are not infrequently found imbeded in the name maves of Jasper with the

ASTERIA is also the name of a figured bone. See Star-
Bone.

ASTERIA, in Ancient Geography, a small island between

thoae of Ithaca and Cephalonia. Strabo. This is called
ASTERIS by Homer in the Odyssey.

ASTERIAS, in Botany. See GENTIANA.

ASTERIAS, in Entomology, a species of Papilio (F. Tis.), the wings of which are black, with two bands of yellow spots; and angle falcatus, with a black dot. Fabricius mantissa. Inhabits America.

ASTERIA, in Natural History, a genus of Ferres in the mollusca tribe, the body of which is depressed, grooved beneath; covered with a coriaceous crust, and furnished with tentacles; mouth central, of five valves. These are the flacile marine, flarish, or flabellia of most authors: all inhabitants of the sea; reproduce parts which have been lost by violence; and more either by swimming or crawling. In shape they vary exceedingly, and hence Gimelius has arranged them under different families, as hirta, falcata, and radiata. The species he enumerates are these: nobilis, pulvillius, militaris, luna, pappos, francis, rubens, fepoata, endeca, minuta, glaebia, reticulata, phrygiana, nodosa, viola-
ecia, fanguculenta, perforata, argentic, equulvat, livi-
gata, membranacea, granulata, rofca, pertula, ophiura, aca-
leta, cilari, filiforina, tenella, pectinata, multitadiata, caput
medusa, euryale, oligetes, nigra, tectular, and fragilis; which see respectively.—A. nolata: five rayed: chik orbit-
ular: covered with glabrous prickles, A. arachnata: disk bred; rays somewhat depressed, and prickly along the margins. Inhabits the North and Mediterranean sea. Mill. Gen. &c.

ASTERIAS, in Ornithology, a term synonymous with algar, &c.; a name by which some old writers have called the common goos-hawk, falco palmaris. Linn. The name affilis has been applied by Ray to the same bird.

ASTERIE, in Entomology, a species of Papilio (Nymph. Gm.) Wings dentated, varied with pale yellow, a large bipaculated spot on the posterior pair, above; beneath pale, with three occular spots. Fab. &c. Linnæus describes this insect as papilio alia dentatis luteis, fugiulat utrinque ocellis fexgualiter; anteriori pupilla gemina. Syll. Nat. It is figured by Cramer and Kleeman.

ASTERION, in Astronomy, one of the Cages Venus-

ASTERION, in Ancient Geography, a river of Peloponnesus, Pauniais.—Allo, a town of Greece, in Eponia. Livy, l. 24. c. 24.—Allo, a town of Thessaly, founded on a mountain, called allo Perisop. Steph. Byz.

ASTERISCOIDES, in Botany. See OSMITES.

ASTERISCUS. See ANTHEMIS, BUCHNHELLM, and SROUGHMORE.

ASTERIS SIMILIS. See ERIGERON.

ASTERISK, a character in form of a small star, set over any word or sentence, to make it the more conspicuous, or to refer to the margin, or elsewhere, for a quotation, explanation, or the like.

The word is a diminutive of a star, a star.

ASTERISM, from occc star, in Astronomy, the name

with Constellation.

ASTERUS, in Ancient Geography, an island on the
east of Ionia, at a distance from the mouth of the Medes:
fourth-east of the promontory of Troglissium, north of that of Pseudium, and W. N.W. from the town of Miltis. It was famous for the victory obtained near it by the Greeks, gained on the same day when they triumphed over the same enemies at Platia.

ASTERUS Urbanus, in Biography, a writer against the
Montanists, was either a bishop or presbyterian, and lived about the beginning of the third century. Copious extracts of a treatise, which was the substance of his disputation U
ASTEROCEPHALUS, the first of the principal stars that compose the Pleiades. Ovid. Fait. iv. 170.

ASTEROPHYTON, in Natural History, the name given to a kind of starfish, which is composed of a great number of cylindrical rays, each branching out into several others, so as to represent the branched filaments of a very intricate shrub.

ASTEROPLATYCARPOS, in Botany. See ONANA.

ASTEROPODIUM, in Natural History, the name given by authors to a kind of extraneous fossil, of an imbricated texture, composed of a number of small convex or concave plates, and serving, when entire, as a base or root to the shell, or starfish.

It is very plain, that this is the remains of some animal body, probably of the starfish kind, to which the shells have also once belonged; but our imperfect knowledge in the animal history, has not yet acquainted us with the particular creature; the most probable conjecture is, that it is the Magellanic starfish, the rays of which nicely and exactly represent some of the most perfect astro- pods.

ASTEROPTERUS, in Botany. See INULA, and LEYSERA.

ASTERUSIA, in Ancient Geography, a mountain towards the sea, in the southern part of the isle of Crete.— Also, a town situated upon mount Caucaus, founded by a Cretan colony, according to Stephe. Byz.

ASTESAN, or County of Alfis, in Geography, a country of Piedmont, in Italy, bounded on the west by the principality of Chiari and Carmagnola, on the north by the Vercellio and the Alexandrin, and on the south by the marquesate of Ceronso; about twenty-five miles long and ten broad.

ASTHAE, or ASTHALA, in Ancient Geography, an island of Asia, on the coast of Gedrosia. Ptolemy.

ASTHAGURA, a town of India, on this side of the Ganges. Ptolemy.

ASTHENIA, in Medicine, a term employed to denote bodily debility. It is derived from ἀσθήνη, ἀσθήνεις, ἄσθηνος, ἄσθενος, robur. In the syllaum of Savage, and some other nosophological writers, it forms a distinct genus, being clasped with syncope, and other similar diacres; but it is commonly used by physicians in a more extended sense, as to embrace all that want variety of chronic complaints, in which there is a general languor of the body, from the vital functions and muscular actions not being performed with that degree of energy which is necessary to health. The general therapeutic treatment proper in cases of debility, confints in the employment of tonic medicines, such as Peruvian bark, bitters, chalybeate, the cold bath, or temperate bath, feblathings, country air, a mild nourishing diet, riding on horseback, &c. It should be remarked, however, that this general tonic plan is not applicable, in its full extent, to all athenic diseases, some of them being complicated with visceral and other local obstructions and inflammations, which require peculiarities of treatment, as will be duly noticed in the course of our observations under those several heads.

ASTHMA, a shortness of breath; from ἀ and σφῖν, σφῖνος, ἂνθελο, I breathe, I pant.

The disease which bears this name may be defined to be a short and laborious respiration, accompanied with a wheezing noise, generally coming on by fits, and going off by a cough, and spitting up of phlegm. It is not suffered in by fever.
In Sauvages's system it is classed under anheletions; in Cullen's, under spastmi. The former enumerates no less than eighteen species thereof; the latter only three, viz., A. spontaneum, A. enthymematicum, and A. pleuriticum. Another writer has further divided this disorder into four species. Some of these distinctions are unfounded, and most of them are of little or no utility in practice. By far the greater number of those cases of difficult respiration, which Sauvages has referred to asthma, belong to dyspnoea; a symptom common to various and opposite diseases, and distinguished from asthma by its manner of coming on, by its duration, and by the fit of morbid phenomena with which it is associated. Thus the shortness of breath which occurs in pleurisy, peripneumony, consumption, catarrh, dropsy of the chest, &c., is only a concomitant of those diseases, but not the disease itself; and is therefore not asthma, but dyspnoea.

The former may be said of those cases in which Floyer has enumerated as instances of continued asthma.

There is strictly but one idiopathic species of asthma, the periodic or convulsive asthma (the asthma of Cullen; the dry or flatulent asthma of others); the tenninal asthma, as it is termed, being for the most part a variety thereof.

The periodic or convulsive asthma has been so well described by the celebrated Floyer, who himself laboured under this disease for the space of thirty years, that we shall briefly take from him the history of its phenomena.

For some hours preceding a fit of asthma, the patient experiences a sense of dreariness; a tending of the pit of the stomach, and is much troubled with flatulency. At the same time there is a heaviness of the head, drowsiness, propensity to yawning, and a discharge of pale urine. If these symptoms come on towards the afternoon, they are followed at night by a tightness and weight across the chest, by oppression of the breath, and some wheezing. There is generally, too, a convulsive cough, with little or no expectoration. In the course of the night, the symptoms become more urgent, the inspirations are made with the utmost labour, the chest and shoulders being lifted up with great violence, and in a convulsive manner. In this diverting state the patient is necessitated to get out of bed, and to remain in an erect posture. Although the expirations are not so difficult as the inspirations, yet they are performed very slowly, and with a wheezing noise. In this stage of the fit, a person can neither speak nor cough. His face appears pale or livid; his hands and feet are cold; and his pulse is generally weak and irregular. He has a great desire for fresh air, and is much oppressed by a close heated room, by duff, smoke, or bad smells; and even by the weight of his clothes upon his chest. After some continuance of the attack, head-ache is superadded to the other symptoms; and, the pulse becoming somewhat accelerated, there is a slight degree of feverishness, the necessary concomitance of fatigue and irritation. As the fit declines, there is a breaking of wind both upwards and downwards, and frequently a motion to stool. The urine, which before the fit was pale, is now high-coloured, and deposits a sediment. If the attack lasts but two or three hours after rising out of bed, the frightfulness of breathing abates, and some phlegm is spit up.

When a short fit happens, it is accompanied only with wind and spitting; with a quickness of the pulse; a disposition to sweat, and a discharge of high-coloured water in the morning. It is not preceded, as in the former case, by oppression at the pit of the stomach, nor by pale urine, nor by much drowsiness over-night. This is what Floyer calls a spitting-fit. It is only a milder form of the other attack.

The duration of an asthmatic paroxism varies in different individuals, and in the same individual at different times. Sometimes it continues only a few hours, at other times lasts three or four days. Hence these cases, very little phlegm, and of that of a dark colour, is spit up for the first two days; on the third or fourth it is condensed up into mucus, of a less viscid consistence, and of a better colour. At the end of four or five days, the cough and spitting generally cease, and the patient remains free from oppression of the breath, until the next return of a fit. The intervals between the attacks are extremely various, sometimes short, sometimes long. The short intervals do not exceed the space of three, fix, or seven days; the longer interruptions extend to twelve, fourteen, or fifteen days. The longer the paroxism, in general, the longer the interval; and vice versa. The late Dr. Heberden has remarked, that some asthmatics experience only four attacks in a year; others only two, viz., in spring and autumn; and some not more than one attack annually, and that every winter. Others only once in two years; but these last, and especially another instance mentioned by him, must be regarded as rare and anomalous cases.

The periods of recurrence are much influenced by changes of the atmosphere. Rainy weather, foggy weather, an approaching fall of snow, a change from frost to thaw, or a change of wind into the east, will often bring on a fit; which, however, may happen from other causes, in every kind of weather. As the fits usually recur, in confirmed asthmatic subjects, once a fortnight, they must often take place on or near the changes of the moon. Hence the asthmatic periods have been supposed to be regulated by the phases of that celestial body. The recurrence of the paroxysms, however, is known to happen at other times; so that it is evident there is no necessary connection between them and the lunar changes. Alterations of the weather, happening at those periods, are (as Floyer has remarked) the probable cause.

Asthma may occur at any age but, except where there is a mal-conformation of the chest, it seldom attacks in early life. It usually afflicts persons of mature or advanced age. People who follow certain occupations are more liable to it than others; such as millers, masons, stone-cutters, woolcombers, flax-dressers, &c. Many of these instances, however, of short breathing belong rather to dyspnoea, than to asthma. Although the attacks are so severe and distressing for the time, yet in the intervals the patient commonly enjoys a tolerable share of health, and is able to engage in the pursuits of business or pleasure, according to his situation in life; nor do they seem, in numerous instances, to have much effect in shortening the natural period of human existence, many asthmatics having been known to live to the age of seventy and upwards. The disease, however, terminates at length in peripneumony, consumption, dropsy, leucæmy, or apoplexy.

Edematous swellings of the legs, ulcers in those parts, the bleeding piles, a fit of the gout, or an eruption on the skin, have suddenly produced, in very desperate cases, a favourable termination of an attack, and have so frightened the recurrence of the paroxysms for a great length of time. Besides the changes of the atmosphere, and certain irritations (such as dust, smoke, &c.) before mentioned, there are other causes which are capable of exciting a fit of asthma; such are errors in diet, violent exercise, long fasting, profuse evacuations, intemperate study, retropulsion of cutaneous eruptions, and of gout; pallsions of the mind, &c. With regard to the proximate cause, Cullen supposed it to consist in a spasmodic contraction of the muscular fibres of the bronchial, preventing the free ingress and egress of the air.
and consequently the due expansion of the lungs. This opinion, however, is not altogether reconcilable with the known structure of the bronchial, and has accordingly been controverted by a late writer (Dr. Bree); who has attributed in its stead, irritation, either from an offending material in the lungs themselves, or from acidity and disease in the stomach, intestines, and other viscera of the abdomen. There is little doubt, however, that the means which he supposes to be the cause, is rather the effect of the morbid action of the lungs. Others have attempted to refer all the phenomena of an afflammatory attack to a epipneumonic affection of the diaphragm (Dufour. Institut Medicin. Practice, vol. iv., pars i. in notae lect. cix.), which, according to Floyer’s description of his own feelings, seems to be rendered stuff, and tied or drawn up by the mediastinum. The rhinence thus opposed to the natural dilatation of the chest, would, it is said, necessarily occasions a vehement and convulsive action of the intercostal and other muscles concerned in respiration. All this, however, is mere conjecture; and it is to be regretted, that divinations have been of very little use towards elucidating this pathological discussion.

Whatever be the proximate cause of asthma, all its symptoms are stamped with the character of spasm and irritation; a circumstance which at once points out the plan of treatment that should be adopted: In regard to which, we are to consider, 1. The remeies which should be resort to during the fits: and, 2. Those which should be employed during the intervals, to prevent their recurrence.

When a fit comes on, the patient, if recumbent, should be raised up, and kept in a sitting posture. All external precure from clothes or bandages should be removed from the breast, and free air should be admitted into the room: which should be kept cool, and free from smoke, dust, and every sort of disagreeable smell. Should there be much tendency to sickness, an ippecacuanha emetic should be proper, after the operation of which an antispasmodic draught should be given, composed of aether, calomel, and opium, mixed with a sufficient quantity of peppermint water, or cinnamon water. In some cases, a few drops of spirit of ammonia may be added to this draught, which should be repeated every hour, or every second hour, according to the urgency of the symptoms. The strong smelling antispasmodics, such as amber, musk, and achatia, should be avoided. From the white oxide of zinc (calcined zinc), or sulphur of zinc (vitrified zinc), less benefit has been derived, than the reports of some authors had given reason to expect. The digitalis has been employed with advantage, according to some late accounts, in the paroxysm of convulsive asthma; but it promises to be more generally useful in that species which is termed the banal asthma, under which we shall therefore mention its doses and mode of exhibition. With a view of promoting a diaphoresis, the aqua ammoniae eactate may be given, in conjunction with the antispasmodics above mentioned; but all heating fomentations will be improper. In some instances, the wine of tartare will be more effective, if taken with good effect to the antispasmodic medicines. Floyer has recommended the internal use of vinegar; but though it may have afforded relief in some cases, we are persuaded it will disagree with the majority of such patients; and will, indeed, be extremely hurtful to hysteric and gouty afflications. For these, the absorbent earths, such as magnesia and chalk (with which liet a few grains of ipecacuanha should be joined), will answer much better. While these medicines are given, a blister should be applied between the shoulders, but not upon the sternum, where its weight would inconvenience the patient. Bleeding is rarely admissible. The diet during the fit should consist of cold toast and water, milk and water in a tepid state, a cup of strong coffee, &c. Solid animal food and puddings should be withheld; nor should a glass of wine be allowed, except to very infirm and aged afflications, or in case of alarming delirium. Even then, a dofe of fal volatile drops in water will generally be preferable.

As the fit declines, and a tendency to spitting thaws itself, that effect should be promted by the exhibition of expectorating medicines; such as ippecacuanha, oxymel of squill, and ammoniacum. Of the hift of these, not more than two or three grains should be given for a dose, so as to excite, in this stage of the disorder, merely nausea, but not vomiting. The two others should be joined together in the form of a draught or mixture, with or without the addition of ather. Cold fomentations should be prevented by a laxative-clyster, or by other means; but it should be remembered, that much evacuation by the bowels is always hurtful in these cases.

Regarding the strong desire expressed by persons labouring under an attack of asthma for fresh air, and that the appearances of the spume are such as feem to indicate an excess of the carbonaceous principle in the blood, it was natural to suppose much relief might be obtained by the inhalation of oxygen gas. Accordingly the gas, mixed with common air in various proportions, has been administered by different practitioners to such patients; but not with the expected success. Other fictitious airs have also been tried, such as hydrogen and hydrocarbonate. But if in any case of asthma, these gaseous substances have produced a beneficial effect, it has been too trifling and inconsiderable to entitle them to be ranked among the remedies that may be relied upon for the cure of this disease. The vapour of radicle vinegar, or acetic acid (see Duncan’s Annals of Medicine, vol. iii.), will be found an equally uncertain auxiliary; and other vapours is much better adapted to that condition of the lungs which occurs in consumptions.

When the fit has gone through its course, such remedies should be prescribed as are calculated to prove its return. These should be taken from the chas of tonics and stimulants, such as the Peruvian bark, bitters, chalybeates, &c. With these should be joined the temperate bath, or cold bath (in summer and autumn), change of air, and regular exercise of walking, or riding on horseback. The benefit derived from following the plough, as affected by Baghiv, is to be attributed partly to the country air, but more to the exercise of walking. A dry and pure air, but not of that an elevated situation, is in general well suited to afflications; there are, however, frequent exceptions to this observation, some patients having fewer and less violent attacks in the contaminated atmosphere of the metropolis and other large towns than in the country. The bowels should be kept regular, by rubarb and aloetic aperients. Small doses of calcined calomel may be given with great advantage, in many cases; and especially where the afflammatory affection is connected with a discharge of the skin. Whenever the patient’s feelings warn him of an approaching attack, he should take an emetic, and after its operation an opiate: and at all times he should encourage a tendency to spitting, by ammoniacum and squill. Illnes have been recommended by some practitioners for lessening the frequency and violence of the paroxysms. It is said that king William continued perfectly free from his afflammatic complaint, during the whole of the time that the wound he received on his shoulder, in the battle of the Boyne, kept open and discharged matter.

The diet, during the intervals of the fits, should be carefully attended to. All flatulent vegetables, all sorts of pastry and puddings, all fat and slimy food, and broths, should be
be avoided. A moderate quantity of butcher's meat, and
poultry, roasted or boiled, will be proper every day, with a
small proportion of the more digestible and nutritious vege-
tables. Strong ale should be wholly forbidden. In some
few instances, no harm seems to have arisen from the use of
fresh small beer or porter; but in general toast and water
will be the most suitable beverage. Wine should be allowed
very sparingly. In regulating its quantity, the age, consi-
tation, and habits of the patient should be duly attended to.
It does not appear that the smoking of tobacco, which
some physicians have recommended, is really beneficial in
their complaints.

As this disease occurs so frequently, and is so obstinate to
a nature, those who have the misfortune to be afflicted with
it necessarily become their own physicians. Hence we have
been induced to extend our observations, on this subject, to
a greater length than we shall hereafter do (with very few
exceptions), in single disaeases. But we have yet to add a
word or two on the

morbous afflatus. Under this term some
physicians have comprehended the anaemia of the lungs;
but we understand by it that species or variety of throaty
sniff or breathing, which is accompanied with a con-
stant cough, and expectoration of mucous, and which is dis-
tinguished from phthisis or asthma by being unattended
with fever. It is distinguished from a dropsy of the chest,
by the absence of a number of the arms; and (after the
cessation of a temporary aggravation of the short-breathing
from accidental causes), by the patient being able to bear
the horizontal posture. It is the putrid afflatus of some
writers. Cullen has referred it to dyspepsia; but it rather
belongs to this head, as it generally begins under the form
of convulsive afflatus; and, like it, is liable to accidental
aggravations from changes of the weather, and the other ex-
citing causes before mentioned. In regard to its therapeutic
treatment, emetics and expectorants (joined with atber
and other antispasmodics) and blisters and fizzes, are as
serviceable here as in the convulsive afflatus; but the employ-
ment of diuretics is more particularly indicated; such as
fauil, acetated hah, and the digitalis. Ten or fifteen drops
of the tincture of this herb, or one grain, or a grain and a
half of the powdered leves, joined with a fourth part of
opium, should be given at a dose, and be repeated twice in
twelve or fourteen hours, until the shortness of the breath is
relieved by a flow of urine, or until such an effect is produced
on the pulse, the head, or the bowels, as shall make it ne-
cessary to suspend the use of the medicine. Description of
femella or daleuana (see Practical Synopsis of the Materia
Medica, vol. i. p. 132. 233.) may be preferable in place of
the digitalis, where this last shall be found to disagree.
The patient should wear flannel next his skin, except during
the summer, and should at all times be particularly attentive
to keep his feet warm and dry.

Among the remedies of the sixteenth century, Willis, Hoffman, and Cullen,
should be consulted on this disease; and among the authors of distinct treatises,
Floyer on Afflatus 1698, Ryan on ditto 1793, and Bree on Difordered Respiration 1820.

ASTI, in Geography, a large city of Piedmont, the
capital of the county of Aosta, situate in a delightful and fer-
tile valley, on the banks of the Tanaro. Few cities in
Lombardy exed it in its palaces and public buildings; and
the surrounding country is embellished by the feats of the
nobility and gentry. By the extent of its walls, which
inclose the suburbs, it may be expected to have been for-
merly well fortified; but those works are now decaying.
The cathedral is a elegant structure with a lofty roof, a
fine cupola, and good painting in fresco; upon this is an
inscription which expresses that it was anciently a temple of
Juno, and converted into a Christian church by St. Peter,
one of Jesus's seventy disciples. It has more than thirty
other churches, parochial and conventual. Several remains
of antiquity are seen in this place; and it is said to have been
a favourite town with Augustus Caesar and the emperors.
It is the see of a bishop, suffragan of the archbishop of
Milan; 24 miles call from Turin, and 20 miles from Alk-
fandria. N. lat. 44° 50'. L. long. 8° 52'. See Asti.

ASTI, in Ancient Geography, a people of Europe, in
Thrace, who presided the town of Calyba.

ASTICA, or Astice, a country of Thrace, extending
along the Euxine sea, and commencing at a small distance
north-west of Constaninople.

ASTIGI, or Astigis, Egya, a town of Spain, in Ex-
tica, upon the Singulis, nearly south of Corduba. This
town was a Roman colony, and denominated "Augusta
Firma."

ASTIGI JULIENSI, a town of Spain, situate between
the river Batis and the sea. Plato.

ASTIPULATIOR, in the Roman order, the perfon by
whole content and leave a nun takes the religious habit. Du
Cano.

ASTONISHMENT, denotes a high degree of wonder
or surprise: Johnson defines it a confusion of mind from fear
or wonder. Dr. Cogan, in his "Philosophical Treatise of
the Passions," considers it high astonishment as the
incubus of the mind, which feels nothing at the infant so
much as its inability to act.

ASTORCHAI, in Despoj, a name by which some au-
tors call the yellow schar, and others the purple, com-
monly called the Arabian.

ASTORES ISLAND, in Geography, lies north-east from
the north point of the island of Madagascar, in the Indian
Ocean. S. lat. 19° 22'. E. long. 53° 20'.

ASTORGA, a city of Spain, in the province of Leon,
situate in a plain near the river Tucia. It is a strong place
and the see of a bishop, suffragan of Compostella. It was
formerly the capital of the Asturias, but is now only the
chief place of a marquisate erected here in 1465. It is
called "the city of priests," from the number of ecclesiastics
belonging to the cathedral; twenty-eight miles nearly west of
Leon. N. lat. 42° 33'. W. long. 6° 16'.

ASTRABAD, a town of Persia, and capital of a district
of the same name, is situate at the south-eastern extremity
of the Caspian sea, near a considerable bay, with a chain of
mountains behind. The Russians land at this bay, and then
proceed to the capital. The province of Astrabad lies in
the north-west part of Persia, having Chorasan on the east,
part of Tartary on the north, and Comis and a branch of
mount Taurus to the south. The country in general is
mountainous, and the soil, except near the banks of the ri-
ers which run through it, sandy and barren. The produc-
tions of this province are silk, rice, and cotton, like those
of Mazanderan, and its exports and imports nearly similar.
The commerce of Astrabad is chiefly with Candahar. This
city lies very convenient for a harbour to the eastern districts of
Chorasan, Buchar, Samarcand, and even India. N.
lat. 56° 50'. E. long. 52°.

ASTRACAN MOUSE, in Zoology, the English name of
the Mus Phesus of Gmelin, and Zarizyn rat of Pennant. See
Phesus Mus.

ASTRAKHAN, or Astrachan, in Geography, a city of
the Russian empire, formerly the capital of the kingdom
of that name, having a large and commodious harbour,
with a dock-yard and spacious quays, situate on an isle in
the Volga, not far from its outlet into the Caspian, in 46°
23'. lat, and 65° 43', long. It contains four monasteries,
The city of Astrakan, or Astrapahan, preserves, in the vicinity of it, the remains of two ancient Roman Catholic churches, and two Armenian, one Roman Catholic monastery with a church, one Lutheran church, several schools, and a number of small houses, and is the seat of an episcopal see, and a provincial council. The number of inhabitants amounts to 18,023, including the foreigners and periodical residents; taken all together, they may be computed at 70,000, as on account of the scarcity of water, and the frequent inundations, only a small number of families can be accommodated in the town. The number of inhabitants amounts to 16,759, when the first vineyards were laid out at Astrakan, and planted with Persian vines. They produce the purple grapes as well as the white grape, both of excellent flavour; and the clusters of the latter grow to an uncommon size. The vintage lasts from the end of August to the end of September, old style, when the greater part of the clusters are piled up, but likewise a great quantity are packed up and sent to all parts of the empire. Cotton is cultivated in a considerable degree, and succeeds extremely well. The manufacture of this staple is carried on in the city of Astrakan, and in the adjacent districts. The manufacture of cotton is carried on in the city of Astrakan, and in the adjacent districts.

The chief employments of the inhabitants are the labours of agriculture, fishing, and manufacturing. Fishing is carried on in the Volga, and the Volga and its tributaries. The chief fish is the sturgeon, and the species include the black, the common, the roe, and the white sturgeon. The sturgeon is caught in the Volga, and its tributaries, and is exported to the Baltic, the Black, and the Caspian Sea. The sturgeon is caught in the Volga, and its tributaries, and is exported to the Baltic, the Black, and the Caspian Sea. The sturgeon is caught in the Volga, and its tributaries, and is exported to the Baltic, the Black, and the Caspian Sea. The sturgeon is caught in the Volga, and its tributaries, and is exported to the Baltic, the Black, and the Caspian Sea.
of the fishery, the curing of the fish, the preparing of ca- 
vir and shingle, which is extremely well made, particularly at 
Gurif, and the making of wine. The white wine pro-
duced here is as well as water, the red only reddish.
Both are exceeding light, but well flavoured sweet table
wines. They commonly lose their agreeable taste after two 
years, turning four, and then they are converted into brandy 
or vinegar. Great quantities of the grapes are dried and sent 
through the country, as raisins, or boiled into a syrup. 
The filkworm employs a great number of hands about the Terek, 
between Kiiuand Mofidok, near Attrakhan, &c. Likewise in 
the silk and cotton manufactories in Attrakhan. In this 
city also yellow, black, and particularly red Russian leather is 
fabricated of the greatest beauty and best quality. The flax-
green, which is manufactured here mostly by Tartars and Ar-
menians, is a valuable species of leather, not prepared in any 
other country. The Tartar soap, which is made at and 
about Attrakhan, of pot-a-docks and the blubber of the seal,
is in great repute, and used in the cloth-manufactories. 
The chief salt-petre works, about sixty works above 
Attrakhan, are situate on an arm of the Volga, and carried 
don by an actuary company. They produce such quantities 
of salt-petre, that, after deducting the flated quantities 
for the powder-mills, many thousand pounds are an-
ually exported from St. Petersburg, on the crown's account.

This is the only government of the empire that has 
coasts on the Caspian. The grand mart of the Caspian 
commerce is Attrakhan. The other Russian ports on this sea 
are Kiliar and Gurief. The principal part of this 
commerce is in the hands of the Armenians; next to these 
are the Russians, then follow the Indians, the Persians, 
the Truckmen and Chivintzar Tartars, and lastly the 
Nogay Tartars belonging to Attrakhan. The commodities 
in which this trade consist, have been already mentioned. 
It is likewise observed, that it is divided into the sea 
and land commerce; the exports by the former amount 
at present to about 1,000,000, and the imports to a million rubles: 
the latter is carried on by way of Kiliar and Mof-
dok, and amounts to about 300,000 rubles, the imports 
being about three-fourths of that sum.—The inland trade 
of this government with the other provinces of the Russian 
empire is very considerable. Its products having been 
particularized above, it needs here only to be observed, that 
in exchange it receives chiefly by the Volga, various kinds 
of European commodities, the greater part whereof are 
again exported to Persia, &c.

Attrakhan is a vicerealty, and consists: 1. of the former 
government of that name, which was a Tartarian kingdom 
till it was conquered by the Russians in the year 1554; 
2. of the Caucasian territory; and 3. of the north-central 
division of the Kuban, which for the most part fell to 
Russia by the peace of 1774, and the border treaty in 
1795. It was erected into a vicerealty in 1755, and has 
its own governor-general.

The ecclesiastical concerns of the Russians are under the 
jurisdiction of the archbishop of Attrakhan and Stavropol. 
The other religious parties have preachers appointed over 
them, or manage their own spiritual affairs independently 
among themselves.

The public expenditure of this government, including 
the pay of the military, is flated at 1,473,737 rubles. Moreover, 
this and the government of Saratof, have affixed them 
in common 75,000 rubles to provide for emergencies with the 
neighbouring tribes.

Along the Ural, from Uralisk to Gurief, is a line of 
forts, for securing the borders against the Kirghises, which 
are garrisoned by Uralian Cossacks, who, in compensation 
for their service, have a grant of the free fishery of the 
Ural. The corps of them, always inreadiness to march, 
consists of 12,000 men.

Along the Kuban and the Terek lines are likewise 
drawn, and on the Volga, from Attrakhan upwards, are 
several forepoles or redoutes.

This considerable distrit of Tartary formerly bore the 
name of Kaphah, in honour of the son of a commander, 
whom his mother brought into the world in the hollow of a 
tree; it was afterwards denominated Nagayra. The city 
was anciently called Tmutorakan; but in process of time 
got the appellation of Adhí-Darchan, which the Russians 
correctly pronounced Attrakhan. Old Attrakhan was 
situate eight versts higher up than where the present city 
stands, and its first site still discovers ruins of ancient edi-
fices. At that time it bore the name of Tmutorakan; and 
Lomonosov positively affirms, that tzar Yaroflad Vladimirov-
itch waged war, in conjunction with his brother Milhuf, 
against the sovereign of Tmutorakan, and terminated hosti-
ilities by entering into an alliance with him; a circumstance 
which would prove, on one hand, that the pretensions of 
Russia upon Attrakhan are of a much earlier date than 
the reign of Ivan Vassilievitch, and, on the other hand, 
authenticates the denomination of Tmutorakan, attributed 
to it. As to the particular time, however, when this 
city was transferred to another spot, as well as that when 
it changed its name, little or no knowledge is at present 
to be obtained.

The term Adhí-Darchan implies, "A pilgrim of Mecca 
has granted liberty." Whene'er it is pretended, that a noble 
Tartar, on his return from a pilgrimage to Mecca, precisely 
at the time when the labourers were at work in laying 
the foundations of the city in its new place, granted liberty 
to one of his slaves, whether as a sort of favourable omen 
to the success of the undertaking, or to testify, according 
to the principles of the Mohammedan religion, his gratitude 
to heaven for the fortunate issue of his journey: however 
this may be, it is asserted that the natives feitied on the 
event for giving the city the appellation of Adhí-Darchan, 
as expressive of their wishes for the perpetual preservation 
of their liberty. The Russians, however, derive its name 
from Aftraîh and khan, maintaining that it ought to be 
pronounced Aftarhkan, as if there had formerly been 
in that country a king or khan Aftarh or Aftara, of whom, 
by the way, not the slightest vestige is to be traced in any 
history.

Aftarhkan then had been in the possession of the Russians 
long before the time when it submitted asylum to the value 
of tzar Ivan Vassilievitch. Formal proofs of this fact are 
found in the archives of the city; where it is related, that 
its first Russian sovereign was Milhuf Vladimirovitch, and 
that this prince caused a church to be built of stone at 
Tmutorakan. It was not till the year 1237, when Dathius, 
whom the Tartars call Bathal, having ravaged all Russia 
and invested both shores of the Volga with his Tartars, that 
the Russians lost the kingdom of Aftarhkan, and were 
obliged to pass their lives, for a great number of years, in 
perpetual wars; which lasted till the Greater Tartary 
received a decisive blow, which was followed by the wars 
of Kazan, when Ivan Vassilievitch began to raise his head, 
at length reconquered the kingdom of Aftarhkan, and annex-
ed it to the Russian empire.
was represented as a virgin with an auricle but dignified countenance; holding a balance in one hand, and a sword in the other.

The poets feign that Jutlicc quitted heaven to reside on earth, in the golden age; but, growing weary of the iniquities of mankind, she left the earth, and returned to heaven, where she commenced a constellation of stars, and from her orb still looks down on the ways of men. Ovid. Met. lib. i. ver. 159.

ASTRÆUS, in Ancient Geography, a river of Greece, in Macedonia.

ASTRAGALUS, in Mythology, one of the giants or Titans, who made war with Jupiter. He was enamoured of Aurora, and she became the mother of the winds and flies.

ASTRAGALUS, in Anatomy, the upper bone of the tarsus, which, by its conjunction with the bones of the leg, forms the ankle-joint. SeeSkeleton, description of the bones of the lower extremity.

Some also apply the name astragalus to the vertebræ of the neck.—Homer, in his Odyssey, uses the term in this sense.

ASTRAGALUS, in Architecture, from ἀστραγαλός, the heel-bone, also the vertebræ of the neck. It is a small moulding, having a semicircular profile, used in various parts of buildings. But it is more particularly applied to express the moulding which separates the shaft from the capital of a column, and probably represented the rings or hoops that were put round wooden columns, to prevent them from splitting. SeeArchitecture, Plate I.

In Egyptian architecture we sometimes meet with astragal at the top of the shafts, and sometimes with several between the top and bottom, though frequently there is no moulding between the shaft and capital.

In the earliest examples of Grecian architecture, such as the Doric temples at Corinth, Athens, Sicily, and Paestum, there are no astragals or projecting mouldings separating the shaft from the capital; but instead of these there are grooves, generally three in number, cut into the solid. The original intention of this does not appear to be sufficiently obvious; nor whether it was done for ornament, or to conceal the joint that would otherwise be seen at that place, between the capital and shaft. In the ancient examples of the Ionic order, the astragal is never omitted under the capital. In the oldest specimen of the Corinthian order, that of the monument of Lycurgus at Athens, there is no astragal, but there is a space between the shaft and capital, in which probably was inserted a circular moulding, or ring of metal, or other material.

In Roman architecture we always find astragals at the top of the shaft, whether the order employed be of the Doric, Ionic, or Corinthian kind; though sometimes they were made in the form of square fillets or hoops, instead of that of circular rings.

The astragal was frequently, by the ancients, cut into the form of heads of various shapes; and many of the moderns, who have been more licentious in their ornaments, have covered it with leaves and flowers. The proportions of the astragal depend entirely upon its application; so that no rules can be given for it.

ASTRAGALUS, in Gunner, is a kind of ring or moulding on a piece of ordnance, at about half a foot distance from the muzzle or mouth; serving as an ornament to the piece, as the former does to a column.

ASTRAGALUS, in Botany. See Astragalus, and Phaca.

ASTRAGALOMANCY, derived from ἀστραγαλὸς, an instrument of divination, a species of divination performed by throwing small pieces, with marks corresponding to the letters of the alphabet; the accidental disposition of which formed the answer required. This kind of divination was practised in a temple of Hercules, at Achaia. Hill. de l'Acad. Inscr. tom. i. p. 102.

ASTRAGALOTE, in Natural History, a species of foxtail, thus called from its resembling a talus, or ankle-bone; whence it is also denominated talair.

Stems leafy, erect; not prostrate.

Species, 1. A. alpinaeoides, foxtail milk vetch. Mill. fig. 58. "Caulecent; spikes cylindrical, subfusiform, calyces and legumes woolly." Stem upright, hairy, about two feet high; leaves pinnate; leaflets ovat, eighteen or twenty pairs; flowers yellow, in close, oblong, axillary spikes; legumes flat in woolly calyces, and have two cells containing three or four square seeds in each. It flowers in June and July. A native of the Alps and Siberia. Cultivated by Miller in 1739. 2. A. chrysanthia. "Caulecent, erect; flowers glomerate, subfusiform, from all the leafy axils." Stalks nearly three feet high, broad at the bottom, and gradually diminishing upwards; leaves very long, which also diminish upward, and form a sort of pyramid; these are winged, cungulilfing of pairs, of large oval lobes terminated by an odd one; flowers in clusters from the side of the leaves; they are of a bright yellow, and succeeded by cylindrical pods; seeds yellow, square. It flowers in July. Discovered in the Levant by Tournefort. 3. A. aptocalis. "Caulecent; heads globular; peduncles very long; leaflets marginate." Stalks erect: long peduncles from the axis, supporting a head of pure yellow flowers, which appear in July. Discovered in the Levant by Tournefort. 4. A. pilosus, pale-flowered milk vetch. "Caulecent, erect, hairy, flowers in spikes; legumes subulate, hairy." Stem more than a foot high, round, hard, branching; leaflets ten or twelve pairs, elliptic, lanceolate, bifid; flowers on axillary peduncles, about fifteen, yellow; leaflets nearly cylindric, whithish, filiform. A native of the Vahis, Siberia, see. It flowers from June till Auguit. Cultivated by Miller in 1732. 5. A. folacinus, furrowed milk vetch. "Caulecent, erect, smooth, ftravelled, stiff; leaflets linear, lanceolate, acute; legumes three-fidled." Stems three feet high, round, smooth, leaflets about nine pairs, with an odd one, smooth, oblong, entire, on very short pedicels; peduncles racemose, axillary, supporting many erect pale violet flowers; legumes smooth, acuminate, triangular; seeds brown, round, kidney-shaped. A native of Siberia. Introduced by Dr. Pictain in 1785. 6. A. galegiformis, goats'-milk milk vetch. "Caulecent, stiff, smooth, flowers in racemes, pendulous; legumes three-fidled, succulent at both ends." Stems more than five feet high; leaflets twelve or fourteen pairs, oval, with an odd one; peduncles axillary, on which are small yellow flowers; legumes smooth, short, pedicelled within the calyx,
with two seeds on each side. Cultivated by Miller in 1739, and June. 7. A. chinensis. "Caulefcent, stiff, smooth; flowers racemose, pendulous; legumes ovate, inflated, mucronate at both ends." This much resembles the plant, but the seeds are different, and the flowers of this are variegated. The seeds were sent from China to Sweden in the year 1760. 8. A. Oenothera, purple-spiked milk vetch. "Caulefcent, procumbent, long petioled; spikes peduncled, banner twice as long as the wings; leaflets linear." Stems procumbent at the base, freed, branching; leaves lanceolate, spreading, with twelve pairs of lobes; peduncles furrowed, stiff, longer than the leaves; bracteate lanceolate, corollas red. The whole plant is sprinkled with white and black villous hairs. Haller describes this plant very differently. A native of Austria. Cultivated here in 1640.

It flowers in June and July. 9. A. uliginosa, violet-coloured milk vetch, Gmel. Sib. 4. 40. t. 17. "Caulefcent, almoft upright; flowers in spikes; legumes almoft upright, naked, bracteate, round-flattled, point reflex." This resembles A. cicer, N° 13, except in the legumes; the top of the keel is violet coloured. It was found by Gmelin in the moorish fields of Siberia, and introduced here by Thouin in 1775. 10. A. caucanasium, Carolina milk vetch, Dill. Ekh. 45. t. 39. f. 45. "Caulefcent upright, even; peduncles in spikes; legumes ovate-cylindric, acuminated by the style." Stems three feet high; leaves composed of eighteen or twenty pairs of oval smooth leaflets; flowers of a greenish yellow on axillary peduncles. A native of Carolina. It flowers in July and August. 11. A. afer, rough milk vetch, Jacq. 1c. rar. t. 33. "Caulefcent, stiff, even, rough; flowers in spikes of elongated peduncles; legumes oblong." Stems annual, two feet high, round, freed, leafy, branched; leaflets composed of about ten pairs of lanceolate-linear acute leaflets; spikes long, with pale flowers; legumes thickening above, acuminate, upright, rough. It flowers in June. Cultivated at Vicenza from seeds sent from Africacan.

**Stems leafy, diffuse.**

12. A. canadensis, woolly milk vetch, Dill. Ekt. 46. t. 39. f. 45. "Caulefcent, diffuse; legumes subhoylynid, mucranate; leaflets almoft naked." Stems round, about two feet high; leaflets ten pairs, smooth on both sides, rather glaucous underneath; peduncles axillary, leafed; flowers yellow; legumes oval, oblong, concave, flat. A native of Virginia and Georgia. It flowers in July. Cultivated by Dr. Sherard in 1732. 13. A. Cicer, bladdered milk vetch, Jacq. Aufl. 3. 251. "Caulefcent, prostrate; legumes subglobular, inflated, mucranate, hairy." Stem eighteen inches, very branching; leaflets twelve or fifteen pairs, oval, obtuse, hirtote; peduncles axillary, supporting erect spikes of twenty or thirty pale yellow flowers; legumes completely two-celled, with many seeds. Miller who cultivated this plant in 1739, gives a description of this species, which is somewhat different from the above. 14. A. microphyllus, small, round-podded milk vetch. "Caulefcent, erect; expanding; leaflets oval; calyxes rather timid; legumes roundish." Stem a foot high, flexuofe, with spreading short branches; leaflets thirteen or fifteen pairs, blunt, sometimes emarginate; peduncles solitary, with horizontal yellow flowers, twice the length of the calyx; legumes inflated, villote. A native of Siberia and Germany; flowering in June. Introduced by Dr. Jacquin. 15. A. glycyphyllum, sweet milk vetch or wild liquorice, Huif. With Smith. Flor. Brit. Eng. Bot. 203. "Caulefcent, prostrate; legumes subtriguenquet; bowed; leaves ovate, longer than the peduncles." Stems prostrate, round, flexuofe, furrowed, a little hairy; leaflets from four to six pairs, ovate or elliptic; flowers large, ovate, somewhat toothed; peduncles shorter than the flowers, spikes with ten or twenty greenish yellow flowers; calyx bell-shaped, oblique, having the superior segments very short; legumes incurved, triquetrocylindric, smooth, many-fed. A native of Britain and other parts of Europe. 16. A. hamata, dwarf yellow-flowered milk vetch. "Caulefcent, procumbent; legumes subhoylynid, recurved, smooth; leaflets obcordate, villote underneath." Root annual, branches fritiated and trailing on the ground; leaflets about eight pairs; peduncles axillary, terminated with pale yellow flowers in June. A native of Meffina and Montpellier. Cultivated here in 1640. 17. A. contortirhizus, wave podded milk vetch. "Caulefcent, procumbent; legumes smooth, ovate, villote." An annual, varying greatly in size in different soils. It is a native of Siberia, and was introduced here in 1783, by Thouin. 18. A. boiticus, triangular-podded milk vetch. "Caulefcent, procumbent; spikes peduncled; legumes prismatic, straight; three-sided, hooked at the top." Annual; branches trailing, near two feet long; leaflets about ten pairs, blunt; peduncles axillary, supporting four or five yellow flowers. It flowers in July. A native of Spain and Portugal. Cultivated by Miller in 1759. 19. A. luxurians, Jacq. Hort. 3. 222. f. 57. "Caulefcent, procumbent; spikes elongated; legumes oblong, three-cornered, marked with a furrow, mucronate, villofe." Stems branching, tubular, prostrate, a foot long, produced as the branches into long rising peduncles, threlaked and ending in a close spike; leaflets about twelve pairs, oblong, sessile, entire; bracteate petioles; flowers pale blue. It is a native of Siberia, and flowers in June and July. 20. A. Stella. "Caulefcent, diffuse; heads peduncled, lateral; legumes flatish, subulate, mucronate." Stems spreading, a foot long;, inflated, hispid with white crowded hairs; branches numerous; leaflets on each side of the midrib nine, ovate, obtufe; flowers ovate, acute; peduncles about the length of the leaves, supporting about fifteen blue flowers; legumes mucronate, hairy, grooved on each side, with a reflex point. A native of Montpellier. 21. A. flourens, flary milk vetch. "Caulefcent, diffuse; heads subacuminate, lateral; legumes subulate, reflected at the point." Annual; stems weak; leaflets ten pairs, hairy; flowers small, axillary, of a copper colour. A native of the south of France. Cultivated by Parkinson, in 1616. 22. A. alyricus, Austroian milk vetch, Jacq. Aufl. 2. 56. t. 195. "Caulefcent, prostrate; smooth, inflated, weak; leaflets sublinear, emarginate; legumes round." From seven inches to a foot high; flowers in clusters, entire; leaflets sublinear, emarginate, about eight pairs; peduncles racemose, with blue flowers. It flowers in May and June. 23. A. longifolius, Jacq. 1c. rar. 37. "Caulefcent, prostrate; legumes ovate, villofe; flowers spikel, erect." Stipulas short, ovate-lanceolate, half stem-clapping; leaflets ten pairs, oblong-ovate, entire, pubescent; branches with a spike of white or pale blue flowers; legumes at the top. 24. A. patagophyllus, "Caulefcent, procumbent; legumes headed, folded back, compressed, converging, crested, with a reflected point." A. procumbens, Mill. Diet. n. 18. A. echinatus, Murr. Prod. 222. A. crinitus, Gouan Illust. 50. Leaflets fifteen, oblong, emarginate, pubescent underneath; petals hairy; flowers ovate, lanceolate; peduncles axillary, decumbent, hairy, terminating in a head of pure purplish flowers; legumes bent in, warded, hooked at the top. Linneus, Miller, and Murray, have described this species differently. A native of Spain. 25. A. patagophyllus, heart-podded milk vetch. "Caulefcent, procumbent; legumes headed, sessile, nodding, cordate, mucronate, folded back, naked." Annual; it sends out from the root three hairy trailing X branches;
branches; leaflets blunt, about twelve pairs; peduncles axillary, naked, terminated by a round head of large deep purplish-coloured flowers; legumes rough, and when opened shaped like a heart, ending in a sharp point, and containing three or four seeds. The stem according to Chevalier Murray does not divide, and has hairs closely pressed to it; leaflets fixed pairs, and not more; corollas purple; Linnum says white. A native of Provence, Spain, &c. in mountainous woods, flowering in July. Cultivated in 1768, by Miller. 26. A. hypoglottis, purple mountain milk vetch. With 643. Smith Brit. 759. Eng. Bot. 254. A. arenarius, Huds. A. epiglottis, Dickl. H. Sicc. f. M. 1. "Calceolus, profusely flowers in heads, legumes ovate, channelled on the back, hairy, hooked at the end." Stems flexuose, prostrate, three or four inches high; leaflets of the pinnas numerous, small, ovate, hairy underneath; peduncles scarcely longer than the leaves, head; bracts very much shorter than the calixes; flowers variegated with white purple; calyx tuberculare, rough hairy black with a little white intermixed; legumes ovate, turged, hairy. It flows in June and July. Found in several parts of England, in fady and chalky pastures. The flowers are sometimes white. 27. A. ferina, Syrian milk vetch. "Calceolus, procumbent; heads peduncled, flowers reflected, legumes tomentose, ovate-oblong. A native of Siberia. 28. A. arenarius. "Subcalceolus, procumbent, flowers fabracteose, erect, leaves tomentose." Stem inclining, fix inches high, branched, covered with a nap; leaflets of the pinnas linear-lanceolate, entire, compound; florets bifid, tomentose; peduncles supporting about four blue flowers, legumes fickle-shaped, tomentose, acuminate, channelled. A native of Scania, in loose sand. 29. A. Glooia, small milk vetch. "Caulesth, diffuse; heads peduncled, imbricate, ovate, flowers erect, legumes ovate, Callous, inflated." Stems seven inches long, villose towards the top; leaflets twenty or twenty-three, small, ovate-oblong, feathered underneath with white hairs. A native of Spain. Cultivated at the Oxford garden in 1638. 30. A. finicus. Phil. Trans. a. 1764. "Cauleolus, prostrate, umbels peduncled, legumes primitary, fubulate at top." Root annual, items spreading on the ground; leaflets fubborneate; flowers purplish, wings white, keel purple. A native of China. 31. A. alpina, Alpine milk vetch, Flor. Dan. i. 51. "Calceolus, procumbent; flowers pendulous, racemose, legumes acute at both ends, hairy." Stems above a foot high; leaflets hispidule, ovate, often ten pairs; florets two, ovate, lanceolate, very short, white; flowers in umbels of twelve or fifteen fuscous white flowers; calyx rough, with black hairs; legume rough, black, inflated, crooked. A native of the mountains of Switzerland and Lapland. Introduced here about the year 1771. 32. A. Amnodus. Pallus 112. 110. "Cauleolus, underhubbly, flowers twin, legumes ovate, twin woody." Annual. Stems branching, woolly; leaflets from five to eleven, rather oblong, hoary. It grows on the sandy hills of Southern Siberia. 33. A. triglottis, Egyptian milk vetch. "Subcalceolus, fcape mostly two-flowered, legumes hooked, fubulate, two-keeled." Annual. Stem fix or seven inches high, hispidule, reddish. Sometimes a fcape appears before the items; leaflets about eleven pairs, oblong, campanulate; hispidule, entire; florets fucous, hairy; peduncles racemose with three or four spreading, pale-yellow flowers. A native of Egypt, flowering in July. Introduced here before 1797. ** Scape naked, without a leafy fcape. 34. A. verticillaris. "Leaflets aggregate, femenverticillate." Leaves pinnate, four or five at each infection, as to appear whorled items. A native of Siberia. 35. A. montana. Jacq. Auct. 2164. "Nearly fimple, scapes longer than the leaf, flowers loosely fisked, erect, legumes ovate, with an inflected point." The whole plant slightly villosa; fipples oblong, induritate, covering the fcape; fcape lanceolate, pointt, rounded at the base, the lower ones shorter and bent down; flowers blue, from eight to ten, according to Haller, but Linnaeus says they are red and erect. A native of the warmer parts of Europe. 56. A. tricolorinus. "Scapes longer than the leaves, flowers loosely fisked, calixes and legumes villosa, hispidule." Calceolus, half a foot high; leaflets six pairs, oval, hoary, entire; peduncles firm, furrowed, higher than the whole plant besides, with a head of from five to eight flowers, having the banner purple, wings yellow, keel white. A native of Dauphinie and Siberia. 37. A. phy- soidea. "Scapes equal to the leaves, legumes subglobular, inflated, naked." Flowers in a spike, yellow, succeeded by swollen pods, containing several greenish seeds; bractes villose. A native of Siberia, flowering in June. 38. A. caprif: us. "Scape erect, leaflets linear, legumes ovate, tumult, villosa." Leaflets from fifteen to twenty pairs, hairy on the edge; peduncles a foot long, fisked, with many pale-yellow flowers; legumes thick, three-fied, mucronate. A native of Barbary and Ruffa. 39. A. urolons, silky milk vetch. Huds. Lightf. With Smith Brit. Eng. Bot. 456. "Stem, fcape erect, longer than the leaves, legumes oblong, inflated, villosa, erect." Radical leaves with many pairs of leaflets, firm, naked; florets fucise; fcape erect, headed, and finally fisked; bracts the length of the calyx, linear-lanceolate; calyx tubular, rough, with black and white hairs; corolla a violet colour; legumes erect, cylindrical, oblong, turged, befet with black hairs predeed down. It grows on the mountains of Scotland. 40. A. montfculata, Montpellier milk vetch. "Scapes decending, the length of the leaves, legumes fubulate, round, rather bowed, fmoother." Scapes procumbent, twice as long as the leaves, leaflets ovate, acute, pubescent, from ten to twenty pairs; fcape simple, bearing a raceme of nearly thirty purple flowers; legumes long, fnder. A native of the fouth of France. Introduced in 1776, by Pitcairn. 41. A. isacall, "Scapes decending, leaflets tomentose, legumes fubulate, rather bowed, hoary, incurved at top." Scapes rough, supporting often twenty flowers; legumes a little bent, turged. It differs from the 42th in having the leaves rounder and hoary, the legumes almost ftraight and more turged. A native of the fouth of France. 42. A. campfiwid, field milk vetch. "Caulexys and legumes villosa, leaflets lanceolate, acute, fcape decumbent." Stem none, but procumbent runners half an inch long; leaflets about fifteen pairs, hairy, fining; fcape radical, bearing ten or twelve flowers in a close raceme; bractes lanceolate, florer than the calyx; corolla a pale-yellow. A native of Swifterland and Germany. Introduced in 1778. 43. A. depreffus, dwarf white-flowered milk vetch. "Scapes shorter than the leaf, legumes nodding, leaflets fubmarginate, naked." Branches very short, peduncle close to the ground; fcapes with nearly seven flowers, small and white; legumes villosa, acuminate, the length of the fcape, smooth; leaflets numerous, oval, with hoary hairs underneath. Cultivated in 1772, in the Oxford botanic garden. 44. A. re- cates, "Scapelos, legumes fubulate, hooked, longer than the leaf, leaflets obcordate." Annual. Stems trailing; leaflets broader at their end, than at their base, and indented as to be nearly heart-shaped; flowers white, in axillary loose spikes; legumes fickle-shaped. Discovered about Alc Hippo, by Dr. Ruffel. 45. A. cefanus, hairy-podded milk vetch, Wood. Med. Bot. fupp. "Scapelos, legumes woody, leaves villosa." Leaflets twenty one to thirty three, oval, fickle, hairy; flowers numerous, radical, subfliccile, yellow; calyx ovate, swelling, white with down, legumes oval, fefet with fine hairs, pointed
A native of Hungary. Since the year 1786, this plant has been much celebrated as a remedy in syphilitic complaints. Its succres in curing old venereal infections was experienced by Quarin, in the general hospital at Vienna, and the efficacy of this plant was afterwards acknowledged over all Germany. Its root is employed in decoction, in the proportion of half an ounce, to a pint of water, and taken warm night and morning.

46. *Tragopogon*, Jacq. t. 4. 52. n. 67. "Nearly: stemless; flowers radical, numerous, subfuscilis." It has no stem or scape, but has branches from the root, spreading on the ground, with small villose-pinnate leaves; calyces hirsute, with black teeth; corollas yellow; legumes roundish, fimbroid.

A native of Switzerland, Siberia, and Armenia. 47. *Tragopanthes*, goat's thorn. Woody. Med. Bot. t. 2. n. 98. "Trunk arboreferent; petioles becoming spinifuscis." stems a foot long, leafy, branching; leaflets about ten pairs, small, ovate, hirsute ovate lanceolate; flowers erect, four or five in a cluster, having a purple keel, and a yellowish white banner and wings. A native of the sea-shore near Malfeile, of Switzerland, mount Ætna, Olympus, &c. Cultivated here in 1641. Miller makes four sorts of tragopanthes. From this species is gathered the gum tragopanthes used for various purposes, as well as an article in the materia medica. It forces its way through the crevices of the bark to which it adheres and concretes. This gum differs from all others, in giving a thick consistence to a much greater quantity of water, which it slowly imbibes, and but imperfectly dissolves. It is used as a demulcent, and peculiarly well adapted for the formation of the troches.

Other species.

48. *A. foetidus*, Villars's Dauph. t. 3. t. 43. f. 1. "Stemless; leaves prostrate, villos, sharply linear; scape erect, with few flowers." Leaflets greenish, yellow, subhirsute, villos, about twenty pairs, much less than those of the campelliris, which it much resembles; but in this the legumes are more inflated, and put forth a greater number of heads of yellow flowers.

A native of Dauphiné, also of mount Cenis, and other high Alps. 49. A. Halleri. "Scapes leafless; leaflets ovate-lanceolate, smooth; legumes inflated, hirsute, crept." This also approaches to the campelliris, but differs in the bractes, in the smoothness of the leafes, in having a longer flower, white, and not a violet-coloured keel. A native of the mountains of the Valais and Piedmont. 50. *A. vulcanioides*, Allion. Ped. t. 19. f. 2. "Stemless, hirsute; scape longer than the leaves; legumes inflated, ovate, in heads." This has the habit of anthus vulcanioides. The corolla is but little extended beyond the calyx; the keel and wings of a dusky colour; the banner of a pale yellow, emarginate; legumes short, rather hirsute, crooked at the flage. A native of mount Cenis. 51. *A. tenusfolia*, upright milk-vetch. "Caulecent, erect; spikes peduncled; banner twice as long as the wings; leaflets linear." Leaflets from eleven to thirteen; peduncles long, straight, obtusely triangular. It resembles *A. onobrychis* so as to be thought a variety, but differs in having rather tomentose leaflets; larger flowers, and silky stipules. A native of Siberia. Introduced here by Pallas, in 1780. 52. *A. virgatus*, green-flowered milk-vetch. "Caulecent, erect; legumes bent back; peduncles many-flowered, longer than the leaf; leaflets lanceolate, acute." A native of Siberia, and introduced by P. S. Pallas, in 1782. 53. *A. Cardamine*, Cavan. Hift. n. 92. t. 84. "Stem subhirsute, upright; pinnules ovate-oblong, somewhat tomentose; peduncles naked, elongated." Stem a foot and a half high, covered with a very short white down; leaflets numerous, ovate-oblong, one-nerved, subtomentose; stipules filiform-clasping, cowled, bised at the tip; peduncles naked, elongated; axillary, ending in spikes of pale violet-flowered flowers. A native of Peru. It flowered in the royal garden at Madrid. 54. *A. lippidus*, Billard, l. e. 67. "Caulecent; procumbent; leaflets and legumes ovate, hirsute; corollas shorter than the calyx." Stem herbaceous, profusely branched, hairy, fix inches high; leaflets ovate-oblong, hirsute; stipules twisted, rigid hairs, tubercled at the base; flowers in spikes, yellow, with lanceolate hirsute bractes; legume ovate-oblong, compressed, a little hirsute; seeds kidney-shaped. 55. *A. membranaceus*, Billard, l. e. 6. "Almost stemless; scape very long; heads globose; legumes woolly." Leaflets forty-three or fifty, ovate-oblong, emarginate, subulate; stipules ovate, lanceolate, shrivelling; flowers in a globose head, purplish, with lanceolate hairy bractes; legume subobtuse, acute, depressed at top, wrapped in leathery wood. 56. *A. lanatus*, Billard, l. e. 6. "Stemless, with a naked scape, the length of the leaf; legumes in close spikes, woolly, half-cordate, three-sided, subulate; leaves villose." Leaf radical; leaflets generally from eleven to twenty-three, ovate, tomentose, fleshy; flowers yellow, on a close spike, with filiform hairy bractes. This and the two preceding species are natives of mount Libanais.

57. *A. arvensis*, L. Trans. 1. 52. "Caulecent, procumbent; legumes suboblong, straight, smooth; leaflets obcordate, villose beneath." Allied to A. hamosus; but differs in having rounded leaves, more flowers on the spike, and especially in having flat pods, which are very short. Native country unknown. Cultivated in the Chelsea garden. 58. *A. diffusus*, L. Herit. Stirp. nov. 6. 167. "Subcaulecent, prostrate; scape twice as long as the leaf; legumes gaping, leaves petiolate, right angled." A. lians, Jacq. l. c. 153. Branches short, round; twigs villose; leaves fix inches long; leaves fifteen to twenty pairs, gradually smaller at the top, lanceolate, entire, acute, concave, villose, hirsute beneath; scape radical, foliary, naked, terminated in spikes crowded with purple flowers; bracte linear, acute, under each flower; legumes oblong, turged, having a groove on each side, villose, one-celled, one-valved. A native of the loftiest mountains of Siberia. 59. *A. metellus*, L. Herit. Stirp. nov. 6. 168. "Suffruticose, procumbent; stipules foliary, filiform-clasping, opposite to the leaves, bised." A native of Peru, where it was found by Dombey. 60. *A. varius*, L. Herit. l. c. 6. 169. "Caulecent, suffruticose, upright; flowers in loose spikes; legumes linear; stipules fuliginose downwards." A hoary little shrub, about a cubit in height; leaflets fix or even pairs, linear or narrow-lanceolate, sharp at both ends; stipules half filiform-clasping, two-parted, acute, spreading, and rolled back; spikes axillary, foliary, on peduncles longer than the leaves; flowers subhirsute, purple, with linear acute villose bractes; legume linear, round, villose. A native of Siberia. 61. *A. argyrotrichus*, L. Herit. l. c. 6. 170. "Suffruticose, prostrate; leaves hairy; petioles spinifuscis; calyces awned. It differs from the tragopanthes in having green leaves, and being smaller; the petals scarcely spinifuscis, and not very thin; the flowers purple; the calyceous teeth having long awns. A native of Switzerland and Provence. 62. *A. pajonensis*, L. Herit. l. c. 6. 170. Trig. orientalis, &c. Tourn. Cor. 30. Proceq. It. 5. 188. t. 88. "Sharply, procumbent; heads filiform-clasping, tomentose; pedicles and leaves pubescent and smooth." This is remarkable for the heads or balls of flowers, which are purple. A native of the Levant. 63. *A. echinosides*, L. Herit. l. c. to. critica, &c. Tourn. Cor. 29. The leaves are minute; the flowers small, white, with a purple line on the banner; peduncles axillary, short, two-flowered. A native of Crete or Candia.

**Proposition and Culture.** All the species may be raised.
from seeds. These should be sown in April on an open border of light earth; the annual sorts where they are to remain; the perennials to be transplanted to the places for which they are defined. They are in general hardy, and require no other care than to draw the plants where they come up too thick, leaving them a foot and a half or two feet asunder, and to keep them clear from weeds. Observe only that some (as n. 26. 35. 37.) require a shady situation and strong soil; others (as n. 6. 39.) an open situation and dry soil: n. 2. & 35. must be planted in a warm border: n. 7. 12. 36. must be raised on a moderate hot-bed, in the spring; and when the plants are fit to be removed, they should be each put into a small pot, filled with light earth, and plunged again into the hot-bed, feeding them from the fun, until they have taken root; after which they should have free air admitted to them daily, in proportion to the warmth of the weather, and should be frequently, but gently, watered. In May, they should be removed to a sheltered situation, and remain till October, when they ought to be placed under a common frame. In the spring they may be turned out of the pots, and planted in a warm border, where they will flower, and sometimes produce seeds. If the winter prove severe, a little old tan should be laid over the roots. The herbaceous sorts, when they are large enough, should be planted into pots, and placed in the shade till they have taken root; after which they are to be removed into an open situation, where they may remain to the end of October, and then placed under a common frame, well secured from the frost. Some of these plants may be set on a warm dry border. These plants may also be increased by slips, which, for want of seeds, is the method commonly used here. The best time for doing this is in April, just as the plants begin to shoot, at which time the tender branches should be clipped off, and the lower part be divided of decayed leaves; then they should be planted in a temperate hot-bed, which must be covered with mats to screen them from the heat of the sun by day, and the cold by night. These slips should be frequently gently watered, until they have taken root; after which they may be exposed to the open air; and, in very dry weather, refreshed with water. On this bed they may remain until the following spring, covering them with mats in very severe weather. In April they may be transplanted either into pots, filled with light sandy earth; or into warm borders, when, if the soil be dry, gravelly, or poor, they will endure almost the severest cold of our climate: but if they are planted in a rich soil, they often decay in winter. See Martyn's Miller's Dict. Astragalus. See Astystlismus, Biserrula, Cotularia, Glycine, Hedysarum, Indigofera, Orozus, Psaca.

Astragalus, from ofrorn, of the Greek oras, hlar, something belonging to the flars, or depending on the flars.

Astragalus, or dieral year. See Year.

Astrantia, in Botany (from στράγωσις, albaum, and ἀστρα, obvium, Lin.), muller-wort. Lin. gen. 327. Schreb. 459. Genn. 20. Clas, pentandra deginos. Nat. Order of umbellatae. Gen. Char. Cal, umbel universal, with very few rays (often three); partial, with very numerous ones; involucr universal, with leaflets doubled to the ray; partial, with leaflets about twenty, lanceolate, spreading, equal, coloured, longer than the umbellula; perianth proper, five-toothed, acute, erect, permanent. Cor. universal, uniform; florets of the ray abortive; proper, with petals five, erect, reflex, bifid. Stam., filaments five, simple, the length of the corolla; anthers simple. Pilt. germ oblong, inferior; styles two, erect, filiform; stigma simple, spreading. Per. fruit ovate, obtuse, crowned, twisted, bipartite. Seed, two, ovate-oblong, covered with the crust of the pericarp, wrinkled.

Ell. Gen. Char. Partial involucres lanceolate, spreading, equal, longer, coloured; flowers very many, abortive.

Species. 1. A. major, great mallet-wort, (2) A. nigra minor. "Leaves five-lobes; lobes trifid." Stem eighteen inches high, little branched; leaves thin, petioled, deeply five-cleft, lobes trifid, and sharply serrate; leaves of the involucr veincd; all the flowers are peduncled, and the peduncles are shorter than the involucr; the umbels are large, and the calyces awned; the involucr is either purple or white; hence Miller, following Tournefort, has made of this two species. A native of the south of Europe, flowering in August. Cultivated here by Gerard. 2. A. cornua, Jacq. Aug. 5. 34. "Leaves five or seven-lobed, simple or bifid." The whole plant is smooth. Stem round, erect, slender, from to fifteen inches high, with only one leaf on it; it is divided at top into trifid branches, in the form of an umbel; number of the umbels very variable; bracts small, ovate, concave, blunt, pale; leaflets of the universal involucr seiffle, acute, entire, or divided into two or three lobes; leaflets of the partial from to twelve, oblong, lanceolate, entire; male and female florets irregularly mixed; the former on longer peduncles; petals white, appearing heart-shaped, by being bent in at the tip. A native of Carniolas, flowering in July and August. 2. A. minor, little or Alpine mallet-wort. "Leaves digitate, serrate." It seldom attains a foot in height. Petioles four inches long; leaves divided into eight segments, deeply serrate; universal involucr composed of several very narrow leaflets; peduncles of the partial umbels very large, slender towards the top, often dividing into three, each having a small umbel, with small white involucres. A native of the Alpine valleys of Switzerland. Cultivated by Miller. 4. A. ciliaris. "Leaves lanceolate, ciliate-ciliata." A foot high, rough, erect, streaked, divided at top into a few flowering branches; radical leaves petioloed; stem-leaves four to five, fiddle; half stem clasping; umbel elongated, three-rayed; umbellules many rayed, very short; involucres two or three-leaved, remembring the leaves; involucres ten, leaves broad-lanceolate, acute, coloured. A native of the Cape of Good Hope. 5. A. Epipactis. Jacq. Augl. 5. 35. App. 1. 41. "Leaves five-parted, obtuse, serrate." Root black on the outside, producing one leaf and one scape; leaf shorter than the scape, three-parted, on a triangular petiole; scape smooth, angular, naked, one-flowered; involucres five-leaved; flowers in a head, yellow. A native of Iridia, Goriaza, and Hungary.

Propagation and Culture. These plants, except the fourth, are very hardy, and may be propagated either by fowling their seeds, or by parting their roots. If from seeds, they should be sown in autumn, on a shady border, and at Michaelmas they should be transplanted where they are to remain, observing to give them a moist and shady situation. Every third or fourth year they ought to be taken up at the end of October, and their roots parted and planted again. The fourth requires the protection of a dry robe in winter.

Astrarius, in Middle Age Writers, the same with manenvarii, those who live in the houle or family, at the time, for influence, when a person dies. Du-Cange.

These are also denominated ofrorn addidui, q. d. tied to the hearth.

Astrarius Hare, is used in our Old Writers, where the auxcellor, by conveyance, hath set his heir apparent, and his family, in a houle, in his life-time. Spelman carries the import of the word farther, as if it denoted
denoted an heir to whom the inheritance was given by his predececor in his own life, by a writing in form.

The word is formed from _aître_, an ancient French term for the heath of a chimney.

**ASTRASSUS, in Ancient Geography, a town of India, on this side of the Ganges. Ptolemy.**

**ASTRA, a land of the Arabian gulf, on the coast of Etiopia. Ptolemy.**

**ASTREA, in Entomology, a species of Phalena (Notica), of a brown colour both above and beneath; dull transparent; and thorax snow-white, dotted with black. This insect inhabits New Holland. Fabricius, &c.**

**ASTRICTOR, in Medicine, the term which, when it refers to theintestinal canal, denotes colliqueness; when it refers to the skin, denotes a want of perspiration. It is seldom used by modern physicians.**

**ASTRICKTOR Toga. See Toga.**

**ASTRILD, in Ornithology, a species of Liuxia that inhabits the Canary Islands and various parts of America and Africa. It is rather larger than the common wren, of a brown colour, undulated with blackish; bill, orbits of the eye, and breast scarlet. Gmel. &c. This is fringilla undulata, Pall. Senegallus fritiatus, Buff. Senegallus rubi, Buff. Was-bill of Edwards, and was-bill grosbeak of Lifatham.**

There are in particular two varieties that deserve attention; namely, the red-rumped grosbeak, and white-rumped grosbeak, (3) Senegallus pectoris expallido, urupugy, fackra rubra; and (γ) Senegallus corpore fusus ex rreo albo of Gmelin. Both of these are about the size of the former; the red-rumped kind has the breast and belly of a dirty white, and, besides the upper tail coverts being crimson, has a bar of the same colour across the vent. In some specimens, the under parts incline to yellow; the sides of the rump, and wing coverts spotted with white; and the bill bordered with black; one of this kind was brought by Somerat from the island of France. Buffon calls the red-rumped variety le feveran, and moineau du Senegal. The white-rumped kind also inhabits Senegal; the throat and sides of the neck are bluish white; the rest of the underparts and rump white, tinged with rofe colour; top of the head, neck, and back blue, palely on the head, and legs red. The colour of the legs distinctly marks this variety from the former, for in the frill-mentioned kind they are brown, and in the second dark grey.

**ASTRINGENS, escua martis. See Crocus.**

**ASTRINGENTS, in the Materia Medica. This term is applied to a class of substances which, according to Dr. Cullen's accurate definition, when applied to the human body, 'produce a contraction and condensation in the soft solids, and thereby increase their density and force of colliquation. If applied to longitudinal fibres, the contraction is made in the length of these; but if applied to circular fibres, they diminish the diameters of the vessels or cavities which the vessels surround.'**

Astringency in any fluid is most accurately detected by the taste, by corroborating the tongue, and giving a fermentation of harshness and roughness to the palate.

Astringents appear to act nearly in a similar manner on the simple or dead animal fibre as on the living solid, in either case thickening and hardening; when applied to the living solid, they produce increase of tone and strength, restrains inordinate actions, and check excessive discharges from any of the vessels or cavities; and to the dead fibre occasion that density, toughness, imperviousness to water in a greater or less degree, and insusceptibility to the common caules of putrefaction, in which consists the proof of TANNING, or preparation of leather.

No single chemical test (except the direct experiment on animal fibre) will always detect the property of astringency, as this is found to reside in many different classes of substances. Acids, especially the stronger mineral, are powerfully astringent; as also are several metallic salts, such as the solutions of iron, zinc, copper, and lead in various acids; likewise a few earthy salts, such as alum and fulminate, or sulphate of lime; also alcohol, or any kind of ardent spirit, the operation of which in hardening animal fibre is very remarkable. But the most numerous class of astringents are those taken from the vegetable kingdom, especially from the barks of several trees, and some of the natural gums resins. Modern chemistry has ascertained some highly important facts concerning the nature of the vegetable astringents, which should be noticed here in order to correct some erroneous opinions that are very prevalent in all medical writers. The property of fixing an indy blackness in solutions of iron, has been constantly given as one of the surest tellts of astringency in vegetables. Of this, the familiar instance of making common writing ink with an infusion of the oak gall-out, is known to everyone; but it should be remembered, that this property is owing to a peculiar acid, the Gallic; and not to the true astringent principle, in modern chemical language called TANNING, to which the acid of galls here happens to be united. Of this we shall treat fully, under these important articles, but the pharmaceutical chemist should now be aware, that the test of blackness with iron is by no means a sole indication of astringency, but only a probable presumption of its presence. Thus one of the strongest of the known astringents, the terra japonica, or catechu, will not give the smallest degree of blackness to solutions of iron, as it contains only tannin, the true astringent principle; and not the Gallic acid. The proper test for this substance, besides the effect on the tongue, is a solution of any kind of animal gelly; of which more hereafter.

When the true astringent principle is naturally mixed with any acid, the tafe of astringens is given, in which the corrigation of the papilla of the tongue is most peculiarly remarkable. The juices of several umrse fruits, the gall-out, and many of those astringents that contain much gallic acid, and give a strong black with iron, are examples of this.

Tannin is itself somewhat bitter, and appears to be also united, in many cases, with some principle which gives it more than its usual bitterness. This is probably the case with most of the astringent bitters employed in medicine, and it is in this combination that astringents obtain their astringent property. In some instances the tannin is united with a sweet substance, as in the examples of the catechu, and the lignum campecheu.

Astringents when employed externally to stop hemorrhage, are then termed STYPTICS.

Astringents are very largely used in medicine, and with the highest advantage. The cases where they are most unequivocally beneficial, and in which the operation may be ascribed purely to the astringent property, are diarrhoea, eratic evacuations from the intestinal canal. They have also been long thought of use in retaining discharges of different kinds, even when not directly applied to the part, so that astringent medicines are frequently given by the stomach, in order to check profuse fluid losses, gleet, and sometimes hemoptysis. Their operation in such cases, however, is much more questionable, and the benefit here produced, perhaps, may with more propriety be ascribed to a tonic or limulant property.

**ASTROBOLI, in Ancient Geography, a people of Asia, near the Indus. Arrian.**

**ASTROBOLISM,**
ASTROBOLISM, derived from &ep;&z, &z, and Ş2222, &f+22, the name with &f&u;clus; though properly applied to plants which are destroyed in the dog-days, as if blighted by that star.

ASTRODICTICUM, an astronomical instrument invented by M. Weighelius, by means of which many perfections shall be able at the same time to behold the same star.

ASTROGNOSTIA, from &ep;&z, &z, and 522222, I know, the art of knowing the fixed stars, their names, ranks, situations in the constellations, and the like.

ASTROITES, in Natural History, a species of Malacora found in the seas of South America. The stars are numerous,immered, and have the disk conico-cylindrical. This is madeporata (radish) aggregated solidly, tellis confertis convexinclusus, centri poro radiante, flavus fructifuscus of Pallas; and after apertus cavernarum minimis in-

equali of Brown’s Nat. Hist. Jam. It is found in large

maffes; and is of a whitish colour. The interlaces are

porous.

ASTROLABE, derived from &ep;&z, &z, and &z2222, I take, alluding to its use in observing the stars; and the Arabs called Aftfahr-lab, formed by corruption from the common Greek name; was originally used for a syltem or assemblage of the several circles of the sphere, in their proper order and situation with respect to each other; and the ancient astrologers appear to have been much the same with our armillary spheres.

The first and most celebrated of this kind was that of Hipparchus, which he made at Alexandria, the capital of Egypt, and lodged in a secure place, where it served for divers astronomical operations. Poolemy made the same use of it; but as the instrument had several inconveniences, he contrived to change its figure, though perfectly natural, and agreeable to the doctrine of the sphere; and to reduce the whole astrolobe upon a plain surface, to which he gave the denomination of the planisphere.—Hence

Astrolabe is used among the moderns for a planisphere; or a stereographic projection of the circles of the sphere upon the plane of some great circle thereof.

The usual planes of projection are that of the equinoctial, the eye being supposed in the pole of the world; that of the meridians, the eye being supposted in the point of intersection of the equinoctial and horizon; and that of the horizon.

Stobler, Gemma Frisius, and Clavius, have treated at large of the astrolobe.—For a farther account of the nature and kinds thereof, see Planisphere.

Astrole, or Sea Astrolobe, more particularly denotes an instrument chiefly used for taking the altitude of the pole, the sun, or stars, at sea.

The common astrolobe, represented Plate Navigation, fig. 1, consists of a large brass ring about fifteen inches in diameter, whose limb, or a convenient part thereof, is divided into degrees and minutes; fitted with a moveable index or label, which turns upon the centre, and carries two lights.—At the zenith is a ring A, to hang it by, in time of observation.

To use the astrolobe, turn it so to the sun as that the rays may pass freely through both the lights F and G, in which case the edge of the label cuts the altitude in the divided limb.

The astrolobe, though now disused, is esteemed by many equal to any of the other instruments used for taking the altitude of M, especially between the tropics, when the sun comes near the zenith.—There are a great many other uses of the astrolobe: on which Clavius, Horion, &c. have written entire volumes.

ASTROLOGICAL Note. See Fate.

ASTROLOGICAL, in botany, the French name of the species of Uranoscopus called japonicus by Gmelin, from its inhabiting the seas about Japan.

ASTROLOGY, the art of foretelling future events, from the aspects, positions, and influences of the heavenly bodies.

The word is compounded of &ep;&z, &z, and &z, differens, whence, in the literal sense of the term, astrology should signify no more than the doctrine or science of the stars; which, indeed, was its original acceptance, and formed the ancient astrology: though, in course of time, an attention has arisen, that which the ancients called astrology, being afterwards termed Astronomy.

Astronomy may be divided into two branches, natural and judicial.

To the former belongs the predicting of natural effects; as, the changes of weather, winds, storms, hurricanes, thunder, floods, earthquakes, &c. This art properly belongs to Physiology, or natural philosophy; and is only to be deduced à priori, from phenomena and observations. Its foundation and merits the reader may gather from what we have laid under Air, Atmosphere, and Weather. For this astrology, Mr. Boyle makes an apology, in his History of the Air.

ASTROLOGY, Judicial or Judicial, which is what we commonly call simple astrology, that which pretends to foretell moral events; i.e. such as have a dependence on the free will and agency of man; as if they were directed by the stars.

This art, which owes its origin to the practice of knavery and credit, and which the celebrated Mr. Briggs denominated a mere syltem of groundless conceits (Ward’s Lives, p. 125), is now universally exploded by the intelligent part of mankind. There was a time, however, when this science, frivolous and ridiculous as it may be juftly denominated, furnished very powerful incentives to the study of astronomy. Without some knowledge of the motions and aspects of the stars, the astrologers would have been unable to draw their horoscopes, and of course to read the fates of men in the face of the heavens. Accordingly, Kepler observes (Pref. ad Rudolph, Tab. p. 4), “that astrology is the foolish daughter of a wise mother, and that, for 100 years past, this wise mother could not have lived without the help of her foolish daughter.” “I repeat bitterly,” says Kepler, “having so much decribed astrology,” and he conceived that the study of astronomy had been greatly neglected, even since men ceased to apply themselves to astrology. Of the origin of this absurd and unfounded science, whatever might be the relative estimation in which it was held, it is not difficult to give a plausible account. When heroes, and persons who by extraordinary services had rendered their names venerable and immortal, received divinemonstrations, come particular celestial bodies, of which the sun, moon, and other planets seemed to be the most suitable, were alligned to these divinities; and after this appropration, folly, which never flows where it begins, proceeded still farther, and ascribed to them the attributes and powers for which the deities, after whom they were named, had been celebrated in the fictions of the mythologists. This, in course of time, laid the foundation of astrology; and hence the planets, Mars, for influence, like the deity of that name, was laid to cause and to be fond of war, and Venus to prelude over love and its pleasures.

The preludies of this kind of astrology maintain, “That the heavens are one great volume or book, wherein God has written the history of the world; and in which every man may read his own fortune, and the transmutations of his time.

—the art, they say, had its rise from the same hands as astronomy.
astronomy itself: while the ancient Assyrians, whose serene uncouthed by favoured their celestial observations, were intent on tracing the paths and periods of the heavenly bodies, they discovered a constant settled relation of analogy between them and things below; and hence were led to conclude thence to be the Putes, the Delphies, so much talked of, which preside at our births, and dispose of our future fate.

"The laws therefore of this relation being ascertained, by a series of observations, and the starry each planet has therem, by knowing the precise time of any person's nativity, they were enabled, from their knowledge in astronomy, to erect a scheme or horoscope of the situation of the planets, at that point of time; and hence by considering their degrees of power and influence, and how each was either strengthened or tempered by some other, to compute what must be the result thereof."

Judicial astrology is commonly said to have been invented in Chaldea, and thence transmitted to the Egyptians, Greeks, and Romans; though none will have it of Egyptian origin, and ascribe the invention to Cham. But it is to the Arabs that we owe it. Of the first invention of a fanciful delineation which very generally prevailed, it is not very easy to ascertain the original inventors. The principles on which it was founded, were very extensive in their dissemination.

The Chaldeans and the Egyptians, and indeed almost all the nations of antiquity, were initiated with the charms of astrology. That of the Chaldeans originated in the notion, that the stars have an influence, either beneficial or malignant, upon the affairs of men, which may be discovered, and made the ground of certain predictions, in particular cases: and the whole art consisted in applying astronomical observations to this fanciful purpose, and by such means imposing upon the credulity of the vulgar. The Egyptian priests would not neglect the cultivation of an art, which together with that of magic, would give them such an irresistible sway over an ignorant and superstitious populace.

Diodorus Siculus (i.e. p. 51.) relates, that the Chaldeans learned these arts from the Egyptians; and he would not have made this assertion, if there had not been at least a general tradition that they were practised from the earliest times in Egypt. Among the Arabians, and in the eastern courts, the truths of science could be recommended only by ignorance and folly, and the astronomer would have been disregarded, had he not debated his horoscopes by the vain predictions of astrology. The truth of this art was allowed by Altabitar (see Altabitar), and the belt of the Arabian astronomers, who drew most of their predictions, not from Venus and Mercury, but from Jupiter and the sun. Abulpharag. Dyn. B. p. 161 - 162.

At Rome, the people were so infatuated with this art, that the astrologers, or, as they were then called, the mathematicians, maintained their ground in spite of all the edicts of the emperors to expel them from the city. Tiberius (A. D. 4.) founded his hopes of the empire to which he aspired, on the predictions of Thrafiyus, who had been with him during his abode at Rhodes. However he would not repose any confidence in his art till he had put him to a trial in which several had miscarried and fallen victims. Accordingly, one of his freedmen conducted the astrologer through deep and difficult paths to a centre-box fixed on the top of a house, erected on a deep rock close to the sea. If Tiberius suspected fraud or falsity in the predictions of those who practised the art, they were thrown into the sea that beat against the rock on which this house of trial stood. Thrafiyus was conducted to this place, and had the good fortune to please Tiberius, by promising him the empire, and by the ingenious turn he gave to every thing he said. Tiberius liked him, whether he could draw his own horoscope, and whether by comparing the time of his birth with the present state of the heavens, he could tell what he was to dread or hope for at that infant. The astrologer, without doubt apprized of the fate of his predecessor, looked at the stars and shuddered; the more he considered them the more he trembled; and at length exclaimed that he was threatened with great and imminent danger. Tiberius, convinced of his skill by this experiment, embraced him and admitted him into the number of his confidential friends. His answers, when he was consulted, Tiberius regarded as oracular; and he determined to learn the science himself. At Rhodes he had left to receive lessons from Thrafiyus, and profited by them to such a degree, that he had the honour in a credulous age of having delivered predictions that were verified by the event. Augustus, however (A. D. 11.), revived the ancient law against astrologers; and to express his contempt for their pretended skill, and to show how much he disregarded any of their predictions, he published and posted up at Rome the theme of his own nativity, or a date of the position of the stars at the instant of his birth. In the year 16, the old ordinances against astrologers were again revived; two of them were capital punished, and the rest banished from Italy. But Tiberius, who believed in astrology, and frequently recourse to it, prevented the rigorous execution of the decree; and those who preferred to renounce their art were permitted to stay at Rome. The old laws against astrologers were again enforced in the year 52, and the Senate passed a very severe decree against them; but these menures were ineffectual to their suppression. In the year 69, Vitellius, though he inclined to credit their predictions, slew an edict against them, commanding them to leave Italy within a limited time: but so great was their confidence at this time in their own security, that they polled up a placard against his order, and commanded the emperor to leave the world before the day appointed for their banishment. The emperor Domitian, though he firmly believed in their delusive arts, passed an edict by which they were all banished from Rome. His credulity proved an occasion of effecting terror to him towards the close of his reign, for an astrologer, called Alchitaris, is said to have predicted the day and manner of his death. The emperor Adrian was very much addicted to both astrology and divination; and thus, occasionally protected and encouraged, and sometimes professed and banished them. The astrologers maintained their influence at Rome to the time of S. Augustin, for the subject of one of his homilies (in P. L. p. 32. ed. Fraden. 1556) is the reconciliation of one of these pretended mathematicians with the church. See Genetetic.

"Tu ut queritor (forsa) quae mihi, quae tibi
Finem Dii dediscat, Leneo! nee Babylonia
Tentator numine: ut mali, quodque erit: paci."

"Ask not: 'tis in fusions to inquire: what date
The limit of your life is fixed by fate;
Nor vainly Babylonian numbers try,
But wisely wait your lot, to live or die.'"

The Bramins, who introduced and practiced this art among the Indians, have hereby made themselves the authors.
A S T

ters of good and evil hours, which gives them great authority; they are consulted as oracles; and they have taken care never to tell their answers but at good rates.

The same superstition has prevailed in more modern ages and nations. The French historians remark, that in the time of queen Catherine de Medicis, astrology was in so much vogue, that the most inconsiderable thing was not to be done without consulting the stars. And in the reigns of king Henry III. and IV. of France, the predictions of astrologers were the common theme of the court conversation.

This predominant humour in that court was well rallied by Barclay, in his "Argenis, lib. ii. on occasion of an astrologer, who had undertaken to instruct king Henry in the event of a war then threatened by the faction of the Guises.

Judicious astrology still retains its credit in the eal, and pretenders are always found ready to take advantage of the popular credulity. Some of the grandeurs retain an astrologer among their dependents, and their learned men do not appear to dispute the truth of their science, though the chief dupes of the imposture are found among the populace.

The astrologers pretend to foretell future events from inspection of the horoscope, and to predict wars, pestilence, and other public calamities; but they are, in general, very superficially acquainted with the principles of the science which they profess.

ASTROLOGUS, in Natural History, a name given by authors to a white and splendid flame, small in size, and of a roundish figure, resembling the eyes of fishes.

ASTROMETEREOLOGIA, the art of foretelling the weather and its changes, from the aspects and configurations of the moon and planets.

This makes a species of astrology, distinguished by some under the denomination of meteorological astrology.

ASTRON, in Ancient Geography, a river of Alba Minor, in the Treade, Pliny.

ASTRONIUM, in Botany (αστρονιομα). Jacq. Amer. 241. Lim. 1111. Schreb. 1515. Juss. 427. Cala, discsh praevio praevio. Generic Char. Male. Cala, prahy five-leaved, coloured, small; leaflets ovate, concave, obtuse, spreading. Cor. petals five, ovate, very obtuse, flat, spreading very much; nectary five, rounded, very small glands in the disk of the flower. Stam. filaments five, fubulate, spreading, the length of the corolla; anthers oblong, incumbent. Female. Cala, prahy five-leaved, coloured; leaflets oblong, concave, obtuse, converging. Cor. petals five, sub-ovate, obtuse, concave, erect, less than the calyx, permanent. Pfl. germ ovate, obtuse; styles three, short, reflex; stigmas subcapitate. Per. none. Calyx incerated, coloured; its leaflets at first expanded into a pendulous star, at length dropping the seed. Seed, one, oval, the length of the calyx, lacinete.

Species, A. gravolet. A tree from twelve to thirty feet in height, abounding with a terebinthine juice. The leaves are unequally pinnate, with three pairs of leaflets, which are oblong, obtuse, acuminate, smooth, veined, three inches in length; panicles lax, half a foot long in the females; flowers small, red. A native of the woods about Carthage in New Spain, flourishing in May and June.

ASTRONOMICAL, something that relates to astronomy.

ASTRONOMICAL Calendar, Characters, Column, Horizon, Hours, Month, Quadrant, Ring-Dial, Sector, Tables, Telcope, Time, Year. See the several substantives.
there was a golden circle of 365 cubits in circumference, and one cubic thick, divided into 365 equal parts, according to the days of the year, and containing the heliacal risings and settings of the stars for each day, &c. See Heliacal.

It is evident, indeed, without placing much reliance upon their accounts, that both Chaldæans and Egyptians were countries extremely proper for astronomical observations, being almost constantly favoured with a pure atmosphere and a serene sky; and whatever may be thought of the tower of Babel, or the circle of Oysmandias, we cannot but form a very advantageous opinion of the knowledge of the Egyptians in practical astronomy, from the position which they have given to their pyramids, whose faces are directed with great precision towards the four cardinal points of the compass. For as it is scarcely possible that a situation so exact could have been the effect of chance, we must conclude that they were acquainted with a correct method of drawing a meridian line; which is a matter of more difficulty than is usually thought; it being well known that Tycho Brahe, the most able astronomer of his time, committed an error of several minutes in tracing that of his observatory of Uraniborg. See Meridian.

The Chaldæans also must have made very considerable advances in this science, if we can rely upon the testimony of Simplicius, who informs us that, at the taking of Babylon by Alexander the Great, they cited a regular series of astronomical observations for 1063 years back; and that these, through the means of Callisthenes, were afterwards communicated to the Greeks by Aristotle. But it is much to be wished that the truth of these ancient observations was better established, particularly as their historian Berosus, who appears to have lived but a little before the time of Alexander, makes no mention of any astronomical monument of this people, which was more than about 480 years anterior to that period. And, indeed, the most ancient Chaldæan observations, of which any mention is made by astronomical writers, are those of three eclipses of the moon, employed by Ptolemy in his Almagest, which were made in the years 27 and 28 of the era of Nabonassar, or 721 and 720 years before Christ.

But though Ptolemy, and perhaps Hipparchus, from whom he had probably taken them, made no use of any observations more ancient than those here mentioned, we cannot from thence conclude that the Chaldæans first began to follow the celestial motions at this period. For such as were made in much earlier times might be suspected on several accounts; and it is besides highly probable that most of those which preceded the era of Nabonassar were not accompanied with dates sufficiently accurate to be employed by these astronomers. The Babylonian calendar, before this era, was in great confusion, not having been properly regulated; and it is obvious that ancient observations, either of this or any similar kind, can be but of little use, except we are able to ascertain the precise time at which they were made.

Besides these eclipses mentioned by Ptolemy, nothing more now remains of the Chaldæan astronomy, except what is attributed to them by some ancient authors, with respect to certain periods of years, which they appear to have formed for the more ready computation of the places of the heavenly bodies. And though the accounts which have been given as to one of the most remarkable of these cycles, by Susids and Pliny, are not wholly free from objections, there can be little doubt of its having been first invented by that people. This is the celebrated period called the Chaldæan Saros, which consists of 223 lunar months, or a little more than 28½ years; and which so far agrees with the combined motions of the sun and moon, as always to bring them again into nearly the same position at the end of each cycle that they had at its commencement.

Both the Chaldæans and Egyptians, indeed, were generally supposed to have possessed a very considerable knowledge of several other branches of this science, besides those mentioned; but for want of proper authorities, this can only be judged of by the results of their more judicious observations, which appear to have had of the system of the world, and by the agreement which has been found among several ancient measures of the circumference of the earth. The Egyptians, in particular, appear to have given a long before the Christian era, that the year consisted of 365 days, and that the planets Mercury and Venus moved round the sun. We are also well assured of the great antiquity of the science among this people, from the recent discoveries which have been made in that country during the late war; and particularly from the figure of a zodiac brought from thence by the French, which Lalande considers as extremely ancient.

But among the various nations which claim the honour of having first cultivated this science, none pretend to possess observations of greater antiquity than the Chinees. The most remarkable of these is a conjunction of five of the planets, which, according to their annals, is said to have taken place in the reign of their emperor Tshihuen-hin, about 2500 years before Christ. They also mention an eclipse of the sun, which happened in the constellation Scorpio, about the year 2150 of the same era; and which is said to have proved fatal to two Chinees astronomers of the names of Ho and Hi, who were condemned to death by the emperor Tchong-kang, on account of their omitting, through negligence and intoxication, to announce the precise time at which it arrived. And from these data, apparently well settled, several eminent astronomers have endeavoured to discover whether these events could have possibly happened about the time here mentioned; but the subject is attended with too many difficulties to afford any satisfactory result.

All that we know of the Chinees astronomy is from the accounts which have been given of it by the Jesuit missionaries, who are much divided in their opinions with respect to its very great antiquity; some supposing it to have flourished at a more earlier period than others. F. Du Halde, however, affirms, that it was cultivated by their great lawgiver Confucius; and that Tchou Kong, the most diligent astronomer that China ever produced, lived more than 1000 years before Christ, and passed whole nights in observing the heliacal bodies, and arranging them into constellations. But whatever might have been the knowledge of this people in former times, the state of astronomy is very low in that country at present, although it is cultivated at Peking by public authority, in the same manner as in most of the capital cities of Europe.

The inhabitants of Japan, Siam, and the Mogul empire, also appear to have been acquainted with astronomy from time immemorial; and the famous observatory at Benares (Ice Observatorio) is a monument both of the great ingenuity of the Indians, and of their skill in that science. A knowledge of this subject is also supposed to have prevailed among the Americans; though, in their divisions of time, they made use of the solar and not of the lunar motions. The Mexicoes, in particular, are said to have discovered a singular prediction for the number 12, which they used as a kind of cycle or period of their computations. And the abbe Clavigero asserts it as a remarkable fact, that having discovered the effects of a few hours in the solar above the lunar year, they made use of intercalary days to bring it to an equality, as was done by Julius Caes
Cæsar in the Roman calendar; but with this difference, that, instead of one day every four years, they interposed 13 days every 52 years, which produces the same effect.

But the most interesting account of the rise and progress of this science hitherto given, is that which is detailed by M. Bailly, in his learned and elaborate history of Ancient and Modern Astronomy; in which he endeavours to trace its origins among the Chaldeans, Egyptians, Persians, Indians, and Chineses, to a very early period. And in consequence of the reference he has made on this subject, he is led to maintain, that the knowledge common to the whole of those nations, has been derived from the same original source: namely, a small ancient and highly-cultivated people of Asia, whose memory every trace is now extinct: but who have been the parent-instructors of all around them.

M. Bailly does not pretend to fix, with certainty, the precise situation of this ancient people; but he offers several reasons for conjecturing that it must have been somewhere about the 49th or 55th degree of north latitude, in the southern regions of Siberia. Among various other coincidences, he observes, that many of the European and Asiatic nations attribute their origin to that quarter, where the civil and religious rites, common to each, were probably first formed; and what he considers as a strong astronomical support of his hypothesis is, that the observations of the stars, collected by Ptolemy, must have been made in a climate where the longest day was 16 hours, which corresponds to the latitude here mentioned. But as that region exhibits no traces of its ever having been inhabited by a polished people, his theory, though highly ingenious, has not sufficient force to draw our assent to his conclusions.

In investigating the antiquity and progress of astronomy among the Indians, M. Bailly examines and compares four different sets of astronomical tables of the Indian philosophers, viz. that of the Sianeme, explained by M. Caffini, in 1689; that brought from India by M. le Gentil of the Academy of Sciences; and two other manuscript tables found among the papers of the late M. de Lille; which, he observes, accord together, and all refer to the meridian of Benares. From these tables it appears, that the Indian astronomy has two principal epochs, the first being founded on a conjunction of the sun, moon and planets, which is said to have taken place 3102 years before Christ; and the other 1491 years before the same era. These periods are connected by the mean motions of the sun, moon and planets, that one of them must necessarily be fictitious; and though the celebrated author above mentioned, has endeavoured to shew that the first of them must have been founded on observations, there is great reason for believing that it was rather imagined for the purpose of giving a common origin to the signs of the zodiac, and the motions of the celestial bodies.

It is true indeed, if, parting from the epoch 1491, we ascend, by means of the Indian tables to the year 3102, before the Christian era, we shall find a general conjunction of the sun, moon, and planets, as these tables suppose; but this conjunction, which is too different from the result given by the best modern tables to have ever taken place, shews that the epoch to which they refer, is not founded upon observations; and, in fact, some elements of the Indian astronomy, seem to indicate that they were determined even long before this first epoch. The equation of the sun's centre, in particular, which they fix at 2° 10' 32", could not, according to the calculations of M. Laplace, have been of this magnitude but near the year 4500 before Christ; and besides this, the equations of the centre of Jupiter and Mars are so different from what they ought to have been at this epoch, that nothing can be concluded from them in favour of their high antiquity.

To conclude, the whole of these tables, and, above all, the conjunction which they suppose at the same epoch, prove, on the contrary, that they must have been constructed, or at least rectified, in much more modern times. The ancient reputation, however, of the Indians, both in this and other sciences, leaves but little doubt, that astronomy was cultivated among them at a very remote period; and of this, the remarkable accuracy with which they have assigned the mean motions of the sun and moon, are sufficient proofs, as such exactitude could only have been obtained from a long series of observations. This opinion has also been ably supported by Mr. Playfair, in a dissertation on the astronomy of the Brames, published in the second volume of the transactions of the Royal Society of Edinburgh, where he has, likewise, adduced many instances of their critical knowledge in the other mathematical sciences, employed in their precepts and calculations.

The Greeks did not begin to cultivate astronomy till a long time after the Egyptians, of whom they were the disciples; and it is extremely difficult, amidst the fables which so much abounded in the earlier periods of their history, to obtain any very correct information with respect to their knowledge in this science. All that we can learn is, that they had made observations on the celestial bodies, and divided the heavens into constellations, 13 or 14 centuries before the Christian era: this being the period, according to the opinion of the most eminent chronologers, to which we must refer the sphere of Eudoxus.

The number of their philosophical institutions, however, afford no observer of any note, till much later times; most of their ancient sects having treated astronomy as a science purely speculative, without properly attending either to facts, or their causes. But notwithstanding the revires in which they often indulged, their knowledge began to be greatly improved by Thales the Milesian, and other Greeks who travelled into Egypt, and brought from thence the chief principles of the science. This philosopher, who died at the age of 96 in the year 548 before Christ, was the founder of the Ionian sect, and appears to have been the first who taught his countrymen the globular figure of the earth, the obliquity of the ecliptic, and the causes of solar and lunar eclipses; which latter phenomena he is also said to have been able to predict.

Thales had for his successors Anaximander, Anaximenes, and Anaxagoras, to the first of whom is attributed the invention of the gnomon, and geographical charts; but for which he was probably indebted to the Egyptians. He is also said to have maintained that the sun was a mass of fire as large as the earth, which, though far below the truth with respect to size, was an opinion, for those early times, that does its author much credit; though to him, as in the case of Galileo, the truths he had discovered were the cause of his persecution. Both himself and his children were proscribed by the Athenians, for his attempting to subject the works of the gods to immutable laws; and his life would have paid the sacrifice of his temerity, but for the care of Pericles, his friend and disciple, who got his sentence of death changed into exile.

Next after the Ionian school was that of Pythagoras, who was born at Samos, about the year 576 before the Christian era, and who, in the celebrity he acquired, far exceeded his predecessors. Like Thales he visited Egypt, and afterwards the Brahmins of India, from whom he is supposed to have obtained many of the astronomical truths which
which he brought with him into Italy, to which country he was obliged to retire on account of the despotism which then prevailed at Athens. Here he first taught the true system of the world, which, in many centuries after, was revised by Copernicus; but hid his doctrines from the vulgar, in imitation of the Egyptian priests who had been his instructors. It was even thought, in this school, that the planets were inhabited bodies, like the earth; and that the stars, which are differentiated through infinite space, are suns, and the centres of other planetary systems. They also considered the comets as permanent bodies, moving round the sun, and not as perishing meteors, formed in the atmosphere, as they were thought to be in after times.

From this time to the foundation of the school of Alexandria, the history of astronomy among the Greeks offers nothing remarkable, except some attempts of Eudoxus to explain the celestial phenomena; and the celebrated cycle of 19 years, which had been imagined by Meton, in order to conciliate the solar and lunar motions. This is the most accurate period, for a short interval of time, that could have been devised for embracing an exact number of revolutions of these two luminaries; and is so simple and useful, that, when Meton proposed it to the Greeks, assembled at the Olympic games, as the halls of their calendar, it was received with great approbation, and unanimously adopted by all their colonies.

In the school of Alexandria, we see, for the first time, a combined system of observations, made with instruments proper for measuring angles, and calculated trigonometrically. Astronomy, accordingly, took a new form, which succeeding ages have only brought to greater perfection. The position of the stars began at this time to be determined; they traced the course of the planets with greater care; and the inequalities of the solar and lunar motions became better known. It was, in short, in this celebrated school, that a new system of astronomy arose, which embraced the whole of the celestial motions; and though inferior to that of Pythagoras, and even fallacious in theory, it afforded the means, by the numerous observations which it furnished, of detecting its own fallacy, and of enabling astronomers in later times to discover the true system of nature.

Arlyphilus and Timochares were the first observers in this rising institution. They flourished about the year 290 before Christ; and by their arduous labours, were the means of greatly improving this science. It was from their observations of the principal zodiacal stars, that Hipparchus was led to discover the precession of the equinoxes; and Ptolemy also founded upon them his theory of the motions of the planets.

Next after these, was Aristarchus of Samos, who made the most delicate elements of the science the objects of his research. Among other things of this kind, he attempted to determine the magnitude and distance of the sun; and though, as may be supposed, the results he obtained were considerably wide of the truth, the methods he employed to resolve these difficult problems, do great honour to his genius. He also endeavoured to revive the opinion of the Pythagorean school, with respect to the motion of the earth; but as his writings upon this subject have not been preserved, we are ignorant of what point he had advanced, by this means, in his elucidation of the celestial phenomena.

The celebrity of his successor Eratosthenes, arises chiefly from his attempt to measure the earth, and his observations on the obliquity of the ecliptic. Having remarked at Syene, a well which was enlightened on the bottom by the fun, on the day of the summer solstice, he observed the meridian height of the sun on the same day at Alexandria; and found that the celestial arc, contained between the two places, was the 50th part of the whole circumference; and as their distance was estimated at 500 miles, he fixed the length of a great circle of the earth at 25,000; but as the length of the radius employed by this astronomer is not known, we cannot appreciate the exactness of his measurement.

Among others who cultivated and improved this science, we may also mention the celebrated Archimedes, who constructed a kind of planetarium or orrery, for representing the principal phenomena of the heavenly bodies. But of all the astronomers of antiquity, Hipparchus of Byzantium is the one, who, by the number and precision of his observations, as well as by the important results which he derived from them, is the most entitled to our esteem. He flourished at Alexandria about the year 162 before the Christian era; and began his astronomical labours by attempting to determine, with more exactness than had hitherto been done, the length of the tropical year, which he fixed at 365 days, 5 hours, and 32 minutes, being near 24 hours too great. Like most of his predecessors, he founded his system upon a uniform circular motion of the sun; but instead of placing the earth in the centre of the solar orbit, he removed it to the distance of 4/13 part of the radius; and fixed the apogee to the sixth degree of Gemini. By means of these data, he formed the first solar tables of which any mention is made in the history of astronomy; and though defective and even erroneous in principle, they are a durable monument of his genius, which three centuries afterwards were respected by Ptolemy, without his preceding to alter them.

The great astronomer next considered the motions of the moon, and endeavoured to measure the exact time of her revolution, by a comparison of ancient eclipses. He also determined the eccentricity and inclination of her orbit, as well as the motion of her nodes and apogee; and calculated all the eclipses that were to happen for 500 years. We are, besides, indebted to him for the important discovery of the precession of the equinoxes (see Perceptions), which was the fruit of the long and difficult enterprise he undertook of making a catalogue of the fixed stars, with their latitudes, longitudes, and apparent magnitudes.

Geography is also indebted to Hipparchus for the method of fixing the situation of places upon the earth, by means of their latitude and longitude; in obtaining the latter of which, he appears to have been the first who employed eclipses of the moon; and as these researches required numerous calculations, they gave birth, under his hands, to spherical trigonometry. Many of his principal works perished with the library of Alexandria; but his catalogue of the stars, and several of his observations, have been preserved by Ptolemy in his Almagest.

Between the time of Hipparchus and Ptolemy, the chief observers of any note are Agrrippa, Menelaus, and Theon; the two latter of which are better known as geometricians than astronomers. We remark, however, in this interval, the reformation of the calendar by Julius Caesar, and a more exact knowledge of the flux and reflux of the ocean (see Tides). Ptolemaeus, a celebrated Greek philosopher, who lived about eighty years before Christ, appears to have been the first who observed the relation of these phenomena with the motions of the moon; and of which Piny, the naturalist, has given a description, remarkable for its accuracy.

Ptolemy, the worthy successor of Hipparchus, was born...
AST

at Pelusium in Egypt, in the beginning of the second century of Christ, and was the first who undertook to
refrain the whole of this science, by establishing it upon a
new foundation. In this enterprise, the system he formed
is now well known to be erroneous; but the edifice he
erected lasted near 1400 years; and even at this time,
though it is entirely destroyed, his Almagest, considered
as the depository of ancient observations, is one of the most
precious monuments of antiquity. See ALMAGEST.

One of the most important discoveries of this astronomer
is that of the ejection of the moon (see EJECTION), which
he has affixed with so much exactness, that M. Le Place,
in opposition to the opinion of other writers, thinks it
sufficient to entitle him to the character of an accurate
observer; and that the charge which has been made against
him, of appropriating the discoveries of his predecessors,
is not well founded.

It may also be remarked, that Ptolemy has rendered great
services to geography, by collecting all the determinations
of the latitudes and longitudes of places then known; and
by his laying the foundation of the method of projections,
for the construction of geographical charts, which was but
little known before his time. In short, the various works
which he executed, upon a variety of subjects, are strong
proofs of a great and enlightened mind, and will always
inure to him a distinguished rank in the history of the sciences.

With the labours of this great astronomer ended the
splendour of the Alexandrian school, which had now subsisted
for more than five centuries, with as much credit to itself
as advantage to the sciences; but the successors of Hipparchus
and Ptolemy, contented themselves with commenting
on their works, without adding anything remarkable to their
discoveries. The knowledge of nature, which had hitherto
been cultivated with so much success, gave way to the
defloration of the Saracens, who were led by a
ferocious zeal to destroy the celebrated library of Alexandria,
which contained so many treasures of learning and genius.

By a singular turn, however, of human affairs, this people
became afterwards the protectors and cultivators of literature
and science, and were then fertile, that this frantic measure
had deprived them of the most precious fruits of their
victories.

The caliph Almanar first introduced a table for the
determination of the eclipses into his empire; and his grandsons, Almanon, who
successively reigned on his throne, rendered very important
improvements in astronomy. Having constructed proper instruments,
he made many accurate observations; and, among others,
determined the obliquity of the ecliptic to be 23°
35'. Under his auspices also, a degree of the meridian was
measured, a second time, in the plains of Singar, on the
shores of the Red Sea. About the same time, or at a somewhat
later period, Alfraganus likewise wrote a treatise on
astronomy; and hence the science began to be greatly cultivated
by the Arabsians; particularly by Alhazen, who gave
a new and improved theory of the sun, from which he derived
results that are much valued for their accuracy; and above all,
asserted directly the diminution of the eccentricity of the
ecliptic, as since demonstrated by the theory of gravity,
and by the secular equation of the moon. His work, intitled "The Science of the Stars," is still extant, and was
long esteemed by the Arabsians. But after his death,
when the Saracens had made many eminent astronomers, several centuries elapsing without producing any very valuable observations, excepting those of some eclipses, observed by Ibn Jum, astronomer to the caliph of Egypt, which serve to
shew the acceleration of the mean motion of the moon.

The Persians, who for a long time were of the same reli-
gion, and subjected to the same sovereigns with the Arabs,
began about the middle of the eleventh century, to throw
off the yoke of the caliphs; and at this period, their calendar
received, by the care of their astronomer, Omar Cheyam,
a new form, founded upon an ingenious intercalation, which
continued in making eight bissare years at the end of every
thirty-three common years. See BISSEXTILE. About the
same time, also, Holugh Hormouk, one of their sovereigns,
afforded the most considerable astronomers at Maragha,
where he continued a magnificent observatory, the care
of which was confided to Noghi-Eddin. But of all the
princes of this nation, the one who distinguished himself the
most, by his zeal for astronomy, was Ulugh Bugh, a grand-
on of the celebrated Tamerlane, who was a great proficient
in this science. He formed, from his own observations,
in Samarcand, the capital of his empire, a new catalogue
of the stars, and the belt tables of the sun and planets that
had been given before those of Tycho Brache. He also
determined, in 1437, with a quadrant 180 feet high, the
obliquity of the ecliptic, which he found equal to 23°
31'.

During this period, the greatest part of Europe was
enveloped in ignorance and barbarity; which would have
probably continued much longer, but for the settlement of
the Moors in Spain, who first introduced a taste for literature
and the sciences into this part of the world. The Arabs
by this means became our instructors, as the Egyptians
had been formerly of the Greeks; and, by a singular fatality,
the learning which they transmitted to us, has disappeared
among this people, as astronomy became neglected in the
temples of Egypt and Chaldea, in proportion to the progress
which it made in the school of Alexandria.

One of the first encouragers of learning in Europe was
Frederick II., who, about 1230, set about restoring some
decayed universities, and founding a new one at Vienna. He also caused the works of Aviriotle and Ptolemy's Al-
magest, to be translated into Latin; from which latter cir-
cumstances we may date the revival of astronomy in Europe.
Two years after this, John of Halifax, commonly known
by the name of Sacro Bosco, compiled from Ptolemy, Al-
fraganus, Alfraganus, and other Arabic astronomers, his
work "De Sphera," which continued in great estimation
for more than 300 years afterwards, and was honoured
with commentaries by Chavins and other learned men. Al-
phonius, king of Castile, may also be reckoned as one of
the most zealous encouragers and protectors of this science;
though, being but ill acquainted with the astronomers of that
time, the tables which he published were not found to answer
the great expence which attended them.

About the same period also Roger Bacon, an English
monk, besides many learned works of various kinds, wrote
several treatises on astronomy; after which but little pro-
gress was made in this science till the time of Purbach,
Regiomontanus, and Walther, who all flourished about the
end of the fourteenth century, and by their labours pre-
pared the way for the great discoveries which followed.

Regiomontanus, in particular, who was born at Koning-
sberg, a town of Franconia, in 1436, and whose proper
name was John Muller, rendered considerable services to
astronomy, not only by his observations and writings, but
by his trigonometrical tables of lines and tangents, which
he computed to a radius of 1,000,000 for every minute of
the quadrant, and by this means greatly facilitated astrono-
mical computations, which had now become both num-
orous and intricate. John Werner, who succeeded Walther
as astronomer at Nuremberg, is also deserving of notice,
as being the first who proposed the method of finding the
longitude
longitude at sea by observing the moon’s distance from the six and certain fixed stars, which is now so successfully practiced in the British navy.

Next after these was Nicholas Copernicus, the celebrated author of the old Pythagorean system of the world, which had been now for a thousand years the basis of all astronomy. He was born at Thorn, in Polish Prussia, in 1473, and having gone through a regular course of studies at Cracow, and afterwards at Rome, he was made by the interest of his uncle, who was bishop of Wormia, a canon of Trawemburg; in which peaceful retreat, after 36 years of observations and meditations, he established his theory of the motion of the earth, with such new and demonstrative arguments in its favour, that it has gradually prevailed from that time, and is now universally received by the learned throughout Europe.

This great man, however, had not the satisfaction of witnessed the success of his undertaking, being threatened by the persecution of religious bigots on the one side, and with an obstinate and violent opposition from those who called themselves philosophers on the other; it was not without the greatest solicitations that he could be prevailed upon to give up his papers to his friends, with permission to make them public; but from continued inquietudes of this kind, he at length compiled, and his book, “De Revolutionibus Orbium Caelestium,” after being suppressed for many years, was at length published, and a copy of it brought to him a few hours before his death. His disciple Rheticus, who has rendered great services to the mathematical sciences by his extensive tables of sines, tangents, and secants, to every ten seconds, was the first who adopted his ideas; but they made but little progress till towards the beginning of the 17th century.

In this interval, however, the science was not wholly neglected. Nonius in particular wrote several valuable treatises on Astronomy and Navigation, and invented some useful instruments, more accurate than those before known; one of these being the almanachal quadrant, on which he divided the degrees into minutes, by a number of concentric circles. Apian also, in 1540, wrote a book called the “Cerarian Astronomy,” in which he shews how to observe the places of the stars and planets by the astrolobe; to resolve astronomical problems by means of certain instruments, and to predict and calculate eclipses; and at the end of his work are added observations of five comets, one of which has been supposed to be the same, with that described by Heronius; and whose return was accordingly looked for in the year 1789, but it did not appear. Gemma Frisius, who lived about this time, is likewise deserving of notice, as being the first who recommended time-keepers for finding the longitude at sea.

The history of the science, about this epoch, also offers us a great number of excellent practical astronomers; one of the most illustrious of whom was William IV, landgrave of Helfe-Caffil, who built an observatory in that city, and furnished it with a number of the best instruments that could be obtained at that time, with which he made his own observations. He also attached to him the celebrated astronomers Rothman, and Julius Burgius, and with their help formed a catalogue of 450 stars with their latitudes and longitudes, adapted to the beginning of the year 1552. It was also from his preceding publications, that Tycho Brahe, one of the greatest observers that ever existed, procured the advantages that he enjoyed under Frederick II, king of Denmark.

This excellent Danish astronomer, who was born at Knaudtorg in the county of Schonen, in 1546, began to mani-

felt his taste for this science at the early age of 14. An eclipse of the sun which happened in 1560, first attracted his attention; and the judicious of the calculation which announced this phenomenon, inspired him with a strong desire of understanding the principles upon which it was founded. But meeting with some opposition from his tutor, and a part of his family, to these pursuits, which probably served only to incite him to them, he made a journey into Germany, where he formed connections, and entered into a correspondence with some of the most eminent astronomers of that country; particularly with the landgrave of Helfe, who received him in the most flattering manner, and recommended him to the notice of his sovereign. But remaining by this means better known, on his return to Denmark, Frederick II. gave him the little island of Hilla, at the entrance of the Baltic, where he built an observatory, under the name of Uraniborg, and in which, during a course of twenty years, he made a prodigious number of observations.

His tranquility, however, in this happy retreat was, at length interrupted; for soon after the death of Frederick, which happened in 1566, he was deprived, through the interpositions of some envious and malicious persons, of his pension and establishment, and was not even allowed to follow his pursuits at Copenhagen; a minister of that time, of the name of Wolheim, having forbid him to continue his observations. Happily, however, he found a powerful protector in the emperor Redolphus II., who ordered him to be properly provided for at his own expense, and gave him a commodious house at Prague. After residing in this city till the year 1601, he was taken off by a sudden death, in the midst of his labours, and at an age while he was yet capable of rendering great services to astronomy.

This great man, as is well known, was the inventor of a kind of Semi-Ptolemaic system of astronomy, that was afterwards called by his name, and of which he early endeavoured to establish instead of the Copernican or true system. But though he was not happy in this respect, he has been of great use to astronomy by his numerous observations and discoveries. Among other things he was well acquainted with the nature of refractions (see Refraction); and hence he was able to determine the places of a great number of the fixed stars, with an accuracy unknown to former times. He also proved, against the opinion which then prevailed, that the comets are higher than the moon (see Comet); and from his observations on this and the rest of the planets, the theories of their motions were afterwards corrected and improved, so that for these services he will always be celebrated and esteemed by astronomers.

Tycho Brahe, in the latter part of his life, had for his disciple and assistant the celebrated Kepler, who was born in 1571, at Wied in the duchy of Wurttemberg, and was one of those rare characters that appear in the world only at particular times, to prepare the way for new and important discoveries. Like his master Tycho, he appears to have attached himself to the science at a very early age; and if it be the privilege of genius to change received ideas, and to announce truths which had never before been discovered, he may fairly be considered as one of the greatest men that had yet appeared. Hipparchus, Ptolemy, Tycho Brahe, and even Copernicus himself, were indebted for a great part of these knowledge to the Egyptians, Chaldaeans, and Indians, who were their masters in this science; but Kepler, by his own talents and industry, has made discoveries of which no traces are to be found in the minds of antiquity.

The philosopher, the most useful to the sciences, is he who to a profound imagination unites a scrupulous judgment, and
and though ardently devious to elevate himself to the cause of the phenomena, is equally apprehensive that he may be mistaken in that which he administers to them. Kepler owed to nature the first of these advantages, and the second to Tycho Brahe, who perceived his genius, and advised him to abandon his attachment to the mysterious analogies of figures and numbers to which he was then addicted, and to attend more closely to facts and their conseqences. This appears to have had its proper effect, and Tycho dying a few years afterwards, Kepler was put in possession of his collection of observations, which he employed to the most useful purposes, having founded upon them three of the most important discoveries that have ever been made in natural philosophy.

It was an opposition of Mars, which determined him to occupy himself, in preference, upon the motion of this planet; and then strongly attached to the Ptolemaic system as modified by Tycho Brahe, as well as to the opinion which had hitherto been generally received, that all the celestial motions must be perfectly circular and uniform, he endeavoured, for a long time, to represent that of Mars according to this hypothesis. At length, however, after many trials of this kind which he has given in detail, in his treatise called "Stella Meris," he discovered that the orbit of Mars is an ellipse of which the sun is placed in one of the foci, and that the planet moves in it in such a manner, that the radius vector, or a line drawn from the centre of the sun to that of the planet, describes areas proportional to the times. This law he also soon afterwards extended to all the planets: and in 1626, he published, according to this theory, his Rudolphine Tables, which will be for ever memorable in astronomy, as being the first that were founded on the true laws of the planetary motions.

It is here worthy of remark, that without the speculations of the Greek mathematicians, upon the curves formed by the sections of a cone, it is hardly probable that we should yet have remained ignorant of some of the most curious and important laws of nature. The ellipse being one of these curves, its lengthened figure suggested to the mind of Kepler the idea that the planet Mars, whose orbit he had found to be more oval than circular, might possibly move in it; and soon after, by means of the numerous properties which the ancient geometers had discovered of the conic sections, he inferred himself of the truth of this hypothesis. The history of the sciences affords many examples of this kind of application of pure geometry, and of the advantages attending it; for every thing, in the immense chain of truths, is connected; and frequently a single observation of apparently trifling consequence, has led to a more intimate knowledge of nature, of which the phenomena are the mathematical results of a small number of invulnerable laws.

The perception of this truth was probably what first gave rise to the mysterious analogies of the Pythagoreans; and Kepler, who had indulged himself in referrings of this kind, was indebted to it for one of his most brilliant discoveries. Being persuaded that the mean distances of the planets from the sun ought to be conformable to these analogies, he compared them, for a long time, both with the properties of the five regular bodies, and with the notes of music. At length, after seventeen years of meditation and calculation, having had the idea of comparing them with the powers of the numbers by which they are expressed, he found that the squares of the times of the revolutions of the planets are to each other as the cubes of their mean distances from the sun; and that the same law applies equally to their satellites.

Astronomy is likewise indebted to Kepler for several other discoveries; which, though not equal to the former, are full of considerable importance. He believed that it was the attraction of the moon which caused the flux and reflux of the ocean; and he had so far an insight into the general law of gravitation, as to suspect, that the irregularities of the lunar motions were occasioned by the combined actions of the earth and the sun. In his work on Optics, he has also explained the mechanism of vision, which was before unknown; and in another performance, called "Stereometria Dolorium," he has presented several views on the nature of infinites, which had considerable influence on the revolution that geometry underwent about the end of the last century.

It is affecting to relate, that this great man, who may be considered as the founder of modern astronomy, had his last days embittered by the horrors of poverty and distress. A small pension, which was scarcely sufficient for his subsistence, was frequently withheld or unpaid; and the trouble and vexation which this occasioned him, obliterated his genius, and shortened his existence. He died on the 15th of November 1631, in the fifty-ninth year of his age, leaving nothing for his wife and family, but the glory of his name, and the fame he had so justly acquired; but as these were insufficient to relieve his own wants, they could afford but little comfort to a helpless wife, and her wretched offspring, whose indigence is laid to have been such that they had not even the common necessaries of life.

In the time of Kepler, there were not wanting several other considerable proficients in astronomy. Edward Wright, an Englishman, made several good meridian observations of the sun, with a quadrant of six feet radius, in the years 1594, 1595, and 1596, from which he improved the theory of the sun's motion, and computed his declination more accurately than had been done before. He also published, in 1599, an excellent work, entitled, "Certain Errors in Navigation discovered and detected," containing a new method of projecting maps and charts, which has commonly, though erroneously, been ascribed to Mercator. The science is also greatly indebted to baron Napier of Scotland, not only for his ever memorable invention of logarithms, which has so wonderfully facilitated the business of calculation, but for some excellent theorems and improvements in spherics. About this time, likewise, Bayer, a German, published his "Uranometria," or complete Celestial Atlas, containing the figures of all the constellations visible in Europe; into which he introduced the highly useful invention of marking the stars by their names, of the letters of the Greek alphabet, which renders them so easy to be referred to with distinctness and precision.

At the same time also, that Kepler, in Germany, was tracing the orbits of the planets, and setting the laws of their motions, Galileo (who was born at Pisa, in Italy, in 1564) was meditating upon the doctrine of motion in general, and investigating its principles; and from the admirable discoveries which he made in this branch of the physical-mechanical sciences, Newton and Huygens were afterwards enabled to derive the most brilliant and complete theories of all the planetary motions. About this period also, a fortunate accident produced the most marvellous instrument that human industry and sagacity could have ever hoped to discover; and which, by giving a far greater extension and precision to astronomical observations, shewed many irregularities and new phenomena, which had hitherto remained unknown.

This invention was that of the telescope, which was no sooner known to Galileo, than he set himself about to improve it; and the discoveries he was by this means enabled to make, were as new as they were surprising. The face of the moon appeared full of cavities and asperities, resembling valleys...
vallies and mountains. The sun, which had generally been considered as a globe of pure fire, was observed to be filled by a number of dark spots, which appeared on various parts of its surface. A great number of new stars were discovered in every part of the heavens; the planet Jupiter was found to be attended with four moons, which moved round him in the same manner that our moon moves round the earth; the phases of Venus appeared like those of the moon, as had before been concluded by Copernicus from his theory; and in short, most of the observations he made furnished new proofs of the truth of the Copernican system.

In publishing the discoveries which he had made with this new instrument, Galileo showed in the most incontrovertible manner, the annual and diurnal motion of the earth; which doctrine, however, was thought so alarming, that it was immediately declared heretical, by a congregation of cardinals, who were assembled upon the occasion; and its venerable author, one of the most virtuous and enlightened men of his age, was obliged to abjure, upon his knees, and in the most solemn manner, a truth, which nature and his own understanding had shown him to be incontrovertible. After this, he was condemned to perpetual imprisonment; from which, however, at the end of a year, he was enlarged, by the solicitations of the grand duke; but, that he might not withdraw himself from the power of the inquisition, he was forbidden to quit the territory of Florence, where he died in 1642; carrying with him the regrets of Europe, enlightened by his labours, and their indignation against the odious treatment which had treated him so unworthily. For the oath of abjuration, and further particulars of this transgression, see Bonnycaile's Altronymy, p. 101. 3d edit. and the article Galileo in this work.

The celebrated Harriot also, who has hitherto been known only as an algebrist, made, much about the same time, similar discoveries with those of Galileo, as appears by his papers not yet printed, which are in the possession of the earl of Egremont. Mr. Harriot, likewise, a young astronomer of great merit, about this time, deserves to be mentioned, on account of his observation of the transit of Venus over the sun's disk (see Transit), on the 24th of November 1639; which event he announced to his friend Mr. Crabtree; and these two together had the singular satisfaction of witnessing, for the first time, a phenomenon which had never before been seen by human eyes. Harriot had even formed a new theory of the moon, which is taken notice of by Newton; but his early death, which happened in the beginning of the year 1642, put a stop to his useful labours.

The discoveries of Huygens succeeded those of Kepler and Galileo; and few men have, perhaps, merited more of the sciences, by the importance and lucidity of his researches. Among other things, his happy application of the pendulum to clocks, is one of the most advantageous presents that was ever made to astronomy. He was also the first who found that the singular appearances of Saturn, are produced by a ring, by which the planet is surrounded; and his acuteness in observing it, led him to the discovery of one of its satellites. Geometry, mechanics, and optics, are also indebted to him for a great number of discoveries; and if this rare genius had had the idea of combining his theories on centrifugal forces, with his inquiries into the development of curves, and the laws of Kepler, he would have rivaled from Newton his theory of circular motions, and that of gravitation; but these are the things in which discoveries generally consist.

Next to Huygens, may be mentioned Hevelius, a burgomaster of Danzig, who rendered himself highly useful to astronomy by his numerous and immense labours: few observers having ever excelled who were more indefatigable. It is to be lamented, however, that he refused to make use of instruments with telescopic lights, an invention introduced about that time by the celebrated Dr. Hook, and which gave a precision to observations unknown to former astronomers. He even contempted their utility, and a warm dispute having arisen between him and Dr. Hook upon this subject, Dr. Halley, then a young man rising fast into fame and eminence, was sent to examine his instruments, which were found to be excellent of their kind. The two astronomers made several observations together, much to their satisfaction; and among them was one of an occultation of Jupiter by the moon, by which they determined the diameter of the latter to be 32° 33′.

About this epoch, astronomy began to be more generally cultivated and improved, in consequence of the establishment of several learned societies, which, by exciting a spirit of emulation and enterprise among their members, greatly contributed to the advancement of every branch of the mathematical and physical sciences. The chief of these were the Royal Society of London, and that of the Academy of Sciences of Paris; both of which have rendered great services to astronomy, as well by the eminent men they have produced, as by the zeal and ardour with which the science has constantly been promoted by them. One of the first effects produced by these establishments, was the great improvement of telescopes and other instruments, which had hitherto been too much neglected for want of proper encouragement. Huygens constructed a telescope of 123 feet; with which he long observed the moon and planets, and was the first that discovered Saturn's ring. The celebrated Cassini also employed instruments of this kind, of 200 and 300 feet focus, with which he saw the five satellites of Saturn, with its zones or belts, as well as the shadows of Jupiter's satellites passing over its body.

The length of refracting telescopes, however, was still a great inconvenience; to remedy which, as well as the great aberration of their rays, Mercurius is said to have first started the idea of making telescopes with reflectors, instead of lenses, in a letter to Descartes; and in 1663, James Gregory of Aberdeen, showed how such an instrument might be constructed. Newton, also, after spending some time on the construction of both these sorts of telescopes, discovered the great inconvenience which arises to refractors, from the different refrangibility of the rays of light, and therefore pursuing the other kind, he presented in the year 1672, to the Royal Society, two reflectors, with spherical specula, as he could not then contrive the means of giving them a parabolic figure. It is proper to observe, however, that the defects of refracting telescopes, arising from the different refrangibility of the rays of light, have since been completely obviated by the ingenious Mr. Dollond. See Achromatic Telescope.

Towards the latter part of the seventeenth century, and the beginning of the eighteenth, practical astronomy seems rather to have languished; but at the same time, the theoretical part was carried to the highest degree of perfection, by the immortal Newton in his "Principia," and by the astronomy of David Gregory. (See Newtonian Philosophy.) About this time also, clock and watch-work was greatly improved by Mr. Graham, who likewise constructed the old eight day clock mural, and, at the Royal Observatory at Greenwich, and the zenith sector of twenty-four feet radius, with which Dr. Bradley discovered the aberration of the fixed stars. (See Aberration.) The reflecting telescope of Gregory and Newton, was also greatly improved by Mr. Hadley; but who
who is still better known for his admirable invention of the reflecting quadrant or sector, now called by his name, and which is universally used at sea, and in all nice observations. Mr. Bird also, about the middle of the eighteenth century, rendered great services to astronomy, by his method of con- structing and dividing large astronomical instruments; which has since been carried to the greatest degree of perfection by the able hand of Mr. James Bradley, whose recent death will be long regretted by astronomers, and men of science in general. Reflecting telescopes were likewise not left improved by Mr. Short, who also first executed the divided object-glass micrometer, which had been proposed and described by M. Louiville and others.

Thus the astronomical improvements in the last century, have been chiefly owing to the greatest perfection of instruments, and to the establishment of regular observatories in various parts of Europe. Romer, a celebrated Danish astronomer, first made use of a meridian telescope; and by observing the eclipses of Jupiter’s satellites, was led to the discovery of the motion of light, which he communicated to the academy of sciences at Paris, in 1675. Dr. Flamstead was also appointed the first astronomer royal at Greenwich, about the same time, where he observed all the celestial phenomena for more than forty-four years; and as the fruits of his labours, published a catalogue of 3000 stars, with their places, to the year 1688, as well as a new polar table, and a theory of the moon according to Huygens. Cassini, also, the first French astronomer royal, greatly distinguished himself by his numerous observations on the sun, moon, and planets, and by the improvements he made in the elements of their motions.

In 1719, Dr. Flamstead was succeeded by Dr. Halley, the friend of Newton, and a man of the first eminence in all the classes of literature and science, who had been for the early age of twenty-one, to the island of St. Helena, to observe the southern stars, a catalogue of which he published in 1679; and a few years afterwards he gave to the public, his "Synopsis Astronomiae Cometarum," in which he ventured to predict the return of a comet in 1758, or 1759. He was the first who discovered the acceleration of the moon’s mean motion; and is the author of a very ingenious method for finding her parallax, by three observed places of a polar eclipse: he also showed the use that might be made of the approaching transit of Venus, in 1761, in determining the distance of the sun from the earth; and recommended the method of determining the longitude by the moon’s distance from the sun and certain fixed stars, which has since been carried into execution at the instance of the present astronomer royal. Dr. Halley also compiled tables of the sun, moon, and planets, with which he compared the observations he made of the moon at Greenwich, amounting to near 1500, and noticed the differences. About this time, an attempt was made in France, to measure a degree of the earth, which was the occasion of a warm dispute concerning its figure. M. Cassini concluded, from the measurement of Picart, that it was an oblong spherical; but Newton, from a consideration of the laws of gravity, and the diurnal motion of the earth, had determined its figure to be that of an oblate spheroid, flattened at the poles, and protuberant at the equator. To determine this point, Louis XIV. ordered two degrees of the meridian to be extended, one under near the equator, and the other as near as possible to the pole, the result of which arduous undertaking was a confirmation of Newton’s investigation. Maff. Maupertuis, Clairaut, &c. were employed on the northern expedition; and Condamine, Bouguer, Don Ullon of Spia, &c. on the southern; who all fulfilled their commissions with great credit to themselves, and advantage to the sciences, making many observations besides those immediately connected with this subject. Among others, it was found, by those who went to the south, that the attraction of the great mountains of Peru had a sensible effect on the plumb lines of their large instruments, which afforded an experimental proof of the Newtonian doctrine of gravitation, that has since been completely verified by the observations of Dr. Maclaren, made on the mountain Schalulien in Scotland. See Attraction of Mountains.

On the death of Dr. Halley, in 1742, he was succeeded by Dr. Bradley, who has rendered himself highly celebrated by two of the finest discoveries that have ever been made in astronomy, the aberration of light and the nutation of the earth’s axis. Among other things, he also formed new and accurate tables of the motions of Jupiter’s satellites, as well as the most correct table of refractions yet extant. Also, with a large transit instrument, and a new mural quadrant of eight feet radius, constructed by Bird, in 1750, he made an immense number of observations, for setting the places of all the stars in the British catalogue, together with near 150 places of the moon, the greater part of which he compared with Mayer’s tables.

Dr. Bradley was succeeded in 1762, in his office of astronomer royal, by Mr. Bihis, but who, being in a declining state of health, died in 1755, and was succeeded by Nevil Macleay, D.D. the present astronomer royal, who has rendered considerable services to this science, by his publication of the "Nautical Almanac" the "Reprint of Tables," &c. and more particularly by the great affinity and zeal he has displayed in bringing the lunar method of determining the longitude at sea into general practice.

In the mean time, many other eminent mathematicians, both of our own, and other countries, were actively employed in endeavouring to promote the science of astronomy.

The theory of the moon was particularly considered by Mctt. Clairaut, d’Alemout, Euler, Simpson, Wollfheim, and Mayer; the latter of whom composed a set of lunar tables, for which, on account of their superior accuracy, he was rewarded with a premium of 3000, by the board of longitude, who brought them into use in the computation of the nautical ephemeris which was published by their order. Some very accurate tables of the satellites of Jupiter, were also composed from observations by Mr. Wargentin, an excellent Swedish astronomer, and which have since been corrected by the author, so as to render them superior to any yet published.

Among the French astronomers who have also contributed to the advancement of this science, we are particularly indebted to M. de la Caille for an excellent set of solar tables, in which he has made allowances for the attractions of Jupiter, Venus, and the Moon, as well as for the observations which he made at the cape of Good Hope, in concert with the most celebrated astronomers in Europe, in order to determine the parallax of the sun, moon, and the planet Mars; and for adjusting the places of the stars in the southern hemisphere, which he has done with great accuracy. In Italy also the science was cultivated with great success by S. Bianchini, Bofchovich, Frill, Munfredi, Zanotti, and others; and in Germany, by Euler, Mayer, Lamber, &c. &c.

Such was the state of astronomy when Dr. Herschel, by augmenting the powers of telescopes beyond the most fanciful expectations, opened a scene altogether unlooked for. By this indigatigeous observer we are made acquainted with a new primary planet belonging to our system, called the Georgium Sidus, attended by fix satellites, which he discovered on the 13th of March 1781, and which being at twice the
the distance of Saturn from the sun, has doubled the bounds formerly assigned to the solar system. We are also indebted to him for a variety of observations on several other interesting astronomical subjects; such as the discovery of two additional satellites to Saturn, of which the number is now seven; a new method of measuring the lunar mountains; the position of the planets on their parallaxes of the fixed stars; catalogues of double, triple, quadruple, &c.; of nebulae; and of the proper motion of the sun and solar system; the accounts of which, together with many other valuable papers, he has communicated from time to time in different parts of the Philosophical Transactions. While in this last year also another new planet has been discovered by M. D'Azzi of Palermo, between Mars and Jupiter, to which he has given the name of Ceres Ferdinandinia; and even the discovery of a third has been announced in some of the foreign journals, but for any regular account of this we must wait for further information. See Geographia Sinus, Ceris Ferdinandinia, and Pallasis.

It is with great pleasure we observe that at no former period has this science been cultivated with more ardour than it is at present, both in this and every other country in Europe. In France, the physico-mathematical part of the science has been greatly improved and extended by the celebrated M. de l'Isle, who, in his elaborate work, the "Mechanique Celeste," has investigated all the phenomena, which the attraction or universal gravitation of matter can produce on the forms and motions of the celestial bodies, by their mutual actions on each other. M. Lalande, the patriarch of astronomers, is also still indefatigable in his pursuits, and by the zeal he constantly manifests for the interests of this science, has greatly promoted the study of it in almost every quarter of the globe; but particularly in Germany, where M. von Zach is equally assiduous in forwarding its improvements. In all its collateral branches also we observe a degree of activity that has never been exceeded. New admissions of the earth have been undertaken both in this country and in France, which, from the great improvements of instruments, and the skill and industry of the observers, promise a greater accuracy in the results than could have been obtained by those who were formerly engaged in this undertaking. From the zeal and abilities of major Mudge, in particular, who is now employed by our government to make a trigonometrical survey of the country, we may expect the most accurate details on this subject that have ever yet been presented to the public.

We shall conclude by observing that there still remains a number of discoveries to be made in this science. We have not yet determined the times of rotation and the proper figures of some of the planets and their satellites; nor do we know with sufficient precision the masses of these bodies. The theory of their motions also consists in a series of approximations, of which the convergence depends both upon the perfection of instruments, and the progress of analysis, and which for that reason ought to acquire continually new degrees of exactness. Observations on the return of comets already observed, as well as on those which may hereafter appear, should likewise be made with great care, and particularly such as may entirely change their orbits, as it has been conjectured was the case, by the action of Jupiter on the one which appeared in 1770; as also such comets which the proximity, and even the shock of these bodies, may occasion to the planets and their satellites; such are the principal objects which should engage the attention of future observers.

For more particular accounts of the writings and authors on this science, the reader may consult Wiedler's "History of Astronomy," which is brought down to the year 1737, as also "Bally's History of Ancient and Modern Astronomy," Montucla's "Histoire des Mathématiques," and the sixth volume of Lalande's Astronomie. The more modern and popular works on the subject are numerous and well known; as those of Encke, Leverrier, Lalande, Benoy, &c.; in the latter of which, in particular, the elementary parts, and general outline of the science, are described with great perspicuity and elegance.

Astronomy is sometimes divided with respect to its different branches, into new and old. Astronomy, Ancient, is such as the art stood under Ptolemy and his followers, with all the apparatus of fields, orbs, epicycles, eccentricities, deferents, and epicycles; &c. Astronomy, Modern, is such as the art has been since Copernicus, by whom three fictitious machines were thrown out, and the constitution of the heavens reduced to more simple, natural, and certain principles.

In Ricciolus's Almagestum Novum, published in 1651, we have the several hypotheses of all the astronomers, ancient as well as modern.—And in Dr. Gregory's Elements of Astronomy Physica & Geometrica, in 1702, the whole modern astronomy, as founded on the discoveries of Copernicus, Kepler, and Sir Isaac Newton. The substance of the old astronomy is given by Tacquet; and of the new astronomy by Whiston, in his Prolegomena Astronomica, in 1717. Mercator's Institutiones Astronomiae, published in 1676, contains the whole doctrine, both according to the ancients and moderns; and Dr. Keill's Introduction to Ancient Astronomy, in 1718, comprehends the modern, to which might be added Vine's Astronomy, in 2 vols. 4to. 1800; and his Practical Astronomy, 4to. 1810.

Astrosopheticum, in Natural History, a name given by some authors to a species of star-fish, composed of a body, or central nucleus, surrounded in the manner of the scales of the common scallop, and parting into five principal rays, from each of which there issue several transverse processes, covered with a hairy down.

Astrorodia. See Asteria, and Starfish.

Astrroscope, in Astronomy, a kind of astronomical instrument, composed of two cones, on whose surface the constellations, with their stars, are delineated, by means of which the stars may easily be known.

The astrroscope is the invention of Wilh. Schukhard, formerly professor of mathematics at Tubingen, who published a treatise expressly on it, in 1678.

Astruscopía, from astartes, star, and -copía. I confess, the art of observing and examining the stars by means of telescopes, in order to discover their nature and properties.

Huygens improved this art considerably in his "Astronomica Compendiosa Tubi Optici, or the Compact Instrument," where he shows how to manage the largest glasses without help of a tube. See Telescope.

Astronomy, in Navigation, the places or positions of the stars in a theme of the heavens. Vital. Lex. Mather.

Astronomy, in Navigation, the places or positions of the stars in a theme of the heavens. Vital. Lex. Mather.

Astronomy, in Navigation, the places or positions of the stars in a theme of the heavens. Vital. Lex. Mather.

Astronomy, in Navigation, the places or positions of the stars in a theme of the heavens. Vital. Lex. Mather.
and in 1702, bachelor of medicine. In the same year he published his dissertation "De motu fermentatii causis," which was soon followed by several controversial pieces on the manner in which the food is digested in the stomach, which he contended was effected by a peculiar heat, exciting fermentations; contrary to the opinion of Pictet, and other mechanical physicians, who attempted to prove that our food was triturated or ground to a pulp in the stomach by the action of the abdominal and other muscles, to which they gave a power equal to several thousand pounds weight. In 1710, he was made professor of anatomy and medicine at Toulouse. In 1716, he returned to Montpellier, where he was called to the professor's chair vacant by the death of Chatelain. In 1720, he published his treatise "De Hydrophobia," and in 1721 "Sur l'Origine des Maladies Epidemiques, principalement de la Pelle," in which he strongly supports the opinion that the plague is a contagious disease, in opposition to Chicanen and other writers, who then, as now, attempted to establish a contrary doctrine. He supposed there was some analogy between the poison of the plague and the venereal disease. He took an early and active part in the dispute between the faculty of medicine and the surgeons at Paris; and as he was well versed in the history of medicine, he showed that in early times the chirurges were examined by physicians previous to their being allowed to practice. In 1729, he was invited to Poland, and made physician to the king, Angoulus the second; but finding this place less favourable to his studies, he returned to France, and fixed himself at Paris; and in 1730, was appointed consulting physician to the king, and soon after, on the death of Geoffroy, professor of medicine in the Royal College at Paris, where the reputation he had previously acquired procured him a numerous and respectable auditory. 

In 1737, he published "Mémoires pour l'Histoire naturelle de Languedoc," in which a particular account is given of the mineral waters of Balaruc. In 1745, he published "Tractatus Pathologicus" and 1748, "Tractatus Therapeuticus," both in 8vo; which were in their time well received, but are superseded now by the adoption of new theories, in their turn to give way to subsequent speculations. In 1756, he published his principal work "De Morbis Veneris," which soon, and deservedly, raised his fame to the highest pitch of eminence. The work was eagerly received, and translated into all the modern languages; the learned in every country being devious of naturalising a production, containing the completest history, description, and mode of treating the disease that had appeared. In the first part, the author labours to shew, that the disease was new, and of a nature different from all others; that it was first imported into Europe by the Spaniards who attended Columbus in the discovery of America. This part has lately been controverted, and palliages from various early writers have been produced, that are palpably to point out the disease; a single symptom or two refuting some of those attending the lues veneris being obliquely noticed in them. He maintains mercury as the sole specific in the cure of the lues veneris, and of the different ways of administering it, prefers that by injection. The author soon after published "Doutes fur l'Isolation de la petite ve- role," propofed a la Faculte de Paris, but without his name; and in 1759, "Treatise des Tumours et des Ulcere," with two Lettres, 1. sur la composition des quelques remedes; et 2. sur la nature et le fieuces des nouveaux remedes qu'on propofe pour la guerison des maladies venereennes." 

In this work which has considerable merit, the author treats largely of hydaitis passed off by fluid and by vomiting, or found in the livers of persons who have died tabid. He is one of the first writers who denies his affect to the opinion that marks, dilatations, and mutilations of the bodies of infants, are occasioned by the imaginations of the mothers. In 1761, he published "Trapeze des Maladies des Femmes," 6 vol. 12mo.; this has been translated into English, as well as his "Art d'Aguacher, reduit a fewes principes;" the last work he lived to finish. The author had tried the effect of eicentia, he tells us, in cancer, but without advantage; and thinks its reputation for resolving felshish had arisen from inculvated glands of the breast which were taken for them, but were not felffus, having disappeared under its use. This opinion has been confirmed by later experience. On the whole, we find in this writer great marks of genius, as well as of labour and research, and he will be deservedly handed down to posterity as one who has contributed considerably to the improvement of the art of medicine. As early as the year 175, he was admitted member of the faculty of medicine at Paris; he was a constant attendant at their meetings, and a zealous protector of their privileges. With an active mind, he had the good fortune to enjoy a strong and vigorous constitution, which enabled him to continue his professional exertions until within a very small time of his death, which happened on the 5th of May 1756, at the age of 82 years. In the second volume of the author's treatise "De Morbis Veneris," he has given a catalogue of all the writers who had treated on the subject before him, with brief sketches of their lives, and analyses of their works. This part appears to have been executed with fidelity, and has afforded us useful and valuable materials in our labours, as has likewise a populous work of the author, his "Memoires pour servir a l'Histoire de la Faculte du Medicin de Montpellier," published by Lorry in 1757, in 4to, and enriched with a beautiful coloured portrait of the author, and an account of his life. Hall, Bibl. Med. & Chirur. Lorry Eloge Ht. de M. Atrone. One very singular work little noticed, and perhaps little deserving notice, as founded solely on speculation and conjecture, was his "Conjectures fur les memoires originaux dont il paroit que Mois: se feri pour compro mer le livre de Geno," Bruxelles, 1759. It does not appear that the works of this celebrated writer were ever collected and published together; but they are certainly deserving that attention. 

ASTRUM, or ASTRON, in Afternoon, a constellation or assemblage of stars. In which sense it is distinguished from ater, which denotes a single star.

Some apply the term, in a more particular sense, to the Great Dog; or rather to the great bright star in his mouth. Vital.

ASTRUM, in Ancient Geography, the name of a large town of the Peloponnesus, in the Argolid.

ASTRUSINO, in Geography, a mountain of Italy, famous for its baths.

ASTROP, a town of Germany, in the circle of Wolphahl, and bishiriph of Ofinbarg, four miles north of Olmibarg.

ASTURA, in Ancient Geography, a river of Italy, and also an island, according to Pliny.—Cicero had a villa of this name near the sea, within view of Circus and Atrium, whither he retired, with his brother and nephew, when he first received at his Tufculan villa the news of the proscription in which they were included, and whence they proposed to transport themselves directly out of the reach of their enemies. Here Cicero is found a vessel ready for him, in which he immediately embarked; but the winds being adverse, he was obliged to land at Circus, near which he spent a night, in great anxiety and irresolution. The question
uestion upon which he deliberated was, what course he should take; and whether he should fly to Brutus or to Cassius, or to S. Pompéius; but, after all his deliberations, none of them pleased him so much as the expedient of dying; so that, as Plutarch says, he had some thoughts of returning to the city, and killing himself in Caesar's house; in order to leave the guilt and curse of his blood upon Caesar's perfidy and ingratitude; but the importunity of his servants induced him to fail forwards to Cæsars, where he landed to repose himself in his Roman villa, about a mile from the coast; "weary of life and the sea, and declaring that he would die in that country which he had often sav'd." Hither he was pursued by the soldiers that were sent in quest of him; and though he fled into the woods, he was overtaken and put to death. Middleton's Cicerio, vol. ii. p. 405.

**ASTURIA.** in Geography, a good harbour on the south-west coast of Italy; about twelve or fourteen leagues south-east from the mouth of the Tiber, at the bottom of a bay east from port Neptune, and nearly east from mount Cerreci.

**ASTURAGAMICOS,** a lake of Lower Canada, eighty-one leagues north-east of Quebec. N. lat. 52° 25'. W. long. 67° 25'.

**ASTURIA,** in Ancient Geography, a kingdom of Spain, subdued by the Roman emperor Augustus, after the people had long resisted, in connection with the Cantabrians, repeated attempts to reduce them under the Roman yoke. But at length the dilfera of famine was fo great, that they determined to surrender; upon which the Cantabrians, who, desperate as their situation was, were resolved to renew their efforts, fell upon them, and compelled 10,000 of them to seek an asylum in the Roman intrenchments. Tiberius, however, refused to admit them into the camp; so that despairing of relief, some fell upon their own fwords, others threw themselves into the flames which they had kindled for this purpose; and others dispatched themselves by poison. The surviving Asturians collected all their strength against the next campaign; but the utmost efforts of their valour and despair proved fruitless. Weakened by repeated defeats, they were under the necessity of submitting to the Roman power, till the subversion of that empire by the Goths. In the beginning of the eighth century Don Pelayo restored the Spanish monarchy in the Asturias, the capital of the Asturians, was, in ancient times, the famous "Colonia Augusta," mentioned by Pline. This place divided the Astures into Augubiani and Transmountani. The seventh Roman legion, intitled "Augubilia Gemina," was settled between the Asturias sea and the capital of this district, called "Asturia Augusta," now Astorga. The country derives its name from the river Astura, and is now denominated "Asturias." It was formerly celebrated by the poets for the gold it produced.

**ASTURIAS,** in Geography, the ancient Asturias, a province of Spain, about forty-eight leagues long, and eighteen broad; bounded on the east by Biscay, on the south by Old Castile and Leon, on the west by Galicia, and on the north by the bay of Biscay. It is usually divided into two parts or districts called Asturia of Oviedo, and Asturia of Santillane; and hence it derives its plural name Asturias. The country is generally mountainous and rugged; and towards the south are the mountains which branch from the Pyrenees, and separate it from Old Castile and Leon; these are covered with extensive forests. The soil, however, produces a sufficiency of corn, great quantities of fruit, and excellent wine. Its horses are in great esteem, and maintain their reputation from the time of the Romans, who preferred them to all the other horses in Spain. The inhabitants, who value themselves even at this day on the purity of their blood, and their descent from the ancient Goths, are poor, but honest, generous, brave, and laborious. The principal towns are Oviedo, Santillane, and San Andero. The eldest son of the king of Spain takes the title of the prince of Asturias, and holds the arms of the country.

**ASTURICANI,** in Ancient Geography, a people of Asticio Sarmatian. Ptolemy.

**ASTURASPES,** a name formerly given to a river of Abythinia, now called Markos. It is one of the rivers represented by the ancients as forming the island of Meroe.

**ASTYAGES,** in Biography, king of the Medes, was the son of Cyaxares, according to Herodotus (i. e. 72.) and Pausanias (i. e. 10. p. 398.) and began his reign, according to Blair's tables, in the year 585 B.C. Sir Isaac Newton (Chron. apud Oper. t. v. p. 222.) says, that Herodotus, followed by Pausanias, has inserted the order of the kings Astyages and Cyaxares; making Cyaxares to be the son and successor of Phraortes, and the father and predecessor of Astyages, the father of Mandane, and grandfather of Cyrus. Considering, he adds, that Cyaxares reigned long, and that no author mentions more kings of Media than one, called Astyages; and that Eschylus, who lived in those days, knew but of two great monarchs of Media and Peria, the father and the son, older than Cyrus, he concludes, that Astyages, the father of Mandane, and grandfather of Cyrus, was the father and predecessor of Cyaxares; and that the son and successor of Cyaxares, was called Darius. Accordingly, he says, that Astyages began his reign at the death of Phraortes, who was slain by the Astyrians in the year of Nabonassar III., or 657 B.C., and reigned 26 years. According to Herodotus, Astyages married his daughter to a Persian nobleman named Cambyses. During her pregnancy he had a dream,signifying that the child that was to be born should rule over all Asia. This prediction alarmed him; and he determined to destroy the child. Harpagus, who was employed for this purpose, disobeyed the royal command, and intruded the nurture and education of the infant Cyrus with one of the king's women. When Cyrus was ten years old, Astyages discovered the fraud, and caused the only son of Harpagus to be killed, and his flesh to be served up to him in a banquet. Harpagus for some time dissembled his indignation at this act of barbarity, but waiting a favorable opportunity of revenge, he called Cyrus, arrived at manhood, from Persia, whither he had been sent to his real parents, and afflicted him to revolt against his grandfather. Astyages was defeated; and caused the Magi, who had led him to imagine that the danger apprehended from his son's revolt was at an end, to be all impaled. In a second engagement he was defeated and made prisoner: upon which he was deposed by Cyrus, after having reigned 35 years, and the Medes were subjected to the Persians. Astyages was confined to his palace, but suffered to close his life by a natural death. Xenophon, in his "Cyropedia," a work which the best critics have considered more as a fiction than a true history, represents Cyrus as having been openly educated at the court of his grandfather Astyages, who retained the crown till his death, and was succeeded by his son Cyaxares II. Astyages has been reckoned by some the "Athalierus" of scripture. Anc. Un. Hist. vol. iv. p. 23. See Media, and Persia.

**ASTYANAX,** in Ancient History, the only son of Hector and Andromache. Calchas, the foothsayer, predicted,
 prudent, that if he lived to manhood, he would be more valiant than his father, and avenge his death. It was therefore determined to dispatch him in his minority. Andromache took pains for concealing him; but, it is said, that Ulysses discovered him, and precipitated him from the top of the Trojan walls. The death of Atyanaus is the principal subject of Euripides' tragedy of the Trojans.

ASTYROMI, in Ancient Geography, were magistrates at Athens who had the inspection of the frits, and also of players on instruments and buffoons. They were ten in number, and corresponded to the plebeian ediles of Rome. See AGORANCEIS.

ASTYPALEA, in Ancient Geography, an island of Achaia, in the Cretan sea, where, according to Cicero (De Nat. Deor. L. iii. c. 180), divine honours were rendered to Achilles. Steph. Byz. says, that this island, one of the Cyclades, was called Pyrrha when the Carians possessed it, and afterwards Pyrrha. Its name Astypalæa, in its proper signification, means the ancient city, and is said to be derived from that of the daughter of Phoenix and Piramde, father of Eurydice, and beloved by Neptune, by whom he had Aneaus, who reigned over the people named Lelegi. Pan. F. vii. c. 4. It was also called Theontrapeza, i.e. the table of the gods, because its soil is fertile, and almost emerald with flowers. It now bears the name of STAMFALIA.—Also, a town of the island of Cos. Strabo. —Allo, a promontory of Afa Minor, in Caria, in the territory of Mindus. Strabo. —Allo, a town of the island of Samos.

ASTYRA, or ASTYEY, a town of Eolis; but it no longer subsisted in the time of Pliny.—Allo, a village of Afa Minor, in the Troades, near mount Ida, in the vicinity of which was a grove consecrated to Diana Atyanalæ. —Allo, a town of Pheneia, in the neighbourhood of the isle of Rhodes, Steph. Byz.

ASTYRON, a town of Illyria, built by the Argonauts.

ASUCAY BAY, in Geography, lies on the south part of the gulf of Sofala, on the S. E. coast of Africa, in the Indian ocean.

ASUM, in Ancient Geography, a town of the island of Crete (Phaestus), the Asoi of Steph. Byz. whence Jupiter derived the appellation of Afais.

ASUM, or OFSUN, in Geography, a town of Africa, on the sea-coast of the kingdom of Addi.

ASUMATZ, a town of Walachia, eight miles east of Bucharest.

ASWAD, a town of Arabia, 28 miles south of Saude.

ASYLA, in Ancient Geography, a town of Spain, in the country of the Turdetani. Ptol.EMY.

ASYLUM, a sanctuary or place of refuge, where a criminal who fleths himself is deemed inviolable, and not to be touched by any officer of justice.

The word is compounded of the privative particle σα, and σιλαμ, I hurt; because no person could be taken out of an asylum without facility.

The first asylum was established at Athens, by the descendants of Hercules, to shelter themselves from the fury of his enemies; to serve as a refuge for children who fled from the ill treatment of their parents, and, as some have said, to be a sanctuary for suppliants in general. This is said by Stat. Theb. xii. and Servius, in Aenid viii. to have been the first asylum; others suppose that it was first built at Thebes by Cadmus, for the reception of all criminals. Paul. I. vii. Εν. i. i. v. 112. Eurip. Hecla, v. 146. In imitation of the asylum of Cadmus, Romulus established one between the two groves on the Capitoline mount, which was free of access to all criminals. The oracle of Delphos, according to Plutarch, sanctioned this political establishment of Romulus with its approbation. When Romulus enlarged his new city, which by this policy was flocked with inhabitants, the asylum was included within the walls, and those who fled to it, being brought under some regulations, became citizens of Rome. Plut. in Rom. I. c. 19. Dion. Hal. i. ii.

The temples, altars, statues, and tombs of heroes, were, anciently, the ordinary retreat of those who found themselves aggrieved by the rigour of the laws, or oppressed by the violence of tyrants; but temples were held the most sacred and inviolable refuge. It was feared, that the gods took upon them to punish the criminal who thus threw himself upon them; and that it would be a great impolicy in man to take vengeance out of the hands of the immortal.

The Israelites had their cities of refuge, which were of God's own appointment; where the guilty, who had not committed any deliberate crime, found safety and protection. As to the heathens, they allowed refuge and impunity even to the vilest and most flagrant offenders, came out of superstition, and others for the sake of populating their cities; and it was by this means, and with such inhabitants, that Thebes, Athens, and Rome, were first florked. We even read of asylums at Lyons and Vienna, among the ancient Gauls; and there are some cities in Germany which still preserve the ancient right of asylum.

Hence, on the medals of several ancient cities, particularly in Syria, we meet with the inscription δισιωσι, to which is added, ΕΠΑΙ. This quality of asylum was given them, according to M. Spanheim, in regard to their temples, and of the gods revered by them.

The same privileges have also been given to deities: thus Diana of Ephesus is called άσυλος. Add, that the camp, formed by Romulus and Remus, was called asylum, and afterwards became a city, in which was a temple erected to the god Asylon. Ας ιωας. It appears from Plautus (Mol. i. 2.), that slaves had particular asylums: such was the temple at Athens; or the tomb of Thelcus: because he never refused to avenge the oppreied, and to succour the wretched. The temple of Diana at Ephesus was an asylum for debtors. In process of time, asylums were so multiplied, that it became necessary to regulate and reform them, in the reign of Tiberius; as we are informed by Tacitus (An. i. 50), and Suetonius (Tiber. c. 37.) says, they were utterly abolished.

The emperors Honorius and Theodosius granting the like immunities to churches, the bishops and monks laid hold of a certain tract or territory, without which they fixed the bounds of the secular jurisdiction: and so well did they manage their privileges, that convents, in a little time, became next akin to fortresses, where the most notorious villains were in safety, and braved the power of the magistrate.

These privileges, at length, were extended not only to the churches and church-yards, but also to the bishops' houses, whence the criminal could not be removed without a legal assurance of life, and an entire remission of the crime. The reason of the extension was, that they might not be obliged to live at ease in the churches, &c. where several of the occasions of life could not be decently performed.

But, at length these asyla, or sanctuaries, were also stripped of most of their immunities, because they served to make guilt and libertinism more bold and daring. In England,
ASYMmetry, derived from the privative α, συν, διά, and ἀφθονός, q. d. without measure, a want of proportion, or correspondence between the parts of a thing. See Symmetry.

In Mathematics, the word is more particularly used for what we more usually call incommensurability; which is when between two quantities there is no common measure: as between the side and diagonal of a square. In numbers, for roots, as \( a^{'} \), \( b^{'} \), &c. are incommensurable to rational numbers.

ASYMPTOTE, in Geometry, a line which continually approaches nearer and nearer to another; yet will never meet with it, though indefinitely produced.

The word is compounded of the privative α, συν, διά, and ἀφθονός, from αφθονός, I fail; q. d. incommensurable, or which never meet. Some Latin authors call these lines inæqua.

Bortius enumerates divers sorts of asymptote; some straight, others curves; some convex, others concave, &c. and farther, proposes an instrument for determining them. Though, in rhetoric, the term asymptote is appropriated to right lines. Asymptotes, then, are property right lines, which approach nearer and nearer to some curve, of which they are said to be the asymptotes; but which, though they and their curve were indefinitely continued, would never meet: consequently asymptotes may be conceived as tangents to their curvatures at an infinite distance. Two curves are also said to be asymptotic, when they thus continually approach, without a possibility of meeting. Thus two parabolas, whose axes are in the same right line, are asymptotic to one another.

Of lines of the second kind, or curves of the first kind, that is, the conic sections, only the hyperbola has asymptotes, which are two in number, the properties of which have been long ago demonstrated by Apollonius Pergaeus.

All curves of the second kind have at least one asymptote; but they may have three; and all curves of the fourth kind may have four asymptotes.

The conchoid, cissoid, and logarithmic curve, though not reputed geometrical curves, have each also one asymptote.

The nature of asymptotes will be easily conceived from the notion of the asymptote of a conchoid. Suppose MAM, &c. (Plate Analysis, fig. 1.) to be a part of a conchoid, C its pole, and the right line BD, so drawn that the parts QA, EA, OM, &c. of right lines drawn from the pole C, are equal to each other; then will the line BD be an asymptote of the curve; because the perpendicular ML, &c. is shorter than MO, and MR than MQ, &c. so that the two lines continually approach; yet the points M, &c. and K, &c. can never coincide, since there is still a portion of a line to keep them alman; which portion of a line is infinitely divisible, and consequently must be diminished infinitely before it becomes nothing.

ASYMPTOTES of the HYPERBOLA are thus described. Suppose a right line DE (Plate I. Conics, fig. 2.) drawn through the vertex A of the hyperbola, parallel to the ordinate EM, and equal to the conjugate axis, viz. the part DA, or AE, equal to the semi-axis: then, two right lines drawn from the centre C of the hyperbola through the points D and E, viz. the right lines CF and CG, are asymptotes of the curve. The parts of any right line, lying between the curve of the common hyperbola and its asymptotes, are equal to one another on both sides, that is \( mf = MR \). Thus also, in hyperbolas of the second kind, if a right line be drawn, intersecting the curve and its three asymptotes in three points, the sum of the two parts of that right line extended in the same direction from any two of the asymptotes to two points of the curve, is equal to the third point which extends in the contrary direction from the third asymptote to the third point of the curve.

If the hyperbola \( G M K \) (fig. 12. N. 2.) be of any kind whose nature with regard to the curve, and its asymptotes, is expressed by this general equation \( x^2 = a^2 - y^2 \), and the right line PM be drawn anywhere parallel to the asymptote CM, and the parallelogram PMGM be completed, this parallelogram is to the hyperbolic space \( PMGB \), contained under the determinate base PM, the curve of the hyperbola \( G M \) infinitely turned towards \( G \), and the part PB of the asymptote indefinitely continued the same way, as \( m - a \) is to \( n \), and \( m - b \) will be greater than \( m \), the said space is finite and quadrable; but when \( m = a \), it will be in the common hyperbola, the ratio of the foregoing parallelogram to that space is \( m + a \) to \( m + n \); that it is infinitely the greater, and cannot be obtained; and when \( m \) is less than \( a \), \( m - m - n \) will be negative, and the greater parallelogram will be to the space a negative number to a positive one, and the said space is called by Dr. Wallis more than infinite. See Hyperbola.

ASYMPTOTE of a Logarithmic Curve. If MS (fig. 33.) be the logarithmic curve, PR an asymptote, PT the tangent, and MP an ordinate; then will the indeterminate space RPMS = PM X PT; and th'o did, generated by the rotation of this curve about the asymptote VP, will be half of a cylinder whose altitude is equal to the length of the subtangent, and the semidiameter of the base equal to the ordinate VQ. See Logarithmic.

ASYMPTOTES, are by some distinguished into various orders. An asymptote is said to be of the first order, when it coincides with the base of the curvilinear figure; of the second order, when it is a right line parallel to the base: of the third order, when it is a right line oblique to the base; of the fourth order, when it is a common parabola, that has its axis perpendicular to the base: and, in general, of the order \( n + 2 \), when it is a parabola, the ordinate of which is always as a power of the base, whose exponent is \( n \). The asymptote is oblique to the base, when the ratio of the first fluxion of the ordinate to the fluxion of the base, approaches to an assemblable ratio, as its limit; but it is parallel to the base, or coincides with it, when this limit is not assemblable.

The determination of the asymptotes of curves, is a curious part of the higher geometry. M. de Fontenelle has given several theorems relating to this subject, in his "Geometrie de l'Hirnfin." See also Stirling's "Linea tertii Ordinis," Pref. vi. where the subject of asymptotes is elaborately discussed, and Cramer, "Introduction à l'Analyse des Lignes courbes," art. 145, &c. in which is given an excellent theory of geometrical lines and their branches. The subject is also treated accurately by Mr. Macaulay, in his Fluxions, book i. ch. 10, where he has been careful to avoid the modern paradoxes concerning infinites and infinitesimals. The areas bounded by curves, and their asymptotes, that is indefinitely extended, sometimes have limits which they may approach, so as to differ less from those limits than by any given quantity. This happens in hyperbolas of all kinds, except the 8th, or Apollonian. The same is also true of the area, contained between the logarithmic curve and its asymptote, See hyperbolic curve. Those who do not try to support the curve and its asymptote to be indefinitely produced, say, that the infinitely extended area becomes equal to \( 1/4 \).

The asymptotes are in the common or Apollonian hyperbola, and in many other curves, has no limit; and it is said to say, there are arcs infinitely great; by which, however, no more is meant, than that the curve, and its asymptote,
asymptote, may be extended, till the space comprehended between them exceeds any given magnitude. Some authors, and Dr. Wallis among the rest, have talked of some of these areas, as if they were more than infinite. This happened from an analogy they imagined between positive, nothing, and negative, and what is finite, infinite, and more than infinite. See Hyperbola.

Solids generated by hyperbolic areas, revolving about their asymptotes, have sometimes also their limits; and sometimes they may be produced, till they exceed any given fold. See art. 327, 329. of the above mentioned author. When a curve, and its asymptote, are supposed to be produced infinitely, and the area, comprised between them, to revolve about the asymptote, the surface generated will be finite or infinite, according as the area of the generating figure is finite or infinite.

For the asymptotes of curves, described by the intersections of right lines revolving about given poles, see Mr. Mac- laurin's Fluxions, art. 313. seq.

ASYMPTOTES, Parabolic. See Parabolic Asymptote.

ASYMPTOTIC Spaces. See Hyperbola.

ASYNDETION, derived from the privativa e, and evades. I find together, a figure in Grammar, implying an omission of words, or a defect of those particles that connect the members of a sentence with one another. The want of such particles represents either the celerity of an action, or the haste and eagerness of the speaker. As, in the instance, "veni, vidi, vici," "I came, I saw, I conquered," in which Caesar expresses his conquest of Pharnaces (Suet. in vit. c. 57.); where the copulative e, and, is omitted; or in that of Cicero concerning Catiline, "abit, execut, evadit, erupit," "he is gone, departed, escaped, broke out," or in that verse of Virgil, "Perte eitl flammas, date vela, impellite remos."

This concise mode of speaking adds a considerable emphasis to an expression; and, by bringing the several parts of a subject nearer together, affects the mind with greater force. Thus Cicero (pro Mur. c. 20.) sets Cato's character in a very strong and beautiful light by the use of this figure. "Nature itself has made you a great and excellent man for integrity, gravity, temperance, magnanimity, justice, in a word, for all virtues."

Asyndeton stands opposed to polysyndeton, where the copulatives are multiplied.

ASYNT Point, or Row Steer, in Geography, a cape on the west coast of Scotland, in the county of Sutherland. N. lat. 58° 15'. Long. 1° 58' W. Edinburgh.

ASYPHUS, in Ancient Geography, a mountain of Africa, in the Marmaric. Poloteny.

ATA, or Atatscha, in Geography, a rivulet of Peria, in the province of Schirwan, serving as a boundary to some of the districts into which it was divided.

ATABULL, in Ancient Geography, a people of Africa, placed by Phiny in the small island of Merrie.

ATABULUS, in Physiology, a kind of wind in Apulia, of a dry pinching quality, and very noxious in its effects.

The ancient naturalists speak of the atabuls in terms of horror, on account of the ravage it made among the fruits of the earth, which it fecordered, or withered up.

ATABYRON, in Geography, the name of a mountain in the island of Rhodes, whereas the island itself was denomina
ted Atalyria. The name is supposed to have been derived from Phrenia, where Atabyr denoted a place of good pafs, and it was applied to the Tainos of scripture, belonging to the tribe of Zabulon. On this mountain was situated a temple of Jupiter, hence called Atalyria, much celebrated by heathen historians and poets. Here, fabulous report lays, brazen oxen announced by their bellowings any approaching calamity. The table is explained by supposing that the priests of this temple pretended to be endowed with the spirit of prophecy. Also, a mountain of Sicily, so called on account of a temple of Jupiter Atabryrus, and of Minerva, that was erected on its summit. Also, a town of Phoenicia, according to Step. Byz.: or of Cadyfisia, according to Polybius.

ATACAMA, in Geography. See ATACAMA.

ATACINI, in Ancient Geography, a people of Europe, in Gaul, who inhabited the banks of the Atax (Aude), whence their name, near the Velese Tectofates, and north of the Sardeni. Their capital was Narbo.

ATAHUALPA, in Biography, the son of Huana Capae, by the daughter of the sovereign of Quito, was appointed by his father, when he died in 1529, his successor in the kingdom of Quito; the rest of his dominions being bequeathed by him to Huascar, his elder son by a mother of the royal race. The designation of Huana Capae concerning the succession, excited general dissifcult at Cuzco; and Huascar, encouraged by his subjects, required his brother to renounce the government of Quito, and to acknowledge him as his lawful superior. Atahualpa, having secured in his interest a large body of troops which had accompanied his father to Quito, and which formed the flower of the Peruvian warriors, first eluded his brother's demand, and then marched against him in hostile array. This contest between the brothers involved Peru in a civil war, which terminated in the defeat and captivity of Huascar, and in the extermination of the royal race by the murder of all the children of the sun, as the descendants of Manco Capac were denominate, whom Atahualpa could feize either by force or stratagem. At this time Pizarro, the Spanish adventurer, arrived in Peru; and being solicited by messengers deputed by Huascar, to aid him in subduing his brother, who was represented as a rebel and an usurper, he directed his course towards Caxamalca, a small town at the distance of twelve days march from St. Michael, where Atahualpa was encamped, with a considerable body of troops. The reigning inca dispatched a messenger to Pizarro, as he was advancing, with a valuable present, offering his alliance, and assuring him of a friendly reception at Caxamalca. Pizarro, on his part, returned professions of regard, and a declaration that he was now advancing, as the ambassador of a very powerful monarch, with an intention to offer Atahualpa aid against those enemies who disputed his title to the throne. This pacific and friendly declaration removed the inca's fears; and Pizarro was allowed to march, without interruption, to Caxamalca; in his approaches to which he received renewed professions of friendship from Atahualpa, and additional presents. The peridious Spaniard determined to avail himself of the unsuspecting simplicity with which Atahualpa relied on his professions, and to seize his person during the interview to which he had invited him. Accordingly he made preparations for this purpose; and as the inca drew near the Spanish quarters, with a numerous and splendid train, the friar Valverde advanced to meet him, with a crucifix in one hand, and a brevity in the other; and in a long discourse explained to him the doctrines of religion, and the authority of the pope, eluding his harangue with a requisition, that the inca would embrace the Christian faith, acknowledge the supreme jurisdiction of the pope, and submit to the king of Castile as his lawful sovereign. This requisition was enforced by promises of protection, if he complied, and by threats of vengeance if he refused to obey the summons. The inca hesitated and demurred; he pleading
his right to empire by hereditary succession; he expressed his forbearance that a foreign priest should dispose of territories which did not belong to him, and without the consent of the rightful proprietor; and he professed that he had no inclination to renounce the religious institutions established by his ancestors, and that he could not abandon the service of the True, the immortal divinity whom he and his people revered, in order to worship the god of the Spaniards, who was subject to death. As to other matters, which he had never heard before, and the meaning of which he did not now understand, he desired to know where the priest had learned such extraordinary things: "in this book," replied Valverde, reaching out to him his breviary. The inca eagerly opened it, and turning over the leaves, lifted it to his ear; "this," says he, "is silent; it tells me nothing:" and he threw it with disdain to the ground. The enraged monk exclaimed to his countrymen; "to arms, Christians, to arms; the word of God is insulted; avenge this profanation on those impious dogs." The farce being now completed, the Spaniards rushed upon the innocent Peruvians, incautiously many of them without mercy, and seized the persons of the inca himself, who was detained in captivity. The dejected prince, anxious to regain his liberty, professed a repentance, and such was the amount of it, that the Spaniards themselves were astonished, even after all they knew concerning the opulence of his kingdom. The apartment in which he was confined was twenty-two feet long, and fifteen broad; and the captive monarch professed to fill it with vellums of gold as high as he could reach. Pizarro cloathed with the allying process, and a line was drawn upon the walls of the chamber to mark the stipulated height to which the treasure was to rise. When this immense mass was nearly collected by the faithful attachment and active zeal of his subjects, the inca was allowed to exercise to his own safety the life of his captive brother Huascar; but though the Spaniards divided among them the rich spoil of Peru, the inca was continued in confinement. He now became an object of contention between the Fields of Pizarro, and those that were newly arrived under Almagro; and the latter demanded his life, that there might be no pretext of inequality in sharing the future plunder of Peru, under the notion of its being the inca's ransom. Pizarro at length concurred to sacrifice the inca; and after a mock trial, Atahuallpa was found guilty, and condemned to be burnt alive. Friar Valverde professed the authority of his sacred function to confirm this sentence, and by his signature warranted it to be just. Atonished at his fate, Atahuallpa endeavoured to avert it by tears, promises, and by entreaties that he might be sent to Spain, where a monarch would be the arbiter of his life. Pizarro was uncertain; and the inca was led to execution. Valverde attended him, and attempted to convert him to embrace the Christian faith, by a promise of procuring a mitigation of his punishment. The dread of a cruel death, at length, extirpated from the trembling victim a desire of receiving baptism. The ceremony was performed; and Atahuallpa, instead of being burnt, was strangled at the stake. This event happened A.D. 1533; and thus terminated the life and reign of the last inca of Peru. Robertson's Hist. Amer. vol. iii. p. 29-57.

ATAJA, in Ichthyology, a name given by some writers to a species of Sciaena, observed by Forliak. It is an inhabitant of the Red Sea.

ATAIR, in Astronom. See ALCAIR.

ATAKKENTI, in Geography, a town of Asia Minor, in the province of Natoth, forty-four miles north-west of Ergez.

ATALA, a small town of Sicily, in the valley of De-
ATE

the ancient peninsula Merœ. The Darœina Arabs, who contently live in tents, bear a mortal enmity to all who inhabit villages, and, as occasion offered, have laid waste the greatest part of Athens. The strength of Teaws, says Bruce, was about twenty-five hoes, of which about ten were armed with coats of mail; and they had about a dozen firelocks. The rest of the inhabitants might amount to 1200 men, naked, miserable and despicable Arabs, like the rest of those that live in villages, who are much inferior to the Arabs that dwell in tents. In this desert and poor country, it is not to be expected that trade of any kind should flourish; but there is a miserable manufacture of coarse woolen cloths, of the size of large towels, sufficient to go round the middle, which is current, like specie, all over Attara; they are called "Dinars," and are used instead of silver money. The mahalle, a very bad copper coin, pieces for smaller matters; so that the currency of Teawa stands thus:

| 20 mahale | 1 cruth |
| 12 cruth | 1 matical |
| 4 matical | 1 vakin |

The vahia of gold is worth about forty-five sellings; but the only commerce of Teawa is carried on by exchange, as salt for grain, cornails for salt; the value of goods varying according to the scarcity or plenty of one foot of commodities with respect to the other. Bruce's Trav. vol. iv. p. 406.

ATCHAIRSKOI, a fortress of Siberia, on the Iritth, twenty-eight miles south-east of Omk.

ATCHAK, one of the Fox islands, about 800 versts distant from the Aleutian isles; lying in 56° N. lat. and extending from W. S. W. towards E. N. E. It resembles Copper island, and has a convenient harbour on the north.

ATCHE, in Commerce, a small silver coin, current in the states of the Grand Seignor, equal to about a third part of the English penny. The atche is the smallest coin used in Turkey; where there is no copper money current, except in the province of Babylon. Some call the atche the little sfer; it is flanked like the para, with Arabic characters. Three or four atches are commonly given in exchange for the para.

ATCHEWEAMENT, in Heraldry, signifies the arms, crests, and supporters, which a person has a lawful right to bear, with all the exterior ornaments, as helmet, mantle, motto, &c. &c. See Funeral Achievement.

ATCHEIN, in Geography. See Acheen.

ATCHI Kounip, a lake of America, in Labrador, which conveys its water southerly, through a connected chain of small lakes, into the river St. Lawrence.

ATCHINSK, one of the fix districts of the province of Tomisk, in Russia, situate on the river Tchulym, falling into the Ob. The town is 424 miles E.S.E. of Tobolisk. N. lat. 56° 26', E. long. 124° 30'.

ATE, derived from ous, in Mythology, the daughter of Jupiter, and the goddes of mischief. She was said to come down from heaven by Jupiter, who, deceived by Juno in causing Euristrus to be born before Hercules, was incensed, and manifested his resentment against Ate, as the cause of the offence, by precipitating her from heaven, and swearing that she should never return thither. Homer, i. xix. 125. Mythologists explain the name thus: Ate is the daughter of Jupiter, because evil happens by the permission of providence; and her banishment from heaven to earth signifies the dreadful effects of divine justice among men.

ATECA, in Geography, a town of Spain, in Arragon, upon the river Xalou, two leagues above Calatmaid; sup-

posed by Clunius to be the ancient "Attacum" of the Celtiberians, placed by others at Danoca.

ATEGA, a weapon among the Saxons, which seems to have been a hand-slat. The word comes from the Saxon acten, i.e., short, or throw, and swa, a weapon.

ATEGA, in Ancient Geography, a town of Spain, situate near the river named "Flumen Sallum," or "Salluma." Pompey having passed this river, encamped between Cenabum and Aetega, to oblige Cesar to raise the siege of the latter place; but it was taken in his presence. It occurs in the route from Antioch to Hipsa.

ATELA, a town of Alta Minor, in the Palmyrene. Ptolomy.

ATELLA, in Antiquity, denotes an exemption from tribute, taxes, or other burthens.

ATELLANAE, in Antiquity, a kind of comic and satiric pieces presented on the Roman theatre; somewhat less ludicrous than the farces on the English stage, and yet less grave and serious than the Greek and Latin comedies and tragedies. The atellae, or fabulous atellae of the Romans, answered to the farce among the Greeks. They were thus called from Atella, a city of Sicily, where they were first represented; and from whence, on account of their mirth and humour, they were introduced into Rome. But they became at length so licentious and impudent, that the senate was obliged to suppress them.

ATELLARA, or ATTALLARI, in Geography, a river of Sicily, which runs into the sea between Syracuse and Cape Pafaro.

ATELLUM, in Ancient Geography, a town of Italy, in Magna Graecia, north-west of Venus.

ATEMPTO GIUSTO, in Afica, implies a steady, just time; not very quick, but firm and exact. A tempo, after revocative, a pause, or inducto, implies a return to the first time.

ATENA, in Geography, a small town of Italy, in the kingdom of Naples, on the river Negro, in the Principato Citra, ten miles west of Marisco Novo.

ATER, in Ancient Geography, a mountain of Africa, in the Syrtis Minor, which, according to Ptolemy, extended itself to a considerable distance from the east to the west, and was called by the Romans, "Mons Ater," because it was scorched by the heat of the sun. The mountains tract, known to the ancients by the name of Mons Ater, is now denominated the "Black Harutch."

ATER, in Conchology, a species of MYTILUS, described in Molin. Hist. Chili, p. 177., and said to be frequent on the shores of that country. It is fulcated or grooved, with the posterior part scaly. Gmel. This shell is rough like some species of pisnae; dull blue; fine black, and not estab-

ATER, a species of STROMBUS found in the boggy parts of the island of Ambonua. This shell is smooth, and has the lip separated before and behind. The length is about two inches; colour black, brown, or bay, and white within; very finely ridged transversely; aperture ovate; spire sub-

ulate,
ulate, and consisting of twelve contiguous fleshy whorls. Gmel. Lüttner, &c.—Müll. in his Hist. Verm. Flav. et Terr. describes it as Nerita tetta subulata lavi, apertura antice postice spinata.

**Ater, in Entomology.** A species of Dermehes found in the neighbourhood of Ufpel, and described by Dr. Thunberg, in Nov. Act. Ulf. p. 2. It is glossy black, with the wing-cases thinly punctured. This is a small insect.

**Ater, a species of Hydrophilus, a native of Europe.** This is black and glabrous; antennae and tarsi reddish. Gmel.

**Ater, a species of Byrrh us that inhabits Germany, and in shape and size resembles byrrhus pilula.** It is black and without spots. Fabr. This is *cifera nigra nitens glabra* of Geoffroy.

**Ater, a species of Tenebra found in Europe.** This is of a black colour, with ferruginous antennae. Linn.

**Ater, a species of Carabus that inhabits Denmark.** This is black; wing-cases frigate; claws somewhat ferruginous. Müll. Zoöl. Dan.

**Ater, a species of Cerambix (Callobium Fabr.) found in the east of Venice.** It is black, with truncated wing-cases, and moderate antennae. Scopoli. Gmel. &c.

**Ater, a species of Gryllus (Acheta Fabr.) that inhabits Surinam.** The colour is dark brown, and the tail of the female is unarmed. De Geer Inf. 3.—Gmel.

**Ater, a species of Cimex (Cicindelar Sec.) This insect is glossy-black, with the apex of the wing-cases very pale. Fabr. Mant. Inhabits Germany, and is about half the size of cimex zofcrea.

**Ater, is also a species of Cimex in the Linnean En. Sv. 944.** The body is entire, and in Gmelin's arrangement it belongs to the fection oblongus. Geoffroy describes it as being black and oblong, and the antennae terminating each in a bristle or hair. Inhabits the north of Europe and Calabria.

**Ater, a species of Cynips, described by Scharao among the insects of Germany, and which form and inhabit very large excrections on the fomes of plants.** It is black, with elevated dots; tarsi of the legs paler.

**Ater, a species of Bombylius described by Scopoli, Scheffer, &c. It inhabits Germany.** The color is black; base of the wings half black; abdomen spotted with white. Fabr. Spec. Inf.—Front of the head and thorax downy, and a white dot before each eye.

**Ater, a species of Asillus found in Europe.** It is black and hairy, with a white beard. Tn. Sv. Scopoli calls it erax prolattus.

**Ater, a minute species of Ips found in England by Mr. Kirby, and described by Mr. Marham, Ent. Brit. It is subcylindrical and black; thorax dotted with impressed points, and carinate along the middle; wing-cases with crenate fisses; foles of the feet pitchy black.—General colour black.**

**Ater, in Natural History, a species of Asgus or Oake.** It inhabits Ceylon; black, fuscated with white, and the scales tiset with black. Laur. Amp. This is amphibiae cecidonia femina of Seba; and augus ater, black-banded flow-worm of Dr. Shaw.

**Ater, a species of Limax (flag or snail), the body of which is black and ruged. Müll. Gmel. of this kind there are several varieties; the first (a) is black, and pale beneath; it is figured by Lüttner, exc. nat. tab. iii. f. 1.—5., and is probably cocklea nudus of Gers. The second variety (b) is black, with a pale greenish dorsal ridge. The third (c) is described by Swammerdam; it is Vol. III.**

black above, white beneath, and the mouth yellowish. The fourth (d) is limax fabrius of Lüttner; the colour of which is chestnut-brown above, white beneath, and mouth yellowish. The fifth kind is of an obscure brown, with a yellowish mouth and fires on each side.

These are found in woods, meadows, and gardens. The length is from an inch and four lines to five inches. The feelers are black in all; the shield rough, with many punctures; back and belly deeply furrowed or wrinkled.

**Ater, in Ornithology, a species of Falco that inhabits Europe.** The cere and legs are yellow, body above brownish-black; and the head, white; tail forked, Gmel. This is a kind of kite, and is somewhat smaller than the common species, *micans*. Buff. calls it milvis nigre; Buff. milan noir; and Cramer, brunnermelnyggeyer. It is also the black gled of Sibbald, and black kite of Latham.

**Ater, a species of Psittacus, of a black colour, glossed with green, with bill and eyes red, and yellow legs.** This is the black maccaw of English writers; ara noir of Buff.; and arauna on machao de la Lact, &c. It lives about the summits of the dry mountains and rocky places in the interior parts of Guiana, and in that respect differs from the other kinds of maccaw found in that country. Buffoon speaks of it as a species well known to the inhabitants of Guiana, but had never seen it; and observes, that though the plumage is black, it is so blended with green, that in the sunshine it has a molt splendid appearance.

**Ater, the Gmelianian specific name of the crested black cuckow of Latham; a kind of Cuculus, with a wedge-formed tail; body shining, black; feathers of the head elongated into a crest; and the first five quill-feathers white at the base. This bird is a native of Africa, being found at the cape of Good Hope, and it is conjectured may be only a variety of cuculus ferratus.**

The length of this kind is twelve inches; the bill an inch and a quarter in length, and rather incurved. Buffon says in his specimem, the tail feathers are not regularly cuscated. The same author supposes his Jacobin huppè de Coromandel, or Coromandel crested cuckow, to vary only through the difference of climate.

**Ater, a species of Parus, that inhabits the woods of Europe and North America, and is known in England by the name of the colemeone.** The head is black; back cinereous; back of the head and breast white. Gmel. &c. The bill and chin of this bird is black; vent, reddish; quill and tail feathers brownish-ash; legs and claws lead-coloured.

**Ater, a species of Parus, called in England the Colemeone.** It is smaller than the blue titmouse, and is pretty common in woods, orchards, and gardens; feeds on insects, and lays a number of eggs. This bird is found throughout Europe, and inhabits likewise Siberia, and some parts of North America. Linneus (Tn. Sec.) describes it specifically as having the head black; back cinerous; hind-part of the head and breast white. Scop. Cram. Gmel. &c. This is parus atricapillus, la mangelja a fete noire of Brifon, av. la petite charbonniere of Buffon; Fritsch calls it kohlmiege.—General description. Length four inches; weight two drachmas; bill black; throat, as well as the head, of the same colour; from the bill, on each side, a broad band of white passing just under the eye to the sides of the neck; between the brist and vent, rufous white; wing-coverts grey, tipped with white, forming two bands of that colour; quill and tail feathers brownish-ash, bordered with grey; tail rather forked; legs and claws lead colour.

**ATERGATIS or Atargatis, called also Denteis, in Mythology.**
Mythology, a goddes of the Syrians, supposed to be the mother of Semiramis. She was represented with the face and breasts of a woman, but the rest of her body resembled a fish. Vossius says the term signifies without fish, and conjectures that the votaries of this deity abstained from fish. According to Antipater, the sylvic philosopher of Tarbus, in his treatise on superition, Atergatis is compounded of ἄτερ, without, and θεῖα, the name of a Syrian queen, who being very fond of fish, forbade the use of it to her subjects; and the Syrians, it is said, did not eat fish. Fabulous report says, that Atergatis was taken with her son Inthys, by Mopsus king of Lydia, who drowned them both in a lake near Afalon, where they were devoured by fishes; and hence, it is added, proceeded the horror of the Syrians against this sort of aliment. Atergatis, lyked Dercetus, says Bryant (Anal. An. Myth. vol. ii. p. 258.), is a compound of ἄτερ or ἄθανος, the same as On or Oiris, an Egyptian deity, and of γατός or catōs, rendered אכילות by the Ionians, a fish. Dagon, Sisdon, and Dercetus, were all names of the same hieroglyphic, and related to the person called Oanes by Berofus and others, and also to the machine wherein he was preferred. He lived both before and after the flood; he was represented at Babylon with two heads; and in other places he was differently exhibited. The meaning of which, according to this writer, was this, that though Oanes was really a man, yet he was typically esteemed an animal of the sea; and on that account they represented him with the skin and scales of a cetaceus or fish. All these characters were originally taken from hieroglyphics in Babylonia; they relate to the name history, and to one particular person who had escaped the waters when the earth was overflowed; and through whom arts and sciences were supposed to have been renewed in the world. Semiramis, whom the generality of historians have represented as a great princeps who reigned in Babylon, is described by other writers as a deity. Thus Athenagoras (Legatio, p. 307.) says, that "the Syrians worship Semiramis;" and he adds, "that she was esteemed the daughter of Dercetus, and the same as the Sura Dea." Diodorus also (i.ii. p. 92.) makes her the daughter of Dercetus by Suras; but Suras, says Bryant, was the sun, and the Deus Sura, was Deus solaris. Hence, many have considered Rhea, Isis, Aiartes, Atergatis, and Semiramis, as one deity. Lucian, (De Sura Dea, vol. ii. p. 885.) tells us, that they were so esteemed by the Syrians of Hierapolis. According to Bryant, they were all different symbols relating to the same object. See Semiramis. It has been also supposed, that the Atergatis, or Derceto, of the proper Palese in general, or of Afalon in particular, was the Babylonian or Aryan Venus. To this purpose Strabo (i. xvi. p. 748.) says, that Atergatis was worshipped at Hieropolis, and he makes her the same with the Syrian goddesses. Others are of the same opinion (Plin. H. N. l. v. c. 23.); and among them Macrobius (in Saturn. l. c. 23.), who styles her the mother of the gods, Altars, and the Hieropolitan or Aryan goddesses. Upon the whole, we may observe, that Atergatis was Venus, Juno, Minerva, Altars, the Syrian goddesses, and consequently the celestial Venus of the Syrians. So that we see her the same goddes transported from the banks of the Euphrates, into which she is said first to have plunged herself, in order to escape the inexorable Typhon (Man. Astron. iv.); and but just varied so far as to leave room for each particular country to claim her origin. The Syrians, who seem to have received her first, and who were nearest to the place of her native abode, preferred her, it is likely, in the most genuine form; the Phoenicians, who were next, altered her no farther than to make her a Phoenician; and the Philistines, or Afalonites, who were a little farther off that they too might make her their own, converted her into a monster, woman upwards and fish downwards; they allowing her to have been in subordination to some other goddesses, who had such power over her as to chastise her by metamorphosis from her just shape. It appears, then, that the worship paid to this goddess was originally derived from Assyria and Babylonia, and was established in other countries by the prevailing power of these two empires. We may also conclude, that the celestial Venus of the Assyrians, Altars, the Phoenicians, and the Derceto or Atergatis of the later Philistines, were all derived from Semiramis, the first real or reputed foundress of Babylon; who seems to have been translated into the queen of heaven the moon, as Belus or Pal, the first Assyrian monarch, was changed into the sun; that all the Jupiter and Junos, and the veil who are supposed to have been once mortal, or converted on earth, are derived from this source; and that, on this Assyrian or Babylonian foundation, the whole superstructure of the Greek polytheism and idolatry was erected. For the Greeks had their religion from the Phoenicians partly, and partly from the Egyptians, who derived theirs originally from the banks of the Euphrates and Tigris, as may be gathered from the religious state of the countries on either side of the Euphrates in the days of Abraham. The Egyptians, indeed, seem in process of time to have erected a system of their own, though not very widely different from the Babylonians and the Phoenicians, who had equally communication with the two nations, seem to have mixed both systems. See Idolatry, and Polytheism.

ATERIUS, a town of Italy, in Samium, belonging to the Marrucini, situated on the sea coast at the mouth of a river of the same name, now called Pescara.

ATERIUM, in Conchology, a species of Nerita, figured by Chemnitz. The shell is thick, opaque, globose, very black, with coloured lines; within white; exterior lip glabrous, inner one tuberculated. Gmel. & c. This kind is very minutely flarated, and its habitat unknown.

ATERIUM, in Entomology, a species of Blatta, of a black colour, and dilatate of spots; the tarsi of the legs are white, knees brown, shanks fimbrius. Herb. This inhabits India.

ATERIUS, a new British species of Chrysomela, described by M. Marshall, Ent. Brit. It is black and shining; thorax highly glossy; wing-cases flarated; legs rather ferruginous.

ATERRIMUS, a species of Curculio, very common in Europe. This is black, with the wing-cases shining. Linn. Fz. Sv. Fabr. &c. Gmelin has also another species of Curculio under the same name; this is of an oblong form, and black colour, with rufous antennae. It inhabits Europe, and it is presumed may be only a variety of Curculio chloropus.

ATERRIMUS, a species of Carabus, entirely of shining black, with a roundish thorax; wing-cases faintly flarated, with four excavated dots near the future. Herb. About half an inch in length.

ATERRIMUS, a species of Elater, found in the north of Europe. The thorax is glosy black; wing-cases black and flarated. Fabr. This is elater utrer, thorax opaco punctato elytrorum flaratis of Linn. Fam. Succ.; and elater tuncto nitidus of Geoffroy.

ATERRIMUS, a species of Ciceta, (Rotundatus Sec.) that inhabits Spain. This insect is deep black, with half the wing-cases transparent. Forst. Nov. Inf.
ATH

ATHENIUS, a species of SCARABAUS (Coquin). It is of a dull black, with obscure russet spots on the wing-cases. Fabricius. It inhabits the cape of Good Hope.

ATHENIUS, in Ornithology, the specific name of the great black Cockatoo of New Holland, a bird of a black colour, with a large and paler crest, and red naked cheeks. Gmel. This kind of Pittacus is called by Buffon kakatoès noir; and is the great black Cockatoo of Edwards. Gloe. t. 315.

ATHENS, or ETTM, in Ancient Geography, a Roman colony settled to the south-west of Patavium in the Venetian territory.

ATTICA, or ATH, in Geography, a country of Egypt, on the east coast of the Nile, 35 miles south of Cairo. It is situated at the foot of a mountain, upon a narrow canal, formed by a pretty large island. Some geographers have supposed that this town or village occupies the site of the ancient city of Vena, or Aphroditeopolis. N. lat. 29° 28′. E. long. 31° 15′.

ATFLOW, Edward, in Botany, studied at New College Oxford, where he took his degree of Doctor in Medicine in 1666, and was in much repute as a physician, particularly among those of the Romish persuasion. He was imprisoned several months; Ant. Wood says, corresponding with Mary Queen of Scotland. The time of his death is not known.

ATHENIUS, or ATH, among our ANGL.SAX. ANCESTERS, signifies an ath, especially that taken by way of purgation. In this sense we meet with breaking of ath, privilege of ath, atha, and arthia.

ATHENIUS, in Geography. See ATH.

ATHABASCA, RIVERS, LAKES, AND COUNTRY, lie in the north-west part of North-America, in about N. lat. 58° 40′, and W. long. 111° 40′. The Elk river is commonly called by the white people the Athabasca river, in N. lat. 56° 42′. In the territory that lies between the Peace river and the lake of the hills, as far as the Elk river which is formed by the quantity of earth and mud that is carried down by the streams of these two great rivers, there are several lakes; the lake Clear Water, which is the deepest, lake Vitting, and the Athabasca lake, which is the largest of the three, and whose denomination in the Indian language implies a flat, low, swampy country, subject to inundations. The two left lakes are now so shallow, that, from the cause just mentioned, there is every reason to expect, that in a few years they will have exchanged their character, and become extensive forests. This country is so level, that at some seasons it is entirely overflowed; and this circumstance accounts for the periodic influx and reflux of the waters between the Lake of the Hills and the Peace river. Till the year 1782, the people of Athabasca feast or carried their furs regularly to Fort Churchill, Hudson's Bay; and some of them have since that time repaired thither. The present trading establishment is situated on an hill bank on the north side of the lake Le Piane, in N. lat. 48° 37′, where the people from Montreal meet thither from the Athabasca country, and exchange furs with them. The traffic to Fort Churchill is now in a great measure discontinued, as the Chippewas were obliged to expend in the course of their journey that ammunition which was its most alluring object. See CHIPPEWAN. Mackenzie's Voyages, Introd. p. 56–91.

ATHABASCA is by some called ARATHALPESCOW, and ATTHAPESCOW, and ATTHAPESCO.

ATHABOLI, or ACATOPOLI, a town of European Turkey, in the province of Romania, 68 miles north-east of Adrianople.

ATHAMADULET, or ATTHAMADULET, the prime or chief minister in the Persian empire.

The Athamadulet is much the same with the grand vizier in Turkey, except that he has not the command of the army, which the vizier has.

The Athamadulet is great chancellor of the kingdom, president of the council, superintendent of the finances; and has the charge of all foreign affairs. He is in effect vicerey or administrator of the kingdom: he issues the king's mandates, or orders, in this style: "Bende depra ali il aline etmadulet," that is, "I, who am the support of the power, the creature of this part, the highest of all ports, &c."

ATHAMANIA, in Ancient Geography, a country of Greece, at the source of the river Achelous, in Atolus, according to Piny; but in Ilium, according to Steph. Byz. Some have made it a part of Thessaly, and others of Epirus. According to Polybius, it was divided from Epirus by the bay of Ambraicia; and according to Strabo, from Atolus, by the river Achelous. M. D'Anville places Athisania between the chain of the Pindus to the east, and a parallel chain to the west. In the midst of this valley ran the river Avas. To the south of this country were the Molossi and Aperantes, to the east the Perinthis, and its capital was Argyraida. At their commencement the Athamanians were a very inconsiderable people; but they appeared with distinction in the wars of the Romans and Atolus against Macedonia, towards the year 157, B. C. Livy relates that the Atholians chose Ammianer, king of the Athamanians, for their mediator in their contest with Philip, and that the Romans solicited his assistance to this end. Their dominion extended over the whole chain of the mountains of Epirus; and they seem to have subsisted at least a century before the war of Troy.

Species, 1. A. Libanotis, mountain spicgel, or rose-paney. With. Smith. Brit. Reln. Cantab. t. 113. Eng. Bot. 158. A. Oreoq. Huetf. "Leaves bipinnate; flat; umbel hemispherical; feeds hieratus." Root perennial, spindle-shaped, woody; stem about two feet high, erect, rather branched, smooth, angular and furrowed, leafy; leaves bipinnate, alternate; leaflets seiso, opposite, pinnatifid, flat, acute, veined. palis, on the under side, a little hieratus; pételos dilated at the base with a membranous margin; umbels cret, hemispherical, flat, and sometimes proliferous; involucres and involucels patent-dolfs, bent with hairy leaves; flowers white, small, uniform, and regular; fruit pubescent; styles penitent, purple, divericate. It grows on Gogmagog hills, Cambridgethire, and flowers in August. It is common in many parts of Sweden, Denmark, &c. 2. A. cerovialis, broad-leaved spicgel, or black hart-root. Jacq.
A T H

Auff.T. t. 69. "Leaves pinnate, decussated, gaft-angled; seeds naked." Root perennial; stem five feet high, firm branching; leaves glaucous, smooth, with black veins underneith, and five pairs of pinnae. Most of the leaves are sessile, ellipti¬cal, acuminate, toothed; corolla white, with a purple outside. A native of the mountains of France, Swifefeld, Germany, &c. 3. A. fiscnta, Siberian fpi¬gnel. Gmel. Sib. 1. 165. u. 3. t. 40. f. 1, 2. "Leaves pin¬nate, gaft-angled." The descriptions of this plant by Lin¬eus, Goun, and Scopoli, are so widely different, that we cannot fuppofe they mean the fame plant. 4. A. cantenfata, clofe-headed fpi¬gnel. "Leaves fubpin¬nate; leaflets imbricate downwards; umbel fex-form." Root perennial; stem ftipulate, a foot high, angular, furrowed; leaflets alternately pinnatifid; umbel very fhole, convex on both fides, placed on branches arifing at the axils. A native of Siberia. Introduced in 1737, by the earl of Bute. 5. A. Orefchiunum, Divaricatet fpi¬gnel; "leaflets divaricate." Root perennial; stem leaves very large, firm, smooth, triply pin¬nate, divided at right and even obfolute divisions; divisions broad, not toothed, but two or three lobed; stem two feet high; petals white, with a blufh of rofe colour. A native of Germany, Sweden, France, &c. 6. A. fiscula, fix-weed-leaved fpi¬gnel. "Lower leaves fufing, primordial umbels fubfufia; feds hairy." Root perennial; items nearly three feet high. The umbels at their first appearance are very compact, but afterwards fpread open and divide into feveral small umbels. The flowers are white, and fuced by oblong woolly fruit. A native of Sicily. Cultivated in England in 1713. 7. A. cretenfis, Cretan fpignel or candy carrot, Jacq. Auff. 1. 62. "Leaflets linear, flat, bifurate; petals two-parted; feds oblong, bifur¬cate." The whole plant in its wild state is fupple; when cul¬tivated it becomes fucculent, brittle, and very fining; item ftricken; leaves tripinnate; pinnales deeply two or three-parted. The universal involucre conflits of five, the partial of from four to seven leaflets; petals white. A native of the south of Europe, flowering in June. The feds have been medicinally employed for the fame purpofes as thofe of wild carrot (fee Daucus). 8. A. annua, annual fpi¬gnel. "Leaves many-parted, divisions linear, roundift, acuminate." It is a native of Candida or Crete, and was introduced in 1770, by Monf. Richard. 9. A. chinensis. "Seeds mem¬braneous, bifurcate; leaves hyperdcomposed, polished, multilit." Stem angular, smooth; leaves like thofe of chro¬phyllum, and smooth; umbel not much expanded. A native of China. 10. A. rapiger, Villars Dauph. 2. 648. "Leaflets bifitate, recurved, fumifh; all the flowers fertile." Stem eighteen inches high; branching finely ftricken; leaves bipinnate; universal involucre two, partial many-leaved; petals white; feds downy. A native of Carriada and Dauphiné. Villars oppofites this to be a var¬iety of the feventh species.

Propagation and Culture. All these plants are propagated by feds, which fould be fown in a bed of light dry ground in autumn, and in the following autumn planted at a foot distance in a bed of light sandy earth, where the roots will continue several years, except the eighth species, which is an annual. The thirteenth has not yet been cultivated in Eng¬land, and will probably require fhruction.

Athamala Meal. See Athusa Meeum.

A T H A N A S. in Entomology, the name given to a spe¬cies of Papilio in Drury's Inf. that inhabits India and South America. It is Papilio Pyrrhus of Linneus and Fabricius. See Pyrrhus.

A Thane, a town of Arabia Felix. Pliny.

A T H A N A G I A, a town of Hilpia citerior, and the capital of the Hergeti, according to Livy, who relates the manner in which this town was fubbected by Scipio.

A Thanasia, among the Ancient Physicians, an epi¬thet given to a kind of antidotes fupposed to have the power of prolonging life, even to immortality.

In the Auguwan difpensatory we flall find a medicine under the appellation of athanasia magna, commended againft dyfenteries and fermentitious qualities.

Species. 1. A. fynvarofa, crof-leaved athanasia, retiaha squaroa, L'Herit. Angl. n. t. 29. "Pedenules one¬flowered, lateral; leaves ovate, recurved." An underfhrub. Leaves alternate, bifitate, pointed, smooth; pedun¬cules axillary, longer than the leaves; chaffs linear, the length of the fators. Introduced in 1774, by Maffon. 2. A. fffifflora, fefifie-flowered athanasia, Rel. latr. l'Herit. 60. "Pedenules one flowered, shorter than the leaf; leaves linear, hairy." A very small plant, found at the Cape by Thunberg. 3. A. pani/la, dwarf athanasia; Rel. pedunculata, L'He¬rit. l. c. "Pedenules one flowered, longer than the leaf; leaves linear, hairy." This is also a small cape plant, difco¬vered by Thunberg. 4. A. orvina, notch-leaved athanasia; "flowers folitary, terminal; leaves linear." Stem thrubby; leaves alternate, obfetely three-cornered; one terminal flower. 5. A. orfifera, one-flowered athanasia; Rel. cu¬rata, L'Herit. l. c. "Flowers folitary, terminal, bifulate; leaves obovate, imbriate, fmoitf." A native of the Cape, difco¬vered by Thunberg. 6. A. epifata, hairy athanasia; "flowers terminal, bifulate; leaves lanceolate, bifurate." This has the appearance of bifphallium capecife, but the leaves are alternate; the flowers are difcoifed and floculofe. A na¬tive of the Cape, and introduced in 1774, by Maffon. 7. A. maritima. (See Santolina Maritima.) 8. A. genifojofa, broom-leaved athanasia; Rel. genif. L'Herit. 60. "Coryms fimpie; leaves lanceolate, undivided, naked, croud¬ed." Stem underfhrubby; leaves biflicate, marked with very fhort lines, fmoitf, somewhat keeled, blunts; coryms small, with three or four bifulate flowers. 9. A. popenfis, villof-leaved athanasia; "coryms fimpie; leaves lanceolate, undivided, villof." This rifes fix or feven feet high. Flowers yellow. 10. A. annua, annual athanasia; "coryms fimpie, contracted; leaves pinnatifid, toothed." Root annual; item about nine inches high, branched at the top; leaves fmoitf, cut into fegments like thofe of buck's horn plantain; flowers of a bright yellow, large. Cultivated by Miller in 1768. (8.) Achillaka inodora, Lin. Sp. Pl. l. 1. A. trifurtata, tritiled-leaved athanasia; "coryms fimpie; leaves threc-leaved, cufiform." Shrubby; five or fix feet higb; leaves
Leaves flat, glaucous, cut at the extremity into three segments; flowers of a bright yellow colour. Cultivated here in 1714. 12. A. crithmifolia, fampshire-leaved anthenia; fantelina, Mill. fig. t. 227. f. 2. "Corymbs simple; leaves semitrifid, linear," divided, more than half their length into three or five narrow segments; flowers yellow. Cultivated in 1726 by Miller. 13. A. linifolium, flax-leaved anthenia; "corymbs simple; leaves linear." Stout round, smooth, like that of flax; leaves alternate, perfectly simple, linear, or subulate, flowers in a terminal corymb ovate and smooth. Found at the Cape by Maffon, and introduced in 1774. 14. A. dentata, tooth-leaved anthenia. (2.) A. keigwata, Lin. Spec. 1181. "Corymbs compound; leaves recurved, the lower linear, toothed, the upper ovate-ferrate." Shrubby, three feet high, with pale yellow flowers. Introduced in 1780, by the counts of Strathmore. 15. A. parviflora, small-flow- ered anthenia; tanacetum crithmifolia. Lin. Spec. 1182. Mill. Dict. No. 6. "Corymbs compound; leaves pinnate, linear." Stem thick, shrubby, fev' en or eight feet high. The leaves fit close to the branches, which are terminated by roundish bunches of bright yellow flowers. It was introduced in 1774 by Maffon. 16. A. pinifata. "Corymbs dense, compound; leaves pinnate, linear, tomentofo." Stem proliferus, shrubby, tomentofo; leaves crowded with five or seven pinnae; calyxes vilif.te. 17. A. pellifata. "Corymbs compound; leaves pinnate, smooth." Found at the Cape by Thunberg. 18. A. dentata. "Corymbs compound; leaves lanceolate toothed, ferrate." Found at the Cape by Thunberg. This differs from the 14th, though it has the same name. 19. A. filiformis. "Corymbs compound; leaves linear, smooth, spreading." This also was discovered at the Cape by Thunberg. 20. A. cinarca, lavender-leaved anthenia. "Corymbs compound; leaves linear, tomentofo, entire." Introduced by Maffon in 1774. All the above species are natives of the cape of Good Hope, except the seventh, and they are all perennial except the tenth.

Propagation and Culture. These plants, with the exception of the annual forl only, may be propagated by cuttngs or slips during the summer months, and planted in pots or upon an old hot-bed closely covered with glasses, shading them during the heat of the day, and occasionally refreshing them with water; they will put out roots in five or six weeks, and in two months they may be taken up and planted in pots filled with light earth, and placed in a shady situation until they have taken new root. After this they should be removed to a sheltered situation, mixing them with other exotic plants, where they may remain to the middle or end of October, when they are to be placed in a dry Rove or glass cafe, where they are to be allowed as much free air as possible, but secured from frost. The annual species is to be propagated by seeds sown on a moderate hot-bed the latter end of March, and as soon as they are advanced enough to remove, they should be transplanted to another gentle hot-bed, at the distance of three inches from each other, observing to shade them till they have taken new root. About the end of May they will be strong enough to be transplanted into the open air, and may be planted in pots to place among other exotics. The British species should be protected from the cold in severe winters.

See Martyn’s Miller’s Dict.

ATHANASIUS, SAIN'T. See Creed.

ATHANASIUS, SAIN'T, in Biography, a celebrated Christian bishop, flourished in the fourth century, and is a native of Egypt, probably of Alexandria. He has transmitted to us no records of his parentage, nor of the precise time and place of his birth. The attention of his early years seems to have been principally devoted to theo-
party regarded him as a saint; and the other represented him as a wicked disturber of the peace of the church. Constanus, however, was intent upon reforming him, and peremptorily demanded it of his brother Constans, threatening him with war in case of non-compliance. Constans submitted, and solicited the return of the exiled prelate to take possession of the Alexandrian see, which was now become vacant by the death of Gregory. The bishop's zeal for the Catholic doctrine of the trinity was not in the least abated by all the reverses of his condition; for in his progress through the various cities that lay in his way to Alexandria, he admonished the people to avoid the Arians, and to admit into their communion none but those who adopted in their creed the words "confessional." In the year 350, he arrived at Alexandria, and was welcomed by his old friends and adherents with every expression of joy; and from this time he enjoyed a short interval of repose. The death of the emperor Constans, and of pope Julius, to whom he was chiefly indebted for his restoration, threatened him with new dangers. Constans was his determined enemy, and he summoned a general council at Arles, in the year 353; and in this council the Arius party prevailed, and all the bishops present, with one exception, signed the condemnation of Athanasius. As Liberius, the successor of pope Julius, was distant from the proceedings of this council, another was held at Milan in the year 355. Here the emperor exercised his utmost influence, and at length a majority of 350 bishops concurred in the condemnation of Athanasius, and those who refused were exiled by the authority of the emperor. The sentence of these councils, however, was cautiously executed by Constans. The prelate was persuaded voluntarily to abdicate his see; but he remained insatiable, notwithstanding all the measures that were used for this purpose. During this interval, a body of soldiers appeared in the midst of Alexandria, and at midnight they invaded the church in which the bishop and his attendants were performing their devotions preparatory to the communion. In this moment of confusion and terror, the prelate remained firm and intrepid, calmly expecting death, and animating the piety of his flock by ordering a psalm of praise to be sung. At length the congregation dispersed, and the bishop was conveyed through the tumultuous crowd to a place of safety. The see of Alexandria was bestowed by the emperor upon George of Capadocia, a strenuous supporter of the Arian cause; and Athanasius was proscribed, with the promise of a large reward to any one who should produce him dead or alive. The persecuted prelate disappeared, and remained for six years in imperceptible obscurity. The place of his retreat was the desert of Thibs; and among monks or hermits anxious to preserve him from the search of his enemies, he found an un molested asylum. From this recluse abode he is said to have sometimes extended his excursions in disguise to visit his confidential friends at Alexandria. Hence he also addressed his enemies with invective, and his friends with consolatory admonitions by his writings. The accession of Julian, who succeeded Constans in 361, and the death of George, bishop of Alexandria, who was in the same year killed in a tumult, opened the way for a third return of Athanasius to the see of Alexandria. With unabated zeal for the Catholic faith, and particularly for the doctrine of the trinity, he summoned a council at Alexandria, at which it was determined, that Arian bishops, who recanted their errors, and signed the Nicene creed, might be admitted to the communion of the church, and restored to their sees. However, Athanasius's endeavours and influence were of short duration. The emperor Julian regarded him with peculiar aversion; and in order to avoid the threatenedJackson of his displeasure, the prelate was obliged again to seek an asylum in the monasteries of the desert. While with this view he was falling up the Nile, his enemies followed him; but as soon as the prelate was informed that they had orders to apprehend him, and knowing that he must soon be overtaken, he instructed the mariners to turn about the boat and meet his pursuers. Having no suspicion that Athanasius was on board, they proceeded to Alexandria, and conveyed himself till the death of Julian in the year 363. Upon the accession of Julian, Athanasius once more retained his episcopal functions, and under the patronage of the emperor, the Nicene creed became the general formula of the churches. After the short reign of Julian, Valens succeeded to the eastern division of the empire; and as he had adopted Arian principles, he fined edicts for banishing the bishops who had regained their sees under Julian; and Athanasius was again in the number of those who were proscribed. The efforts of his friends at Alexandria were exerted in his favour; but whilst they were preparing to defend him by force, he thought it most prudent to retire; and on this occasion, which has been denominated his fifth exile, he concealed himself for four months in the monument belonging to his family. The emperor reinstated the castell; and the venerable prelate closed his days in tranquillity in the 40th, or as some say in the 48th year of his prelacy, and in the year of Christ 373.

It is not easy to form a just estimate of the talents, learning, and character of Athanasius, amid the admixture of his friends, and the reproaches of his enemies. "The immortal name of Athanasius," says Mr. Gibbon, "will never be separated from the Catholic doctrine of the trinity, to which he devoted his life; every day, every year, every faculty of his being."—Amidst the inflamed passions of his times, he was patient of labour, jealous of fame, careless of safety; and though his mind was tainted by the contagion of fanaticism, Athanasius displayed a superiority of character and abilities which would have qualified him, far better than the degenerate sons of Constantine, for the government of a great monarchy. His learning was much less profound and extensive than that of Eustochius of Caesarea, and his rude eloquence could not be compared with the polished oratory of Gregory or Basil; but whenever the prince of Egypt was called upon to justify his sentiments or his conduct, his unpremeditated style, either of speaking or of writing, was clear, forcible, and persuasive. He has always been received in the orthodox school as one of the most accurate matter of the Christian theology; and he was supposed to possess two profound sciences. He adapted himself to the episcopal character, the knowledge of jurisprudence, and that of divinity. Some fortunate conjectures of future events, which impartial reasoners might be f bringing to the experience and judgment of Athanasius, were attributed by his friends to heavenly inspiration, and imputed by his enemies to infernal magic. But as Athanasius was continually engaged with the prejudices and passions of every order of men from the monk to the emperor, the knowledge of human nature was his first and most important science. —" Athanasius was capable of distinguishing how far he might boldly command, and where he must dexterously inimitable, how long he might contend with power, and when he must withdraw from persecution; and while he directed the thunders of the church against heresy and rebellion, he could assume, in the bosom of his own party, the flexible and indulgent temper of a prudent leader. The election of Athanasius has not ceased to the reproach of irregularity and precipitation; but the propriety of
of his behaviour conciliated the affections both of the clergy and of the people. The Alexandrians were impatient to ride in arms for the defence of an eloquent and liberal papal. In his edicts, he always derived support, or at least conflation with the faithful attachment of his parochial clergy; and the hundred bishops of Egypt adhered with unqualified zeal to the cause of Athanasius. In the model epigraph which pride and policy would affect, he frequently performed the episcopal visitation of his provinces, from the mouth of the Nile to the confines of Ethiopia; familiarly conversing with the means of the populace, and humbly fultating the fants and hermits of the desert. Nor was it only in ecclesiastical assemblies among men whose education and manners were similar to his own, that Athanasius displayed the ascendency of his genius; he appeared with cally and respectful in the courts of princes, and on the various turns of his prosperous and fortunate career, he never lost the confidence of his friends, or the esteem of his enemies."

The works of Athanasius were numerous, and confided chiefly of apologetics for himself, or invectives against his enemies, or controversial treatises against Arianism. His style is clear, cally, and not deficient of dignity and ornament. In his reasonings he is sufficiently copious; and in his attacks upon the Arians more than sufficiently acrimonius. The more valuable of his genuine writings are his first book "Against the Gentiles," "Apologies," "Letter to those that lead a Monastic Life," "Letters to Serapion," "Two books on the Incarnation," "Conference with the Arians," "The Life of St. Antony," and "The Abridgment of the Holy Scriptures." The latter of these pieces contains an enumeration of all the canonical books of the Old and New Testament, with a summary of their contents, and an account of their respective authors; and it treats particularly of the four gospels. This "Abridgment or Synopsis of the Holy Scriptures" has been reckoned genuine by some; but it is supposed by others to have been falsely ascribed to him, and in the Benedictine edition of his works, it is rejected. His "Psalms and Psalms Epistle," which is generally allowed to be genuine, contains several valuable testimonies in favour of the sacred books now received as canonical.

Dupin, and also Cave, have distinctly enumerated both the genuine and fictitious works of Athanasius. For an account of the latter, see Cave. The works of Athanasius were first printed only in a Latin translation, and in an imperfect state by Calamaus, in Venice, in 1492; and enlarged editions appeared at Paris, in 1520; at Rome, in 1523; at Cologne, in 1524; at Paris, in 1528; and at Paris, in 1568. The Greek text was first published in 2 vols. fol. by Campanus, in Heidelberg, in 1601; and at Paris, in 1627. The best edition was printed in 3 vols. fol. by a learned Benedictine, Bernard de Montaureon, at Paris, in 1618. This was reprinted with improvements, and an additional volume, at Padua, in 1774. 4 vols. fol. Sacra-

ATHANOR, sometimes corruptly written Acanor, is a term derived from the Greek Ἀκανός, London, and was ap-
plied by the ancient chemists to a species of furnace provided with a magazine of fuel, by which a long-continued heat might be kept up without the necessity of constant attend-
ance. Some say that the word athanor is borrowed from the Arabs, who call an oven Tamaror, from the HebrewTamur, an oven or furnace; whence with the additional word Ἀκανός, Tamaror, &c. This apparatus was particularly used in those tedious alchemical processes which were deemed necessary, in order to convert the inferior metals into gold; hence it is not unfrequently described by the name σμειρίακες. The patience of modern chemists being inferior to that of their predecessors, or rather being no longer upheld by the hope of riches, the most powerful, and at the same time, the most difficult of all motives, revolves from the idea of commencing experiments that demand weeks, and even whole months for their completion. Hence it is, that perpetual lamps and furnaces are now become obsolete.

The body of the athanor may be varied at pleasure, ac-
cording to the particular purpose which it is intended to serve, but it is connected by the top, or one of the sides, with a hollow perpendicular tower communicating freely by one or more openings at its base, with the fire place. This tower is furnished with a movable cover, which fits accurately, so as to be nearly air tight, into the top.

When the athanor is to be used, the fire place must be filled with the proper quantity of lighted charcoal, and then as much unlighted charcoal, in moderate sized pieces, as the tower will hold, is to be poured in by the top, which is after wards to be carefully closed by its cover. In proportion as the fuel in the grate is consumed, the deficiency is supplied by that of the tower, which falls through the holes at the base, which while in the tower, having no communication with the external air, can only burn when it arrives at the grate below. The combustion is thus kept up till all the charcoal in the tower or magazine is consumed.

Although this furnace might still be advantageously applied in certain cases which require a long and moderate, rather than a short and violent heat, yet it is not without faults of inconvenience; the charcoal in the grates falls into the tower, and the fire goes out with want of a proper supply, or it falls irregularly, and by large quantities at a time, and heats the lighted charcoal through the grate into the ash.

ATHAPUSCOW, in Geography, a large lake in the north-west parts of North America. Mr. Hearn, who travelled these parts in 1779, describes it as full of islands covered with tall trees which appeared like masts. According to the report of the natives, it was 120 leagues long from east to west, and twenty wide. It is floored with a great number of fish, as pike, trout, perch, barbel, and two forts called by the natives Tillameg and Methy. The northern shore consists of confused rocks and hills, but the southern is level and beautiful; and there are many wild cattle and moose deer; the former, particularly the bulls, being larger than the English black cattle. The centre of this lake is placed by Mr. Hearn in N. lat. 62° and W. long. 122°. It is probably the same with the Slave Lake of Mackenzie, in the same latitude, but in longitude 116°. The Athapuscow River, which Mr. Hearn found about two miles in breadth, is the Slave River of Mackenzie. See Slave Lake and River.

ATHAR, in Scripture Geography, a city of Palestine, in the tribe of Simeon. John xix. 7.

ATHAROTH, a town of Judæa, in the tribe of Gad, given

ATHBOY, in Geography, a market and poll town in the county of Meath, and chief place of a canton in the district of Cram, three miles north of Cram.

ATHEIST, derived from the privative a, and θεος, God, a person who does not believe the existence of a God, nor a Providence; and who has no religion, true or false. In general, a man is said to be an atheist, who owes no being superior to nature; that is, to men, and the other sensible beings in the world.

In this sense, Spinoza may be said to be an atheist, and it is an impropriety to rank him, as the learned commonly do, among deists, since he allows of no other God beside nature, or the universe, of which mankind makes a part; and there is no atheist but allows of the existence of the world, and of his own existence in particular. See Spinoza.

Plato distinguishes three kinds of atheists. Some, who deny, absolutely, that there are any gods; others, who allow the existence of gods, but maintain that they do not concern themselves with human affairs, and do deny a Providence; and others, who believe there are gods, but think they are easily appeased, and that they may remit the greatest crimes for the smallest supplication.

The learned Budworth (Intelleclual Syllum, b. i. c. 3. vol. i. p. 104—178.) reduces the ancient atheism of the Greek philosophers into four different forms, comprehending the two classes of hylozoics or hylopathics, and atomic or atomists, under the denominations of Anaximandrians, Democritians, Stratonic, and Stoical. The Anaximandrians attempted to solve the phenomena of nature by having recourse to the unmeaning language of qualities and forms. These were contained actually or potentially in that infinite chaos of matter, delusive of all understanding and life, which was the first principle or only real nomen of Anaximander; and by their fortuitous separation and agglutination, they produced, first, the elements of earth, water, air, and fire; and then the bodies of the firm, moon, and stars, and both the bodies and souls of men and other animals; and, finally, innumerable or infinite such worlds as the one, as to many secondary or native gods. (Plato De Leg. l. x. p. 666.) See ANAXIMANDER, AND ANAXIMANDRIANS.

Some have called this scheme of atheism, which deduces all things from matter by means of qualities and forms, Peripatetic or Aristotle, because Aristotle used this kind of language in his physiology. But as Aristotle cannot be justly denominated an atheist, Budworth distinguishes this form of atheism by the appellation of Anaximandrian. Democritus and Lucretius new-modelled atheism from the Anaximandrian and Hylopathian into the atomic form, and derived the original and production of all things from atoms, devoid of all forms and qualities, and poising only, as first principles, magnitude, figure, size, and motion; and as they conceived that life and understanding, and other qualities, could be only accidental and secondary results from certain fortuitous conjunctions and juxtapositions of atoms, they excluded a deity, and every thing like counsel and design from the formation of the universe. The Epicureans borrowed many of their notions from Democritus, and framed a system very much resembling the atomical or Democritian. See DEMOCRITUS, AND EPICURUS. The Stratonic or Atheist of the universe, which, as Aristotle maintained, was subordinate to a sentient and intellectual nature, or corporeal soul and mind of the universe, which predicated over it; and this seems to have been the genuine doctrine of Heracleitus and Zeno; whilst others rejected the latter principle, and maintained, that the plastic or atomistic nature, devoid of all animality or conscious intelligence, was the highest principle in the universe. All the ancient atheists agreed in this, viz. that there was nothing but matter or body in the universe; whilst some thought it animate, and were called hylozoics; and others thought it inanimate, and were denominated atomics. Hobbes seems to have inclined to the opinion of the Stratonic; for he supposes (Phys. c. 25. § 5.) that all matter, as mind, is endowed not only with figure and a capacity of motion, but also with an actual sense or perception, and wants only the organs and memory of animals to express its sensation. Sir William Temple, according to the account given of him by bishop Burnet (Hist. Time. vol. i. p. 531, 8vo.) thought that the present system of things is necessary and eternal. The Chinefe have been represented as a nation of atheists. Accordingly Burnet (ubi supr.) states it as the opinion of sir W. Temple, that Confucius and his followers are to be reckoned among those who were atheists themselves, and left religion to the people. But Couplet maintains, that Confucius and the earlier teachers among the Chinefe, were venerationists to pure religion. Confucius, however, says little of those duties that relate immediately to God; and though he speaks of the great spirits in heaven and earth, what he says coincides merely with the notion of a plastic power, similar to that maintained by some of the Grecian philosophers.

Some distinguish speculative atheists, or those who are from principle and theory—from practical atheists, whose wicked lives lead them to believe, or rather to wish, that there were no God.

Dr. Clarke (Demonstration of the Being of a God, p. 2. 8vo.) says, that atheism arises either from a stupid ignorance, or from corruption of principles and manners, or from the reasonings of false philosophy; and he adds, that the latter, who are the only atheistical perfons capable of being reasoned with at all, must of necessity own, that supposing it cannot be proved to be true, yet it is a thing very desirable, and which any wise man would wish to be true, for the great benefit and happiness of man, that there was a God, an intelligent and wise, a just and good being, to govern the world. Whatever hypothesis these men can possibly frame, whatever...
whatever argument they can invent, by which they would exclude God and Providence out of the world; that very argument or hypothesis, will of necessity lead them to this conclusion. If they argue, that our notion of God arises not from nature and reason, but from the art and contrivance of politicians; that argument itself forces them to confess, that it is manifestly for the interest of human society, that it should be believed there is a God. If they suppose that the world was made by chance, and is every moment subject to be destroyed by chance again; no man can be so absurd as to contend, that it is as comfortable and desirable to live in such an uncertain state of things, and so continually liable to ruin, without any hope of renovation; as in a world that were under the preservation and conduct of a powerful, wise, and good God. If they argue against the being of God, from the faults and defects which they imagine they can find in the frame and constitution of the visible and material world; this supposition obliges them to acknowledge, that it would have been better the world had been made by an intelligent and wise Being, who might have prevented all faults and imperfections. If they argue against Providence, from the faultiness and inequality which they think they discover in the management of the moral world; this is a plain confession, that it is a thing more fit and desirable in itself, that the world should be governed by a just and good Being, than by mere chance or unintelligible necessity. Lastly, if they suppose the world to be eternally and necessarily self-existent, and consequently that every thing in it is established by a blind and eternal fatality: no rational man can at the same time deny, but that liberty and choice, or a free power of acting, is a more eligible state, than to be determined thus in all our actions, as a stone is to move downward, by an absolute and inevitable fate. In a word, which way soever they turn themselves, and whatever hypothesis they make, concerning the original and frame of things, nothing is so certain and undeniable, as that man, considered without the protection and conduct of a superior Being, is in a far worse case; than upon supposition of the being and government of God, and of men's being under his peculiar conduct, protection, and favour. Nevertheless, absurd and joyless as is the system of atheism, Diogoras and Théodorus among the ancients, and Vanini among the moderns, have been reckoned martyrs for it. Mr. Boyle has pretended to prove, that it is better to be an atheist than an idolater; or in other words, that it is less dangerous to have no religion at all than a bad one. "I had rather," said he, "it should be said of me, that I had no existence, than that I am a villain." This, as Montefquieu (Sp. of Laws, vol. ii. p. 145.) justly observes, is only a sophism, founded on this, that it is of no importance to the human race to believe that a certain man exists, whereas it is extremely useful for them to believe the existence of a God. From the idea of his non-existence, immediately follows that of our independence; but if we cannot conceive this idea, that of disobedience. To say that religion is not a restraining motive, because it does not always restrain, is equally absurd as to say that the civil laws are not a restraining motive. It is a false way of reasoning against religion, to collect in a large work a long detail of the evils it has produced, if we do not give at the same time an enumeration of the advantages which have flowed from it. Was it of no advantage for subjects to have religion, it would still be of some if princes had it, and if they whitened with foam the only rein which can restrain those who fear not human laws. A prince who loves and fears religion is a lion, who roops to the hand that breaks, or the voice that appeases him. He who fears and hates religion is like the savage beast that grows and bites the chain which prevents his flying on the passerby. He who has no religion at all is that terrible animal, who perceives his liberty only when he tears in pieces, and when he devours. The question is not to know, whether it would be better that a certain man or a certain people had no religion, than to abuse what they have; but to know which is the least evil, that religion be sometimes abused, or that there be no such restraint as religion on mankind.

Cicero represents it as a probable opinion, that they who apply themselves to the study of philosophy believe there are no gods.—This muti, doubtful, be meant of the academic philosophy, to which Cicero himself was attached, and which doubted of every thing: on the contrary, the Newtonian philosophers are continually resorting to a Deity, whom they always find at the end of their chain in natural causes. Some foreigners have even charged them with making too much use of the notion of a God in philosophy, contrary to the rule of Horace—

"Nece Deus irritat, nif dignus vindice nodus."

Among us, the philosophers have been the principal advocates for the existence of a Deity. Witness the writings of Sir Isaac Newton, Boyle, Ray, Cheyne, Nieuwenti, &c. To which may be added divers others, who, though of the clergy (as was also Ray), yet have distinguished themselves by their philosophical pieces, in behalf of the existence of a God; e.g. Derham, Butley, Whiston, Samuel and John Clarke, Fenelon, &c. So true is that saying of Lord Bacon, that though a smattering of philosophy may lead a man into atheism, a deep draught will certainly bring him back again to the belief of a God and Providence. See God, Providence, and Religion.

ATHELNEY, among our Saxon ancestors, was a title of honour properly belonging to the eldest son of the reigning prince, or the presumptive heir of the crown.

The word is formed from the Saxon atheling, of athel, noble. It is sometimes also written, adeling, edeling, etheling, and etheling.

King Edward the Confessor, being without issue, and intending to make Edgar, to whom he was great uncle by the mother's side, his heir, first gave him the honourable appellation of etheling.

Antiquaries observe, that it was frequent among the Saxons to annex the word ling, or ling, to a Christian name, to denote the son, or younger; as Edmundling, for the son of Edmund; Edging, for the son of Edgar; and, accordingly, some have thought etheling might primarily import the son of a nobleman, or prince; and Sir Henry Spelman observes, that all noblemen had anciently been called Ethling; however, from a passage in the laws ascribed to Edward the Confessor, it appears, that in times, and for at least a century afterwards, this word was appropriated to the royal family by the English. In reality, atheling, when applied to the heir of the crown, seems rather to denote a person endowed with noble qualities than the son of a nobleman; and corresponds to the nobilis Caesar among the Romans.

ATHELNEY, Life of, in Geography, a spot of rising ground, on the north side of St. Andrew's, in the county of Somerset, about one mile E. N. E. of Taunton, bounded on the north-west by the river Tone; over which is a wooden bridge, still called Athelney bridge. The name given by the Saxons to this island was Ethelinga, or the isle of nobles, whence it was derived, by contraction, Athelney. It was formerly surrounded by almost imitable marshes and morasses, and will be for ever memorable for the retreat of King Alfred from the fury of the Danes, when they had over-run the eastern part of his dominions. Having bravely encountered
encountered his enemies for nine successive years, according to the statement of the registrar of Athelney, he was at length reduced to the necessity of seeking refuge from their violence in this little island. After he had left this retirement, and his enemies were totally defeated, he founded a monastery for Benedictine monks, on the spot which had given him shelter, and dedicated it to the honour of St. Savier, and St. Peter the apostle, and endowed the establishment with the whole isle of Athelney (amounting to about two acres of firm land), exempt from taxes and all other burdens. In process of time other privileges and benefactions were conferred on the monks, and confirmed by different kings and nobles.

ATHELSTAN, in Biography, king of England, was of illegitimate birth, and yet, being of mature age and capacity, succeeded his father Edward the Elder, in preference to his lawful children, in the year 925. Soon after his accession, he marched to Northumberland in order to quell some commotions among the Danes, and conferred the title of king on Sithre, a Danish nobleman: but, upon the death of Sithre, when his two sons Anlaf and Godfrid, or Guthurit, assumed the regal authority without his consent, he expelled them both; one taking refuge in Ireland, and the other in Scotland. The protection afforded to the latter by Constatine, king of Scotland, brought on a war, which terminated so much to the disadvantage of Constatine, that he was obliged, for the preservation of his crown, to do homage to Athelstan. Holi- nties, however, were renewed; and a confederacy was formed by Constatine, Anlaf, and some Welch princes, whose united forces were totally defeated by Athelstan, at Brunanburgh in Northumberland, A.D. 938. In consequence of this victory, the king of England enjoyed his crown without molestation; and having governed the kingdom with great ability, he died at Gloucester in 941, after a reign of sixteen years, and was succeeded by his brother Edmund. In this reign commerce was greatly encouraged, and a law was passed, conferring the rank of thane on every merchant who had made three sea-voyages on his own account. Athelstan, with a view of further facilitating and promoting commerce, established a mint, or mints, in every town in England that had any considerable foreign trade, so that the merchants might have an opportunity of converting the bullion which they brought home for their goods into current coin, without much expense or trouble. These towns were London, Canterbury, Winchester, Rochester, Exeter, Lewes, Hat- tings, Chichester, Southampton, Wareham, and Shaftes- bury. By these and similar regulations the shipping and commerce of England were so much increased, that Athelstan maintained the dominion of the sea, and obliged the Danes and Norwegian princes to court his friendship. Hume's Hist. vol. i. p. 102, &c. Henry's Hist. vol. iii. p. 94, &c. vol. iv. p. 257, &c.

ATHEMON, in Entomology, a species of Papilio. (Pleb. ruf. Linn.; Hesperia Fabr.) The wings are entire and brownish.

ATHENA, in the Ancient Physic, a platter or liniment, commended against wounds of the head and nerves, of which we find descriptions given by Oribius, Zlius, and Reginet.

ATHENAE, in Ancient Geography. See ATHENS.

ATHENAE is also a name given to various other places: as, a town of Arabia. Play.—Alfo, a place at the easter extremity of the Euxine sea, where was a temple of Minerva. Arrian.—Alfo, a town of the Peloponnesius, in Laconia. Steph. Byz. and Suidas.—Alfo, a place of Asia Minor, in Caria. Steph. Byz.—Alfo, a town of Greece, in Boeotia, situate on the river Triton, overwhelmed, according to Strabo, by an inundation.—Alfo, a town of Acarnania: another of Liguria; another of Italy; and another of Sicily. Steph. Byz.

ATHENAEA, in Antiquity, a feast of the ancient Greeks, held in honour of Minerva, who was called Athena. These were afterwards called PANATHENAEA.

ATHENAEA, in Botany (probably from Atheneus). Schreb. 661. Ircoucana. Aubl. Guian. 127. Clafs, odan- drea monegynia. Gen. Char. Cal. perianth one-leaved, coloured, five-parted; parts oblong, acute, erect, spreading at top. Cor. none. Stam. filaments eight, filiform, erect; of which five are of the length of the calyx, the other three alternate ones a little shorter; authors neglect; eight plumose bristles, shorter than the filaments, growing together with the filaments to a gland surrounding the germ. Pet. germ superior, ovate, surrounded at the base by an annular gland; style fleshy, longer than the filaments; stigma depressed, five-parted. Per. capsule globose, one-celled, three-valved; valves somewhat fleshy; seeds three to five, rounded, covered with a papyraceous membrane, affixed to the receptacle in the bottom of the capsule. Ett. Gen. Char. Cal. coloured, five-parted. Cor. none. Bristles eight, feathery, between the filaments; stigma five- parted; capsule globose, one-celled, three-valved. Seeds, three to five.

Species, A. guianensis. Ircoucanaguianensis. Aubl. l. c. 1. This is a branching shrub with a stem four or five inches in diameter, covered with a wrinkled gray bark; leaves alternate, ovate, smooth, toothed, deciduous, four inches long; petals very short, having a small sharp frillipulse on each side of the base; flowers in bundles, from the axils, and upon the tubeckles of the stem and branches, each on a peduncle; calyx white; there is no corolla; seeds covered with a viscid membrane, of a scarlet colour; the bark, leaves, and fruit are sharply aromatic; the latex, by the Creoles, is called Café diable. A native of Cayenne, and the neighboring continent of Guiana, growing in a sandy soil, about half a mile or more from the thore.

ATHENAEOUS, in Antiquity, a public place wherein the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their verses.

The word is derived from Athens. A learned city, where many of these assemblies were held; or from the name of Minerva, Athen, goddess of polite arts and sciences; intimating, that Athenaeum was a place consecrated to Minerva, or rather set apart for the exercises over which the professed.

The Athenaeum were built in form of amphitheatres; and were all encompassed with seats, which Siciinus calls cunei.

The three most celebrated Athenaeum were those at Athens, at Rome, and at Lyons: the second of which, according to Aurelius Victor, was built by the emperor Adrian, for the accommodation of the professors of the liberal arts, and of those who wanted to read their writings before a considerable number of people. It appears from the beginning of Jure- nala's Satires, that this manner of reading in public was very common; and that Fronto lent the use of his house and gardens to the poets, who had occasion to recite their verses before a numerous audience. This was done by others; but as it belonged to the person, who wished to read his compositions, to furnish the room, and to pay the charge of the seats, it is probable, that the emperor Adrian, for the encouragement of works of taste and science, constructed the Athenaeum with a view of obviating this inconvenience. Hence the name has been applied to all kinds of buildings or colleges intended for teaching the sciences and languages.

ATHENEUS,
ATHENAEUS, in Biography, a Greek grammarian, was born at Naucratis in Egypt, and flourished in the third century. Suidas has erroneously referred him to the time of Antoninus Pius; but it appears from his own work (Deipnosophists. I. xii. p. 537. ed. Cafaub.), that he wrote after the death of Commodus, and after the time of Oippianus the poet. (Ib. I. ii. p. 13.) He was one of the most learned men of the age in which he lived; and, for the extent of his reading, and tenaciousness of his memory, he has not been improperly called the Varro, or Pliny, of the Greeks. The only work of this author extant is a valuable compilation from various writings, to which we have no access, entitled Αντιεικαθαρίας, "Deipnosophists," or "The Table Conversation of the Sophists." In this work the author has introduced a great number of learned persons of all professions, and represented them as conversing together on a variety of subjects at the table of Larenctus, a citizen of Rome. It contains a large collection of facts and anec- dothes, forming a rich treasure of antiquities, which served more to amuse the reader than to supply correct information. The author has interfered with his several narratives many falsical reflections and scandalous stories, which tend to asperce and degrade the characters of the philosophers of whose names and writings he has given an account; and, therefore, the work, copious as it is in useful instruction, must be perused with caution. It consists of fifteen books; but of the two first, part of the third, and also of the hill, we have merely an abridgment. Few works have suffered more from the carelessness of transcribers, and the negligence of editors. The first edition was published by Aldus Manutius, in Greek, at Venice, in 1514; and at Bâlî, in 1555, with a bad Latin translation by Natalis Comes. Dalechamp devoted his leisure hours, for thirty years, to the translation of Athenæus, which was published with annotations, by Caufabon, in folio, at Leyden, in 1583, 1597, 1612, and 1657. This work was also translated into French by Marolles in 1580. Caufabon mentions an abridgment of this work by an unknown author, and at a period which he could not precisely ascertain, though he supposed it to have been made before the time of Enuthatis. Pref. Caufab. in Athen. Suidas. Gen. Dict. Fabr. Bibl. Græc. I. iv. c. 22. § 5—8. &c.

Athenæus, a popular orator and Periatic philosopher, was born at Seleucia in Cilicia, had a share in the government, and was for some time a demagogue in his own country. In the time of Augustus he came to Rome, and became an intimate friend of Murena. He was charged with being concerned in his conspiracy; but the emperor not finding him guilty, let him at liberty. Upon his return to Rome after his flight on this occasion, he repeated to his friends these words of Euripides:

"Hem nupere kypone kai skainov poleis Astion."

"From death's dread feasts and gloomy gates I come."

The manner of his death was tragical, as he was crushed by the fall of his house. Strabo, I. xiv. I. ii. p. 587.

Athenæus, born at Attalia, in Cilicia, in the 4th year of our era, as M. Goulin conjectures, was the principal of the sect of pneumaticians. Galen, who gives a particular account of the doctrines of these philosophers, says, they cemected the qualities of cold and heat, moisture and dryness, as four elements, entering into the composition of all bodies. To these a fifth was added, called spirit, to which Athenæus attributed the motion of the pulse. Spirit was also supposed to give life and energy to body. Galen represents Athenæus as a voluminous writer; no part, however, of his works remains, except some chapters preferred by Oribalbus, which throw very little light on the manner in which he applied his doctrine to practice. Le Clerc, Hist. de Med.

ATHENAGORUM, in Ancient Geography, a district of India; supposed by major Renell, from its situation, to be Oude.

ATHENAGORAS, in Biography, a Christian philosopher, was a native of Athens, and flourished towards the close of the second century. His youth was spent among the philosophers of his time; and being removed from Athens to Alexandria, he became a convert to Christianity. The manner of his conversion, according to Philip Sidetes, a writer of the fifth century held in no high estimation, was as follows. Proposing to write against the Christians and defying the rendering his work the more complete, he read the scriptures, and was thus converted. Philip adds, that he was the first president of the catechetical school of Alexandria, and master of Clement who wrote the Stromata. Little upon which we can rely is said concerning Athenagoras by the ancients, and his character and opinions are chiefly deduced from his own works. The principal of these was his "Apology for Christians," dedicated to Marcus Aurelius Antoninus, and Lucius Aurelius Commodus, whose names are prefixed to it, says Fabricus, in all the manuscripts, and probably written about the year 157 or 178. In this work he refutes the calumnies of the pagans against the doctrines and manners of the Christians. He also explains the notions of the Stoics and Peripatetics, concerning God and divine things, and exposes with accurate and strong reasoning their respective errors. He discovers much partiality for the system of Plato, and supports his arguments by the authority of this philosopher, and hence he has been ranked among the Platonizing fathers. In what he advances concerning God and the Logos, or divine reason, he evidently blends the doctrines of Paganism with the doctrines of Christianity. According to Athenagoras, God is underived, indivisible, and distinct from matter; there are middle natures between God and Matter; from the beginning, God, the eternal mind, being from eternity rational, had the Logos within himself; the Logos of God is the reason of the Father in idea and energy; and for since the father and Logos are one, by him and through him all things are made; the Logos was produced, that the ideas of all things might subsist, and they are contained in his spirit. On the imperfect and untractable nature of matter, on angels, demons, and other natures compounded of matter and spirit, and on other philosophical topics, Athenagoras reasons with all the facility of the Grecian schools, so that in every page he is seen to have been by profusion and sophistry; and indeed he is said to have retained the name and habit of a philosopher with a view of gaining greater credit to the Christian doctrine among the unconverted. In moral philosophy, he adopted the common authorities, particularly with respect to marriages. He reprents celibacy as meritorious, and second marriages as legalised adultery. In Athenagoras's "Discurso de la Resurrección del Defunto," probably written after the "Apology," he argues rather from reason than scripture, in order to prove the possibility and truth of a resurrection. His writings, upon the whole, manifest an happy union of Attic elegance with philosophical penetration; so that he is reckoned a polite writer, and his Greek is Attic, though his style is rendered less agreeable.
A TH

by frequent parentheses. The two treatises of Athenagoras have been usually printed together, in Greek and Latin. They were published in 4to. at Paris, in 1541; by H. Stephens, at Paris, in 8vo. in 1557; by Rechenberg, at Leipz., in 1604, in 2 vols. 8vo.; by Hall, bishop of Oxford, with notes, at Oxford, in 1682, 12mo., and with various notes by Dechair, from the same Sheldon press, in 1752, 8vo. The romance under the name of Athenagoras, said to be a translation from a Greek MS. brought from the east, and published in 1599, and in 1612, in French by M. Purnec, intituled "True and Perfect Love", written in Greek by Athenagoras an Athenian philosopher, containing the little love of Theogonius and Charites, of Phereides and Melanargus," is a fiction, and was probably written in imitation of Theognis and Charicles of Hellidius, after the overthrow of Greece by Alaric, or the destruction of the Greek empire by the Turks. Cave, H. L. ii. 1. p. 59.

ATHENIANS, in Ancient Geography. See Athens, and Attica.

ATHENIENSII PORTUS, or the port of the Athenians, was a harbour of Greece, between the port Bucephalon and the promontory of Spireneon, on the eastern side of the Argolid, in the Saronic gulf.

ATHENION, in Biography, a Greek historical painter, who flourished in the year 300 before Christ.

ATHENIPPUM, in the Ancient Physic, a collyrium, commended against divers diseases of the eyes; thus denominated from its inventor Athenippos.

Its description is given by Scribonius Largus, and by Gerasius after him.

Galen mentions another Athenippum, of a different composition, by which it appears, this was a denomination common to several collyriums.

ATHENS, in Biography, a famous Grecian statuary, who flourished at Chios, about 538 years before Christ. See BUPLAI.

ATHENODORUS, a Stoic philosopher, was a native of Caria, near Tarsus, in Cilicia, and the preceptor and friend of Augustus. During his residence at Rome, he was much respected by the emperor on account of his wisdom and probity, admitted into his confidence, and allowed to give him free and faithful counsel. Augustus, being addicted to gallantry, indulged a criminal passion for the wife of a senator, who was a friend of Athenodorus, and who communicated to him his designs. The philosopher availed himself of this opportunity of impressing upon the mind of the emperor a sense of the danger to which he exposed himself by such practices. Accordingly, he dressed himself in woman's clothes, and, providing himself with a poignard, put himself into the chair in which the lady was to have been conveyed. When he appeared before Augustus in this disguise, he said to him, "See, sir, to what danger you expose yourself! An enraged husband may arm himself in this manner, and revenge with your blood the injury you offer him." The admonition is said to have produced its desired effect; the emperor received it with deference; and he became more circumspect for the future. Zosimus (i. i. c. 6) attributes the mild plan of government adopted by Augustus to the influence of the counsels of Athenodorus. Before he left the court of Augustus, he is said by Plutarch (Apophthegm. Oper. t. 2. p. 257.) to have warned the emperor against excess of passion, and, as a preservative, to have advised him to rehearse the twenty-four letters of the alphabet, before he allowed himself to say or do any thing. Upon this, Augustus took him by the hand, saying to him, "I want your assistance still longer," and kept him for another year. Such was his interest with Augustus, that he obtained for his fellow citizens, the inhabitants of Tarsus, relief from some of the taxes which oppressed them; and on this account he was honoured by them with an annual festival. At an advanced age the emperor permitted him to return to his native country; and finding it distracted by factions, which had been excited by Boethus, whom Antony had inveted with power, he excused himself with prudence and firmness, in order to refrain and suppresse them. By reciting the esteemed odes of Tarsus, correcting the abuses which threatened its ruin, and introducing a new code of municipal law, he contributed to the revival and permanence of its prosperity. Having served his country faithfully during a prolonged life, he closed it with honour, and with the regret of his fellow-citizens, at the advanced age of eighty-two years. He was a considerate writer; and several of his works are cited by the ancients. Strabo says, (i. i. p. 6), that he wrote concerning the ocean and its tides; and Stephanus (art. Augustus) informs us, that he wrote the history of his own country; but none of his works are now extant. This Athenodorus is not the same who is mentioned by Suetonius (in Claud. c. 4.), as having been enticed by Augustus with the charge of the education of Claudius Nero, afterwards emperor. Fabricius, however, affirms that they were the same person. Gen. Dict. Strabo, i. t. 1. p. 691. Brucker's Hist. Phil. by Enf. vol. ii. p. 117.

ATHENODORUS Cordylius, a Stoic philosopher of Tarsus, was probably a native of Pergamus, lived about 50 years before Christ, and was the intimate friend and companion of Cato of Utica. He was keeper of the public library at Pergamus; and having refused several solicitations to leave this retreat, he was at last prevailed upon by Cato, who visited Asia for this purpose, to join him in the war which he had undertaken for the reformation of Roman liberty. Cato is said to have valued himself upon the success of his application to Athenodorus, more than if he had shared the conquests of Lucullus or Pompey. Strabo says, that he lived and died with Cato. Fabriues fuggests, that this Athenodorus was the author of a work against the Categories of Aristotel, mentiofed by Porphyry, Simplicius, and Cicero. Fabric. Grac. l. iii. c. 15. t. i. p. 391.

ATHENODORUS, a famous ancient sculptor, who was born at Rhodes. According to Pliny, he was a scholar of Polycleitus, who flourished about the eighty-seventh Olympiad, or 432 years before Christ. He was one of the three who jointly executed the famous group of Laocoon: the other two were Agelander and Poldore.

ATHENOPOLIS, in Ancient Geography, a town of Gallia Narbonensis, on the coast of the Malienes, between port Citharilla and Forum Julii, according to Pliny. Its precise situation is not now known.

ATHENY, in Geography, a borough town of the county of Galway, in Ireland, which gives name to a barony. Within an extensive circuit of dilapidated walls, and their ruinous towers, the remains of castles and abbeys, that are intermixed with the cottages of a now small village, present a monument of its former confluence. There are also many ruins of castles and churches in its neighbourhood. At this town was fought a battle between Tadhg O'Connor, prince of Connaught, an associate of Edward Bruce, and an English army under William de Burgo and Richard de Bermingham
ATHENS, in Ancient Geography and History, a celebrated city, called by Homer the city of commerce, or ere, the city, was the capital of Attica, and the seat of the Grecian empire. It was founded by Cecrops, about 1536 years before Christ, and from him called "Cecropia." It afterwards, as some say, in the reign of Erechtheus, about 1487 years B.C., or according to others, in the reign of Erechtheus, about 1397 years B.C., assumed the name of Athens, from Minerva, denominated by the Greeks Aēra, and considered as the protectress of the city. Cecropia was seated upon a hill or rock in the midst of a spacious and fertile plain, partly with a view of securing it against piratical invaders, and partly to prevent its being overwhelmed by inundations, which were much dreaded in those ancient times. In process of time, as the number of inhabitants increased, the whole plain was covered with buildings, which were denominated from their situation, "the lower city," and Cecropia was called "Acropolis," or "the upper city." See ACROPOLIS. The old city, or citadel, was sixty stadia, or about 24 leagues in circuit; it was fenced with wooden palaces, and as some say, set about with olive-trees; and it was also fortified with a strong wall, partly built by Cinna, the son of Miltiades, out of the spoils of the Persian wars, and situate on the south side of the citadel; and partly on the north side, by Agoras and Hyperbius, who, according to Pausanias (in Attic, i. 42. p. 67.), migrated from Sicily to Aecarnania, and denominated from them, who were called Pelaioi, the Pelasgic wall. The only entrance into the citadel was by one gate on the south-east, constructed at a great expense by Pericles, and denominated Propylæum. See PROPELLEUM. The inside of the citadel was adorned with innumerable edifices, statues, and monuments, all of which it would be too tedious to recount. The most remarkable are the following. At the entrance was a temple dedicated to Victory, adorned with paintings which were principally the work of Polygnotus, and constructed of white marble. Within the citadel were an immense number of statues erected by religion or gratitude, on which the chieftains of Myron, Phidias, Alcamenes, and other artists of renown, seem to have bestowed animation. Of these statues some were those of famous Athenian generals, such as Pericles, Phormio, Iphicrates, and Timotheus; and others, those of the gods. About the middle of the citadel were the magnificent temple of Minerva, denominated Heoctompedon, and Parthenon (see PARTHENON); and the temple of Minerva Polias and Neptune Erechtheus, one part of which was consecrated to the former, and the other to the latter. On one side was exhibited the olive-tree which sprang out of the earth at the command of the goddess, and which so greatly multiplied in Attica; and on the other, the well, whence they pretend that Neptune caused the water of the sea to gush out. Thus these deities are said to have contended for the honour of conferring their names on the rising city; but the gods decided in favour of Minerva, and the Athenians for ages preferred agriculture to commerce. Here, however, they have erected one common altar, which is called the altar of oblivion. Before the statue of the goddess was suspended a golden lamp, the work of Callimachus, which was supplied with oil once a year, the week of which was made of amathus, and which burned night and day. The columns of the front of the temple of Neptune are standing, together with the architrave; and also the screen and portico of Minerva Polias, with a portion of the cell retaining traces of the partition wall. The order of this building is Ionic. The portico is now used as a powder magazine, and near it is a battery commanding the town. The Turks use it to give notice of their ramazan and lailam, and on other public occasions. Contiguous to this temple was the Pandroseion. (See PANDROSEION.) Behind Minerva's temple was the public treasury, called OPISTHODOMOS, surrounded by a double wall.

The Peripteral city comprised all the buildings that surrounded the citadel, together with the harbours of Phalerum, Munychia, and the Pireus. The whole circle of the city in its most flourishing state was no less than 12 leagues, according to Arilides, than a day's journey; or, according to more exact computation, 178 stadia, or about 22 Roman miles. The port of Phalerum was connected with the city by a wall 35 stadia, or 1 ½ league in length, built by Themistocles, of stones, fastened by iron and lead, and forty cubits high; and that of Pireus was joined to it by a wall 25 stadia or 1 ½ league long, and erected by Pericles. These were almost closed at their extremity by a third wall of 60 stadia; and they included not only these two harbours, but also that of Munychia, which lay between them, but also a multitude of houses, temples, and monuments of every kind; so that the entire circumference of the city has been estimated at nearly 200 stadia, or above 75 leagues. In the wall that encompassed the city there were several gates, the principal of which were those of Ægeus, of Diocharis, of the Diomans, of Melite, of Acharnos, of Hippades, of Thrasis, or Dipylon, of Ition, sacred gate, and that of the Pireus. The streets of Athens were in general irregular, and the houses small and inconvenient. Besides the rock of the museum, close to the citadel on the south-west, separated by a valley from the hill on which the Aereopagus stood, other eminences contributed to render the city extremely uneven. In these hillocks they had several springs of water, but not sufficient, without additional wells and cisterns, for the supply of the inhabitants. The city was encompassed by the rivers Ilissus and Cephissus, which joined their streams in the marsh of Phalerum, and near the banks of which were several public walks, and also public and private buildings. The three harbours of Athens were the PHALERUM, MUNYCHIA, and PIREUS; for an account of which see the articles. The principal edifices and places of note in and about the city are the following:

Without the gate of Pireus is a cenotaph, erected by the Athenians in honour of Euripides, who died in Macedonia, on which is inscribed "the glory of Euripides has all Greece for a monument;" and within this gate is a fluted building, called Pompion, in which are kept the sacred utensils used at festivals, and from which commence the processions of young persons exhibited on occasions of this kind. In an adjoining temple dedicated to Ceres are admirable statues of the goddesses, Proserpine, and young Iacchus, executed by Praxiteles. In the street leading from the Pireus to the citadel, are numerous porticoes, some of which stood detached, and others contiguous to buildings, to which they serve as vestibules. To the left of this street is the quarter of the Palaia, which was very populous; and contiguous to this was that of the Ceramicus, or pottery grounds, so called from the earthenware formerly fabricated there. This extensive space was divided into narrow streets; one with the walls, where the academy was situated; and another within, in which was the great square or forum. In the royal portico, where the record of the archons held his tribunal, and where the areopagus sometimes
The number and the kind which were necessary for the cultivation of the arts and for the adornment of the city. Among these were the statues of the gods, which were often deified by the people of Athens, and were placed in the temples, the market places, and the streets. The most famous of these statues were the works of Phidias, the sculptor of the Parthenon, and of Praxiteles, the sculptor of the statue of Zeus at Olympia. The most celebrated of these statues were the statue of Zeus at Olympia, the statue of Athena Parthenos in the Parthenon, and the statue of Athena Nike in the Acropolis.

The city of Athens was also renowned for its beautiful gardens and parks, which were maintained by the state and were open to the public. Among these were the gardens of the Acropolis, the gardens of the temple of Athena, and the gardens of the temple of Poseidon at the island of Salamis.

The city of Athens was also noted for its beautiful architecture, which was characterized by the use of the Doric and Ionic orders of architecture. Among the most famous of these buildings were the temple of Athena Parthenos in the Parthenon, the temple of Zeus at Olympia, and the temple of Poseidon at the island of Salamis.

The city of Athens was also noted for its beautiful bridges, which were constructed of stone and were well designed. Among these were the bridge over the river Eridanus, the bridge over the river Ilissus, and the bridge over the river Lucius.

Acropolis and the hill of the Areopagus. Near to the grove of Aglauros was the Prytaneum, north of the Acropolis, and this was the second flation of Paunianias. The first route from this station is explained as descending from the Prytaneum to the lower parts of Athens; and it includes the temple of Seraef, of the goddesses Lucina, of the Olympian Jupiter, and the Delphian Apollo, the Gardens, the Lyceum, the river Ilythus, the temple of Diane the huntress, and the Stadium. Without describing any objects in his return from the Stadium to the Prytaneum, Paunianias commences his second route from that station by the way called Triposes, in which, he says, there are temples, triposes, and other works deserving notice; and, in the following order he mentions the temple of Dionysus, the temple of Bacchus, the imitation of the tent of Xerxes, the theatre of Bacchus, the wall called Southern, the tomb of Calus, the temples of Aesculapius, of Theseus, of Earth, and of Virid Ceres, and then enters the Propylea of the Acropolis. Within the Acropolis, he describes, among other objects, the Parthenon, the temples of Erechtheus, Polias, and Pandrofus; and his descriptions agree so exactly with the remains found there, that this part of his topography affords an evidence of his precision in other respects. He then passes from the Acropolis over the Areopagus, thence to the tombs, and to the Academy; and this route is in the order of their situation; for he had before passed, under the north-eaft side of the Acropolis, in his route from the temple of Theseus to the Prytaneum. The tombs, which are in the neighbourhood of the Museon, according to Dr. Chandler, were evidently in the situation to which Paunianias alludes; and the academy is known to have been to the west of the walls of the city. It has been the uniform opinion of antiquaries, that the old city of Athens was built on the northern side of the Acropolis; and the inscription of Adrian's arch is a confirmation that the addition to the city, built by that emperor, and called after him Adrianople, was on the southern side. Mr. Stewart, however, in his "Antiquities of Athens" (vol. iii.), conjectures, that the ancient city was on the south side of the Acropolis; but it has been alleged, that there are no remains which countenance this supposition; and, besides it should be recollected, that the Pelasgi, who fortified the Acropolis, were permitted to dwell beneath the walls; they were afterwards acceded by the Athenians of way-laying their daughters, as they went from the city to fetch water from the Ilythus: this could not possibly have happened, without supposing that the ancient city was on the north side of the Acropolis, and that the part inhabited by the Pelasgi was on the south side; for no other part would correspond to the account of the Pelasgi being in a situation between the city and the river. The Pelasgi were afterwards driven out of Attica; the spot on which they dwelt was excrated; and the Delphic oracle advised, that it should be kept rough and uncultivated. It is, however, well known, that this spot, in after times, was inhabited; but it is somewhat singular, that, except the theatre and some few monuments, immediately under the walls of the Acropolis, the whole of the plain between the Acropolis and the Ilythus, contains no remains of ancient works, besides one solitary column. This furnishes a strong argument against the supposition of the ancient city being erected in this situation; for undoubtedly the chief monuments of their grandeur would be contained within the city. This circumstance also accounts for Paunianias passing by, without describing any thing as situated there; it was idle in antiquities, and therefore furnished no object deserving his notice. For these observations, we are indebted to an anonymous writer.

See Monthly Review enlarged, vol. xvi. p. 56. For the plans of Athens, annexed to the travels of Anacharsis, see the Maps of this work.

ATHENS, and the Athenians. History of. It has been already observed, that the city of Athens was founded by Cecrops about 1550 years B.C. This prince reigned fifty years. Under the reign of his successor, various circumstances combined to determine the character and situation of the nation. The succession of princes appears, with few exceptions, the succession of improvement. Under the reign of Eriehthonius, the colony of Cecrops accustomed horses, already docile to the bit, to draw wheel carriages; and this was followed by the labour of bees, which useful race of insects they carefully preferred on mount Hymettus. Under Pandion, they made new progress in agriculture; but a long drought having destroyed the hopes of the husbandman, the harvists of Egypt supplied the wants of the colony, which thence contracted a taste for commerce. Eriehthonius, his successor, rendered his reign illustrious by useful institutions, and the Athenians dedicated a temple to him after his death. A considerable portion of barbarism still remained; the country, very imperfectly cultivated, maintained great numbers of savage animals, and still more savage men. The Grecian woods and mountains abounded in lions, bears, and other fierce animals, that often roamed from their haunts, and spread terror and defolation among the adjoining valleys. The valiies themselves teemed with men of brutal strength and courage, who avoided themselves of the weakness of government, to perpetrate horrid deeds of violence and cruelty. About the year 1300 B.C. the first worthies of Greece, animated rather with the daring and useful, than with the romantic spirit of chivalry (Plutarch's Theseus), fet themselves with one accord to remedy evils which threatened the excellence of society. These traveled over Greece, and freed it from the violence both of kings and individuals: they appeared to the Greeks as beings of a superior order; and that infant people, no less extravagant in their gratitude than fears, rewarded the exploits with so much glory, that the honour of protecting them became the first ambition of noble minds. Of these, one of the most eminent was Theseus, the son of Egeus king of Athens, who was ardently desirous of riving the exploits of Hercules. The Pallantides, a powerful family of Athens, having attempted to wrest the sceptre from the aged hands of Egeus, young Theseus, now approaching to man's estate, overcame the projects of the conspirators. (Plutarch's Theseus.) Marathon, the second city in Attica, had its environs infested by a ferocious bull; the heroic prince subdued this terrible animal (Plutarch's Theseus); and the Athenians regarded his successes with alazonishment and admiration. But his countrymen had soon after a call for their wonder and gratitude in a much more signal achievement, and more momentous benefit. Minos, king of Crete, accused them of having put to death his son Androgaeus, and compelled them by force to deliver him, at stated intervals, a certain number of youths and maidens. These were to be chosen by lot, and their destiny was death or slavery. (Plutarch's Theseus.) It was now the third time that the pledges of their affections were to be torn from their unhappy parents. All Athens was in tears, but Theseus revived her hopes. He undertook to free the city from this odious tribute; and to accomplish the noble project, voluntarily enrolled himself in the number of the victims, and embarked for Crete. The adventures of Theseus in Crete, exhibited by the inventive and often fanciful poetry of the Greeks, contain a great portion of the marvellous, through which a skilful and different reader may
At that time would permit. Strangers, invited to become citizens, flocked thither from all parts, and were incorporated with the ancient inhabitants. He added the territory of Megara to the country; he placed a column on the isthmus of Corinth, as a boundary between Attica and Peloponnese; and revived, near this pillar, the Ithian games, in imitation of those lately instituted by Hercules at Olympia. Every thing now seemed favourable to his views: he governed a free people, retained in obedience, by his moderation and his bounties; he dictated laws of peace and humanity to the neighboring nations, and enjoyed a foretaste of that profound veneration with which succeeding ages gradually honored the memory of great men. Thueus also engaged in new undertakings of value, some of them very unprofitable (see Thueus, Hercules, and Perithous), and all of them prejudicial to his country, by occupying that time which might have been employed in the farther improvement of the state. But with these exceptions, Thueus was a very great and beneficial sovereign, and his reign was a very important epoch in Athenian history. For several ages, however, Athens was only a secondary power: in the time of Homer, that state sent but fifty ships, whereas other countries sent eighty, and Mycene a hundred. The compliment of men to each, being 120, the troops amounted to about 6000.

Full fifty more from Athens flem the main, Led by Menelues thro' the liquid plain; No chief like thee, Menelues! Greece could yield, To martial armies in the duty field, Th' extended wings of battle to display, Or close th' emboddied host in firm array. Neclor alone, improv'd by length of days, For martial conduct bore an equal praise.

See Pope's Homer's Iliad, i. ii. At the time of the Trojan war, B. C. 1184, Athens, like other states of Greece, was subjected to a limited monarchy, but not infirmly hereditary. Menelues succeeded Thueus, in preference to the son of that monarch. Menelues was succeeded by Demephon, who disdained himself at the siege of Troy, and on his return was eminent for political improvement. By him was erected the famous court of the Ephesians, for trying wilful murder by a tribunal to which the British jury bears a considerable analogy. By this court, the king himself afterwards submitted to be tried, for having accidentally killed one of his subjects. He reigned thirty-three years, and was succeeded by his son Oxyntes, who reigned twelve years. Oxyntes was succeeded by his son Aphydas, who was murdered by Thymetas, the bastard son of Olympos. Thymetas demonstrated himself very worthy to reign, and was at length dethroned to make room for a man who had disdained himself in the following manner. There happened to arise a contile between the king of Barotia and the Athenians, about a frontier town. The hostile prince challenged Thymetas to determine their dispute by a single combat. The Athenian sovereign chose to decline, but Melanthus, an exile from Meffenia, who then resided at Athens, accepted the challenge. When they encountered, Melanthus demanded of his adversary, why, contrary to articles, he had brought a second into the field? He turned about to fee who the alleged second was, whereupon Melanthus run him through the body. Delighted with this victory, the Athenians did not regard the means by which it had been obtained, and appointed the conqueror their king. Melanthus was succeeded by his son Codrus: this prince was attacked by the Heracleis: having heard that the oracle promised the victory to that army which should lose its general in the battle, he voluntarily devoted himself
man of worth, possessed of real knowledge, and firmly attached to his country. Other marks of character might perhaps embellish his eulogy, but are not necessary to his memory. Like all preceding and subsequent legislators, he formed a code of laws and morals; he took the citizen at the moment of his birth, prescribed the manner of his earliest education, followed him through the different stages of his life, and, connecting these partial views with the main object, flattered himself he should be able to form free men, and virtuous citizens: but he only produced malcontents, and his regulations excited so many murmurs, that he was compelled to take refuge in the island of Aegina, where he soon after died.

His laws were strongly impregnated with the peculiarities of his character; they were as severe as his manners had ever been rigid. Death was the punishment he inflicted on idleness, and the only punishment he decreed for the slightest offences, as well as for the most atrocious crimes; he was accustomed to say, that he knew of none milder for the former, and could devise no other for the latter. It seems as if his powerful mind, virtuous even to excess, was incapable of any indulgence for crimes at which it recoiled, or for those weaknesses over which it triumphed without an effort. As he had not attempted any change in the form of government, the intestine divisions augmented from day to day. One of the principal citizens, named Cylon, formed the project of seizing on the sovereign authority; he was besieged in the citadel, where he had long defended himself, and at length, wanting provisions, and destitute of every hope of succour, eluded, by flight, the punishment due to his crime. His followers took refuge in the temple of Minerva; from which asylum they were enticed by the promise of life, and instantly massacred. Some of these unfortunate men were murdered even on the altars of the awful Eumenides. The indignation excited by this action was universal; the people at once executed the perjury, and murdered at the impaty of the victors; and the whole city expected that some dreadful calamity would be immediately inflicted by celestial vengeance. Amidst this general conformation, news was brought that the city of Nisaia and the isle of Salamis had fallen by the arms of the Megarensians. To this melancholy intelligence succeeded, soon after, an epidemic distemper. The public imagination, already agitated, was suddenly feized with panic terrors, and haunted by a thousand terrifying chimeras. The augurs and oracles being consulted, declared that the city, polluted by the profanation of the holy places, must be purified by the ceremonies of expiation. The Athenians, therefore, sent to Creté for Ephimeudis, B.C. 642, considered as a man who had an intercourse with the gods (Pausanias, l. i.), and who saw into futurity. He really appears to have been a reformer endowed with talents and knowledge to engage confidence in his opinions, and authority of manners to command respect. The first years of his youth he passed in solitary places, and seemed wholly absorbed in the study of nature, forming his imagination to enthusiasm, by fasting, silence, and meditation, without any other ambition than by making himself acquainted with the will of the gods, to secure his dominion over the minds of men. His successes surpassed his hopes, and he acquired such a reputation for wisdom and sanctity, that, in times of public calamity, nations intreated from him the favour of purifying them by rites, which, as they alleged, he could render more acceptable to the divinity. Athens received him with transports of hope and fear. He directed that new temples and new altars should be built to immolate the victims he had chosen, and that these sacrifices should

Vol. III.
should be accompanied by certain hymns. As while speaking he fancied agitated with a divine inspiration, his impi-
tuous eloquence was irresistible. He availed himself of the ascendency he had acquired, to effect several changes in the religious ceremonies, and in the manners of the people; and by various useful regulations, he endeavored to bring the Athenians to the two principles of social union and justice. But the reform of Epimenides, though beneficial as far as it extended, was very inadequate to the evils. The people were still suffering under combined anarchy and oppression; the magistrates plundered the treasury and the temples; and often betrayed for bribes the interests of their country: the rich tyrannized over the poor, the poor continually alarmed the safety of the rich: the rapacity of creditors knew no bounds; they compelled the insolvent debtors to cultivate their lands like cattle, to perform the service of beasts of burden (Gilles, v. i. 107.), and to transfer to them their sons and daughters, whom they exported as slaves to foreign countries. In such a disordered situation, there arose for their relief the illustrious Solon, B.C. 594. This celebrated sage distingushed himself by military policy and warlike efforts. The Athenians had been long engaged in a war against the Megarensians, concerning the island of Salamis; fatigued and broken by tedious and arduous holi-
drics, they abandoned the enterprise in despair, and even made a law enacting the punishment of death against any one who should propose the capture of that island. Solon, aware of the importance of a poliehen that commanded the coasts of Attica, and deeming the national dependence inglorious as well as impolitic, ardently desired to rule his countrymen to more vigorous counsels; but the new penal law restrained his efforts. At length he devised an exped-
dient for patriotically tranfgressing the pufilanimous law, and avoiding the punishment. He accordingly counter-
feited infancy, and caufed his family to report that he was actually mad (Plutarch's Solon); the rumour being spread and generally believed, he composed a poem, describing the advantages of Salamis, and inciting the Athenians to renew the war. His verses, strong and impressive, produced the desired effect. The people were roused, an expedition was undertaken, and Solon is, by Plutarch, said to have devised the following stratagem for cutting off the Megarensians, who then occupied Salamis. With his friend Piliftros he sailed at the head of an armament to Colias, there finding a number of women sacrificing to Ceres, he sent a confidential perfon to Salamis, instructed to proffes himself a defeter, and to tell the Megarensians, if that they defired to feize the chief Athenian women, to make all fail to Colias. The Mega-
rengians, taking the ftrory for truth, prefently manned a fhip; and Solon defeiyng this fhip just as it put off from the island, commanded the women to be gone, and ordered fome bearded youths, drelled in the women's clothes, their shoes and mitres, and privately armed with daggers, to dance and ftan near the fhoare, till the enemies had landed, and the fhip was in their power. Things being thus ordered, the Megarensians were allured with the appearance, and coming near the shore, strove who fhouid leap out fift, as it were only to feize the women; but were fo warmly received, that not one of them efcaped. The Athenians failed for the island, thus deprived of its defenders, and annexed Salamis to the territories of Athens. The fame which Solon thus acquired, he foon increafed by his policy and conduct with regard to another fubjeft of foreign policy.

The Criffians were a flourishing state, not far from Del-
phi, and, commanding the approaches to that rendezvous of Grecian superflition, derived considerable emolument from the expeiences of the devotees. But with the advan-
tages they were not fatisfied; they began to exaft vexatious and exorbitant duties from the merchants who came to ex-
pofe their wares in the facred city; which, on account of the great concourse of profligate pilgrims from every quarter, soon became the feat, not of devotion only, but of dilipa-
dation, vanity, and licentious pleasure. It was in vain for the merchants to claim against these unexampled impofitions; the taxes were continually increafed; the evil admitted not the expectation of either remedy or relief; and the strangers, faimiliarized to it by custom, began to submit without mur-
mur; and perhaps endur'd the hardship with greater pa-
tience, when they perceived that they drew back the tax in the increased price of their commodities. Encouraged by this acquiefcence in their tyranny, the Criffians levied a fevere impol on the pilgrims, whether Greeks or Barbarians, who visited the temple of Apollo; a measure directly inconfiftent with a decree of the Amphictyons, which declared that all men should have free access to the oracle, as well as extremely hurtful to the interell of the Delphians, who foon felt a gradual diminution of their profits from the holy flame. The Criffians, totally regardless of the feeling of religion, plundered the temple of Delphi, with many circum-
cufonances of aggravating atrocity. Solon roused his coun-
trymen to avenge the fachilege; and to his ingenuity and skill it was chiefly owing that the Criffians were vanquifh'd (Gillies, vol. i. 221.), but Solon was defined to render himself, by legislation, most beneficial to his country. The general opinion of his genius and virtues, joined to the experience of his military talents, success in wars, and political adrest, had procured him distinguished influence over the people. His experienced ability, and above all, his approved wisdom and equity, pointed him out for the noblest and most sublime employment of humanity, that of regulating the laws and government of a free people. Such, at leaft, the Athenians may be confidered, when their unanimous fuffrage rendered Solon the absolute umpire of their whole constitution and policy. When he undertook the reform of the rate, tyranny and disorder prevailed; the wretched populace, deriving courage from defpair, had determined no longer to submit to fuch multiplied rigours; and, before the wisdom of the lawgiver interposed, they had taken the resolution to elect and follow fome warlike leader, to attack and butcher their oppressors, eftabift an equal partition of lands, and in-
stitute a new form of government. But the numerous cli-
ents and retainers, who, in a country little acquainted with arts and manufactures, depended on the wealthy proprieters of the lands and mines of Attica, rendered this undertaking alike dangerous to both parties; fo that both became willing rather to submit their differences to law, than to decide them by the fword. The impartiality of Solon merited the unlimited confidence of his country. He maintained the ancient division of property, but abolished debts; he efa-
blift the rate of interest at 12 per cent, which it afterwards remained; but forbade that the insolvent debtor should become the flave of his creditor, or be compelled to fell his children into fervitude. After these preliminary regulations, which seemed immediately necessary to the public peace, Solon proceeded, with an impartial and steady hand, to new model the government; on this generous, but equitable principle, that a few ought not, as hitherto, command, and the many obey; but that the collective body of the people, legally convened into a national assembly, were entitled to decide, by a plurality of voices, the alternatives of peace and war; contract or dissolve alliances with foreign states; enjoy all the branches of legislative or foreign power; and elect, approve, and judge the magistrates or ministers entrusted, for a limited time, with the executive authority. Strangers, and
and all those who could not ascertain their Athenian descent, both in the male and female line, were totally excluded from the assembly and courts of justice. The regulations of Solon marked the utmost attention to preverse the pure blood of Athens unmixed and uncorrupted; nor could any foreigner, whatever merit he might claim with the public, be admitted to the rank of a citizen, unless he abandoned for ever his native country, professed the knowledge of some highly useful or ingenious art, and, in both cases, had been chosen by ballot, in a full assembly of six thousand Athenians.

The numbers of this convention, and still more their impetuosity and ignorance, must have proved inconsistent with good government, if Solon had not secured the veil of the republic from the waves of popular frenzy, by the two firm anchors of the senate and the areopagus; tribunals originally of great dignity, and of very extensive power, into which men of a certain description only could be received as members. Solon divided the Athenians into four classes, according to the produce of their estates. The first consisted of those whose lands annually yielded five hundred measures of liquid, as well as dry commodities, and the minimum of whose yearly-income may be calculated at fifty thousand drachmae, which is equivalent, if we estimate the relative value of money by the price of labour, and of the things most necessary to life, to about sixty thousand pounds sterling in the present age. The second class consisted of those whose estates produced three hundred; the third two hundred; the fourth, and by far the most numerous class of Athenians, either possessed no landed property, or at least enjoyed not a revenue in land equal to twenty-four pounds sterling, or, agreeably to the above proportion, two hundred and forty pounds of our present currency. All ranks of citizens were alike admitted to vote in the public assembly, and to judge in the courts of justice, whether civil or criminal, which were properly so many committees of the assembly. But the three first classes were exclusively entitled to sit in the senate, to decide in the areopagus, or to hold any office of magistracy. To these dignities they were elected by the free suffrages of the people, to whom they were accountable for their administration, and by whom they might be punished for malversation or negligence, although they derived no emolument from the diligent discharge of their duty. The senate of four hundred, which, eighty-six years after its institution, was augmented to five hundred by Chlithenes, enjoyed the important prerogatives of convoking the popular assembly; previously examining all matters before they came to be decided by the people, which gave them a negative before debate in all public resolutions; and of making laws, which had force during a year, without requiring the consent of the populace. Besides this general superintendence and authority, the senate was exclusively invested with many particular branches of the executive power. The president of that council had the custody of the public archives and treasury; the senate alone built ships, equipped fleets and armies, seized and confined state criminals, examined and punished several offences, which were not expressly forbidden by any positive law. The weight of such a council, which assembled every day, except festivals, infused a large mixture of aristocracy into the Athenian constitution; this, as we shall immediately explain, was still further increased by the authority of the Areopagus.

The principal magistrates in Athens were the nine archons. (See Archon.) These nine archons, or presidents of the several courts of justice, like all other Athenian magistrates, were, at the expiration of their annual office, accountable to the people; and when their conduct, after a severe scrutiny, appeared to merit public approbation and gratitude, they were received, and remained for life, members of the areopagus, a senate involved in a general inspection over the laws and religion, as well as over the lives and manners of the citizens; and which, in dangerous emergencies, was even entitled to assume dictatorial power. See Lyfias, Hecataeus, Anacharsis, vol. i. and Gillies's Greece, vol. ii. Thus did the senate of the areopagus, and that of the four hundred, become two counterpoises sufficiently powerful to secure the republic against the storms from which all states are incessantly in danger (see Plutarch, in Solon.); the former, by repressing the enterprises of the rich by its general censure; and the latter, by restraining by its decrees and its presence the excesses of the multitude. New laws were enacted in support of these regulations. The constitution might be attacked either by the general factions which had so long agitated the different orders of the state, or by the ambition and intrigues of certain individuals. To guard against these dangers, Solon denounced punishments against those citizens who, in time of public commotion, refused openly to declare for one of the parties. (Plutarch, in Solon.) His view, in this admirable institution, was to route much of merit and integrity from a state of fatal inactivity, to oppose them to the factions, and fave the republic by the courage and ascendency of virtue. By a second law, every citizen convicted of having attempted to make himself master of the sovereign authority, was condemned to death. Lastly, in the case of an attempt to erect another government on the ruins of the popular form, this wise legislator could imagine but one method to reanimate the nation; and that was by obliging the magistrates to resign their employments; and hence this stern and menacing decree:—it shall be lawful for every citizen, not only to put to death a tyrant and his accomplices, but any magistrate who shall continue to exercise his functions after the disfranchisement of the democracy. Such is the great outline of the constitution established by Solon, according to which every Athenian citizen enjoyed the inestimable privilege of being judged by his peers, and tried by laws to which he himself had consented. Although the legislative and judicial powers were thus lodged with the people, men of property and ability were alone entrusted with the administration of government; and as power in some measure followed property, the same expedient which served to maintain a due distinction of ranks in society, tended also to promote the industry and frugality of the multitude, that they might thereby become entitled to share those honours and office to which persons of a certain estate or capacity could aspire. (See Gilles, vol. ii. p. 114.) Conformable to this constitution was the code of laws which was framed by this illustrious legislator. As a system of jurisprudence, the institutions of Solon possess extraordinary excellence. They have the merit of easily coalescing with great variety and dišlimilarity of political systems, and are indeed well adapted to any limited government. Transferred into the Roman law, they have, in the forcible and eloquent language of Dr. Gilles, served after an interval of above sixteen hundred years, to abolish the barbarous practices of the Gothic nations, and to introduce justice, security, and refinement among the modern inhabitants of Europe. The laws of Solon consider the citizen in the various relations of domestic, civil, and political society. They accurately mark the duties belonging to these relations, and prescribe the rules for directing and enforcing the performance of them, and for preventing their violation. To form the citizen early to the habits most beneficial to the community, the laws of Solon describe the plan of his education. They recommend the exercises corporeal, intellectual, and moral, which tend
should be accompanied by certain hymns. As while speaking he seemed agitated with a divine inspiration, his impetuous eloquence was irresistible. He availed himself of the ascendency he had acquired, to effect several changes in the religious ceremonies, and in the manners of the people; and by various useful regulations, he endeavoured to bring the Athenians to the two principles of social union and justice. But the reform of Epimenides, though beneficial as far as it extended, was very inadequate to the evils. The people were still suffering under combined anarchy and oppression; the magistrates plundered the treasury and the temples; and often betrayed for bribes the interests of their country: the rich tyrannized over the poor, the poor continually alarmed the safety of the rich; the rapacity of creditors knew no bounds; they compelled the indebted debtors to cultivate their lands like cattle, to perform the service of beasts of burden (Gilles, v. ii. 167.), and to transfer to them their sons and daughters, whom they exported as slaves to foreign countries. In such a distracted situation, there arose for their relief the illustrious Solon, B.C. 594. This celebrated sage first distinguished himself by military policy and warlike efforts. The Athenians had been long engaged in a war against the Megarensians, concerning the island of Salamis; fatigued and broken by tedious and arduous hostilities, they abandoned the enterprise in despair, and even made a law enacting the punishment of death against any one who should propose the capture of that island. Solon, aware of the importance of a polition that commanded the coasts of Attica, and deeming the national independency inglorious as well as impolitic, ardently desired to route his countrymen to more vigorous counsels; but the new penal law restrained his efforts. At length he devised an expedient for patriotically transforming the pusillanimous law, and avoiding the punishment. He accordingly counterfeited insanity, and caused his family to report that he was actually mad (Plutarch’s Solon); the rumour being spread and generally believed, he composed a poem, describing the advantages of Salamis, and inciting the Athenians to renew the war. His verses, strong and impregnable, produced the desired effect. The people were roused, an expedition was undertaken, and Solon is, by Plutarch, said to have devised the following stratagem for cutting off the Megarensians, who then occupied Salamis. With his friend Polibrotus he failed at the head of an armed garrison to Colos, there finding a number of women faceless to Ceres, he sent a confidential perfon to Salamis, infefted to profess himself a defeter, and to tell the Megarensians, that if they desired to deceive the chief Athenian women, to make all fail to Colos. The Megarensians, taking the story for truth, presenty manned a ship; and Solon defoying this ship just as it put off from the island, commanded the women to be gone, and ordered some beardless youths, defecled in these women’s clothes, their shoes and mitres, and privately armed with daggers, to dance and wanton near the shore, till the enemies had landed, and the ship was in their power. Things being thus ordered, the Megarensians were allure with the appearance, and, coming near the shore, frove who should leap out first, as it were only to seize the women; but were so warmly received, that not one of them escaped. The Athenians failed for the island, thus deprived of its defenders, and annexed Salamis to the territories of Athens. The fame which Solon thus acquired, he soon increased by his policy and conduct with regard to another subjed of foreign policy.

The Cretans were a flourishing state, not far from Delphi, and, commanding the approaches to that rendezvous of Grecian superstition, derived considerable emolument from the expenses of the devotees. But with these advan-
tages they were not satisfied; they began to exact vexations and exorbitant duties from the merchants who came to export their wares in the sacred city; which, on account of the great concourse of profligate pilgrims from every quarter, soon became the seat, not of devotion only, but of dilapidation, vanity, and licentious pleasure. It was in vain for the merchants to exclaim against these unexampled impositions; the taxes were continually increased; the evil admitted not the expectation of other remedy or relief; and the strangers, familiarized to it by custom, began to submit without murmur; and perhaps endured the hardship with greater patience, when they perceived that they drew back the tax in the increased price of their commodities. Encouraged by this acquiescence in their tyranny, the Cretans levied a severe impost on the pilgrims, whether Greeks or Barbarians, who visited the temple of Apollo; a measure directly inconsistent with a decree of the Amphictyons, which declared that all men should have free access to the oracle, as well as extremely hurtful to the interest of the Delphians, who soon felt a gradual diminution of their profits from the holy shrine. The Cretans, totally regardless of the sentiments of religion, plundered the temple of Delphi, with many circumstances of aggravating atrocity. Solon roused his countrymen to avenge the sacrilege; and to his ingenuity and skill it was chiefly owing that the Cretans were vanquished (Gillies, v. i. 221.), but Solon was defined to render himself, by legislation, most beneficial to his country. The general opinion of his genius and virtues, joined to the experience of his military talents, success in wars, and political address, had procured him distinguished influence over the people. His experienced ability, and above all, his approved wisdom and equity, pointed him out for the noblest and most sublime employment of humanity, that of regulating the laws and government of a free people. Such, at last, the Athenians may be considered, when their unanimous suffrage rendered Solon the absolute umpire of their whole constitution and policy. When he undertook the reform of the state, tyranny and disorder prevailed; the wretched populace, deriving courage from despair, had determined no longer to submit to such multiplied rigours; and, before the wisdom of the lawgiver interposed, they had taken the resolution to elect and follow some warlike leader, to attack and butcher their oppressors, establish an equal partition of lands, and insti-
tute a new form of government. But the numerous clients and retainers, who, in a country little acquainted with arts and manufactures, depended on the wealthy proprietors of the lands and mines of Attica, rendered this undertaking alike dangerous to both parties; so that both became willing rather to submit their differences to law, than to decide them by the sword. The impartiality of Solon merited the unlimited confidence of his country. He maintained the ancient division of property, but abolished debts; he estab-
lished the rate of interest at 12 per cent. at which it afterwards remained; but forbade that the insolent debtor should become the slave of his creditor, or be compelled to sell his children into servitude. After these preliminary regulations, which seemed immediately necessary to the public peace, Solon proceeded, with an impartial and ready hand, to new model the government; on this generous, but equitable principle, that a few ought not, as hitherto, command, and the many obey; but that the collective body of the people, legally convened into a national assembly, were entitled to decide, by a plurality of voices, the alternatives of peace and war; contract or dissolve alliances with foreign states; enjoy all the branches of legislative or sovereign power; and elect, approve, and judge the magistrates or ministers entrusted, for a limited time, with the executive authority. Strangers, and
and all those who could not ascertain their Athenian descent, both in the male and female line, were totally excluded from the assembly and courts of justice. The regulations of Solon marked the utmost attention to preserve the pure blood of Athens unmixed and uncorrupted; nor could any foreigner, whatever merit he might claim with the public, be admitted to the rank of a citizen, unless he abandoned for ever his native country, professed the knowledge of some highly useful or ingenious art, and, in both cases, had been chosen by ballot, in a full assembly of six thousand Athenians.

The numbers of this convention, and still more their impetuosity and ignorance, must have proved inconstant with good government, if Solon had not secured the veil of the republic from the waves of popular frenzy, by the two firm anchors of the senate and the areopagus; tribunals originally of great dignity, and of very extensive power, into which men of a certain description only could be received as members. Solon divided the Athenians into four classes, according to the produce of their estates. The first consisted of those whose lands annually yielded five hundred measures of liquid, as well as dry commodities, and the minimum of whole yearly income may be calculated at sixty pounds sterling, which is equivalent, if we estimate the relative value of money by the produce of labour, and of the things most necessary to life, to about six hundred pounds sterling in the present age. The second class consisted of those whose estates produced three hundred; the third two hundred; the fourth, and by far the most numerous classes of Athenians, either possessed no landed property, or at least enjoyed not a revenue in land equal to twenty-four pounds sterling, or, agreeably to the above proportion, two hundred and forty pounds of our present currency. All ranks of citizens were slicl admitted to vote in the public assembly, and to judge in the courts of justice, whether civil or criminal, which were properly so many committees of the assembly. But the three first classes were exclusively entitled to sit in the senate, to decide in the areopagus, or to hold any office of magistracy. To these dignities they were elected by the free suffrages of the people, to whom they were accountable for their administration, and by whom they might be punished for malversation or negligence, although they derived no emolument from the diligent discharge of their duty. The senate of four hundred, which, eighty-six years after its institution, was augmented to five hundred by Chiphenes, enjoyed the important prerogatives of convoking the popular assembly; previously examining all matters before they came to be decided by the people, which gave them a negative before debate in all public resolutions; and of making laws, which had force during a year, without requiring the consent of the populace. Besides this general superintendence and authority, the senate was exclusively invested with many particular branches of the executive power. The president of that council had the custody of the public archives and treasury; the senate alone built ships, equipped fleets and armies, seized and confined state criminals, examined and punished several offences, which were not expressly forbidden by any positive law. The weight of such a council, which assembl commonly every day, except festivals, infused a large mixture of arbitracy into the Athenian constitution; this, as we shall immediately explain, was still farther incresed by the authority of the Areopagus.

The principal magistrates in Athens were the nine archons. (See Archon.) These nine archons, or presidents of the several courts of justice, like all other Athenian magistrates, were, at the expiration of their annual office, accountable to the people; and when their conduct, after a severe scrutiny, appeared to merit public approbation and gratitude, they were received, and remained for life, members of the areopagus, a senate invested with a general inspection over the laws and religion, as well as over the lives and manners of the citizens; and which, in dangerous emergencies, was even entitled to assume dictatorial power. See Lyssus, Isocrates, Archidiasis, vol. 1. and Gillies's Greece, vol. ii. 'Thus did the senate of the areopagus, and that of the four hundred, become two counterpoises sufficiently powerful to secure the republic against the storms from which all states are incessantly in danger (see Plutarch, in Solon.); the former, by repressing the enterprizes of the rich by its general censure; and the latter, by restraining by its decrees and its presence the excesses of the multitude. New laws were enacted in support of these regulations. The constitution might be attacked either by the general factions which had to long agitated the different orders of the state, or by the ambition and intrigues of certain individuals. To guard against these dangers, Solon denounced punishments against those citizens who, in time of public commotion, refused openly to declare for one of the parties. (Plutarch, in Solon.) His view, in this admirable institution, was to refine men of merit and integrity from a state of fatal inactivity, to oppose them to the factions, and save the republic by the courage and ascendency of virtue. By a second law, every citizen convicted of having attempted to make himself master of the sovereign authority, was condemned to death. Lastly, in the case of an attempt to erect another government on the ruins of the popular form, this wise legislator could imagine but one method to reanimate the nation; and that was by obliging the magistrates to resign their employments; and hence this stern and menacing decree:—it shall be lawful for every citizen, not only to put to death a tyrant and his accomplices, but any magistrate who shall continue to exercise his functions after the destruction of the democracy. Such is the great outline of the constitution established by Solon, according to which every Athenian citizen enjoyed the inestimable privilege of being judged by his peers, and tried by laws to which he himself had contributed. Although the legislative and judicial powers were thus lodged with the people, men of property and ability were alone entrusted with the administration of government; and as power in some measure followed property, the same expedient which served to maintain a due diffusion of ranks in society, tended also to promote the industry and frugality of the multitude, that they might thereby become entitled to flare those honours and offices to which persons of a certain estate only could aspire. (See Gillies, vol. ii. p. 114.) Conformable to this constitution was the code of laws which was framed by this illustrious legislator. As a system of jurisprudence, the institutions of Solon possess extraordinary excellence. They have the merit of easily confounding with great variety and diffimilarity of political systems, and are indeed well adapted to any limited government. Transferred into the Roman law, they have, in the forcible and eloquent language of Dr. Gillies, served after an interval of above sixteen hundred years, to abolish the barbarous practices of the Gothic nations, and to introduce justice, security, and refinement among the modern inhabitants of Europe. The laws of Solon consider the citizen in the various relations of domestic, civil, and political society. They accurately mark the duties belonging to these relations, and prescribe the rules for directing and enforcing the performance of them, and for preventing their violation. To form the citizen early to the habits most beneficial to the community, the laws of Solon describe the plan of his education. They recommend the exercises corporeal, intellectual, and moral, which tend
most powerfully to invigorate the bodily constitution; to enlarge, refine, and direct the understanding; to form, strengthen, and liberalize the heart. They strongly reprobate idleness, and recommend industry, pointing out the objects, private and national, for which it would be most usefully and honourably exerted. They forcibly incite temperance, and censure the contrary as a principal source of misconduct. Although the Athenian law was transplanted into the Roman on many subjects; in several there is a very considerable difference. In Athens, the institutions regarding women, and the relations in which they are concerned, were much more liberal than those of Rome, although they fall greatly short of those in modern times, when men respect the natural equality of the sex. Solon considers marriage as an engagement of mutual love and affection, the ends of which are to give happiness to the family, and useful citizens to the state. He does not consider the wife, as the Romans afterwards did, as only part of the family property, which the husband, the proprietor, was to use as he pleased. He regards her as the domestic companion of her husband, nearly equal to him in the care of the children: he rigorously punishes those who violate the obligations of the married state: he permits divorce, not according to the caprice of the husband, but after a discussion before a magistrate: he permits women to separate from their husbands on the same ground as men from their wives. His law for the protection of unmarried women was highly equitable. Whoever seduced a woman of before unimpeached conduct, was, if unmarried, obliged to atone to her by marriage for the injury. On this law hinge the plots of Molière's plays. The married destroyer of virgin innocence was punished with a salutary rigour. The reciprocal duties of parent and child Solon did not leave to the mere operation of natural affection, but added positive laws. These enjoined parents to bestow such pains on the education of their children as might enable them to perform their various duties as men and citizens. They obliged children to maintain their parents in declining years, two cafes excepted; e. g. if the children had been born of a courtzean, or had been educated to no profession. In the first cafe, they supposed that children owe nothing to parents who had begotten them to disgrace; in the second, who defined them to uncleanness and dependence. Domestic tribunals were not permitted by Solon's laws. A citizen could only be judged by his peers, and by them only deprived of his civil liberty, or life. The magistrates civil, military, and ecclesiastically, were by Solon's laws entitled to respect and obedience, whilst they acted agreeably to the end of their office. (See Anacharsis, Gilleis, and Aristotle's Politicks.) These are a few of the outlines of the provision made by Solon's laws for maintaining what judge Blackstone stylesthe rights of persons. The laws of Solon respecting property were founded on principles of pure ethics, and regarded moral conduct as well as the preservation of property and political expediency. They considered private virtue as well as private right and public tranquillity; they not only provided that one man should not injure another, but endeavoured to prevent such motives from exciting as tend to produce injury. Thus by the Athenian law, the next heir is incapable of being guardian to a minor, because it might be apprehended that such a guardian might be more delinquent of appropriating the inheritance than of promoting the good of the ward. That regulation therefore considers moral motives, and withholds temptations. All the institutions of Solon respecting successions and settlements united the two considerations of regard to property and to moral principle. Solon allowed the citizen to dispose of his property at pleasure; at the same time by his regulations he guards against the arts of legacy hunters; and thus while he respects property, withholds motives to injustice. In that part of his code which treats of what the civilians termed actions, and judge Blackstone private wrongs, Solon's description of injuries, and measures of redress, are nearly the same as in the Roman and English law. They all proceed upon a plain and obvious principle in ethics, that every injury done must be redressed. The injuries which may be done to an individual, affect either his liberty, property, character, or person, and are in general nearly the fame in all countries. On this principle (says Gibbon, speaking of that branch of law), the civilians of every country have created a similar jurisprudence, the fair conclusion of universal reason and justice. In that part which the civilians style penal law, and Blackstone public wrongs, Solon differs very considerably from the Roman law, and agrees with the English. This difference is partly in the description of crimes, and partly in the mode of cognizance. Public wrongs are either such actions or omissions as tend to affect the tranquillity and happiness of a state. The same actions therefore must be wrong in very different degrees in different states and circumstances. The perfection of a penal code depends on the consideration in the description of laws, between crimes and public injuries in the first place; and in the second, between crimes and punishment. If every action which generally hurts the public, is by the laws a crime, and if the punishment be exactly in proportion to the crime, and be not inflicted without certain proof of the commissio, that must be a good penal code. A wise lawgiver apports punishment to crime, but does not consider punishing justice only, he also takes preventive into his consideration. One of the many great excellencies of our English law is, that it has adopted efficacious means for preventing crimes. To this branch of legislation Solon also had paid considerable attention. The prevention of crimes depends chiefly on two things: first, vigilance in observing the conduct of those who, either from their general character, or from particular circumstances, may be supposed most likely to commit them; secondly, on the previous care bestowed on the morals of the people. This last is undoubtedly the surest way of preventing crimes from being general. As a great source of criminal conduct is idleness, Solon enacted a law which obliged every citizen to exercise some trade or profession. "None," says the learned and immortal Drummond, "among the various institutions of Solon has been more deservedly celebrated than that which obliged every citizen to exercise some trade or profession. In countries where the climate naturally disposes men to sloth and inactivity, every law which incites the mind to exertion, or which roufes the latent energy of its faculties, must necessarily be attended with the most salutary effects." This law had a tendency not only to prevent the negative evil of sloth, but the positive evil of active criminality. By the institutions of Solon, extravagance, intemperance, and debauchery underwent a severe animadversion. Magistrates were empowered to watch the bodings of noxious practices which might, if not stamped, ripen into crimes. Solon's description of the various kinds and measures of crimes is very accurate, and the annexed punishment is generally proportionate. No action of pernicious tendency is by the Athenian laws exempted from penal animadversion. By the Roman law, suicide (according to the juft and striking description of Blackstone, "the pretended heroism, but real cowardice of the Stoic philosophers, who destroyed themselves to avoid those ills which they had not the fortitude to endure") was not only not punished, but was
was encouraged. By Solon’s laws, the self-murderer was branded with public infamy, and exposed to what, according to the religious notions of his countrymen, constituted public punishment. Solon describes the various species of fraud, theft, robbery, and homicide with the greatest accuracy. Of the last in particular, the different shades from what our laws call chance murder, to murder, are delineated with a most discriminating precision. It is not only the description of crime, and the annexation of punishment, that is of importance in penal codes, but also the tribunal which is to take cognizance of the crime. By Solon’s laws, every Athenian citizen had a right to be tried by his peers; the Athenian law was in this superior to the Roman, which, in many cases, admitted domicilic trials. The former took cognizance of the crimes of his own family. Thus at Rome, the accused frequently was not tried by a tribunal of his peers, bound to act according to a fixed law, but by an arbitrary judge, whose own will was his only rule. Solon, like every wise lawgiver, endeavoured to extend the influence of religion over the minds of his countrymen. He enjoined a profound veneration for divinities, and described actions as pleasing or displeasing to them, according to the intention of the agent combined with the known tendency of the act; aware that the internal sentiments of religion are strengthened and confirmed by external rites, he strictly enjoined the regular performance of rites and ceremonies.

Such was the code of Solon, such the civil and political institutions which contributed so powerfully to render this small territory so very great a state. The laws of Solon were to continue in force only for a century. Concerning that conduct depends chiefly upon habits, he thought that the practice of a hundred years would confirm the Athenians in the habitual observance of such beneficial rules. But the restrictions being contrary to the licence of strong passions, appeared to many encroachments upon natural liberty; and they wished for modifications which might admit fuller scope to their desires. When the first novelty was worn off, Solon was surrounded by a crowd of importunate citizens, who overwhelmed him with petitions, advice, commendations, or reproaches. Some prefixed him for an explanation of particular laws, capable, according to them, of different interpretations; others propounded a variety of things to be added, modified, or suppressed. Solon having exhausted his patience, and tried every conciliatory method in vain, was sensible that time alone could perfect and give strength to his work; he therefore departed, after requesting permission to absent himself for ten years (see Plutarch, in Solon), and binding the Athenians by a solemn oath, not to make any alteration in his laws during his absence. (See Herodotus, Com.) The adventures of Solon during his peregrinations, belonging to himself individually, and not to the Athenians, will be seen under the articles Solon, Crosis, &c. The object of his travels being, as Herodotus informs us, to view mankind; after having, like Ulysses, traversed many countries, and seen many men, he returned to his native country to behold the operation and effects of his institutions. He found that much time is required before men, who have been either the slaves of despotism or the sharers in licentiousness, can be reconciled to just and equitable laws. The Athenians were ready again to sink into anarchy. (See Plutarch’s Life of Solon.) The three parties, which had so long rent the republic, licent to have suspended their hatred during the legislation only to vent it with more violence in his absence; in one point alone were they united, in defying a change in the constitution, without any other motive than a secret rufellefs, or any object but vague hope. Solon, received with the most distinguished honours, wished to avail himself of the favourable dispositions to calms difficulties too frequently resisting. At first, he thought himself powerfully seconded by Pisistratus, who was at the head of the popular faction; and who, apparently eager to maintain equality among the citizens, declared himself an irreconcilable enemy to every innovation which might tend to its destruction; but he soon discovered that this profound politician concealed the most unaided ambition under the mask of an affected moderation. Never did a man unite more qualities to captivate the minds of the people: he was of an illustrious birth, and possessed of great wealth, acknowledged wealth (see Herodotus, in Crophore, his fifth book), a commanding figure, a persuasive eloquence, to which the musical tone of his voice lent new charms, and a mind enriched with the talents beloved by nature, and the information procured by study. No man was a greater master of his passions, or knew better how to turn to advantage those virtues he really possessed, and those of which he had only the appearance. His facetex has proved that in projects of tedious execution, nothing can be brought to more decided superiority than mildness and flexibility of character. With such eminent advantages, Pisistratus, accessible to the lowest citizens, evaded on them those confusions and successes, which dry up the fount of his enmity, or palliate the bitterness of suffering. Solon, attentive to his proceedings, penetrated his intentions: but whilst he was employed in devising means to guard against their consequences, Pisistratus appeared in the forum covered with wounds he had artfully procured, imploring protection of the people whom he had so frequently protected. (See Herodotus, Com.) The assembly being immediately convened, he accused the senate and the chiefs of the other factions of attempting his life; and displaying his full bleeding wounds: “Behold!” he exclaimed, “the reward of my love for the democracy, and of the zeal with which I have defended your rights.” At these words only menacing exclaimations were heard on all sides; the principal citizens kept silence in astonishment, or took flight. Solon, filled with indignation at their cowardice and the infatuation of the people, vain attempted to renovate the courage of the former, and to dispel the frenzy of the latter; his voice, enfeebled by years, was easily overpowered by the clamours excited by pity, rage, and apprehension. The assembly concluded by voting Pisistratus a strong guard for the defence of his person (B.C. 516). From this moment all his projects were accomplished; he fearlessly employed his force to take possession of the city, and after dispersing the multitude, seized without opposition on the supreme authority. But though Pisistratus by this usurpation destroyed for a time the political liberty of Athens, his power eventually gave stability to the laws which Solon had introduced. That extraordinary tyrant, for so the Greeks stiled him, was not more distinguished by the loftiness of his genius, than the humanity of his disposition; and had not the violence of contending factions, and the fury of his enemies, inflamed his natural love of power, the name of Pisistratus would stand the foremost in the list of Grecian patriots and heroes. His valor and conduct were signalized in the conquest of Naxos, Samos, Naxos, Delos, and Sigean; and if he displayed himself in acquiring the sovereignty, he displayed still more moderation and virtue in administering it. He assumed, indeed, the royal dignities of prince and general, and took care that the chief offices of justice should be filled by his partisans; but he maintained the regular course of law and justice, not only by his authority, but by his example; having appeared in per-
Hipparchus, in particular, was fond of letters. Aracoen and Simonides, invited to his court, met with a most flattering reception: the first being loaded with honours, and the second with presents. He delvered also to participate with his father in the glory of extending the fame of Homer. He could be reproached, as well as his brother, with too freely abandoning himself to pleasures, and with inspiring the Athenians with a taste for luxury. Fortunately, nevertheless, if in the midst of these excelles he had not committted an act of injustice, in which he was the first victim.

Two young Athenians, Harmodius and Aristogiton, united in bonds of the tenderest friendship, having received from this prince an affront it was impossible to forget, conspired his destruction, and that of his brother. Some of their friends entered into this complicity, and its execution was fixed for the solemnity of the panathenaia: they hoped that the crowd of Athenians, who, during the ceremonies of this festival, were permitted to bear arms, would fecond their efforts, or at least protect them against the fury of the guards who attended on the fons of Pisistratus. With this view, after covering their poignards with branches of myrtle, they repaired to the place where the princes were arranging a procession, which they were to precede to the temple of Minerva. When they arrived, they saw one of the conspirators in familiar conversation with Hippias, and concluded themselves betrayed; but resolving dearly to fell their lives, retired for a moment, and finding Hipparchus, plunged a dagger in his heart. Harmodius infantly fell beneath the redoubled blows of the prince's guards. Aristogiton, seized almost at the fame instant, was put to the torture; but far from naming his accomplices, he accused the most faithful parti-

fans of Hippias, who ordered them to be dragged to infall punishment. "Haft thou ill other wretches to discover?" exclaimed the tyrant, transported with fury. "There are none left but thee," replies the Athenian; "I die, and enjoy in death the satisfaction of having deprived thee of thy bet friends." From this moment Hippias abandoned himself to the perpetration of every kind of injustice (Thucydi-des b. 6. c. 59.); but the yoke he had laid heavy on the Athenians was broken thirteen years after. (B.C. 510.) Chilthenes, chief of the Atecmenses, a powerful house of Athens, at all times inimical to the family of Pisistratus, collected all the malcontents about his person; and having obtained the affiance of the Lacedaemonians, by means of the Pythia of Delphi, whom he had gained over to his interest, marched against Hippias, and forced him to abdicate the tyranny. No sooner had the Athenians recovered their liberty, than they rendered the highest honours to the memory of Harmodius and Aristogiton. Structures were erected to them in the forum; it was enacted that their names should be forever celebrated at the festival of the panathenaea, and should, on no pretext whatever, be given to slaves. The poets eternalized their glory by poems and songs, and very extensive privileges were granted in perpetuity to their descendants. Chilthenes, who had so greatly contributed to the expulsion of the Pisistratides, had still to struggle for many years against a powerful faction; but at length obtaining in the flat the authority to which he was entitled by his great talents, he confirmed the constitution established by Solon, which the Pisistratides had never attempted entirely to subvert. (Anacharsis's Travels, vol. i. p. 174.) The power of Athens was great in ancient times; but it became incomparably greater after the re-establishment of freedom. So advantageous to the powers of the human mind is the enjoyment of liberty, even in its least perfect form, that in a few years after the expulsion of Hippias, the Athenians acquired an ascendancy in Greece, which was fatal to their enemies, painful to their rivals, and even dangerous to themselves. They chastified the insolence of the Euboeans and Aegina, who contended with them in naval power; and humbled the pride of Thebes, which rivalled them in military glory. Favoured, as they fondly believed, by the protection of their tutelary Minerva; and animated, as they strongly felt, by the possession of an equal freedom; they adorned their capital with the richest spoils of their vanquished enemies. Their influence was extensive; the northern parts of Greece and the main of their power, still greater than their power itself, alarmed the fears and jealousy of the Peloponnesians. The Spartans, in particular, who had ascribed them in restoring the democracy, now perceived the error of which they had been guilty, in promoting the greatness of an ambitious rival. In order to prevent the dangerous consequences of their folly, they summoned to a congreff all their allies in Peloponnesus, that their united might might concert proper measures for re- fossil, etc. it was too late, the encroachments of the Athenians, which threatened the liberties of all Greece. Their allies readily obeyed the welcome summons, and the deputies of the several states, having assembled in the Spartan forum, eagerly listened to the speakers appointed to explain the intentions of that republic. The Lacedaemonian orators acknowledged the mistaken policy of their country, in expelling from Athens the family of Pisistratus, and delivering the government of that city into the hands of an ungrateful populace, who had since treated them with much indignity. But why (they proceeded) should we relate private injuries? Have they not insulted all their neighbours? Does not their pride daily increase with their power? And is there not reason
reason to dread, that their growing ambition may endanger, and at length destroy, the public safety? In order to prevent this evil, we have recalled Hippias from banishment. And let us, therefore, by our united efforts, reanimate the son of Piithratus in that power and authority of which we most injudiciously deprived him. The speech of the Lacedaemonians produced not the intended effect. The Peloponnesians, however jealous of the Athenian pretensions, were fill more jealous of the power of tyrants; and many of them, who had experienced the haughtiness of Sparta, were not dissatisfied with beholding a rival to that republic in the northern division of Greece. The other deputies expressed their dissent by silent disapprobation: but Sosicles, the Corinthian, declared his sentiments at great length, in a speech which alike marks the slyly character of the age, and the youthful vigour of Cretian eloquence. "Then surely, Lacedaemonians, will the heavens sink below the earth, and the earth rise sublime in the air; men will inhabit the depths of the sea, and fishes will take possession of the land; when you, formerly the bulwarks of liberty, shall demolish the popular governments of Greece, and establish tyrannies in their room, than which nothing can be more unjust or more pernicious." After this pompous oration, the Corinthian proceeded to describe and exaggerate the calamities which his own countrymen had suffered from the usurpation of Cypselus, and his son, Periander. Having related, at great length, the proud, cruel, and detestable actions of those princes; "Such," added he, "are the genuine fruits of absolute power: but I adjure you by the Grecian gods! attempt not to re-establish it in Athens. The Corinthians were feized with astonishment when they heard that you had lent for Hippias; I myself was amazed at beholding him in this assembly; yet we never suspected that you proposed to restore him, in triumph, to his much injured city. If you still persist in this fatal resolution, know that the Corinthians disavow all part in a design equally unjust and impious." The other deputies lifted with pleasure to the boldness of Sosicles, who expressed the sentiments which they themselves felt, but which their respect for the Lacedaemonians obliged them to conceal. Hippias alone opposed the general voice of the assembly, attesting the familar bonds which his opponent had invoked, and prophesying, that at some future time the Corinthians would repent of their present conduct, and regret their cruel injustice to the son of Piithratus, when their own citizens, as well as the rest of Greece, should painfully experience the dangerous ambition of Athens. This remonstrance, which was so fully justified in the sequel, produced no immediate effect in the assembly: the Lacedaemonians finally yielded to the general requit of their confederates, and abanined from their intended innovation in the government of a Grecian city.

(See Herodotus, book v.) Precisely at this juncture (B.C. 501.) Arisigoras arrived at Athens, explained the revolt of the Asiatic Greeks from the government of Artaphernes, and solicited the assistance of the Athenians, in defending their own colonies against the oppressive violence of the common foe. Many arguments were not necessary to make the people of Athens adopt a measure which gratified their own passions. The eloquent Miletian, however, described the wealth and extent of Persia, the grandeur and populousness of its cities, and above all, the fruitful efficiency and puissant weakness of their inhabitants, who, unable to support the ponderous shield, or to impose the manly yoke, invited as an easy prey, the victorious arms of a more unlike invader. The speech of Arisigoras was well fitted to excite the ambition and avarice of Athens. The assembly immediately decreed that assistance should be sent to Ionia. Twenty ships were fitted out with all convenient speed, which reinforced by five more belonging to Eretria, a town of Euboea, rendezvoused in the harbour of Miletus. Arisigoras spent not long time in his embassy to the other states of Greece, and soon met the Athenian allies at the place appointed. It was here determined, that while the commander in chief regulated the civil affairs of the Ionians, his brother Charopius should conduct a military expedition against the wealthy capital of Lydia. The Athenians, deeming it necessary to prevent the appearance of the common enemy, and still more detestable of plunder, eagerly engaged in this undertaking. The united fleets left the harbour of Miletus, and sailed to Ephesus, where the troops were disembarked; and, in three days, accomplishing a journey of seventy miles, appeared before the walls of Sardis. The Persian governor little expected such a visit; his soldiers were not prepared to take the field; and the extensive walls of the city could not be defended on all sides against the besiegers; and the Greeks, without opposition, entered Sardis, in order to plunder the accumulated wealth of that ancient capital. But an accident prevented them from reaping the fruits of their success. The remonstrance of a rapacious soldier disappointed of his prey, let fire to the house of a Lydian, situate on the skirts of the town, which conflagrated-for the most part of combustible materials, the houses being all roofed, and many of them walled with lime; a mode of building doubly dangerous in that great climate. The flames readily communicated from one house to another; and, in a short time, the whole circumference of the place was surrounded with a wall of fire. Sardis was built in the Grecian, not in the Eastern fashion, having on the banks of the Pactolus, which intersected the town, a spacious quay, which commonly served for the market-place. Thither the Persians, driven from the extremities, betook themselves to refuge against the fury of the flames.

Darius was extremely enraged against the Greeks, and especially the Athenians, for having abetted revolt among his subjects. The proud monarch of the East, when informed that the citizens of Athens had co-operated with the Ionians, in the taking and burning of Sardis, discovered evident marks of the most furious resentment; shooting an arrow into the air, he prayed that heaven might afflict him in punishing the audacious insolence of that republic; and every time he sat down to table, an attendant reminded him of the Athenians, left the delight of Eastern luxury should seduce him from his fell purpose of revenge. The execution of his design was entrusted to Mardonius, a Persian nobleman of the first rank, who, perfidious as well as hereditary advantages had enticed him to the marriage of Miltiades, daughter of Darius; and whose youth and experience was compensated, in the opinion of his master, by his superior
superior genius for war, and innate love of glory. In the second spring after the cruel punishment of the Ionians, Mardonius approached the European coast with an armament sufficient to inspire terror into Greece. The rich island of Thasus, whose golden mines yielded a revenue of near three hundred talents, submitted to his fleet; while his land forces added the barbarous province of Macedon to the Persian empire. But having sailed southward from Thasus, the whole armament was overtaken and almost destroyed by a violent storm, while endeavouring to double the promontory of mount Athos, which is connected with the Macedonian shore by a narrow neck of land, but forms a long and lofty ridge in the sea. Three hundred vessels were dashed against the rocks; twenty thousand men perished in the waves. This disaster totally defeated the design of the expedition; and Mardonius having recovered the shattered remains of his fleet and army, returned to the court of Peria, where by flattering the pride, he averted the resentment of Darius; while he represented, that the Persian forces, invincible by the power of man, had yielded to the fury of the elements. The address of Mardonius rescued him from the punishment of his misfortunes; but his misfortunes removed him from the command of Lower Asia. Two generals were appointed in his room, of whom Datis, a Mede, was the more distinguished by his age and experience, while Artaphernes, a Persian, was the more conspicuous for his rank and nobility, being descended of the royal blood. That his lieutenants might appear with a degree of splendor suitable to the majesty of Peria, Darius assembled an army of 500,000 men, consisting of the flower of the provincial troops of his empire. The preparation of an adequate number of transports and ships of war occasioned but a short delay. The maritime provinces of the empire, Egypt, Phoenicia, and the coasts of the Euxine and Egean seas, were commanded to fit out, with all possible expedition, their whole naval strength; the old vessels were repaired, many new ones were built; and in the course of the same year in which the preparations commenced, a fleet of six hundred sail were ready to put to sea. This immense armament the Persian generals were ordered to employ in extending their conquests on the side of Europe, in subduing the republics of Greece, and more particularly in challenging the interference of the Etruscans and Athenians, the only nations which had compered with the revolt of the Ionians, and affiliated rebellious people in the destruction of Sardis. With respect to the other nations which might be reduced by his arms, the orders of Darius were general, and the particular treatment of the vanquished was left to the discretion of his lieutenants; but concerning the Athenians and Etruscans, he gave the most positive commands that their territories should be laid waste, their houses and temples burnt or demolished, and their persons carried in captivity to the eastern extremities of his empire. Secure of effecting this purpose, his generals were furnished with a great number of chains for confining the Grecian prisoners; a haughty premeditation (to use the language of antiquity), in the superiority of man over the power of fortune, which on this, as on other occasions, was punished by the just vengeance of heaven. (B.C. 492.) The Persian fleet enjoyed a prosperous voyage to the isle of Samos, from whence they were ready to proceed to the Athenian coast. The late disaster which befell the armament commanded by Mardonius, deterred them from pursuing a direct course along the shores of Thrace and Macedonia; they determined to steer in a direct line through the Cyclades, a cluster of seventeen small islands lying opposite to the territories of Argos and Attica. The approach of such an immemorable host, whose transports darkened the broad surface of the Ægean, struck terror into the unwatlike inhabitants of those delightful islands. The Naxians took refuge in their inaccessible mountains. The natives of Delos, the favourite residence of Latona and her divine children, abandoned the awful majesty of their temple, which was overshadowed by the holy and lofty mount Cynthus. Paros, famous for its marble; Andros, celebrated for its vines; Ceos, the birth place of the plaince Simonides; Syros, the native country of the ingenious and philosophic Pherecydes; Ios, the tomb of Homer; the indolent Amorgos; as well as all the other islands which surrounded the once sacred shores of Delos, either spontaneously offered the usual acknowledgment of earth and water as a testimony of their friendship, or submitted, after a feeble resistance, to the Persian arms. The invaders next proceeded southward to the isle of Eubœa, where, after almost a continued engagement of six days, their strength and numbers, afflicted by the perils of two traitors, finally prevailed over the valor and obstinacy of the Etruscans. Hitherto every thing was prosperous; but a more difficult task remained, in the execution of which the Persians (happily for Europe) experienced a fatal revers of fortune. After the reduction of Eubœa, the Athenian coast separated from that island only by the narrow strait of Eupirus, seemed to invite the generals of Darius to an easy conquest. They readily accepted the invitation, as the punishment of Athens was the main object which their master had in view when he fitted out his feemingly invincible armada. The measures which they adopted for accomplishing this design appear abundantly judicious; the greater part of the army was left to guard the islands which they had subdued; the uuefes multitude of attendants were transported to the coast of Asia; with a hundred thousand chosen infantry, and a due proportion of horse, the Persian generals set sail from Eubœa, and safely arrived on the Marathonian shore, a district of Attica, about thirty miles from the capital, confounding chiefly of level ground, and therefore admitting the operations of cavalry, which formed the main strength of the barbarian army, and with which the Greeks were very poorly provided. Here the Persians pitched their camp, by the advice of Hippias the banished king of Athens, whole perfect knowledge of the country, and intimate acquaintance with the affairs of Greece, rendered his opinion on all occasions repectable. To combat this mighty force, the Athenians could not bring the twelfth part of the number, but their handful breathed the spirit of freedom, which was paramount to a countless multitude, the tools of despotism. It was first deliberated whether they ought to await the Persians in the city, or meet their foes in the field. There are emergencies in which the most adventurous boldness is the foundest wisdom; happily for the Athenians they had citizens able both to discover and apply this maxim. Three men then flourished in Athens, qualified and destined to give new energy to the state. These were Miltiades, Aristides, and Themistocles. Their characters will best display themselves in the narrative of their actions. Miltiades had long carried on war in Thrace, where he acquired a splendid reputation; Aristides and Themistocles, younger than himself, had from their infancy manifested a rivalry, which would have been the ruin of the state, had they not sacrificed it on all emergencies to the public welfare. The example and harangues of these three illustrious citizens kindled the flames of the noblest heroism in the minds of the Athenians. Levies were immediately made. Each of the ten tribes furnished a thousand foot soldiers, with a commander at their head.
No sooner were the troops assembled, than they marched out of the city into the plain of Marathon, where the inhabitants of Platea sent them a reinforcement of a thousand infantry. Scarcely were the two armies in sight of each other, before Miltiades proposed to attack the enemy; Aristides, and several of the commanders, warmly supported this measure; but the rest, terrified at the excessive disproportion of the armies, were desirous of waiting for succour from Lacedaemon. Opinions being divided, they had recourse to that of the eunuch, or chief of the militia, who was consulted on such occasions to put an end to the equality of suffrages. Miltiades addressed himself to the army of a man deeply impressed with the importance of present circumstances: "Athens (said he) is on the point of experiencing the greatest of vicissitudes; ready to become the first power of Greece, or the theatre of the tyranny and fury of Hippias; from you alone, Callimachus, the new awakens her destiny. If we suffer the horde of the troops to cool, they will shamefully bow beneath the Persian yoke: but if we lead them on to battle, the gods and victory will favour us. A word from your mouth must now precipitate your country into slavery, or preserve her liberty." (See Herodotus, l. vi. c. 109.) Callimachus gave his suffrage, and the battle was resolved. To ensure success, Aristides, and the other generals after his example, yielded to Miltiades the honour of the command which belonged to them in rotation; but, to screen them from every hazard, he preferred waiting for the day which of right placed him at the head of the army. When that day arrived, Miltiades drew up his troops at the foot of a mountain, on a spot of ground covered over with trees, to impede the Persian cavalry. The Plateans were placed on the left wing; Callimachus commanded the right; Aristides and Themistocles were in the centre of the battle, and Miltiades everywhere. (See Herodotus, l. vi.) At the first signal, the Greeks advanced over this space running. The Persians astonish'd at a mode of attack so new to both nations; for a moment prepared motionless; but to the impetuous fury of the enemy, they soon opposed a more sedate and not less formidable fury. After an obstinate conflict of some hours, victory began to declare herself in the two wings of the Persian army. The right dispersed the enemy in the plain, while the left drove them back on a morass that had the appearance of a meadow, in which they flung left and were lost. Both these bodies of troops now flew to the succour of Aristides and Themistocles, ready to give way to the flower of the Persian troops, placed by Datis in the centre of his battle. From this moment the rout became general. The Persians, repulsed on all sides, found their only asylum in the fleet, which had approached the shore. The conquerors pursued them with fire and sword, and took, burnt, or sunk, the greater part of their vessels; the rest escaped by dint of rowing. The banished tyrant of Athens fell in the engagement; two Athenian generals, and about two hundred citizens, were found among the slain: the Persians left fix thousand of their best troops in the scene of action. The joy excited among the Athenians by a victory, which not only delivered them from the dread of their enemies, but raised them to distinguished pre-eminence among their rivals and allies, is evident from a remarkable incident which happened immediately after the battle. As soon as fortune had visibly declared in their favour, a soldier was dispatched from the army to convey the welcome news to the capital. He ran with incredible velocity, and appeared, covered with dust and blood, in the presence of the senators; excesses of fatigue conspired with the transports of enthusiasm to exhaust the vigour of his frame: he had only time to exclaim in two words, "Rise, with the victors!" and immediately expired. The Athenians had lost nothing to eternize those who fell in the battle. Honorable funerals were bestowed on them; their ashes were engraved on half oval medals cast on the plain of Marathon. In the intervals between them were erected trophies bearing the arms of the Persians. An artist of eminence painted all the circumstances of the battle in one of the most frequented porticoes of the city: Miltiades was there represented at the head of the generals, and in the act of exhorting the troops to fight for their country. The high pile of trophies were bel lows and the horse of Miltiades, and he was appointed commander of an expedition against the Persian garrisons. The first operations of the Athenian armament were crowned with success. Several islands were subdued, and considerable sums of money collected. But the fleet arriving before Plataea, everything proved adverse to the Athenians. The Persians made a very vigorous defence, their strength, however, began to decline, and they must have been overpowered, but for a fortunate accident. An extensive groyne, happening to be let on in a neighbouring island, was believed by the besiegers to indicate the approach of a Persian fleet. The same opinion gained ground among the Persians, who determined by their utmost efforts to preserve the place until they should be relieved by the assistance of their pretectors. Miltiades had received a dangerous wound during the siege; and the weakness of his body impairing the faculties of his mind, he gave orders to draw off his victorious troops, and returned with the whole fleet to Athens. The Athenian citizens, and particularly the more eminent and illustrious, had universally rivals and enemies. The competitions for civil offices, or military command, occasioned eternal animosities among those jealous republicans, Xantippus, a person of great distinction, and father of the celebrated Pericles, who, in the succeeding age, obtained the first rank in the Athenian government, eagerly seized an opportunity of deprefling the character of a man which had so long surpassed that of every competitor. He was accused of suffering himself to be corrupted by Persian money, and notwithstanding the solicitations of the most virtuous citizen, was condemned to be thrown into the dungeon in which malefactors are left to perish. The magistracy opposing the execution of this infamous decree, his punishment was commuted into a fine of fifty talents; and as he was unable to pay this sum, Athens law the vanquisher of Baris expire in chains of the wounds he had received in the service of the state. But the glory of Miltiades survived him; and the Athenians, however unjust to his person, were not unkindful of his fame. At the distance of half a century, when the battle of Marathon was painted by order of the state, they directed the figure of Miltiades to be placed in the fore ground, animating the troops to victory; a reward which, Dr. Gillies observes, "during the virtuous simplicity of the ancient commonwealth, conferred more real honour than all that magnificent profusion of crowns and robes, which, in the latter times of the republic, were rather exerted by general fear, than bestowed by public admiration." "The jealousies (continues the same author), resentments, dangers, and calamities, which often attended power and pre-eminence, have never yet proved sufficient to deter an ambitious mind from the pursuit of greatness." The rivals of Miltiades were animated by the glory of his elevation, not deprest by the example of his fall. His successor, Xantippus, though he had acted the principal part in removing this favourite of the people, was not deemed worthy to succeed to his power.
Two candidates appeared for the public confidence and esteem, who alternately outstripped each other in the race of ambition, and whose characters deferve attention even in Athenian history, as they had a powerful influence on the fortune of Athens. (See Dr. Gillies’s History of Greece, vol. i. p. 407.) The character of Aristides has been already seen in biographical detail (see article Aristides): here it is to be viewed merely in its combination with events and with characters which affect the history of Athens.

The character of Themistocles was of a more doubtful kind. The trophy, which Miltiades had raised at Marathon, disturbed his rest; he was inflamed with a desire to emulate the glory of this exploit; and while he enabled Athens to maintain a superiority in Greece, he was ambitious to acquire for himself a superiority in Athens. His talents were well adapted to accomplish both these purposes; eloquent, active, enterprising, he had strengthened his natural endowments by all the force of education and habit. Laws, government, revenue, and arms, every branch of political and military knowledge, were the great objects of his study. In the courts of justice he successfully displayed his abilities in defence of his private friends, or in acquitting the enemies of the state. He was forward to give his opinion upon every matter of public deliberation; and his advice, founded in wisdom, and supported by eloquence, commonly prevailed in the assembly. Yet with all these great qualities, his mind was less smitten with the native charms of virtue, than captivated by her splendid ornaments. Glory was the idol which he adored; he could suffer, without remorse, the general cause of the confederacy, in order to promote the grandeur of Athens; and history full leaves it as doubtful, as did his own conduct, whether, had an opportunity offered, he would not have facilitated the happiness of his country to his private interest and ambition.

The discernment of Aristides perceived the danger of allowing a man of such equivocal merit to be entrusted with the sole government of the republic; and on this account, rather than from any motives of personal animosity, he opposed every measure that might contribute to his elevation. In this patriotic view, he frequently solicited the fame honours which were ambitiously courted by Themistocles, especially when no other candidate appeared capable of balancing the credit of the latter. A rivalry thus began, and long continued between them; and the whole people of Athens could only decide the much contended pre-eminence. The interdict of Themistocles so far prevailed over the authority of his opponent, that he procured his own nomination to the command of the fleet; with which he effected the conquest of the small islands in the Ægean, and thus completed the design of Miltiades. While he acquired fame and fortune abroad, Aristides increased his popularity at home. The opposition to his power, arising from the splendid eloquence and popular virtues of his rival, was now fortunately removed; and he became the chief leader of the people. His opinion gave law to the courts of justice; or rather such was the effect of his equity and discernment, he alone became sovereign umpire in Athens. In all important differences he was chosen arbitrator, and the ordinary judges were deprived of the dignity and advantages formerly resulting from their office. This consequence of his authority, offending the pride of the Athenian magistrates, was sufficient to excite their resentment; which, of itself, might have effected the ruin of any individual. But their views on this occasion were powerfully promoted by the triumphant return of Themistocles from his naval expedition. The admiral had acquired considerable riches; but wealth he despised, except as an instrument of ambition. The spoils of the conquered islands were profusely lavished in shows, festivals, dances, and theatrical entertainments, exhibited for the public amusement. His generous manners and flowing affability were contrasted with the stern dignity of his rival; and the result of the comparison added great force to his influence, that since his own necessary absence in the service of the republic, Aristides had acquired a degree of influence inconsistent with the constitution; and, by arrogating to himself an universal and unexampled jurisdiction in the state, had established a silent tyranny, without pomp or guards, over the minds of his fellow-citizens. Aristeides, trusting to the sense and integrity of his own heart, continued to employ any unworthy means, either for gaining the favor of the people, or for averting the danger of the future. The contest, therefore, ended in his downfall for ten years, by a law intitled the Ostracism (from the name of the materials on which votes were marked), by which the majority of the Athenian assembly might expel any citizen, however inoffensive or meritorious had been his past conduct, who, by his present power and greatness, seemed capable of disturbing the equality of republican government. This singular institution, which had been established soon after the Athenians had delivered themselves from the tyranny of Hippias, the son of Pisistratus, was evidently intended to prevent any peril in future from attaining the same unlawful authority. At Athens, even virtue was proscribed, when it seemed to endanger the public freedom; and only four years after the battle of Marathon, in which he had displayed equal valour and wisdom, Aristeides, the justest and most respectable of the Greeks, became the victim of popular jealousy; an example of cruel rigor, which will for ever brand the spirit of democratical policy. The banishment of Aristides exposed the Athenians fuller more than formerly to the danger which they hoped to avoid by this severe measure. The removal of such a formidable opponent enabled Themistocles to govern without control; army, navy, and revenue, all were submitted to his inspeciton. It happened, indeed, most fortunately for the fame of this great man, as well as for the liberty of Athens, that his active ambition was called to the glorious task of subduing the enemies of his country. The smaller islands in the Ægean were already reduced to obedience; but the possession of them was uncertain while the fleet of Ægina covered the sea, and bid defiance to the Athenians. This small isle, or rather this rock, inhabited time immemorial by merchants and pirates, and situate in the Saronic gulf, which divides the territories from the northern shores of Peloponnesus, was a formidable enemy to the republic; the jealousy of commerce and naval power embittered their mutual rivalry; and as the inhabitants of Ægina, who were governed by a few leading men, had entered into an alliance with the Persians, there was every circumstance united which could provoke to the utmost hatred and resentment of the Athenians. A motive less powerful than the excess of republican antipathy could not probably have prevailed on them to embrace the measure which they now adopted by the advice of Themistocles. There was a considerable revenue arising from the silver mines of mount Laurium, which had been hitherto employed in relieving the private wants of the citizens, or dissipated in their public amusements. This annual income Themistocles persuaded them to dedicate to the useful purpose of building ships of war, by which they might seize or destroy the fleet of Ægina. The proposal was approved, an hundred galleys were equipped, the naval strength of Ægina was broken, and fewens animated the Athenians to aspire at obtaining the unrivalled empire of the sea. Corecyra formed the only remaining obstacle to their ambition. This island, which,
ATH

which, under the name of Phocaea, is celebrated by Homer for its amazing riches and fertility, had been still further improved by a colony of Corinthians. It extends an hundred miles along the western shores of Epirus, and the natural abundance of its productions, the convenience of its harbours, and the adventurous spirit of its new inhabitants, gave them an undisputed advantage over their neighbours in navigation and commerce. They became successively the rivals, the enemies, and the superiors of Corinth, their mother country; and their successful cruises infected the coasts, and disturbed the commerce of the islands and continent of Greece. It belonged to Athens, who had too lately punished the perfidy of *Aegina, to chastise the insidious Cetaceans. The naval depredations of these islanders made them be regarded as common enemies, and Themistocles, when, by feizmg part of their fleet, he broke the linens of their power, not only gratified the ambition of his republic, but performed a signal service to the whole of the Grecian confederacy. Victorious by sea and land, against Greeks and Barbarians, Athens might now seem entitled to enjoy the fruits of a glorious security. It was generally believed in Greece, that the late defater of the Persians would deter them from invading a second time the coasts of Europe. But Themistocles, who, in the words of Thucydides (lib. i.), was no less faggious in seeing the future, than in managing the present, regarded the battle of Marathon not as the end of the war, but as the prelude to new and more glorious combats. He continually exhorted his fellow-citizens to keep themselves in readiness for action; above all, to increase, with unremitting alacrity, the strength of their fleet; and, in consequence of this judicious advice, the Athenians were enabled to oppose the immense armies of Xerxes (of which the most formidable tidings soon arrived from every quarter), with two hundred galleys of a superior size and construction to any hitherto known in Greece. (See Gillies's Greece, vol. i. p. 414.)

Meanwhile the reduction of revolted provinces had given employment and Inure to the Persian arms. Nine years after the battle of Marathon, and in the fourth year of his reign (B.C. 481.), Xerxes found himself uncontrolled master of the East, and in possession of such a fleet and army as startled him with the hopes of universal empire. The three last years of Darius were spent in preparing for the Grecian expedition. Xerxes, who succeeded to his father's and to his revenge, dedicated four years more to the fame holy purpose. Amidst his various wars and pleasures, he took care that the artificians of Egypt and Phoenicia, as well as all the maritime provinces of Lower Asia, should labour with unremitting diligence, in fitting out an armament adequate to the extent of his ambition. Twelve hundred ships of war, and three thousand ships of burthen, were at length ready to receive his commands. The former were of a larger size and firmer construction than any hitherto seen in the ancient world; they carried on board, at maximum, 200 men, and thirty Persians who served as marines. The ship of burthen contained, in general, eighty men, fewer being found incapable of rowing them. The whole amounted to 4200 ships, and about 500,000 men, who were ordered to rendezvous in the most fertile roads and harbours of Ionia. We are not exactly informed of the number of the land forces, which were assembled at Susa. It is certain, however, that they were extremely numerous, and it is probable that they would continually increase on the march from Susa to Sardis, by the confluence of many tributary nations, to the Imperial standard of Xerxes. The Persian army consisted of 1,700,000 infantry, and 80,000 cavalry, besides 20,000 Arabsians, riders of camels, and Libyan charioteers: when to these were added sailors and marines, the number amounted to 2,317,610; this was the number of fighting men whom Xerxes brought from Asia, exclusively of attendants and slaves. Besides, there were immense numbers of women and eunuchs, who, according to eastern luxury and debauchery, followed the camp, in all the ostentatious pageantry and fabulous magnificence of despotic pomp; so that, to use the words of the animated Barthelemy, 5,000,000 had been torn from their native homes, and were preparing to destroy whole nations, to gratify the ambition of an individual named Mardonius. In Europe he was joined by 300,000 of Thracians, Macedonians, and northern Greeks, who mainly defended their brave countrymen of Sparta and Athens; so that the whole exceeded 2,600,000 men. (This account is transcribed from Herodotus, l. vi.) The number of this army, as recorded by the first Greek historian, has never been equalled by any of ancient or modern times, from Herodotus to his literary descendant Gillies. But little availed the bodies of Asiatic slaves, against the fouls of European freemen. Having wintered at Sardis, he sent ambassadors to demand earth and water, as a mark of submission, from all the Grecian states except Athens and Sparta, whom he presumptuously referred for the severest punishment. (B.C. 480.) The slow march of his immense army, and, still more, its tedious transportation across the seas which separate Europe from Asia, ill suited the rapid violence of his revenge. Xerxes therefore ordered a bridge of boats to be raised on the Hellespont, which, in the narrow part, is only seven fathoms, or seven eights of a mile in breadth. Here the bridge was formed with great labour; but whether owing to the awkwardness of its construction, or to the violence of a succeeding tempest, it was no sooner built than destroyed. The great king ordered the directors of the work to be beheaded; and, proud of his tyrannic power over feeble men, displayed an impotent rage against the elements. In all the madness of despotic, he commanded the Hellespont to be punished with 300 stripes, and a pair of fetters to be dropped into the sea; adding these frantic and ridiculous expreitations:—"It is thus, thou salt and bitter water, that thy matter purifies thy unprovoked injury; and he is determined to pass thy treacherous streams, not withstanding all the influence of thy malice." After this absurd ceremony, a new bridge was made of a double range of vessels, fixed by strong anchors on both sides, and joined together by cables of hemp and reed, falled to immense beams driven into the opposite shores. The decks of the vessels, which exceeded 600 in number, were strewed with trunks of trees and earth, and their surface was still farther smoothed by a covering of planks. The fids were then raised with wicker work, to prevent the fear and impatience of the horses; and upon this singular edifice the main strength of the army passed in seven days and nights, from the Asiatic city of Abydos, to that of Selcots in Europe. The army began its march, divided into three bodies, one of which followed the sea shore, and the two others proceeded at stated distances, through the interior part of the country. (See Herodotus, l. vii.) The measures that had been adopted, procured them certain means of sublimity. Three thousand vessels laden with provisions kept along the coast, regulating their motions by those of the army. The Egyptians and Phoenicians had previously flored many of the maritime towns of Thrace and Macedonia, and the Persians at every station were fed and provided with every thing by the inhabitants of the adjacent countries, who, long apprised of their arrival, were prepared for their reception. But before this general transportation, a considerable part of the forces had been already sent to
The coast of Macedonia, in order to dig across the Ithmus which joins to that coast the high promontory of Athos. The ditch which befoe the fleet commanded by Mardonius, in doubling the cape of this celebrated peninsula, was full present to the mind of Xerxes. The neck of land, only a mile and a half in breadth, was adorned by the Grecian city of Samos; and the promontory being rich and fertile, was well inhabited both by Greeks and Barbarians. The cutting of this narrow Ithmus, by a canal of sufficient width to allow two galleys to sail abreast, was a matter not beyond the power of a potentate who commanded the labour of so many provincials; but it is observed by Herodotus, to have been a work of more ostentation than utility, as the vessels, according to the custom of the age, might have been conveyed over land with greater expedition, and with less trouble and expense. The Persian forces were now safely conducted into Europe; and the chief obstacle to the easy navigation of their fleet along the coasts of Thrace, Macedonia, and Thessaly, to the centre of the Grecian states, was removed by the dividing of mount Athos. Through the fertile plains of Leifer Aphi, the whole army had kept in a body; but the difficulty of supplies obliged them to separate into three divisions in their march through the less cultivated countries of Europe. Before this evacuation took place, the whole fleet and army were reviewed by Xerxes, near Doricene, a city of Thrace, at the mouth of the river Hidras. This celebrated muster we shall narrate in the words of Dr. Gillyes. "Such an immense collection of men assembled in arms, and attended with every circumstance of martial magnificence, gave an opportunity for seeing, or at least for supposing, many affecting scenes. The ambition of the great king had torn him from his palace of Sura, but it could not tear him from the objects of his affection, and the ministers of his pleasure. He was followed by his women, and by his flatterers, and all the effeminate pride of a court was blended with the pomp of war. While the great body of the army lay every night in the open air, Xerxes and his attendants were provided with magnificent tents. The splendor of his chariots, the mettle of his horses, which far excelled the swiftest racers of Thessaly, the unequaled number of his troops, and above all, the bravery of the immortal band (a body of 10,000 Persian cavalry, so named because their number was constantly maintained from the flower of the whole army), seemed sufficient, to the admiring crowd, to raise the glory of their sovereign above the condition of humanity; especially fine, among so many thousands of men as palled in review, none could be compared to Xerxes in strength, in beauty, or in stature. But amidst this splendor of external greatness, Xerxes felt himself unhappy. Having ascended an eminence to view his camp and fleet, his pride was humbled with the reflection, that no one of all the immensurable host could survive an hundred years. The haughty monarch of Aphiia was melted into tears. The conversion of his kinsman and counsellor, Artabanus, was still calculated to confound his melancholy. That respectable old man, whose wisdom had often moderated the youthful ardour of Xerxes, and who had been as affiduous to prevent, as Mardonius had been to promote, the Grecian war, took notice that the majesty of human life was an object far more lamentable than that of fire. In the narrow space allotted, has not every one of them in our presence, and indeed the whole human race, often wished rather to die than to live? The tumult of passions disturbs the belf of our days; diseases and weakness accompany old age; and death, so vainly dreaded, is the sure and hospitable refuge of wretched mortals." (See Gillyes, vol. i. p. 424.) Xerxes often conversed with Demaratus, an exiled king of Sparta, who had taken refuge with the Persian monarch, and their dialogues, detailed by Herodotus, admirably illustrate the opposite circumstances and characters of the Persians and Grecians. The following is nearly the substance. "Do you imagine," said the despot, "that the Greeks will dare to refilt my forces?" Demaratus, having obtained permission to speak the truth, replied, "The Greeks are to be feared, because they are poor and virtuous. Without pronouncing the eulogium of the other states, I shall only speak to you of the Lacedemonians. They will scorn the idea of slavery. Should all Greece submit to your arms, they will be but the more ardent in defence of their liberty. Inquire not the number of their troops; were they but a single thousand, nay, were they but fewer, they would present themselves to the combat." The Persian king, at hearing this, laughed aloud; and after comparing his forces with those of the Lacedemonians: "Do you not see," said he, "that the greatest part of my folders would take to flight, were they not retained by masts and bows? As a similar dread cannot operate on those Spartans, who are represented to us as so free and independent, it is evident that they are evermore effectually brave certain death; and what is there to constrain them to it?" "The law," replied Demaratus; "that law which has more power over them, than you have over your subjects; that law which faith to them, beheld your enemies; the question is not to number them; you must conquer or die." Xerxes was rather amused than instructed by this discourse. His hopes of success seemed built on too solid principles to be shaken by the opinion of a prejudiced Greek. Every day messengers arrived with the submission of new nations. He proceeded on his march, till he arrived at the pafs of Thermopylae. This is a defile situated at the foot of mountain Octa, between Thessaly and Phocis; a pafs no more than ninety feet broad, and the only one by which the height of Xerxes could penetrate into Achaia. (9) Thither the Grecian army, not exceeding 11,000, directed its course: of these 4,000 only were more immediately destined to defend the passage. But finding himself insulted, and being informed by Demaratus, that a handful of men might at this place stop for a considerable time all his forces, he endeavoured to corrupt Leonidas by magnificent presents, and the most tempting promises, even that of making him supreme lord of Greece. But Leonidas having rejected all his temptations with disdain, Xerxes thereupon commanded him by a messenger to send him his arms. "Let your king come and take them," answered Leonidas. Then the Medes advanced against the Greeks: but being unable to fullfill their attack, were obliged to retreat. The troops of Persians, distinguished by the name of Immortal, next charged the Greeks, and fought with great valour, so that the pafs was choked up with the dead. While the left troops of Xerxes were thus sacrificed to the Spartan valour, an inhabitant of the country having discovered to the Persians a secret path conducting to an eminence that commanded the pafs, a large detachment was immediately sent to take possession of it. Leonidas receiving intelligence that the tops of the rocks forming the pafs were occupied by 20,000 Persian troops, whose darts must soon overwhelm him and his small party, irritated the greater part of his men to retire, and relieve themselves for a more advantageous opportunity of serving their country; while he himself with about 300 Spartans and a few Thebians, would maintain the pafs till the last. The rest having accordingly departed, "Come my friends," said Leonidas, "let us dine cheerfully, in the hope of surpping together in the other world." His brave companions, encouraged by the example of their chief, thought...
thought of nothing now but to sell their lives as dearly as possible; believing it incumbent on them, as the leading people of Greece, to devote themselves to certain death, thereby to convince the Barbarians how much it must cost them to reduce a free people to slavery. In the dead of night, this heroic troop advancing directly forwards to the tent of the king, penetrated to the middle of the Persian camp, cut off all that came in their way, and spread the most dreadful confirmation among the enemy. But daylight at last discovering them distinctly to the Persians, they were immediately surrounded, and being rather overwhelmed than conquered, breathed their last above heaps of slaughtered enemies; leaving to after ages an example of intrepidity before unknown, and hardly to be paralleled in history. The Persians are said to have left upwards of 20,000 men in this engagement, and, among the rest, the two brothers of Xerxes. To the memory of these brave defenders of Greece, a superb monument was afterwards erected, bearing two inscriptions: the one in honour of all those who had served on that occasion: importing, that an army of four thousand Peloponnesian Greeks had there stopped the progress of the whole Persian force; the other in honour of Leonidas and his 300 Spartans, expressed, in a few simple words, to this effect: "Go, passenger, tell at Sparta, that we died here in obedience to her laws." This famous action at Thermopylae, in the opinion of Diocondorus Siculus, contributed very highly to the subsequent advantages obtained by the Greeks: for the Persians, astonished at so striking an instance of desperate valour, thence concluded, that it was hardly possible to subdue a nation of such undaunted resolution; and the Greeks likewise perceived, from the same example, that valour and discipline are capable of vanquishing the greatest multitude; and that therefore it was possible to overcome the Persians.

But the principal defence of Greece rested with the Athenians. The very day that Leonidas fell at Thermopylae, the Athenian fleet, commanded by Themistocles, having discovered, while cruising off Artemisia, a promontory of Euboea, a detachment of the enemy's fleet amounting to two hundred vessels, attacked them in the night, and sunk more than thirty of them, and the rest were left that same night wrecked on the coast of Euboea by a storm that succeeded the engagement. The Athenians receiving next day a reinforcement of fifty-three ships more, attacked those of the Cilicians, and sunk many of them. A general engagement ensued the same day, in which both parties fought with great bravery; and though neither could boast of the victory, yet the loss was most considerable on the side of the Persians. From the event of these several actions, the Athenians learned, that victory is not always determined by the greater number of ships. Hearing, in the mean time of what had passed at Thermopylae, the Greeks thought it advisable to retire nearer home, and therefore set sail for Salamis, a small island not far from Attica. Xerxes having now advanced into Phocis, after marking his march all along with the effects of his resentment, the Peloponnesians resolved to fortify themselves within the isthmus. The Athenians, therefore, seeing themselves on the eve of being crushed under the whole weight of the Persian power, felt, on this extremity, to confult the oracle; who told them, that the only means of preserving their city were the wooden walls. "These wooden walls, pointed out by the oracle, were interpreted by Themistocles to be their ships; and he told his countrymen, that the fice means of preservation left was, to abandon the city, and to betake themselves to their fleet. This advice was not at all ratified by the people, who shuddered at the thoughts of deserting their gods, and the towns of their ancestors. Themistocles, however, proceeded at last in persuading them, that the existence of Athens depended, not on its houses nor its temples, but on the lives of its citizens; and that the gods themselves had, by the mouth of the oracle, plainly declared it to be their pleasure, that the Athenians ought to leave their city for a while. The people at last, convinced by his eloquence, contented to go on board of their ships. It is difficult to say, whether we are more affected on this occasion by the melancholy situation of the Athenians, thus compelled by a barbarous prince to desert their native country; or by the heroic resolution of these Athenians, to go in this manner into a fort of voluntary submission, rather than submit to the oppressors. The Athenians conveyed their women, children, and the greater part of their old men, to Trazine, a small town on the sea coast of Peloponnesus, where they were received with all the marks of humanity which their situation required. But many of their oldest men were left in the citadel, being unable, by reason of their great age and infirmities, to undergo the fatigue of transport. Xerxes in the mean time, approaching Athens, sent a detachment of his army to plunder the temple of Delphi, which contained immense riches. But Herodotus and Diodorus Siculus tell us, that most of the soldiers sent on this errand perished in a violent tempest. The Persian army arriving at Athens, found nothing but silence and solitude within the walls. They attacked the citadel, which, after a brave resistance by its feeble garrison, was taken by them, and all within it were put to the sword. Xerxes ordered the rest of the city to be set on fire. In the mean time, differences were likely to arise in the Grecian fleet commanded by Eurybiades; one half of them being of opinion that they ought to advance towards the isthmus of Corinth, to be at hand to support their army; and the other, that they ought by no means to quit the advantageous port of Salamis. The latter opinion was supported by Themistocles; who, on this occasion, gave another proof of his extraordinary moderation and coolness of temper. For while he was maintaining his opinion with some warmth against Eurybiades, who was a man of a choleric disposition, the latter flew in a passion, and lifted up his hand to strike him: Themistocles cried out to him, "Strike, but hear me." His eloquence and firmness at last prevailed, and the Greeks saw that, being extremely inferior to the enemy in the number as well as in the size of their ships, it was of the highest importance to avail themselves of their present situation, and to give battle in such a narrow strait as that of Salamis, where the enemy could not bring all their fleet into action. They resolved, therefore, to prepare to fight the Persians in this strait. The Persians determined to give battle, contrary to the opinion of queen Artemisia, who, foregoing to them, that the loss of a few ships might inevitably be attended with the destruction of their army on land. But her advice, though the most prudent, was rejected, Xerxes having himself declared his sentiments for their coming to action. Themistocles, in the mean time, to put it entirely out of the power of his countrymen to retire from Salamis, contrived to have false intelligence conveyed to Xerxes of their intending to decline the engagement, and to make their escape, and therefore advising him to order his fleet hastily to advance and block them up. This stratagem he communicated to Aristides, who undertook to exhibit the rest of the commanding officers with whom he was in great credit, not to be dismayed at seeing themselves hemmed in, but to behave with their usual intrepidity. This stratagem had the desired effect; and
and the Greeks seeing no other possibility of escaping, except by fighting their way through the midst of the enemy, prepared for the engagement. Xerxes, who was on shore, being delirous of seeing the battle, ordered a superb throne to be erected for him on an eminence. The fleet of the Greeks consisted of three hundred and eighty fail. Themistocles, who that day commanded it, waited for the rising of a wind, which regularly began to blow at a certain hour, in a direction exactly in the face of the enemy. The Persians began the attack with great bravery; but the small fleet of the Greeks, acting by the skill of its commanders under every advantage, soon threw the enemy's first line into confusion, and funk the Persian admiral. Those that followed him, intimidated by his fate, partly betook themselves to flight, and partly were sunk. On the wings, however, the action continued very warm and obstinate; but the wind being against the Persians, the unwieldy size of their ships rendered them very difficult to be managed, and their great number rather embarrassing than aiding them in such a narrow trait, they could not long fulfill the impetuosity of the Athenians, but fell into a general disorder. The Ionians, mindful of their Grecian extraction, were the first that fled; and they were quickly followed by the rest of the Persian fleet, which soon appeared scattered up and down in flight and confusion. Queen Artemisia signalized herself by a courage far above her sex. In the height of the battle, perceiving herself to be on the point of falling into the hands of the Greeks, she immediately hung out Grecian colours, and attacking one of the Persian galleys, funk it. The Greek that pursued her, deceived by this stratagem, believed her to be one of his own party, and quitted the pursuit. The victory went to the Greeks forty ships; but of the Persians two hundred were either taken or sunk. This engagement, one of the most memorable recorded in ancient history, entailed immortal fame on the Grecian wisdom and courage. The renowned Cimon, though yet but a young man, distinguished himself highly on that occasion, and gave evident marks of his future greatness. But as the principal glory belonged to Themistocles, the eyes of all the Greeks were fixed on him, and the highest honours were conferred on the deliverer of Greece. At this time every sentiment of jealousy was overlooked, and none exceeded the Laconians in their encomiums on Themistocles, whom they crowned with laurel, the reward of wisdom and valour. When he appeared at the Olympic games, the whole assembly rose up to give him place; every eye was fixed on him alone; and that day was the most glorious of his life.

The Persians and Greeks were in expectation of a new battle; but Mardonius was by no means satisfied with the orders given by Xerxes; he read in the soul of that prince nothing but the meanest sentiments combined with projects of revenge, to which he possibly might fall a victim. "My lord," said he, approaching him, "desire to recall your courage; your expectations were not founded on your fleet, but on that formidable army with which you have entrapped me. The Greeks are no more able to resist you now than heretofore; nothing can shelter them from the punishment due to their ancient offences, and the fruitless advantage they have lately gained. If we determine on a retreat, we shall for ever be the objects of their derision; and the opprobrium that has fallen on the Phoenicians, the Egyptians, and other nations who fought on board your vessels, will recoil on your faithful Persians. Allow me to propose another method to save their glory and your own; I would advise you to lead back the greater part of your troops to Peria, and leave me three hundred thousand men,

with whom I shall be able to reduce all Greece." (See Herodotus, i. viii.) Xerxes, who in his own mind was rejoiced at the proposal, assembled his council, admitted to it Artemisia, and requested her opinion on the project of Mardonius. The queen discovering the real sentiments of Xerxes, gave an advice which she knew would be pleasing. "Leave," she said, "to Mardonius, the care of completing your work. If he succeeds, yours will be all the glory; if he perishes, or is defeated, your empire will not, on that account, be shaken, nor Persia consider the loss of a battle as any great misfortune, when you shall have secured your person." When the Greeks had leisure to examine the extent and completeness of their successes, they determined, in the full emotion of triumph and retribution, to pursue the shattered remains of the enemy. That no Barbarian might escape, they proposed immediately to fall westward, to destroy the Persian bridge over the Hellespont, and thus to intercept their return. This design was recommended, and chiefly supported by the Athenians, who, having experienced the greatest share of the danger, felt most sensibly the joys of deliverance. But upon more mature deliberation, it occurred that the Persians were still sufficiently numerous to afford just grounds of terror. To their cowardice and inexperience, not to their want of strength, the Greeks owed all their advantages over them; but should the impossibility of retreat be added to their other calamities, they might derive courage from despair, and, by efforts liñeto unexerted, repair the confusions of their past errors and misfortunes. These confusions, first fagged, it is said, by Eurybiades the Spartan, were adopted by Themistocles, who convinced his countrymen that the jealousy of the Grecian gods, unwilling that one man should be lord of Europe and Asia, rather than their own princes, had given them the victory over Xerxes; a prince of such fuly and madness, that he had treated with equal irreverence things human and divine, destroyed the sacred temples, overturned the venerable altars and images, and impiously insulted the gods of the Hellepont with stripes and fetters. That it was the duty of the Athenians, after having gloriously repelled the common enemy, to provide for the subsistence of their wives and families, to fow their lands, rebuild their houses, and thus to repair, by the most industrious activity, the dreadful ravages committed on their territories. (See Gillies, vol. i. p. 482.) Themistocles had no sooner persuaded the Athenians to embrace his opinion, than he secretly dispatched his confidant Sicius to acquaint the great king with the danger which he had so nearly escaped, and to advise him to pursue his journey with all possible expedition. Xerxes readily believed a piece of information, which agreed with the suggelions of his own timidity. The rapidity of his march, confounded with other circumstances above mentioned, in proving fatal to the lives of his followers; and the crafty Athenian, who knowing the infallible affections of the multitude, wished to defile the gratitude of a king, gained the double advantage of dispelling sooner than could otherwise have happened, that destructive cloud of Barbarians which hovered over his country, and of convincing their leader that he was in part indebted for his safety to that very man whose counsels, rather than the arms of Greece, had occasioned his affliction and disgrace.

Mardonius (B. C. 479), after wintering in Thessaly, took the field, and began his operations by making very advantageous offers to the Athenians, to detach them from their confederacy with the other states; promising much to restore their city, and to give them a vaster sum of money, but to let them at the head of all Greece. Aridides, then archon,
archon, answered the messengers of Mardonius, that all the
gold in the world was insufficient to corrupt the Athenians,
or to induce them to defect the defence of the common
liberty of their country; that while the sun continued to
light the world, the Athenians would remain the mortal
enemies of the Persians, and would revenge, to the utmost
of their power, the mischief they had brought upon their
country, and the burning of their houses and temples. As
soon as Mardonius received the answer of the Athenians,
and thence saw that no motive could induce them to break
their engagements, he ordered his army to march towards
Attica. The Athenians, on the approach of the Persian
army, left their city a second time, and retired to Salamis.
Mardonius thereupon sent new deputies to them, with
terms still more advantageous than the former: but the
Athenians were so far from accepting them, that they
floned to death one Lyridas, only for saying that they
ought to give an audience to the deputies. The Persian
general, provoked at the temerity with which the Athe-
nians treated all his proposals, entered Athens, and burnt
every thing that had formerly escaped the fury of Xerxes.
In this situation, the Athenians complained to the Laced-
emonians of their not having sent them the stipulated fue-
ceons; the latter were then fully intent on maintaining
their ground within the Peloponnese, and defending the
entry of the Ilissus; but in compliance with the requisition
of the Athenians, who made a great outcry against the
flowners of their proceedings, they sent to their assistance
five thousand Spartans, each of whom was attended by
seven helots. These forces, joined with those of the Athe-
nians and Peloponnesians, formed altogether an army of about
70,000 men; which, after assembling at Eleusis, followed
Mardonius into Boeotia, and encamped on the foot of mount
Citheron. Paullaneas, son of Cleombrotus, and vicerey of
Sparta, commanded the Lacedemonian troops, and Artilides
tho' of the Athenians; the Persian army then amounted to
300,000 men. Paullaneas, in the mean time, advanced
towards Plataea, with his forces drawn up in battle array;
the Athenians being on the right wing, and opposed to the
Persian troops, and the Lacedemonians on the left, opposed
to the Greek troops in the service of the Persians. The
Megareans, who were encamped on the plain, having been
attacked by the Persian cavalry, were, after a very brave
and long resistance, on the point of giving way, when three
hundred Athenians ran to their relief. The battle then be-
came more obdurate than before; but Magi, who com-
manded the Persian cavalry, being slain, his men betook
themselves to flight. The death of this officer, who was
reckoned the ablest in the Persian army, spread universal
confusion through all their troops. Ten days inter-
vened between this action and the general engagement. Ar-
tabazus was of opinion, that the Persians ought to avoid a
general battle; but Mardonius, a man of a violent fiery
disposition, thought otherwise. Paullaneas and Artilides,
informed of the design of the Persians to attack them,
drew up their army in order of battle near to the city of
Plataea, which Mardonius perceiving, changed the intended
order of his attack. But the Greeks, finding themselves
straitened for water in their present situation, resolved to
deep. Mardonius believing this movement to be a flight,
immediately advanced with his men, uttering loud huzzas,
and charged the rear of the Greek array, composed of the
Lacedemonians, who, forming themselves into a column,
opposed the enemy with their usual valor, and falling on
the Persians with the greatest fury, made a dreadful slaugh-
ter. Mardonius fell in the beginning of the action. The
main body of the Greek army advancing in the mean time
to the charge, in separate detachments, completed the over-
throw of the Persians. In another quarter of the field, the
40,000 Greeks in the Persian service, who were engaged
with the troops commanded by Ariobates, hearing of the
flight of the Barbarians, followed their example, and re-
treated likewise, but rallied in their camp, and there en-
trenched themselves. The Lacedemonians, however, sup-
ported by the Athenians, attacked and forced their en-
trenchments; after which, nothing was to be seen but a gen-
eral massacre, for the Persians being too numerous to be
made prisoners, received no quarter, and were all put to
the sword. Artabazus, after distinguishing himself both as a
skilful and as a brave soldier, collected the scattered re-
 mains of the Persian army, amounting now to no more than
44,000 men, and returned with all possible expedition to-
wards Persia. The loss of the Greeks in this engagement
was about 10,000 men. The Greeks, as a monument of
this memorable victory, erected a statue to Jupiter in the
temple of Olympia, inscribed with the names of all the
nates of Greece who had fought at Plataea. It came next
under consideration, whether the prize of valour ought to
be adjudged to the Athenians or to the Lacedemonians.
But to avoid all controversy on this head, whereby the gen-
eral joy arising from the victory might be disturbed, the
question was, by the influence of Ariobates, referred to the
determination of the other Greeks, who, to prevent any
jealousy between those rival states, adjudged it to belong to
the Plataeans. Then, after sending a troop of gold solid
to the temple at Delphos, and setting apart a tenth of the
pool, as an offering to the gods, to be applied to religious
purposes, they divided with great justice the rest of the
pool, which was so immense, that Julian is of opinion it
was the first great source of the corruption of the Greek
manners. By the persuasion of Ariobates, the Greeks
passed a solemn decree, obliging all the states to send deputi-
ties to Plataea, to offer sacrifices to Jupiter the deliverer,
instituting public games at that place every fifth year; and
ordering a fleet of a hundred ships, and an army of 10,000
foot, and as many horse, to be kept always on foot, for
making continual war on the Barbarians. The Plataeans
were appointed to celebrate the anniversary of all those who
had fallen in this battle, which they regularly performed
with much pomp and ceremony. The Persian fleet, having,
in the mean time, failed towards Samos, that of the Greeks,
under the command of Leuctchides the Lacedemonian, and
Xatippus the Athenian, advanced as far as Delos, upon the
earnest entreaty of the inhabitants of Chios, who begged
be delivered from their subjection to the barbarians; and
likewise in consequence of secret intelligence received by
them of the intention of the Ionians to revolt. The Per-
sians, hearing of the approach of the Greeks, retired to My-
cale in Alcina Minor, where they drew their vessels on shore,
and surrounded them with a deep ditch. The Greeks, how-
ever, pursued them thither, and with the assistance of the
Ionians, attacked them. The battle was at first bravely
fought on both sides; but the Milesians and Samians, fol-
lowed by the rest of the Asiatic Greeks, having defected
from the Persians, the latter were vanquished, and 40,000
of them cut in pieces. The Athenians took possession of
the enemy's camp, burnt the Persian fleet, and returned to
Samos with a vast deal of plunder. This engagement hap-
pened on the same day with that of Plataea. Thus did that
memorable day for ever free the Greeks from any future
Persian invasions, and deliver them from those innumerable
armies of Barbarians, which like clouds of locusts had con-
sumed their country for two whole years. These grievous
defeats were never forgotten by the Persian monarchs; and
they entirely cured Xenexes of all desire of undertaking any other enterprises of the same kind. He thought no more of executing vengeance on the Greeks; and to effect all remembrance of his past disfigure, he gave himself wholly up to every sort of voluptuosities and debauchery. His court became one general scene of the most shameful excesses, murder and incest succeeding each other in perpetual round. This weak licentious prince was at length put to death by his own subjects. The severe effects of tyranny, formerly experienced by the Athenians, had excited in them such a strong desire of liberty, that to preserve it, they boldly hazarded the greatest dangers. Their bravery, however, was admirably supported and condueted by the wisdom and skill of their generals, who were particularly attentive to choose such a situation for giving battle, that the enemy could not much avail themselves of their valour superiority in point of number.

Thus by their vigorous efforts, and the wisdom of their leaders, delivered from the Persian invasion, the Athenians brought back their wives and children to Athens, of which they rebuilt the walls, and considerably increased the extent. The Lacedemonians taking umbrage at this, from an apprehension all Athens should become too powerful, represented to the Athenians, that it was the general interest of Greece to have no fortified place without the Peloponnesus, because in case of a fresh invasion, it might serve for a retreat and warlike magazine to the enemy. Themistocles, having procured himself to be named ambassador to Lacedemon, there to justify the conduct of his countrymen, maintained in open Senate that it was as much for the common advantage of the allies, as for that of the Athenians, that the latter had fortified their city with good walls; that besides, it was but equitable that they, as well as the rest, should take proper measures for their own safety; and in fine, that they were able to defend themselves either against foreign or domiciliary enemies. In the next place, Themistocles, solely intent on increasing the power of the republic, fortified Piraeus (B.C. 477), the famous harbour of Athens, in the same manner as he had done the city, and persuaded the Athenians to augment their fleet yearly with twenty ships. The object of this skilful politician was to deprive the Lacedemonians of the superiority hitherto possessed by them over the other states of Greece. But it must not be concealed that he was not very ferupulous with regard to the means employed by him for that purpose. An instance of this was his project of burning the Grecian fleet in the harbour of Pegaeus, whither it had retired to winter after the defeat of Mardonius; or, according to some authors, that part of it only which belonged to the Lacedemonians. But not daring openly to propound this scheme, he was defended by the people to communicate the matter privately to Aristides, who having been accordingly informed of it, declared to the people, that though the project of Themistocles was indeed highly useful, yet at the same time, it was most injurious. Themistocles was therefore prohibited from putting it in execution. How becoming, thus to see a whole fleet prefer what was just to what was useful! and what a high idea of the justice of Aristides must we conceive, when we see him chosen singly by a whole people, to determine whether a project of the utmost general importance was just or unjust! At the same time, the allies prepared to restore to their freedom the Grecian cities in which the Persians had left garrisons. A numerous fleet, under the command of Paunfania and Aristides, obliged the enemy to abandon the isle of Cyprus; and the city Byzantium, situated on the Hellespont. The conduct of Paunfania in this expedition was so infantile, as to disgust the allies, who refused any longer to obey the Spartans, and thenceforward to fight under the orders of the Athenians. (B.C. 476.) The further proceedings of the Lacedemonian general, and his fate, will be found under the article Pausanias, and Sparta. The Spartans, with a praiseworthy moderation, yielded to the Athenians the command of the sea. About this time, Themistocles experienced the valour of fortune, and thetranitory nature of popular favour. The civil administration of this illustrious Athenian was no less eminent and successful than his political and military efforts. By yielding more protection to strangers than they enjoyed in neighbouring cities, he augmented not only the population, but the wealth of Athens; and that description of men paid an annual contribution in return for their security. This, together with other branches of the revenue, he employed in building annually about sixty galleys, the addition of which to the Athenian navy abundantly compensated such losses as were fulfilled by the accidents of the sea in foreign parts. Notwithstanding the envy and malice of worthless demagogues, who insulted the Athenian assembly and courts of justice, Themistocles was fast advancing to the attainment of the same authority at home which Aristides enjoyed abroad, when complaints arrived from Sparta, that he had conspired with Paunfania to betray the public liberty. The known resentment of the Spartans against this extraordinary man sufficiently explains the reason why they, who were so dilatory in their proceedings against Paunfania himself, should be so eager to bring to punishment his supposed accomplice. But it is not easy to conceive how the Athenians could admit such an accusation against a citizen, whose singular valour and conduct had gained the decisive victory at Salamis; whose counsels and advice had fortified their city with impregnable strength; whose foresight and activity had procured them a fleet which no nation in the world could rival; and whose abilities and patriotism had not only saved his country from the most formidable invasion recorded in history, and which was principally directed against Athens, but amidst the terrors of this invasion, the treachery of false friends, and the violence of open enemies, had so eminently contributed to raise his republic to the first rank in the Grecian confederacy. Yet such, on the one hand, was the effect of that envy which in republics always accompanies excellence; and such, on the other, the influence of Spartan bribery and intrigues, that Themistocles was banished by the oligarchs, a punishment inflicted on men whose aspiring ambition seemed dangerous to freedom, which required not the proof of any particular delinquency, and which had effect only during a term of years. (Gilles, vol. ii. p. 65.) This ill-fated man retired into Persia, where his treatment and death will be seen under the article Themistocles. Aristides also died about the same time (B.C. 467 or 471;) and the conduct of the Persian war was devolved on his colleague Cimon, who united the integrity of that great man to the weight of Aristides his father, and the decisive boldness of Themistocles. But as we far, an ambition for eminence which difdains base imitation, he not only reflected the most distinguished excellencies of his predecessors, but improved and adorned them by an elegant liberality of manners, an indigent humanity, and candid condescension; virtues which long secured him the affections of his fellow citizens; while his military talents and authority, always directed by moderation and justice, maintained an absolute sway over the allies of the republic. His first operations were employed against the coast of Thrace, which the taking of Byzantium seemed to render an easy conquest. The only places in that country fitted to make an obstinate resistance, were the
the towns of Eion and Amphipolis, both situate on the river Strymon; the former near its junction with the Strymonic gulf, the latter more remote from the shore, but entirely surrounded by an arm of the gulf, and the principal branches of that copious river. Amphipolis, however, was taken, and planted by a numerous colony of Athenians. But Eion still opposed a vigorous resistance: Boges, the Persian governor, having determined rather to perish than surrender. After long baffling the efforts of the besiegers, by such persevering courage and activity as none of his countrymen had displayed in the course of the war, this fierce barbarian was at length not tamed but exasperated by hunger. His companions and attendants, equally desperate with their leader, followed his intrepid example; and mounting the ramparts with one accord, threw into the middle stream of the Strymon their gold, silver, and other precious effects. After thus atting their implacable hatred to the assailants, they calmly descended, lighted a funeral pile, butchered their wives and children, and again mounting the walls, precipitated themselves with fury into the thickest of the flames. After this, Cimon flushed the other states in that country, drove from Syria the pirates that infested the Terean sea, established an Athenian colony in their place, and made himself master of Naxos. Cruising along the coasts of Asia, he reduced all the maritime cities of Caria and Lycia, and left not the Persians in possession of a single inch of ground between Ionia and Pamphylia. Hearing that the Persian fleet lay at anchor at the mouth of the river Eurymedon, waiting for a reinforcement of Phenician ships, that they might attack him with their united forces; he immediately sailed against the former to prevent their junction; charged them with such vigour, that they were obliged, in spite of their great superiority, to run their ships a-ground; and took more than a hundred of them. Without giving his men time to breathe after their victory, he instantly landed them, and attacked the army of the enemy, which was drawn up on the banks of the Eurymedon. The Persians sustained the first charge of the Greeks with great firmness. But the troops of Cimon, animated by their late success, broke them at last, put them fairly to flight, made a great number of them prisoners, and got a vast booty. Cimon crowned his victories with the capture of the Phenician fleet which was coming to the assistance of the Persians, and by that means gave a fatal blow to the Persian naval power. The rich spoil of the Barbarian camp rewarded the enterprise and celerity of the Greeks, who, loaded with wealth and glory, returned home during winter, and piously dedicated to Apollo a tenth of the plunder acquired by these ever memorable achievements. A considerable portion of the remainder was employed in strengthening the fortifications of Athens. Agreeably to the Grecian custom, the general was entitled to a valuable share. Cimon received it as a testimony of the public esteem, and expended it for the public use, embellishing his beloved native city with shady walks, gardens, porticoes, schools of exercise, and other works of general pleasure and utility. (See Gillies, vol. ii. p. 74.)

While Cimon was extending the power, glory, and influence of the Athenians abroad, a man of very great talents acquired the direction of affairs at home. This was Pericles, one of the most extraordinary men that ever Athens herself produced. His mind naturally of the first consequence and vigour, was enriched by extensive and varied knowledge, adorned by elegant literature, and fortified by the profound philosophy. Damon, professedly a teacher of rhetoric, but really master of history, politics, and all the learning of the times, was his tutor. Ataxagoras instructed him in philosophy. That wise man had made it his chief study to confirm the most important and pleasing doctrine, that a Being of supreme intelligence and benevolence governs the world, regards the virtuous, and punishes the vicious. From him (says Dr. Gilly) Pericles early learned to control the tempers of youthful passions, which so often blight the promising hopes of youthful manhood; to preserve an unshaken constancy in all the vicissitudes of fortune, since all are the varied dispensations of the same wise Providence. Pericles in means for the attainment of his objects; skillful in the varied application of them, according to the variation of circumstances; having the ready and complete command of his own great intellect and extensive information, both in forming and executing plans; courageous, temperate, steady, yet ready, decisive, yet cautious; bold, yet prudent; enterprising, yet circumspect; he excelled in politics, in war, and in every pursuit which required combined genius and conduct. His eloquence united plenteous of information, force of genius, and nervousness of style: it was either convincing or persuasive, according to the objects he had in view; at one time, its majesty commanded the hearers; at another, its softness and delicacy infused themselves into their hearts. The superior talents of this celebrated statesman greatly increased the prosperity of the country, and his policy was peculiarly beneficial in improving the advantages that had been acquired in war by his predecessors, or his contemporaries. He promoted agriculture and manufactures, and greatly extended the commerce and maritime power of his country. Riches flowed in from all quarters to Athens, and were in a considerable degree employed in strengthening and adorning the city. He encouraged the fine arts, literature, and philosophy. Under him flourished Polygnotus, Parthenios and Phidas, those ingenious artists, who so happily made painting, sculpture, and statuary, the vehicles of sentiment and character, as well as of external feature and figure. Respected by him, lived Anaxagoras, the father of moral philosophy; and Euripides, who, in the garb of fiction, exhibits the just and elevated reasoning of the pure and virtuous sentiments of both. Taste, genius, and philosophy, were never more prevalent than at Athens in the age of Pericles. But with the many advantages which were conferred upon the Athenians by Pericles, there were mixed several disadvantages, but rather in ultimate effect than in immediate appearance. There were two parties at Athens, the aristocratical and democratical. Cimon, by blood and affinity was connected with the former, and by his dispositions and character was fitted for gaining an ascendancy over the chief people in the state, than for counting the multitude. With all the powers and accomplishments which could form a patriotic and beneficial statesman and soldier, he wanted the dexterous versatility which conciliates the favour of the multitude. Pericles, with genius and strength of mind that must have rendered him a leader in any class of men, in any age or country, chose popularity as the road to the gratification of ambition, and indulged the inclinations of the populace, as well as pursued the interest of the state. With this view he promoted luxury, licentiousness, and profusion. The firm and rigid virtue of Cimon was adverse to such a pernicious waste of the treasures which his exertions had acquired. Between two such great men, embracing opposite principles and parties, rivalry naturally arose. Foreign politics, as well as domestic, enframed their differences. Cimon, aristocratical in his own principles, was attached to the Spartans, and wished an amity to subsist between Sparta and Athens. The Athenian multitude, elated with their signal successes, and wishing to dominator over all Greece, was hostile to Sparta, which would be the
most powerful obstacle to the accomplishment of their designs. The Spartans, on the other hand, were extremely jealous of the progress of the Athenians, and of the formidable power they had acquired. Cimon endeavoured to appease Pericles, to promote, this hostile spirit between the two chief nations of Greece; and his schemes appeared to be the more successful. But their animosity, before it broke out into action, was diverted by a calamity equally sudden and unforeseen. In the year four hundred and sixty-nine before Christ, Sparta was overwhelmed by an earthquake. Taygetus and the neighbouring mountains were shaken to the foundation, and twenty thousand Lacedemonian citizens or subjects perished in this dreadful disaster. Amidst the ruins of Sparta, one description of a city beheld the public misfortunes not only without horror, but with a secret satisfaction. The oppressed Spartan feels, known by the appellations of Helots and Meffenchians, assembled in crowds from the villages in which they were cantoned, and took measures for delivering themselves, during the cruelty of the elements, from the not less inexorable cruelty of their unfeeling tyrants. The prudent arrangements of king Archidamus, who, foreseeing the revolt, had summoned the citizens to arms, prevented them from getting immediate possession of the capital; but they rendered themselves masters of the ancient and strong fortresses of Ithome, from which they continued many years to infest the Lacedemonian territories. Cimon eagerly seconded the application of the Spartans, and the Athenians were prevailed on to send them the required assistance, and the combined forces proceeded to the siege of the fortresses. The besiegers, however, met with so little success, that the Spartans disbanded their Athenian auxiliaries, on pretence indeed that their help was no longer necessary, but in reality, from a suspicion that they favoured the interest of the rebels. The Athenians were greatly offended by this caprice, and Pericles instructed his partisan Ephialtes to remind the people that Cimon was the chief promoter of sending assistance to the Spartans. The illiberal captain was accused, and a farther charge laid against him that by presents from the Macedonians he was prevailed upon to let slip a manifest opportunity of enlarging his conquests, after taking from the Persians the gold mines of Thrace. To this accusation Cimon replied, that to the utmost of his power he had prosecuted the war against the Thracians and other enemies of the state of Athens; but that it was true he had not made any inroads in Macedonia, because he did not imagine that he was to act as a public enemy to mankind, and because he was struck with respect for a nation model of their courage, just in their dealings, and strictly honourable in their behaviour towards him and the Athenians; that if his countrymen looked upon this as a crime, he must abide their judgment; but, for his part, he could never be brought to think such conduct amiss. His defence however was unsustained, and he was banished for ten years. (B.C. 460.)

Pericles, thus free from the control of Cimon, confirmed his own credit with the people, and made innovations on the established form of government. He deprived the Areopagus of the power of judging in the most important questions that had formerly belonged to their jurisdiction; he rendered the other courts of justice subservient to his pleasure; and he became so absolute in Athens, that under this republican government he policed a power almost despotic. To secure the permanency of his power, while he promoted industry and beneficial action, he gratified their love of pleasure. The city now (to use the language of Dr. Gillies) afforded a perpetual scene of triumph and festivity. Dramatic entertainments, to which they were passionately addicted, were no longer performed in flight unadorned edifices, but in stone or marble theatres, erected at great expense; and embellished with the most precious productions of nature and of art. The treasury was opened not only to supply the decorations of this favourite amusement, but to enable the poorer citizens to enjoy without incurring any private expense; and thus at the cost of the state, or rather of its tributary allies and colonies, to feast and delight their ears and fancy with the combined charms of music and poetry. The pleasure of the eye was peculiarly consoled and gratified in the architecture of the theatres and other ornamented buildings; for as Themistocles had strengthened, Pericles adorned his native city; and unless we had the concurring testimony of antiquity, as well as the immortal remains of the Parthenon or temple of Minerva, which still excite the admiration of travellers, it would be difficult to believe that in the space of a few years there could have been created those inimitable wonders of art, those innumerable temples, theatres, statues, altars, baths, gymnasia, and porticos, which, in the language of ancient panegyrists, rendered Athens the eye and light of Greece. Sumis earned in honourable contests with the Persians, or extorted from dependant allies, were expended in multiplying theatres, in giving gratuitous admission to the poorer citizens to those, and also to feasts and revels, in procuring parasites, dancers, and buffoons, to flatten and gratify the coarse taste of the corning populace, in importing the delicacies of distant countries, in preparing them with all the refinements of cookery to gratify their palates, in encouraging the reception of beautiful courtiers, in costly perfumes and splendid dresses, in delighting the ears and fancy with the charms of music; in short, in gratifying the senses and the vanity of the multitude, without the exertion of their own labour. Meanwhile Pericles anxiously and ably promoted the supremacy of Athens over the rest of Greece. Stimulated and afflilied by the Spartans, the Thebans made war upon the Athenians; but the active vigilance of Pericles sent an army to Brotia; the valour and conduct of Myronides the Athenian general obtained a decisive victory near the walls of Tanagra. Pericles placed Athenian garrisons in several Brotian fortresses; he made the neighbouring republics of Corinth and Megara feel and acknowledge the superiority of Athens, and after sending Tmolus, a commander ended rather with an impetuous than well-regulated courage, to ravage the coast of the Peloponnesus, he failed thither next year in person, and made the Lacedemonians and their allies deeply regret, that they had too soon discovered their animosity against a republic alike capable to protect its friends, and take vengeance upon its enemies. While the Athenians were thus triumphing over the states of Greece, they found an inducement to undertake an expedition against the territories of the Persian king. Egypt taking advantage of the successive defeats of the Persian monarch, revolted, and headed by Inarus a Libyan chief, expelled the Persians. Inarus in order to strengthen his interest by foreign alliance, dispatched an embassy to Athens, craving the assistance of that victorious republic against its most odious and inconstant enemy. The application was successful, and the Athenians sent an army to Egypt. On their junction with the king of Libya, they gave battle to the Persians, put them to flight, and got possession of a part of Memphis. Next year however the scene was greatly altered; for after several fruitless assaults, they were at last obliged to raise the siege of that city on the approach of the enemy, and to retire to Biblis, an island in the Nile. In this place they withheld an eight months siege. But their fleet happening to lie at anchor in the Nile, the Persians by changing
the course of the river, rendered the ground round the ships dry, took every one of them, and put the greatest part of their crews to the sword. The army being thus disabused from opposing the enemy any longer, partly perished and partly dispersed. During these misfortunes the Athenians became sensible of the injustice of their treatment of Cimon, and recalled him after five years banishment. Soon after his return, that great man succeeded in bringing about a peace between his countrymen and the Lacedaemonians (B.C. 455); and with a view of diverting the Athenians, grown prehensile by their late good fortune, from making war on their neighbours, he resolved to find occupation for their arms abroad. Departing, therefore, for Cyprus with a fleet of a hundred and forty vessels under his command, and being there joined by sixty more from Egypt, he attacked Artabazus, the admiral of Artaxerxes, and took a hundred of his ships: he next made a descent upon Cilicia, and totally defeated Megabazus, another officer of that prince: he then returned to Cyprus to form the siege of Citium. In the course of the siege, Cimon fell sick: perceiving his end approaching, he beseeched his men to keep his death a secret. They followed his advice, and, proceeding with their operations, obtained a signal victory, in which they took a hundred of the enemy's ships, and then failed back in triumph to Attica. Artaxerxes, finding his inability to contend with the Athenians, sent deputies to Athens to solicit peace. His ambassadors were favourably heard in the Athenian assembly by those who were more solicitous about confirming their usurpations over their allies and colonies, than ambitious of extending their Asiatic conquests. Cimon, who invariably maintained the contrary syllable, was now no more. A peace, therefore, was concluded on the following conditions: that all the Greek colonies in Lower Asia should be declared independent of the Persian empire; that the services of the great king should not approach within three days journey of the western coast; and that no Persian vessel should appear between the Cyanean rocks and the Chalidonian isles; that is, in the wide extent of the Egean and Mediterranean seas, between the northern extremity of the Thracian Bosporus and the southern promontory of Lycia. On such terms the Athenians and their allies stipulated to withdraw their armament from Cyprus, and to abate thenceforward from modelling the territories of the king of Persia. Such was the conclusion of this memorable war, which, since the burning of Sardis, the first decisive act of hostility, had been carried on with little intermission, during fifty-one years. The fame magnanimous republic which first ventured to oppose the pretensions of Persia, dictated to that haughty empire the most humiliating conditions of peace; an important and illfounded plea in Grecian history, which was often celebrated with pompous panegyric during the declining ages of Athenian glory.

Having terminated the war against the Asiatic foe with such honour and advantage, the Athenians directed more conquest and undivided efforts to render themselves paramount in Greece; and, during twenty years, various contents arose between the Athenians and neighbouring states. Without pursuing the detail of these contentions, and the various truces by which they received a temporary suspension, we shall merely mention the refult, which was extremely favourable to Athens, so that the republic rose into unprecedented power. With her prosperity the pride of Athens rose in proportion, until her neighbours, both apprehensive and envious of her power, and farther inflamed by resentment by her insolence, formed for her humiliation a confederacy which brought on the Peloponnesian war.
in an application so very agreeable to the dispositions of those whose co-operation they desired, and a general concordacy was formed, consisting of all the seven republics of the Peloponnesus (B.C. 431), except Argos and Achaia; the first of which from ambition, and the second perhaps from moderation, preferred, in the beginning of the war, a fulsome neutrality. Of the nine northern republics, Acarnania alone declined joining the allies, its coast being particularly exposed to the ravages of the Corcyrean fleets. The cities of Naupactus and Platea, for reasons that will soon appear, were totally devoted to their Athenian protectors; whose cause was likewise embraced by several petty princes of Thessaly. But all the other states beyond the isthmus longed to follow the standard of Sparta, and to humble the aspiring ambition of their too powerful neighbour.

While they were preparing for this concert, the Peloponnesians sent hostile embassies and manifestoes to the Athenians, requiring them to grant independence to the colonies, and announcing the force by which the requisition would be supported. Alarmd by this menacing combination, the Athenian populace were filled with rage against Pericles, whom they accused of having caused this concordacy by his general conduct, and especially by a decree which he passed against the inhabitants of Megara, which had retired from the authority of Athens, and impudently asserted that city to the private pique of his favourite mistress Aphiota; and with the petty subtilty of a vulgar maid, conceived him to have appropriated to his own the great portions of the national treasure. Though the transcendent virtues of Pericles were not unalloyed, yet his was not the vice of common minds; avarice made no part of his composition: he proved that his private expenses were justly proportioned to the measure of his patrimony; many instances were brought of his generous contempt of wealth in the service of his country; and it appeared, after the strictest examination, that his fortune had not increased since he was entrapped with the exchequer. He contended that the situation of the republic did not justify dependence or submition to the dictates of an imperious rival. Their financial resources, military and political strength, and above all the spirit of the people, enabled them to resist with effect the efforts of their banded enemies, and by a detail of the various constitutions of Athenian greatness contrived with those of their rivals, illustrated his proposition. He therefore proposed that the answer to their demands should disclaim their right to interrose, disfavor every intention of commencing hostilities, but declare the readiness and ability of the Athenian republic to repel force by force. Such an answer, in the relative disposition of the parties, was deemed tantamount to a declaration of war.

The war which now ensued, is celebrated in Grecian history by the name of the Peloponnesian war. It lasted for twenty-seven years; twenty-one of which are the subject of the history of Thucydides; but death having prevented that illustrious author from pursueing it to its termination, its continuation and conclusion was reserved for Xenophon.

Hostilities were begun by the Thebans, who attacked Platea, a city of Boeotia, in alliance, as we have just mentioned, with Athens. All Greece was immediately in motion. The Lacedaemonians march towards the isthmus of Corinth, a narrow neck of land about six miles broad, which joins the Peloponnesus to the country properly called Greece. Archidamus, one of the Spartan kings, before advancing farther, dispatches an ambassador to the Athenians, to require of them to relinquish their pretensions. But the Athenians command the messenger to retire, without deigning even to give him an audience.

The Lacedaemonians thereupon advanced with an army of 60,000 men, while that of the Athenians amounted to no more than 18,000; but, to make up the odds, the latter had a fleet of 300 gallys. On the approach of the Lacedaemonian army, the inhabitants of the country abandoned their habitations, and carrying away every thing they could, took refuge in Athens. The plan of operations pursued by the Athenians, on the suggestion of Pericles, was to weary out the enemy by maintaining the war. The Lacedaemonians entering Attica, laid siege to Eubea, but being obliged after a few fruitless assailts, to relinquish that attempt, they advanced still nearer to Athens, and encamped within half a league of the city. Unwilling while to much inferior in point of numbers, to hazard the fate of the republic in a general battle, Pericles found it difficult to prevent the Athenians, exasperated at the sight of the ravages committed on their country, from falling forth upon the enemy. But by means of his admirable art in managing the multitude, he kept both the senate and the people from assembling to deliberate, though at the expense of numberless insults from his enemies; in spite of which he persevered in his plan, unmoved either by threats or entreaties.

In the mean time he dispatched a fleet of one hundred ships to ravage the coasts of the Peloponnesus; which being joined by that of the allies, made a descent upon Laconia, and laid waste the territories of Sparta. The Lacedaemonians finding all their endeavours to draw the Athenians out of their city ineffectual, and receiving intelligence of the ravages committed in Laconia by the Athenian fleet, found themselves under the necessity of withdrawing from Attica. On the setting out of the expedition against the coast of Laconia, an extraordinary eclipse of the sun happened just as Pericles was going on board of his galley. Pericles, perceiving the Athenians to be terrified at this phenomenon, which they considered as an unlucky omen, threw his cloak over the face of the pilot, and asked him if he saw? the pilot having answered in the negative, Pericles explained to the by-standers, that the body of the moon, being in like manner interposed at that instant between their sail and the sun, prevented them from seeing his light. When the Lacedaemonians retired out of Attica, the Athenians appropriated a hundred talents of money, and a hundred of their best ships, for the more immediate defence of their country, in case of a fresh invasion, prohibiting any person, under pain of death, from proposing a different application of those resources. They then expelled from the island of Eginia its present inhabitants, whom they regarded as the principal cause of the war; and they divided that island by lot among the citizens of Athens. They made an alliance with the kings of Macedon and Thrace; subdued the island of Cephalonia; laid waste the territory of Megara; and took the harbour of Nisium; this concluded the first campaign. The Athenians next celebrated funeral rites to the memory of those who had fallen since the beginning of the war. For this purpose, a large tent was constructed, wherein they exposed the bones of the slain, which were covered with flowers and perfumes. Then the bones were carried with much pomp and solemnity to a fuburb of the city called Ceramickus, where they were deposited in a monument designed to be the tomb of those who fell in war, and lastly, one of the citizens pronounced a funeral oration in their praise; a charge which on this occasion was undertaken by Pericles himself. Though always superlatively eloquent, he at this time seemed to outdo himself; and in pronouncing the eulogium on those who were no more, he omitted no argument that might inflame the courage of the survivors. Thucydides has preserved this
this famous oration, of which the beautiful expressions and lofty sentiments are equally admired. The army of the Lacedaemonians and their allies returned into Athens, and laid every thing waste with fire and sword. But the plague, which then raged among the Athenians, was still more pernicious to them, depriv ing them of their best citizens and bravest soldiers; and Athens exhibited nothing but a melancholy scene of sickness and death. Of this dreadful scourge, an awfully striking account is exhibited in the energetic description of Thucydides. Without dwelling on the corporeal symptoms which the historian presents in his affecting narrative of this foemen, we shall merely give the fulness of its moral effects. At the beginning of this dreadful calamity, sublime examples of filial piety and generous friendship were displayed; but as the consequences were always fatal to the children and friends, they were but rarely repeated afterwards. Then the most respectable ties were broken; the eyes about to close for ever, beheld on all sides only the most profound solitude, and death no longer produced a tear. This callous insensibility gave birth to an unbridled licentiousness. The death of so many worthy men, mingled without distinction in the same tomb with villains; the destruction of so many fortunes, become suddenly the inheritance or prey of the lowest citizens, made a lively impression on those who have no other principle but fear. Perceiving that the gods no longer protected or regarded virtue, and that the vengeance of the laws would not be so prompt as the death impending over them, they imagined that the falsity of human professions pointed out the nie that they should make of them, and that having but a few moments to live, they were justified at least in pulling them in the midst of pleasures.

Notwithstanding the disasters in which Athens was involved, the elevated soul of Pericles, with unbroken fortitude, planned the extirpation of his country, as far as it was practicable by human means. A numerous family fell succcivively victims to the rapacious peddlers. Though a tenderly affectionate father, he bore the disaster with magnanimous serenity. At the funeral of the lads of his sons, he dropped, indeed, a few reluctant tears of paternal tenderness; but ashamed of this momentary weakness, he bent his undaunted mind to the defence of the republic. Having collected an hundred Athenian, together with fifty Chian and Lesbos refuges, he sailed through the Aegean gulf, and ravaged the unprotected coasts of Elis, Arcos, and Laconia. The plague breaking out in the fleet, defeated the success of the expedition, and revisiting Athens with redoubled fury, almost defolated the city. Maddened by their accumulated sufferings, the Athenians imputed their miserable situation to Pericles: they decried him of his authority, and condemned him to a fine: but they soon acknowledged their folly and injustice. He was again prevailed on to resume the reins of administration, and his last efforts were employed to stimulate his country to that vigour of counsels and of conduct which only could preserve her power, honour, and independence: temporary disaster might afflict, but in the nature of things its duration could not be long; Athens would ultimately triumph, if she were true to herself. “Of the two elements,” he said, “defined for the use of men, the sea and the land, we absolutely command the one, nor is there any kingdom, or republic, or confederacy, that pretends to dispute our dominion. Let this consideration elevate our hopes, and personal afflications will disappear at the view of public prosperity. Let us bear, with resignation, the strokes of Providence, and we shall repel with vigour the assaults of our enemies. It is the hereditary and glorious distinction of our republic, never to yield to adversity. We have defied danger, expended treasure and blood, and amidst obstinate and formidable wars, augmented the power, and extended the fame of a city, unrivalled in wealth, populousness, and splendor, and governed by laws and institutions worthy of its magnificence and renown. If Athens must perish, (as what human grandeur is not subject to decay?) let her never fall at least through our pusillanimity; a fall that would cancel the merit of our former virtue, and destroy at once that edifice of glory which it has been the work of ages to rear. When our walls and harbours are no more, when the terror of our navy shall have ceased, and our external magnificence have fallen to decay, the glory of Athens shall remain. This is the prize which I have hitherto exhor ted, and shall exhort you to defend, regardless of the clamours of states, the fulacigns of cowardice, or the perfec tion of envy.” These were the last efforts of this illustrious man: he was soon after seized with the plague which proved fatal. On his death-bed, retaining his understanding, his chief comfort was, not the splendor of his genius, and achievements, but the recollection of his well-spent life. When he was about to yield his last breath, the leading men of Athens assembled around his bed, were soothing their affliction by recounting his victories, and the number of his trophies. “These actions,” said he to them, “raising himself up with difficulty, “are the works of fortune, and common to myself with other generals; the only eulogium I merit is, that I have never been the cause that any citizen should wear mourning.” (Gillies.)

After the death of Pericles, two persons contended for the direction of affairs; Cleon, a turbulent and impatient demagogue, devoid of talents, or of any moral qualities which entitled him to pre-eminence, but a great favourite with the lower populace; and Nicias, a man of solid ability, prudence, and integrity; and for several years the war was successful or unsuccessful accordingly as the one or the other predominated.

About this time the Peloponnesians invaded Plataea, a city in alliance with Athens. This siege is not only remarkable for the obstinate resistance of the besieged, but for being the first recorded in history which was conducted with any fort of regularity. Both parties here made use of mounds of earth, the one to attack, the other to defend. The Peloponnesians hurled the town by means of bundles of flints, to which they set fire. On the other hand, the besieged neglected no expedition to frustrate the various attempts of the enemy. But the most surprising circumstance of all is, that so small a place as Plataea, which contained no more than four hundred inhabitants, and eighty Athenians, was capable of making so vigorous a resistance against a powerful army. The enemy at last changed the siege into a blockade, and surrounded the town with two ditches. The Boeotians were left to guard these intrenchments, and the bulk of the army marched away. The besieged having lost all hope of succour, resolved to attempt to make their escape out of the town; which about one half of them effected by a very daring stratagem, suggeested and executed by defpair. The remaining half dismayed at the dangers attending the attempt, continued in the town. But finding themselves unable to defend it any longer, they were at last obliged to surrender at discretion: eight Spartans went to decide their fate; the miserable Platæans pleaded in vain that they had been forced, through necessity, to frde with the Athenians, in order to obtain their protection against the Thebans, by whom they were grievously oppressed. They were all murdered in cold blood; their wives were carried into slavery; and their town was razed to the ground. Such was the melancholy
melancholy fate of the Plataeans, who, during the Persian war, had rendered the most signal services to Greece.

The fifth (B.C. 427) year of the war was principally distinguished by the fediton of Corecyra. In the course of hostilities, the Corinthians had captured a considerable number of those islanders, and wisely treated them with a gentleness and kindness which gained their affections. Having brought them to this disposition, they earnestly persuaded them, when they should return to their country, to employ their efforts for reconciling the children with their parent country, and detaching their fellow citizens from Athens, the tyrant over her allies. The Corecyreans were disaffected, and arriving at home, endeavoured to reconcile their countrymen to the Peloponnesians. The aristocratical party very readily agreed, and formed a conspiracy for massacring the leaders of the democratic party. The commons applied to the Athenians, who sent a fleet to assist their partisans. The Peloponnesians also sent a squadron to support the nobles: but the Athenians preferring their maritime superiority, their enemies retired, and the democrats were paramount. Their cruelty was so signal, as from that time to give the name of Corecyrean to every faction of uncommon atrocity. The following account, in the elegant language of Dr. Gillies, contains an awful monument of the dreadful effects of intestine dissention.

"The unhappy prisoners were first confined in a dungeon. Dragged fuelly from thence, in parties of twenty at a time, they were compelled to pass in pain, their hands tied behind their backs, between two ranks of their enemies, armed with whips, prongs, and every instrument of lacerations and disgraceful torture. The wretched left in prison were long ignorant of the ignominious cruelty inflicted on their companions: but, as soon as they learned the abominable scenes transmitted, they refused to quit their confinements, guarded the entrance, and invited, with one consent, the Athenians to murder them. But the Athenians wanted either humanity or firmness to commit this kind cruelty. The Corecyrean populace ventured not to force a passage from despair. They mounted the prison walls, uncovered the roof, and overwhelmed those below with stones, darts, and arrows. These weapons were destructive to many, and furnished others with the means of destroying themselves, or each other. They laid down their heads, opened their breasts, exposed their necks, mutually soliciting, in plaintive or frantic accents, the fatal stroke. The whole night (for night intervened) was spent in this horrid scene; and the morning presented a spectacle too shocking for description. The obdurate hearts of the Corecyreans were incapable of pity or remorse; but their relenting eyes could not bear the sight; and they commanded the bodies of their fellow citizens, now breathless or expiring, to be thrown on carts, and conveyed without the walls." Thus ended the sedition of Corecyra; but its consequences were not soon to end. The contagion of that unhappy island, engendered a political malady, which spread its baneful influence over Greece. The aristocratical, and still more, the popular governments of that country, had ever been liable to faction, which occasionally blazed into sedition. But this morbid tendency, congenial to the constitution of republics, thenceforth assumed a more dangerous appearance, and betrayed more alarming symptoms. In every republic, and almost in every city, the intriguing and ambitious found the ready protection of Athens, or of Sparta, according as their selfish and guilty designs were concerted under the pretence of maintaining the prerogatives of the nobles, or afflicting the privileges of the people. A virtuous and moderate aristocracy, an equal impartial freedom, these are the colourings which served to justify violence, and varnish guilt. Sheltered by the specious coverings of fair names, the prodigal afflatus delivered himself from the importunity of his creditor. The father, with unnatural cruelty, punished the licentious extravagance of his son; the son avenged, by paricide, the item severity of his father. The debates of the public assembly were decided by the sword. Not satisfied with victory, men thirsted for blood. This general disorder overwhelmed laws human and divine. The ordinary course of
of events was reversed; sentiments lost their natural force, and words their usual meaning. Dulness and stupidity triumphed over abilities and refinement; for while the crafty and ingenious were laying fine spun snares for enemies, men of blunter minds had immediate recourse to the sword and poignard. Hitherto the war had been carried on without any material advantage to either party. The following year, (B.C. 426.) more critical events took place: Demosthenes, a general of merit and enterprise, commanded the Athenian forces at Naupactus, which had been beset on the unfortunate Messenians; by whose assistance, together with that of the Athenian allies in Acarnania, Demosthenes undertook to subdue Eotolia. The Messenians being continually harassed by the Thebians, persuaded Demosthenes that it would be easy to overrun their country, before the inhabitants, who lived in scattered villages, widely separated from each other, could collect their force, or attempt resistance. In pursuance of this advice, Demosthenes entered Eotolia, took and plundered the towns, and drove the inhabitants before him. During several days he marched unrelished; but having proceeded to Argolism, the principal, or rather only city in the province, he found that his design had by no means escaped the notice of the enemy. Living in a country abounding in defiles, and involved in woods, the Thebians, though irregular and deftory in their warfare, yet employing a species of bush fighting and unlike to that which, two or twenty centuries afterwards, has been used by the American Indians, defeated the regularly disciplined troops of Athens, and Demosthenes was obliged to take refuge in Naupactus. The Athenian general, however, soon found means to irritate those Barbarians to venture a contest in the plains, and, with great ease, obtained a signal victory. Elevated with this success, Demosthenes undertook an expedition to the western shore of Peloponnesus, and seized Pylos. The Spartans eager to recover this important port, attempted to dislodge the enemy, but were defeated, and obliged to take refuge in Sphacteria, a small island upon the coast; and the Athenians, having masters of the sea, surrounded their retreat, and cut off all supplies of provisions. Anxious to save those troops, the Spartans sent ambassadors to Athens with propositions of peace. The ambassadors frankly owned the extreme necessity that had obliged the Lacedaemonians to submit to so humiliating a defeat, but the Athenians in mind of the uncertain fate of arms, and exhorted them to embrace this opportunity of restoring tranquillity to Greece. But the Athenians grown presumptuous by their good fortune, as well as by the flattering oration of their favourite demagogue Cleon, required, as a preliminary condition, that the troops confined in the island should lay down their arms, and be conducted to Athens, upon the promise of the Athenians to let them at liberty as soon as the Lacedaemonians had delivered up the places conquered by them, from the Athenians. The Lacedaemonians refused to comply with this condition, and both parties prepared themselves for war. The Athenians, in the mean time, were very vigilant to prevent any provisions from poffing into the island of Sphacteria. The Lacedaemonians, on the other hand, engaged the whole country round to contribute their utmost efforts to relieve the beleaguered troops, and promised to set free all the slaves who should succeed in carrying them provisions; which many did, at the extreme hazard of their lives. In the mean time, the Athenians in Pylos began, on their part, to be threatened for provisions. Cleon persuaded the people, that the flower of the siege was owing to the inactivity of their commanders; and maintained, that a little vigour must very soon reduce the island, which he offered to accomplish himself. Having been accordingly set thither, and having joined Demosthenes, they landed together in Sphacteria, and beat the enemy to the extremity of the island. The Lacedaemonians, however, took possession of a fortification, and defended, with the utmost desperate courage, the only passage by which they could be attacked. But the general of the Messenians, having discovered a difficult path that led to the fortification, marched that way, and appearing unexpectedly on the rear of the Lacedaemonians, called aloud to them to lay down their arms. The Lacedaemonians exhausted with heat and fatigue, obeyed the summons, by laying their shields on the ground; and, after a short conference, they surrendered at discretion. The Athenians, after creating a trophy, reembarked on board of their fleet. This siege continued sixty-two days. Cleon is said to have caused 128 of those unhappy Spartans, to be murdered. The rest were conveyed to Athens, and thrown into prison, till peace should take place; the Athenians threatening, at the same time, to put them all to death, if the Lacedaemonians made any more incursions into their country. Soon after happened the federal war of Megara. The inhabitants of that town, after expelling their magistrates, quarrelled among themselves, one party being for recalling their magistrates, the other, for deliv ering their town into the hands of the Athenians. Braidas, in the mean time, the chief officer of the Lacedaemonians then had, having come before Megara, its gates are immediately thrown open to him. The exiled magistrates returning soon after, and resuming their authority, condemn to death one hundred inhabitants of the opposite faction. Braidas advances into Thrace, subdues several cities, and lays siege to Amphipolis, a place of much importance to the Athenians, who thence got the greatest part of their wood. They therefore dispatched Thucydides, the famous historian, to its relief; but the place was taken before his arrival. His countrymen, however, attempted to take it, the annual, and banished him at the instigation of Cleon. The Athenians having about the same time advanced into Boccia, under the command of Demosthenes and Hippocrates, were defeated near Delium by the Thebans, who, after their victory, besieged and took that town. No decisive advantage had been hitherto obtained by either party. The Athenians and Lacedaemonians therefore agreed on a truce for a year; which Braidas, who had been successful in all his enterprises, bore with great impatience. Cleon, on the other hand, who had acquired much authority in Athens by means of his bold and vehement eloquence, incited his countrymen to renew the war. Being more presumptuous than skilful in military operations, he resolved to attempt the taking of Amphipolis, hoping to be assisted by a body of troops from Pheidias king of Macedon. But Braidas got the start of him, and threw himself into the town. To increase the presumption of Cleon, the Spartan general, who was well acquainted with his character, affected to be afraid of an encounter; but after making the proper dispositions, Braidas fell in unexpectedly, and attacked the left wing of the Athenians, which, being the flower of their army, made a vigorous resistance. Braidas, however, at last broke them, and killed six hundred, with very little loss on his own side. This attack disconcerted and terrifed Cleon, who was killed by a Spartan soldier as he was flying from the battle. Braidas was of the number of the slain on the side of the Lacedaemonians. He was an excellent officer, equally brave and prudent, and deserved to be ranked among the Lacedaemonian heroes. It was the mother of this general, who, on hearing the exploits of her son committed,
mended, answered, "It is true, my son was a brave man; but I doubt not that Sparta has many citizens as brave as he."

The battle of Amphipolis removed the principal obstacles to peace. There was not any Spartan general qualified to accomplish the designs of Brasidas; and the Athenians, dejected by defeat, and humbled by disgrace, wanted the bold imposing eloquence of Cleon, to dignify their weaknesses, and varnish their misfortunes. (Gilles.) With the dilhcarted remains of an enfeebled armament, they despaired of recovering their Macedonian possessions; and the greater part returned home, well disposed for an accommodation with the enemy. These dispositions were confirmed by the pacific temper of Nicias, who had succeeded to the influence of Cleon, and who fortunately discovered in the moderation of Pleistoanax, king of Sparta, a cool judge extremely solicitous to promote his views. During winter, several friendly conferences were held between the commissioners of the two republics; and towards the commencement of the ensuing spring, a treaty of peace, and from afterwards a defensive alliance, for fifty years, was ratified by the kings and ephors of Sparta on the one side, and by the archons and generals of Athens on the other. In consequence of this negotiation, which was intended to comprehend the respective allies, of the contracting powers, all places and prisoners taken in the course of the war, were to be mutually restored; the revolted cities in Macedon were specified by name; but it was regulated that the Athenians should not require from them any higher revenue than that appropriated by the judicious of Arilixides. (See Thucydides.)

While the Athenians were thus engaged in wars, and often employed in injustice, their city produced a peripatet who taught his countrymen and mankind the purest ethics that ever flowed from a human source. Socrates was now in the full vigour of his genius, which he employed in simplifying practical philosophy to the comprehension of common minds, and to inculcate the necessary connection between piety and virtue and happiness. (See Xenophon's Memorabilia.) From the perfections of the supreme intelligence he deduced his just government of the universe, which implied the immortality of the human soul. But the great object of his research was to discover the general laws by which, even in this life, the superintending providence had variously dispensed to men good and evil, happiness and misery. These laws he regarded as the promulgated will of the gods, with which, when clearly ascertained, it became our duty invariably to comply; since nothing but the most short-sighted folly could risk the divine displeasure, in order to avoid pain or poverty, sickness or death, for life to enjoy passing gratifications, which leave a fleft behind them. Reassuming on such principles, and taking experience only for his guide, he deduced with admirable peripetinence the interests and duties of nations and individuals in all the complicated relations of society. The actions of men furnished the materials, their instruction formed the object, their happiness was the end of his discourse. Wherever his lessons might be most generally useful, there he was always to be found, frequenting at an early hour the Academy, Lyceum, and other public gymnasia; punctually attending the forum at mid-day, the hour of full assembly; and in the evening, joining, without the affectation of austerity, in the convivial entertainments of his friends, or accompanying them in the delightful walks which adorned the banks of the Illyus. As a husband, a father, a citizen, and a folder, the steady practice of his duty continually illustrated his doctrines. The conversation and example of this truly practical philosopher (and this is his highest praise) persuaded many of his fellow citizens sincerely to embrace a virtuous course of life; and even those who allowed the current of their passions to prevail over the conviction of their sober hours, were still charmed with the wonderful effect, as well as the singular accuracy, of his various knowledge, with the acuteness and penetration of his various arguments; the beauty, vivacity, and persuasiveness of his style, with which he assumed the tone of reason or of ridicule, surpafled whatever had been deemed eloquent. Among the Athenian youth whom this fage attempted to form to virtue, was the celebrated Aleibides, but a previously corrupted education rendered his task extremely difficult. The tender years of Aleibides were committed to the illiberal discipline of mercenary preceptors; his youth and inexperience were befet by the destructive adulation of servile flatterers (Plutarch's Aleibides), until the young Athenian, having begun to relish the poems of Homer, the admiration of which is congenial to every great mind (Ibid.], learned from thence to despise the pedantry of the one, and to detest the meanness of the other. From Homer, Aleibides early imbibed that ambition for excellence which is the great lefso of the immortal bard. Having attained the verge of manhood, he readily distinguished, among the crowd of rhetoricians and sophists, the superior merit of Socrates. The sage, whose company was courted by his other disciples, himself courted the company of Aleibides; and when the ungrateful youth sometimes escaped to his licentious companions, the philosopher pursued him with the eagerness of a father or master, anxious to recover a fugitive son or flame. See Aleibides. But this favourite laboured under a defect which could not be compensated by the highest birth, the most splendid fortune, the noblest endowments of mind and body, and even the inestimable friendship of Socrates. He wanted an honest heart. This we are warranted to affirm on the authority of contemporary writers, Lyfias and Xenophon, who acknowledged that first admiration, and then interest, was the foundation of his attachment to the illustrious sage, by whose instruction he expected to become not a good but an able man. Some inclination to virtue he might, in such company, perhaps feel, but more probably reign; and the niciel discomfiture might mistake the real character of a man who could adopt at pleasure the most opposite manners; and who, as will appear from the subsequent events of his various life, could surpass the splendid magnificence of Athens, or the rigid frugality of Sparta; could conform, as interest required, to the laborious exercises of the Thebans, or to the voluptuous indulgence of Ionia; assume the soft effeminacy of an Eastern prince, or rival the furious vices of the drunken Thracians. (Neposi's Aleibides.)

The first specimen of his political conduct discovered the extraordinary resources of his versatile mind. He opposed the peace of Nicias, as the work of a rival whom he wished to disgrace. His ambition longed for war, and the Spartans deferred his resentment, having in all their transactions with Athens, testified the utmost respect for Nicias, while they were at no pains to conceal their want of regard for himself, though his family had been long connected with their republic by an intercourse of hospitality, and he had endeavored to strengthen that connexion by his personal good offices to the Lacedemonians taken in Spatetera. To gratify at once his resentment, his ambition, and his jealousy, he determined to renew the war with Sparta; a design by no means difficult at the present juncture. In compliance with the peace of Nicias,
Nicias, the Spartans withdrew their troops from Amphipolis; but they would restore neither the city nor the neighbouring places in Macedon to the dominion of Athens. The Athenians, accordingly to the treaty, allowed the captives taken in Sparta to meet the longing embraces of their kinmen and friends; but good policy forbade their surrendering Pylus, until the enemy had performed some of the conditions stipulated in return. Mutual unwillingness or inability to comply with the articles of peace, fowed the seeds of animosity, which found a favourable foil in both republics. The authority of those magistrates who supported the pacific measures of Nicias and Pleistades had disappeared. The Spartan youth wished, by new hostilities, to cancel the memory of a war, which had been carried on without profit, and terminated with dishonour; but the wiser part perceived that better success could not be expected while the Athenians possessed Pylus. In their eagerness to recover that fortress, they renewed their alliance with the Thbians, from whom they received Panaceum, which they hoped to exchange for Pylus; forgetting in this transgression an important clause in their treaty with Athens, "that neither of the contracting powers should, without mutual communication and consent, conclude any new alliance." The Thbians rejoined in the prospect of embroiling the affairs of Athens and Sparta: and the Corinthians, guided by the fame hostile views, readily concurred with the Thbians, and openly re-entered into the Lacedemonian confederacy. The Peloponnesian war was renewed with various success. The address of Alcibiades prevailed on the Argives to join the Athenians: and though the Spartans gained a considerable victory at Mantinea, the Athenians were on the whole pre-eminent. Elated with successes, the Athenians undertook the conquest of the island of Melos, a state that never had been dependent on Athens, nor ever interfered in the Peloponnesian war. The Athenians sent ambassadors to require the illanders to surrender. The conference between their deputies and the Melian statesmen is detailed by Thucydides, and is one of the most curious and interesting pieces recorded in ancient political history. It may indeed well be styled the moral creed of conquering adventurers, more openly promulgated than in modern manifestoes, but containing the same sentiments which dotted in our own times the Jamesine scheme for the subjugation of Poland, with this difference, that modern robbers on a great scale, by some specious plea of right, do homage to the justice which they transgress; whereas the Athenian deputy did not seek common pretexts by such an unbounded pretext. He stated the real title to the feizure of other people's property, superior power; that the strong may use what freedom they please with the weak. There is not a single word said tending to prove either just right in the Athenians, or aggression in the Melians. The Athenian states the power of his country, and the miseries the Melians would suffer if they attempted resistance. The peroration to this celebrated diffusion fully illustrates the principles on which the Athenians proceeded, and sums up the diplomatic reasoning: "You are determined," said the Athenian ambassador, "it seems, to learn by fatal experience, that fear never compelled the Athenians to desist from their designs, especially never to raise the siege of any place which they had once invested. For during the whole of this long conference, you have not mentioned a single particular capable of affording any just ground of confidence. Deceived by the splendor of words, you talk of honour and independence, rejecting the offers of a powerful state, whose arms you are unable to resist, and whose protection you might obtain at the expense of a moderate tribute. Left shame should have any share in this dangerous behaviour, we shall leave you to consult privately, only reminding you once more, that your present deliberations involve the fate of your country." The Athenian ambassadors retired, and shortly afterwards the Melians recalled them, and declared their unanimous resolution not to betray in one unlucky hour the thirty years which they had maintained for seven hundred years; depending on the vigorous assistance of their Lacedemonian kinmen, and training especially in that chaste providence which had hitherto preserved them amid the general convulsions of Greece. But, they entreated the Athenians to accept their offers of neutrality, and to abide from unprovoked violence. The ambassadors prepared for returning to the camp, leaving the conclusions of this acute threat, "that of all men, in such a delicate situation, the Melians alone thought the future more certain than the past, and would grudgily suffer for their folly, in preferring to the proposals of certain and immediate safety, the decifiveness of hope, the infallibility of fortune, and the vain prospect of Lacedemonian aid." The Athenians, irritated by opposition, resolved without delay the capital of Melos, which was blocked up for several months by sea and land. The besieged, after suffering cruelly by famine, made several desperate sallies, fired the Athenian magazines, and destroyed part of their works. But towards the end of winter, their resistance was defeated by the vigorous efforts of the enemy, combined with domicile treason. The melians above the age of fourteen were put to the sword; the women and children were subjected to perpetual servitude; and five hundred new inhabitants, drawn from the surrounding colonies of Athens, were sent to occupy the vacant lands which had been cultivated and adorned for seven centuries by the labour of the exterminated Melians.

Successful injustice encouraged the Athenians to more audacious schemes of aggression and conquest, and they hoped to subjugate the whole course of the Mediterranean. Under these visionary fancies, they projected an expedition to Sicily, which proved to fatal to Athenian greatness. With the usual policy of conquerors, they maintained a close intercourse with the weaker states of a country which they projected to subdue. Since the death of Pericles, they had concluded a treaty with the Leonines, who being hard pressed by the Syracusans, applied for assistance to their new confederates; for this purpose they sent an embassy to Athens, at the head of which was the celebrated orator Gorgias, who pleaded the cause of the Leonines in an oration so elegant and pathetic, that the request of the ambassadors was granted; and the Athenians sent a fleet to Rhegium, to afford the Leonines. Next year (B.C. 415), they sent thither a more numerous fleet still, under pretence of affisting the towns oppressed by the Syracusans, but in fact to open to themselves a way to the conquest of Sicily. Alcibiades, by his harangues, inflamed the Athenians still more and more to this undertaking, and talked of nothing less than extending the conquests of Athens over Africa and Italy. While the minds of the Athenians were full of these mighty projects, ambassadors arrived from the Egitians, to implore their assistance against the Selinuntines, who were supported by the Syracusans; offering at the same time to pay the troops that should be sent to their assistance. The Athenians, tempted by these promises, named Alcibiades, Nicias, and Lamachus, to command a fleet destined to succour the Egitians. Nicias remonstrated against this expedition in the strongest terms, and painted out to the most lively colours what ruinous consequences might thence result to the republic. He represented to the Athenians, that they had but too many enemies on their hands already, with-
out going abroad to seek for more; and that though they were hardly beginning to recover from the misfortunes occasioned by the late war and plague, they were wantonly exposing themselves to a greater danger still. Nicias, in this harangue, likewise reflected indirectly on the luxury of Alcibiades, who had now carried his extravagance to an incredible pitch. The expense of the furniture of his house, and of his retinue, was prodigious. His table was as sumptuous as that of any prince; and he contended at the Olympic games with seven different sets of horses. To support so expensive a life, it was absolutely necessary for him to poffefs vast funds; and Nicias, no doubt meant to intimate, that Alcibiades expected, to have an opportunity by this expedition to repair his private fortune, which must have been greatly dissipated by such enormous expences. Alcibiades answered the harangue of Nicias, by telling the audience, that his magnificence was intended to reflect honour on his country; he put them in mind of his services to the commonwealth; he assured them that the cities of Sicily were so weary of the oppression of their petty sovereigns, that they would instantly open their gates to the first power which should appear to deliver them from their present slavery; and he concluded with telling them, that to carry their arms abroad was the surest way to damp the courage of their enemies, and that the Athenians must always continue masters at sea, in spite of the Lacedemonians. The Athenians, delighted with this flattering speech of Alcibiades, entirely disregarded that of Nicias, who was a man of a soft pusillanimous disposition, and of an irrefolute temper. They therefore perfilled in their resolution to undertake this expedition, and began to make the necessary preparations for it with the utmost dispatch. (Thucydides.) Just as the Athenian fleet was on the point of setting sail, several evil prefigurations fell out that extremely perplexed the minds of the people. 1st. The fail of Adonis happened at this time, which was celebrated by the women uttering pitious groans and lamentations; and it was customary for all the inhabitants on that occasion to wear mourning. 2dly. The flates of Mercury, one of which flood before the entry of every house, were all mained in the fame night, and the author of this piece of hallucination could not be discovered. The wild libertine character of Alcibiades expofed him to fufpicions of having been concerned in this mischiefe. But the affection entertained for him by the soldiers and sailors, who declared that they would not proceed on the expedition, if the smallest violence was offered to his person, preferred him at prefent from any trouble on that account. Alcibiades demanded to be tried, that he might have an opportunity of justifying himself before his departure. But the people, impatient for the expedition proceeding, obliged him to fet sail. The view of the fleet under fail attracted the admiration both of the citizens and of strangers; for never had a single city in the western world displayed so grand and magnificent an armament. It confifted of a hundred and thirty-fix vessels, carrying fix thousand two hundred and eighty foldiers, of whom the greater part were heavy armed. Besides thefe, there were thirty fhips loaded with provifions, and the whole was attended by one hundred bars, without including merchant fhips, or the after augmentations of the fleet. Besides the fea forces, there was a body of troops for the land service, and among thefe a few cavalry. All the forces were equipped in the moft complete manner; and upon the whole, there could hardly be a grander or more beautiful exhibition. (B. C. 414.) When the troops were embarked, the whole fleet on a signal given by a trumpet, withdrew anchor, attended with a general shout of the spectators, pouring out their most carnall vows for the succed of their fellow-citizens. The fleet directed its course towards Rhegium, whither they dispatched some fhips before the rest, to fee that the money promised by the Egyprians was ready; of which, however, they found no more than thirty talents provided. Nicias avoided himself of this circumstance to enforce the reasons he had infifted on against the expedition, and advised to terminate the dispute between the Egyprians and Selinontes in an amiable manner; to oblige the former to fulfill their engagements; and then to return to Athens. Alcibiades, on the contrary, said it would be disgraceful to return without performing some signal exploit with so powerful an armament; that they ought to endeavor to detach the Greeks in Sicily from their connection with Syracufe, to bring them over to their own party, and after obtaining from them reinforcements both of troops and provisions, to attack Syracufe. Lamachus advised to march immediately against Syracufe; but the opinion of Alcibiades prevailed. They therefore continued their course for Sicily, where Alcibiades reduced Catana. At Athens, the enemies of Alcibiades intent alone on gratifying their resentment, without regarding the public interest, took advantage of his absence to renew against him an accusation of having in a daubach profused the mysteries of Propherine and Ceres; and they prosecuted the accusation with the most inveterate malice and animosity. Many perfons were accused, and thrown into prifon, without being even permitted to be heard; and a veife was dispatched to bring Alcibiades to fland trial before the people. To this he apparently confented, and went on board of the galley; but on arriving at Thurium, he disappeared. Not having therefore obeyed the summons within the limited time, he was condemned to death for contumacy, and his effects were confiscated. (Thucydides, I. vi.) The departure of Alcibiades spread apprehension through the army. Nicias, now chief commander, by his irrefolute conduct, suffered the ardour of the Athenians to cool, and he spent the greatest part of the summer inactive at Catana. The Athenian soldiors, impatient of fuch dilatory proceedings, reproached their general, who, to placfe the army, resolved to befiege Syracufe. Though flow in counsel, yet vigorous in conduct, he conducted his attacks with fo much ability, that the inhabitants were inclined to surrender. Already feveral fates of Sicily and Italy had declared in his favour, when a Lacedemonian general named Gylippus entered the beleiged city, with a few troops which he had brought from Peloponnese, or collected in Sicily. Nicias might have prevented him from landing in the island, but lost the opportunity; an irreparable fault, which proved the source of all his misfortunes. Gylippus revied the courage of the Syracufans, defeated the Athenians, and held them blockaded up in their intrenchments. Athens sent to Sicily another fleet confiding of about feventy-three galleys, under the command of Demofthenes and Eurymedon, and a second army of five thousand men heavily armed, and fome light troops. Demofthenes having left two thousand men at the attack of an important poll, and confidering that the fea would foon be no longer navigable, and that the troops were waiting away by disorders, proposed to abandon the enterprife, or transport the army to some healthier situation. When they were on the point of fetting sail, Nicias, terrified at an eclipse of the moon, which fpread confternation through the camp, confulted the augurs, who directed him to wait twenty-seven days longer. Before the expiration of this time, the Athenians, vanquished by fea and land, no longer able to remain under the walls of Syracufe for want of provifions, nor to escape out of the harbour, the mouth
mouth of which was flung up by the Syracusans, took the
refuge to abandon their camp, their fiek, and their ships,
and retired to land into some town of Sicily. They began
to march to the number of forty thousand men, including
not only the troops furnished them by the states of
Italy and Sicily, but the crews of the galleys, the work-
men, and slaves. The Syracusans, by feizing the deities,
and breaking down bridges, and other obstructions, in-
pealed the retreat of the Athenians, while at every step they
hurried their rank and rear. The retiring forces for eight
whole days had to struggle against new obstacles continually
increasing. But Demosthenes, who commanded the re-
guard, composed of six thousand men, lying in his
march, was pushed into a corner, and after prodigies of
valour, obliged to surrender on condition that his soldiers
should have their lives granted them, and be spared the hor-
sors of a dungeon. Nicias, having failed in his negotiation
he had entered into, conducted the remainder of the army as
far as the river Aenarius. On his arrival there, the greater
part of the soldiers tormented by a burning thirst, rushed
in confusion into the river, while others were driven into it
by the enemy. Such as attempted to save themselves by
swimming found on the opposite shore steep banks lined
with dartmen, who made a terrible slaughter of them. Eight
thousand men perished in the attack; till at length
Nicias thus addressed Gylippus: “Dispo.te of me as you
shall think proper; but flew mercy at least to these unhappy
soldiers.” Gylippus immediately put an end to the car-
nage. The Syracusans returned to their city, bringing
back with them seven thousand prisoners, who were thrown
into the quarries, where for many months they experienced
inconceivable miseries. Numbers of them perished there,
and others were sold as slaves. Nicias and Demosthenes
were among the massacred. A few escaped both death and
bondage through the charms of dramatic poetry, by recit-
ing palliages from the beautiful and pathetic tragedies of
Euripides.

The discomfiture of the expedition to Sicily filled Athens
with consternation and dismay; and the reason to dread
still greater calamities. Her allies were ready to shake off
the yoke; the other states of Greece were conspiring her
ruin; the Peloponnesians already thought themselves justi-
fied by her example in breaking the truce. Already the
discovered in their operations, more skilfully planned and
conducted, the spirit of vengeance, and the superior genius
by which they were directed. Alcibiades enjoyed at Laced-
emon that respect and influence he every where obtained.
It was by his advice that the Lacedaemonians adopted the
resolutions of sending succours to the Syracusans, renewing
their inroads into Attica, and fortifying, at the distance of
one hundred and twenty fand from Athens, the port of
Decina, which held that city blocked on the sud side. To
annihilate the power of Athens, it was necessary to favour
the revolt of her allies, and destroy her navy. Alcibiades
repaired to the coasts of Aega Minor; and Chios, Miletus,
and other flourishing cities, declared for the Lacedaemonians.
By his accomplishments he captivated Tissaphernes, the
Governor of Sardis; and the king of Persia engaged to pay
the fleet of Peloponnesus. This second war, conducted
with more regularity than the former, would quickly have
been terminated, had not Alcibiades, pursued by Agis,
king of Lacedaemon, whose wife he had seduced, and by
the other chiefs of the league, who took umbrage at his
glory, at length considered that, after avenging himself
on his country, it now only remained for him to protect it from
inevitable ruin. With this view, he contrived to suspend
the operations of Tissaphernes, and the departure of the
Perian succour, under the pretext that it was the interest
of the great king to suffer the nations of Greece mutually
to extirpate each other. The Athenians having soon after
revised the decree for his banishment, he put himself at
their head, reduced the strong holds of theHellas, forced
one of the Persian governors to sign an advantageous
measure with the Athenians, and the Lacedaemonians to
forsake for peace. Their demand was rejected; for, deeming
themselves invincible henceforth under Alcibiades, the Athe-
nians made a rapid transition from the most profound con-
firmation to the most insolent presumption. The hatred
with which they were animated against that general was as
quickly succeeded by the most extravagant gratitude, and the
most unbounded affection. When he returned to his
own country, his arrival, and the pains he took to justify
his conduct, were a series of triumphs for himself, and of
public rejoicings for the multitude. When, amid the ac-
clamations of the whole city, they saw him fail from the
Paros with a fleet of a hundred ships, no doubt was enter-
tained but that his rapid victories would soon force the
inhabitants of the Peloponnesus to submit to the law of the
conqueror; the arrival of a courier was every moment ex-
pected with the news of the destruction of the enemy, and
the conquest of Hieon. In the midst of these flattering ex-
pectations, they learnt that the fortune of the Athenian galle-
ys had fallen into the hands of the Lacedaemonians. The
engagement took place during the absence, and in contempt of
the precise orders, of Alcibiades, who had been obliged to
pass into Hieon to levy contributions for the subsistence of
his troops. On the first intelligence of this check, he in-
fantly returned, and offered battle to the victor, who did
not venture to accept it. He had retrieved the honour of
Athens; the loss was trifling, but it sufficed for the jealousy
of his enemies. They exasperated the people, who stripped
him of the general command of the armies with as much
precipitation as they had manifested in investng him with
that dignity. After the second exile of Alcibiades, the
war continued for several years, the Spartans being now
commanded by Lyfander, after Alcibiades, the first general
of Greece. Till the twenty-seventh year of the war, the suc-
cesses was various, and operations were principally maritime.
The great object of the Peloponnesians was the reduction of
the Athenian colonies; and the northern parts of the
Aegean sea were the chief scenes of warfare. In the twenty-
seventh campaign, a large Athenian fleet was stationed at
the mouth of the river Egos. Considering themselves as
incontrovertibly superior to the enemy, many of the Athe-
nian soldiers left the ships, and were carelessly dispersed on
shore. Alcibiades, being in that neighbourhood, and, even
in handiwork, anxious for the welfare of his country,
warned the Athenian generals of their hazardous position,
and the want of discipline among their followers and
fame; after representing to them the danger of their situa-
tion, as an inhospitable coast, without either harbours or
cities to which they might retire in case of necessity, he offered
to co-operate with them, by falling upon the enemy at
land, with some Thracian troops under his command. But
the generals despised his advice, and refused, out of jealousy,
to accept of his service. Lyfander, in the mean time, prepared
to attack the Athenians when totally off their guard. Hav-
ing learned from his scouts, that the enemy were straggling
with even more than their usual carelessness, Lyfander
embraced the opportunity, and bore down upon the ships thus
defeited by the chief portion of the fighting men. The
victory was complete, if that can be called a victory where
there was scarcely any resistance. The vigilant activity of
Conon endeavoured feasonably to assemble the strength of
the
the Athenians; but his advice was disdained by officers incapable and unworthy of command, and his orders were defied by seamen unaccustomed and unwilling to obey. At length they became fainént of the danger, when it was too late to avoid it. Their ships were taken, either altogether empty, or manned with such feeble crews as were unable to work, much less to defend them. The troops and sailors who flocked to the shore from different quarters, and with disordered precipitation, were attacked by the regular onset and disciplined valour of the Peloponnesians. Those who fought were slain; the remainder fled into the utmost recesses of the Chersones, or took refuge in the Athenian fortresses, which were scattered over that peninsula. Out of a fleet of an hundred and eighty sail, only nine vessels had escaped, eight of which were conducted by Conon to the friendly island of Cyprus, while the ninth carried to Athens the melancholy news of a disaster equally unexpected and fatal. Lysander proposed to pursue his blow to the destruction of the Athenians, reduced all the colonies of Athens under the dominion of Sparta, and proceeded to the siege of Athens. While he invested this city by sea, a powerful army co-operated with him by land. The Athenians, having defended themselves for three months, were reduced to the extremity of direst, and at length this celebrated city was captured, dismantled, and rendered a dependency of Sparta. Such was the ruinous termination of the Peloponnesian war. (B.C. 404.) The conquerors placed the government in the hands of thirty persons, who, from their capacity and cruelty, earned and acquired the name of the thirty tyrants. During the fury Athens had scarcely any political existence, and its history is only marked by domestic injustice and misery. The unhappy Athenians call their eyes on Alcibiades, in the confidence that he could, and the hopes that he would, effect their deliverance. But Lysander, entertaining a similar idea of the powers and disposition of that illustrious exile, prevailed on Pharnabazus, the Persian satrap, to perpetrate his murder. The thirty tyrants, freed from the fear of such an avenger, proceeded to greater enormity than ever; until Thrasybulus, inheriting the magnanimous spirit of a free Athenian, put himself at the head of his injured countrymen, expelled the tyrants (B.C. 401), and favoured by the disaffections of the Spartan leaders, re-established a free government in Athens. Deprived, however, of her colonial, naval, and many of her commercial resources, Athens continued of little importance in the public transactions of Greece. The chief domestic event which distinguishes this part of Athenian history, is the fate of Socrates; but of the life as well as of the death of this extraordinary sage, a full account will be given under the appropriate article.

While the Athenians had thus lost not only pre-eminence but independence and political importance, they were still distinguished for good and bad qualities, which had flourished so conspicuously in the days of their prosperity. Genius was still transcendent, though directed to different objects from those which had employed Themistocles and a Cinon. Instead of active efforts for aggrandizing their country, Athenian talents were now chiefly employed in pursuits destined to delight and instruct all the enlightened world. Poetry, history, and philosophy by different means purified the same end, the promotion of wisdom, virtue, and happiness. But as epic and dramatic excellence had been already carried to the highest conceivable perfection, the poetry of Athens at this period was left superfluous; the history and philosophy, Thucydides and Socrates being dead. Xenophon and Plato occupied the highest rank.

The overbearing influence with which the Spartans exercised their supremacy over the Grecian states, proved ultimately the means of their degradation, and enabled the Athenians to recover a certain portion of their political power, and their consequence among their neighbours. The confederacy which was formed against Sparta enabled the Athenians to defeat the Lacedaemonians at sea, to regain their naval superiority, and to rebuild their harbour and walls. (B.C. 394.) This revolution from dependency to maritime supremacy they owed to the courage and policy of the celebrated Conon. (See Conon.) Thrasybulus seconded the exploits of Conon, and the Athenians resumed the command of maritime settlements, which had been wrested from them ten years before by the victorious Spartans. The reviving fortune of the Athenians recalled their military energies, and various commanders started up, not unworthy of the native country of Pericles and Alcibiades. Iphicrates, Chabrias, and Timotheus, gave glorious specimens of valour and conduct; but the peace of Antalcidas (B.C. 387) suspended their exertions. For several years after this treaty, the Spartans endeavoured by stratagem and furprise to re-establish their predominacy; they feized the citadel of Thebes, and attempted to make themselves masters of the harbour of Athens, though nominally at peace with both countries. The Athenians joined with the Thebans in revenging this outrage: Chabrias repulsed the army of Sparta, while Iphicrates and Timotheus destroyed her fleets, and Athns reëst to an equality with her rival. Peace being again concluded between the Spartans and Athenians, the latter were speculators of the contest between Sparta and Thebes, where the renowned Epaminondas gave at Leuctra (B.C. 371) such a blow to Spartan power; the Athenians were invited by the victors to join in an alliance for crushing their antient enemies; but they regarded found policy more than resentment, and would not throw their weight into the Theban scale, already preponderant. The Theban hero having ill farther reduced the Spartans, and invaded Laconia, the Athenians took active leads for rendering assistance to the now weaker party, and sent an army to defend Peloponnæus; but the battle of Mantinea (B.C. 363) arrested Epaminondas in the career of victory. After him no Theban arose fit for imitating his example, or executing his designs. The Thebans became languid; the Spartans on the other hand were exhausted. Athens did not fail to take advantage of the contests which had weakened her two successors in the dominion of Greece. Taught by experience, they did not attempt to subdue the territories of her warlike neighbours; but the numerous islands of the Ægean and Ionian seas, the remote coasts of Thrace and Asia, invited the activity of their fleet, which they might now employ in foreign conquests, fearful of domestic envy. It appears, that soon after the death of Epaminondas, Eubœa again acknowledged the authority of Athens, an event facilitated by the defection of the Theban partisans belonging to that place, in the battle of Mantinea. From the Thracian Bosphorus to Rhodes, several places along both shores submitted (B.C. 362.) to the arms of Timotheus, Chabrias, and Iphicrates; men, who, having survived Agis and Epaminondas, were far superior in abilities and in virtue, to the contemporary generals of other republics. The Cyclades and Coreya courted the friendship of a people able to interrupt their navigation, and to destroy their commerce: Byzantium had become their ally; and there was reason to hope that Amphipolis would soon be reduced to subjection. Such multiplied advantages revived the ancient grandeur of Athens, which once more commanded the sea, with a fleet of near three hundred sail, and employed the half of her citizens and subjects in flaps of war or commerce. This tide
of prosperity, flowing to grateful after adversity and oppre-
ッション， proved eventually the cause of their ruin. The popu-
lace abandoned themselves to idleness, dissipation, and fen-
uality; and to supply their extravagance, fought projects of
injustice and rapacity. To direct the formation, and head
the execution of such schemes, a daring and profligate
leader presented himself in Chares, whose soldier-like ap-
pearance, blunt address, and bold impetuous valor, matched
his selfish ambition, and rendered him the idol of the popu-
lace. His person was gigantic and robust, his voice com-
manding, his manners haughty: he offended positively, and
promised boldly; and his presumption was so excessive, that
it concealed his incapacity, not only from others, but from
himself. Though an enterprising and successful partisan, he
was unacquainted with the great duties of a general; and
his defects appear the more striking and palpable, when
compared with the abilities of Iphicrates and Timotho-
this contemporaries, who prevailed as often by address as by
force, and whose conquests were secured to the republic
by the moderation, justice, and humanity with which they
had been obtained, and with which they continued to be go-

cerned. Chares proposed a very different mode of adminis-
tration; he exerted his counselsmen to supply the defects of
their treasury, and to acquire the materials of those plea-
ures which they regarded as essential to their happiness,
by plundering the wealth of their allies and colonies.
This counsel was too faithfully obeyed; the vexations
anciently exercised against the tributary and dependent states,
were renewed and exceeded. The weaker communities
complained and remonstrated against this intolerable rapacity
and oppression; while the islands of Chios, Cos, Rhodes,
as well as the cities of Byzantium, prepared openly to revolt,
and engaged with each other to repel force by force, until
they should obtain peace and independence (B.C. 355).
Chares, probably the chief instrument as well as the adviser
of the arbitrary measures which had occasioned the revolt,
was sent out with a powerful fleet and army to quash at
once the hopes of the insurgents. He failed towards Chios,
with an intention to seize the capital of that island, which
was supposed to be the centre and prime mover of rebellion.
The confederates, informed of his motions, had already
drawn thither the greatest part of their forces; the city of
Chios was besieged by sea and land; the islands defended
themselves with vigour; Chares found it difficult to repulse
their foes: his fleet attempted to enter their harbour with-
out success; the ship of Chabrias alone penetrated thus far;
and that able commander, whose valour and integrity merited
a better fortune, though deserted by the fleet, yet forsook
not the flag entrusted to him by the republic. His compa-
nions threw away their shields, and faved themselves by
swimming to the Athenian squadron, which was still within
their reach: but Chabrias, fighting bravely, fell by the darts
of the Chians, preferring an honourable death to a disgrace-
ful life. Encouraged by advantages over their enemy, who
had at first affected to despoil them, the insurgents augment
their fleet, and ravaged the islands of Lemnos and Samos.
The Athenians, indignant that the territories of their faithful
allies should fall a prey to the depredations of rebels, fitted
out, early in the next year, a new armament under the com-
mand of Mnæthus, the son of Iphicrates, and con-in-law to
Timothoé, expecting that the new commander would re-
spectfully listen to the advice of those great men, who per-
haps declined acting as principals in an expedition, where
Chares professed any share of authority. That general had
raised the siege of Chios, and now cruised in the Hellepont;
where, being joined by Mnæthus, the united squadron
amounted to an hundred and twenty sail. It was imme-
dately determined to cause a diversion of the enemy's forces
from Samos and Lemnos, by laying siege to Byzantium. The
design succeeded; the allies withdrew from these
islands, collected their whole naval strength, and prepared
vigorously for defending the principal city in their confed-
ecry. The hostile armaments approached each other with
a resolution to join battle, when a sudden and violent storm
arose, which rendered it impossible for the Athenians to bear
up to the enemy, or even to keep the sea, without being ex-
posed to shipwreck. Chares alone confidently insisted on
continuing the attack, while the other commanders, more
cautiously and experienced, perceived the disadvantage, and
declared the unequal danger. His impetuosity, thus over-
rulled by the prudence of his colleagues, was converted into
remonstrance and fury: he called the failors and followers
witnesses their opposition, which he branded with every obvi-
ous epithet of reproach; and, with the first opportunity, dis-
patched proper messengers to Athens, to accuse them of
inconstancy, cowardice, and total neglect of duty. The ac-
cusation was supported by vocal orators in the pay of Chares;
Timothoé and Iphicrates were tried capitally. 'The former
trusted to his innocence and eloquence; the latter used a
very extraordinary expedient to sway the judges, conform-
able, however, to the spirit of that age, when courts of juf-
tice were frequently instruments of oppression, governed by
every species of undue influence, easily corrupted and easily
intimidated. The statesmen, or light infantry, who had
been armed, disciplined, and long commanded by Iphicrates,
enjoyed the fame reputation in Greece, which the \('Tabian" foddiers afterwards did in Italy. They were called "Iph-
icoceans" troops, from the name of this commander, to
whom they owed their merit and their fame, and to whose
person (notwithstanding the strictness of his discipline) they
were strongly attached by the ties of gratitude and esteem.
The youngest and bravest of this celebrated band readily
obeyed the injunctions of their admired general: surrounded,
on the day of trial, the benches of the magistrates, and took
care feamously to display the points of their daggers.
It was the law of Athens, that after preliminaries had been ad-
justed, and the judges assembled, the parties should be heard,
and the trial begun and ended on the same day; nor could
any person be tried twice for the same offense. The rapidity
of this mode of procedure favoured the views of Iphicrates;
the magistrates were overawed by the imminence of a dan-
ger which they had neither strength to resist nor time to
delude; they were compelled to an immediate decision; but
instead of the sentence of death, which was expected, they
imposed a fine on the delinquents, which no Athenian
citizen in that age was in condition to pay. This severity
drove into banishment those able and illustrious commanders.
Timothoé failed to Chalcis, in Euboea, and afterwards to
the isle of Lesbos, both which places his valour and abilities
had recovered for the republic, and which, being chosus as
his residence in disgrace, sufficiently evince the mildness
of his government, and his moderation in prosperity. Iphi-
crates travelled into Thrace, where he long resided; he had
formerly married the daughter of the Thracian princes, yet he lived and died in ob-
scenity; nor did either he or Timothoé henceforth take
any share in the affairs of their grateful country. Thus did
the former war delay or remove Iphicrates, Chabrias, and
Timothoé, the best generals whom Greece could boast; and,
believing Phocion excepted, the last venerable remains of Ath-
enian virtue. (See Gillies vol. iii. p. 484.)

Sunk in idleness, amusement, and vice, the Athenians
wanted nothing to complete their destruction but an ambi-
tious and enterprising foreign enemy. This they found in
Philip
Philip, king of Macedon, who first extended his power in countries not immediately connected with Greece, and at the same time increased the means of farther extension. Meanwhile a war broke out in Greece; first between the Thracians and Paeonians, concerning lands annexed to the temple of Delphi, which afterwards involved the greater part of Greece, and among others the Athenians. Philip, taking advantage of these divisions, marched towards the interior of Greece, knowing that the Athenians were the most immediately interested to oppose his progress, and the Peloponnesians, if they exerted themselves, to do it effectually; he directed a great part of his policy to the prevention of these exertions. He was aware that in a democracy the governors are the tools of the demagogues; by flattery, by cajolery, and by bribery, he effectually procured the favour of those leaders of the populace. One patriot, however, he could never corrupt; Demosthenes exerted the whole force of his eloquent eloquence (from B.C. 356 to 356) to route the Athenians to a sense of their danger, from the encroachments of Philip. (For the nature and character of Demosthenes's eloquence, see article DEMOSTHENES.) This oration occasionally restored his countrymen from their lethargy, but never to such great exertions as he declared necessary, and as the circumstances required; on gaining some partial advantages, they returned to their idleness and licentiousness. Philip amused them by embassies, seduced them by their demagogues, and continued his encroachments: when they should have been sending powerful auxiliaries, they sent ambassadors: these, Demosthenes excepted, Philip corrupted; and the interdicts of the Athenians were betrayed. In vain Demosthenes demonstrated the views of Philip, and treachery of the demagogues; he could not stimulate them to vigorous and persevering efforts, until Philip's power became too formidable for resistance. A combination of the tides of Greece was as length formed against Philip; but too late to be successful. The allies were totally defeated at Cheronae (B.C. 338), and the Athenians became a dependency of Macedon. A popular writer (see Travels of Anacharsis, vol. i. p. 112.) observes, that the history of the Athenians, properly speaking, commences about 150 years after the first olympiad; and concluded at the battle of Chersonae, it contains scarcely more than 300 years. In this series of years it is easy to discover certain important intervals, which mark the rise, progress, and decline of their empire; and if these areas be distinguished by characteristic names, the first may be called the age of Solon, or of the laws; the second, the age of Themistocles and Aristides, or the age of glory; and the third, that of Pericles, or the age of luxury and the arts.

The Athenians after the battle of Chersonae never recovered their importance. During the contests of Alexander's successors, they followed the fortunes of different chief-tains, but chiefly adhered to the side of Demetrius, the powerful despot, who established himself on the throne of Macedon. When the intrigues of the second Philip with the renowned Hannibal provoked the Romans to invade Greece, the Athenians joined the invaders, and Athens became the dependent ally of the conquerors. In the Mithridatic war, Athens having been conquered by the Asiatic monarch, was besieged by Sylla (B.C. 87), who took and plundered their city, demolished its walls and fortifications, butchered its inhabitants, and reduced it to a state of devastation. When this form subsided, Athens enjoyed profound tranquillity till the civil war broke out between Caesar and Pompey; when it took part with the latter, and was reduced to great straits by Calenus, the lieutenant of Caesar. Disappointed in their hopes of being relieved by Pompey, the Athenians surrendered at discretion, and were more kindly treated than they expected; for Caesar not only pardoned them, but took them under his protection, alleging, "that he spared the living for the sake of the dead." But when from servitude, they no sooner heard of Caesar's death than they openly declared for his murderers; receiving Brutus and Cassius into their city, and even erecting statues to them, which were placed next to those of Harmondus and Arrilucton. After the defeat of Brutus and Cassius, they attached themselves to Antony, who restored them to their former privileges, and enlarged their dominions, by subjecting to Athens the islands of Cea, Scyllus, Paparathus, and Egina. Of this island, however, they were deprived by Augustus, and forbidden to sell the freedom of their city, as a punishment which he inflicted upon them for their ingratitude to Julius Caesar. Towards the latter end of the reign of Augustus, they revolted, but were soon reduced to their former obedience. Germanicus, the adopted son of Tiberius, honoured them with the privilege of having a kteis, which was considered as a mark of favour. This grant was confirmed to them by Tiberius and his successors, under whose protection they maintained their ancient form of government till the reign of Vespasian, who reduced Attica, with the rest of Greece, to a Roman province, saying, "that the Greeks knew not how to enjoy their liberty." But the emperor Adrian, who had been prator of Athens before his accession to the imperial dignity, restored them to the full enjoyment of their former privileges. He repaired the two ports of the Piræus and Munychia, and added a whole district of new buildings to the old city. This quarter was called Adrianopolis, from Adrian, whom the Athenians hailed the second founder of their city. The privileges granted by Adrian were confirmed and extended by his successors M. Antoninus Pius and M. Antoninus the philosopher. Severus abridged them of many privileges in revenge for an affront which he received at Athens, while he resided in that city. They were favoured by Valerian; but the city was taken and plundered by the Goths in the reign of Gallienus, or of Claudius (A.D. 267 or 268); but the invaders were soon obliged, by a precipitate flight, to abandon their new conquest. Constantine the Great was a peculiar patron and benefactor of the Athenians. He honoured their chief magistrate with the title of grand duke, an office at first annual, but afterwards hereditary; and granted them many privileges, which were confirmed and enlarged by Constantius, who also put them in possession of several islands in the Archipelago. In the time of Theodosius I. 350 years after Christ, the Goths laid waste Thessaly and Epirus; but Theodore, general of the Acheans, preferred the cities of Greece from pillage; and a statue of marble was erected to him at Athens by order of the city. During the reigns of Arcadius and Honorius, the Athenians were cruelly harried and pillaged by the Goths under Maric (A.D. 350), who reduced all their lately and manifestly increase into heaps of ruins, and removed the invaluable treasures of antiquity. Synesius, a writer of that age, says, that Athens resembled the bleeding and empty skin of a slaughtered victim. After Athens became only part of a Roman province, it still remained the central point in the republic of letters, and continued to be frequented by all who desired to acquire that storehouse so highly valued by the ancients, and that standard table which enabled them to estimate, with peculiar accuracy, the real beauties of every work of genius and art. Here too, and here only, were to be learned the true principles of eloquence. All therefore, who applied themselves to public speaking, and
Cicero in particular, repaired to Athens, to study under the ablest masters of oratory. Thither did the same Cicero send his son to hear the lectures of Cratinus; but his Horace was sent by his father; every Roman of any rank or consideration followed the same course; and Greek learning, according to the testimony of Plutarch, was accounted to require a branch of education among that judicious people, that a Roman, who did not understand the Greek language, never arrived at any high degree of estimation. When St. Paul visited Athens, it was the seat of philosophy; and we cannot enough admire the superior eloquence of that apostle, in his manner of addressing so intelligent an audience. He adapted his discourse to the character of his hearers, by the sublimity of its oration; and he very properly mentioned the altar which he found there (see Altar); and his quotation from Aratus, one of their best-known poets, was particularly pertinent. Nor was Athens only celebrated for the residence of philosophers, and the institution of youth; men of rank and fortune found pleasure in a retreat which contributed so much to their liberal enjoyment. The progressive state of literature and philosophy at Athens, is thus described by a popular historian:

"Athens, after her Persian triumphs, adopted the philosophy of Ionia and the rhetoric of Sicily; and these studies became the patrimony of a city, whole inhabitants, about thirty thousand males, condened, within the period of a single life, the genius of ages and millions. Our sense of the dignity of human nature, is exalted by the simple recollection, that Iocrates was the companion of Plato and Xenophon; that he assisted, perhaps with the historian Thucydides, at the first representations of the Oedipus of Sophocles and the Hippigene of Euripides; and that his pupils Xanthippus and Demochenes contended for the crown of oratorism in the presence of Aristotle, the master of Theophrastus, who taught at Athens with the founders of the Stoic and Epicurean sects. The ingenious youth of Attica enjoyed the benefits of their domestic education, which was communicated without envy to the rival cities. Two thousand disciples heard the lessons of Theophrastus; the schools of rhetoric must have been still more populous than those of philosophy; and a rapid succession of students diffused the fame of their teachers, as far as the utmost limits of the Grecian language and name. Those limits were enlarged by the victories of Alexander; the arts of Athens farved her freedom and dominion; and the Greek colonies which the Macedonians planted in Egypt, and scattered over Asia, undertook long and frequent pilgrimages to worship the muses in their favourite temple on the banks of the Nile. The Latin conquerors respectfully listened to the instructions of their subjects and captives; the names of Cicero and Horace were enrolled in the schools of Athens; and after the perfect settlement of the Roman empire, the natives of Italy, of Africa, and of Britain, converted in the groves of the academy with their fellow-students of the East. The studies of philosophy and eloquence are congenial to a popular state, which encourages the freedom of inquiry, and submits only to the force of persuasion. In the republics of Greece and Rome, the art of speaking was the powerful engine of patriotism or ambition; and the schools of rhetoric poured forth a colony of flatemen and legislators. When the liberty of public debate was suppressed, the orator, in the honourable profession of an advocate, might plead the cause of innocence and justice; he might abuse his talents in the more prejiable trade of panegyric; and the fame precepts continued to dictate the fanciful declamations of the sophist, and the chaffer histories of historical composition. The systems which professed to unfold the nature of God, of man, and of the universe, entertained the curiosity of the philosophic student; and according to the temper of his mind, he might doubt with the sceptics, or decide with the Boeots. Sublimely speculate with Plato, or soberly argue with Aristotle. The pride of the adverse sect had fixed an unattainable term of mortal happiness and perfection; but the race was glorious and fabulous; the disciples of Zeno, and even those of Epicurus, were taught both to act and to suffer; and the death of Peripatetics was not less fatal than that of Socrates, to hinder a tyrant by the discovery of his impotence. The light of science could not indeed be confined within the walls of Athens. Her innumerable writers addressed themselves to the human race; the living masters emigrated to Italy and Asia; Berenice, in later times, was devoted to the study of the law; astronomy and physic were cultivated in the museum of Alexandria; but the Attic schools of rhetoric and philosophy maintained their superior reputation from the Peloponnesian war to the reign of Justinian. Athens, though situated in a barren soil, possessed a pure air, a free navigation, and the monuments of ancient art. That crowded retirement was seldom disturbed by the bustle of trade or government; and the left of the Athenians were distinguished by their lively wit, the purity of their taste and language, their social manners, and some traces, at least in discourse, of the magnanimity of their fathers. In the suburbs of the city, the academy of the Platonists, the gymnasium of the Peripatetics, the portico of the Stoics, and the garden of the Epicureans, were planted with trees and decorated with statues; and the philosophers, instead of being immured in a cloistery, delivered their instructions in spacious and pleasant walks, which, at different hours, were accustomed to the exercices of the mind and body. The genius of the founders still lived in those venerable seats; the ambition of succeeding to the maiters of human reason, excited a generous emulation; and the merit of the candidates was determined, on each vacancy, by the free voices of an enlightened people. The Athenian professors were paid by their disciples, according to their mutual wants and abilities; the price appears to have varied from a mina to a talent; and Iocrates himself, who deserves the avarice of the sophist, was in his school of rhetoric, about thirty pounds from each of his hundred pupils. The wages of industry are just and honourable, yet the same Iocrates shed tears at the first receipt of a stipend; the Stoic might blush when he was hired to preach the contempt of money; and I should be forry to discover, that Aristotle or Plato so far degenerated from the example of Socrates, as to exchange knowledge for gold. But some property of lands and houses was settled by the permission of the laws, and the legacies of deceased friends, on the philosophic chairs of Athens. Epicurus bequeathed to his disciples the garden which he had purchased for eighty mina or two hundred and fifty pounds, with a fund sufficient for their frugal subsistence and monthly festivals; and the patrimony of Plato afforded an annual rent, which, in eight centuries, was gradually increased from three to one thousand pieces of gold. The schools of Athens were protected by the wiflet and most virtuous of the Roman princes. The library which Hadrian founded, was placed in a portico adorned with pictures, statues, and a roof of alabaster, and supported by one hundred columns of Phrygian marble. The public fablers were aligned by the generous spirit of the Antonines, and each profitor, of politics, rhetoric, of the Platonics, the Peripatetic, the Stoic, and the Epicurean philosophy, received an annual stipend of ten thousand drachmata, or more than three hundred"
dred pounds sterling. After the death of Marcellus, these liberal donations, and the privileges attached to the thrones of science, were abolished and revived, diminished and enlarged: but some vestige of royal bounty may be found under the successors of Constantine; and their arbitrary choice of an unworthy candidate might tempt the philosophers of Athens to regret the days of independence and poverty. It is remarkable, that the impartial favour of the Antonines was bestowed on the four adverse sects of philosophy, which they considered as equally useful, or at least as equally innocent. Socrates had formerly been the glory and the reproach of his country; and the first leibons of Epicurus so strangely scandalized the pious ears of the Athenians, that by his exile, and that of his antagonists, they silenced all vain disputes concerning the belief of gods. But in the ensuing year they recalled the halcyon decree, restored the liberty of the schools, and were convinced by the experience of ages, that the moral character of philosophers is not affected by the diversity of their theological speculations.

But the schools of Athens were suppressed by an edict of Julianus; an edict, which excited the grief and indignation of the few remaining notaries of Grecian science and superlition. Seven friends and philosophers, Diogenes and Hermias, Eulalius and Priscian, Damascenus, Iphodore, and Simplicius, who disdained from the religion of their sovereign, resolved to seek in a foreign land the freedom of which they were deprived in their native country. Accordingly the seven sages fought an asylum in Persia, under the protection of Chosroes; but disgraced and disappointed, they hastily returned, and declared that they had rather die on the borders of the empire, than enjoy the wealth and favour of the barbarian. These associates ended their lives in peace and obscurity; and as they left no disciples, they terminate the long list of Grecian philosophers, who may be justly praised, notwithstanding their defects, as the wisest and most virtuous of their contemporaries.

From the time of Arcadius and Honorinus, nothing memorable concerning the Athenian state has been recorded in history till the thirteenth century; when it was in the possession of Baldwin, as Nicetas informs us, and unsuccessfully besieged by Theodorus Lascaris, one of the generals of the Greek emperor. In the 252 years, from A.D. 1204. to A.D. 1456., that elapsed between the fall and conquest of Constantinople; the possession of Greece was disputed by a multitude of petty tyrants. However, in the partition of the empire, the principality of Athens and Thessaly was assigned to Otto de la Roche, a noble warrior of Burgundy, with the title of great duke. Otto followed the Standard of Boniface, the marquis of Montferrat; and the ampleflate which he acquired, was peaceably inherited by his son and two grandsons, till the family was changed by the marriage of an heiress into the elder branch of the house of Brienne. The son of that marriage, Walter de Brienne, succeeded to the duchy of Athens; but his family and nation were expelled by the Catalans, who seized possession of Attica and Bœotia. During fourteen years they were the terror of the Grecian states. Their factions drove them to acknowledge the sovereignty of the house of Aragon; and, during the remainder of the fourteenth century, Athens, as a government or an appanage, was successively bestowed by the kings of Sicily. After the French and Catalans, the third dynasty was that of the Acciaioli, a family, plebian at Florence, potent at Naples, and sovereign in Greece. Athens, which they embellished with new buildings, became the capital of a state, that extended over Thessal, Argos, Corinth, Delphi, and a part of Thessaly; and their reign was finally determined by Mahomet the second, about the year 1455, who striped the last duke, and educated his sons in the discipline and religion of the Saracens. This fatal catastrophe, which happened near 2000 years after the time of Pindar, brought Athens, together with the whole of Greece, under the despotic dominion of the Turks. In 1454, the Venetians landed at the Piræus, surprised the city, and carried off their plunder and captives to Euboea. In 1487, it was taken, after a short siege, by the Venetians; and not many years after, taken by the Turks, under whose yoke it has ever since continued.

As to the present state of Athens, though the valor of its former in it, it still contains about 8 or 10,000 inhabitants; of these, three fourths are Greeks in nation and language; and the Turks, who compose the remainder, have relished, in their intercourse with the citizens, somewhat of the pride and gravity of their national character. The olive-tree, the gift of Minerva, flourishes in Attica; nor has the honey of mount Hymettus lost any part of its exquisite flavour: but the languid trade is monopolized by strangers; and the agriculture of a barren land is abandoned to the vagrant Walachians. The Athenians are full distinguished by the subtilty and acuteness of their understandings; but these qualities, unable embodied by freedom and enlightened by study, will degenerate into a low and selfish cunning; and it is a proverbial saying of the country, "From the Jews of Thessalonica, the Turks of Negropont, and the Greeks of Athens, good Lord deliver us!" This artful people has cluded the tyranny of the Turkish bashaws, by an expeditious which alleviates their servitude and aggravates their flame. About the middle of the last century (the 17th), the Athenians chose for their protector the Kilîar Aga, or chief black eunuch of the seraglio. This Ethiopian slave, who poxes the sultan's ear, condescends to accept the tribute of 50,000 crowns; his lieutenant, the Waywode, whom he annually confirms, may retrench for his own about five or six thousand more; and such is the policy of the citizens, that they seldom fail to remove and punish an oppresive governor. Their private differences are decided by the archbishop, one of the richelt prelates of the Greek church, since he poxes a revenue of 1000 l. per annum; and by a tribunal of the eight genonti or elders, chosen in the eight quarters of the city; the noble families cannot trace their pedigree above 500 years; but their principal members are distinguished by a grave demeanour, a far-capt, and the lofty appellation of archon. By whom, when he delights in the contrail, the modern language of Athens is represented as the most corrupt and barbarous of the feventy dialects of the vulgar Greek; this picture is too darkly coloured; but it would not be easy, in the country of Plato and Democritus, to find a reader, or a copy of their works. The Athenians walk with a fitful indifference among the glorious ruins of antiquity, and such is the desuetude of their character, that they are incapable of admiring the genius of their predecessors."

Gibbon's Hist. vol. xi. p. 355. &c. For the modern account of Athens and the Athenians, see Spon, Voyage en Grece, t. ii. p. 190—199; Wheeler's Travels into Greece, p. 337—414; Stuart and Rivett's Antiquities of Athens, vols. i. ii. and iii. passim; and Chandler's Travels into Greece, p. 137—172. It is now called Athini, and Setines; which feem.

ATHENIANS, Character and Manners of the. These people were highly susceptible of lively and transient sensations; and, accordingly, they lend distinguished beyond all other nations for uniting the most discordant qualities, and such as were often perverted and made occasions of misleading them. History represents them to us (see the authorities.
ties cited in the "Travels of Anacharsis," vol. ii p. 260.), sometimes as an old dotard, who may be deceived with impunity; or as an infant, who requires continual amusement; and sometimes as displaying the discernment and sentiments of elevated minds; as passionately fond of pleasure and of liberty, of indolence and of glory; or intoxicated with flat-
ty, and yet receiving merited reproach with applause; as posing with a pretension to apprehend at a word the plans prop-
osed to them, but too impatient to listen to the particulars, or to foresee their consequences, as making their magistrates tremble before them, and at the same moment pardoning their most bitter enemies; as passing with the rapidity of lightning from rage to compassion, from dependence to indifference, from injustice to repentance; as beyond conception sickle; and so frivolous, that in the most fortunate, and even the most desperate situation of their affairs, a single
word spoken at random, a happy folly of pleasantry, the smallest object, the most trivial incident, provided it were unexpected, sufficed to dispel their fears, or to divert them from attention to their most important interests. As nothing
was more easy than to excite and inflame the passions of
such a people, it was equally easy to acquire, and also to lose, their confidence. A popular leader, whilst in favour with them, might without difficulty persuade them to adopt
good or evil measures with an equal degree of ardour.
When guided by firm and virtuous men, they bestowed
public offices of trust or power on those, who united great
abilities with eminent virtue: at other times, they made a
choice at which they ought to have blushed; and they were
thus frequently the sport of flattering orators and ambitious
tyrants. Such, however, was their inherent detestation of
tyranny, that they were extremely jealous, on many memo-
able occasions, of their privileges, and both zealous and
active in defence of their liberty, whenever they thought
it attacked and violated by men in power. Indeed, an ar-
dent love of liberty was their predominant quality, and the
main spring of their government. They left, without hesita-
tion, their cities and their houses, to fight at sea or by land
the common enemy, who threatened them with the danger of
detriment. It was a glorious day for Athens, when all
her allies yielding to the advantageous offers of the king of
Perisa, the reply by Arilides to the ambassadors of that
monarch; "that it was impossible for all the gold in the world
to tempt the republic of Athens, and to prevail with her
to sell her liberty, and that of Greece." By such sentiments,
and a conduct actuated by them, the Athenians not only
came to the heathen of Greece, but likewise guarded the
rest of Europe from a Persian invasion. The Athenians,
however, notwithstanding their attachment to the rights
of their country, and the jealousy with which they watched
over them, were volatile, capricious, and inclined; and
this disposition betrayed them into errors, incompatible
with true patriotism. Whilst the Athenians indulged views of
conquest that were extensive and astonishing, they were, in
private life, and in their domestic arrangements and expendi-
ture, frugal, simple, and unostentatious; but when the
honour of the state required it, sumptuous and magnificent.
Their conquests, their riches, and their connections with
the inhabitants of Asia Minor, never betrayed them into
luxury, pomp, and profusion. Xenophon observes, that a
citizen was not distinguished from a slave by his dress: and
it is remarked with approbation by Demosthenes, that in
the best times of the republic, the houses of Themistocles
and Arilides could not be distinguished from those of their
neighbours. The wealthiest citizen, and the most renowned
general, were not ashamed to go themselves to market. In the
form and disposition of the several articles of dress, the men
were expected to study decency, and the women to unite
dignity with taste. The latter, whenever they went out, wore a
veil over their heads: and they painted their eye-brows with
black, and applied to their faces a layer of creuse or white
lead, with deep tints of rouge. Their hair, which they
crowned with flowers, was sprinkled over with a yellow-
coloured powder. Shut up in their apartments, they never
participated in the pleasures of the companies assembled by
their husbands. In the day, the law permitted them to go
out only on certain occasions, and never in the night time, but
in a carriage, and with a flambeau to light them; but not-
withstanding the restraint of this law, the women of the
lower classes indulged themselves with greater liberty. In
public feasts they were present at the spectacles as well as
the ceremonies of the temple; but they were generally atten-
ded by eunuchs, or female slaves. At an early period the Athe-
nians were so jealous, that they would not permit their women
to fly themselves at the window; but this restraint was grad-
ually relaxed, and later laws were introduced to guard against
seduction and insolence. (See Adultery.) M. de Paus, in his "Recherches Philosophiques sur les Grecs,"
shows how the authority of Athenians and Plutarch, represents
the Athenian matrons as addicted to drunkenness, and the most dif-
solute sensuality: he says that they were turbulent and
quarrelsome, and that, notwithstanding all the concussions
of their husbands, domestic peace was very seldom found
in their habitations. It is certain, that the feasts of Bacchus,
and some other religious institutions which the women
claimed a right to celebrate, could not tend to inspire either
gentle-nuns of manners or purity of morals. Courtezans
were protected at Athens by the laws, but the public man-
ners were contaminated by this licence. Females of this
description, however, were not allowed to appear in the
streets with rich trinkets or jewels, nor were men in office
permitted to appear with them in public. The Athenians
were naturally abstruse; their chief food consisted of fair
meat and vegetables. The necessities of the poor were sup-
plied either from the public treasury, or other means. In
Athens there were several societies, the members of which
entered into a solemn engagement to assist each other in
cases of judicial prosecution; and there was one society,
whole only object was to observe and collect every species
of ridiculous absurdity, and to divert itself with pleasantry
and bon-mots. At Athens, a small number of citizens
enriched themselves by commerce, and by silver mines which
they possessed at Laurion, in which they found a decent fortune when they possessed estates to the value
of fifteen or twenty talents (the talent being equal to about
253 l. sterling), and when they were able to give their
daughters a marriage portion of 100 minas, or about
575 l. sterling.

The tale of the Athenians for literature and science is
well known. The inhabitants of Athens, says Cicero
(De Orat. and Orat. pro Flacco), were the inventors of all
learning, the men who invented and perfected eloquence,
and from whom humanity, learning, religion, and laws
were diffused through the whole world; nevertheless, he
adds, "they only knew what was right, but would not do
it." When the Athenians, says the sagacious Mr. Harris
(Philosophical Inquiries, part iii. c. 3.), had delivered
themselves from the tyranny of Pisistratus, and after this
had defeated the valetudinous efforts of the Persians under
Darius and Xerxes, they may be considered as at the summit
of their national glory; and for more than half a century
afterwards, they maintained, without control, the sove-
ignity of Greece. As their tale was naturally good, arts
of every kind soon arose among them, and flourished.
Vol. III.
Valour had given them reputation; reputation gave them an ascendant; and that ascendant produced a security, which left their minds at ease, and gave them leisure to cultivate every thing liberal or elegant. It was then that Pericles adorned the city with temples, theatres, and other beautiful public buildings. Phidias, the great sculptor, was employed as his architect, who, when he had erected edifices, adorned them himself, and added statues and baso-relieves, the admiration of every beholder. It was then that Polygnutus and Myron painted; that Sophocles and Euripides wrote; and not long after that they fav the "divine" Socrates. And though their military strength and political sovereignty were impaired by the Lacedaemonians, humiliated by the Thebans under Epaminondas, and wholly crushed by Philip the Macedonian; yet, happily for mankind, their love of literature and arts did not link along with it. Just at the close of their golden days of empire, adorned Xenophon and Plato, the disciples of Socrates, and from Plato defended that race of philosophers called the "Old Academy," which was succeeded by the "New Academy." (See Academy.) With the study of philosophy was united that of rhetoric, upon which treatises were written by the ablest Greek philosophers. To this object they were incited by the intrinsic beauty of their language, as it was then spoken among the learned and polite. "The fame love of elegance which made them attend to their style, made them attend even to the places where their philosophy was taught. Such was the academy of Plato; the Lyceum of Aristotle; the portico or colonnade of Zeno, the walls of which were decorated by various paintings of Polygnutus and Myron; and the gardens of Epicurus. These public institutions were called among the Greeks by the name of Gymnasia, in which were taught all those exercises, and all those arts, which tended to cultivate not only the body but the mind. Dr. Gillies, in his "History of Greece," has dwelt with a degree of enthusiasm on the advantages, both natural and moral, resulting from the gymnastic exercises and public games; but M. de Pauw (ubi supra) differs in opinion, affording that nothing could be more pernicious, or tend more to enervate the human race, than these exercises. As to the moral advantages of these public games, it is not very easy to decide; but their physiological effect is much less questionable, and cannot be justly disputed.

**Athens, Population of.** From comparing the several accounts of the population of Attica in the time of Pericles, of Demodhenes, and of Demetrius Philærus, M. de Pauw (ubi supra) conjectures, that the number of citizens was predicated nearly at the same level, in consequence of the adoption of strangers, to repair the extraordinary devastations of war and disease, and of emigrations, when the number exceeded that which the rules of policy had established; this was 20,000 men; and he supposes that there was an equal number of women. In the time of Demetrius Philærus, the strangers settled in Attica amounted to 10,000, and the slaves to 400,000; so that the whole number may be estimated at 450,000 to about eighty-six square leagues of territory, or above 5000 on an average to each square league. This, he observes, is a much greater population than that of France, which, according to M. Necker's calculations, contains not more than 900 inhabitants to a square league.

The people of Athens were comprehended under the classes of freemen or citizens, ἑλέουσαι; sojourners, or Μηνιαῖοι; and slaves, or ὅδε. Cecropes distributed them into four ἄρσεν, or tribes, each tribe being subdivided into three parts, and each of these into thirty families. The names of the tribes were different at different times; and their number was increased by Chilitheis to ten; and they were afterwards augmented to twelve. These tribes had public seats, at which they met to promote friendship and good neighbourly-This to each tribe belonged several little boroughs in Attica, called Ἀγοραί; of these there were 174, besides other boroughs that belonged to no particular tribe. It was enacted, that all strangers who intended to live at Athens, should be compelled, after a short residence, to enroll their names among the free citizens, and that none but persons of eminent meritious character should be citizens. This privilege was conferred by the popular assembly. It was also enacted, that none should reside as free citizens at Athens, except those who were banished from their own country, or who voluntarily settled there with their whole families. They were admitted to their rights by certain ceremonials, and enrolled in a certain tribe. Solon declared, that none should be accounted free but such as were Athenians both by father and mother; this regulation was revived, after dispute, by Pericles, and at his motion repeated; and after the expulsion of the thirty tyrants, Solon's law was restored. In the Cydastries there was a court of judicature, to which causes of illegitimacy belonged; and great care was taken that none should be enrolled as citizens, whose title was not examined and approved.

The Μηνιαῖοι, or sojourners, were those who came from a foreign country and settled in Attica, being admitted by the council of Areopagus, and publicly registered. Of these, several services were required; and both men and women paid an annual tax. Those who failed to pay it were seized and expelled to faye by the officers of the public revenue: such, according to Diogenes, was the fate of Xenocrates the philosopher; but those who rendered any service to the public, were exempted from the payment of all imposts, except such as were demanded of free citizens. Such persons as did not constantly reside at Athens, were called ἄρσεν, or strangers.

The slaves were of two sorts; such as became so from poverty, the chance of war, or the perfidy of those who trafficked in them, and who were at liberty to change their masters, and to release themselves from servitude; and such as were at the absolute disposal of their masters. Slaves were not allowed to imitate freemen in their dress and manners. They were forbidden to wear long hair, and what is more abominable, Solon prohibited them to love boys, as if this practice were honourable: they were not permitted to plead for themselves, or to be witnesses in any causa; confederate was extorted from them by torture; nor were they allowed to worship certain deities, to be called by honourable names, and to bear arms. They were reduced to obedience, and punished by corporal severities; they were sometimes marked on the forehead, or disgraced in any other part of the body. Nevertheless they were allowed at Athens to take refuge in the temple of Theseus, when they were oppressed, and it was for their sake that they were not to be found in the city; and in various respects their condition was preferable to that of slaves in other places, as they might purchase their freedom, and were sometimes advanced to the dignity of citizens. In the first day of every month, the merchants, called ἀστρευόμενοι, exposed them for sale in the slave market. In the time of Adrian, masters were prohibited from putting their slaves to death.

**Athens, Magistrates and Government of.** By the law of Solon, no man who had not a good estate, could bear the office of a magistrate; but by the law of Aristides, every
man was admitted to a share in the commonwealth; but before he was admitted, he was obliged to give an account of his past life before judges in that part of the forum called *Agora.* It was a capital crime for a person to enter into public office in debt. The magistrates of Athens were of three sorts, viz. * archon,* who were elected by the people, and so called because chosen by holding up of hands; * ephors,* who were promoted by lots drawn by the Thesmothetes, in the temple of Theseus; and * pleaders,* who were extraordinary officers appointed by particular tribes, to superintend public affairs. The magistrates entered on their office on the first day of the month Hecatombon. The first and most important of these magistracies was that of the archons. (See *Archon.*) Among the inferior magistrates may be reckoned the * nomophylacs,* the * phylarchs,* the * phylarchs,* the * phylarchs,* the * demarchs,* the * lixarch,* the * toxotai,* and the * nomothetes,* to whom were added the * rhetores,* which see respectively. There were other magistrates who had the superintendence and regulation of the general assembly of the people called *Ecclesia;* such as the * epistates,* the * Prytanes,* and the * prolethei.* (See also *Sextane,* and * Prytaneum.*) The courts of justice, exclusive of the * Areopagus,* were ten in number, of which four had cognizance of criminal, and six of civil causes. These courts were painted with various colours, and on each was engraved one of the ten first letters of the Greek alphabet; and hence they were denominated Alpha, Beta, &c. The names of those who were to hear and determine causes, and the names also of their father and borough, inscribed upon tablets, were delivered to the Thesmothetes, who returned it with another tablet on which was inscribed the letter of one of the courts according to the lots. These tablets were carried to the crier of the several courts directed by the letters, who gave to every man a tablet inscribed with his own name and the name of the court in which he was to sit; and having received a sceptre, the usual ensign of judicial power, they were severally admitted into the court. When their respective causes were determined, they returned the sceptre to the Prytanes, from whom they received their due reward, sometimes one obolus, and sometimes three obols. No man was allowed to sit in more than one court in a day; and if they were convicted of bribery, they were fined. The first criminal court after the Areopagus was that of the * Ephetae;* the second was called * Delphinius;* the third, * Prytaneum;* and the last * Piresiatum:* see the respective articles. Of the judicatory courts for civil causes, the first was the * paraeuston;* the second, the * cairon;* the third, * trigonon;* the fourth, the * court of Lyuce;* the fifth, that of * Melicthos;* and the sixth, * Helen.* All the Athenians who were free citizens were allowed to sit in these courts as judges; but they were previously obliged to take a solemn oath, by Apollo Phoebus, Ceres, and Jupiter the king, that they would pass a just sentence, and according to law, and to the bell of their judgment. This oath was administered near the river Ilissus, in a place called "Ardeum," from a person of that name, who, in a public sedition united the contending parties, and engaged them to confirm their treaties of peace by mutual oaths in this place; whence common swearers were called *arpodaves.* There were other courts of laws consequence, where the * athenia,* or * epiarchia,* or other magistrates, took cognizance of causes belonging to their several offices. Such were the courts at * Cyclopiarchs,* Odeum, the temple of Theseus, * Boudon, &c.* In the judicial process, the plaintiff delivered to the magistrate the name of the person against whom he brought his action, with an account of his offence; this was followed by an inquiry on the part of the magistrate, whether it belonged to his cognizance, and whether it ought to be tried, called "Anarchia;" the plaintiff then, with permission of the magistrate, summoned his adversary to appear; but if he refused to appear, he was dragged by force. When both plaintiff and defendant were before the magistrate, he inquired of the former whether the writs were all ready, which was the second * Anarchia:* when no plea was urged on the part of either plaintiff or defendant for putting off the trial, an oath was administered to both parties. These oaths, with those of the witnesses, and other matters relating to the action, were written upon tablets, and deposited in a vessel, which was delivered to the judges. The judges being appointed by lots, took their places at the assigned day in the tribunal. The magistrate then proposed the cause to them, and gave them authority to determine it. The public crier read the indictment containing the grounds of the accusation which were noted down by the judges. If the defendant did not appear, sentence was immediately passed against him; but if he presented himself within ten days, aliasing reasons for his absence, the former sentence was reversed, and the trial was to be brought forward by the defendant within two months; but if it was not brought on, the former sentence was confirmed. Before trial, both parties deposited a sum of money in the hands of the magistrate who introduced their cause into the court; who, if the money was not paid, erased their cause from the roll. The deposit, which was 3 drachmas for a cause of the value of 100 drachmas to 1000; and 30 for more than 1000 and less than 10,000; was divided among the judges; and the person who lost his cause refunded the money to his adversary, and paid the charges. The witnesses in the trial were to be free-born, and defending of credit; and they were considered as infamous if they had forfeited their privileges by perjury. The testimony was sometimes given aloud in open court, and sometimes in writing upon a tablet of wax. If the parties required it, they were allowed advocates, whose speeches were limited as to length of time, measured by a water glass. When the parties had finished, the crier was commanded by the presiding magistrate, to order the judges to bring in their verdict; and where the law had provided penalties, a verdict of guilty or not guilty was sufficient; but where the laws were silent, another sentence was necessary, determining the punishment due to the offence. When the laws were silent, the judges might limit the punishment: sentence was at first given by black and white sea-shells called *euphrate,* or pebbles called *tieps,* talla of brass were afterwards used, and then beans; the white beans were whole, and used to acquit; and the black were bored through, to condemn. The cause while pending was engraved on a tablet and exposed to public view, and hung up at the statue of the hero named *Lysa.* If the person convicted was guilty, he was delivered to the *rhetor* to receive punishment: but if he was fined, the *vuljeta* fixed the fine paid; if unable to pay it, he was delivered to perpetual imprisonment. If the plaintiff had unjustly accused his adversary, he was sentenced to suffer that punishment which the law inflicted on the crime with which his adversary was accused. The plaintiff was called * buno,* the cause *Atobienes,* and the accused * buno.* And was the name of the indictment before conviction, and was written before it. When the trial was closed, the judges went to the temple of Lyuce, returned their fetes, and received their money. The Athenian judgments were of two kinds: public, concerning those crimes which affected the state, called *spondan,* and all persons were encouraged by law to avenge the public wrong, by bringing the criminal to punishment; and
private, concerning all controversies between private persons, called δικαίας; and no one could prosecute an offender except he who was injured, or some of his family. The public judgments were murder, malicious wounding, a confabulation of the city, poison, conspiracy against the life of another, sacrilege punished with death, impurity, treason, fornication; whoredom, punishable by fine; ebullency; refusing to serve in war; and cowardice, punishable with infamy; deception of the fleet and of the army, punished by fine; defection from their post, as leaving the infantry for the cavalry; refusing to serve in the fleet, and losing their shield, punished with infamy; charging men with debts already paid, punished by fine; an action for false arrests, for beating a free man or reducing him to slavery, assault or fraudulent accusation, punished by a fine; receiving bribes for any public affair, or persevering justice, fined ten times the value of what they received, and punished with the highest degree of infamy; for offering bribes for the perversion of justice, and particularly in causes relating to the freedom of the city; for erasing a name out of the public debt-book before the debt was discharged; digging a mine without the public knowledge, a twenty-fourth part of the metal belonging to the public; against magistrates who had neglected to render their accounts; for proposing a new law, and acting contrary to the established laws; against magistrates, ambassadors, and other public officers, who had misemployed the public money, or otherwise offended; against ambassadors who had forfeited their trust; against defaced tumultuous perils; an action for debts due to the public, falsely charged upon those who had never paid the fines imposed upon them; for the discovery of any secret injury; and again for such as exported corn from Attica, appropriated the public money or land, or for misappropriating the property of orphans; against those who confided their crimes without standing a trial; against those who protected murderers; and again such as had been guilty of certain state offences. Of private judgments, which were very numerous, the principal were against those who had done an injury punished with fine, an action of assault, a law-suit generally for the recovery of an estate, a suit concerning relationship, an action of divorce, an action by a master or patron against his clients who were freed slaves, and who refused to perform the services incumbent upon them, an action against foreigners who neglected to choose a patron, an action of ingratitude, against those who had violated the chastity of women, or injured the persons of men, an action concerning marriage, against those who would not divide their property among joint claimants, for demanding rent, against guardians who had defrauded their wards, of slander, by which the criminal was fined 500 drachmas, against those who had suborned false witnesses, against thieves, an action claiming an estate against those who refused to render that with which they were entrusted, against those who would not fulfill their contracts, and a suit between debtors and creditors.

The criminal punishments of the Athenians were αίματα, infamy or disgrace; δικαίας, a deep pit into which condemned persons were cast headlong (see BARATHRUM); ειδώλια, or the ignominious punishment of hanging or strangling; εριστά, the punishment of fetters or imprisonment; κατακόμβες, latrines, by which a criminal was reduced to the condition of a slave; ραπτείς, peculiar fine laid upon the criminal, according to the nature of his offence; death, inflicted for various offences; θυγατέρια, a precipe from which the malefactor was thrown headlong; κελαδία, a collar usually made of wood; λαπανοστήωμα, laceration, a common punishment for adultery; κρύσταλλος, with which the criminal was beheaded; fetters with five holes; αἰματεύρης, a round instrument to confine the hand; κρύσταλλος, consisting of two beams laid across one another, to which the malefactor was nailed; πολλαπλασία, a pillar, on which the crimes of the offender were engraved; γραφήματα, marks impressed with a hot iron upon slaves; τρικλώνια, of the same club, with which malefactors were beaten to death; κτίστασις, small cords, by which criminals were flayed upon the rack; ομπλεκταρί, poleon, of which various forts were used, but the most common was the juice of hemlock; κατακόμβες, or banishment, of which there were several forts; ειδώλια, the fetters, in which the legs were festered; κελαδία, a piece of wood to which the criminal was bound; κτίστασις, drowning in the sea; and τουρία, or burning. Public honours and rewards were αγαθοθρία, (see ATHELEIA), or an immunity from taxes and other public duties; ἀγαθά, the honour of a statue erected in any public place; αγορά, or the liberty of the first seats at public entertainments; θυγατέρια, an entertainment at the public expense, given to those who had deserved well of their country; and εριστά, crowns conferred by the vote of the people in the public assembly, by the senators in council, by the tribes to their own members, and by the demotic in their own δικαίας, or borough.

As to the laws of the Athenians, it was a received opinion that they were taught the use of laws by Ceres; but it is certain that Theseus retained the privilege of making and preferring laws. Draco was the next law-giver, and his laws were called δικαίας; these were all, except those of murder, repealed by Solon, whose laws were distinguished by the term μορία. The theomothers wore to the observance of them, on the penalty of dedicating a statue as large as life to the Delphian Apollo; and the people were enjoined to obey them for a hundred years. Pisistratus afterwards esteemed for himself, and left to his sons, the authority of a law-giver; but the laws of Solon were in some degree enforced by Cleitones, who himself added new ones. These continued in force till the Peloponnesian war, when the government was altered by the four hundred, and afterwards by the thirty tyrants. The ancient laws were again restored by Euclides, and others by the influence of Diocrates, Aristophanes, and afterwards by Demetrius Phalereus, and thefe, with Ελεύθερος and Τάλτος, were the chief legislators of Athens. (Suidas.) The laws were annually revised; and a new law was to be proposed before an old one could be repealed. Solon, and other law-givers who succeeded him, committed their laws to writing. The laws of Solon were engraved on tablets of wood; and some affirm, that the original in his hand-writing were always kept in the citadel, and copies of them in the pytaneum. The laws were all engraved on the wall in the θυγατέρια φοί, or royal portico, for the inspection of the public. This was the custom after the expulsion of the thirty tyrants.

Athenians, Commerce of the. The harbour of Piræus was much frequented, not only by Grecian vessels, but also by those of the nations which the Greeks denominated Barbarians. But as the Athenians were actuated by the spirit of conquest, and aspired to the sovereignty of the sea, in order to obtain that of the land, they directed their attention to the navy with this view; and therefore their commerce was restrained to the procuring from other countries the commodities and productions necessary to their subsistence. Nevertheless, the Athenians adopted a variety of regulations, and enacted many laws for extending commerce, and preventing as much as possible the litigations and obstructions which impeded its operations. They inflicted a fine of a thousand drachmas (about 37 l. 10s.), and sometimes the punishment of imprisonment, on him who accused
As Attica produced but little corn, the exportation of it was prohibited; and those who fetched it from foreign countries were forbidden, under rigorous penalties, to carry it to any other market but that of Athens. A great quantity was brought from Egypt and Sicily; and a greater quantity from Panticapaeum and Thasos, cities of the Chersonesus Taurica, because the sovereignty of that country, the master of the Cimmerian Bosporus, exempted the Athenian vessels from paying the duty which he levied on the exportation of that commodity. In consequence of this privilege, they traded in preference to the Cimmerian Bosporus, from which Athens received annually 450,000 medimni of corn. The Athenians also imported from Panticaeum, and the different coasts of the Euxine sea, timber for building, slaves, felt, honey, wax, wool, leather, and goat-skins; from Byzantium, and other parts of Thrace and Macedonia, salt-fish and wood; from Phrygia and Miletus, carpets, coverlets, and the fine wool of which they made their cloths; from the islands of the Ægean sea, wines of the various kinds of fruits which they produced; and from Thrace, Thessaly, Phrygia, and other countries, a great number of flax. Oil was the only commodity that Solon allowed them to exchange for foreign merchandise; the exportation of all other productions from Attica was prohibited; nor was it permitted to carry out of the country, without paying heavy duties, the timber of the fir, the cypress, the plane, and other trees which grow in the environs of Athens. In their timber mines the Athenians found a great resource for their commerce. As several states debased their coin, the money of Athens, in greater estimation than that of other countries, procured for them an advantageous exchange. In general, they purchased wine in the islands of the Ægean sea, or on the coasts of Thrace; for it was principally by means of this commodity that they trafficked with the people who inhabited the borders of the Euxine sea. The tallie conspicuous in the works of their artists, rendered the productions of their skill and industry definable; so that they exported to distant countries swords and arms of different kinds, cloths, beds, and various utensils. Books were with them also an article of trade. They maintained correspondents in almost all the places to which they were attracted by the hope of gain; and, on the other hand, many of the states of Greece appointed agents at Athens to superintend the interests of their trade. The Athenians for the most part employed their money in trade; but they were not allowed to lend it for any place but Athens. The lender had his security on the merchandise or goods of the borrower; and as the dangers of the sea were partly rilfed by the former, and the profit of the latter might be very considerable, the interest of money thus lent might rise as high as 30 per cent. more or less, according to the length and hazards of the voyage. The landed interest amounted to 12 per cent. per annuum, sometimes to 16 per cent. monthly, and among the lower classes of the people, the quarter of the principal was exacted for daily interest. Commerce, by increasing the circulation of wealth, gave rise to the occupation of bankers, and thus its circulation was still more facilitated.

**ATHENS, Money of,** was of three sorts. Silver was first coined, afterwards gold, and lastly copper. The most common coins were those of silver, and they were of different value. Above the drachma (9 d. English), consisting of six oboli, was the didrachma, or double drachma, and the tetradrachma or quadruple drachma; below it were the pieces of 3, 5, and 2 oboli; after which were the obolus and hemiobolus (i.e. 6d., 4½d., 3d., 1½d., and ½d. English). The latter being found inconvenient for common use, copper money was coined about the beginning of the Peloponnesian war, and pieces of that metal were struck, which were not worth more than the eighth part of an obolus. The largest piece of gold weighed two drachmas, and was worth twenty silver drachmas (i.e. fifteen shillings English). Gold was very scarce in Greece; it was brought from Lydia and Macedonia, where the peacocks collected the small pieces which the rains washed down from the neighbouring mountains. See Money.

**ATHENS, Revenues of,** sometimes amounted to the sum of 2000 talents or 450,000 l. and these revenues were of two kinds; those which were raised in the country itself, and those that were drawn from the tributary cities and states. The first class comprehended the products of the houses, lands, and woods appertaining to the state, and farmed out for a certain sum; the twenty-fourth part reaped from the silver mines, payable by individuals who had permission to work them; the annual tribute received from freedmen and the 10,000 foreigners settled in Attica; the fines and confiscations, the principal of which went into the treasury of the state; the fifth levied on corn and other merchandise imported, and also on several commodities that were exported from the Piraeus; which, during the Peloponnesian war, were farmed at thirty-six talents ($1000 l.); and a number of other taxes of less importance, yielded by commodities sold in the market, and levied on fish as kept curteans in their houses. Most of these duties were farmed; and the farmers remitted, before the ninth month of the year, the sum stipulated to the receivers of the revenue. The second and principal branch of the revenues of the state, confined in the tributes which were paid by a number of cities and islands dependent upon it. Its claims of this kind were founded on the abuse of power. After the battle of Platea, the conquerors having resolved to revenge on Persia the inults offered to Greece, the inhabitants of the islands who had entered into the league agreed to set apart every year a considerable sum to defray the expenses of the war. The Athenians collected in different places 460 talents (103,500 l.); and by degrees, as their power increased, they changed the gratuitous contributions of the allied cities, into an humiliating exaction, imposing on some the obligation to provide ships whenever they should be called upon, and demanding of others the annual tribute to which they had formerly subscribed themselves. In the same manner they taxed their new conquests, and the sum total of the foreign contributions amounted, at the beginning of the Peloponnesian war, to 600 talents ($135,000 l.) and towards the middle of the same war, to twelve or thirteen hundred. The conquests of Philip reduced this sum to 400 talents, and the Athenians flattered themselves they should again be able to advance it to 1200 ($375,000 l.). The 460 talents drawn annually from the cities and states against the Persians, and deposited by the Athenians in their citadel, at first amounted to the sum of 10,000 talents ($2,500,000 l.) according to Isocrates (i. p. 365.) or 9700 ($2,182,500 l.) according to Thucydides (iii. c. 13.) Pericles, during his administration, had laid up 8000; but having expended 3700, either in the embellishment of the city, or the expenses of the siege of Potidae, the 9700 were reduced to 6300 ($1350,000 l.) at the beginning of the Peloponnesian war. This war was subsided by a truce, which the Athenians entered into with the Macedonians, and the contributions which they had then received amounted to 12 or 1500 talents; and during the seven years of the truce, they placed 7000 talents ($1,575,000 l.) in the public treasury. These revenues, however considerable, were insufficient
sufficient to defray the expenses of the state; and recourse was frequently had to free gifts and forced contributions. Of all the branches of public expenditure, the maintenance of the navy was the most heavy: when an armament was to be fitted out, each of the ten tribes levied in its district the same number of talents as there were galleys to be equipped, and demanded them from the same number of companies, composed sometimes of sixteen persons liable to contribute. Democritus made an amendment in the mode of ascertaining this tax. The decree proposed by him for this purpose was as follows: every citizen, whose fortune amounted to ten talents, was to furnish the state with one galley; if he possessed twenty talents, with two; and however rich he might be, no more should be required of him than three galleys and a hallop. Those whose substance was less than ten talents were to join in contributing a galley.

Athenians, Religion of the. From the earliest times the objects of religious worship multiplied among the Athenians. They received the twelve principal divinities from the Egyptians, and others from the Libyans and different nations; and they were so fearful of omitting religious worship, that they even erected altars to the unknown God. (Plutarch, in Attic.) See ALTAR. As the proceeds of time a law was enacted, prohibiting, under pain of death, the introduction of any foreign worship, without a decree of the archons. It was an ancient practice, to conferate, by monuments and festivals, the memory of kings, and other distinguished persons, who had rendered essential service to their country, or to mankind. To this class the Athenians referred Theseus, Erechtheus, such as deferred to have their names appropriated to the ten tribes, and many others, as Hercules, &c. But the worship of the latter derived from that of the gods, in the ceremonies that accompanied it, as well as in the object to which it was directed. Before the deity they prostrated themselves, imploring his protection, thanking him for his bounties, and acknowledging their dependence. In honour of the heroes, and as a memorial of their illustrious deeds, they consecrated temples, altars, and groves, and celebrated festivals and games. Incense was burnt on their altars, and libations were poured over their tombs to procure repose to their manses. The religion of the common people entirely consisted in prayers, sacrifices, and purifications. Individuals prefixed their prayers to the gods at the commencement of any undertaking: and they offered up their addresses in the morning, the evening, at the rising and setting of the sun and moon. Sometimes they repaired to the temple with downcast eyes and dejected countenances; they kneeling the ground, offered their prayers standing, on their knees, and prostrate, and held branches in their hands, which they lifted up towards heaven, or stretched out towards the stature of the god, after applying it to their months. In addressing the infernal deities, they struck the earth with their feet or hands. Some pronounced their devout addresses in a low voice; but Pythagoras wished them always to be uttered aloud, that nothing might be affed which could excite a blush. At the feaons of worship, the space before the temple and the porches that surrounded it, were full of people; so joyfully has the apostle Paul characterized the Athenians, when he called them (Acts, xvii. 23), ἀνέπλεπτος, ἰαφόροις, "too superstitious," as the common translation renders it; or perhaps it might be rendered less offensively and more conformably to the conciliatory address, which the apostle would have used on such an occasion, and also to the frequent use of the term, "very devout." See Lardner's Works, vol. i. p. 193. The priests were the principal ministers of religion; and they were next in precedence to the kings and chief magistrates. They obtained their office by inheritance, sometimes by lot, by the appointment of the prince, or by popular election: and they were required to be unmannered in body, chaste and uncontaminated by the pleasures of the world, in their disposition and character, and in their habits devoted to retirement and piety. Of these priests there were several orders, and among them there was one, denominated ἀγαθόπτους, high priests, who had the superintendence of the temple. Some temples were served by priests, as particularly that of Bacchus in the quarter of the marble. The revenues assigned for the maintenance of the priests and temples were derived from different sources, as a certain part of the produce of penalties and confiscations, and of the spoils taken from the enemy, and the offerings of individuals. They formed, however, no separate and independent body; nor had the ministers of different temples any common interest; and in causes which respected them personally, they were amenable to the ordinary tribunals. Functions of inferior dignity, that related to the service of the temple, were intrusted to lay officers: some of whom were guardians of the treasure, and others assisted as witnesses and inspectors at solemn sacrifices. Next to the priests, were the footshawks and interpreters of omens. The worship of the Athenians was originally performed in the open air, upon the tops of mountains; and on these spots temples were afterwards erected, and dedicated to Jupiter, Apollo, and the other gods. Their altars also, were constructed of various materials and of different dimensions, according to the variety of gods to whom they were consecrated. Both temples and altars were places of refuge or asylum for malefactors and criminals of all descriptions: and it was deemed an act of sacrilege to force them from their sanctuary. See ASYLUM. Their sacrifices also were of various kinds, as to their object and design, the materials of which they consisted, and the places in which they were offered, and the ceremonies that attended them. (See SACRIFICE.) As public worship was prescribed by one of the fundamental laws, and therefore closely connected with the constitution, it was impossible to attack religion, without endangering that constitution. It was consequently the duty of the magistrates to maintain it, and to oppose all innovations visibly tending to its destruction. Hence the poet Alcibiades was accused of having, in one of his tragedies, revealed the doctrine of the mysteries; Diogenes under a similar charge, saved himself by flight; Protagoras was criminally prosecuted, and obliged to fly; Probus of Ceos was condemned to drink poison; Anaxagoras was imprisoned, and his life was preferred by the interpretation and influence of Pericles; and the life of Alcmene was endangered by a charge of his having been concerned in the mutilation of the statues of Mercury. See each of these biographical articles.

Athens, in Geography, a township in America, in Windham county, Vermont, thirty-two miles north-east from Bennington, and about six miles from Connecticut river, having 950 inhabitants.

Atherdee. See AREE.

Atherina, or Atherine, in Ichthyology, one of the Linnaean genera of abdominal fishes; and distinguished by having the upper jaw rather flat, six rays in the gill membrane, and a silver stripe on each side of the body. Gmelin notices five species of this genus, viz. Epethina, Menidia, Silama, Japonica, and Brownii; which he respectively.

Atherinoides, a species of Clupea, distinguished from the other fishes of the same genus by having a silvery lateral line. Gmelin observes, that this fish from its broad silvery
Athens.

ATHAS. See ADIGE.

ATHAS, in Geography, a Jew, was a famous printer of Amsterdam, in the seventeenth century; and in 1661, and 1663, he printed two editions of the Hebrew bible, in two volumes 8vo., for which he obtained of the States-General an honorary recompense of a medal, and a chain of gold. He also printed the bible in Spanish, German, and English. He died in 1700. Dic. Hist.

ATHIE, in Geography, a town in France, in the department of the Somme, and chief place of a canton in the district of Peronne. Two leagues S.E. of Peronne.

ATHINI, or SETINES, the modern Athens, is not inconsiderable, says Chandler (Travels in Greece), either in extent, or in the number of its inhabitants. It enjoys a fine temperature, and a serene sky; the air is clear and wholesome. The town stands beneath the acropolis or citadel, and does not encompass the rock, as it formerly did, but spreads into the plain, chiefly on the west and north-west. The houses are mostly plain and straggling, with many large areas or courts before them. The water is conveyed to them in channels from mount Hymettus, and in the market-place is a large fountain. The Turks have several mosques, and public baths. The Greeks have convents for men and women, with many churches, in which service is regularly performed, and oratories or chapels, frequented on the anniversaries of the saints to whom they are dedicated. Besides the more stately antiquities, of which some notice has been taken under Athens, there are many detached pieces that have been found in the town, near the fountains, and also in the streets, the walls, the houses, and the churches. Among these are fragments of sculpture, a marble chair or two, which probably belonged to the gymnasia or theatres, a fun-dial at the cath. icon or cathedral, inferred, as it is said, with the name of Euclid; and at the archiepiscopal house, a curious vase of marble, used as a cinerary for receiving water, but once, probably, serving as a public standard or measure. Many columns, mantled statues, and pedestrals, are scattered about; and also a fine mutilated Herma. The acropolis, or citadel, is now a fortress, with a thick irregular wall, standing on the brink of precipices, and including a large area, about twice as long as broad. Some portions of the ancient wall remain, and it is repaired with patches of pieces of columns, and with marble taken from the ruins. The garrison consists of a few Turks, who reside there with their families, and are called by the Greeks "Cadimis," or soldiers of the calif. Their houses overlook the city, plain, and gulf; but the situation is as airy as pleasant; the rock is lofty, abrupt, and inaccessible, except the front, which is towards the Piraeus; and on that quarter is a mountainous ridge, within cannon shot. The acropolis furnished says Chandler, an ample field to the ancient Virtuosi. It was filled with monuments of ancient glory, and exhibited an amazing display of beauty, of opulence, and of art; each commanded, as it were, for the interior. Hidrachmus, named Periplus is the guide, employed in this place fifteen books. Polemo Peregretus, four volumes; and Strabo, in the Augustan age, allirms, that as many would be required in treating of other portions of Athens and of Attica. The number of statues, in particular, was prodigious. Therius Nero, who was fond of images, plundered the acropolis, as well as Delphi and Olympia; and yet Athens, and each of these places, had not fewer than 3000 remaining in the time of Pausan. This banquet of the furies, continues this traveller, has long been withdrawn; and is now become like the tale of a vision. The spectator views with concern the marble ruins intermixed with mean flat-roofed cottages, and extant amid rubbish; the sad memorials of a noble people. The antiquities of this city have been also described by Wheeler and Span, who visited it in the time of Charles II.; and by Mr. le Roy and many others. Mr. Stuart, however, who resided there between three and four years, has surpassed others in the accuracy and elegance of his plans and of his description. Span, in speaking of Attica, says, that the road near Athens was pleasant, and the very pavements polished. Wheeler, his fellow-traveller, speaking of the civilization of the Athenians, observes, that even the shepherds bid them welcome, and wished them a good journey; and that their bad fortune had not been able to deprive them of that falsity of wit which they professed by nature; and that, notwithstanding the barbarism that hath long prevailed, they seem to be much more polished in their manners and conversation than any others in those parts. Stuart confirms, with regard to the present Athenians, the account given by Span and Wheeler of their ancestors; as he found among them the same address, and the same natural acuteness, though severely curbed by their despotic masters. At their convivial meetings, it was a frequent custom for one of them to take a lyre, or a species of guitar, and after a short prelude on the instrument, to accompany the instrumental music with his voice; suddenly changing some extempore verses, seldom exceeding two or three strophes: this performer delivered the lyre to his neighbour; who, after he had done, delivered it to another; and thus the instrument circulated, till it had passed round the table. He adds, that, notwithstanding the various fortune of Athens as a city, Attica was still famous for olives, and mount Hymettus for honey. Thus "human institutions perish, but nature is permanent."

The present Athens, Athens, or Scinias, is the capital of Attica, a province of European Turkey, the see of an archbishop; and contains, as some say, 20,000, or, according to others, 150,000 inhabitants, chiefly Greeks. The chief articles of trade are silk, wax, wool, and oil. It is a fair-port, and situated on the north-east coast of the gulf of Ligo in the archipelago, with a fine and large harbour, narrow at the entrance, and commanded by the Ortik. Mr. Let. 38° 57'; Lath. 23° 7.'

ATHIS, a town of France, in the department of the Oise, and chief place of a canton in the district of Dormont; thirteen miles south-west of Falaise.
ATH

ATH, in Ancient Geography, a town of Asia, situate on the western bank of the Euphrates, south-west of Nippurium.

ATHLETÆ, in Antiquity, persons of strength and agility, disciplined to perform in the public games. The word is formed from atthos, corunm, combat; whence also atthin, the prize, or reward, adjudged to the victor.

Under athletes were comprehended wrestlers, boxers, runners, leapers, throwers of the discus, and those practiced in other exercises exhibited in the Olympic, Pythian, and other solemn sports; for the conquerors in which there were established prizes.

From the various exercises, the athletes were also denominated enostari, and by the Latins quinquertainment; at least such as professed them all.

Those who were designed for this profession, frequented the gymnasia or palestra from their youth; and they were obliged to submit to the most strict discipline and abstinence, their fare was coarse and scanty; they were prohibited the use of wine, and enjoined continence; and thus Horace (Art. Poët. v. 412.) describes them:

"Quod studet optatam curu contingere metam,
Multa tuit fecitque puer; indavit et alit;
Abhinituit venere, et vino."

The apostle Paul, in his first epistle to the Corinthians (ch. x. 25.) enforces temperance by an allusion to the athlete; and Tertullian encourages the martyrs by the same reference. But when the privilege of being supported at the public expense, was granted to each of the athletes as were victorious, they abandoned their habits of abstinence and exercise, and indulged themselves to a very shamefaced degree of indolence and of gluttony. Before their exercises, their bodies were rubbed with oils and various unguents, in order to render them supple and vigorous; and they practiced a kind of noviciate in the gymnasia for several months, that by previous application and practice they might be fit for the contests in which they engaged. At first they made use of a belt, with an apron annexed to it, for the sake of decency; but they afterwards laid aside this covering, and engaged in several of the contests naked. To this inculp on public decency, some of the bell writers of antiquity have attributed that infamous passion, to the indulgence of which the Greeks were notoriously addicted. The women, indeed, were prohibited from approaching the places where these public games were celebrated. Before they were admitted to the combat, they were examined as to their birth, for none but Greeks were admitted; as to their condition, which was required to be free; and as to their manners, which were to be irreproachable. The name and country of each champion were registered, and a herald, before the commencement of the contest, proclaimed their names. They solemnly vowed not to employ any unfair means, and to conform to the established regulations by which the games were conducted.

ATHLETIC CROWN. See CROWN.

ATHLETIC HABIT denotes a strong hale constitution of body, which was the object the athletes aimed at, and to which their diet corresponded.

ATHLETIC WEIGHT. See WEIGHT.

ATHLONE, in Geography, the most considerable town of the county of Westmeath, in Ireland, situated on the river Shannon, over which it has a long bridge of many arches, so that it was formerly an important pass into the western province. It is partly in the county of Roscommon, and is the most central town in the island. Notwithstanding its advantageous situation for trade and improvement, it is said to be in many parts a poor, ruinous, dirty looking place. In the middle of the bridge is a monument, with some figures, together with queen Elizabeth's effigies of arms, and some inscriptions declaring the time and founders of the building. The castle, which was on the Roscommon side, called the Irish town, was built by king John, on a high raised round hill resembling a Danish rath or fort, so as to command the bridge and the adjacent country. This was the residence of the lord president of Connacht, who held in it their courts of justice. In the time of the civil war, it was strongly fortified on both sides of the river; and the English under the lord president hold a long siege in the castle, in 1641 and 1642. During the whole of this melancholy period, it was a place of great strength and importance, generally in the possession of the Irish or Catholic party; till, in 1645, it was taken by sir Charles Coote, at the head of the parliamentary forces. After the defeat of James the Second at the Boyne, his adherents remained at Athlone, and having destroyed the English town which was called of the Shannon, and broken the bridge, resolved to maintain the Irish district on the west. For this purpose they strongly entrenched themselves; and in the following year the general St. Ruth took his station with the main army behind the town. The English, under Ginckle, succeeded however in passing the river after many unsuccessful attempts, and by a surprizing effort of valor got possession of the town and castle, which was in great measure to be attributed to the carelessness and confidence of St. Ruth, the French general. General Ginckle received a title from the town, which is still enjoyed by his descendants. W. long. 7° 49'. N. lat. 53° 21' 30'.

ATHLOTHETA, in Antiquity; an officer appointed to superintend the public games, and adjudge the prizes.

The athlotheta was the same with what was otherwise called aymneta, brabentia, aganarch, agonotheta, &c.

ATHNACH, the name of one of the principal of the Hebrew accents, which serves not only to regulate the voice, but to distinguish the members of a sentence, whence its name athnach, i.e. respiratio; on this account it is called kig, and paige, and answers to our colon, and sometimes to a note of interrogation: it is marked under a letter thus (').

ATHOL, in Geography, the most northern district of Perthshire, in Scotland, extending about 43 miles in length, and 30 in breadth, and bounded on the north by Badenoch, on the west by Lochaber, on the east and south-east by Mar and Gowrie, on the south by Strathspey and Perth proper, and on the south-west by Braidenbarne. It is mountainous, and contains part of the ancient Caledonian forest; but the mountains are intermixed with fruitful valleys. It has several villages, but no towns of any importance. The most famous places are Blair-castle, seated on the river Tilt, near its influx into the Garry, an agreeable stream that flows into the Tay, and belonging to the duke of Athol, whose title is derived from the district; and the paps of Gilliecranky, memorable on account of the battle fought here in the beginning of king William's reign, between his general M'Kay, and the highlanders who adhered to king James.

ATHOL, a township of America, in Worcester county, Massachusetts, comprizing 16,000 acres of rocky land, and watered with streams and rivers, and containing 448 inhabitants; 35 miles north-west from Worcester, and 72 from Boston.

ATHOR, or ATHYS, in Mythology, the name of one of the most ancient divinities of Egypt; signifying in the Coptic language, 'night.' By this name the priests did not originally mean to denote the obscurity which is occasion
tioned by the disappearance of the sun, but the darkness which overspread chaos presciently to the creation, and from which the Almighty Creator called forth into an habitable state the material universe. This mysterious night was in their opinion the origin of things. Orpheus, initiated in the mysteries of the Egyptians, communicated them to the Greeks, and recommended them by the harmonious verses. Pausanias, when he visited Greece, saw at Megara "the oracle of the night," where every thing was taught that related to Athor. This symbolical deity, by which the Egyptians characterized the principle of things, became, in the language of the Greek philosopher, the "Venus Celestis," or the mother of the world. Orpheus taught them this part of their theology in his hymn to the night, where he says, "I shall sing the night, mother of gods and men, the origin of the creation, whom we shall call Vener." The poets soon took possession of this metaphysical idea, and as they must have a deity for embellishing their poems, they made her spring from the froth of the sea, and represented her as animating the world, and giving life to everything that breathed. See Ovid de Fast. lib. xvi. c. 91. and Lucan, lib. ii. c. x. &c. The Egyptian priests, who had painted night as a divinity, apprised that the minds of the vulgar required finable objects, made another metamorphosis of night into the moon, the planet of the night, and the moon was represented by the cow, whose horns exhibited, as their imagination suggeted, her first phaases. The philosophers farther extended this doctrine; and they believed the name of night, Athor, and Venus, on the period during which the sun, having passed the equinox, remains in the southern hemisphere, when the days are shortest and the nights longest. See Macrobius, lib. i. c. 21. The following passage from Plutarch (De Iniud. &c.) proves that this opinion originated in Egypt. "In the month of Athor (the third month of the Egyptian year), the Egyptians say that Osiris (or the sun), is dead. Then the nights become longer, the darkness increases, and the force of the light is diminished. On this occasion, the priests perform mournful ceremonies. They expel to the people a gilded ox covered with a black veil, in token of the grief of the goddehis (or the moon); for in Egypt the ox is the symbol of Osiris, and of the earth." Athor had temples in Egypt. Herodotus mentions "Athor-Baki," the city of Athor, which Strabo (I. 17.) and Diadorus (I. i.) render by the name of Aphroditopolis, the city of Venus. Aelian (De Anim. lib. i. c. 27.) speaking of Chufas, a town of the Hermopolitan nome, says, that in this town they worship Venus; and that a peculiar worship was also paid to the cow. He also informs us, that Isis, or the moon, was represented by the horns of the cow. Jabloncki, Pantheon Egypt. vol. i. Savary's Letters, vol. ii. p. 354—364.

ATHOS, in Geography, a famous mountain of Greece, in the Chaldic region of Macedonia, seated on a precipice, the coasts of which form the Sinus Stromonicus, or gulf of Contea, and the Sinus Siniticus, or gulf of Monte Sano, and joined to the land by an illusus about twelve leagues broad. The circuit of this precipice, and of the base of mount Athos, is commonly reckoned to contain about forty leagues. N. lat. 40° 10'. E. long. 24° 45'. This mountain consists of a chain of eminences or summits, seven or eight leagues long, and three or four broad, one of which attracts particular attention on account of its height and habitations, and is denominated Athos, Agioboros or holy mountain, and Monte Sano. Of its elevation very extravagant and incredible accounts have been given by some ancient writers. Mela reports, that it is so high as to reach above the clouds. Martianus Capella states that it was five miles high; and it was believed that no rain fell upon it, as the air ascended to the heights of its summit remained dry and undispirited. Plutarch and Pline have ascertained that it is a shadow, at the summer solstice, on the market-place of Myrina, the principal city of the island Lemnos. On this account, it is said, the inhabitants of the city erected a bronze cow at the termination of the shadow, on which was inscribed this verse:

"Athenia ait prionis mundi summa; steei."

"Half Lemnos, call both Athos' shadow hide."

According to Pline, the distance between the foot of mount Athos and the island of Lemnos was 8480 paces; and according to Delphi (Obit. lib. i. c. 25.), eight leagues. The Greeks, mindful of the singular situation and towering aspect of this mountain, erected upon it so many churches, monasteries, and hermitages, that it became almost wholly inhabited by devotees; and this circumstance gave occasion to its being denominated "the holy mountain," which it still retains, though many of the consecrated buildings are decayed. Among modern travellers, there is a considerable difference of opinion about its height: some make it thirty miles in circumference, and two in perpendicular elevation; and add, that it may be travelled over in three days, and seen at the distance of ninety miles: others rate the altitude of its conical summit at 3300 feet. The cold on its summit is extreme; nevertheless it abounds with many different kinds of plants and trees, particularly the pine and fir, and it supplies a multitude of springs and streams. Its variety of monasteries and churches gives it a picturesque appearance. It is now inhabited by Calories, a fort of Greek monks, of the order of St. Basil, who never marry, and fare hardly, as they abstain from flesh, and habit chiefly on olives pickled when they are ripe. Their number is reckoned about 6000, and they inhabit several parts of the mountain, on which are twenty-four monasteries, raised to the height of five or six stories, and surrounded with high walls, flanked with towers, and guarded with artillery against the assaults of banditti and robbers. They are much respected by the Turks, and receive alms from them. They have the character of being very indolent, and they clothe themselves like hermits. They had formerly several valuable Greek manuscripts, and employed themselves in writing copies of the Greek Testament (see Alexandria Manuf.); but they are now become so illiterate, that they can scarcely read or write.

As the sea on this coast is very tempestuous, and the Perisan fleet had suffered shipwreck in doubling this promontory, Xerxes is said, for preventing a similar disalter, to have cut a passage through the mountain of sufficient width, to admit two galleys, with three banks of oars each, to pass in front: by these means he favored from the continent the cities of Dion, Olyphusus, Acrotoon, Thybros, and Cleone. Before he began his works, he is said to have written a letter, addressed to the mountain, in the following terms: "Athos, thou proud and aspiring mountain, that liftest up thy head to the skies, I advise thee not to be so audacious, as to put rocks and stones in the way of my workmen: if thou dost oppose me, I will cut thee entirely down, and throw thee entirely into the sea." Modern travellers inform us, that they perceive no trace of this work; and many of them are of Juvenal's opinion:

"Perforatus Athos, et quiequid Gracia mendax."

Andet in historia.

Dinocrates, an architect in the suit of Alexander, proposed to this conqueror to perpetuate his memory by forming

H h
ing a statue of this mountain, holding in one hand a city, and representing a river as flowing from the other. But the extravagant proposal was not accepted.

ATHOTIS, or Ptolemy, in Biography, king of Thesben, and according to the practice of the early ages, priest and physician, is said to have cultivated, and written on anatomy. The precise time in which he lived is not known, though supposed to be about 2000 years before the birth of Chrīst.

ATHULLA, in Entomology, a very little species of Papilio (Nymph. Phal. Gmel.) found in the northern parts of Ruflia. The wings are fuscous, dotted with black, the lower ones white on the under side, dotted with black, and marked with two fuscous bands. This is Papilio Phaele of Esper, and belongs to the family Saturi in the Fabrician System. Ofb. Papilio Athulua minor of Esper, Pup. p. 89, is a variety of the Papilio Dictyna of Fabricius.

ATHWART, in Navigation, is synonymous with acroos the line of the course.

ATHWART the fore-foot, is a phrase that denotes the flight of a cannon-ball from one ship across the course of another, to intercept the latter, and oblige her to shorten sail, that the former may come near enough to examine her.

ATHWART-hoof, expresses the situation of a ship, when she is driven by wind or tide, or any other accident, across the fore-part of another.

ATHWART-ships, reaching across the ships from one side to the other.

ATHY, in Geography, a town of the county of Kildar, near the borders of the Queen's county, 32 miles from Dublin, at which the affizes are held alternately with Nass. It is situated on the river Barrow, which is navigable hence to the sea, and which a branch of the grand canal from Dublin to the Shannon meets at this town. It was founded in the twelfth century, on account of a ford over the river; and became of importance as a port, and sometimes as a frontier town of the English pale, in thedimensions which harassed the country for many centuries, whilst the old towns of Ardree and Ardfeil in its neighbourhood gradually decayed; and the position of either can now only be ascertained from a Danish rath, and some ruins. It was early granted the immunities of a merchant or market town, being mentioned as such in a statute of Henry VI; and it was made a borough by James I. in 1615, in consequence of which two members were returned to parliament previously to the union, under the patronage of the duke of Leinster.

Athy contained 550 houses in 1793, of which 160 were flatted and built of lime and stone, and 390 thatched cabins; the population of which might be estimated at about 3500.

There were at that time no manufactories which deflected the name, notwithstanding the advantages derived from the canal; and the unhappy state of that part of the country since gives too much reason to suppose that no improvement has yet taken place. The exports from the neighbouring country to Dublin, by the canal, consisted of coals, corn, flour, butter, and potatoes, to the amount of above 26,000 pounds per annum. N. lat. 52° 51', W. long. 7° 1'. Anthol. Hibern. vol. I. Dr. Beautour's Map and Memoir.

ATHYNA, a small town of Hungary, in Slavonia proper, and county of Pofega, beyond the Drave.

ATI, or ATT, a small canton of Africa, in Guinea, upon the Golden Coast, north of Fantiu, and to the call of Ambiboro.

ATIA. See Ondu et Atia.

ATIBAR, a name given by the inhabitants of the kingdom of Gago, in Africa, to gold-dust; from which word the Europeans, and especially the French, have composed the word tiber, which also signifies gold-dust among those who trade in that commodity.

ATICHY, in Geography, a town of France, in the department of the Oise, and chief place of a canton in the district of Noyon, eight miles east of Compiegne.

ATICK-OM-AISHISH, in Ornithology, the name by which the species of Oasia Houlsonia is known in Hudson's bay. Latham. Sonnini, in his "Additions à l'Histoire Naturelle de Buffon," adopts the first part of this long denomination, Atick, as the name of this species. See Houdsonia Oasia.

ATIENZA, in Geography, a town of Spain, in Old Castile, with an ancient castle, situate among the mountains called "Sierra d'Atienza," between Sigueneça and Borgo d'Olima.

ATIMIA, infancy or disgrace, in Antiquity, a punishment among the Athenians, inflicted for various crimes. A person suffered this punishment, when, retaining his property, he was deprived of some privilege, enjoyed in common with other citizens: and also, when he suffered a temporary deprivation of the privilege of free citizens, and his goods were confiscated. Those who were indebted to the public treasury, till their debts were paid, incurred this penalty. Also, when the criminal and his pohterity were deprived of every right of a free citizen. This was incurred by thòse who were guilty of theft or piracy, or other similar offenses. Infamous persons were not allowed to give evidence.

ATINGA, in Ethnology, a species of Didon, of an oblong form, and beft with rounded spines. Gmelin, &c. In Mol. Ad. Fr. it is described as ohracion dioon corpore spines unique armato; and in Amoen. Ac. ohracion concanoblongus, aècles unique longis tectiformibus, in primis in lateribus. It is called by Maregræva guanajues atinga, and is Patinga, or poifon armé of French writers. In England it is known by the name of porcupine fih.

This species lives in the American seas, and about the cape of Good Hope: and keeps the shores for the sake of its food, which consists of crabs and saltaceous vermes or shell-fish. The length rather exceeds twelve inches; the body is compressed at the sides, and blunt; the back rather broad, round, and dusky; belly broad, long, white, and spotted all over with black. The head is small, broad above, and rather compressed on the sides; eyes large, iris yellow; nostrils simple and tubular; mouth narrow; upper jaw rather longeft, and angular in the middle; finç yellow, spotted with black; margin brownish, and the rays ramone. This creature has the power of dilating its body, and erecting its spines at pleasure. It is usually taken in nets, but will also take bait, which is commonly the tail of a crab, fastened on the hook. The flesh is edible; but if the relation of Plio may be depended upon, it should be prepared for the table with the utmost caution; he tells us that the gall is very poisonous, and that should the flesh become impregnated with it (which must be the cafe if the gall-bladder burst in gutting the fish), the most dangerous consequences might ensue to those who eat of it; the fenes of the afflicted persons fail, their limbs become languid, and their tongue immovable, cold sweats succeed, and in this state they die, unless some speedy remedy be applied.

Gmelin deems ohracion holocanthus aècles capitis colloque longioribus Lin. Syll. Nat. and filhix alter of Willughby, to be a variety of the preceding species; it is distinguished by having the spines of the head and neck longer than in the other.

ATINGACU CANUCU, in Ornithology, the name afiigned by Maregræva in "The History of Brazil," Ray, Willughby,

the
of reflects the condition of the bed of the Atlantic, from lat. 25° south upwards to the pole, to the conclusion of these enormous mists of water. The bare inspection of a map, he says, is sufficient to show that this vast.space was hollowed by the impression of water: the protrusion from cape Raso to the river of the Amazons, or La Plata, in south America, corresponding with the incision on the African side, from the river of Congo to cape Palmas; and the African protrusion from the limits of Gibraltar to cape Palmas, answering to the immense cavity between New York and cape St. Roque. The preclusion of such vast tracks of land cannot appear improbable, adds this author, when we consider the shock it must have received, and the enormous load with which it was charged. Nor are such preclusion and abstraction unsupposed, since we have had frequent instances of mountains swallowed up, and some very lately in Calabria. Irish Trans. vol. vi. p. 288. See Ocean.

ATLANTIDES, in Astronomy, a denomination given to the Pleiades, or seven stars, sometimes also called virgins. They are thus called, as being supported by the poets, to have been the daughters either of Atlas, or his brother, Neptune, who were translated into heaven. See Atlas.

ATLANTIS, in Antiquity, an island spoken of by Plato, and many other writers, under some extraordinary circumstances; and rendered famous by a controversy among the moderns, concerning its place and existence. The island took its name from Atlas, Neptune’s eldest son, who, they tell us, succeeded his father in the government of it.

The most distinct account of this celebrated country is given us in Plato’s Timæus and Critias; which amounts, in a few words, to what follows. “The Atlantis was a large island in the Western ocean, situated before, or opposite to, the limits of Gades. Out of this island there was an easy passage into some others, which lay near a large continent, exceeding all Libya and Asia. Neptune settled in this island, which he distributed among his ten sons; to the youngest fell the extremity of the island called Gadir, which in the language of the country signifies fertile, or abundant in fields. The descendents of Neptune reigned here from father to son, for a great number of generations, in the order of primogeniture, during the space of 9000 years. They also possessed several other islands; and passing into Europe and Africa, subdued all Libya as far as Egypt, and all Europe to Africa Minor. At length the island sunk under water; and, for a long time afterwards, the sea thereabouts was full of flats and shelves.”

This island was 30,000 stadia in length, and 2000 in breadth; it was in a very high degree fertile and productive, abounding with pasture and arable, and in metals and trees. The northern part of it had various mountainous, which were floored with villages and magnificent habitations. The inhabitants were numerous and powerful, and distinguished both by arts and arms. It was governed by ten archons, who, in their respective districts, adhered to established customs, and were invested with the power of life and death over their subjects. This federative republic was established, according to Plato in a dialogue of which only a fragment remains, by a law derived from Neptune himself its first founder, engraved upon a column and placed in a temple. Assemblies were held alternately every five years, in which all public affairs were the subjects of deliberation. The offences of citizens were examined by the archons and punished according to the degree of their aggravation. Plato in this dialogue has recited severall ceremonies which were observed by the archons in the exercise of their legislative and judicial offices.

The actual existence and local situation of the Atlantic island has given occasion to many different opinions. The reality of Plato’s Atlantis has had many advocates. Buffon (Nat. Hist. by Smellie, vol. i. p. 507), after citing the passage relating to it from Plato’s Timæus, adds; “this ancient tradition is not devoid of probability. The lands swallowed up by the waters, were, perhaps, those which united Ireland to the Azores, and the Azores to the continent of America, for in Ireland there are the same foils, the same fæa-bodies, as appear in America, and some of them are found in no other part of Europe.”

M. Bailly, in his “Lettres sur l’Atlantide de Platon, &c.” published at Paris, in 1779, 8vo., maintains the existence of the Atlantides, and their island Atlantis, by the authorities of Homer, Sanchonathan, and Didorus Siculus, in addition to that of Plato. In proof of the opinion that Plato’s account of the Atlantic island is not a fiction of his own devising, a late writer (see Taylor’s translation of the Cratylus, Phædo, Parmenides, and Timæus of Plato, 1797) alleges the following relation of one Marcellus who wrote an history of Ethiopian affairs, according to Proclus in Tim. p. 55. “That such and so great an island once existed is evinced by those who have composed histories of things relative to the external sea; for they relate that in their times there were seven islands in the Atlantic sea sacred to Proserpine; and besides these, three others of an immense magnitude, one of which was sacred to Plato, another to Ammon, and another, which is the middle of these, and is of a thousand stadia, to Neptune. And besides this, that the inhabitants of this last island preferred the memory of the prodigious magnitude of the Atlantic island as related by their ancestors, and of its governing for many periods all the islands in the Atlantic sea: and such is the relation of Marcellus in his Ethiopic history.”

The learned Rudbeck, professor in the university of Upsal, in an express treatise, intituled, “Atlantica, sive Manichaei,” maintains, very strenuously, that Plato’s Atlantis is Sweden and Norway; and attributes to his country whatever the ancients have said of their Atlantis or Atlantic island.

M. Bailly (ubi supra, letter 24), after citing many ancient testimonies which concur in placing this famous life in the north, quotes that of Plutarch, who confirms these testimonies by a circumstantial description of the life of Ogygia, or the Atlantis, which he represents as situated in the north of Europe, and as having near it three islands more, in one of which the inhabitants of the country say, that Saturn is kept prisoner by Jupiter. Thrice four islands may, as M. Bailly conjectures, be Iceland, Greenland, Spitzberg, and Nova Zembla, or some others nearer the Pole. He contends the opinion of Rudbeck as not conformable with the account of Plato, who represents the Atlantis as an island, which Sweden is not. Adhering still to his judgment, M. Bailly, perfused by a variety of plausible circumstances, which he has ingeniously combined, places that famous island among those of the Frozen Ocean. In this he is strongly seconded by Plutarch, who tells us that the Atlantis is in a region where “the fun during a whole summer month is scarcely an hour below the horizon, and where that short night had its darkness diminished by a twilight.” This, it may be said, is a palpable indication of a northern climate; but how is this situation reconcilable with the fertility of the soil, the mildness of the air, particularly the fruit called the columns of Hercules, which Plutarch and Plato mention among the circumstances pertaining to the abode
ahode of the Atlantis? how is it also possible to conceive astronomy cultivated in a frozen and cloudy region, where the observations of the heavenly bodies must have been inconvenient and impracticable? These difficulties, lays our fanciful author, cannot be removed without supposing a change of air and climate in those regions by the gradual cooling of the earth, and its progressive motion towards universal conglomeration. Such is the "fairytale" of this learned and ingenuous author. Sir W. Jones, the learned president of the Asiatic Society, in his elaborate account of the Persians (Atlantic Ref. vol. ii. p. 4.),forgetless that one may consider "Iran" as the ancient India, for to the Greeks and Arabs it would have called it: or at least as the noblest peninsula in this habitable globe; and he adds, "if M. Bailly had fixed on it as the Asiatic of Plato, he might have supported his opinion with far stronger arguments than any that he has adduced in favour of Nova Zembla. If the account indeed, of the Atlante," says this writer, "the not surely an Egyptian or an Utopian fable, I should be more inclined to place them in Iran than in any region with which I am acquainted."

Others will have America to be the Atlantis; and hence infer that the new world was not unknown to the ancients: but what Plato says, does by no means support this supposition. America should rather seem to be the vast continent beyond the Atlantis, and the other islands mentioned by Plato.

Kircher, in his Mundus Subterraneus; and Beckman, in his History of Islands, chap. v. advance the most probable opinion, if the reality of this island be admitted.—The Atlantis, according to them, was a large island which extended from the Canaries to the Azores; and these islands are the remains thereof not swallowed up by the sea.

AtlanTis, New, is the name of a fictitious, philosophical commonwealth, of which a description has been given by Lord Bacon.

The New Atlantis is supposed to be an island in the South-sea, to which the author was driven in a voyage from Peru to Japan. The composition is an ingenious fable, formed after the manner of the Utopia of Sir Thomas More, or Campanella's City of the Sun. Its chief design is to exhibit a model or description of a college, instituted for the interpretation of nature, and the production of great and marvellous works, for the benefit of men, under the name of Solomon's house, or the college of the six days work. Thus much, at least, is finished; and with great beauty and magnificence. The author also proposes a frame of laws, or of the civil state or of a commonwealth: but this part is not executed. Bae. Works, tom. iii. p. 235.

ATLAS, in Biography and Mythology, an ancient king of Mauritania, the son of Uranus and brother of Prometheus, who is said to have lived about the time of Moses, or about 1582 years B.C. He is represented as having been an excellent astronomer, as an observer of the stars, and as the inventor of the sphere. The poets have exhibited him as bearing the heavens on his shoulders, and thus he is seen in the famous statue at the Farnese palace in Rome; and one of them represents him as groaning under the burden, on account of the multitude of gods whom superintendence had placed in this elevated mansion. He was metamorphosed into a mountain for his inhospitality to Perseus. His daughters, it is said, were transformed into stars, in conmemoramion of his astronomical talents and observations; seven of them forming the Pleiades, and the other seven the Hyades.

ATLAs, in Geography, a celebrated mountain or rather chain of mountains, in Africa, which is so high, that it seems to bear the heavens. Hence the fable, in which Atlas, the king of this country, is said to bear the heavens on his shoulders.

The ancients, however, ascribed to this mountain a magnitude and an elevation to which it has no claim; as it can no where stand in competition with the Alps or the Apennines. They seem to have confounded it as one high mountain, not as a ridge. Thus Pliny (l. c. 1. Text.) describes it as a detached mountain, rising from the sands to a great height on the shores of the ocean to which it gave its name; and yet, in the same chapter, he represents it as a range padded by Sustonius Paulinus on his progress to the Niger. Strabo (l. xi. Text.) mentions its being called Dyris, (Ice Atlas) by the ancients, and as being beyond the pillars of Hercules, on turning to the left or south. Dr. Shaw (Trav. p. 5.) represents it as a remarkable chain of eminences, which sometimes borders upon the Sahara, and sometimes lies within the Tell. He adds, "that if we conceived, in an easy ascent, a number of hills, usually of the perpendicular height of 4, 5, or 600 yards, with a succession of several groves, and ranges of fruit and forest trees, growing one behind another, upon them; and if to this prospect we sometimes add a rocky precipice of stupendous eminence, and more difficult ascent, and place upon the side, or summit of it, a mud-walled Dashkrah of the Kabyle, we shall then have a just and lively picture of mount Atlas, without giving the least credit to the nocturnal flames, the melodious sounds, or lascivious revels of such imaginary beings, as Pliny, Solum, and others, have in a peculiar manner attributed to it."

According to some modern accounts, this ridge divides the kingdom of Algiers from the Biskuldergir, or its direction is south-west and north-east; and therefore it may be considered as extending from Cape Geer in a north-east direction, and giving source to many rivers flowing north and south, till it terminates in the kingdom of Tunis. This main ridge in some places may present a double chain, and in others diverge its branches. Its structure towards the western extremity is granite and primitive. M. Lemprevre, in his journey to Morocco, seems to have clearly ascertained the range of Atlas. The town of Santa Cruz lands near its furthest extremity; while Tarudant, to which he passes through an open plain, lies on the south of the Atlas. Hence it appears, that Cape Geer is its termination, or the great Atlas of Ptolemy, while the smaller Atlas is a branch extending towards Safir or Cape Cantin; and another branch, now called the Leifer Atlas, reaches to Tangier. According to Clericr (Pretend State of Morocco, vol. i. p. 13.), Mount Atlas is the eastern boundary of all the western provinces of Morocco. He represents it as formed by an endless chain of lofty eminences, divided into different countries, inhabited by a multitude of tribes, whose ferocity permits no stranger to approach. He professes to be unable to describe these mountains accurately; but adds, that nothing would be more interesting to the curiosity of the philosopher, or conducing more to the improvement of our knowledge in Natural History, than a journey over mount Atlas. The climate, though extremely cold in winter, is very healthy and pleasant, the valleys are well cultivated, abound in fruits, and are diversified with forests and plentiful springs; the streams of which, uniting at a little distance, form great rivers, and lose themselves in the ocean. According to the reports of the Moors, there are many quarries of marble, granite, and other valuable stones, in these mountains; and it is probable, there are also mines, but the inhabitants have no idea of working them. "
of these riches: they consider their liberty, which their situation enables them to defend, as the most inclined of all creatures.

As the province of Morocco lies to the west of mount Atlas, part of the ancient Numidide, called the kingdom of Tafiket, situate in a sandy plain, lies to the east: and from Morocco to this province, there is no road but by crofing one of the extremities of the Atlas, either by the side of the province of Sus, or by that of Fer; the latter road, being left sultry than the other, is most frequented.

Atlas, in Anatomy, the name of the first vertebra of the neck, which supports the head. See VERTEBRA, and Skeleton.

Atlas, in Commerce, a silk fattia manufactured in the East Indies. It must be owned that the manufacture of this silk is wonderful, especially of the flowered satijes; in which the gold and silk are wrought together in such a manner, as no workman in Europe can imitate; yet they are far from having that fine glossy and lustre, which the French know how to give their silks.

In the Chinese manufactures of this sort, they eold paper on one side with gold leaf, then cut it into long slips, and weave it into their silk, which makes them with very little cost look very rich and fine. The same long slips are twisted or turned about silk threads to artificially, as to look finer than gold thread, though it be of no great value.

Atlas, in Entomology, a species of Phalena, belonging to the Bombyx tribe. The wings are falted or hooked, yellow-brown and varied; a transparent spot in the middle of each wing, with a smaller one next that on the anterior pair. Linn. Fabr. &c.

Phalena Atlas is the largest insect of the moth tribe hitherto discovered, and is indeed a gigantic creature. The species is common in China, but is not peculiar to that country, being found in other parts of Asia, and in America. The influence of climate may be easily traced in the varieties from different countries; that from Surinam is the largest, and of the deepest colours. The Chinese kind is the next in size; the colours incline to orange, and the anterior wings are more falted or hooked at the ends; there are two other Asiatic varieties known, that are still smaller, and have the wings extremely falted.

The larva of Phalena Atlas is figured by M. Merian in her Insecta Surinamensia, Plate 52; it is about four inches in length, green, with a yellow stripe disposed longitudinally. Upon each segment are four distinct round tubercles, of a coral-like orange colour, which are surrounded with very delicate hairs. The pupa is large, and is inclosed in a web of an ochraceous colour. The silk of this web is of a strong texture, and it has been imagined, if woven, would be superior in durability to that of the common silk-worm. Seba has also represented the larva, (f. 1. pl. 57, vol. iv.), in his Thesaurus Nature. It is figured by him nearly six inches in length, and bulky in proportion; the Phalena or Moth is also larger than that figured by Merian, which is a small specimen of the Surinam kind. According to Merian, there are three broods of this insect in a year; they are very common, and feed on the orange trees. Linnaeus says, that they adhere so tenaciously to the leaves, that they can scarcely be taken off. An opinion has been long prevalent, that the web of this insect might easily be manufactured into a very durable silk; and it certainly admits of doubt whether the Chinese do not actually rear the moth for this purpose. Silk is an important article in China, and other Eastern countries, where the use of linen is little known; the Jesuit missionaries mention several sorts in use among the Chinese, some of which is admired for its beauty, and others for durability; these kinds are probably the produce of different insects, and Phalena Atlas may be of that number. Lefter and Lyonet, in their "Theologie des Insectes," say, that at this day there are to be found in China, in the province of Canton, silk worms in a wild state, which, without any care being taken of them, make in the woods a kind of silk, which the inhabitants afterwards gather from the trees; it is grey, without lustre, and is used to make a very thick and strong cloth, named there Kien Tekleon; and by some European naturalists, it is imagined to be the product of this very species." Vide Donov. Inf. China (Atlas). We shall again resume this subject under the articles Phalena, Silk-worms, &c. in treating of those analogous creatures which produce a silk of such strength or beauty as to be useful, or promise to become so, in the concerns of man: a subject this that highly merits consideration; and which we shall endeavour to elucidate as copiously and accurately, as the magnitude and importance of the articles demand.

Atlas, a species of Scarabaeus, found in South America. The thorax is armed with three horns, the middle one of which is very short; horn on the head recurved. Linn. and Fabr. Ent. Syll.

Atlas Amboineus (Papilio f.), a name given by some Entomological writers to the Linnean Papilio Priumus. Muf. petrop. 644. &c.

Atlas is also a title given to books of universal geography, containing maps of the known parts of the world; as if they were viewed from the top of that celebrated mountain, which the ancients esteemed the highest in the world; or rather on account of their holding the whole world like Atlas. The same name is given to maps of the stars.

A TL E N B U R G, or ALTENBURG, in Geography, a town of Germany, in the circle of Lower Saxony, and duchy of Lauenburg, on the Elbe; four miles west of Lauenburg.

ALTLITA, in Entomology, a species of Papilio found in the East Indies. This butterfly is indented, brown, plofed with blue; beneath fulvous, with undulated glaucous flares, and five blind eye-shaped spots. Fabrises and Donov. Inf. India. Gmelin has overlooked this species in his Syll. Nat.

ATLITES, a name under which the species of Papilio LAEMEDIA, was at first described in Amon. Acad. 6. p. 407. 72.

ATMOSPHERE, formed of όηνος, υάμπουρ, and ςαράξα, a sphere, an appendage of our earth; consisting of a thin, fluid, elastic substance, called air, which surrounds the terrestrial globe to a considerable height, gravitates towards its centre, on its surface, is carried along with it round the sun, and partakes of all its motions both annual and diurnal. By atmosphere is understood the whole mias, or asblage of ambient air: though among some of the more accurate writers, the atmosphere is restrained to that part of the air next the earth, which receives vapours and exhalations, and refracts the rays of light. The farther or higher spaces, though perhaps not wholly delitue of air, are supposed to be filled by a finer fluid called ether, and are hence called ethereal regions.

For the nature, composition, properties, and different states and uses of the atmosphere, see Air, the sequel of this article, Eudiometer, and Eudiometry; where this subject will be treated of at large as its importance requires.

A late eminent author considers the atmosphere as a large chemical,
chemical vessel, wherein the matter of all the kinds of sublunary bodies is copiously floating; and thus exposed to the continual action of that immense furnace the sun, whence proceed innumerable operations, sublimations, separations, compositions, digestions, fermentations, putrefactions, &c.

We have a large apparatus of instruments, contrived for indicating and measuring the state and alterations of the atmosphere; as Anemometers, Barometers, Eudiometers, Hygrometers, Manometers, Thermometers, &c.

Atmosphere, Electricity of the. Decide those large quantities of the electric matter, with which the clouds are charged in a thunder-storm, it has been observed, firrly by M. Monnier in 1752, and afterwards repeatedly and with peculiar attention by others, particularly by the abbé Mazens in 1753, and Mr. Kenny, that the atmosphere is never wholly deliquescent of the electrical fluid. A person electrified negatively may satisfy himself of this, by extending his arm in the open air, and presenting a long sharp needle with its point upwards; for the electric matter collected from the remote air will appear luminous, as it converges to the point of the needle. Mr. Canton's balls are likewise an excellent contrivance for the same purpose, and may be made use of, not only for determining the electricity of the atmosphere in general, but the positive or negative quality of it. According to this ingenious philosopher, delicate atmospheric air, when heated, becomes negatively electric; and when cooled, the electricity is of the positive kind, even when the air is not permitted to expand or contract; and the expansion or contraction of atmospheric air occasions changes in its electrical state.

But no electrician, in the earlier stage of this science, conducted his observations in this way with greater accuracy and farther pursued them, than S. Bocca \*\*\*. (See "Bec\*\*\*caro's Essay on Atmospheric Electricity, annexed to the English translation of his "Electricity," p. 421, &c.) From him we learn, that the atmosphere discovers no figs of electricity in windy and clear weather, nor in moist weather without rain, nor when the sky is covered with dense and black clouds with a slow motion; but he always observed a moderate, though interrupted electricity, for the most part of the positive kind, in a clear sky, when the weather was calm; and in rainy weather without lightening, a little before the rain fell, and during the continuance of it, till the rain was almost over. The electricity of the atmosphere, according to Bocca, was always positive, during the day and in dry weather, but always negative, when a bright or serene atmosphere succeeded dark and moist weather. The quantity of atmospheric electricity was found to increase after the rising of the sun, and during his progress; and its augmentation was the more considerable, as the moisture of the air was diminished; but it decreased in the evening. In days equally dry, the degree of electricity at noon was proportional to the degree of heat; and in a serene atmosphere, with little wind, a considerable quantity of the electric matter commonly arose after fun-let, during the precipitation of dew. Thick fogs were observed, during their ascent into dry air, to carry with them a considerable quantity of the electric matter. And the electricity was stronger, as his rods were larger, and the fogs, which were extended and inflated in the open air, were longer.

Mr. Cavallo (Complete Treatise on Electricity, vol. ii. p. 43, ed. 4.) deduces the following conclusions from his experiments and observations on this subject; viz. that there is in the atmosphere at all times a quantity of electric matter—that the electricity of the atmosphere, and of fogs, is always positive—that, in general, the strongest electricity is observable in thick fogs, and also in frowly weather; and the weakest, when it is cloudy and warm, and rain approaches—that it does not seem to be less by night than in the day—and that the electricity is stronger in places more elevated than those that are lower; and therefore, according to this rule, if it may be extended to any distance from the earth, the electricity in the higher regions of the atmosphere must be exceedingly strong. Mr. Read, in his "Summary View of the Spontaneous Electricity of the Earth and Atmosphere," observes, that the electricity of the atmosphere in moderate weather, was always found to be positive; in storms and disturbed states of the air, frequently negative; and suddenly and repeatedly changing from one state to the other. Warm small rain was found to be very slightly electric; large drops, strongly; hail showers, the most intensely of all. In an easterly wind of long continuance, and reckoned unhealthful, the electricity was so faint, as to require the needle of all known tellis for discovering its existence. The vapours of water, as soon as it had attained the height of five or six inches of inflation in the air, was found to be permanently and positively electrified; and the surface from which it evaporated, negatively. Vapours have a greater capacity for electricity, or aborbs and requires more of this fluid, than water in its dense state; and therefore rarefaction must diminish, and condensation increase, the sensible electric charge of the vapour. Hence, in serene weather, the atmosphere is subject to a regular flux and reflux, or increase and diminution of electricity, twice in every twenty-four hours, depending on the action of the sun, and the consequent evaporation and state of the vapours. This diligent observer and judicious researcher further observes, that a limited portion of the earth's surface is often sensibly electrified; over it, there is always a proportion of the contrary electricity in the atmosphere; and when an electrified cloud is carried forward by wind, an equal and opposite electric charge keeps pace with it on the earth, till the two charges, becoming more augmented, or approaching nearer to one another, or meeting with some conducting eminence, rush together, and produce an explosion.

The subject of atmospheric electricity has engaged the particular attention of M. Saussure; and few persons have had more favourable opportunities for observing the phenomena that attend it, or possest a more extensive acquaintance with meteorology in general, for enabling him to illustrate these phenomena by apposite observations, than this author. He confirms the fact noticed by others, and previously known, that aerial electricity varies according to the situation, being generally strongest in elevated and inflated situations, and not observable under trees, in streets, houses, or enclosed places. But it is not so much the height, as the situation of the places, which determines the degree of electricity: for the projecting angle of a high hill will often exhibit a stronger electricity than the plain at the top of the hill, as there are fewer points in the former to deprive the air of its electricity. The intensity of the atmospheric electricity is subject to a great variety of changes, of which some depend on obvious circumstances and others are altogether inexplicable. The latter changes, according to M. Saussure, were sometimes the result of the succession, that he had not time to note their down. When rain falls without a storm, these changes are not so sudden; but with respect to the intensity of the electric force, they are very irregular; whilst the quality of it is more constant. Rain or snow almost always gives positive electricity. In cloudy weather, without rains or storms, the electricity generally follows the same laws as in serene weather. Its intensity
intensity is generally diminished by strong winds, which
blend the different flrata of the atmosphere, cause them to
fumble towards the ground, and thus distribute the electricity
uniformly between the earth and the air. M. Sauflire
has observed a strong electricity, with a strong north wind.
In foggy weather, the electricity is the strongest, unless the
fog is about to be diffused into rain. The various modific-
ations of electricity in the atmosphere are observed with
the greatest advantage in serene weather. M. Sauflire
found, in winter and in such weather, that the electricity
was generally weakest in the evening, when the dew had
fallen, and so continued till sun-rise; afterwards its intensity
augmented by degrees, sometimes sooner and sometimes
later: but usually before noon it attained a certain maximum,
from which it again declined till the fall of the dew, when
it would be sometimes stronger than it had been during the
whole day; after which it would again gradually decrease
during the whole night; but it was never quite destroyed
in weather perfectly serene. Hence it may be inferred
that atmospheric electricity, like the water of the ocean,
is subject to a flux and reflux, which produce an increase
and diminution twice in twenty-four hours. The moments
of its greatest force are some hours after the rising and set-
ting of the sun; and those in which it is weakest precede
its rising and setting. Of this periodical flux, M. Sauflire
has given a remarkable instance, deduced from his observa-
tions in an extraordinary degree of heat, and at an elevation
of sixty feet above the level of the lake of Geneva. From
the refutation of eighteen of these observations, made during
three successive days, when the sky was quite serene, we
learn, that the electricity was pretty strong at nine in the
morning; that from this time it gradually decreased till
about six in the evening, which was its first minimum; after
which it increased again till eight, its second maximum;
and then gradually declined till six in the morning, which
was the period of its second minimum; after which, it
again increased till ten in the morning, which was the first
maximum of the following day: but as this day was cloudy,
its periods were less regular. The electricity of serene
weather is less easily observed in summer than in winter.
In summer, if the ground has been dry for some days, and
the air is also dry, the electricity increases from the rising
of the sun, till three or four in the afternoon, when it is
strongest; it then decreases till the dew begins to fall,
when it again increases; but after this it declines and is
almost reduced to nothing during the night. However,
the serene days that succeed rainy weather in summer gene-
nerally exhibit the fame diurnal periods or flates of electricity,
with those that are observable in winter. The electricity
of the air is invariably positive in serene weather, both in
winter and summer, in the day and in the night, in the sun
and in the dew. Hence it should seem, that the electricity
of the air is essentially positive; and that whenever it ap-
pears to be negative, as in particular rains or storms, this
state is produced by some clouds which have been exposed
to the prelacies of the electric fluid contained in the upper
part of the atmosphere, or to more elevated clouds that
have discharged a part of their fluid upon the earth, or
upon other clouds. M. Sauflire, having collected thef and
familiar phenomena, as the result of numerous and repeated
observations, instituted a set of experiments on evaporation,
in order to investigate and aferent their cause. These
our limits will not allow us to detail; but the general result
was, that evaporation, which seems to be the vehicle that
carrys electric matter into the atmosphere, from china and
silver always produces negative electricity; and from iron
and copper, generally positive electricity; and hence it may
be inferred, that electricity is positive with those bodies that
are capable of decomposing water, or of being decomposed
themselves by their contact with the water; and negative,
with all those which are not at all decomposed or altered.
As to the producing causes or sources of atmospheric electricity,
we may observe in general, that they may be
reduced to four, viz. friction, evaporation, heat and cold,
and condensation and expansion: and with respect to the
changes and modifications to which the atmospheric electricity
is continually subject, they may be attributed to the
operation of the various causes that produce it, and to
the chemical processes that are constantly carried on by
means of the various ingredients that compose the atmo-
sphere. M. Volta (Phil. Trans. vol. lxxii. p. 32), in
reference to this subject observes, that as the vapours on their
condensing lose part of their latent heat, on account of their
capacity being diminished, they part with some electric
fluid. Hence (he says) originates the positive electricity
which is always more or less predominant in the atmosphere,
when the sky is clear, viz. at that height where the vapours
begin to be condensed. Accordingly the atmospheric electricity
is stronger in fogs, in which case the vapours are more condensed, so as to be almost reduced to drops, and is still stronger when these fogs become clouds. In
accounting for clouds, negatively electrified, he supposes that
when a cloud, positively electrified, has been once formed, its
sphere of action is extended a great way round, so that if
another cloud comes within that sphere, its electric fluid,
according to the well known laws of electric atmospheres,
must retire to the parts of it which are motl remote from
the first cloud: and from thence the electric fluid may be
communicated to other clouds, or vapours, or terrestrial
prominences: thus, a cloud may be electrified negatively,
which cloud may, after the same manner, occasion a positive
electricity in another cloud, &c. This explains not only
the negative electricity, which is often obtained from the
atmosphere in cloudy weather; and the frequent changes
from positive to negative electricity, and contrarywise, in
stormy weather; but also the waving motion observed in
the clouds, and the hanging down of them, so nearly to
touch the earth. For an account of the instruments that
are used for discovering and estimating the electricity of the
atmosphere, see Collector, Condenser, Conductors,
and Electrometer: and for further observations on this
subject, see also Electricity, Evaporation, Light-
ning, Rain, Vapour, &c.

Atmosphere, Figure of the. The atmosphere envelopes
all parts of the surface of our globe; if therefore both the
one and the other continued at rest, and were not endowed
with a diurnal motion round their axis, then the atmosphere
would be exactly spherical, according to all the laws of
gravity; for all the points of the surface of a fluid in a state
of rest, must be equally removed from its center. But the
earth and the ambient atmosphere are invested with a diurnal
motion, which carries both the one and the other round
their axis: and the different parts of both having a centri-
fugal force, the tendency of which is more considerable, and
that of the centripetal lbs., as the parts are more remote
from the axis; the figure of the atmosphere must become
an oblate spheroid, because the parts that correspond to the
equator are farther removed from the axis, than the parts
which correspond to the poles.

Besides, the figure of the atmosphere must represent such
a spheroid, because the sun strikes more directly on the air
which encompasses the equator, and is comprehended be-
tween the two tropics, than on that which pertains to the
polar regions. Whence it follows, that the mass of air, or
part of the atmosphere, adjoining to the poles, being less
heated, cannot expand so much, nor reach so high. Never-
theless,
the force which contributes to elevate the air, diminishes the pressure on the surface of the earth, higher columns of it at any near the equator, all other circumstances being the same, may not be heavier than those that are lower at or near the poles.

Mr. Kirwan (Irish Trans. for 1786, p. 61.), stating the height of the mercury in the barometer on the level of the sea, indicating the natural state of the atmosphere, to be thirty inches under the equator and under the poles, observes, that in order to produce this state, the weight of the atmosphere must be everywhere equal at the surface of the sea; and as the weight of the atmosphere proceeds from its density and height, this equality of weight requires that the atmosphere should be lowest where its density is greatest, and highest where its density is least. These extremes of density take place in the equatorial and polar regions. Under the equator, the centripetal force, the distance from the centre of the earth, and the heat are all at their maximum; in the vicinity of the poles, on the contrary, they are at their minimum. From this reasoning it follows, that the atmosphere must be highest under the equator, and lowest under the poles, with several intermediate gradations. Kirwan supposes the rarefaction of the atmosphere in the polar regions to proceed from the more boralis and australis, which he takes to be a combustion of inflammable air, caused by electricity; and as this air is lighter than any other, it consequently occupies the highest regions of the atmosphere.

See Aurora, and Barometer.

Atmosphere. Weight and Pressure of the. The weight of the atmosphere, depending partly upon its height, and partly upon its density, and its consequent pressure, are properties that have been long ascertained by means of the ascent of mercury in the barometer, and of water in pumps, syphons, and other similar engines. (See Atmosphere, Height of.)

The density of the atmosphere may be easily estimated by comparing the weight of a column of atmospheric air with that of a corresponding column of quicksilver, or of water, by which it is counterbalanced. Upon this principle it has been found, that the pressure of the atmosphere sustains a column of quicksilver, in the tube of the barometer, of the height of about thirty inches; and hence it follows, that the whole pressure of the atmosphere is equal to the weight of a column of quicksilver, having an equal height, and about thirty inches in height. But as a cubical inch of quicksilver weighs about 8 oz. 1.453 grains; avoidingpoise, the weight of 30 cubical inches will be 15 pounds, nearly. Such, therefore, is the weight of the atmosphere on every square inch of surface. It has been also found, by pumps and other hydraulic engines, that the pressure of the atmosphere sustains a column of water from 34 to 35 feet, by 34.5 feet, high; and as a cubical inch of water weighs 9.25 grains, and a cubical foot 728.392 grains, nearly 1000 ounces avoidingpoise, or 62.4 pounds, the amount of the pressure of the atmosphere on a square foot will be 34.5 x 62.4, or 2156.25 pounds; and a square foot, containing 144 square inches, 2156.25 x 144, or nearly 15 pounds, will be its pressure on a square inch. Hence it follows, that if a man's body contains 15 square feet, which is near the truth, he will sustain a weight equal to 2156.25 x 15 = 32343.75 pounds, or about 14 tons, when the quicksilver in the barometer stands at 30 inches.

This pressure is so great, that it would be absolutely insupportable, and even fatal to us, if it were not equal in every part, and counterbalanced by the spring of some other elastic fluid within us, which is diffused through the whole body, and reacts with an equal force against the outward pressure. The nature of this internal elastic fluid is not clearly understood, nor indeed is its existence positively ascertained. But whatever it be, it is such as to counteract the weight of the atmosphere. However, if any considerable pressure be superposed to that of the air, as e.g. by descending into deep water, it is always felt in a greater or less degree (see Divinity), more especially when the change is sudden; and, on the other hand, if the pressure of the atmosphere be taken off by any part of the human body, as from the hand placed over the exhausted receiver of an air-pump, the weight of the superincumbent atmosphere is felt, and the fluid of the hand is thrust down, as it were by motion, into the globe. We might add, that the heat of our bodies transmits the air contiguously to their surfaces, and therefore a living animal does not sustain an equal atmospheric pressure with that of inanimate and cold substances. Moreover, as the earth's surface contains, in round numbers, 200,000,000 square miles, and every square mile 27,875,000 square feet, there must be 5,757,680,000,000,000 square feet on the earth's surface; which, multiplied by 2156.25 pounds, will give 12,022,760,000,000,000,000,000 for the pressure or weight of the whole atmosphere.

Mr. Cotes (Hydrostatical and Pneumatical Lects. p. 112) mentions the result of a computation which he made of the weight of all the air, which presses upon the whole surface of the earth; and he observes, that it is equal to the pressure of a globe of lead, nearly 60 miles in diameter. The computation proceeds upon these principles; that the weight of a column of air, reaching to the top of the atmosphere, is most commonly equal to a column of water, having the same bases, and the altitude of 33.5 feet; that the semidiameter of the earth is equal to 209,4555 feet; and that the specific gravity of water is to that of lead as 1000 to 11,525.

The difference of the weight of the atmosphere, and of its consequent pressure, at different times, and in different situations, is a circumstance that deserves our particular notice. This difference in the same situation arise from changes in the state of the atmosphere; and it chiefly occurs in places at some distance from the equator. It is indicated, and of course easily estimated, by the different height to which the mercury is raised in the barometer. As the greatest variation of the height of the mercury occupies a range of about 3 inches, or from 2889 to 2886 inches, or 2889 to 2886 of the whole range, a column of air of any affordable height, equal to the weight of a cylinder of mercury of the same base, and of the altitude of 3 inches, will be taken off from the pressure upon a body of an equal base, at such times as the mercury is three inches lower in the barometer; and therefore every square inch of the surface of our bodies is relieved upon at one time more than another, by a weight of air equal to that of three cubic inches of mercury. As this is about 1/4th of the whole quantity, the difference of the pressure, which the human body sustains at one time more than another, amounts to about 1 ton. The reason why we are not sensible of this pressure is explained in the following manner by Borellus, de Mot. nat. a grav. fac. prop. 29, &c.

After saying that food, perfectly rammed in a hard vessel, is not capable, by any means, of being penetrated or parted, not even by a wedge; and likewise that water, contained in a bladder compressed equally on all sides, cannot yield or give way in any part: he proceeds; "in like manner, within the skin of an animal is contained a diversity of parts, some hard, as bones; others soft, as muscles, nerves, membranes, &c.; some fluid, as blood, fat, &c. Now it is not possible the bones should be broke or displaced in the body, unless the weight lay heavier on one part than on another, as we sometimes
sometimes seen in porters. If the pressure be subdivided, so
that it lie equally all around, upwards, downwards, and side-
ways, and no part of the skin be exempt therefrom, it is
impossible any fracture or luxation should follow. The same
may be observed of the muscles and nerves; which though
soft, yet being composed of solid fibres, do naturally fulfill
each other, and refill the common weight. The same holds
of blood and other humour; and as water does not admit
any manifest condensation, so the animal humours contained
in their vessels may suffer an attrition from an impulse made
in one or more particular places, but can never be forced out
of their vessels by an universal compression. It follows, that
as none of the parts undergo either separation, luxation,
contusion or other change of situation; it is impossible
that any sense of pain should ensue, which can only be the
effect of a solution of continuity. This is confirmed by
what we see in divers," &c. See Diving.
The same is farther confirmed by Mr. Boyle, who,
including a young frog in a vessel half full of water, and in-
truding so much air that the water might sublinate eight times
the weight it otherwise would; yet the animal, notwithstanding
the great tenderness of its skin, did not seem at all
affected thereby.

Besides, it ought to be considered that the pressure of the
atmosphere is uniform and equal on all parts of the body;
and that we have been accustomed to it by long experience.
It should also be recollected, that when the ordinary weight
of the atmosphere is augmented, the weather is commonly
dry and clear; and the circulation is promoted; the blood
is driven to the internal parts; a more abundant secretion of
the juices takes place; and the tonic tension of the solid
parts is increased; and these circumstances combined pro-
duce an additional flow of spirits, and render us more lively
and active. The same beneficial effect is observable even
in brute animals. On the contrary, when the weight of the
air is diminished, the weather is usually moist and foggy,
and the animal frame becomes sensible of oppression, listless-
ness, and inactivity. These changes in the state of the at-
mosphere, which are felt more or less by persons of all
descriptions, and of which valetudinarians frequently com-
plain, would be more sensibly experienced, if they occurred
by very sudden transitions; for to this circumstance the sensa-
tion of uneasiness and indisposition is chiefly to be attributed;
and accordingly great and sudden changes in the state of the
barometer and atmosphere, are generally accompanied with
a corresponding alteration in the corporeal frame and animal
spirits. But when a change of this kind occurs gradually,
and when the same state of the atmosphere continues for some
time, its effect is less sensibly perceived; as the body
possesses a power of accommodating itself to such change.
The spring of that elastic fluid, to which we have already
referred, serves as a counterpoise to the preasure of the at-
mosphere, and when this is diminished it becomes more re-
Iaxed, so that the equilibrium between the one and the
other is maintained. Hence it happens, that in moist foggy
weather, when the pressure of the atmosphere is least con-
 siderable, our veins never swell, nor are we sensible of any
internal expansion of our bodies; but, on the contrary, the
veins are more distended, the circulation becomes more
languid, and we seem to be oppressed with a weight. Upon
the whole, we may observe, that the pressure of the atmo-
sphere resembles a kind of bandage, which being drawn
tighter, as in the case of increased preasure, constricts the
veins of the body, and accelerates the circulation; and
which being more relaxed, as in the diminished pressure,
occasions a dilatation of the vessels, and is attended by a more
Bow and languid circulation. But this is a subject, in the
elucidation of which physiologists are not agreed. As
variations of the atmospheric preasure in the same place pro-
duce effects that are sensibly felt, particularly by persons
of delicate and tender constitution, whatever explication my
be given of these effects, and to whatever intermediate
causes they may be ascribed; the changes of preasure are
also perceived in different situations, as they are more elev-
ated or depressed. Indeed if the ascent from lower to
higher situations, and vice versa, be gradual, the body adapts
itself to the changes that attend them, and they are fearely,
if at all, perceivable; but in the case of a more rapid ascent
or descent, or when the difference of height is very con-
 siderable, the effects are more sensible and apparent. Many
facts and observations to this purpose have been furnished by
those who have ascended in balloons, or descended in diving-bells.
(See Aerostation, and Diving.) The accounts given by
persons who have ascended considerable eminences above the
level of the sea, have been very various; nor is it certain that
the effects they have perceived have been owing wholly or
merely to the variation of the atmospheric pressure. Some have
complained of a total alteration, which they have ascribed to
the dilatation of the corporeal vessels, or obstructions to the
functions of the respiratory organs, of violent takings of
vomiting blood, and, in some cases, of the extrusion of
blood through the fine coats of the lungs, and an enfla-
ning hemoptysis. M. Saufifre, in his ascent to the top
of the Mont Blanc, felt great uneasiness, as he advanced
upwards. He informs us, that his respiration was much
oppressed, the circulation of blood accelerated, and the
pulse quickened, that he was feared with other symptoms
of a fever; and that his strength was also very much
exhausted. These symptoms of oppression and dizziness,
however, did not begin to appear till he had ascended to the
perpendicular height of 24 miles above the level of the sea;
and upon an additional ascent of 1\ of a mile, he found the
symptoms above recited. To some other concurring causes,
besides the rarity of the atmosphere, it is natural to ascrib-
seme of these symptoms; and, indeed, he himself says, that
the atmosphere at the top of the mountain was much im-
pregnated with carbonic acid, which is known to be per-
nicious to animals, and to be productive of some of the
above-mentioned effects. In other cases, persons in elevated
situations have experienced no effects like those in which M.
Saufifre has related, and which the mechanical theory of
diminished pressure would lead us to expect. Mr. Brydson
and M. Howel mention no inconvenience of this kind to
which they were subject on the top of the Mont Aetna; nor
do the French mathematicians, who were for some time on
the summit of a very high eminence of the Andes, make
any other complaint besides that of the difficulty of respiration
(See Andes.) But Dr. Heberden, who ascended to the
top of Tenerife, a mountain higher than Aetna, makes
no mention even of this circumstance. It has also been
alleged, that no inconvenience has been experienced by a
gradual descent in the diving-bell to considerable depths in
the sea, as long as the persons who had defecled have
remained in the air in the bell; though they have found a
very material difference on exposing themselves to the pre-
ure of the water. See Diving.

It is not easy to assign the true cause of the variations
of the atmospheric weight and pressure that occur in the same
situations. In places within the tropic, where these varia-
tions are not very considerable, the chief cause seems to be
the heat of the sun; and its effects are regular and uniform,
as the mercury in the barometer subsides about half an
inch in the day, and rises again to its former height in the
night. But in the temperate zones the range is much greater, ex-
tending
tending from 28 to 31 inches, and shewing, by its various altitudes, corresponding variations in the weather. The causes that influence the variations of the one, produce also a similar effect on the other; and if the former were known, the latter might be ascertained. The immediate causes may probably be reduced to the two following: viz. an emission of latent heat from the vapours of the atmosphere, or of electric fluid from these or from the earth. Both these causes are observed to produce the same effect with the solar heat in the tropical climates, which is that of rarefying the air by blending with it, or setting loose a lighter fluid, which did not previously act with such power in any particular place. For a more particular account of different theories on this subject, see Barometer, Hail, Meteorology, Rain, Snow, Weather, and Wind. Of the importance and ulity of this property of the atmosphere, many instances occur in the animal economy, chemical processes, and mechanical operations. See Cuffing, Respiration, Colour, Combustion, Vapor, Pump, and Syphon.

With the gravity and pressure of the air are nearly connected its other properties of density and opacity. The density of the atmosphere must principally depend on its gravity; and, in general, increase and decrease in the same proportion. In the lower and intermediate states of the atmospheric air, this ratio obtains; but it is not uniform and constant in all elevations. In the higher regions of the atmosphere, where the electric fluid abounds, this fluid may diminish the gravity of the atmosphere, without affecting its density. Besides, the density of the atmosphere in the torrid zone will not decrease so fast in proportion to the height of the column, as in the temperate and frigid zones; because the column is longer, and because a greater portion of atmospheric air occupies the higher parts of this column. Consequently the density of the atmosphere at the equator, which is left at the surface of the earth, must at a certain height equal, and at a greater height exceed, the density of the atmosphere in the temperate zones and at the poles. As a current of atmospheric air is continually ascending at the equator, and part of it occupies the higher regions of the atmosphere, and as its fluidity will prevent its accumulation at the equator, it will of course descend towards the poles; and during our winter, a greater portion of the equatorial column will flow to the northern than to the southern hemisphere; but a less portion will pursue this course during the summer. The mercurial column, therefore, will be always higher with us in winter, and the corresponding range of the barometer more considerable than in summer, and vice versa. The density of the atmosphere will be materially affected by the caloric or matter of heat which it contains, and of course it will depend in great measure on the degree of cold which prevails. Where the cold is greatest, the density of the atmosphere will also be greatest, and its height will be diminished. In those countries which stand with high mountains that are generally covered with snow, the cold will be more intense than in others less elevated, though situate in the same latitude; and of course the height of the atmospheric columns will be proportionally lower. Hence the superior air in its passage to the poles will be retarded, and accumulate over them. Such accumulations will take place over the north-western parts of Asia, and over North America; and on this account the barometer usually stands higher, and its range is more uniform than in Europe. Similar accumulations are also formed in the southern parts of the old continent; for instance, over the mountainous tracts of Thibet, Tartary, Turkey in Europe, Africa, and even in some degree on the Pyrenees and Alps.

When these accumulations have for any time prevailed, the density of the atmosphere becomes too considerable to be balanced by the surrounding gravitation, and of course it will descend towards the regions of the atmosphere that lie over the adjacent countries, and produce cold winds, that will raise the mercury in the barometer. Thus the north-west winds in Europe are occasionally accompanied by a rise of the barometer, because they proceed from accumulations of the atmosphere in the north-western parts of Asia, or about the pole; and hence it is, that the north-west wind from the mountains of Thibet, raises the barometer at Calcutta.

As the mean heat of our hemisphere is not permanent, the density of the atmosphere, and consequently the quantity of equatorial air, which flows towards the poles, must be subject to corresponding variations. The accumulations of atmospheric air on the mountainous parts of the south of Europe and Asia, occasionally exceed their usual limits, which is partly owing to earlier falls of snow, or to the exclusion of the solar rays by fogs of long continuance. In this case the atmosphere in the polar regions will sustain a corresponding diminution of density. In the torrid zone and equatorial regions the heat is uniform; and the density of the atmosphere, modified by it, as well as the height of the atmosphere, will not be subject to much variation. Kirwan, Irish Trans. for 1788, p. 60. See Density. See also Barometer, under which article the cause of the variations in the weight and pressure of the atmosphere is particularly discussed. For the effects of the removal of the pressure of the atmosphere, see Air, Pump, and Vacuum. For the elasticity of the atmosphere, see Air, and Elasticity of the Air.

Atmosphere, Height of the. The height of the atmosphere has been a subject of particular investigation; more especially since it was discovered by the Torricellian tube, that air is endued with weight and pressure. And, indeed, if the air posessed an elastic power, but were every where of the same density, from the surface of the earth to the extreme limit of the atmosphere, like water, which is equally dense at all depths, the whole height of the atmosphere might be ascertained without difficulty. It has already been observed, that the weight of a column of air, reaching to the top of the atmosphere, is equal to the weight of the mercury contained in the barometer, and counterbalancing it; and the proportion of weight likewise being known between equal lengths of air and mercury; it will be easy to find the height of such a column, and consequently that of the atmosphere itself. For a column of air, one inch high, being to an equal column of mercury as 1 to 11346.6; it is evident that 11346.6 inch columns of air, which is a column 54 feet high, would be equal in weight to one inch of mercury; and consequently the 30 inches of mercury sustained in the barometer, require a column of air 28410 feet high; whence the height of the atmosphere would only be 28410 feet, or little more than five English miles and a quarter high.

But the air, by its elastic property, expands and contracts; and it being found by repeated experiments in England, France, and Italy, that the spaces it takes up, when compressed by different weights, are reciprocally proportional to those weights themselves; or, that the air takes up the less space, the more it is pressed; it follows, that the air in the upper regions of the atmosphere, where the weight is so much less, must be much rarer than near the surface of the earth; and, consequently, that the height of the atmosphere must be much greater than is above signified.

Mr. Cotes, in his Hydrostatical Lectures, L. XI. has destra-
demonstrated, in a very familiar and intelligible manner, that if any number of distances from the surface of the earth be taken in an arithmetical progression, the densities of the air at those distances will be in a geometrical progression.

Let \( \text{An} \) (Plate IX. \textit{Pneumatica,} p. 72.) represent a vertical line from the surface of the earth \( ax \) to the top of the atmosphere \( xx \); and let the side \( ax \) be divided into inches \( ab, bc, cd, &c. \) and let the lines \( bk, el, du, &c. \) be drawn parallel to \( ax \). It is evident that the air contained between these parallel lines becomes rarer as we ascend, because every ascending parallel successively is prefixed by a less column of superincumbent air than the next below it. Suppose then that the air \( ab \) is everywhere uniform, but denser than the air \( ik \), and upwards. Let the air \( Hk \) be reduced into a less space \( hq \), so as to become of equal density with the air \( ab \), by making the space \( bq \) less than \( bI \), in the proportion that the air \( hq \) is less dense than the air \( ab \). And let a similar construction be continued, so as to reduce every inch breadth of air to the same density with the air \( ab \). The spaces \( ek, bq, er \), &c. will evidently be as the densities of the several lines of air \( ab, bk, el \), &c. and the quantity or weight of the superincumbent air belonging to each of these spaces, and reaching to the top of the atmosphere, will always be as the sum of all the spaces situated above any space proposed; the quantity or weight being, by the construction of the figure, as the space which it occupies. Since then the density of the air is as the force which compresses it, and this force is the quantity of superincumbent air, the densities of the air between \( ax \) and \( bk, bk, el \), &c. and \( du, &c. \) are to each other as the densities of air above \( ax, bk, el \), &c. up to the extremity of the atmosphere. But these densities, by what we have already shown, are as the spaces \( ek, bq, er \), &c. and the quantities of superincumbent air are as the spaces \( x\beta\beta\epsilon\rho\sigma\beta\omicron\nu, x\epsilon\gamma\nu\tau\omicron, x\delta\iota\omicron\beta\omicron\xi, &c. \); therefore the spaces \( ab, bq, er \), &c. are to each other respectively as the spaces \( x\beta\beta\epsilon\rho\sigma\beta\omicron\nu, x\epsilon\gamma\nu\tau\omicron, x\delta\iota\omicron\beta\omicron\xi, &c. \). Now the former spaces \( ab, bq, er \); being the differences of the latter, and mutually proportional, are, by a well-known theorem in proportion, in a geometrical progression; as the distances \( ab, ac, ad \), are in an arithmetical progression. And thus the densities of the air belonging to every one of the inches, continued to the extremity of the atmosphere, decrease in the same geometrical progression; and every least variation of altitude will cause the same proportionable variation of density in the air. As the ratio of the air is reciprocally as its density, we may conclude that if the densities from the earth increase in an arithmetical progression, the different degrees of rarity of the air increase in a geometrical progression.

Whence it is evident, since an arithmetical series adapted to a geometrical one, is analogous to the logarithms of the fold geometrical one, that the distances are every where proportional to the logarithms of the corresponding rarities. It is also plain, that, as the distances or altitudes are proportional to the logarithms of the densities or weights of the air, any height taken from the earth's surface, which is the difference of two altitudes to the top of the atmosphere, is proportional to the difference of the logarithms of the two densities there, or to the logarithm of the ratio of those densities, and their corresponding compressing forces, as measured by the two heights of the barometer there.

This law was first observed and demonstrated by Dr. Halley, from the nature of the hyperbola; and afterwards by Dr. Gregory, by means of the logarithmic line. See Phil. Tract. No. 181. or Abr. ibid. vol. ii. p. 15, and Greg. Altrn. lib. v. prop. 3. See the further illustration and proof of it under the article \textit{Atmospherical Logarithms.}

From this proposition, having made two or three barometrical observations of the rarity or density of the air at two or three different known heights, it is easy to deduce a general rule for determining its rarity or density at any other height, or the height corresponding to any rarity or density; and consequently the altitude of the whole atmosphere, supposing the utmost degree of rarity known, beyond which the air cannot go.

But it is to be observed, that these computations of the rarity of the atmosphere, at different heights, are founded on this principle, that the density of the air is everywhere proportional to the superincumbent weight. And this rule holds true only upon the supposition that the heat is uniform at different distances from the earth: for if the air be hotter in one place than another, the air will be more rarefied in the hotter part than it will be in the cooler, although pressed by the same weight, or at the same altitude, above the earth's surface.

It must not be here omitted, that some observations made by Caflini, and his associates, from to render this method precarious. In continuing the reduction line of the observatory at Paris, they measured the altitudes of several mountains with great accuracy; noting the height of the barometer at the top of each; and found, that the rarefactions of the air, as you ascend from the level of the earth, are much greater than they ought to be, according to this proportion.

Suspecting therefore the jullness of the experiments, the Royal Academy made divers others, under great dilatations of air, far exceeding the rarities found on the tops of the mountains; the result whereof was, that they all exactly answered the proportion of the incumbent weights. Whence it should follow, that the higher air about the tops of mountains is of a different nature, and observes a different law from that near the earth.

This may be owing to the great quantity of gross vapours and exhalations here, more than were, which vapours being less elastic, and not capable of so much rarefaction as the pure air above, the rarefactions of the pure air increase in a greater ratio than the weights diminish. M. Fontanelle, however, from some experiments made by M. de la Hire, accounts for the phenomenon in a different manner; alleging, that the elastic power of air is increased by the admixture of humidity therewith; and consequently that the air near the tops of mountains, being moister than that below, becomes thereby more elastic, and rarifies in a greater ratio than naturally and in a drier rate it would. But Dr. Jurasheus, that the experiments produced to support this system are by no means conclusive. Append. ad \textit{Vatrienii Geograph.}

M. Bouquey likewise, in the Memoirs of the Royal Academy of Sciences at Paris for the year 1753, intimated his opinion, that the condensations of the atmosphere did not observe the same law at different heights; and endeavoured to account for the variation, by supposing that particles of air at different heights are possessed of unequal degrees of elasticity. If this were the case it would be impossible to apply the barometer to the manifestation of heights with any degree of certainty. But M. de Luc has shown, by his more accurate experiments, that this pretended inequality of spring in the particles of air does not subsist; and that its condensations and dilatations follow the same law uniformly at all heights and in all climates, excepting only the differences that are caused by heat, and other local circumstances. Admitting therefore the principle above stated, as applicable to all altitudes within our reach, or as far as the summits of the highest mountains on earth, when a correction is made merely for the difference of heat or temperament, it
ture, he determined the altitudes of hills both by the barometer and also by geometrical measurement; and showing how to allow for the difference of temperature, he has given a rule for the measurement of heights by the barometer, deduced from a greater number of experiments, and much more accurate than any before published. See his "Recherches sur les Modifications de l'Atmosphère," vol. ii. Similar rules have also been deduced from accurate experiments by Sir George Cheyneburg and general Roy, both concerning to show that such a rule for the altitudes and densities holds true for all heights that are accessible to us, when the electricity of the air is corrected on account of its density; and the result of their experiments shewed, that the difference of the logarithms of the heights of the mercury in the barometer at two stations, multiplied by 10,000, is equal to the altitude. English fathoms of the one place above the other; that is, when the temperature of the air is about 31° or 32 degrees of Fahrenheit's thermometer; and a certain quantity more or less, according as the actual temperature is different from that degree. See the principles and application of these rules, detailed more at large, under the article Barometer. But it may be here observed, that the same rule may be deduced independently of a train of experiments, merely by means of the density of the air at the surface of the earth. Thus, let D denote the density of the air at one place, and d the density at the other; both measured by the column of mercury in the barometer; then the difference of altitude between the two places will be proportional to the log. of D — the log. of d, or to the log. of $\frac{D}{d}$. But as this formula expresses only the relation between different altitudes, with respect to their densities, recourse must be had to some experiment in order to obtain the real altitude which corresponds to any given density, or the density which corresponds to a given altitude. The first and most natural is that which results from the known specific gravity of air, with respect to the whole pressure of the atmosphere on the surface of the earth.

Now, as the altitude $a$ is always as the log. of $\frac{D}{d}$, assume $b$, so that $a$ may be $= b \times \log. \frac{D}{d}$, where $b$ will be of one constant value for all altitudes, and to determine that value, suppose a case in which we know the altitude $a$ corresponding to a known density $d$; e.g. take $a = 1$ foot or 1 inch, or some small interval; and because the density $D$ may be measured by the pressure of the whole atmosphere, or the uniform column of 27,600 feet, when the temperature is 55°, 27,600 feet will therefore denote the density $D$ at the lower place, and 27,559 the less density $d$ at one foot above it; consequently, we have this equation, viz. $1 = b \times \log. \frac{27,600}{27,599}$, which by the nature of logarithms is nearly $= b \times \frac{100}{27,600} = \frac{b}{27,600}$ nearly; and hence $b = 63551$ feet, which gives this formula for any altitude in general; viz. $a = \frac{63551 \times \log. \frac{D}{d}}{m}$, or $a = 63551 \times \log. \frac{M}{m}$ feet, or dividing by 6, the number of feet in a fathom, $10,592 \times \log. \frac{M}{m}$ fathoms, where $M$ denotes the column of mercury which is equal to the pressure of the atmosphere at the bottom, and $m$ that at the top of the altitude $a$; and where $M$ and $m$ may be taken in any measure, either feet or inches, etc. This formula is adapted to the mean temperature of the air 31°, but it has been found by the experiments of Sir George Cheyneburg and general Roy, that for every degree of temperature, indicated by the thermometer, corrected from 55°, the medium between the temperature at the top and bottom of the altitude $a$, that the altitude will vary by $\frac{a}{29551}$ part, which must be added when the medium exceeds 31°, and otherwise subtracted. It should also be observed, that a column of 30 inches of mercury varies its length about the 32nd part of an inch for every degree of heat, or one the 570th part of the whole column. This formula may be rendered much more convenient for use by reducing the factor $10,592$ to 10,000 by changing the temperature proportionally from 55°; thus, as the difference 592 is the 100th part of the whole factor 10,592, and $100 \times 375$ is the 375th part of 353; therefore the change of the temperature, corresponding to the change of the factor $b$, is 25°, which reduces the 55° to 31°. Consequently, the formula becomes $a = 10,000 \times \log. \frac{M}{m}$ fathoms, when the temperature is 31°, or nearly the freezing point; and for every degree above that, the result must be increased by so many times its 453th part, and proportionally diminished below it.

This formula may be compared under the following practical precepts: 1. Observe the height of the barometer at the bottom of any height or depth proposed to be measured, together with the temperature of the mercury by means of the thermometer attached to the barometer, and also the temperature of the air in the shade by another thermometer which is detached from the barometer. 2. Let the same thing be done also at the top of the fall height or depth, and as nearly as possible at the same time; reduce these altitudes of the mercury to the same temperature, if it be thought necessary, by correcting either the one or the other, viz. augmenting the height of the mercury in the colder temperature, or diminishing that in the warmer, by its 960th part for every degree of difference between the two; and the altitudes of the mercury so corrected are these denoted by $M$ and $m$ in the above formula. 3. Take out the common logarithms of the two heights of mercury so corrected, and subtract the less from the greater, cutting off from the right hand side of the remainder three places for decimals, and then those on the left hand will be fathoms in whole numbers, the tables of logarithms being supposed to comprehend seven places of decimals. 4. Correct the number last found for the difference of the temperature of the air, in the following manner: viz. take half the sum of the two temperatures of the air, shown by the detached thermometers, for the mean one; and for every degree by which this differs from the standard temperature of 31°, take so many times the 453th part of the fathoms above found, and add them if the mean temperature be more than 31°, but subtract them if it be below 31°, and the sum or difference will be the true altitude in fathoms, or being multiplied by 6, it will give the true altitude in English feet.

**Example I.** To find the altitude, when the height of the barometers and thermometers is as follows, viz.

The altitude sought is \{406.65 fathoms, or 24399.90 feet.

M. De Luc found that the height of the atmosphere, supposing its limits where the mercury would stand only at one line, and the thermometer indicating 0 in his scale, 171 in that of Reaumer, and about 701 in Fahrenheit’s, is 25105.45 toises, or 11 leagues and 3 toises; and in the same circumstances, if the mercury in the barometer sunk to 1 1/2 of a line, the height of that part of the atmosphere would be 25105.45 toises.

Upon the principles above stated, the following table is calculated: supposing first as a mean of the observations at the Puy de Dome in France, and those on Snowdon-hill in Wales, that at the altitude of seven miles, the air is four times rarer than at the surface of the earth.

lowed it. It must be added, that in this calculation, the
direct and reflected rays are supposed to be right lines; whereas in fact they are curves, formed by the perpetual re-
fration which the rays undergo in passing through a series of
different densities of air. Comparing them upon them, as
two similar curves, or rather as a single curve, one ex-
tric whereof is a tangent to the earth; its vertex, equally
distant from both the extremes, determines the height of
the atmosphere; which therefore will be found somewhat
lower than in the former case; the point of concurrence of
two right lines, which are here only tangents to the
curve, the one at one end, and the other at the other,
being higher than the vertex of the curve. In this way,
M. de la Hire finds the atmosphere 36562 fathoms, or 16

The nature of the curve, which is described by a ray of
light in passing through the atmosphere, has been the sub-
ject of affidied investigation. M. de la Hire took great
pains to demonstrate, that, supposing the density of the at-
mosphere proportional to its weight, this curve is a cycloid:
and he says, that if the ray be a tangent to the atmosphere,
the diameter of its generating circle will be the height of
the atmosphere; and that this diameter increases, till at last,
when the rays are perpendicular, it becomes infinite, or the
circle degenerates into a right line. This reasoning
supposes that the surface of the atmosphere is a plane; but since
it is a curve, he observes that these cycloids become in fact
epicycloids. Hermannus, in his “Phoronomia,” has detected
the error of M. de la Hire, and shown that this curve is in-
finitely extended, and has an asymptote: and Dr. Brook
Taylor observes, “Method. Inclm.” p. 168, that it is
one of the most intricate and perplexed that can well be
proposed. This ingenious author computes the refractive
power of the air, be to the force of gravity at the
surface of the earth, as 320,000,000 to 1.

The extreme rarity of the atmosphere at considerable
altitudes, such as those of forty or fifty miles, bounding
the production of twilight, has perplexed philoso-
phers in accounting for meteors, which, whatever be
their origin, whether electrical or otherwise, are ob-
served at a much greater elevation than that to which the
refractive power of the atmospheric air extends. A very
remarkable one of this kind was observed by Dr. Hal-
ley in the month of March 1719; the altitude of which
he computed to have been between 69 and 734 English
miles; its diameter being 2800 yards or more than a mile
and a half, and its velocity about 350 miles in a minute.
Others of a similar kind, but of a greater altitude and ve-
cocity, have been observed by others; and particularly one
seen in August 1783, whose height above the earth could
not be less than ninety miles, and its diameter was not less
than the former, whilst its velocity was certainly not less
than 1000 miles in a minute. From analogy and reasoning
it is very probable, that such meteors are not essentially
different from those that are seen near the surface of the
earth. Nevertheless in the high regions where they are
observed, the atmosphere, according to our computation,
ought not to have density sufficient to support flame and
to propagate found; and yet such meteors are commonly
accompanied by one or more explosions, and are accompanied,
as it has been reported, with a hissing noise as they pass
over our heads. The meteor of 1719 was not only very bright,
so that for some time it changed the night into day, but
was attended with an explosion that was heard over all the
island of Britain, occasioning a violent concussion of the
atmosphere, and seeming to shake the earth itself. And yet,
in the regions in which this meteor moved, the air ought to
have been 300 thousand times rarer than the air we breathe,
or 1000 times rarer than the vacuum commonly made by a
good air-pump. Dr. Halley conjectures, that the immense
magnitude of such bodies may compensate for the rarity
of the medium in which they move. Allowing them to be
electrical phenomena, difficulties occur in explaining several
circumstances attending them; and particularly the splendor
of their appearance, which requires a circumambient fluid
capable of confining and condensing the electric matter
of which they are composed. From late experiments, it has
been inferred, that the electric fluid cannot pervade a perfect
vacuum. See Meteors.

Atmosphere, Refraction and Reflection of the. That
the atmosphere has a refractive power, which is the cause
of many phenomena, is unquestionable. This power is ef-
certained by the production of twilight above noticed, and
by many other facts and experiments. Alhazen the Arabi-
ian, who lived about A. D. 1100, seems to have been
more inquisitive into the nature of refraction than the pre-
ceeding writers. But neither Alhazen, nor his follower
Vicelio, knew any thing of its just quantity, which was not
known to any tolerable degree of exactness, till Tycho
Brahe, with incredible diligence, settled it. But neither
Tycho, nor Kepler, discovered in what manner the rays of
light were refracted by the atmosphere. Tycho thought
the refraction was chiefly caused by dense vapours, very
near the earth’s surface. Kepler placed the cause wholly
in the higher regions of the atmosphere, which he took to
be uniformly dense; and hence he determined its altitude
to be little more than that of the highest mountains. But
the true constitution of the atmosphere, deduced afterwards
from the Torricellian experiment, afforded a juster idea of
these refractions, especially after it appeared by a repeti-
tion of Mr. Lowthorp’s experiment, that the air’s refractive
power is proportional to its density. By this variation of
the air’s density, a ray of light, in passing through the
atmosphere, is continually refracted at every point, and
thereby describes a curve, and not a straight line, as it
would have done were there no atmosphere, or were its
density uniform. See Refraction.

The atmosphere, or air, has also a refractive power; and
this power is the cause that enlightens objects to uniformly
on all sides. The absence of this power would occasion a
strange alteration in the appearance of things; their shadows
would be so very dark, and their sides enlightened by the
sun so very bright, that probably we could see no more of
them than their bright halves; so that, for a view of the
other halves, we must turn them half round, or, if immove-
able, must wait till the sun could come round upon them.
Such a polished unreflective atmosphere would indeed have
been so very commodious for astrononomical observations
upon the course of the sun and planets among the fixed stars,
visible by day as well as by night; but then such a sudden
transition from darkness to light, and from light to darkness
immediately, upon the rising and setting of the sun, without
any twilight, and even upon turning from or to the sun at
nour day, would have been very inconvenient and offensive
to our eyes.

However, though the atmosphere is greatly affiant to
the illumination of objects, yet it must also be observed
that it drops a great deal of light. By M. Bouguer’s ex-
periments, it seems that the light of the sun is fre-
quently 2000 times weaker in the horizon, than at the altitude
of 66 degrees; and that the proportion of her light at the
altitudes of 66 and 19 degrees, is about 3 to 2. The
lights of the sun must bear the same proportion to each
other at those heights, which M. Bouguer made choise of.
as being the meridian heights of the sun, at the summer and winter solstices, in the latitude of Carstrie in France. Smith’s Optica, Rem. 95.

See Light, and Reflection.

Atmosphere, Salubrity of the. See Eudiometry.

Atmosphere. Temperature of the. The variable temperature of the atmosphere, at different seasons and in different situations, has been the subject of elaborate investigation by many philosophers, and many speculations and theories have been proposed in order to account for the changes which it undergoes. That the presence of the sun is the principal source of heat as well as light, and its absence of cold, is too obvious to have been ever doubted; and the effect produced by the greater or less obliquity of its rays has been long and universally observed and acknowledged. From this fact, however, the ancient philosophers of Greece and Rome too hastily inferred, that the torrid zone, under a vertical sun, and the frigid zone, where its rays fall very obliquely, were uninhabitable. Time corrected this mistake; and presented new phenomena which it has been found difficult to explain. The hottest days are frequently felt in the coldest climates, and the greatest cold, as well as perpetual snow, are found in countries bordering on, or even immediately under the equator. In the same latitudes, very different temperatures have been observed, not only in different, but even in the same hemisphere. The temperature of the eastern coast of North America differs widely from that of the western opposite coast of Europe, but agrees nearly with that of the eastern coast of Asia lying between the same parallels. Mem. Philad. vol. i.

Thick, and similar circumstances, have made it necessary for meteorologists to recur to other causes of varying temperature, besides the immediate agency or absence of the solar rays. Dr. Halley has, indeed, proved, that, abstracting from the intervention of fogs, mists, and mountains of ice, the hottest weather, might in summer, take place even under the poles, the duration of the sun’s light more than compensating for the obliquity of its direction (see Heat); but as many physical causes obstruct the activity of the solar rays in these and other regions, it was still necessary to recur to some other cause. At length M. De Mairan (Mem. Acad. Par. 1719 and 1757) discovered, that the vigour of the cold of winter is tempered by the heat imparted to the atmosphere by the earth itself; which heat, probably puffed from its origin, is preserved and renewed by the incessant influences of the sun, to which one half of its surface is constantly exposed.

Admitting this fact, the temperature of the atmosphere must depend on the capacity of the earth for receiving and retaining heat, and for communicating it to the surrounding medium. But as the earth is composed of land and water, it should be considered that the capacities of these constituent parts for receiving both heat and cold are very different. Land, particularly when dry, receives heat from the sun’s rays very readily, but transmits it through its own substance to great depths very slowly; and on the other hand, water, by reason of its transparency, receives heat very slowly, but diffuses what it receives more readily. Dr. Hales found, that in the month of August 1723, when the air, and the surface of the earth, were both at 98°, a thermometer, placed only two inches under the surface, stood at 85°; another 16 inches under the surface indicated 70°; and a third 24 inches deep, stood at 68°. The two last thermometers preferred the same temperature both day and night, till the end of the month, and then fell to 63° or 61°; the earth obliquely retaining its heat, at that depth, though the temperature of the air frequently varied.

On the 26th of October, a thermometer, exposed to the air, stood at 35.5°; but one sunk two inches in the earth was heated to 45.85°; another at the depth of 16 inches stood at 48.8°; and another 24 inches deep, showed 52°; and from the 11th to the 12th of November, when the temperature of the external air was 27°, a thermometer placed at the depth of 24 inches stood at 43.5°; but from the month of March to that of September of the following year, the external air was constantly warmer than the earth at the depth of 16 inches or 2 feet: the season, however, was very rainy, and the evaporation, thus occasioned, prevented the earth from being warmed to so much as it otherwise might have been. Hales Veget. Statics, vol. i. p. 61. &c. From these experiments it may be inferred, that the surface of the earth is much heated during the summer, but that the heat decays very slowly, a great part of it being communicated to the air; that during the winter, the earth gives out to the air the heat which it had received during the summer; and that wet summers must be succeded by cold winters. The experiments of Dr. Hales furnish nearly the same results with those of Mariette (Sur le Froid et le Chaud, p. 189.); who found, that the earth is gradually heated during the summer, and as gradually cooled during the winter months; and that, at the distance of a few feet under the surface, it is constantly warmer than the external air; and, the excess was found to remain till April, when the surface is again heated by the sun’s rays, and slowly transmits its heat downwards. Hence it appears, that at the distance of about 30 to 90 feet below the surface, provided that there be a communication with the external air, or at a less depth if there be no such communication, the temperature of the earth admits of great fluctuation, and generally approaches to the mean annual heat. Then the temperature of spring is nearly the same as the annual mean, and varies very little. M. Van Swinden has observed, that the greatest cold, and even that which exceeds 0 of Fahrenheit’s scale, if it lasts no more than a few days, penetrates no deeper than 20 inches when the earth is covered with snow, and not above 10 inches if no snow lies on the surface; and this fact exhibits the important and useful purpuses afforded by this covering in high northern latitudes. Such facts tend to prove, that the heat of the earth does not increase as we descend into it; but at the greatest depth it is nearly the same as the mean annual temperature of the latitude. It has been observed, that land is capable of receiving much more heat or cold than water. To this purpose, Dr. Raymond found, in the neighbourhood of Marilels, land frequently heated to 160°; but he never found the sea hotter than 75°; and in winter he frequently observed the earth cooled down to 14° or 15°, but the sea never lower than 44° or 45°. (Mem. de la Socict. de Med. de Paris, an. 1778. p. 70.) From these facts it is an obvious inference, that the atmosphere which lies over the sea should maintain a more uniform temperature than that over the land; and this is found to be the fact; nor is it difficult to give a satisfactory explanation of it. During summer, the temperature of the sea on its surface is constantly diminished by the processes of evaporation; and in the winter, when the superficial water is cooled, it descends by its augmented gravity to the bottom, and its place is occupied by water of a higher temperature. This alternate change of this heavier and lighter air proceeds, and the winter chapels before the atmosphere has diminished the temperature of the water below a certain degree. Between the mean annual temperature of the atmosphere over the ocean, and that of countries situated at a considerable distance from it, there is a very perceptible difference. As the sea is never heated to the same degree as the land, the
the mean temperature of summer over the sea may be considered as lower than that over the land. In winter, when the force of the sun's rays is weakened, the sea imparts its heat to the atmosphere much more readily than the earth. The mean temperature on sea, is, therefore, at this season higher than on land, and in cold countries this difference in the expansion of heat is so very considerable, that it more than counterbalances the difference which takes place in summer; infomuch that in high latitudes, the mean annual temperature at sea ought to exceed that on the land. Mr. Kirwan observes, that, in order to find the temperature in any place, situate between the latitudes 70° and 55°, the standard temperature for the same latitude should be lowered 3° of a degree for every 50 miles of distance; since in winter the cold always increases in proportion to the distance from the standard. At a lefs distance than 50 miles the atmosphere on the ocean and land are so blended together by the agency of sea and land winds, that little difference is perceptible in the annual mean temperature. In lower latitudes than 30°, the solar rays even in winter act with, no incon siderable force, the surface of the earth also retains a pretty considerable degree of heat, and consequently the mean annual temperatures of the sea and land preserve a greater equality. In proportion as we approach to the equator, the force of the sun's rays in winter acts with additional energy, and the mean temperature of the land atmosphere at this season approximates nearer and nearer to that of the sea, till at the equator they become equal.

In latitudes distant from the equator, islands are warmer than continents, because they participate more of the temperature of the sea. Countries that lie southward of any sea, are warmer than those that have the same sea to the south of them, at least in our hemisphere, because the winds that should cool them in winter are tempered, by passing to them from that sea; and those that are northward of the sea are cooled in summer by the breezes that issue from it; but a northern or southern bearing of the sea renders a country warmer, than if it lay either to the east or west.Tracts of land which are covered with trees and luxuriant vegetables, are much colder than those which have the surface of vegetable matter; for though living vegetables alter their temperature slowly, and with difficulty, yet the evaporation from their numerous surfaces is much greater than from the same space of land uncovered with vegetation; and besides, when they are tall and close, as forests, they exclude the sun's rays, and shelter the winter snows from the wind and sun. From some experiments of Mr. Williams (Philad. Trans. vol. ii. p. 150.) it appears, that forests discharge one-third more vapour into the atmosphere, than the same space of ground would do if actually covered with water. From this reasoning it appears, that woody countries are much colder than those that are open and cultivated; and it will enable us to account for the amelioration of climate that attends agricultural cultivation. See Clim.

Another principal source of heat, besides the sun's rays and earth, which may be regarded as a repository of heat, is the condensation of vapour. It is well known, that vapour contains a quantity of the matter of heat, which produces no other effect but that of making it assume an aerial expanded state, until the vapour is condensed into a liquid, but during this condensation a quantity of sensible heat is let loose, which warms the surrounding atmosphere. This condensation is frequently occasioned by the attraction of an electrical cloud; and hence proceeds the faltrines which we often experience before rain. Vol. III.

Notwithstanding the variations of temperature that occur in every climate, and at every season, there is a mean temperature from which the atmosphere 61.5° deviates beyond a certain number of degrees. In order to determine the Mr. Playfair, professor of mathematics in the university of Edinburgh (see Edinb. Trans. vol. v. part 2. for 1824, p. 193;), divides every month into three parts, and exhibits the state of the barometer and thermometer for each of these divisions. In his tables the three first columns contain the greatest, least, and mean height of the barometer; and the fourth column gives the temperature of the air in the room where the barometer is kept. The fifth and sixth columns give the greatest weight of the thermometer in the air, observed during the twenty days to which the numbers refer; the next three give the mean height, as observed at three different times every day: viz. at night in the morning, ten in the evening, and as nearly as possible to the hottest time of the day, or some time between mid-day and three in the afternoon. The mean of all these is taken for the mean temperature of the day, which being computed for each day, the mean of all these mean temperatures is left down for the mean temperature of the atmosphere for every one of the thirty-six divisions of the year. The mean of the three divisions of every month is given in the next column, under the title of the mean temperature of the month. It is prefixed, says Mr. Playfair, that the mean temperatures, which are the points most difficult to be ascertained, are given with tolerable exactness, as they are deduced from three observations made every day, of which the first, viz. at night in the morning, is not far from the medium temperature of the whole day, and the other two are as near as circumstances will allow, to the two extremes of greatest heat and greatest cold. At Edinburgh, the mean temperature for the year 1777 was 48.2°; for 1778, 49.28°; and for 1799, 46.13°. From a mean of the observations made at the house of the Royal Society, from 1773 to 1782, the annual temperature of London appears to be 51.9°, or in round numbers 52°.

The greatest mean annual temperature prevails at the equator, or in the second degree of north latitude. As we recede from the equator, the mean temperature gradually decreases, and it is most diminished at the poles. This diminution takes place in such a manner, that the mean annual temperatures of all the latitudes are arithmetical means between the mean annual temperatures of the equator and of the pole. The ratio between the decrease of temperature, and the distance from the equator, was first ascertained by Mr. Tobias Mayer of Gottingen (Oper. Ined. vol. i.); and by means of an equation deduced from it, and rendered more clear, accurate, and general. Mr. Kirwan has calculated the mean annual temperature of every degree of latitude between the equator and the pole. He supposes the mean annual heat to be the greatest under the equator, and least under the poles; that at the equator he calls m, and that at the north pole $m - n$, and putting $n$ for any other latitude, the temperature of that latitude will be $m - n$ or $n$. Hence, as the mean annual temperature of lat. 40°, determined by the belt observations, is 62°, and the temperature of lat. 50° is found to be 52.9°; thus the value of $m$ and $n$ being known, the mean annual temperatures of the equator, and of the poles, may be determined; for the square of the fine of 40° is 0.41, and the square of the fine of 50° is 0.59; then $m = 0.41$ and $n = 62$ and $m - n = 52.9$; consequently 62 + 0.41 = 52.9 + 0.58 $n$. Whence the value of $n$ is found to be 53 nearly, and $m$ in the first equation is 84; and therefore the mean temperature of the
the equator is 84, and that of the pole 31. Upon these principles the following table was calculated.

</table>

In forming this table, Mr. Kirwan sought for a standard situation, with whose temperature, in every latitude, we may compare and appreciate the temperature of all other situations in the same latitudes, on water only. Accordingly, he chose that situation for a standard, which is most free from any baffle the most permanent causes of alteration, viz. that part of the Atlantic that lies between the 80th degree of northern, and the 45th degree of southern latitude, and extending westward as far as the gulf stream, and to within a few leagues of the coast of America; and all that part of the Pacific ocean, reaching from N. lat. 45° to S. lat. 40° from the 20th to the 27th degree of longitude, east from London, which is by far the greater part of the surface of the globe. Within this space the mean annual temperature is as expressed in the table; and the author has added the degrees of latitudes beyond 80° in the northern hemisphere, though not strictly within the standard.

Mr. Kirwan has also attempted to ascertain the mean monthly temperature of the standard ocean. With this view he finds, that in every latitude, the mean temperature of the month of April seems to approach very nearly to the mean annual heat of that latitude; and as far as heat depends on the action of the solar rays, the mean heat of every month is as the mean altitude of the fun, or rather, as the sine of the fun's mean altitude during that month. Hence to find the mean heat of May, say, as the sine of the fun's mean altitude in April is to the mean heat of April, so is the sine of the fun's mean altitude in May to the mean heat of May. By a similar process, the temperatures of June, July, and August may be found; but this would give the temperatures of the succeeding months too low; because it does not comprehend the quantity of heat accruing to the atmosphere by communication of the internal heat of the globe, which in every latitude is nearly the same as the mean annual heat of that latitude. Hence the real temperature of these months must be regarded as an arithmetical mean between the astronomical and terrestrial highs. E.g. In lat. 51°, the astronomical heat of the month of September is 44.46°, and the mean annual heat is 52.4°; consequently the real heat of this month is

\[
\frac{44.46 + 52.4}{2} = 48.43°
\]

which is more conformable to observation. Mr. Kirwan has with great labour formed a table, showing the monthly mean temperature of the standard ocean from lat. 80° to lat. 10°. Hence he shows, that the coldest weather in all climates prevails in the month of January; and that July is the warmest month in all latitudes above 25°; but in lower latitudes, August is generally the warmest; that December and January, and also June and July, differ but little; that the differences between the hottest and coldest months, within 20° of the equator, are inconceivable, and that they increase as we recede from the equator; that in the highest latitudes we often meet with a heat of 75 or 80 degrees; that every habitable latitude enjoys for two months a heat of 60 degrees at least, which seems to be necessary for the growth and maturity of corn; and that the quickness of vegetation in the higher latitudes proceeds from the duration of the sun above the horizon; that as the cold of the higher latitudes, and the heat of the lower, are moderated by the vicinity of seas and mountains, these, instead of being irregular and fortuitous, may be regarded as a wise and beneficial provision of nature, in this respect as well as in many others. Mr. Kirwan has also shown, that the greatest cold within the twenty-four hours generally happens half an hour before sun-rise, in all latitudes; the greatest heat in all latitudes between 60° and 45° is found about half past two o'clock in the afternoon; between lat. 45° and 35° at two o'clock; between lat. 35° and 25°, at half past one; and between lat. 25° and the equator, at one o'clock. On the other hand, the difference between the heat of day and night is not so great as on land, particularly in low latitudes.

| TABLE exhibiting a Comparison of the Temperature of London, with that of other noted Places. |
|---------------------------------|---------------------------------|---------------------------------|
| City                          | Annual | Jun. | July |
| London                        | 1000   | 1005 | 1005 |
| Paris                         | 1028   | 1040 | 1037 |

| Berlin                        | 942    |      |      |
| Stockholm                     | 811    | 1583 | 964  |
| Peterburgh                    | 745    | 5598 | 1005 |
| Vienna                        | 957    | 1505 | 1037 |
| Pekin                         | 1575   | 1570 | 1213 |
| Bordeaux                      | 1600   | 925  | 1139 |
| Montpellier                   | 1170   | 870  | 1195 |
| Madrid                        | 1319   | 599  | 1126 |
| Spanish Town in Jamaica       | 1557   |      |      |
| Madrid                        | 1595   | 491  | 1349 |

The first column of this table exhibits the differences of the annual temperature; the second, that of January; and the third that of July; that of London, as the standard, being
be'ring estimated at 70°. The degree of cold is estimated in the second column, and the degree of heat in the first and third.

A View of the Annual Temperature of different Places, according to the Order of their Latitudes.

As the earth is the chief source of heat in the ambient atmosphere, distance from the earth is a source of cold; and the greatest cold must prevail in the highest regions of the atmosphere, more especially as clear unclouded air seems to receive no heat from the rays of the sun, whether direct or reflected. Thus, if the focus of the most powerful burning glasses be directed at pure air, it does not produce the smallest degree of heat, because the air being transparent, a free passage is afforded to the sun's rays. At the level of the sea, the temperature corresponds to that of the standard ocean; but as we ascend above that level, the temperature is gradually diminished; but at a certain height we arrive at the region of perpetual congelation, and M. Bouguer gives "the lower term of congelation." The height of this varies according to the latitude of the place, and at that height it constantly freezes at night in every spot. At the equator it is at its highest elevation, that is, the degree towards the earth as we advance towards the pole. On the flat land of America, one of the chief lands, under the line, M. Bouguer found the cold to extend from 70 to 90 degrees below the freezing point, every place, before it fine. He fixe's the height of "the lower term of congelation," between the tropics, at an elevation of 153777 feet; but in lat. 25° he thinks that it falls considerably in summer, at the height of 13000 feet from the level of the sea. At full greater heights it never freezes, but here the cold decreases, but heavier vapours do not seem to prevail; this height is called by M. Bouguer, "the upper term of congelation," and he fixe's it under the equator at the height of 28900 feet at most. Mr. Kirwan takes it of importance to adjust the height of both these terms. To this purpose, he observes that under the equator the height of both is nearly constant; but under other latitudes it is variable both in summer and winter, according to the degree of heat which prevails on the surface of the earth. And it is a mean annual temperature peculiar to each latitude, so there is a mean height for each of these terms peculiar to each latitude. And if we take the differences between the mean temperatures of every latitude and the point of congelation, it is evident that whatever proportion the difference under the equator bears to the height of either of the above terms, the same proportion will the difference peculiar to every other latitude bear to the height of these terms. Thus, the mean height of the equator being 34, the difference of this and 52 is 52; and the mean height of lat. 24° being 72° 3', the difference between this and 52 is 40.5. Then, as 52 : 153777 :: 40.5 : 112072. In this manner Mr. Kirwan calculated the following table.

In this manner, the height of both terms of congelation may be calculated in every latitude for every degree of heat observed at the surface of the earth, on which it evidently depends; for when that is at 32°, the lower height of congelation must be also on the surface. Hence if the height of the lower term of congelation in any latitude be known, and also the general temperature at the surface of the earth, the decrement of heat at any lower height may be found. The heat is observed to decrease in ascending into the atmosphere nearly in an arithmetical progression; and thus, having the first and last terms, if we make so many terms in the progression as there are hundreds of feet in the distance of the line of congelation, we shall be able to determine the decrement.
ment at each term. Let \( L = \) the entire decrement or difference between the heat at the surface and \( 32^\circ \); \( D = \) the distance of the lower line of congelation, in feet; \( n = \) the number of terms = \( \frac{D}{100} \); \( d = \) the first decrement = \( \frac{L}{n} \); and \( R = \) the rank of any given term, whose decrement is required. Then the decrement at any given term is \( R \cdot d \); and, subtracting this from the heat at the surface, we have the heat at that given height. The temperature at the upper term of congelation may be ascertained in the same manner, or that of any other height in the atmosphere, except over mountains; for the air over mountains is generally warmer than air of the same height over the sea or over plains.

Sometimes the temperature of the upper air is higher than that of the lower, particularly when a large mass of vapour is condensed by electrical agency; for no part of the heat given out by that cause being lost by communication with air much colder, that which surrounds the condensed vapour must be heated to a considerable degree. Air, rendered opaque by clouds, transmits less, and absorbs more light, and is therefore more heated than clear air. Sometimes winds, in opposite directions and different temperatures, flow at different heights, the uppermost being often the warmest; all which circumstances, especially in cloudy weather, render all calculations of the height of the terms of congelation on any particular day precarious, though when they regard a particular month or season, they may be sufficiently exact.

With regard to the effect of elevation on the temperature of the atmosphere, we may observe, that as heat is propagated through the atmosphere, chiefly by contact and communication with the earth, lofty mountains of limited surface cannot warm it to any considerable degree, as they receive the sun's rays more obliquely, and communicating less with the common mass of the earth, are less heated than plains. Hence it happens that the steepest mountains are always the coldest. Indeed, the coldness of the atmosphere on the tops of mountains has been ascribed, by M. Lambert and M. De Luc, to the greater rarity of the igneous fluid, or elementary fire, in such elevated situations, than on the plains. M. Lambert is of opinion, that it is rarer above by the action of the air, and that it is condensed below by its own weight. Without absolutely deciding the question, he seems inclined to admit the identity of fire and light.

M. De Luc compares elementary fire to a continuous fluid, whose parts are condensed by being mutually compressed; and though he denies that fire and light are the same, yet he supposes that light puts into motion the igneous fluid contained in bodies, and that it acts with greater force near the earth than at a distance from its surface, by means of this fluid, which he calls an heavy and elastic one, by being more condensed than at a greater height. M. Bouguer has demonstrated, by simple and obvious principles and facts, that in order to account for the diminution of heat on mountains, it is unnecessary to recur to obious hypotheses. In his account of what was experienced on the mountains of Peru, he says, "it was proper, in order to explain this subject, to infer on the short duration of the sun's rays, which cannot strike the different faces of mountains but for a few hours, and even this not always. A horizontal plain, when the sun is clear, is exposed at mid-day to the perpendicular and undiminished action of these rays, while they fall but obliquely on a plain not much inclined, or on the sides of a high pile of steep rocks. But let us conceive for a moment an inflated point, half the height of the atmosphere, at a distance from all mountains as well as from the clouds which float in the air. The more a medium is transparent, the less heat it ought to receive by the immediate action of the sun. The free passage which a very transparent body allows to the rays of light, shews that its small particles are hardly touched by them. Indeed what impression could they make on it, when they pass through almost without obstruction? Light, when it consists of parallel rays, does not, by passing through a foot of free atmospheric air, near the earth, lose an hundred thousandth part of its force. From this we may judge how few rays are weakened, or can act on this fluid, in their passage through a stratum of the diameter, not of an inch or line, but of a particle. Yet the futility and transparency are still greater at great heights, as was obvious on the Cordilleras, when we looked at distant objects. Lastly, the greater air is heated below by the contact or neighbourhood of bodies of greater density than itself, which it surrounds, and on which it rests; and the heat may be communicated by little and little to a certain distance. The inferior parts of the atmosphere by this means contract daily a very considerable degree of heat, and may receive it in proportion to its density or bulk. But it is evident that the same thing cannot happen at the distance of a league and an half or two leagues above the surface of the earth, although the light there may be something more active. The air and the wind therefore must at this height be extremely cold, and colder in proportion to the elevation." This theory is adopted by Sauflure, who has superadded the following fact to prove, that the force of the sun's rays, considered abstractedly and independently of any extrinsic source of cold, is no less powerful on mountains than on plains; viz. that the power of burning leaves and mirrors is the same at all heights. For ascertaining this fact, he produced a burning glass, so weak in its effect, that at Geneva it would not set fire to tinder. This glass was carried to the summit of Mount Salève, 3000 feet high, and it there produced the same effect, and even with greater ease. Hence he concluded, that the principal source of cold on the tops of mountains is their being perpetually surrounded by an atmosphere, which cannot be much heated by the rays of the sun, on account of its transparency, or by their reflection from the earth, by reason of its distance; but he wished also to know, whether the direct solar rays had the same power on the top of a high mountain as on the plain below, whilst the body on which they acted was placed in such a manner as to be unaffected by the surrounding air. With this view he instituted a lot of experiments, from which he deduced the following conclusions; viz. that a difference of 777 toises in height diminishes the heat which the rays of the sun are able to communicate to a body exposed to the external air, 14° of the thermometer; that it diminishes the heat of a body partially exposed, only 6°; and that it augments by 1° the heat of a third body completely defended from the air. Hence it appears, that the atmosphere counteracts the operation of the solar rays in producing heat, by a power which is exerted at all distances, from the surface to the higher regions. From the experiments of M. Pictet, to this purpose, it is inferred, that even in places exposed to the rays of the sun, the heat at five feet from the ground is greater only by 1° or 2° than at fifty feet above the surface, although the ground was at that time 15° or 20° warmer than the air immediately in contact with it. This difference, however, though it is, does not obtain in higher regions; for if it did, the cold on the top of the mountain of Salève, 3000 feet above the lake of Geneva, would be 60° greater than at the foot of it; whereas it really is only 10°. In the night the case is reversed; for the stratum of air, at five
five feet from the ground, was found by M. Phileet to be
colder than that at 500. Definite, different strata are found
to poise very different and variable degrees of cold, without
any regard to the altitude or depression of their situation.
In 1785, Dr. Wilson of Glasgow (Phil. Trans. for 1782,
p. 467; and for 1784, p. 368.) found a remarkable cold close
to the surface of the ground; so that the thermometer, when
laid on the surface of the snow and hoar-frost, sunk many
degrees lower than one suspended twenty-four feet above it.

Hence it has been concluded, that snow, falling from the
higher regions of the atmosphere, is generally colder than the
lower air.

With respect to the precise effect of elevation, Mr. Kirwan
found it to be nearly as follows: when the elevation is mo-
derate and gradual, such as that of the interior parts of
most countries very distant from the sea, its effects are so
blended with those of distance from the standard ocean, that
the same allowance in the diminution of temperature is to
be made for both. By a gradual elevation, he means such
as rifes at a less rate than six feet per mile, counting from
the near isle or confiderable sea. If the elevation proceeds at
a greater rate, then for every 200 feet of elevation, the annual
temperature of the standard must be diminished in that lati-
tude, as follows:

If the elevation be at the rate of

| 6 feet per mile | - | - | \(\frac{1}{4}\) of a degree. |
| 7 feet | - | - | \(\frac{2}{2}\) |
| 13 feet | - | - | \(\frac{3}{4}\) |
| 15 feet, or upwards | - | - | - |

For every 20 miles distance from the standard ocean, the
mean annual temperature in different latitudes must be de-
preeplyed or raised, nearly at the following rate:

From lat. 700 to lat. 950 cooled, \(\frac{1}{4}\) of a degree.

See on this subject Kirwan's Estimate of the Temperature of
different latitudes, 1787, paffim.

It has been observed, that in clear weather, though the
surface of the earth be then most liable to be heated by the
sun, yet after sun-set, and during the night, the air is colder
near the ground, and particularly in the valleys. The expedi-
ments made on this subject for a whole year, by Mr. James
Six, may be seen in the sixth volume of the Philosophical
Transactions, but our limits will not allow our
citing them. The conclusions deduced from them are
these: that a greater diminution of heat frequently takes
place near the earth in the night time, than at any altitude
in the atmosphere within the limits of the writer's inquiry;
that is, 220 feet from the ground; and that at such times the
greatest degrees of cold are always met with nearest the sur-
fact of the earth. This is a constant operation of nature,
under certain circumstances of the atmosphere, and occurs at
all seasons of the year; and this difference never happens in
any considerable degree, except when the air is still, and the
sky perfectly unclouded. The refrigeration was not at all
impeded, but rather promoted, by the moist vapour, as
dews and fogs. In very severe frosts, when the air fre-
quently deposits a quantity of frozen vapour, it is commonly
found greatest; but the excess of heat, which in the day was
found in the lowest station in summer, was diminished in
winter almost to nothing. The fact of the mercury's falling
in a thermometer, included in a receiver, when the air
begins to be rarefied, has been usually attributed, not to any
degree of cold thus produced, but to the sudden expansion of
the bulb of the thermometer, in consequence of the removal
of the atmospheric pressure; but from some experiments of
Dr. Darwin (see Philos. Trans. vol. 78. p. 423, &c.) it appears,
that the atmosphere always becomes warmer by compression,
and colder by dilatation from a compressed state. This
ingenious author mentions a curious phenomenon observed
in the mountains of Hungary, on a very large scale in the
Chemudian mountains, Hungary. In this machine the air,
in a large vessel, is compressed by a column of water 200
feet high; a stopcock is then opened; and as the air issues
out with great velocity, and in consequence of his precious
condensation becomes immediately much expanded, the
moisture contained in it is not only precipitated, as in the
subsection of receiver, but still down and shower of snow, with icicles
hanging to the model of the cock. See Phil. Trans. for 1761,
vol. 52. From this phenomenon, as well as from his ex-
periments, Dr. Darwin infers, that there is good reason for
concluding, that in all circumstances where air is mecha-
nically expanded, it becomes capable of attracting the third
matter of heat from other bodies in contact with it. (See
Calorics.) Now (says he), as the wet region of air
which surrounds our globe is perpetually moving along its
surface, climbing up the sides of mountains, and descending
into the valleys; as it passes along, it must be perpetually
varying its degree of heat, according to the elevation of the
country it traverses; for, in rising to the summits of moun-
tains, it becomes expanded, having so much of the pre-
fluence of the superincumbent air taken away; and when this
expanded, it attracts or absoís heat from the mountain in
continuity with it; and, when it descends into the valleys, and
again compressed into less expansire, it again gives out the
heat it has acquired to the bodies in contact with it.

The same thing must happen in respect to the higher regions
of the atmosphere, which are regions of perpetual free
s, as has lately been discovered by the aerial navigators. When
large districts of air, from the lower part of the atmosphere,
are raised two or three miles high, they become so much
expanded by the great diminution of the pressure over them,
and hence become so cold, that hail or snow is produced by
the precipitation of the vapour; and as there is, in these
high regions of the atmosphere, nothing else for the ex-
panded air to acquire heat from after it has parted with its
vapour, the same degree of cold continues, till the air
on descending to the earth, acquires its former state of con-
 densation and of warmth.

The Andes, almost under the line, rests its base on burn-
ing sands; about its middle height is a moist pleasant
and temperate climate covering an extensive plain, on which
is built the city of Quito; while its forehead is encircled with
eternal snow, perhaps coeval with the mountain. Yet, ac-
cording to the accounts of Don Ullon, these three dif-
cordant climates feldom encroach much on each other's
 territories. The hot winds below, if they ascend, become
cooled by their expansion; and hence they cannot effect
the snow upon the summit; and the cold winds, that sweep
the summit, become condensed as they descend, and of
temperate warmth before they reach the fertile plains of
Quito.

The temperature of the atmosphere, and the vicissitudes
of its heat and cold, are subject to a variety of irregularities,
which no theory that has yet been propound is able to suf-
iciently explain. For other observations on this subject,
see the articles Clouds, Cold, Congelation, Evaporation,

Atmosphere, (Vol. of the). These are so numerous and
various, that it would require a very minute and extended
detail
ATM

detail to recite even the principal of them. Of its indif- 

pensable necessity to the existence of animal and vegetable 

life, influences frequently occur in the course of this work. 

Animals and vegetables, in their immense variety, and from 

their lates of eggs and seeds to their fullest maturity, owe 

the commencement and continuance of their being to the 

atmosphere that surrounds them. How much it contributes 

to the fertility of the earth, by means of the rains that 

compose it, and to the convenience and comfort of man- 

kind, by furnishing a fit receptacle for the vapours that 
deep in refreshing showers, and for the winds that form 
an infinite variety of society and commerce with the distant nations, 
and by affording those reflections and refractions of light 

which bedeck over surrounding objects, and which form 

plentiful transitions from darkness to day, and from day to 
night, by means of twilight, it is altogether needless to 

specify. The subject would afford scope for much declama- 
tion; and we might derive from it arguments that would 
impress a thoughtful mind with just and honourable senti- 
ments of the creator. How necessary it is to the various 
operations of art and science, as well as to the common 

purposes of life, will simply appear under the several articles 

which it would be almost superfluous to mention. See 

AIR, and the several articles to which we have already 

referred.

ATMOSPHERE. Method of navigating in it. See Aero- 

station.

ATMOSPHERE of the Sun, Moon, Planets, and Comets. See 

the several articles.

ATMOSPHERE of solid or consistent Bodies, is a kind of 
sphere formed by the effluvia, or minute corpuscles emitted 
from them. Mr. Boyle endeavours to show that all bodies, 
even the hardest and most coherent, as gems, &c. have their 
atmospheres. See Gem.

ATMOSPHERE, in Electricity, denotes that medium which 

was conceived to be diffused over the surface of electrified 

bodies, and to consist of effluvia issuing from them; whereby 

other bodies immersed in it become endowed with an elec- 
tricity contrary to that of the body to which the atmosphere 

belongs. This was first taken notice of at a very early period 
in the history of this science, by Otto Guericke, and after- 
wards by the academicians of Florence, who contrived to 
render the electric atmosphere visible, by means of smoke 

attracted by, and uniting itself to a piece of amber, and 
gently revolved from it, and vanishing as the amber could. 

But Dr. Franklin exhibited this electric atmosphere with 
great advantage, by dropping rosin on hot iron plates held 
under bodies electrified, from which the smoke rose, and 

encompassed the bodies, giving them a very beautiful ap- 
ppearance. He made other observations on these atmos- 

pheres; he took notice that they and the air did not seem 
to exclude one another; that they were immovably re- 
tained by the bodies from which they issued; and that the 
same body, in different circumstances of dilution and con- 

tration, is capable of receiving or retaining more or less of 
the electric fluid on its surface. However, the theory 
of electrical atmospheres was not sufficiently explained and 
understood for a considerable time; and the investigation 
led to many very curious experiments and observations. 
Mr. Canton took the lead, and was followed by Dr. Frank- 
lin; Meff. Wieleke and Epinus prosecuted the discovery, and 
completely the discovery. The experiments of the two 
former gentlemen prepared the way for the conclusion 
that was afterwards drawn from them by the latter, though 

they retained the common opinion of electric atmospheres, 

and endeavoured to explain the phenomena by it. The 

conclusion was, that the electric fluid, when there is a re- 

dundancy of it in any body, repels the electric fluid in any 
other body, when they are brought within the sphere of 
each other's influence, and drives it into the remote parts 
of the body, or quite out of it, if there be any outlet for 
that purpose. By atmosphere, M. Epinus says, no more is to be un- 

derstood, than the sphere of a body belonging to any body, or 

the neighbouring air electrified by it. Sir J. Beccaria 

concurs in the same opinion, that electrified bodies have no 
other atmosphere than the electricity communicated to the 
neighbouring air, and which goes with the air, and not with 
the electrified bodies. And Mr. Canton likewise, 

having relinquished the opinion that electric atmospheres 

were composed of effluvia from excited or electrified bodies, 

maintained that they only result from an alteration in the 

state, that the electric fluid contained in, or belonging to 
the air surrounding these bodies to a certain distance; for in- 

stance, that excited gases repels the electric fluid from it, 

and consequently beyond that distance makes it more dense; 

whereso excited wax attracts the electric fluid existing in 

the air nearer to it, making it rarer than it was before. 

In the course of experiments that were performed on this 
occasion, Meff. Wieleke and Epinus succeeded in charging 

a plate of air, by suspending large boards of wood covered 
with tin, with the flat sides parallel to one another, and 

at some inches distance; for they found, that, upon electrifi- 
ying one of the boards positively, the other was always 

negative; and a shock was produced by forming a com- 

munication between the upper and lower plates. Beccaria 

has largely considered the subject of electric atmospheres, 
in his Artificial Electricity, p. 179, &c. Eng. edit. Dr. 

Priestley's Hist. of Electricity, vol. ii. sect. 7. Cavallo's 

Electricity, vol. i. p. 241. vol. ii. p. 282. See CONDENSER, 

and CONDUCTOR, Luminous; and Experiments in Electrici- 

ty.

ATMOSPHERE, Magnetic, denotes the sphere within which 

the virtue of the magnet, &c. acts.

ATMOSPHERICAL Logarithms. See LOGARITHMIC.

ATNAH, or Carrier Indians, in Geography, a tribe of 

Indians in the north-west continent of America, inhabiting 
the banks of the Columbia river, south of the Nagiller 
Indians, about N. lat. 52°, and W. long. 123°. The 

Atmah language, of which Mr. Mackenzie obtained some 
specimens, has no affinity to any with which he was ac- 

quainted. Mackenzie's Journal of a Voyage through the 

N. W. Continent of America, p. 258.

ATOM, formed of the privative an, and ρρωμα, I divide, 
in Philosophy, a part or particle of matter, so minute as to 

be indivisible.

Atoms are properly the minutest nature, the last or ultimate 
particles into which bodies are divisible; and are con- 

ceived as the first rudiments, or component parts of all phy- 

sical magnitude; or the pre-existing and incorruptible mat- 

ter whereby bodies were formed.

The notion of atoms arises hence, that matter is not divi- 

sible in infinitum. And hence the Peripatetics are led to 
deny the reality of atoms; together with that of mathematical 
points as atoms, say they, either has parts, or it has 

none; if it hath none, it is a mere mathematical point; if 

it hath, then do those parts also consist of others, and so on 
to infinity.

But this is to recede from the genuine character of atoms, 
which are not esteemed indivisible, because of their wave 
of bigens, or parts (for all physical magnitude must have three 
dimensions, length, breadth, and thickness, and all extension 

is divisible); but they are indivisible on account of their soli- 

dity, hardness, and impenetrability, which preclude all divi- 

sion
As atoms are the first matter, it is necessary they should be indissoluble, in order to their being incorruptible. For Isaac Newton adds, that it is also required, they be immovable, in order to the world's continuing in the same state, and bodies being of the same nature now as formerly. To this purpose he observes, at the close of his inquiry into the nature, laws, and constitution of matter, that God in the beginning created matter in solid, manifold, hard, impermeable, moveable particles, incomparably harder than any of the porous bodies compounded of them; may, so far as never to wear or break in pieces; so human power being able to divide what God made one at the creation, while these particles continue entire, they may compose bodies of one and the same texture in all ages; but if they should wear away, or break in pieces, the nature of things depending upon them would be changed. See Divisibility, and Solidity.

Hence the ancients were also led to maintain atoms eternal; because what is immovable, must be eternal. They also added gravity; and, in consequence thereto, motion to their atoms; and farther observing that atoms thus falling perpendicularly, could not join or unite together, they superadded a fortuitous or side motion, and furnished them with certain hooked parts, in order to enable them to catch and hang the better together. And from a casual and fortuitous jumble of these atoms, they supposed the whole universe to be formed.

ATOMARIA, a species of Condylostely, described by Fabricius, about half an inch in length. This shell is oblong, snow-white, dotted with brown, and at each end two dully marks. Martini, Gmel. &c.

ATOMARIA, in Entomology, a species of Conops (Myos, Fabr.), found in Europe. It is greyish, with an ovate abdomen; wings brown, crowded with white dots. Gmelin.

ATOMARIA, a species of Pyrgana found in Germany. The wings are pale-grey with numerous black dots.

ATOMARIA, a species of Phalana (Geometra) that inhabits Europe. The wings are entirely yellow, streaked and speckled with brown. Gmelin, &c. This is Phalana pennata of Scopoli, and Phalana artemisiaria. Phalana glarearia of Wien. Schmett. is supposed to be a variety of this species by Gmelin. The larvae from which this moth is produced is smooth and greyish, with numerous ferruginous interrupted lines, and two tubercles on the posterior part; fed on Centaurea fimbriata.

ATOMARIA, a species of Nototema, about the size of a louse, and inhabits the river Velchova in Russia. It is white; above and wing-cases pale-greyish; wings milky. Phil. It.

ATOMARIA, a species of Silphia. (Spilocidium Fabr.) This insect is smooth and black; wing-cases marked with cremaster stripes; legs pale. Fabr. Gmel. &c. A native of Europe.

ATOMARIA, a species of Scarabaeus (Melobomus) that inhabits the Cape of Good Hope. In size and appearance this insect resembles S. formidus. It is powdered with white; thorax caecalculated and black; wing-cases brown; abdomen white, with black dots.

ATOMARIA, a species of Cuculio found in Europe. This insect is brown; wing-cases fringed, with the intercices smooth, finely punctuated, and fringed with specks of greyish brown hairs. Mart. Levk. p. 18. n. 380. Lin. Another cuculio atomaria occurs in Lin. Mart. Levk. p. 19, 599; and which does not seem to differ specifically from the foregoing: C. atomaria fuscus, elysios; atomic grisulis p. f.;

ATOMARIA, a species of Carabus that inhabits Europe. It is apterous, black, and glistering; wing-cases rather smooth, with minute, scattered, confluent drop of a purple colour; margin purple. Müll. Levk.

ATOMARIA, a species of Carabus (Retusus), var. with greenish and brown; wings white, dotted with brown. Linn.

ATOMELLA, a species of Phalana (Timen). The antennae are of a moderate length; head and yellow, fine must; two ferrugineous dots in the eye, and a yellow marginal spot. Lin. &c. Habits Europe.

ATOMICAL Philosophy, denotes the doctrine of atoms; or a method of accounting for the origin and formation of all things, from the supposition of atoms, endowed with gravity and motion.

The ancients, according to the account given of it by Dr. Calvini (Int. Rerum S. scrips. b. 1. vol. i. p. 7. Lib. 6 ch. 5.), supposed that there is nothing thin but air, the matter, that is, the world itself, and therefore, that nothing is to be attributed to it, but what is included in the nature and idea of it, viz. more or less magnitude, with divisibility into parts, figure and position, together with motion or rest; but fast that the parts of it can ever move finally, but is always moved by force external. And consequently it supposes, that there is no body having citis besides the simple elements of magnitude, figure, fire, and motion, which are all clearly visible. It is a theory of extended substance, to take the corpuscles or atoms; and therefore, not of any accidental form, disting. from the matter nor of any other qualities really existing in the bodies without, besides the results or aggregates of these simple elements, and the disposition of the inconsiderable parts of bodies in respect of figure, sit, and motion; nor of any intentional species or there, propagated from the objects to our senses: nor lastly, of any other kind of motion or action really distinct from local motion, such as generation and alteration, they being neither intelligible as modes of extended substance, nor any way really efficacious. Forasmuch as the forms and qualities of bodies may well be conceived to be mutable, but the result of these simple elements of magnitude, figure, fire, and motion, variously combined together in the same manner as syllables and words, in great variety, result from the different combinations and conjunctions of a few letters, or the simple elements of speech; and the corporal part of sensation, and particularly that of vision, may be solved only by local motion of bodies, that is, either by corporeal bodies (called for lakht, or luma, and are), spreading continually from the surface of the objects, or rather, as the later and more refined atomists conceived, by pressure made from the object to the eye, by means of light in the medium. So that the fientify motion in the eye of the body (the sensitive medium, that is, the eye, and situated, moving every way from it upon the optic nerves), doth by that as it were by a staff touch it. Again, generation and corruption may be sufficiently explained by conversion and re-creation, or local motion, without substantial forms and qualities. And, lastly, those fabulous ideas of fire and cold, heat and cold, sweet and bitter, as they are distinct things from the figure, sit, and motion of the insensible parts of bodies, seem plainly to be nothing else but our own fancies, passions, and sensations; whereas they are only mistaken for qualities in the bodies without us.

As to the origin and history of this atomic philosophy,
Dr. Cudworth observes, that though adopted by Epicurus, it has been commonly ascribed to Democritus, who was prior both to Aristotle and Plato; but Leucippus represents
and that Democritus did generally join theology and incorporation
with the atomical physics; and he has also proved by the most conclusive reasoning, that atheism, so far from being a
natural and necessary appendage to atomism, is totally dif-
tinct from it; that there is, neither in reason nor in fact, any
inconsistency between the atomical physics and theology;
and that there is, on the contrary, a most natural cognition
or alliance between them. Ubi supra, p. 27, &c.

The atomic philosophy of Democritus and Leucippus was cultivated
and improved by Epicurus, though he would not acknowledge
that he had borrowed his hypothesis from any; and
from him it obtained the denomination of the Epicurean
philosophy. See the articles Democritus, Leucippus,
Epicurus, and Epicurean Philosophy. See also Cosmo-
gony.

The opinion of Dr. Cudworth with respect to the anti-
quity of the atomic physics has been contested by some
later writers. The learned Bishop Warburton, in his "Di-
vine Legation of Moses," admits it as a settled point, that
Democritus and Leucippus were the authors of this phys-
ology; and Brucker (Hist. Philos. by Enfield, vol. i.
p. 63) thinks, that the single evidence of Pofidonius, the
floic, who lived so many ages after the time of Mofchus,
to whom Cicero allows little credit, and of whose authority
Strabo and Sextus Empiricus, who refer to him, intimate
some suspicion, is too feeble to support the whole weight
of this opinion. But the circumstance, says this writer,
which most of all invalidates it, is, that the method
of philosophizing by hypotheses or syllae, which was followed
by the Greek philosophers, was inconsistent with the genius
and character of the barbaric philosophy, which confined
in simple assertion, and relied entirely upon traditional
authority. He adds, that the part of the history of Pytha-
goras which relates to this subject, has been involved in ob-
scurity by the later Platonists; and that neither the doctrine
of monads, nor any of those syllae which are said to have
been derived from Mofchus, are the same with the atomic doc-
trine of Epicurus. He therefore concludes, that, whatever
credit the corporeal syllae may derive from other sources,
it has no claim to be considered as the ancient doctrine
of the Phoenicians. We incline however to admit the testimo-
naries and arguments of Dr. Cudworth; and with the disli-

cion which he has adopted between the atomic physics
derived from tradition before the time of Democritus and
Leucippus, and that syllae of materialism and atheism
connected with it by their speculations, and with this re-
proach annexed to it transmitted to Epicurus and his fol-
lowers, by whom it was again modified, it seems most
probable, that the atomic philosophy was not first invented
by these speculative philosophers, but derived by tradition
from Phoenicia or Egypt. The atomic philosophy has
been revived by some moderns, and particularly by Gassendi
and others, who, rejecting the eternity of atoms and their
fortuitous motion, have made it a very intelligible and rati-
onal syllae. It is now espoused and adhered to by a great
part of the philosophical world, under the denomination of
the Corpuscular Philosophy; which see. It is the philoso-
phy of Newton, Locke, and all their followers; and it
claims regard, among other considerations, from its being
the genuine philosophy of the first and most ancient atomists.
The scholastic divines among the Mahometans, who are
very orthodox as to the creation of the world by God, do
also admit both atoms and a vacuum; but their atoms are
different from those of Leucippus, for they have no magni-
tude and are all like one another: and they suppose, as that
philosopher ought to have done, that every atom of a
living body is alive, that every atom of a sentient body is en-

Dr. Cudworth has shown, by a variety of citations from ancient writers, that the atomists before

Leucippus, who was somewhat senior to Democritus, as the first
inventor of it. Aristotle, who often mentions this philo-
sophy, commonly ascribes it to Leucippus and Democritus
jointly. Plato refers its original to Protagoras, who was
an auditor of Democritus. "However," says the learned
Cudworth (ubi supra, p. 126), "we are of opinion, that nei-
er Democritus, nor Protagoras, nor Leucippus, was the
first inventor of this philosophy; and our reason is, because
they were all three of them atheists (though Protagoras
alone was banished for that crime by the Athenians); and
we cannot think that any atheist could be the inventors of
it; much less that it was the genuine spawn and brood of
atheism itself, as some conceit, because however these
atheists adopted it for themselves, endeavouring to serve
their turns of it, yet if rightly understood, it is the most ef-
effual engine against atheism that can be." This learned
writer alleges also historical probability for the opinion
that this philosophy was much more ancient than either
Democritus or Leucippus. To this purpose he observes,
that Pofidonius, as we learn from Empiricus and Strabo,
availed it for an old tradition, that the first inventor of this
atomical philosophy was one Mofchus, a Phoenician, who
according to Strabo, lived before the Trojan war, and who
has been supposed by some particulars to be the same with
Mofchus the Jewish lawyer. See Moschus.

Dr. Cudworth further maintains, that Pythagoras, who is
thought to have converted at Sidon with the Jewish philo-
sophers, priests, and poets, who were the successors of Mofchus,
to have borrowed many things from the Jews; and to have transla-
ted them into his philosophy, was not unacquainted with the
atomical physiology, and he therefore concludes, that the phi-
losophy of Democritus was Pythagorean; and the philosophy
of Pythagoras, Democritical or atomical. Accordingly, he
alleges the authority of Echphantus, a famous Pythagorean,
and other testimonies, to prove that the Monads of Pytha-
goras were nothing else but corporeal atoms. In or-
der to reconcile Arifotle with himself, and to preserve the
credit of Laertius, both of whom ascribe this philosophy to
Democritus and Leucippus, as its first authors, Cudworth
fuggetts, that although the atomical physiology was in use
long before Democritus and Leucippus, yet these two with
their confederate atheists, of whom Protagoras seems to have
been one, were undoubtedly the first "that ever made this
physiology to be a complete and entire philosophy by itself,
so as to derive the original of all things in the whole univer-
se from fentlelefs atoms, that had nothing but figure and motion,
together with vacuum, and made up such a syllae of it, as from
whence it would follow there could not be any God, not so
much as a corporeal one." The atomical philosophy, accord-
ing to this learned writer, exifted before and without athe-
ism; and Democritus and Leucippus are to be regarded as
the first inventors or founders of the atomical philosophy
"atheized and adulterated." Consequently, there have
been two sorts of atomists in the world; the one atheistical,
the other religious. The first and most ancient atomists,
having incorporated substance, used that physiology in a
way of subordination to theology and metaphysics. The
others, allowing no other substance but body, made fentleles
atoms and figures, without any mind and understanding,
(i.e. without any God) to be the original of all things;
which latter is that, which was vulgarly known by the name of
atomical philosophy, of which Democritus and Leucippus
were the source. Dr. Cudworth has shewn, by a variety
of citations from ancient writers, that the atomists before

Democritus did generally join theology and incorporation
with their atomical physiology; and he has also proved by the
most conclusive reasoning, that atheism, so far from being a
natural and necessary appendage to atomism, is totally dis-
tinct from it; that there is, neither in reason nor in fact, any
inconsistency between the atomical physiology and theology;
and that there is, on the contrary, a most natural cognition
or alliance between them. Ubi supra, p. 27, &c.
duded with fenfe, and that the understanding refuses in an atom; though they differ as to the soul and knowledge, whether they consist in a single atom, or a collection of several. Malmo, in More Nevechin. c. 73.

The atomic system, adopted by modern philosophers, and extended by Le Sage and De Luc to great subtleties, supposes that matter fills its space merely by its existence; that it is absolutely impenetrable; that its division can be carried to a certain length only, ending in atoms, which, though extended, are not further divisible; that there are empty interstices between the atoms; that the particles of elastic fluids, as air, vapours, caloric, &c., do not touch each other, and consequently they form different fluids, as they are called; and that the rarity or density of a body depends solely on the quantity of empty interstices, in a certain volume of space occupied by the matter constituting that body. In these respects, the system is opposed to that denominated the dynamic system, illustrated by Kant in his “Metaphysical Elements of Natural Philosophy.” See Dynamic System.

A late writer has distinguished between common, and philosophic atoms. Under the former appellation he comprehends those who think with the vulgar, not only that matter exists externally, but that it really populates all those properties which animate the senses; such as cold, heat, colour, sound, &c. Under the general name of philosophic atomists, he comprehends all those philosophers, who admit the essential properties of matter, such as extension, impenetrability, cohesion and mobility, and who reject the real or external existence of those properties that are called sensible qualities. These latter atomists further distinguish into two classes: viz. simple, and mixed; simple or pure atomists acknowledge extension and impenetrability alone, and the attributes necessarily arising from these, as inertia and cohesion. According to them, matter is merely passive, endowed with no internal powers; and cohesion, though not necessarily contained in the idea of matter, is essential to the idea of extension; so that all changes are effected by powers foreign to matter: in nature, the power of God: in creatures, the powers of the soul. Mixed atomists, or Dynamists, place powers in matter itself, which in their opinion belong to it, and inhere in it in such a manner that they are independent of spiritual sub stance, and are either formed in bodies, or superadded as attributes of material existences. Of this kind are gravity, effusiveness, irritability, attraction, repulsion, &c. These powers operate according to the organization of bodies. To atomists of each class this writer opposes the Idealists, who entertain the same opinions concerning the primary qualities of bodies, which are held by atomists concerning the secondary. As the latter maintain that no light can exist without being seen, or found without being heard, so the former affirm that neither impenetrability nor extension can have place independently of our conceptions. This opinion, which seems to have been counteracted by Plato, is fully developed in the system of Berkeley. Malebranche is placed by this writer among the Idealists, as his mathematical points, constituent of extension, vanish into nothing when we attempt to analyze them. Locke, by supposing that matter may be made capable of thought, approaches to the Dynamists. Leibnitz and Wolf may be deemed Idealists; since, in reality, they allow of no material existence out of the mind; for although the monads are the occasion of our ideas, yet their ideas have nothing in common with the object. Kant, who derives no sensations from the attention of the soul to real existences, though he acknowledges that our ideas are in some other manner excited, by something existing out of the mind, is placed also under the class of Idealists; as, according to him, all our observations and determinations are founded on appearances. Of Dr. Priceley this anonymous writer remarks, that, although he makes the soul material, he makes matter spiritual; and therefore he is ranked with the mixed atomists. See account of Prize Dissertations, by Taylor’s Theological Society, vol. x. in Monthly Review Enlarged, vol. iii. p. 741.

ATOMOS, in Entomology, a species of Cancer found in running water in Europe. It is linear; has four, with a single fang; legs fourteen, with two oval valves on each side between the fourth and fifth pair.

ATONEMENT, in Theology, is a term that has been variously explained and applied by divines of different opinions. However, there are three principal senses, in which, with fulsome modifications, the term has been usually understood. The first is, that which has been adopted by those who are commonly called Calvinists; and it supposes, that the death and sufferings of Jesus Christ, partaking of the divine and human nature in one person, being with respect to the former equal to the Father, were such, confounded in their degree and value, as to be a proper equivalent for the penalty annexed by the divine law to the transgression of those of the elect who are penitent and believing. Divine justice, it is said, required its victim, either in the infinite or his substitute; Jesus became the surety; he paid the debt, and satisfied the demand. Others, who have not espoused the doctrine of the proper deity of Christ in the sense of the Trinitarians, or who have not contended for an absolute and strict equivalent to the demerit and consequent punishment of transgression, have expressed their notion of this doctrine in a manner somewhat different. Accordingly, Dr. Watts, in his “Redeemer and Sanctifier” (see his works, vol. iii. p. 741), explains his sentiments in the following manner. “By atonement for sin, I do not mean any such thing as shall in a proper and literal sense appease the wrath of God, the offended governor, which is supposed to be kindled against his sinful creatures, and shall incline his heart to mercy, which was before determined upon vengeance; for though this doctrine may be so represented sometimes after the manner of men, yet this is an idea or supposition in many respects inconsistent with the attributes and actions of the blessed God, and with the doctrine of the New Testament. In that book God represents himself as rich in mercy, and for this reason he pitied sinful creatures who had broken his law, and had deserved to die, before he had received any atonement; and therefore God himself provided and sent his own son to become a sacrifice of atonement, and a ransom for them; he appointed him to be a surety for us, the just for the unjust, and to suffer death in the room and stead of sinners. By the words “atonement,” or “propitiation,” I mean therefore some soothing or painful thing done or suffered, or both, by Jesus Christ the son of God, in the room and stead of sinful men, as a punishment on account of their sins; and this by the wise and righteous appointment of God, the universal governor, shall excite the penitent offender from the punishment that was due, and obtain his pardon, because it shall give a recompense to the authority of the divine lawmaker for the affront which was put upon him by the sins of men, and shall make some reparation of honour to his holy law which was broken. And this is not only intended to manifest the evil nature and the defect of sin, together with God’s hated
hatred of it; but it shall also answer the demand and design of the threatening by such actual pain or punishment, though it is laid on the surety instead of the offender; and thus it may secure the law from being broken, in time to come, as effectually as if the offenders themselves had been punished. Such a pain, penance, or punishment, are the humiliation and sufferings of Jesus Christ, his labours and sorrow; and it is in this sense that the language of expiation or atonement, of propitiation and ransom, is so often used. See 1 Pet. ii. 23. 2 Cor. v. 21. Gal. iii. 10. Now by these appointed sufferings of the Son of God, in the room and stead of sinful men, there is an honourable amends made to the governor of the world for the violation of his law, and a glorious way made for the exercise of mercy in the pardoning of the offender, and that without any imputation of reflection upon the holiness of God's nature and conduct, or any lujdiction of the justice of his government, as if he would connive at sin; since he discovers and declares, that in passing by the sins of his people in former ages, and in pardoning and justifying persons who now believe in Christ, he will manifest his justice and righteousness by requiring such a sacrifice whereby sin shall be punished, though the sinner be spared. See Rom. iii. 24—26. To this purpose, Whitby (in Heb. v. 3.) observes, that Christ, after he became our surety, was not, nor could be delivered from those sufferings which were the punishment of our sins; he being as our expiatory sacrifice, not only on the occasion of our sins, but in our stead, to bear the punishment of our iniquity. (See Satisfaction.) In the sense above explained, the death and sufferings of Christ were properly vicarious. The advocates for this opinion have sometimes asserted, without reserve or qualification, that the necessity of an atonement arose from the immutable nature, and the indissoluble demands of divine justice; and that God could not, in confidence with his moral attributes, have pardoned fin without receiving a plenary satisfaction; that this satisfaction or atonement could not have been given by any other being but his own eternal and equal Son; and that even he could not have effectied this great and ultimate object of his mediatorial office, unless our sins had been imputed to him in the same degree as his merits are imputed to us. (See Imputation.) On the other hand, those who have carried Calvinism to the extreme in other points, have nevertheless maintained, that punitive justice was not essential to the divine nature, and that God might have pardoned sin by virtue of his own absolute authority, independently of an atonement. Dr. Owen, however, has opposed this tenet in a Latin tract, intitled, "Distrina de jutizia divina." "Christ's death," says the learned biblical writer, Dr. Clarke (Sermons vol. viii. p. 366.), "was truly and properly, in the strictest meaning of the word, an expiatory sacrifice. For if sinners, by having diminished the honour, and defiled the authority of God's laws, were become liable to the justice and vengeance of God; if the Son of God in our nature, by vindicating the honour of God's laws, hath discharged this obligation, and obtained remission for us; and if the obtaining this remission was by the shedding of his blood, which is called 'the price of our redemption' (1 Cor. vi. 20); it follows, that the wrath of God was appeased by the death of Christ, and that God was graciously pleased to accept this vicarious suffering of his Son, in the stead of the punishment that was due to the sinner in his own person: which is the express and most proper notion of an expiatory sacrifice." To the same purpose this excellent writer observes in another place (vol. v. p. 203.), that "Christ hath vindicated the honour of God's laws, by taking upon himself the punishment of their sins who repent, and embrace the terms of the gospel. He confounded to be made fin for us, i.e. to be made a sacrifice for our sins, that we through that expiation might become subjects capable of the mercy of God. He took upon him our nature, and was clothed in flesh, partly indeed that he might preach the will of God to mankind in a nearer and more confounding conversation with them; but, principally, that he who in the form of God could not suffer, might become capable of suffering by being made in the likeness of man. He led a most innocent and spotless life, that he might indeed set us an example, that we should follow his steps; but chiefly, because, as it was required that the typical sacrifices under the law should be whole and without blemish, so it was necessary, that he who was to be the real expiatory sacrifice for the sins of others, should have none that needed expiation of his own.—He suffered a shameful and ignominious death upon the cross, that he might indeed give us an example of patience and readiness to suffer; but the principal design of it was, that he might put away fin by the sacrifice of himself, and obtain eternal redemption for us through faith in his blood. His resurrection was the demonstration of this sacrifice's being accepted by God; and his ascension into heaven was in order to plead the merits of his sufferings before God, and intercede for those who, according to the terms of the gospel-covenant, should be capable of receiving the gracious benefits purchased by his death." Similar sentiments of the doctrine of atonement are largely illustrated in a treatise, by Mr. M. Tomkins, who was an avowed Arminian with regard to the Trinity, intituled, "Jesus Christ, the Mediator between God and Man," of which a second edition was printed in London, in 1761. This writer, having produced several passages of scripture, that speak of Christ's death as a sacrifice, and which declare him to be constituted a high-priest, and having established, as he conceives, beyond all reasonable doubt, the literal sense of those scriptures, proceeds to consider what was the notion of expiatory sacrifices, and of the priestly office under the law of Moses. (See Sacrifice.) These sacrifices, he shews, were intended to make atonement for the person who offered them; i.e. according to his statement they were, by divine appointment, of avails to free him from the guilt he had contracted, and to prevent the punishment to which he was liable. See Num. viii. 19. xvi. 46. These sacrifices he considers as a proper expiation, or a real propitiation; not that they were the canic of a merciful disposition in God, and in that sense rendered him propitious who was before impenitent; but they were appointments for procuring pardon, and the priests by offering them obtained from the mercy of God those blessings of which they otherwise must have been deprived. Hence he infers, that the effects attributed to the blood of Christ correspond with such effects of these legal sacrifices, and that his acting as our high-priest answers to the office of the high-priest under the law. See Heb. viii. ix. 8. 23. x. 1. He proceeds to shew, that our pardon and acceptance with God, and our freedom of access, are represented, in the New Testament, as the fruit of the suffering of Christ not merely as an act of obedience, but as a sacrifice for sin, as a demonstration of God's displeasure against it, and of his regard to the righteous function of the original law, which denounced death to the transgressors of it. With this view, when God resolves to shew mercy to sinners, he also determines that his only begotten son, not indeed without his content, shall suffer death, the penalty which the original law had denounced against transgressors. Thus Christ, by suffering death, prevented or warded off those effects or consequences of fin, which would otherwise have come upon mankind; and accordingly his death and
his mediation are very justly represented as the means of procuring for us the blessings of which we are made partakers. See Heb. ix. 12. 1 Cor. vi. 20, viii. 23. Rev. v. 9. This representation of the matter gave rise to the term satisfaction, which has been generally used by writers in treating of this subject. (See Satisfaction.) This author having flated his notion of the death of Christ as an atonement for sin, obviates the objections that have been urged against the opinion he has adopted. But we must refer for further particulars to the author's treatise, p. 155, &c. See also Chapman's Enthusius, vol. ii. ch. iv. v, vi.

The second explanation of the term atonement, which has sometimes been called the Arminian doctrine, supposes that the sufferings of Jesus Christ were inconsiderably severer; and that the object of them was to exhibit the evil and demerit of sin, and the displeasure of God against it, who would not even forgive a sincere penitent, without thus manifesting his hatred of wickedness. This coincides, in a degree, with the illustration of this doctrine already given; it has been denounced the moderate doctrine, and has been adopted, with certain modifications, by many divines and others. A third hypothesis relating to this subject is that of the learned Dr. John Taylor (see his "Scripture Doctrine of Atonement examined," &c. and also his "Key to the Apologetic Writings," prefixed to his "Paraphrase, &c. on the Epistle to the Romans," ch. viii.), that the scriptures represent the death of Christ as an act of obedience so acceptable to God, that, as the reward of it, he thought fit to grant unto mankind, corrupt and wicked, the forgivenes of sin (absolutely, in relation to antecedent sufferings; and upon condition of repentance, in relation to eternal life), and to erect a new dispensation furnished with all proper means to draw us from sin unto God, and to bring us to the pollicence of immortality. The blood of Christ, says this writer, or that by which he has bought or redeemed us, is his love and goodnese to men, and his obedience to God, exercised indeed through the whole of his state of humiliation in this world, but most eminently exhibited in his death. It is his complete and spotless righteousness, his humility, goodness, and obedience unto death, which makes his blood precious in the sight and hand of God, and gives his death its worth and efficiency. Obedience was the sacrifice which he offered unto God for us. "It was his righteousness, or righteousnes, and benevolent action, his obedient death, or the sacrifice of his love and obedience, which made atonement for the sin of the world; for, and in this sense, that God, on account of his goodness and perfect obedience, so highly pleasing unto him, thought fit to grant unto mankind, whom he might in strict justice have destroyed for their general corruption and wickednes (John, iii. 17), the forgivenes of sins, not imputing unto them their trespasses (2 Cor. v. 19) or their sins which were past, or which they had already committed (Rom. iii. 25), and for which they deferred to fall under the dreadful effects of God's wrath. And not only did he forgive former trespasses to all the living and to all the penitent and obedient dead, but further he erected a glorious and perfect dispensation of grace, exceeding any which had gone before it in means, promises, and prospects; at the head of which he set his Son, our Lord Jesus Christ, invested with universal power in heaven and on earth, constituting him king and governor over the new body, which he designed to form, captain of our salvation, the high-priest of our profession, the mediator and surety of the new covenant, to negotiate and manage all affairs relating to our present instruction and sanctification, to raise all the dead out of their graves, and to put the obedient and faithful into possession of eternal life."—As in various instances, the virtues, acts, and prayers of good men were the means of God's bestowing pardon and sundry blessings upon others, so much more, according to this author, must the perfect righteousness of obedience and goodnes of the Son of God, be a reason for remitting the sins of mankind, so far as, in the nature of things, they are capable of remission, or of being atoned? For the sins of the impious, who finally neglect and renounce all means of reformation, cannot be atoned or forgiven. Grace or favour, through the atonement of Christ, may be so far known to them, as to allow them space and means to repent; but none besides the penitent who truly improve the divine goodnes and patience, can receive the benefit of eternal salvation through the atonement of Christ. The wisdom, as well as the grace of this dispensation, are illustrated, when we consider, that pardon in the gospel is raised to a very high degree; and repentance is there made available, not only to exempt from punishment, but also to gain a new and glorious state of being in eternal life, which is a grant of favour extended far beyond the natural value of repentance. Besides, the grant of remission of sin, and of other blessings of the gospel, through the blood of Christ, has a strong and direct tendency to promote our sanctification, and to render us penitent and obedient; and therefore this constitution must be acquiesced in as perfectly wise and benevolent." Dr. Taylor, in examining the notion of atonement above stated and considered as the satisfying divine justice, by another's suffering the punishment due to the criminal's sin in his head, adds a variety of passages pertaining to this subject, and those more especially in which the Hebrew word P2, by which, or its derivatives, atonement is expressed in the Old Testament: and though he discards the notions of the imputation of our sins to Christ, his suffering in our stead the punishment due to us, or his paying an equivalent to divine justice, yet he concludes his examination with inferring from it, that the sacrifice of Christ was, truly and properly, in the highest degree, and far beyond any other, peculiar and expiatory, to make atonement for, or to take away sin; not only to give us an example, not only to assure us of that which we profess to procure our Lord a commision to publish the forgivenes of sin; but moreover to obtain that forgivenes by doing what God in his wisdom and goodnes judged fit and expedient to be done in order to the forgivenes of sin; and without which he did not think it fit or expedient to grant the forgivenes of sin. The truly excellent Bishop Butler, in delivering his sentiments on this subject (Apoloogy, &c. p. 2), observes, "that some have endeavoured to explain the efficacy of what Christ has done and suffered for us beyond what the scripture has authorized; others, probably, because they could not explain it, have been for taking it away, and confining his office as redeemer of the world to his institution, example, and government of the church. Whereas the doctrine of the gospel appears to be, not only that he taught the efficacy of repentance, but rendered it of the efficacy which it is by what he did and suffered for us; that he obtained for us the benefit of having our repentance accepted to eternal life, &c. Hose and in what way it had this particular efficacy, there are not wanting persons who have endeavoured to explain it; but we do not find that the scriptures have explained it. It is our will that it was full, and to accept the benefit, without disputing how it was full, and to enjoy the good thereof." To the same purpose, Dr. Price, who formed his sentiments very much on the general plan of Butler's Apology, says, in his "Sermons on the Christian Doctrine," p. 35, that Christ defended this earth from a state of
existence of dignity; and that, after having passed through human life, enduring all its sorrows, he delivered himself up to death, and thus acquired the power of delivering us from death. By offering himself a sacrifice on the cross, he vindicated the honour of those laws which sinners had broken, and rendered the exercise of favour to them consistent with the holiness and wisdom of God's government; and by his resurrection from the dead, he proved the efficacy and acceptability of his sacrifice. In a word, Christ not only declared, but obtained the availability of repentance to pardon; and became by his interposition, not only the conveyer, but the author and the means of our future immortality?—

"in such a fence that we owe them to him, as well as primarily to God." This author has declined the use of the terms satisfaction and atonement, because they do not occur in scripture; but others have alleged, that though the literal expressions do not occur, the philosophy of the sacred writers warrants the use of them.

Among other writers who have totally rejected the doctrine of atonement according to either of the explanations above given of it, we may mention Dr. Prießly, who reckons it in the class of the corruptions of Christianity. See History of the Corruptions of Christianity, vol. ii. p. 152, &c. In all the books of scripture, says this writer, we nowhere find the principle on which the doctrine of atonement is founded, which is a display, on the part of God, of justice and of his abhorrence of sin, so that God could not pardon it without an adequate satisfaction being made to his justice, and the honour of his laws and government. Admitting the popular doctrine of atonement, the whole of the Old Testament, as he conceives, is a most unaccountable book, and the religion it exhibits is defective in the most essential article. The Jews in our Saviour's time, it is said, had certainly no idea of this doctrine; for if they had, they would have expected a suffering, and not a triumphant Messiah. And it is alleged, that our Lord and his apostles are silent with regard to it. This author undertakes to explain the fence in which Christ is represented as a sacrifice, and other figurative interpretations of it, independently of this doctrine. He proceeds to examine the sentiments of the Apocryphal fathers, and though he allows that figurative expressions occur in their writings which seem to favour the doctrine of atonement, yet the general strain flows, as he apprehends, that they had no proper idea of it. It is also argued, that this doctrine is not enunciated as an article of Christian faith in any ancient summary of Christian doctrine. To the too literal interpretation of the figurative language of scripture, Dr. Prießly attributes that advance towards the doctrine of atonement, which was observed in the third and fourth centuries. Grotius flows (Opera, vol. iv. p. 347.) that this doctrine is maintained by Theodorus Abacara, a Greek writer of the ninth century; but in the Latin church it does not seem to have been fixed in the eleventh century, although there are obvious and indisputable references to it in the writings of Anfelm, and also in Theophilos, a Greek writer cited by Grotius. Wickliffe evidently believed the absolute necessity of the death of Christ in order to the forgiveness of sin, and after the reformation by Luther, the doctrine of satisfaction, or atonement for sin was reduced to a regular system grounded on certain principles, and purified to its proper extent. It was unequivocally avowed in the confession of faith professed to Charles V. at Augsburg, in 1530; in the Helvetic confession of the year 1536; and at the synod of Dort, in 1618. It is now the doctrine of the established churches of England and Scotland; and it is very generally retained, at least in some qualified fences, by divines and others, both Trinitarian and Arian. Socinus discarded it, and his followers have almost universally expounded it. We observe, that though the word atonement frequently occurs in the Old Testament, we meet with it but once in the New Testament; and in other places the same original word, ἄνελπτικος, is rendered justification. As for those who reject the generally received doctrine of the atonement, they maintain, that the great object of our Lord's mission was to teach the doctrine of a resurrection to a future immortal life, and that hence arose the peculiar necessity and utility of his own death and resurrection as a proof of his doctrine. See Expiation, Illustration, Propitiation, Sacrifice, and Satisfaction.

Atonement, Day of. See First of Expiation.

ATONIA, arsen, in Medicine, a term which signifies a want of tone, firmness, or strength, in the muscular fibres; in other words, a relaxation thereof; from a privative and περι, tendo, f erete, or extend. This condition takes place either partially or generally in most forms of chronic discharges, and in the convalescent period of acute diseases. The remedies are the Peruvian bark, bitters, chalybeates, the sulphuric acid, cold bathing, country air, and exercise, with a mild and nourishing diet.

ATONICS, in Grammar, denote words unaccented. See Accent.

ATOOI, or A'TOWAI, in Geography, the most northern and the largest of the west group of the Sandwich islands, being about 300 miles in circumference; containing, according to the statement in the third volume of Captain Cook's voyage, about 54,000 inhabitants. It has a good road and anchoring place on the south west side of the island, called Wymoo. It is observed, in the account of Portlock's and Dixon's Voyage to the north-west coast of America, that the east side of the island rises gradually from the sea, till it terminates in high land, near the centre of the island. The height of the most elevated land or mountain, according to Marshand (ubi infra. p. 16.), is 1216 toises. The hills are clothed to the summit with lofty trees, exhibiting a beautiful verdure. The land next the shore on the east side is uncultivated and desert of inhabitants; but to the westward it is generally cultivated, and huts are scattered along the shore. The domestic animals on this island are dogs, cats, and fowls. Its principal vegetable productions are yams, sweet potatoes, the sugar cane, and a sweet root called by the natives, tce. Some trees were found about fifteen feet high, with spreading branches, a smooth bark, and a nut resembling a walnut; others about nine feet high, with blossoms of a beautiful pink colour: and a variety with nuts, like our horse chestnuts, which are used by the natives as substitutes for candles, and give an excellent light. The island affords a supply of fresh water. In Marshand's Voyage (vol. ii. p. 80.); we have an account of two English sailors, who had been carried off from an English brig by the natives of this island, and who confirmed the report of captain Cook concerning the natives of the Sandwich islands, that these islanders are cannibals, and eat their prisoners. The relation, however, is disputed; and it is suggested, that the natives of these islands cut in pieces the bodies of their dead enemies, burn their flesh, and preserve their bones as trophies for perpetuating the memory of their exploit. Thus, it is said, they don't with the body of the unfortunate captain Cook. In the voyage of Vancouver, who visited this island in 1792, we are informed, that the prostitution of the women is here carried to the most wanton excess. Vol. i. p. 171. N. lat. 22°. E. long. 200° 30'. See Sandwich Islands.

ATOTOTL, in Ornithology, a name under which Seba describes...
describes the purple creeper, or *Corithia purpurea* of Gmel. avis virginiana planiscia de Atox dicta. Spre Maff. t. 32. Sec Purga CERTIA.

ATOURIA, in Geography, a small town of Portugal, in the province of Estremadura, seated on an eminence near the sea, opposite to the rocks called Burlings, defended by a castle, and containing about 1300 inhabitants; two miles and a half of Peniche.

ATOURI, a large tribe of Arabs that afflicts the inhumans of Suez, and from thence go up between the R. de sea and the mountains that bound the east part of the valley of Egypt. See Howadat.

AYOQUE, a deep and large river of America, in Mexico.

ATRA, in Conchology, a species of Patella, described by Schott. The shell is black and striated; vertex pale, bottom with a speckle brownish spot, and surrounded with a horse-shoe shaped band of white. About an inch and a quarter in length. The country is unknown.

ATRA, a species of Helix, about two inches in length, and coiling of seven whorls. The shell is tapering, black, and minutely flinted and whorls rather convex; aperture oblong-oval. Guat. left.

ATRA, in Conchology, a species of Canopus (Area Fabr.) that inhabits Denmark and Germany. The shell is cylindrical and incrusted; body black. Guat. The mouth of this insect is white; ant nose black, with a yellowish band; legs black; posterior trigone yellow.

ATRA, a species of Podaria (Bosc), entirely of a fanny-black colour, and without spots. This is *Bombyx hieraci* of Fabricius, and *Tinea granulata* of Wien Schmetter. The larva is black and hairy, with a fanginous dorval line; it secretes itself within a follicle composed of dried leaves and straw. The pupa is fegestinuous brown.

ATRA, a species of Caceca (Cereus Fabr.) of a large size, that is found in South America. It is black, with a margional fanginuous stripe on both sides of the wing-cases. Fabricius &c.

ATRA, a species of Podura, very common in Europe. It is globular, brown, and shining; antennae long, and of many joints. Fann Sue. Linn. Act. stockh. 1743.

ATRA, a species of Patella (Hepus Fabr.) of a black colour, with striated wing-cases. Fabr. Gmel. &c. This is *Pycnodus nigra*, a nitida, corpore ovato, thorace convexo, antennae pedibusque fuscis, of Degener. Inhabits Europe.

ATRA, a species of Buprestis, that inhabits Germany, and in some respects resembles *Buprestis vulpina*. The wing-cases are entire, somewhat linear and punctuated; thorax deflexed; body black and elongated. Fabricius.

ATRA, a species of Lampris (Lamso Fabr.) of a deep black colour; thorax orbicular, and with the wing-cases red; an impressed black spot on the back. This is a native of Europe. Mec. Linn.

ATRA, a species of Cantharis, the body of which is entirely of a deep black. Fabricius. A native of the north of Europe.

ATRA, a species of Neckalinos, of a black colour, with all the thighs clubbed. Inhabits the south of Europe. Fabricius. The thigh in one sex simple.

ATRA, a species of Leptura, the body of which is totally black. Fabricius. The legs of this kind are sometimes fanginuous. Pod serves it *Leptura athepis*, and Geoffroy, *Stenocoryx toxis nigra*. Inhabits the south of Europe.

ATRA, a species of Curculio, of an oblong form, and black colour, with nervous antennae. A native of Europe, and supposed to be a variety of *C. chloropus*. Gmel. Fabr. &c.

ATRA, a species of Hispa, the body of which is entirely deep black. Schr. der Barth. &c. Gmel. Fabricius describes it as having a flat, antennae; thorax and wing-cases purple; and body black. Geoffroy calls it *Cricera atra spinosa*. It inhabits the south of Europe and the north of Asia, and feeds on the routes of graft.

ATRA, a species of Chrysolina (Ellen Fabr.), found in Germany. It is glossy or fanning black, with the base of the antennae, and sides of the feet pitchy-black. Gmel. Geoffroy, &c.

ATRA, a species of *C. cinnella* of a black colour, with two yellow spots; tarsus of the thorax and tail yellow. Thunberg. The body of this insect is very glossy and glabrous.

ATRA, in Conchology, a species of Macrastira, called in the Arctic Zoology the *Dolly Fy-rett*. It is of an olive colour; breast cinnabar; belly pale red; tarsus yellow; head, tail, and quill feathers black; margin of the fécundaries, and outer web of the extreme tail feathers white. Geoffroy, &c. This is a native of New York, where it appears in March, and departs in August; feeds on bees, and lays five small white eggs; legs black.

ATRA, a species of Tanagra that inhabits Guiana. This bird is cinnabar; face, chin, and throat black in the male, and brown in the female. Buffon calls it *Canal* ou *Chiepe*, and Tangara a cranette noire de Cayenne. The length of this bird is seven inches; the bill and legs black; beak of the upper mandible white.

ATRA, a species of Trinca that inhabits the banks of the Rhine. The head and neck are black; back and wings brownish intermixed with black; breast and belly cinnabar, undulated with black and white. Sander.

ATRA, a species of Ardea, entirely of a black colour, with a smooth head and face, bare of feathers. Gmel. The wings are gilded with blue. Brid. calls it ardea nigra; Buff. héron noir; and Latham the black heron. It inhabits Silecia.

ATRA, in Ancient Geography, the capital of the Arabians of Singara; who formed a tribe, which possessed an independent territory of Mefopotamia. Trajan besieged this place in the year 117, but by the resistance of the inhabitants, and the heat of the season, he was obliged to abandon the enterprise. The town was seated on the top of a high mountain in a dry and desert country, and encompassed by a strong wall. It retained its reputation under Severus, but was ruined under the reign of the emperor Jovian.

ATRABILARIE Capsule, in Anatomy. See Caps.

ATRABILIS, Black Bile, in Medicine. The ancients (says Dr. Percivall) as appears from Galen, supposed the atrabilis to be derived either from the drugs of the blood, or from yellow bile torrefied and highly condensed. A celebrated modern anatomist is of opinion that it is blood, which having lodged some time in the intestinal canal, has acquired a blackness and putridity. But is it not (this elegant and ingenious writer asks) more probable, that in general it is no other than gall become acid by stagnation in the vesica felles, and rendered viscid by the adsorption of its fluid parts? When discharged into the duodenum in this state, it occasions universal disturbance and disorder till evacuated either by vomiting or purging. A young gentleman who laboured under a malady produced by intemperance, and which at last proved fatal, voided several times both by flood and vomiting a considerable quantity of black, tenacious, and most offensive bile. The symptoms which preceded the discharge, and which ceased soon afterwards, were...
were a quick pulse, head-ache, delirium, hiccups, intense third, inward heat, and an uncommon fever in his breast. A lady aged thirty, unhappily addicted to habits which have a peculiarly pernicious effect upon the liver, after a confluxion of the belly during six days, was feved with a violent and incessant vomiting of black and viscid bile. The infusion feem linonatium, warmed with the tincture of Columbo, soon checked her retching, and operating by stool, prevented the return of her vomiting. The matter discharged in both these cases bore not the least resemblance to gummous blood. Dr. Percival adds, that he has several times observed the fevrile symptoms in children, which are ascribed to deputation, relieved by these pitchy fluids; and that he recollects three cases of the diftace called acute asthma by Dr. Millar, in which the paroxysms seemed to be critically terminated by a similar evacuation. Whichever, in these instances, the black bile was the cause or the effect of the disease, cannot (he observes) with certainty be determined; but the former appears to him to be the more probable opinion. Percival's Essays, Medical, Philosophical, and Experimental, vol. i. p. 342. 4th edit. This view of the subject is very satisfactory; but as an evacuant, peculiarly adapted to this disorder, we would suggest the employment of calomel. Black bile was supplied by the ancients to constituite a peculiar temperament, which they termed the stibulinary or melancholic temperament. See Temperaments.

The diftace termed Melena, or morbus nigre, in which there is a dark-coloured bloody discharge, unaccompanied by griping pains and acute fever, seems to be a species of diarrhoea. (See Meleus.) Before we close this article, we would observe, that black or pitchy fluids may be occasioned either by diseased bile, or by the effusion of venous blood into the intestinal canal. An experienced practitioner will seldom be at a loss to distinguish the difference; but if any doubt arises, recourse must be had to chemical analysis.

ATRACES, in Ancient Geography, a people of Europe, in that part of Greece called Aetolia. Their country was watered by the river Atran, whence their name.

ATRACTYLIS, in Botany (from atract, to draw, &c. frrnulles, a filament), disaff-thistle, Lin. Gen. 930. Reich. 1259. Schreib. 255. Clafs. fpicifera p6gam6my equalis, Nat. Ord. compositae Gen. Char. Out many-leaved, linear, large, roughened, permanent, confiding the common one; common ovate, imbricate; the ftalks oblong, very many, lanceolate, converging, unarmed. Cor. compofite radiate; corollae hermaphrodite, numerous, tubular on the ditf; herm. ligulare in the ray; proper of the ditf funnel-form, five cleft of; the ray, ligulare, flat, five-toothed. Stem. filaments five, capillary, very short; anther cylindric, tubular. Pist. of the ditf; germ very short; style filiform, the length of the ftamens. Stigma bifid; of the ray very like that of the ditf, but obtuse and withered. Per. none; calyx converging. Seeds turbine, comprized; down pubescent. Rec. villosc, flat. Eff. Gen. Char. Cor. radiated; corollae of the ray five-toothed.

Species. 1. A. grunifera, gummy rooted artaxylon. "Flowers fermenfs." From the root which is perennial, fifteen to twenty narrow finely fliored leaves, armed with fpies on their edges. They lie close to the ground, and between them the flower is situated; it is white at the border, but yellow at the ditf. A native of Italy. The root about fable with a gummy matter, which has occasioned it to be cheated for the fane purposes as maffeft. 2. A. humila, dwarf artaxylon, Cavan. Hfp. 40. 1. 154. 2. Barr. rar. 1127.

t. 592. "Leaves tooth-finiated; flower radiate, fenned with an expanding involucre; femg herbageous." Stems nearly a foot high; leaves incerted, fpires at the edges; flowers purple, in heads on the branches; &c. biennial. A native of France and Spain, flowering in June. Cavaratille's description of this plant differs from the above. 3. A. cancellatus, netted artaxylon. "Involucres laticol, cellying, linear, toothed; calyces ovate; flowers fliored." Annual, eight or nine inches high, producing two or three fender branches, each terminated by a head of flowers like those of the thistle, with an involucre composed of feveral narrow leaves, armed with fpies on their fides, and curiously netted over, which keeps off the flies; fiores purple. A native of the South of Europe. It was cultivated here in the time of Parkinson. 4. A. lanceata; lance-shaped artaxylon. "Involucres pinnate, leaves lanceolate, ciliate, smooth." Stem a foot high, fliored, branching; leaves alternate, acute, fefile, erect; flowers on the branches terminal, foliary, fubfoliary. It differs from the third in having smooth leaves, and a leaffy item. 5. A. ovata; oval-shaped artaxylon. "Involucres pinnate, leaves ovate, ciliate smooth." Stem fimple, threafed, fervcely a foot high; leaves alternate, petioled, acute,erved, pule underneath; petals with ciliate edges; flowers terminating, foliary. Both these last are natives of Japan. 6. A. oppositifolia; opposite-leaved artaxylon. "Leaves opposite." Leaves and calyxes tomentofe underneath. Receptacle with hair-like chaff. In the ligulate ftorks the anthers are effeite, and there is neither style nor stigma. A native of the Cape of Good Hope. 7. A. purpurata; purple-flowered artaxylon, Smith. Ist. med. 5. 67. "Leaves flat, rufined." Stem round, woolly; leaves crowded, a span in length, acute, irregularly toothed, veined, tomentofe underneath; peduncles longer than the leaves, branched, angular, ruged, woolly, covered at top with linear acute fiales; flowers large, erect, fpecious, purple; receptacle naked. Found by Mutis in New Grenada. S. A. Mexticana; Mexican artaxylon, Smith. Icon. med. 66. "Leaves oblong, quite entire." Stem thrubby; branches simple, leafy, without fpies, covered with a downy fubfance; leaves alternate, lanceolate, acuminate, with netted veins; beneath very white, tomentofe; petals keeled, tomentofe; flower terminating, nodding, purple, fupported by two or three bracteate-shaped leaves; receptacle with very short chaffs. Found by Mutis in Mexico.

Propagation and Culture. "1, 3, 3 are propagated by seeds, which must be obtained from the countries in which they grow naturally: these should be sown on a border of light earth, in a warm situation, early in April, and when the plants come up, and are fit to transplant, they should be thinned, and those which are drawn out may be transplanted, leaving the others two feet asunder; after which, the only culture they require is, to keep them clear from weeds in summer, and in winter to cover the roots with some old tanner's bark to prevent the froit from penetrating the ground. The other species are yet strangers to European gardens; and whenever they are introduced, will require the protection of a green-houfe or hove. See Martin's Miller's Diet.

ATRACTYLIS. See Carthusius.

ATR A D I E S, in Antiquity, denotes a fatal day, whercen the Romans received fome memorable defeat. The word literally imports a black day; a denomination taken from the colour, which is the emblem of death, and mourning. Whence the Thracians had a custom of marking all their happy days with white Plains, or calcis, and their unhappy days with black ones, which they call, at the close of each day,
day, into an urn. At the person's death, the stones were taken out, and from a comparison of the numbers of each complexion, a judgment was made of the felicity or infelicity of his course of life.

The dies atri, or atrii, were afterwards denominated nepheli, and pesseri. Such, in particular, was the day when the tribunes were defeated by the Gauls, at the river Allia and lost the city; also that on which the battle of Cannae was fought; and several others marked in the Roman calendar, as atria, or unfortunate.

Eff. Gen. Char. Col. four-leaved. Pet. twelve. Seeds, tallied. see: 1. A. japonica, Japanese atrage. 2. Eriol, leaves opposite, trinate; leaflets ovate, galled. Stem angular, fringed, subdichotomous, villose, two feet high; leaflets acute, toothed, very thinly villose; petals flat-clasping; flowers from the divisions of the stem, few, on elongated one-flowered filiform peduncles; petals more than twenty, purplish within, white-tomentose without. Were it not for the number of its petals it would belong to the anemone. A native of Japan. 2. A. alpina. Alpine atrage. Jacq. Aufl. 3. t. 241. Clematis Siberica, Mill. fig. t. 234. "Leaves doubly ternate, ferrate, outer petals four-fold." Stems slender, weak, covered with brown thin bark; leaflets two inches long, of a deep green colour; peduncles naked, three or four inches long, one-flowered; calyx yellowish, white within. This plant is differently described by several botanists, and Jacquin affirms that the Austrian plant is specifically different from the Alpine. A native of the High Alps of Switzerland, &c. 3. A. cepaefis, Cape atrage. "Leaves ternate; leaflets galled, toothed, outer petals five-fold." Scapes simple, fix or seven inches long; involucre in the middle of the scape, composed of several, ovate, villose, foliaceous flaps; leaves wedge-shaped, triquet, acute, naked; petals about twenty, white, the fix lower ones broader, villose underneath, puberul. A native of the Cape of Good Hope. 4. A. tenuifolia, fine-leaved atrage. "Leaves doubly pinnate; pinnules linear, entire." Found at the Cape by Thunberg. 5. A. ceylonensis, Ceylonese atrage. "Tendril two-leaved." Caulose, slender; leaves opposite, compound, conjugate; leaflets ovate, entire, or sometimes with a finge toothed, three nerves, on very short footstalks; panicule terminal, composed of a twice trifid peduncle, bearing commonly nine flowers; petals twice the length of the calyx, puberul. A native of Ceylon.

Propagation and Culture. The second species may be increased by cuttings or layers in the same manner as Clematis. In a strong soil, and trained against a wall, it will rise to the height of fix or eight feet. The flowers appear early, and if the season prove favourable, they make a handsome appearance; but as this plant is apt to put out leaves very early in the spring, it is frequently nipped by the frosts. The other species have not yet been cultivated in England. See Martyn's Miller's Dict.

ATRAMENII. See Isk.

ATRANUMATA, in Entomology, a species of Phalena (Genus), that inhabits Europe. The wings are white, sprinkled with black dots.

ATRAMITAE, in Ancient Geography, a name given to the inhabitants of Hadramaut, or Hadramuth, a rich and flourishing country of Arabia Felix. See Hadramaut.

ATRANI, in Geography, a town of Naples, in the Principato Citera, situate between two cliffs, joined together by buildings. Along the valley a road winds up to Ravello and Scala, two episcopal cities, or rather bustling villages, on the mountain top. It is not far from the city of Amalfi.

ATRAPHAXIDIS, in Entomology, a species of Cryptoeuphalus, about the size of C. quadrifidus. It is black, with three red spots; wing-caps tachit, with three black spots; fans; Rufus, Fabr. This is coryphaena atraphaxidis of Pallas, and inhabits Siberia.

Species. 1. A. spinosa, prickly-branched atraphaxis. L'Herit. Stirp. Nov. 27. t. 14. "Branches spiny." It rives four or five feet high, sending out many weak lateral branches, armed with spines, and furnished with small spear-shaped smooth leaves, of an all-colour. Flowers at the ends of the shoots in clusters, each consisting of two white petals tinged with purple, included in a two-leaved calyx, of a white herbaceous colour. L'Heritier has described this plant very particularly, vide l.c. It is a native of Armenia, Siberia, and Peru, flowering in August. Cultivated by Miller in 1759. 2. A. nudula, waved-naped atraphaxis. Dill. Eth. 36. t. 32. f. 56. (called arbutus africana, &c.) "Without spines." Stems about a foot long; leaves ovate, obtuse, waved at the edges, alternate, longer than the internodes. Flowers in oblong spikes, at the ends of the stem and branches, furnished with short bractes. Calyx yellow, involving the fruit. The flowers are commonly quadrid, but sometimes they are fix-parted, with eight flaments. Several authors make this to be a species of polygonum, while others would unite the two genera.
Atrata, in Curiology, a species of Patella. This shell is rather convex, narrow, white, lined with red, outside spotted with black, with elevated, convex, unequal frizz; aperture at the vertex oblong, bordered with chesnut, Sclerotic. This shell is about three quarters of an inch in length, with a crenated margin, and the vertical aperture surrounded with a reddish ring within.

Atrata, a species of Neptis, found in the Atlantic, American, and South seas. Shell deep, black, glabrous, very thinly flared above; both lips white; exterior one very finely culated, and somewhat toothed within; inner one concave, rugose, and tuberculated. Chelmit.

Atrata, in Entomology, a species of Scolla that inhabits America. It is hairy and black; wings farinaceous, and black at the tip. Fabricius.

Atrata, a species of Tiphula. The wings are glaucous; marginal dot and body black; first segment of the abdomen and legs rufous. Fur. Suec. Linn. This is tiphula subtenuis of Degeer. Inhabits Europe. The abdomen of the female is recurved, fuscous, and very pointed.

Atrata, a species of Musca (Rhesia Fabr.) that inhabits Italy. It is black, and without spots; wings hyaline, with a black marginal spot. Fabr. Gmel.

Atrata, a species of Mutilla that is found in Africa. It is black; thorax rufous above; abdomen black, with two white bands. Fabricius. This is mutilla atrata, abdomen fascia alba, thorace immaculato. Linn. Syll. Nat. It is hairy, and has brownish wings.

Atrata, a species of Formica, with four spines on the thorax; neat depressed and margined, with two spines on each side. This is formica quadriramus of Degeer, and tapidoch of Marcgrave Braf. 232. It inhabits South America; is black, with an obtuse head; jaws very short; pediole of the abdomen minute and tuberculated.

Atrata, a species of Tenetredo, of a black colour; back with a yellow-green band, and three curves of the same colour. Inhabits England. Forster's Nov. Inf.

Atrata, a species of Pterygnaea that inhabits Siberia. It is black; wings whitish, with many spots, and two bands of black. Lepechin.

Atrata, a species of Phalaena (Geometra). The first wings whitish, and black at the base, with a broad black stripe; second pair brownish, with two white undulated streaks. Linn. &c.

Atrata, a species of Cicada found in China, and described in Donovan's Insecta of China, under the name of cicada atrata, great black Chinese frog-hopper. The colour is black, with white wings, black at the base, and veined with yellowish brown. This is supposed from its being extremely common in China, to be the species of Cicada observed by Sir George Staunton, in the route of the British embassy to the court of Pekin, and noticed in his work under the trivial name of the noisy cicada. "The music emitted by a species of cicada," says that writer, "was not of the vocal kind, but produced by the motion of two flaps or lantelle, which cover the abdomen, or belly of the insect. It is the signal of invitation from the male of that species to allure the female, which latter is quite unprovided with these organs of courtship."—On this subject it is remarked, in the History of Chinese Insects referred to above, that these organs of sound are by no means peculiar to the individual species for George describes; all the males in that section of Linnaean cicadae which Fabricius calls tettigoniidae, are furnished with such lamellae, and emit a sound in like manner; and the males of those species included in the other sections of that genus are certainly furnished with them also, although in some kinds they are very small, and in a few instances not visible to the naked eye. These organs will be noticed more particularly in speaking of the genus cicada.

Atrata, a species of Melops (Mylophor Fabr.) It is of a deep glossy black, with a yellow-waved band near the apex. It is found near the Caffian sea. Pallas.

Atrata, a species of Lytsa, the body of which is entirely brown and immaculate. Fabricius. Inhabits Barbary.

Atrata, a species of Silpha. It is black; wing-cases punctured, with three elevated lines; thorax entire. A native of Europe.

Atrata, a species of Cicindelil (Elaphrus Fabricius), described by Pallas as being entirely black and opaque. Pallas. I. App. n. 42. A native of Siberia; in form and size resembles Cicindela germanica, and it is conjectured by Gmelin may not properly belong to the Elaphrus genus.

Atrata, a species of Chrysomela, described by Geo- froy as a native of France. This kind is black, with wings of a blood-red colour. Gmel.

Atrata, a species of Cassida, about the size of cassida nebulosa, or rather smaller. It is black, with the shield of the head fimbriate in front. Found in Austria.

Atrata, in Ornithology, a species of Tanagra that is entirely black and shining. This is consilia atris of Linn. Syll. Nat., and black tanger of Latham. Is a native of India, and has the back glossed with shining bluish. About the size of a thrush.

Atrata, a species of Motacilla, called by Latham the black red-tail. This bird is six inches in length; colour black; crown lead-colour; quill feathers black; exterior margins of the ciliae rufous; the two middle ones black. Gmelin. Its country is unknown.

Atrato, in Geography, a considerable river of America, which runs into the Gulf of Mexico, near Carthagena.

Atratorius, in Entomology, a species of Ichneumon, with the feutel white; thorax without spots; three half segments of the abdomen edged with white; legs fuscous. A native of Germany.

Atratus, Hugh, in biography, born at Excham, in Worcestershire, made such proficiency in philosophy, mathematics, and medicine, that he was esteemed the phoenix of his age. He was invited to Rome by Pope Nicholas III. and addicted himself to the church, in 1281, he was advanced to the cardinalate. He died of the plague in 1287. The works attributed to him are, "Canones medicinae, super Opus Februum Isiaci Opificium," "De Genealogis Humanis," Elyor.

Atratus, in Curiology, a species of Turbo, of a blackish colour, with double alternate black and cicerous moniliform belts of granulations; and a single tooth on the pillar lip. About the size of a nut, and inhabits the Nicobar islands. Gmelin.

Atratus, a species of Murex of a deep black; whores transversely flared with tubercles; pillar with a single plain; tail straight, Born.; whores of the spine ten in number; lip crenulated.

Atratus, in Entomology, a species of Tenebrion (Stenurus Fabr.) It is a native of Egypt, and is entirely black and glossy. Gmel. Fabr. &c. The wing-cases are united, and the anterior legs bidentate.

Atratus, a species of Curculio found at the cape of Good Hope. It is glabrous, shining-black; wing-cases fluted.

Britain; Wallingford oblong Gaul Berkfiiire, Entomology, Thofe their brown; a few even Ml for membrane The dufty fuppofed deep C.
Ornithology, Cimex, Umcl legs whom There are C.
Atratus, a species of Cerambyx (Prionus Fabr.) that inhabits Ceylon. The thorax is bidentated on each side; body black; antennae moderate, with ferrated pines in front. Gmelin, &c.
Atratus, an European species of Canabius, of a black colour, with orbicular thorax, pale wing-cafes, varied with black; antennae and legs ferruginous-brown. Muf. Lekk. Linn.
Atratus, a species of Tencrio found in Egypt; it is entirely black and glabrous. Gmel. The wing-cafes are united, and the anterior legs bidentated.
Atratus, a species of Cinex, of an oblong form (Oblongus Seet.) and entirely of a deep black. Geoffroy. Inhabits France.
Atratus, a species of Hemorobius found in Africa. The wings are whitish, first pair spotted with black; body black. This is a large insect, and inhabits Africa; the thorax is hairy, and the abdomen cylindrical. Fabricius.
Atratus, a species of Ichneumon that inhabits Europe. It is black; abdomen ferruginous, with the four extreme segments black; legs rufous; antennae ferruginous, annulated with brown, and tipped with black. A native of Europe. Muf. Lekk. Linn. Obj. 1. In Gmelin's subdivision of the ichneumon genus, this insect belongs to that family which has the feulated and thorax of the same colour, and the antennae annulated or banded. Another species occurs under the same specific name, which belongs to that family in which the feulated and thorax are of one colour, and the antennae black. This is a large insect, and inhabits America. It is black; head, legs, and stipe on the tail, yellow; fling very long. Fabricius. The mandibles and stipes between the eyes are black; wings dull; stipe thrice the length of the body.
Atratus, in Natural History, a species of Echinus that inhabits India. It is hemiperialicular, and rather depressed, with very short, obtuse, truncated pines; the marginal ones clubbed and depressed. Gmelin. This is Cidaris violacea of Klein, and Violita gel-mander of Phell. Zee-eg. p. 30. The form of this kind is rather orbicular, cinnereous inclining to violet; spicis ten, very finely granulated, with a row of larger tubercles, in the larger ones disposed in a quincunx order, and a double row in the smaller ones; avenues brown, excavated, granulated, with four rows of pores; pines violet, some of them clubbed, some angulated at the tip, and some cylindrical.
Atribati, or Atribati, in Ancient Geography, a people of Britain, situated next to the Bibroci, in part of Berkshire and part of Oxfordshire. According to Camden they inhabited Berkshire; but Baxter says that their country was Oxfordshire. They occupied, as it is said, nearly the whole of the western parts of Berkshire, from the river Loden on the south-call, the banks of the Thames on the north-west and west, and the hills of East Ilsley, Lamborn, and Abilbury on the south. The Atribati were one of those Belgian colonies which had come out of Gaul into Britain, and there retained their ancient name: for they were a tribe of the Belgae, who inhabited the country which is now called Artois. They are mentioned by Cesar among the nations which compos'd the Belgian confederacy against him; and the quota of troops which they engaged to furnish on that occasion was 15,000. Comius of Arras was a king or chieftain among the Atribati in Gaul in Cesar's time; and he seems to have posses'd some authority, or at least some influence, over our Atribatii in Britain; for he was deputed by Cesar to persuade them to submission. Hence it is probable that this colony of the Atribatii had not been settled in Britain very long before that time. These were among those British tribes which submitted to Cesar; nor do we hear of any remarkable resistance which they made against the Romans at their next invasion under Claudius. It is probable, that before this second invasion they had been subdued by some of the neighbouring states, perhaps by the powerful nation of the Cattivellani, which will account for their being so little mentioned in history. Calliva Atratium, mentioned in Antonine's Itinerary, and called by Polemy, Calca, seems to have been the capital of the Atribatii; though our antiquaries differ in their sentiments concerning the situation of this ancient city; one, with Horley, placing it at Silchester in Hampshire, near the confines of Berkshire; Stukeley, at Farhamp; and most others, with Camden and Baxter, placing it at Wallingford in Berkshire. It has been doubted, whether the country of the Atratii and Atribatii was within the Roman province, or in that called Britannia Prima, or in that called Flavia Caesaris; but it seems most probable that it was in the last of these provinces. Henry's Hist. vol. i. p. 248. vol. ii. p. 413. See Ascalites.
Atrrella, in Entomology, a species of Phalena (Timia) that inhabits Italy. The wings and body are black and bronzed; apex of the posterior ones, and the tail tateaceous.
ATRESIA, from α, and τής; whence τής, to perforare; in Surgery, imperforation, or the state of those persons who want some natural aperture.
ATRETI, those perfons of either sex, in whom the anus, or genitals, are imperforate, or closo, whether naturally, or occasioned by some accident or diffecc, as the growth of some lefliy excrecence, or a membrane which lops the orifice.
ATRI, in Geography, a town of Italy, in the kingdom of Naples, and province of Abruozzo Ultra; nine miles call of Teramo. See Adria.
ATRIB, a village of Egypt, on the right bank of the Damikta branch of the Nile. A little below, runs a large canal, which empties itself into the lake Memzela, towards the easter part of it. The cottages that compose this village, cover the ruins of the ancient Atrib, which, according to Ammianus Marcellinus, was one of the most considerable towns in Egypt. But no remains of its former extent and grandeur now exit.
ATRIBUNIE, a river that runs through the western part of the island of St. Domingo, and empties itself into the sea.
ATRICAPILLA, in Ornithology, a species of Emberiza, of a reddish brown above, beneath cinnereous; chin white; crown yellow; forehead, and stripe through the eyes black. This is Emberiza atricapilla of Gmelin, and black crowned bunting of Latham. It inhabits the Sandwich Isles. There is a variety of this bird in which the breast is waved with black; and also another bird corresponding with the first in some respects, but in which the crown is not yellow; this is suppos'd to be the female.
The black-crowned bunting is seven inches in length; upper part of the plumage reddish brown, and each feather marked longitudinally with a dusky colour; coverts and quills edged with a paler colour; the throat, breast, and belly are ash-colour; the bill marked along the middle with yellowish bull; tail brown; legs brown; claws dusky. Lath.
Atricapilla, a species of Muscicapa, called by English naturalists the cold-finch and pied fly-catcher. The colour is black; beneath, spot on the front, and another on the wings, white; outer web of the exterior tail feather white. Kramer, Gmelin, &c. This is motacilla remigesibus ultimo dimidiatum extremorum albo of Linn. Eu. Suec. rubetra anglicana of Britten. peculiar atricapilla &c mutatas Ablr. Orn. 2. p. 758. le turquet d'Angleterre of Buffon, cold-finch of Willagby, and pied fly-catcher of Pennant and Latham.

The length of this bird is four inches and three quarters; bill black; irides hazel; general colours black and white; the upper part of the body, wings, and tail black; upper tail coverts intermixed with black and white, and sometimes entirely black; legs of the same colour. Female brown in those parts where the male is black, and delineate of the white spot on the forehead. This bird inhabits Europe. In England it is rare, and chiefly found in Yorkshire, Lancashire, and Derbyshire. Vide Lath. Gen. Syn.—Donov. Brit. Birds, &c.

Of this species there are two or three varieties: the first, muscicapa nigra, and the gale-mouche noir of Buffon. Orn. a bird about five inches and a half in length, and differing from the last in having a mixture of grey on the upper parts, the thighs mixed brown and white, and the three outermost tail feathers white on the margin. The other is motacilla nigra tergata of Cramer, and the gale-mouche noir a collier of Buffon: this is like the first kind, but has the white on the neck pealing entirely round, and forming a collar. It is met with in Lorraine and Brie, where it arrives in the middle of April. The principal food of this bird is flies. A third kind, called by Linneus muscicapa variegata, inhabits India; this is about the size of the white wagtail; general colour brown; forehead, frons of the head, and underparts white; and a line of white extending also from the shoulders to the middle of the back; outer feathers white at the tip.

Atricapilla, a species of Motacilla, well known in England by the name of black-cap, and in France by that of la fauvette à tête noire. It is specifically described as being tesselaceous, cinereous beneath; cap dusky or black. Linn. &c. The length is five inches and a quarter; bill brown; top of the head black; upper parts of the body greenish, ash-colour; sides of the head and under parts grey, becoming almost white near the vent; quills and tail cinereous brown; the two middle tail feathers rather shorter than the rest; legs lead colour; claws black. The female differs in having the head of a ferruginous chiefcut colour instead of black.

This bird inhabits Italy, and other parts of Europe to the northward of that country, and is not unfrequent in England during the summer months; it arrives here in the spring, and retires in September. In Italy it builds twice a year, according to Olina, with us only once; the nest is generally placed in some low bush, and is composed of dried草, mixed with a little wool, and green mosses; the infide is lined with the fibres of plants, and thinly covered with horse-hair; the eggs are five in number, of a pale reddish-brown colour, mottled, and sprinkled with a few larger dark spots. It feeds on insects, but not exclusively on them, as it will eat the fruits of spurge, laurel, and ivy. The song of this bird is amazingly fine, and in some particular resembles that of the nightingale; emulating in delightful sweetness and melody the note of that charming song-titfres, and being only deficient in that wild variety and extent of modulation, for which the nightingale is so much admired. The black-cap is from this circumstance called by some the mock-nightingale.

Dr. Latham describes three varieties of this species of warbler; one in which the body is entirely variegated with black and white only; curruca albo et nigro varia of Brifon, scissula varia of Aldrovandus, and first variety of Gmelin. Another, a bird somewhat larger, having the upper parts almost black, with a white throat, and sides almost grey; this is curruca furofere nigerianas, gula aliss of Gmelin, the second variety of that author, and petite colonbodes of Buffon. And the third variety is foulvete verdure de la Loufane of Buffon, and curruca fulvus grife, gula superciliaris aliss of Gmelin; the under parts of this is greyish; the throat, and streak above the eye white; the hind part of the neck deep ash-colour; sides and back pale brown, tinged with green; wings and tail blackish.

Atricapillus, in Entomology, a species of Turdus, of a brown colour, with a black head; belly and rump rufous; and a black spot on the wing. Gmelin. This is nerte à tête noire du cap de Bon Espércce of Buffon. It inhabits the cape of Good Hope; and is about nine inches in length; the belly is striped with brown; tail cuneated, the feathers pale at the tips.

Atricapillus, a species of Carabas, of the winged kind. The thorax is rufous; wing-cases tesselaceous and obsolete; head black. Fabricius. Of Gmelin describes it as being yellow, with a black head and very obtuse wing-cases.

Atricapillus, a species of Staphylinus that is found in England. The thorax is rufous; wing-cases fuscous, with a dot at the base and posterior margin white. Fabricius.

Atricapillus, in Ornithology, a species of Lanius that inhabits Surinam, and is called by one the Surinam frirke. The tail is wedge-shaped, and with the crown, neck, shoulders, and wings, black; body above monfé-colour; beneath of a bluish ash-colour. Merrem. Beyer. &c. The length of this bird is five inches; wings short; margins of the wing-coverts and secondary quill-feathers white; all the tail-feathers, except the two middle ones, tipped with white.

Atricapillus, a species of Psittacus called by Brifon ara Moluccenfis varia. It is a native of the Moluccas, and about fourteen inches in length; colour above blue; chin, throat, and breast red; belly and vent green; crown black; neck green and red. Gmelin. The wings and upper tail-coverts are blue, lower green, varied with red; tail green above, beneath red, edged with black. Klein calls this psittacus capite negro, collari variis, and Buffon grande pericée à bandeau noir.

Atricapillus, a species of Charadrius, called by Latham the black-crowned plover. Above it is cinereous brown, beneath white; bill and legs red; crown black, en-circled with white; neck and breast cinereous, and terminating in a transverse dusky streak. Inhabit New York. Gmelin. The front is black; bill black at the apex; base of the tail white, blackish near the extremity, tips white.

Atricapillus, a species of Parus, found in North America, and called the Canada titmouf of Pennant and Latham. The cap and throat are black; body cinereous, and white beneath. Brifon calls this parus atricapillus canadensis, and Buffon melange à tête noire de Canada. The length of this bird is four inches and a half; it feeds on worms and insects, and bears cold with remarkable perseverance. The upper tail-coverts are white; greater wing-coverts brown, edged with grey; quill feathers brown, with the exterior edges grey, and the inner ones whitish; middle tail-feathers cinereous; lateral ones brown, with grey margins and claws blackish. Gmelin, &c.

Atrices, or Atrices, in Surgery, small tabules about
about the anus, which sometimes disappear, and then return again, at least while in their early flake.

The atrices are ranked in the number of consolida or fist.

Some authors also give the denomination atrices to a kind of latent wounds in the extremity of the rectum, which however do not perforate the fame.

**ATRICILLA**, in Ornithology, a species of *Larus* of gull, called by Willughby Batther's great ash-coloured fawm; and in the Arctic Zoology of Pennant and Gen. Syn. of Latham, the laughing-gull. Briff. names it gavia ribundus, and Buff. mouette rieule. This bird is very common about the shores of America, and places contiguous. Its food is fish and marine worms; and it is specifically distinguished from the rest of the gull tribe by being of a hoary grey colour, with a blackish head, red bill, and black legs. Oeum. Nov. Act. Stockh. &c.

**ATRIC II.**, in Entomology, a species of *Chrysopaella*, from a black colour, with the thorax, wing-sheaves, and parts of the legs taltaceous. Linn. Faun. Spec. Fabricius describes it as chrysonella saltatoria nigra, thorace-elytrique cinereus. Spec. Inf. *Chrysonella melanocephala* of Degeer is supposed to be a variety of this species, by Gmelin. Inhabits Europe, and is found on various plants.

**ATRICILLOIDES**, in Ornithology, a species of *Larus*, that inhabits Siberia, about the salt lakes. The colour is reddish white, with the head, orbits, and neck black; back and wings cinereous; legs scarlet. Foulk. I. 3. p. 355.

**ATRIENS**, in Antiquity, a kind of servants or officers, in the great families at Rome, who had the care and inspection of the atria, and the things lodged therein.

These are otherwise called atrarii, though some make a distinction between atrarii and atriai; suggesting that the latter were an inferior order of servants, perhaps affil-

ants of the atrienes, and employed in the more servile of the offices of the atrium, as to attend at the door, sweep the area, &c.

The atricides are represented as servants of authority and command over the rest; they acted as procurators, or agents of their master, in selling his goods, &c. To their care was committed the statues and images of the master's ancestors, &c. which were placed round the atrium; and which they carried in procession at funerals, &c.

In the villas, or country-houses, the atricien had the care of the other furniture and utensils, particularly those of metal, which they were to keep bright from rust. Other things they were to hang from time to time in the fun, to keep them dry, &c. They were clothed in a short white linen habit, to distinguish them, and prevent their loitering from home.

**ATRIP**, in Nautical Language, is applied either to the anchor or falls. The anchor is arip, when it is drawn out of the ground in a perpendicular direction, either by the cable or buoy-rope. The top-falls are arrip, when they are hoisted up to the mast-head, or their utmost extent.

**ATRIPALDA**, in Geography, a small town of Naples, in the Principato Ulter, built upon the ruins of the ancient Abellum Maricum, and standing upon an eminence com-

posed of strata of soft coloured tufa. The inhabitants are suppos'd to have retired from it in the middle ages, and to have founded the present city of Avellino, as more conven-

tient for traffic. Atripalda carries on some trade in paper, cloth, and hard-ware. 'This town was first held in fe by the Montforts; it was afterwards granted by Ferdinand I. to George Caflriot, or Scand-berg, prince of Epirus, as a reward for his timely assistance in 1400; and it now gives the title of duke to the prince of Avellino's eldest son.

**Species.** 1. *A. bulbosa*, tall, shruny orache, or Spanish sea-fur-purflane. Stem shruny; leaves deltoid, entire. Root perennial, woody, branched. The whole shrub is white; stems from four to six inches high or more, dividing into woody brittle branches; leaves scattered on long foot-

s; flowers small, purplish, at the ends of the branches. It grows in hedges near the sea about Nice, also in Spain, Portugal, Sicily, &c. According to Parkinson it was cultivated here in 1653; 2. *A. portulacoides*, dwarf shruny orache, or common sea-fur-purflane. Hudf. With. Lightf. Eng. Bot. 4. 1. 261. Stem shruny; leaves oblong. A low underhurbr; leaves narrow, whitish; branches angular; flowering, glaucous; flowers in crowded spikes terminal, yellow. It grows near the sea in salt marshes, flowering in July and August. 3. *A. plana.* Stem underhurbr of procumbent; leaves ovate, feillé, quite entire; the lower ones subdentate. Stem three or four feet long, with de-

clining branches; leaves thickish, of a silver glaucous colour; flowers yellow at the axils of the upper branches. A native of France and Spain. 4. *A. rosea*. Villars Dauph. 2. 565. Stem herbaceous; leaves hoary, ferrated; fruit quadrangular, toothed. Stem erect, somewhat angular, white, smooth, branched, a foot and a half high; leaves al-

ternate, subflabellate, rhomb-heart-shaped, finnate-toothed, co-

vered with a farinaeous white powder; flowers in close clus-

ters, axillary; valves of the fruit hoary and finely notched. A native of the south of Europe. Annual. 5. *A. merika*, Siberian orache. Stem herbaceous; leaves deltoid angular, calyxes of the fruit muricated on the outside. This is the same here as the *A. hortensis*. The fruit is tomen-

tofo at the base, and muricate on the outside; the leaves are silvery beneath, and the flowers white. A native of Siberia. Annual. 6. *A. tartarica*, Tartarian orache. Hudf. 431. n. 2. 6. "Stem herbaceous; leaves deltoid, finnate-toothed, waved, alternate." According to Linnaeus, this rific

five or six feet high. Mr. Hudson considers it as a variety of the lachma produced by cultivation. 7. *A. hortensis*, garden orache. Gem. Sib. 5. 71. Gerin. Frut. 1. 352. "Stem erect, herbaceous; leaves triangular." Root an-

nual; stem above three feet high; leaves thick, pale, and variable in their shape; calyxes of the calyx ovate-cordate, frayed, entire. A native of Tartary, and cultivated by Gerard in 1596. It was formerly cultivated as a culinary herb, being used as spinae, and it is still eaten by the French. There are some varieties of it which depend wholly upon colour. 8. *A. bidentatis*, jagged sea orache. Hudf. With. Lightf. Eng. Bot. 5. 107. "Stem herba-

ceous;
Propagation and Culture. 1, 2, 3. may be increased by cuttings planted in any of the summer months, on a shady border; where, if they be daily watered, they will be in a little to transplant the Michaelmas following. 7. must be grown for use in the spring, or at Michaelmas, soon after the seeds are ripe, which is better. These plants require no other care, but to hoe them when they are about an inch high; to cut them down where they are too thick, leaving them about four inches afooter, and to clear them from weeds. When the plants are about four inches high, it will be proper to hoe them a second time, and if this be well performed in dry weather, the ground will remain clean until the plant is fit for use. Where it is grown on a rich soil, and the plants are allowed a proper distance, the leaves will be very large and in that the excellence of the herb confits. Unless it be eaten when young, the flalks become tough and good for nothing. The seeds will ripen in August, when the plants may be cut or pulled up and laid on a cloth to dry; after which the seeds may be beaten out and put in bags to dry. Moif of the other sorts, so far from being cultivated in gardens, are to be rooted out from them as rank weeds, Martyn's Miller's Diet.

Atriplaxis. See Atriplex, Asyris, Blitum, Chenopodium, and Galenia.

Atriplex, in Entomology, a species of Scardebus (Melolontha). This insect is oblong, vilose, pale; future and apex of the wing-cases black; head of the head reflected. A native of Barbary, and feeds on the atriplex halmifola; in size and appearance resembles S. rubicorns.

Atriplex, a species of Cusculio that is found on the shores of Norway. It is long and black: thorax shining; wing-cases fluted and obtuse. Gmelin.

Atriplex, a species of Phalina (Noton). The first wings are clouded with brown, with a yellow bifid mark in the middle. Pn. Sv. Fabr. &c. The larva is naked, reddish, dotted with white, and marked along the back with a brown line. Pupa, naked and brown.

Atriplex, a species of Aphid that infests the atriplex hortensis. The body is glossy black, plaited at the sides; thanks pale; tail obtuse. Fabr. &c.

Atriostrix, a species of Cusculio. It is cincinnati, with the frout arched and black. Inhabits Leipzig, Paykull.

Atrium, in Ancient Architecture, one of the interior divisions of the ancient Roman houses. Aulus Gallus tells us, that even in his time many learned perons confounded together the terms atrium and velibulum. Cecilius Gallus teaches us, that the velibulum was not a part of the interior of the house, but only a large recet at the principal entrance, perhaps analogous to the modern loggias of the Italians. Cicero, in a letter to Atticus, seems to express the same thing, when he says, that in passing through the faced drect, when he was purfied by affaffins, he took refuge in the velibulum of Tatius. "Seecefl in velibulum Caii Tatii Domitianus." From the time of Aulus Gallus, the fate uncertainty of the exact meaning of these words continued, and they became almost synonymous. It must be till more difficult at the present time, to assign to the atrium its true situation and use.

Martial places the colossus of Nero in the atrium, and Suzonius in the velibulum; from whence it refults that one of them must have employed one of these terms improperly. Vitrarius even sometimes employs the word atrium for cavedium. Virgil by this verbe, "apparet domus aenus et atria longa patefcent," gives us to understand, that the atrium was an interior part of buildings; and it appears certain,
certain, that this was a particular place in private houses, palaces, and temples.

From the description which Vitruvius gives us of it, it appears to have been an oblong room, having its breadth divided into three parts by two rows of columns. He gives rules for placing these columns according to the general proportion of the atrium.

The atrium was situated after the cavendum which was what we commonly call the court, and immediately before the tablinum. It was in the atrium that the Romans placed the statues of their ancestors, and it was also sometimes used as an eating room, though they had also other places defined for the purposes of the table. This is proved by Virgil, who in describing the place where they made their repast, says,

"Crateras magnos flatantem et vina coronant,
Fit inceptus tecinis vocemque per ampla volutant.
Atria dependent lynchii laqueabius aureis."

It follows from this, that we must consider the atrium as one of the interior parts of the house, in which it differed from the vestibulum, and that it was covered, which distinguishes it still more from the cavendum or the eminentium.

Some temples had also an atrium: of this number was the temple of Vesta, and that of Liberty. It was in the latter (says Titus Livius) that they deposited the holocausts of the Tarentines. It appears that it was a covered semi-circular court, if we may judge from the ancient marble plan of Rome, which is preferred in the capital, on which we still read these words "atrium libertatis."

If we may believe the historians, the ufe and form of the atrium were borrowed from the Etruscans, and this appellation comes from the city of Atria, or Adria, which gives name to the Atrici or Adriatic sea, and where this sort of porticoes was much used.

Atrium, in Ecclesiastical Antiquity, denotes an open place or court, before a church, making part of what was called the narthex, or ante-temple.

The atrium, in the ancient churches, was a large area, or square plat of ground, surrounded with a portico or colonnade, situated between the porch or vestibule of the church, and the body of the church.

Some have mistaken the atrium with the porch or vestibule, from which it was distinct; others with the narthex, of which it was only a part.

The atrium was the mansion of those who were not suffered to enter farther into the church. More particularly, it was the place where the first clafs of penitents ftood, to beg the prayers of the faithful, as they went into the church.

Atrium is also used, in the Canon Laws, for the cemetery, or church-yard.

In this fence we find a law, prohibiting buildings to be raised in atria ecclesie, except for the clergy; which the glossary explains thus: id eft in cemeterio, which includes the space of forty paces round a round a large church or chapel.

A T R O P A, in Botany, (from Atropos, the third flate, who was suppos'd to cut the thread of life) deathly nightshade. Lin. g. 249. Schreb. 335; Juss. 125; Garvin. t. 131. Claffe, pentandria monogyna. Nat. Ord. Eriaceæ. Species. Juss. Gen. Char. Cal. pennath one-leaved, five-parted, gibbous; divisions acute, permanent. Cor. one-petalled, bell-shaped; tube very short; border ventricose, ovate; longer than the calyx; mouth small, five-crested, spreading; divisions subaqueous. Stam. Filaments five, pubescent from the base of the column, and of the same length with it, converging at the base, above diverging outwardly, bowed; anthers thickish, rising, glob. germ feroxiatum: style filiform, the length of the flamen, inclin'd. Stigmea headed, rising tranverfely, oblong. Per. berry globular, sitting on a large calyx, two celled. Receptacle fleshy, convex on both sides, reniform. Seeds, very many, reniform.

Specios. 1. A. Mandragora, mandrake, Woodv. Med. Bot. t. 225. "Stemclefs, flapes one-flowered." Root perennial, large, tapering, three or four feet long, externally brown, internally whifh. From the crown of the root arises a circle of leaves, which are large, ovate, flattened; veined, they fit close to the root, and are of a deep green colour, and fettled finel; among these arise three or four fhort slender flapes, each supporting a fingle flower of an herbaceous white colour; fruit a globular loft berry of a yellowish colour, and about the fize of a nutmeg. A native of the fouth of Europe. It was cultivated here, according to Turner, in 1562. The supernations and absurd florics related of the mandrake would not now for a moment impofe on the molt credulous and ignorant. The fupposed reftemblance of fome of the roots to the human form, the danger of taking them out of the ground, as well as their furprising effects, feem to have been the invention of charlatanical knavery and imposture. Beoherave efed the leaves as a cataplaft with fuccefs in cafes of indurated tumours, and Hoffberg experienced the like effects from the roots in glandular swellings; the latter also found that three grains of the root given internally had a confiderable narcotic effect in mitigating arthritic pains. See Woodv. l. c. 2. A. belladonna, deadly nightshade, Huds. 93. With. 252. Smith. Brit. 253. Curt. Lond. t. 16. Woodv. Med. Bot. t. 1. Eng. Bot. 592. "Stem herbaceous; leaves ovate, entire." Root perennial, thick, fleshy, creeping; it falks herbaceous, annual, erect, firm, three feet high, round, branched, leafy, subpubefcent; leaves lateral, two together, of an unequal fize, petioled, ovate, acute, entire, smooth, and of a dull green colour; peduncles lateral, subaxillary, solitary, one-flowered, nodding; flowers of a dirty violet colour; calyx rather pubefcent, vilceous; anthers large, white; berry defulted, furrowed; when ripe of a fhining black colour, and abounding with a purplish juice. It grows in waste-ground and gloomy lanes. &c. This plant has been long known as a very strong poison of the narcotic kind; the berries, which are faid to be lefs powerful fully than the leaves, have produced many instances of their fatal effects, particularly upon children, who are readily tempt'd to eat this fruit by its alluring appearance and sweet taste. Whether these berries eaten in different fates of maturity renders them more or lefs deleterious, has not been acertained; but we are told that in fome-inflances, one berry, or even half of one, has produced a fatal effect; while Halker informs us, that he has been a fellow-fludent of his cat more than three or four without fuffering any inconvenience from them. The confumptions produced by this poison are vertigo, delirium, great thirst, painful dégélution, and retchings, followed by furor, ilidor dentium, and convulsions; the eye-lids are drawn down, the uvæ dilated and immovable, the face becomes red and tumid, and fimits affect the mouth and jaw; the fenfibibility and irritability of the body fuffer fuch great diminution, that large and repeated doxes of the strongest emetics produce no fenfible effect;
effect; the pulse is small, hard, quick; and subful tus ten-
dinium, rufius fardionus, and coma, close the fatal scene.
Vinegar liberally drank has been found most efficacious in
obviating the effects of this poison. On opening the bodies
of those poisoned by this plant, inflammation and erosions
of the stomach and intestines have been discovered. A simi-
lar effect was produced in the stomach of a horse, at the
Veterinary College, from a large dose of opium, viz. three
ounces. The leaves of the belladonna were first used exter-
nally to diffus setharios and cancerous tumours, and as
an application to ill-conditioned ulcers, and their good
effects in this way at length induced physicians to employ
them internally for the same disorders, and we find a con-
iderable number of well-authenticated facts, which prove
them to have been of important service. Dr. Cullen says,
"I have had a cancer of the lip entirely cured by bell-
adonna; a fheeriness in a woman’s breast entirely diffus-
de by the use of it; a fore a little below the eye, which had
put on a cancerous appearance, was much mended by the
internal use of this plant; but the patient having learned
somewhat of the poisonous nature of the medicine, refused
to continue the use of it, upon which the fore again spread,
and was painful; but upon a return to the use of bellad-
ant, it was again reused to a considerable degree;
when the same fore again returning, the use of it was
again laid aside, and with the same consequence.”
The root is much less powerful than the leaves. See Wood’s. I. e.
and Murray App. Med. 3 A. phaloides, Peruvian deadly
night-shade. “Stem herbaceous; leaves entire-angular;
calyces cloved, acute-angular.” Root annual, fibrous;
stem spreading, two feet high; leaves alternate, smooth,
oblong, running down the footstalk; peduncles fubaxillary,
solitary, naked, one-flowered; calyx ovate, deeply five-
parted; leaflets fagitate-ovate; corolla bell-shaped, slightly
fivetoned, blue, with a white eye, having five blue spots;
berry about the size of a cherry, with five sharp angles,
and inclosed in a ventricole bladder. A native of Peru.
Cultivated by Miller. 4. A. folancea. “Stem shrubby;
peduncles solitary; corolla bell-shaped; leaves subovate.”
Six feet high, somewhat branched and angular; leaves alter-
ate, usually many from the buds, petioled, entire, naked;
peduncles axillary, one-flowered, fiform; the length of
the leaves; flowers pendulous. A native of the cape of Good
Hope. 5. A. arboreum, tree atropa, belladonna frett-
eens, &c. Plumb. 46. f. 1. “Stem shrubby; peduncles
crowded; corolla revolute; leaves oblong.” A small tree
or shrub. Leaves alternate, in tufts towards the ends of
the branches, lanceolate-ovate, acute, entire, nervcd, of
a dark colour; flowers peduncled, heaped, white, fragrant,
noddling; peduncles numerous, one-flowered, white, or
white; corolla somewhat bell-shaped, narrow at the bottom, swelling
at top; filaments twice as long as the corolla. This spe-
cies is often tetradrious. A native of South America and
Jamaica. 6. A. frutescent, shrubby atropa. “Stem shrubby;
peduncles crowded; leaves cordate ovate, obtusa.” Six or
eight feet high; leaves alternate, roundish; flowers come out
between the leaves on short peduncles, and reflexed to the
colour of belladonna, but much smaller, and of a dirty yellow
7. A. herbaeeus, herbaceous atropa, Mill. Dict. n. 3. “Stem
herbaceous; leaves ovate, nerved, with waved edges.” Root
perenni; leaves clamelled, upon two feet high, dividing
into two or three branches; leaves four inches long and
three broad, having several transverse prominent ribs on
the under side; flowers white, bell-shaped. The seeds were
sent to Mrs. Miller from Campeachy. 8. A. procumbens,
wheel-flowered atropa, Cavan. Hisp. n. 80. t. 72. “Stem
procumbent, herbaceous; leaves twin, unequal, ovate,
smooth; flowers in umbels.” Root annual; stem grooved,
much branched, three feet high; leaves sharp-ovate, running
down the petiole, smooth, entire, one-nerved, glaucou;
common peduncle, solitary, scarcely an inch in
length; nys of the umbel from two to five; corolla her-
бaceous, yellow, wheel-shaped, which sufficiently differ-
itises it from all its congeners. A native of Mexico.

Propagation and Culture. 1. Mandrake is propagated by
seeds, as soon as they are ripe, when they are to be sown
upon a bed of light earth, and occasionally watered with
water. In August they must be taken up very carefully
and transplanted into the places where they are to remain,
observing that the soil be light and deep, for the roots run
far down, and will grow to a large size in a few years if
not interrupted by gravel or chalk, or rotted in winter by
wet soil. The plant should also have a warm situation.
The root will remain found above fifty years, and continue
to be as vigorous as a young plant. Deadly nightshade
may be propagated both by its roots and by its seeds; it
requires a shady situation. If the seeds of the third spe-
cies be permitted to fatten, the plants will come up the
following spring, and may then be transplanted into the
borders of the pleasure garden, where they will grow to
a large size. Species 4th, 6th. may be propagated by
seeds, which should be sown in a hot-bed in the spring;
and when fit to be removed, they should be each put into
a separate small pot filled with loamy earth, and thinned
until they take root. The 4th and 5th may be placed with
other hardy exotic plants in a sheltered situation, and in
October they must be removed into the green-house. The
5th, 7th, and 8th, must be kept in the bark-flour. The
7th may be increased by parting the roots. See Martyn’s
Millar’s Dict.”

ATROPATENE, of ATROPA, in Ancient Geogra-
phy, a country of Asia, occupying the north-west part of
Media, and lying between mount Taurus and the Caspian
sea. It is said to have taken its name from one Atropatus,
who, being governor of this province in the time of Darius,
the last Persian monarch, oppressed Alexander the Great,
and upon the defection of the Persian monarchy, feized
this part of Media, and transmitted it to his polity,
who held it as sovereign to the time of Strabo. (Geog.
lib. xi. p. 525.) It was a cold, barren, and inhospitable
country, and on that account allotted by Salamanzer for
the residence of many captive Iraclites, after the conquest
of their kingdom. Its inhabitants, according to Polybius
(l. v. p. 462.), were good soldiers; and we learn from
Strabo, that its kings could bring into the field 40,000
foot and 20,000 horse. The metropolis of Atropatene was
Gaza.

ATROPHY (ατρόφεις) from ατρ', privative, and τροφή,
nutrition, in Medicine, a defect of nourishment, and consequent
emaciation. It differs from phthisis, by being unaccom-
ppanied with cough, and purulent expectoration; and from
tubes, by the absence of hectic fever. This distinction,
however, of systematic writers, between tubes and atrophy
is not altogether so satisfactory as could be wished; since
atrophy in its advanced stage is often attended with a symp-
tomatic fever resembling the hectic. In the fourth volume
of his First Lines of the Practice of Physic, Dr. Cullen has
hastily acknowledged that he was not satisfied with his
arrangement of the several species of atrophia and tubes.
He even expresses a doubt, whether the distinction attempted
in Nofology, between the two diseases, will properly apply;
being of opinion that there are certain affections of the same
nature, which sometimes appear with, and sometimes without
fever.
fever. If, however, in compliance with system, the distinction is to be made, we would restrict the term tabes to emaciations proceeding either from glandular and visceral obstruction, or from putrefaction and ulceration. If this be done, the tabetic species of tabes in Cullen’s Nomenclature will rank under atrophy; of which we shall then have six species placed in the following order: viz. Atrophia transitoria; A. ameliorata; A. debilium; A. cacochymica; A. veneris; A. complacent ductus thoracie. The causes which induce the first-mentioned species, are long-continued and profuse evacuations; such as an insufficient flow of saliva, profuse perspirations, diathesis alba, flour albus, seminal emisions, abuse of venery, continuing to suckle too often or too long in the case of nurses, &c. &c.; chronic diarrhoea and retention of the food; and, after being swallowed, are among other causes enumerated by practical writers: of these two, the first brings on that emaciation which is commonly known under the name of marasmus; the latter (viz. vomiting), when it arises from a fébrilité of one of the orifices of the stomac, or other organic disease of that viscus, we would rather refer to the causes which produce tabes. When the vomiting depends upon mere irritability, without injured organisation, it will then give rise to atrophy. The most frequent form under which the atrophy ameliorata appears, is, that which is described by medical writers under the name of tabes dorsalis. It is occasioned by a loss of strength and force of the seminal fluid, and happens to those who are too much addicted to venery, to those who inflame their imaginations with licentious ideas, and especially to young women who indulge themselves in the obscene and debauched practice of onanism. This diseased was well known to the ancients, and is described in the collection of writings attributed to Hippocrates. (vak. v. 222, lib. ii.) With the frequent emisions of semen there is a pain in the back and loins, colics, headaches, giddiness, and diminution of fight; oppression of the breath, hurry of the spirits, restlessness nights, latitude, paleness of the countenance, wasting of the flesh, pains of the joints, tremors, and in some instances palsy, with a failing of the memory and dejection of mind. In putting about the cure we must first remove the exciting causes, by forbidding venereal intercourse, and restraining manual pollution (manumutation). The soft downy bed must be exchanged for a hard one, and early rising enjoined. The patient must abstain from strong wines, especially white wines, hot liquors, and seasoned food, and take to a plain, mild, nutritious diet, of which milk and its preparations should constitute the chief part. Sago, tapioca, animal jellies, and eggs, will also be proper. The common cold-bath or sea-bathing should be employed, with daily exercise on horse-back; and besides the free use of cow’s milk, alls milk should be taken at least once a day. The proper medicines will be the Peruvian bark, the hellebore, the infusion of the red root, the infusion of catechu, and chalybeates; or if the salt-hardened metallic preparations prove too stimulant, the zincum vitriolatum. In some of these cafes, mild opiates, or the eicuta, may also be given with advantage. Collyrions should be prevented by occasional doses of the eleutheraeum femina, or oleum mentis, or magnesia and rhabarbar. (See Tiffot in O’Nan.) The same means will be equally suited to most of the other varieties of atrophia transitoria. When it is occasioned by profuse perspirations, the filiphophor acid should be given with the other tonics; and when the urinary evacuation is excessive, the same remedies as in diabetes; which fee. When this disorder occurs in nurses giving too much suck, the allurant vegetable substances (the Peruvian bark excepted) and metallic salts above mentioned will not be proper; a more liberal use of fermented liquor and animal food should be allowed, and the infant should be weaned. When it proceeds from a diarrhoea, opiates may be given more freely, joined with tannaceous powders, and small doses of specie-cusana. When it is occasioned by the food being rejected from the stomac shortly after it is swallowed, the peculiar condition of that organ, on which the vomiting depends, must be ascertained and remedied accordingly. In such cases, glyders of milk and animal jellies should be administered once or twice every day, until the disposition to inverted action is removed.

A. debilium. To this species belong the nervous atrophy, and the emaciation which accompanies old age. It depends upon a debility of the organs of digestion and nutrition. In the first instance, it is sometimes the consequence of close application to bathing or fludic; and excessive anxiety, grief, a longing after one’s native country or a beloved object, with other depressing passions. In such cases, a removal from the scene of fludic or hussines, and from the source of anxiety, regular exercise and proper recreations, will form the basis of the cure. At the same time, bitters, chalybeates, and opiates, should not be omitted. (Morton de Atrophia, lea Phthisi nervosa.) When the disorder is the consequence of old age, much relief cannot be expected. In that case, little more can be done than to render the diet as nutritious as possible.

A. cacochymica. When the emaciation in this species is connected with a fecubitic acrimony, the remedies proper for correcting the state must be employed; such as subacid fruits, fresh malt liquor, &c. all salted meats being strictly avoided. When it is connected with a phthisic acrimony, the cure should be attended by mercurials, opiates, and the guaiacum and farfaparilla decoctions, with the warm bath. When it occurs in a ricketsy constitution, the same treatment as in rachitis will be proper. (See Rickets.) If this species (the A. cacochymica) is accompanied with securitic or phthisic forces, it should be referred to tabes.

A. veneris. This happens when the vegetative powers are impaired or destroyed by vegetable or mineral poisons. Among the vegetable poisons which prove the cause of atrophy, may be mentioned the album of green tea in water, and the chewing of tobacco in men. In like manner the opium-eaters in the Levant and other parts of the east are affected with atrophy. Another poison extracted from vegetable substances undergoing fermentation, which produces the same effect, is alcohol, or brandy, rum, &c. Among the mineral poisons which have been observed to cause this disfigurement, may be mentioned lead and arsenic. The remedies in this species of atrophy must be varied according to the kind of poison by which it was induced. (See Poisoness.) In the Nosological System of Dr. Cullen, this species of emaciation is ranked under tabes; but as it is not accompanied either with glandular obstruction, or with putrefaction or ulceration, we have conceived it to belong to the present genus, and have accordingly introduced it here.
The last species we have to notice is the A. à compressione ductus thoracici. This takes place when the thoracic duct is so compressed by a tumor or other mechanical cause, that the transmission of the chyle through it is either partially or wholly intercepted. In the latter case it is irremediable. Fortunately this species of atrophy is of very rare occurrence. See Morton's Phthisiologia; and Hoffian de Atrophia, Suppl. II. 1. Cullen's Practice of Physic, vol. iv.

ATROPICA, in Entomology, a species of Mantis described by Pallas. It is native of the island of Java; on the thorax are four spines; wing-cafes short and mucronate at the base.

ATROPOS, a species of Sphinx, with yellow posterior wings falcated with brown, and yellow abdomen with black rings. Varieties of this species differing in size, colour, and some peculiarities of the marks on the anterior wings, are found in Egypt, India, the cape of Good Hope, America, and Europe. It is the largest of the European insects of the lepidopterous tribe, and is certainly a beautiful creature. In England this kind is rare, and is called the death's head hawk-moth, from certain characteristic and very singular marks on the thorax, by which the figure of a human skull is strongly depicted. These insects for this reason have generally been regarded as an ominous prefiguration of some approaching calamity by the peafantry in most countries where they have appeared by chance; and Linnæus has himself named it after one of the three fates of the heathen mythology. The larva feeds on the jasmine, potato, and elder; is solitary, yellow, with oblique, blue, green, and black lateral stripes, and a reflected tail; pupa reddish. Vide Donov. Brit. Inf. t. 289. Linnæus in Amencl. Acad. names this insect caput mortuum; and Geoffroy in Hist. des Insectes, le sphinx à tête de mort.

ATROPOS is also a species of Musca, about half an inch in length, that inhabits Austria. It is rather downy; thorax whitish with three black spots; abdomen black, with interrupted yellow bands, and margin of the segments of the same colour. Schrank Beyrl.

ATROPOS, in Mythology, one of the Parce or Fates, whose office it was to cut the thread of life.

ATROPOS, in Zoology, a species of Coluber, described by Linnæus in Muf. Ad. Tr. & Gmel. Syst. Nat. as having 15 abdominal plates, and 21 subcaudal scales. It is a native of America, and deemed an extremely poisonous serpent; the colour hoary grey, with a quadruple series of brown ocellated spots, each with a white iring or margin. The head is heart-shaped, gibbous, with four and sometimes more black spots; and the scales are lanceolate. Gmel. It is cobra atropos of Laur. Amph.

Dr. Shaw observes that this species is of a thick and short form, scarcely exceeding fifteen or sixteen inches in length; the head is large and viverine, marked with four or five large dusky spots, and covered with small scales; the remainder of the animal of a pale brown, marked all along the upper part by four rows of very large, alternate, round, black spots bordered with white; the abdomen ash-colour, and tail very short, measuring about a ninth part of its whole length; the scales on all the upper parts are of a slightly sharpened form, and carinated. Gen. Zool. v. 3. p. 2. 404.

ATRO-VIOLESCENS, in Entomology, a species of Chrysomela, once taken in the month of September, in the county of Norfolk. It is ovate, violaceous-black; wing-cafes dilated; legs pitchy-black. Marsh. Ent. Brit.

ATROVIRES, in Zoology, a species of Coluber, described by the count of Cepede under the title of "la eoleuvre verte et jaune," and by Dr. Shaw, under that of coluber atrovirens, C. atrovirens, flavo maculatus, abdomen flavo, lateribus nigro punctato. Black-green snake, speckled with yellow; the abdomen yellow, with a row of black spots down each side. French name.

"This fccms," says Dr. Shaw, "to be the species figured by Aldrovandus, under the name of anguis fclapulip niger, and which appears to have been so little attended to by modern naturalists, as to have been generally confounded with the ringed snake (C. natrix), till it was again brought to notice by Monf. Daubenton, and afterwards by the count de Cepede, who has accurately described it, and who informs us that it is very frequent in some of the provinces of France, being found in woods and moit shady places; in its general fize and appearance it resembles the ringed snake or natrix, but differs in colour, being of an extremely dark or blackish green, so as to appear black on a cursory view, the fides being marked by numerous rows of yellow fpecks of different forms, some elongated and some square, and which form somewhat more decided or diftinctly marked stripes towards the head; the eyes and edges of the mouth are bordered with yellow fcales; the abdomen is also yellow, each fcutum being marked on each side by a black fpeck. This snake is an animal of a perfectly harmless nature, and like the ringed snake, is capable of being tamed to a confiderable degree."—"On the approach of winter, it retires, like the latter, into subterraneous retreats, and palies that feaon in a flate of torpidity, from which it recovers in the spring, when it casts its skin, and appears in its highest beauty."

ATROX, in Zoology, a kind of Coluber, which according to Linnæus is specifically characterized by having 169 abdominal plates, and 69 subcaudal scales. Amoc. Acad. This creature is a native of Asia, and is about a foot and a half in length; the colour hoary; fcales carinated; beneath marked, with dark brown, transverse, alternate spots; head depressed, compressed, angulated, and covered with minute scales. Gmelin makes "diapls indica" of Laur. Amph. a variety of this species. Dr. Shaw describes it in his Gen. Zool. as being the "grey brown snake, with transverse linear whitish stripes, and dusky abdomen, with white transverse variegations; and names it the fierce snake." This author also notices one error of Linnæus respecting this species that deserves particular remark. "In the Muleum Adolphi Friderici, p. 33" says he, "this species, by a mistake, inscribed angulatus, while the figure on plate 22 of that work, represents the body marked by a few horizontal narrow, transverse whitish bands reaching to the abdomen, which is spotted with small, round, white fpecks; the dusky transverse fpecks appearing only beneath the tail; the general colour of the abdomen, however, in this fike is rather deep brown or blackish, beautifully variegated or marbled by numerous narrow transverse bands, accompanied here and there with small fpecks; the tail is remarkably short and slender. In the Syllema Natura a mistaken reference appears to be made to a figure in Seba representing a very different species. The C. atrox is a poisonous snake, and is a native of the island of Ceylon."

ATISCHARIS, in Geography, a tribe of the Mandrines, who inhabited the banks of the middle Amoor, in Siberia, before it was taken possession of by the Kuffians. They then subsisted in a state of independence; but they were afterwards removed, by order of the Chinese government, from the Amoor farther towards China.

ATTACAMA, in Geography, one of the fourteen jurisdictions belonging to the archbishopric of Plata, in the province of Chares, in South America. It is the western boundary of the province, extending to the South sea; and
and the principal town, called also Atacama, is no less than 120 leagues from Plata. Its jurisdiction is of a considerable extent, and a great part of it very fruitful; but intermixed with some deserts, particularly towards the south, where it divides the kingdoms of Peru and Chili. On the coast in this province there is annually a very large fishery of Tolo, a fish common in the South sea, with which a very great trade is carried on with the island provinces, this being the chief food in Lent and other days of abstinence. There is a great desert of the same name, and a chain of mountains, which separate Peru, on the north, from the province of Quito. The cold in these mountains is sometimes so extremely severe, that those who pass it are occasionally frozen to death. S. lat. 22°. W. long. 80° 29'.

ATTACANA, in Ancient Geography, a town of Acha, in greater Armenia. Ptolemy.

ATTACCO, in Music, is a kind of short subject or point, not restricted to all the laws of regular fugue. Sometimes it is a species of the principal theme itself, treated rather as an imitation than a subject of regular fugue, and may be answered in any interval, at pleasure.

Example.

ATTACCHIAMENTA DORONIUM, in Law, a distress taken upon goods or chattels, where a man is sued for personal estate or debt, by the legal attachators or bailiffs, as security to answer an action.

ATTACCHIAMENTA DE SPINIS ET BOSCO, is a privilege granted to the officers of a forest to take to their own use thorns, brash, and wind-falls, within their own precincts.

ATTACHING, or ATTACHMENT, denotes the apprehending a person or thing, either by a precept or writ. The word is formed of the French attachter, to follow, or take; and that from the corrupt Latin attachior, of atterser, to adhere to; or rather, as others think, from the Celtic tach, a nail; and tachas, to nail; or the Saxon tæcin, to take.

Lambard makes this difference between an arrest and an attachment; that an arrest proceeds out of an inferior court by precept only, and an attachment out of a higher court, either by precept or writ; and that a precept to arrest hath these formal words, duci facias, &c. and a writ of attachment threat, "precipimus in quid attachments tamen, & habes sum certam nobis."

By this it appears, that he who arrests carries the party arrested to another higher person, to be disposed of forthwith; whereas he that attaches keeps the party attached, and presents him in court at the day assigned in the attachment.

There is this farther difference, that an arrest lies only upon the body of a man; and an attachment sometimes on his goods too; for a man may be attached by an hundred sheep.

Moreover, attachment is a process from a court of record, awarded by the justices at their discretion, on a bare suggestion, or on their own knowledge; and is properly grantable in cases of contempts, against which all courts of record, but more especially those of Wellminser-hall, and above all the court of B. R. may proceed in a summary manner.

The contempts that are thus punished, are either direct, which openly insulfs or resist the powers of the courts, or the persons of the judges who pride there; or the are consequent, which, without such gross influence or direct opposition, plainly tend to create an universal disregard of their authority. The principal instances of either sort that have been usually punishable by attachments, are of the following kinds: 1. Those committed by inferior judges and magistrates by acting unjustly, oppressively, or irregularly, in administering those portions of justice which are entrusted

Vol. III.
trusted to their distribution; or by disobeying the king's
writs issuing out of the superior courts, by proceeding in a
cause after it is put a flop to or removed by writ of pro-
hibition, certiorari, error, supersedeas, or the like. 2. Thos.
committed by sheriffs, bailiffs, gaolers, and other officers
of the court, by abusing the process of the law, or deceiving
defendants, by any acts of oppression, extortion, libellous
behaviour, or on any other culpable neglect of duty. 3. Thos.
committed by attorneys and solicitors, who are also officers of
the respective courts, by gross infinities of fraud and cor-
ruption, injustice to their clients, or other dishonest prac-
tice. 4. Thos. committed by jurors in collateral matters
relating to the discharge of their office; such as making
default when summoned, refusing to be sworn, or to
give any verdict, eating or drinking without the leave of
the court, and especially at the cost of either party; and
other irregularities of a similar kind; but not in the mere
exercise of their judicial capacities, as by giving a false or
erroneous verdict. 5. Thos. committed by witnesses; by
making default when summoned, refusing to be sworn or
examined, or prevaricating in their evidence when sworn.
6. Thos. committed by parties to any suit or proceeding
before the court; as by disobedience to any rule or order
made in the progress of a cause; by non-payment of costs
awarded by the court upon a motion; or by non-obser-
vance of awards duly made by arbitrators and umpires, after hav-
ing entered into a rule for submitting to such determination.
7. Thos. committed by any other person under the degree
of a peer; and even by peers themselves, when enormous
and accompanied with violence, such as forcible rescous, and
the like; or when they import a disobedience to the king's
great prerogative writs of prohibition, habeas corpus, and
the writ.

Some of these contempts may arise in the face of the
court; as by rude and contumelious behaviour; by obli-

gnancy, perseverance, and prevarication; by breaking the
peace; or any wilful disturbance whatever: others, in the
absence of the party; as by disobeying, or treating with
disrepect, the king's writ, or the rules or process of the
court; by perverting such writ to the purposes of private
malice, extortion, injuriousness; by breaking or writing con-
temptuously of the court, or judges acting in their judicial
capacity; by making false accounts (or even true ones,
without proper permission) of causes then depending in judg-
ment; and by any thing, in short, that demonstrates a
gross want of that regard and respect, which, when once
courts are deprived of, degrade and destroy their authority
among the people. The processes of attachment for these
and similar contempts must necessarily be as ancient as the
laws themselves; for laws, without a competent authority
to secure their administration from disobedience and con-
tempt, would be vain and nugatory. This has accordingly
been exercised as early as the annals of our law extend.

If the contempt be committed in the face of the court,
the offender may be instantly apprehended and imprisoned,
at the direction of the judges, without any further proof
or examination. But in matters at a distance, and of which
the court cannot have so perfect a knowledge, unless by the
confession of the party, or the testimony of others, if the
judges upon affidavit fee sufficient ground toulpel that a
contempt has been committed, they either make a rule on
the fulfilpect party to show caufe why an attachment
should not issue against him; or in very flagrant instances
of contempt, the attachment issues in the first instance; as
it also does, if no sufficient caufe be shown to discharge, and
therefore the court confirms and makes absolute the original
rule. This process of attachment is merely intended to
bring the party into court; and, when there, he must either
stand committed, or put in bail, in order to answer upon
oath to such interrogatories as shall be administered to him,
for the better information of the court with respect to the
circumstances of the contempt. These interrogatories are
in the nature of a charge or accusatian, and must by the
court of the cause be exhibited within the first four days;
and if any of the interrogatories is improper, the defendant
may refuse to answer it, and move the court to have it
fruck out. If the party can clear himself upon oath, he is
discharged; but, if perjured, may be prosecuted for the
perorly. If he confesses the contempt, the court will pre-
ceed to correct him by fine or imprisonmenl, or both, and
sometimes by a corpus or infamous punishment. If the
contempt be of such a nature, that, when the fact is once
acknowledged, the court can receive no farther information
by interrogatories than it is already posessed of (as in the
case of a recous), the defendant may be admitted to make
such simple acknowledgement, and receive his judgment,
without answering to any interrogatories; but if he willfully
and obstinately refuses to answer, or answers in an evasive
manner, it is then clearly guilty of a high and repeated con-
tempt, to be punished at the discretion of the court.

Blackstone's Com. vol. iv.
The terrors of attachment in case of disobedience on the
part of unwilling witnesses, as well as the compulsory proce-
s for obtaining their attendance, are of excellent use in the
thorough investigation of truth: and upon the same prin-
ciple, in the Athenian courts, the witnesses who were sum-
moned to attend the trial, had their choice of three things,
either to fiewar to the truth of the fact in question, to deny
or objure it, or else to pay a fine of a thousand drachmas.

Attachment, Writ of, called also Pona, is a writ issuing
out of the court of Common Pleas, and grounded on the
non-attendance of the defendant at the return of the original
writ; which commands the sheriff to attach him, by taking
clage, that is, certain of his goods, which he shall forfeit,
if he doth not appear; or by making him find false pledges
or forfeits which shall be amerced in case of his non-appear-
ance. This is the first and immediate process, without any previous
summons, uppon actions of trespass vi et armis, or for other
injuries, which though not forcible, are yet trespasses against
the peace, as deceit and conspiracy: where the evidence of
the wrong requires a more speedy remedy, and therefore
the original writ commands the defendant to be at once
attached, without any precedent warning. See Process.

Attachment out of Chancery, is a writ in the nature of a
capias, directed to the sheriff, and commanding him to
attack, or take up the defendant, and bring him into court.
It is had of course, upon an affidavit made that the defendant
was served with a subpœna, and appears not; or it issueth
upon not performing some order or decree.

After the return of this attachment by the sheriff, quad
non est inventus in balivus faire; another attachment, with
proclamations, issues which, besides the ordinary form of
attachment, directs the sheriff that he cause proclama-

tions to be made, throughout the county, to summon the defan-

tant, upon his allegiance personally to appear and answer:
and if this be also returned with non est inventus, and he fail
stands out in contempt, a commissio of rebellion is awarded
against him. See Commission of Rebellion.

Attachment, Foreign, is an attachment of goods or
money found within a liberty or city, to satisfy some credi-
tor within such city or liberty.

Under the custum of London, if a plaint be exhibited
in the mayor's or the sheriff's court (the proceeding in the former
being the most advantageous) against A, and the procefs be

ATT

returned nil, and thereupon the plaintiff sugetests that another person within London is indicted to A, the debtor shall be warned (whence he is called the garnishee), and if he does not deny himself to be indicted to A, the debt shall be attached in his hands. The custom of foreign attachment is said to prevail in Exeter and other places. But a foreign attachment cannot be had when a suit is depending in any of the courts at Westminster. Cro. Eliz. 66. And nothing is attachable, but for a certain and due debt; though by the custom of London, money may be attached before due, as a debt, but not levied before due. Sid. 327. 1 Nefl. Abr. 282, 283.

Foreign attachments in London, upon plaint of debt, are made after this manner: A owes B 100l. and C is indebted to A 100l.; B enters an action against A of 100l. and by virtue of that action a levant attaches 100l. in the hands of C, as the money of A, to the use of B, which is returned upon that action. Upon this the plaintiff is immediately to see an attorney before the next court, or the defendant may then put in bail to the attachment, and nonsuit the plaintiff. Four court days must pass before the plaintiff can cause C, the garnishee, in whose hands the money was attached, to swear cause why B should not condemn the 100l. attached in the hands of C as the money of A the defendant in the action (though not in the attachment) to the use of B the plaintiff; and the garnishee C may appear in court by his attorney, wage his law, and plead that he hath no money in his hands of the defendant's, or other special matter; but the plaintiff may hinder his waging of law, by producing two sufficient citizens to swear that the garnishee had either money or goods, in his hands, of A at the time of the attachment, of which affidavit is to be made before the lord mayor, and being filed, may be pleaded by way of elopement: then the plaintiff must put in bail, that if the defendant come within a year and a day into court, and he can discharge himself of the money condemned in court, and that he owed nothing to the plaintiff at the time in the plaint mentioned, the said money shall be forthcoming, &c. If the garnishee fail to appear by his attorney, being warned by the officer to come into court to swear cause as aforesaid, he is taken by default for want of appearing, and judgment given against him for the goods, and money attached in his hands, and he is without remedy either at common law or in equity; for if taken in execution he must pay the money condemned, though he hath not one penny, or go into prison; but the garnishee appearing to swear cause why the money or goods attached in his hands ought not to be condemned to the use of the plaintiff, having feed an attorney, may plead as aforesaid, that he hath no money nor goods in his hands, of the party's against whom the attachment is made: and it will then be tried by a jury, and judgment awarded, &c. but after trial, bail may be put in, whereby the attachment shall be dissolved, but the garnishee, &c. and his security will then be liable to what debt the plaintiff shall make out to be due, upon the action: and an attachment is never thoroughly perfected, till there is a bail, and satisfaction upon record. Privilege London.

But the original defendant must be summoned, and have notice: otherwise judgment against the garnishee will be erroneous; and the money paid or levied in execution; or it will not discharge the debt from the garnishee to the defendant (though it was allowed that the custom of the city court is to give no notice). 3 Will. 297. 2 Black. Rep. 834. See 1 Ld. Raym. 727. Where a foreign attachment is pleaded to an action, the custom is to set forth that he who levied the plaint shall have execution of the debt owing by himself, and by which he was attached, if the plaintiff in the original action shall not disprove it within a year and a day; now if the plaintiff in the action below does not set forth such conditional judgment given by the court, it is wrong, because he doth not bring his cause within the custom. Vide 2 Lutw. 985.

A sum of money was to be paid at Michaelmas, and it was attached before that day: adjudged, that a foreign attachment cannot reach a debt before it is due: therefore, though the judgment on the attachment was after Michaelmas, yet the money being attached before it was due, it is for that reason void. Cro. Eliz. 184. For further matter, see Com. Dig. tit. Attachment.

Money due to an executor or administrator, as such, cannot be attached. It would give a simple contract-creditor priority over judgments. Fisher v. Lane and others, 3 Will. 297. Nor 10U money in the hands of the garnishee. Doug. 383.

Debtor and creditor being both citizens of London, the debtor delivered several goods to the Exeter carrier then in London, to carry and deliver them at Exeter, and the creditor attached them in the hands of the carrier for the debt due to him from his debtor: adjudged, that the action should be discharged, because the carrier is privileged in his person and goods, and not only in the goods which are his own, but in those of other men, of which he is in possession, for he is answerable for them. 1 Leon. 189. See Jacob's Law Dict. by Tonlins, art. Attachment.

Attachment of the Forreft, or Woodmote, is one of the four courts held in the forest. (See Courts of Forreft, &c.) The court of attachments seems so called, because the verderors of the forest have therein no other authority, but to receive the attachments of offenders against vert and venison taken by the foresters, to enrol them, and to certify them under their seals, to the court of justice-forester, or sweinmote; for this court can only inquire of, and not convict offenders. This attachment is by three means; by goods and chattels; by body, pledges, and mainprize; or by body only. Offenders may be attached by their bodies, if taken with the mainour (or mainewere, a main), that is, in the very act of killing venison, or dealing wood, or preparing to do, or by force and immediate pursuit after the act is done; otherwise, they must be attached by their goods. This court is held every forty days throughout the year; whence it is also termed forty days court.

Attachment of Privilege is, by virtue of a man's privilege, to callmother to that court whereby he himself belongs, and in respect whereof he is privileged to answer some action; or, it is a power to apprehend a man in a place privileged. Corporation courts have sometimes power by charter to issue attachments, and some courts-baron grant attachments of debt. Kitch. 79.

Attack, an attempt upon any person or thing; or the act of beginning a combat or dispute.

Attack, in the Military Act, signifies an engagement having for its object the forcing of an entrenched post, or dislodging an adverse army from its lines, when in a situation calculated to impede the progress of an invading army.

War is naturally an offensive operation. In the earlier ages we find it carried on by a series of engagements uniformly on the principle of attack, and unconnected with any of those skilful manoeuvres which the ready genius of mankind has since carried into execution for their mutual destruction. The ultimate object of a battle consisted in plundering, in case of success, a small tract of the enemy's country, and
in burning a few miserable villages. Superiority of numbers generally injured the advantage. The vanquished were exterminated. The victors withdrew with their hard earned booty, diminished in numbers, and exhausted by fatigue.

The Greeks, who first brought the military art to some degree of perfection, were fully sensible of the advantages to be derived from the attack. Even at the famous plain of Marathon (vid. Marathon), where, by the most moderate accounts, the Persian army exceeded them ten times in number, they had the temerity to forlorn a well-chosen position; and (Herodotus, l. vi. c. 112.) advance running to the onset; a degree of rashness, which, though in the instance before us crowned with the most glorious success, can never find an excuse in the eyes of military judgment. At the final engagement of Thermopylae, the defair of Leonidas drove him to pursue a similar conduct. (Herod. l. vii. c. 223.)

The particular circumstances of his situation, and the celebrity of his death, extenuate in part his conduct.

Among the Greeks, the Lacedaemonians alone advanced to battle in silence, and at a steady pace, regulated by the sound of musical instruments. (Thucyd. l. v. c. 70.) On the contrary, the other Greek nations rushed forward with the utmost eagerness and velocity, clashing their spars upon their bucklers, and, at the moment of the onset, raising a loud shout, to alarum and terrify their enemies. This mode of attack was generally irresistible, where only opposed by an undisciplined and tumultuous assembly of Asiatics. Witness the battle of Cynaxa (vid. Cynaxa), where a phalanx of 13,000 Greeks dashed in an instant the almost innumerable forces of Artaxerxes Mmnon; and, if it had not been for the fatal temerity of Cyrus the younger, would infallibly have placed the crown of Periis on his head. (Xenophon, Anat. l. i. c. 8.)

In engagements with every nation, the vigorous onset of the Greeks was attended with splendid victory. Even in the declining ages of their monarchy, when the arbitrary sway of Macedonian tyranny had extinguished within their bosoms that spirit of liberty which glowing so fervently at Marathon and Platea, their formidable phalanx was regarded with apprehension by Roman intrepidity; and in the famous and decisive battle of Pydna (vid. Pydna), the firmness and talents of a Paulus Emilius depaupered of victory, till a happy and well-timed exertion of his superior military abilities decided the doubtful contest. (Plut. in Alex. Paul.)

The Romans, those great makers in the art of war, were not ignorant of the advantages of acting offensively, nor how to improve them. The impetus of their legion, a heavy and well-organized body of infantry, exceeded in effect that of the Macedonian phalanx; and no weight of armour, no exertion of courage, no resolution, however daring, could preserve the front of that army unbroken, which once experienced the terrible discharge of the Roman pilum.

In every age the syllen of attack has been preferred by experienced generals (with some few exceptions, justified always by coincident circumstances), to that of protracting a war by tedious and indecisive manoeuvres, and it has generally been attended with success. Hannibal, Sylla, Alexander, Caesar, the greatest captains of antiquity, never suffered a favourable opportunity of engaging to escape them. Their attacks were general, violent, frequently unexpected, and rarely unattended with the most ample successs.

Of later days, we may reckon among the commanders, who, in their eagerness to engage an enemy, have sometimes overlooked the bounds prefixed to genius by modern tactics, a Conde, a Gustavus, an Eugene, a Charles the Twelfth, and a Frederick the Great, whose rapid manoeuvres frequently baffled the most acute observation of their antagonists, and the impetuosity of whose attacks seldom gave time for effectual opposition.

It is scarcely necessary to insist upon the manifest advantages of an attacking army pellmell over that which acts upon the defensive. With numbers generally superior, a confidence in their own strength, and spirits which defy opposition, they rarely encounter an enemy able, or resolute enough to repulse them.

In the course of the late war, Europe has beheld with surprize the syllen of attack, which before only affected a tract of country comparatively trifling, carried to an extent and a perfection truly astonishing. In 1794, armies acting offensively, though in bodies widely dilated, pierced, as if animated by the same soul, in all directions, from the frontiers of France to the left bank of the Rhine, and the centre of the Batavian territories. Two years after, at the same moment when Moreau was penetrating by the circle of Swabia, and along the Danube to the Austrian borders, the army of the Sambre and Meuse advanced through France, and Buonaparte fought his way through Italy to gain the summit of the Alp Alps. According to the new principle, success in a general engagement, however complete, in no wise contributed to terminate the campaign. A battle gained only opened the road to new attacks. A town taken merely furnished materials for fresh sieges. The armies railed each other in overcoming, with incredible expedition, obstacles which formerly would have been deemed insurmountable; and as long as any vestige of an adverse power remained to face them in the field, all successes was regarded as incomplete.

In the fluctuating campaign of 1799, the same syllen was carried to a still greater extent. The rocks and mountains of Switzerland furnished fresh subjects for plans of a nature still more difficult, intricate, and complicated. The line of attack and defence was lengthened in an unexampled manner, and from the Zuyder Zee to the Al帻ian formed but one vast field of battle, on which French, Auffrians, Ruffians, Helveticans, Dutch, English, and Italians, alternately destroyed each other; and itrove, with infinite vicissitude of fortune, but finally with nearly equivalent successes, to gain a dear-bought advantage. Attack, in Esfiging, signifies the operations carried on by the besiegers, with mines, laps, trenches, batteries, &c. against an enemy's fortres. The rules of war naturally preclude the weakest side of the place as the point of attack. Nevertheless, prince Eugene thought proper to infringe upon them in the infuerce of the siege of Lille, where, to favour the movements of the covering army, he directed his approaches against the strongest part of the fortifications. Two, or even three attacks, are formed in sieges where dispatch is neceflary. In such cases, their communications should be cay, carefully constructed, and indistinctly maintained.

Attack, Falls, is an attack but faintly prosecuted, though sufficiently fierce to induce the enemy to divide his forces, and more especially to weaken, if possible, that part of his position, or works, which is the object of the true assault.

ATTACOTTI, in Ancient History, a savage people of Great Britain, mentioned by Ammianus Marcellinus (l. 27. c. 8.) and St. Jerom (tom. ii. p. 75.), as well as in the Notitia Imperii, whose situation is not precisely ascertained by antiquaries. Some have supposed that they inhabited Wales, and alluded, that their name was derived from the British words "at a coit, or coed," signifying amongst woods. But it is probable, that they were seated somewhere further north
ATTAGEN. ATTAGAS, in Ornithology, names given by Briff. and Buff. to the red or moor-game, or red grouse, in Gmelin's arrangement the fourth variety of tetrao labatus. Linn. & Gmel. Briff. also calls tetrao umbellus of Gmelin attagen Pennfylveanis.

ATTAINDER, in Law, is that claim or infamy which is incurred by a man who has committed felony, treason, or other crime, and who is capitally convicted for the fame.

This, by the common law, is the immediate infparable consequence of the sentence of death that is pronounced. The law, in this case, sets a note of infamy upon the criminal, puts him out of its protection, and takes no further care of him than barely to see him executed. He is then called attaint, atidinisus, flained or blackened. He is no longer of any credit or reputation, he cannot be a witnes in any court; neither is he capable of performing the functions of another man: for, by an anticipation of his punishment, he is already dead in law. This is after "judgment"; for there is a great difference between a man "convicted," and "attainted," though they are frequently, through inaccuracy, confounded together. The latter conviction only, a man is liable to none of these disabilities; for, in the contemplation of law, there is still a possibility of his innocence. Something may be offered in arrest of judgment; the indictment may be erroneous, which will render his guilt uncertain, and thereupon the present conviction may be quashed; he may obtain a pardon, or be allowed the benefit of clergy; both which suppose some latent sparks of merit, which plead in extenuation of his fault. But when judgment is once pronounced, both law and fact contrive to prove him completely guilty; and there is not the remotest possibility of any thing to be said in his favour. Upon judgment, therefore, of death, and not before, the "attainder" of a criminal commences: and upon such circumstances as are equivalent to judgment of death; as judgment of outlawry on a capital crime, pronounced for abetting or fleeing from justice, which tacitly confounds the guilt. And, therefore, upon judgment of outlawry, or of death, for treason or felony, a man shall be said to be "attained."

A man is "attained by appearance" or by process. "Attainder" on appearance is by confession, or verdict, &c.: by confession, when the prisoner, upon his inditement, being asked whether guilty or not guilty; owns himself guilty, without putting himself upon his country; and formerly confession was allowed before the coroner in facturi, upon which the offender was to aubare the realm, and this was called "attainder" by aquisition. "Attainder" by verdict, is when the prisoner at the bar pleads not guilty, and is found guilty by the verdict of the jury of life and death. "Attainder" by process, otherwise called "attainder" by default, or by outlawry, is when a party files, and is not found, until he hath been five times publicly called or proclaimed in the county, and, at last, upon his default, is pronounced or returned outlawed. Stannard. Pl. Co. 44. 122. 182. Persons may also be attainted by act of parliament. Accordingly acts of attainder have been passed in several reigns, on the discovery of plots and rebellions, from the reign of King Charles I., when an act was made for the attainder of several persons guilty of the murder of King Charles I., to this time. Among thefe, the most remarkable is that for attainting Sir John Fenwick for conspiring against King William; this act having been made for attainting and confining him of high treason on the oath of one witness, just after a law had been enacted, "that no person should be tried, or attainted, of high treason, where corruption of blood is incurred, but by the oath of two lawful witnesses, unlefs the party confess, stand mute, &c." Stat. 7 and 8 W. III. c. 3. However, Sir John Fenwick was convicted on the oath of two witnesses, though only one appeared against him on his trial; and it was alleged, that Sir John had tampered with and prevailed on one of the witnesses to withdraw.

The confquences of "attainder" are forfeiture, and corruption of blood; which latter cannot be regularly taken out but by act of parliament. See these articles.

"Attainders" may be reversed or falsified by writ of error, or by plea; in the former cafe it must be by the king's leave, &c.; and in the latter it may be by denying the treason, pleading a pardon by act of parliament, &c. 3 Inst. 232.

By a king's taking the crown upon him, all attainers of his perfon are "ipso facto" purged, without any reversal. 1 Inst. 26. Finch. L. 82. Wood. 17. This was the declaration of parliament, made in favour of Henry VII.

ATTAINDER, Bill of, is a bill brought into parliament for attainting, condemning, and executing a person for high treason. See ATTAINDER.

ATTAINCTA, in Law, a writ which lieth to inquire, whether a jury of twelve men gave a false verdict, that to the judgment following thereupon may be reversed; and this must be brought in the time of him for whom the verdict was given, and of two at least of the jurors who gave it. This lay, at the common law, only upon writs of afville; and seems to have been coeval with that institution by king Henry I. at the instance of his chief justic peace; being probably meant as a check upon the civil power then reposed in the recognizers of afville, of finding a verdict according to their own personal knowledge, without the examination of witnesses. And even here it extended no farther than to such instances, where the afville was joined upon the very point of afville (the heirship, disfelfin, &c.), and not on any collateral matter, as vellage, bailiady, or any other disputed fact. (See Assisa in jurisvd., &c.) It seems that no attaint lay against the inquilt or jury that determined such collateral afville; nor did such a process obtain after the trial by inquilt or jury, in the old Norman or feudal actions prosecuted by a writ of entry; nor did any attaint lie in treaspe, debt, or other action personal, by the old common law; because these were always determined by common inquests or juries. At length the statute of Wilm. 1. (3 Edw. I. c. 38.) allowed an attaint to be sued upon inquests, as well as afville, which were taken upon any plea of land or of freedom. But this was at the king's discretion, and to it is not applied by the author of Fieta, a writer contemporary with the statute; though Sir Edward Coke (2 Inst. 130. 237; 3) seems to hold a different opinion. Other subordinate statutes (1 Edw. III. l. 2. 6. 7. Edw. III. c. 7. 82. Edw. III. c. 8.) introduced the same remedy in all pleas of treasons; and the statute 34 Edw. III. c. 7, extended it to all pleas whatsoever, personal as well as real; excepting only the writ of right, in such cases where the life or afville is joined on the mere right, and not on any collateral question.
The jury who are to try this false verdict must be twenty-four, and are called the grand jury; for the law wills not that the oath of the jury of twelve men should be attainted or set aside by an equal number, nor by less than double the former. Bract. I. 4. tr. 5. c. 4. § 1. Bract. I. 5. c. 22. § 7. If the matter in dispute be of forty pounds value in personal, or of forty shillings a year in lands and tenements, then by flat 15 Hen. VI. c. 5. each grand juror must have freehold to the annual value of twenty pounds. And he that brings the attain can give no other evidence to the grand jury than what was originally given to the petit. But those against whom it is brought are allowed, in affirnance of the petit verdict, to produce new matter; because the petit jury may have formed their verdict upon evidence of their own knowledge, which never appeared in court. If the grand jury found the verdict a false one, the judgment by the common law was, that the jurors should lose their "liberam legem," and become for ever infamous; should forfeit their goods and the profits of their lands; should themselves be imprisoned, and their wives and children thrown out of doors; should have their houses razed, their trees extirpated, and their meadows ploughed; and that the plaintiff should be restor'd to all that he lost by reason of the unjust verdict. But as the severity of the punishment had its usual effect in preventing the law from being executed, therefore by the statute 11 Hen. VII. c. 24. revised by 23 Hen. VIII. c. 3. and made perpetual by 13 Eliz. c. 25. an attain is allowed to be brought after the death of the party, and a more moderate punishment was inflicted upon attainted jurors; viz. perpetual infamy; and if the cause of action were above forty pounds value, a forfeiture of twenty pounds a-piece by the jurors; or if under 40l. then five pounds a-piece; to be divided between the king and the party injured. So that a man may now bring an attainit either upon the statute or at common law, at his election (3 Inst. 164.; and in both of them may reverse the former judgment. But the practice of setting aside verdicts upon motion, and granting new trials, has so superseded the use of both forts of attains, that few infallacles of attains occur in our books later than the sixteenth century. Cro. Eliz. 309. Cro Jac. 90. By the old Gothic constitution, indeed, no certificate of a judge was allowed, in matters & evidence, to counterveil the oath of the jury; but their verdict, however erroneous, was absolutely final and conclusive. Yet there was a procedure, from whence our attain may be derived. If upon a lawful trial before a superior tribunal, the jury were found to have given a false verdict, they were fined, and rendered infamous for the future. Steinhuck de jure Goth. l. i. c. 4. Blackstone's Comm. vol.iii. p. 402, &c.

ATTAINED, ATTAIN'T, or ATTAIN'D, in Law. See ATTAIN'D.

ATTIK, in Geography, the largest of the islands commonly denominated the Aleutiky or Alcuitan islands. It seems to have a larger extent of surface than Behring's island, and has an oblong form, lying more west than east. In these islands no volcanic traces have been discovered, and here are no land animals but sea-foxes and rock-foxes, more frequently blue than white. The sea-otters come hither but singly, whereas sea-lions, sea-bears, manatees, and some other sea-animals frequent these shores in herds. See Aleutian Islands.

ATTALIA, in Ancient Geography, a town of Asia, in Pamphylia, on the coast of the Ida, which there formed a gulf of the same name, now called the gulf of Satalia. Strabo (l. xiv. p. 454.) says, that it was built by Attalus Philadelphus, king of Pergamus, who founded a colony there, and that it was the chief residence of the prefect. St. Paul proceeded from Perga to this town. Acts xiv. 25. — Alfo, a town of Asia, in Lydia.

ATTALICÉ Vestes, in Antiquity, garments made of a kind of cloth or gold. They took the denomination from Attalus, surnamed Philiometer, a wealthy king of Pergamus, who was the firil, according to Pliny, who procured gold to be woven into cloth. Hist. Nat. lib. iii. cap. 48.

ATTALIS, in Ancient Geography, the name of a tribe of Attica.

ATTALUS, in Biography, the name of several kings of Pergamus.—Attalus I. succeeded his cousin Eumenes I. in the year 241 B.C. Having expelled the Gauls who had settled in his country, he assumed the title of king, and extended his conquests of the Asiatic provinces as far as mount Taurus. But in the difficulties to which he was afterwars reduced by the united forces of his grandfather Aeæus and Seleucæus, he availed himself of the feecours afforded him by the Gauls settled in Thrace, and recovered his dominions of which he had been dispossessed. He then purified his conquests in Ionia, till his career was stopped by the refusal of the Gauls to advance any farther. Upon this he returned to the Hellepont, and allowed his allies to settle there, in a very fertile and extensive region. For the security of the territories he had acquired, he formed an alliance with the Romans, whom he vigorously affifted in their two wars against Philip of Macedon. In conjunction with the Athenians he invaded Macedonia, and recalled Philip from his enterprise against Athens; and on this account the Athenians gave his name to one of their tribes. At Thebes in Boetia, whilst he was haranguing the people, and urging them to take arms against Philip, he was seized with a apoplexy; and being conveyed to Pergamus, he soon after died, in the 73d year of his age, and 43d of his reign. He is represented as a generous and amiable prince, a liberal encourager of literature, and also a writer. Of his veneration for Homer the following singular inference is mentioned by Suidas and Valerius Maximus; viz. his causing the grammerian Daphnidas to be thrown from a rock, for speaking disrespectfully of this celebrated bard.—Attalus II. was the second son of Attalus I. and called Philadelphus, from his fidelity and affection to his brother Eumenes, who was king of Pergamus before him. Upon a false rumour of the death of Eumenes, he ha'ilily assumed the regal enigms, and married his brother's wife; but on his brother's safe return, he manifested every token of satisfaction and allegiance, and bore an alharb as one of his guards. Eumenes kindly embraced him, and in a whifper cautioned him "not again to be in such haste to marry his wife, till he was sure of his death." Attalus was actively attached to the Romans in their war against Peræs; and made successive visits to Rome for the purpose of executing his brother from the charge of indifference to their interest. At his death, Eumenes bequeathed both his kingdom and his wife to Attalus; and appointed him guardian of his infant son, which truth he faithfully executed. Attalus
ATTALUS commenced his reign in the year 159 B.C. and after a reign of 21 years, distinguished principally by his successes in reasserting Attic power. He passed the throne of Cappadocia, and by his conduct with Prusias king of Bithynia, which terminated after alternate defeats and successes in the devolution and affadation of this prince, he died in his 82d year. He was a patron of literature, acknowledged as the founder of two cities in Asia; viz. Attalas and Philadelphia, and esteemed much by the Romans, by whom he was considered as one of their most faithful allies—Attalus III. was the son of Eumenes II. and succeeded his uncle in the year 138 B.C. His disposition was cruel and fupicious, and led him to sacrifice most of his own family, and several persons of distinction in his court, with their wives and children. From his real or affected love for his mother Stratonicus, he was designated Philometor. After filling his capital and kingdom with deplorable distresses, he retired into solitude, and sequestered from all social intercourse, devoted himself to the culture of a garden, in which he planted a variety of poisonous herbs; and these he occasionally sent in packets, mixed with pufle, to those who were the objects of his gloomy fupicions. This conduct indicates infancy; but it has been ascribed to Varro and Cohnella to a fondness for horticulture, and the study of medicinal simples; and Attalus has been numbered among those who were deft on these fubjects. By the heat and toil which he experienced in the chemical employment of calling a fortune of his mother, he was thrown into a fever, which terminated his life and reign in the year 135 B.C. The Roman people were by his testament the heirs of his goods, which they interpreted to mean his dominions and subjedts. Their claim to this rich inheritance was contested, but at length established. The wealth of Attalus seemed to have been a proverbial expression, and is frequently alluded to by the Roman poets. See PERGAMUS.

ATTALUS, a Christian martyr, was a native of Pergamum in Phrygia, and fell a sacrifice to persecution at Lyons, in the 17th year of the emperor Marcus Antoninus, and the 177th year of our Lord. In an epistle of the churches of Vienne and Lyons, addressed to the churches of Asia and Phrygia, containing a relation of the sufferings of their martyrs, Attalus is denominated "the pillar and support of the churches there," and a zealous champion for the truth. He was led round the amphitheatre with a beard carried before him, on which was inscribed, "This is Attalus the Christian!" whilst the people were incessant in expressing their great indignation against him. For the gratification of the people he was delivered to the wild beasts, and after having been run through with a sword, he was set in an iron chair and burned to death. The conduct of Attalus, as well as that of his fellow-sufferers, manifested a fortitude that was invincible. Eusebius, l. v. Prep. c. i. Lardner's works, vol. vii. p. 425, &c.

ATTALYDA, in Ancient Geography, a town of Asia, in Lydia.

ATTAMINATUS, in Entomology, a species of Scarabaeus, with the thorax black and gibbous; head tuberculated; wing-cafes tteftaceous, with five black spots on each. Marsham's Ent. Brit. Panzer names this little insect S. inquinatus, Ent. Germ.

ATTAR OF ROOS. See OTTAR.

ATTARSOAK, in Zoology, a name assigned by Cranz (Grönc. p. 163.), to the species of Phoca, greenlandica, or harp seal of Penants. See GROENLANDICA.

ATTELABOIDES, in Entomology, a species of Carabus that inhabits Coromandel, and is about the size of the European species leucophthalmos. It is apterous and black, with a narrow thorax; the posterior part of the head attenuated; wing-cafes furrowed and truncated. Fabric. 

ATTELABOIDES, a species of Circulio that inhabits Brazil. The flills are rough, varied with brown and gray; legs vaneigated; and thighs clavate. It is thus specifically defined by Fabricius; "ostro elytrique unibulculus," beak and wing-cafes with a single tubercle.

ATTELABOIDES, a species of Rhinomacer that inhabits the pine. It is downy; antennae and legs tteftaceous. A native of Sweden. Gmel. &c.

ATTELABOIDES, a species of Formica of a black colour; two spines on the thorax; legs furrowed; posterior part of the head attenuated. Fabricius. Inhabits Brazil.

ATTELABOIDES, a species of Cimex (Relvius Scott.), found in New Holland. It is tteftaceous, varied with black; anterior part of the thorax tteftaceous, with two black teeth. Fabricius. The snout is pale, with a black dorsal line; a black band in the middle of the thorax; anterior margin of the wing-cafes black; wings black; body tteftaceous beneath; thighs annulated with black.

ATTELABUS, a genus of Coleopteres infects in the Linnean sytem, that is distinguished by having the head inclined and pointed behind; antennae moniliform, and thickest near the end. Linn. &c.

Of this genus, Gmelin enumerates thirty-four species, including the Fabrician cler, and spindydes defcribed in Spec. Inf.—Fabricius in his Ent. Syll. defcribes thirty-seven species of the attelabi exclusively; his character of the genus is, feelers filiform; jaws buds; lip horned, concealing the feelers; antennae moniliform, and situated on the beak.

This genus Linnaeus observes is very obscure, the insects arranged under it differing much from one another in their external appearance. But this obscurity a later writer remarks, "proceeds rather from Linnaeus not having known a sufficient number of insects proper to be arranged under it; and his placing with those, the species included in the Clerus genus by Geoffroy, in which the generic character he alligns for his attelabi are not found, than to any defect in the characters themselves." Scopoli distinguishes the attelabi by the following character; hinder part of the head gradually diminishing in size; eyes prominent; thorax somewhat broader than the diameter of the head, and of a cylindrical form. Among these are included some of the Linnean chrysoloma, whose bodies are oblong and narrower than the thorax. The clerus of Geoffroy and Schefler is partly taken from the Linnean attelabi, and partly from the dermelle of that author; the characters they allign it are, antennae club-formed, and placed on the head; the knob composed of three joints; no probosces; thorax almost cylindrical, and without margin; siles of the feet spiny.

The body of the insect in the genus attelabus is commonly of an ovate form; the head projecting, ovate, and narrow behind, where it unites with the thorax; the eyes are globose and situated in front; the antennae short and approximate, moniliform, and composed of eleven joints, of which that at the base is large, and the three at the extreme form an ovale of a somewhat lengthened shape; thorax and scutel are both round-ended; wing-cafes as long as the abdomen, and rather convex; legs short and the feet of four joints. The insects of this genus approach very nearly to les brachicères, les brentes, les rhinomaces, les macrocéphales, and les bruches of modern French naturalists, but are sufficiently distinguished by their antennae.

The
The larva of the attelabi, according to some writers, are furnished with fix feet; are very fat, of a whitish colour, and have an annulated body. The head is protected by a hard scaly covering, and the mouth furnished with two very strong jaws, with which it does great mischief. It attacks the leaves, the flowers, the fruits, and even the stalks and roots of different plants; but most of the species penetrate into the plants and feed entirely on the pithyous or spongy parts within. Preparatory to the transformation to the pupa state, some species spin a silky web, and others form a little ball of a very solid kind, in which they remain during the second state. The perfect insects inhabit the same plants as the larva, but are deemed less injurious to them.

Gmelin, as before observed, describes thirty four species of this genus: these are coryli, avellanea, bilocular, denigratus, erythropterus, bipustulatus, genmnatus, indicus, eurelia-noides, fumanaemes, pennyananeces, melanros, angnatus, rubucollis, pubicoccus, betula, nutillarius, dubius, icnionym-nias, formicanus, sphagucus, fegurtatus, quadraculmaculatus, unifasciatus, octopuncatus, tricolor, bifasciatus, sphylius, ammios, spiaris, cyanus, erabroniformis, ceramboidea, supreloides; which see respectively.

Of a few of the figures in the third entomological plate of this work having been inadvertently misplaced, the insect inferred g. 15. attelebus will be found to belong to another genus, and that marked g. 13. bruchus being one of the Linnzean attelebii, may serve to illustrate this genus, till another figure can be given.

ATTELEBUSA, in Ancient Geography, an island in the Mediterranean sea, on the coast of Lyzia. Ptolemy calls it Atelebufa, and places it on the coast of Pamphylia. Pliny.

ATTENIEN. See Atellane.

ATTENA, in Ancient Geography, a town of Ethiopia, below Egypt. Pliny.

ATTENBY, in Geography, a town of Sweden, in the island of Oeland.

ATTENDANT, or Attendent, in a general sense. See Assistant, Retinue, and Satellites.

ATTENDANT, in Law, signifies one that owes duty, or service to another, or depends in some manner upon him.

Where the wife is endowed of lands by guardian, she shall be attendant on the guardian, and on the heir at his full age.

ATTENDORN, in Geography, a town of Germany, in the archbishopric of Cologne, and duchy of Westphalia, located on the river Bëhis, and seven leagues south of Arenberg.

ATTENHOVE, a town of Brabant, one league north-east of Londen.

ATTENTION, Attentio, compounded of ad, to, and tradire, I stretch, a due application of the ear, or the mind, to any thing said or done, in order to acquire a knowledge of it.

Attention of mind, is not properly an act of the understanding, but rather of the will, by which it calls the understanding from the consideration of other objects, and directs it to the thing in hand. Nevertheless, our attention is not always voluntary: an interfering object seizes, and fixes it beyond all power of control.

It is by the attention that is given to any object of sense or intellect, that we form a distinct notion of it, or discover its nature, its attributes, or its relations; and so great indeed is the effect of attention, that, without it, it is impossible to acquire or retain a distinct notion of any object of thought.

To this purpose it is said, that Sir Isaac Newton, when he was complimented upon the force of genius which had made such improvements in mathematics and natural philosophy, made this reply, no less judicious than modest, “that, if he had made any improvements in those sciences, it was owing more to patient attention, than to any other talent.” As it is very helpful to memory, if not essential to it, that the perception of the idea which we wish to remember should remain in the mind for a certain space of time, and should be contemplated by itself exclusively of every thing else, we can be at no loss to account for the assistance which the memory derives from attention, which confine partly, if not entirely, in the effort of the mind, to detain the idea or the perception, and to exclude the other objects that disturb its notice.

Hence it happens that in solitude, or the stillness of the night, the attention is undiverted and uninterfaced by surrounding objects, the impression made by any one object is stronger and deeper: and the memory becomes more retentive. When one faculty of the mind is intensely engaged about any object, the other faculties are laid, as it were, fast asleep; hence a man feels not what is before his eyes, when his mind is occupied about other things. In the tumult of a battle, a man may be shot through the body without knowing any thing of the matter, till he discovers it by the loss of blood or of strength. The most acute sensibility of pain may be damped if the attention be vigorously directed to another object. The anecdote relating to the attention of Archimedes at the siege of Syracuse is well known. (See Archimedes.) When there is no particular object that draws away our attention, there is a defutorineiefs of thought in man, and in some more than in others, which makes it very difficult to give that fixed attention to important objects which reason requires. A habit of attention may be acquired by practice; and the study of the mathematical sciences has a peculiar aptitude to direct and fix it. Attention is one of those operations of the mind, which, according to Dr. Reid’s distribution (Elements, p. 78.), belong to the class of those that are voluntary.

Attention, in respect of hearing, is the stretching or straining of the membrane tympani, so as to make it more susceptible of sounds, and better prepared to catch even a feeble agitation of the air. Or it is the adjusting the tension of that membrane to the degree of loudness or lowness of the sound to which we are attentive.

“Sounds,” says the celebrated Bacon in his Natural History, “are meliorated by the intention of the sense, where the common sense is collected most to the particular sense of hearing, and the sight suspended. Therefore sounds are sweeter, as well as greater, in the night than in the day; and I suppose they are sweeter to blind men than to others; and it is manifest, that between sleeping and waking, when all the senses are blind and suspended; music is far sweeter than when one is fully waked.”

ATTENIANTS; in Medicine. This term is applied to those medicines which are supposed to posse the power of removing the concreted parts of a fluid to the same state of fluidity which they possessed before concretion. It is nearly synonymous with reflexion. A very reasonable doubt has been entertained, whether there is properly any such attenuating power residing in any medicine, independent either of more dilution, or else of the stimulant property. The idea, however, of the operation of attendants is the following:—many of the older physicians, and after them the Boerhaavians, supposed obstruction in the circulating system to be produced by the red blood, or a thinner impervious humour joined with it, stagnating in their proper vessels, or wedged into other vessels of a smaller diameter
than the fangiferous by an error loci. This, they supposed, would produce a greater motion and heat, owing to the resistance of the vessels, which would incline the humours very much to a state of putrefaction. Of these concretions some are soluble by water alone, such as the foling, saponaconous, and mucous; but others require the dissolving power of certain medicines; and hence in the former case, edulents alone were sufficient to remove the obstruction, but in the latter, recourse must be had to the attentuants. Concretions supposed to be produced by an inflammatory spittle of the blood, and oily, fibaceous, and calculous concretions, were considered as yielding to the internal use of various salts, such as sal ammoniac, and fixed alkali, also soaps, decoctions of the acrid and alkalofeant vegetables, and bile (which is a kind of natural soap), all of which were considered as highly attenutuant; and the reader will here perceive how chiefly the experiments of the laboratory were applied to the living animal. Another species of attenuating or resolving remedies was the whole cakes of mercureal medicines, which are known to produce the most violent flow of saliva, and thin, thick humours from the body, the consequence (as was imagined) of the power possessed by this mineral to resolve and break down acrid matter impacted in the glands and minute vesicles.

The term attenuant is not now much employed in its original sense; the alleged caufe of obstructions being entirely disputed, as well as the supposed solvent power of these medicines upon the concocted humours, whilst remaining in the vessels of the body.

ATTENUATUM, in Entomology, a species of Lepidoptera that inhabits Europe, and is both described and figured by several authors. The wing-cases are attenuated and fulvous, with four black bands; legs telfaceous.

ATTENUATUM, a species of Buprestis that inhabits Rio Janeiro. The wing-cases taper towards the end, terminate in two teeth, and are frilled; body brassy-green, beneath coppery. Fabricius.

ATTENUATUM, a species of Vespa with a fangiferous abdomen, and black petiole, with yellow band. This kind inhabits America. Fabricius, &c. Offs. The antenna are fangiferous, tipped with black; head black, with the lip yellow.

ATTENUATION, compounded of ad, and teniis, thin, the act of attenuating; that is, of making any fluid thinner and less confidnet than it was before.

Attenuation is defined more generally by Chauvin, the dividing or separating the minute parts of any body, which before, by their mutual nexus or implication, formed a more continuous mass. Accordingly, among alchemists, we sometimes find the word used for pulverization, or the act of reducing a body into an impalpable powder, by grinding, pounding, or the like.

ATTENUATUS, in Entomology, a species of Carabus. (Cercopis attenuatus Fabr.Append.) This insect is apterus, black, wing-cases rather coppery, with three rows of raised dots; thorax narrow; head very narrow. Pann.

ATTENUATUS, in Natural History, a species of Echinonychus, described by Müll. Zool. Dan. It is globiferous, with an equal smooth yellow body, and neck telfiform. Sometimes found in the interstices of the shoroun. This is sena longicollis of Pallas.

ATTENUATUS, pedunculus, in Botany, denotes a foot-flake that grows smaller towards the flower.

ATTENY, in Geography, a town of India, in the kingdom of Deccan, beautifully situate in a forest of palm-trees, not far from the sea, about twenty-two leagues north of Vithapur.

Vol. III.
ing year he afflicted Sacheverell in his famous trial, who re-
commended him by a legacy of 500l., and in performing the
office of prosecutor to the lower house of convocation. In
1711 he was appointed by the convocation one of the com-
mittee for comparing Mr. Whiston's doctrines with those of
the church of England; and he was principally concerned in
drawing up “A representation of the present state of
religion,” which, though too exceptional in its principles,
and too violent in its spirit to be presented to the queen,
was nevertheless printed and privately dispersed. In 1712,
Mr. Atterbury was made dean of Christ-church; and in
1713 he attained, by the recommendation of the earl of
Oxford, the height of his promotion, that of the bishopric
of Rochester, and deanery of Welthamstede. It is said, that
he aspired to the primacy; but the death of the queen, in
1714, disconcerted all his projects, and disappointed all his
hopes of higher advancement. The accession of George I.
was an event which he had reason to deplore. The per-
sonal dislike of the king, of which he had mortifying evi-
dence, was retaliated on his part by diatribe to the esta-
blished government. In the first year of this reign, during
the rebellion in Scotland, he, and one other bishop at his in-
itiation, refused to sign the “Declaration” of the bishops;
and his name occurs in the most violent protests against
the measures of government. Not content with a constitutional
opposition, he engaged in a correspondence with the pre-
tender’s party, in order to bring about a revolution in favour
of the abdicated family; and in August 1723, he was ap-
prehended on this account, and committed to the Tower.
Whilst he was under examination, previous to his commit-
ment, he is said to have adopted our Saviour’s answer to
the Jewish council: “If I tell you, you will not believe me;
and if I also ask you, you will not answer me, nor let me go.”
In the month of March of the following year, a
bill was brought into the house of commons for “inflicting
certain pains and penalties on Francis bishop of Rochester;”
and having passed the commons, it was sent up to the lords
for their concurrence. In this house it was strongly op-
posed, and the bishop, in his defence, made an able and
eloquent speech, closing, after a solemn protestation of his
innocence, and an appeal to the searcher of hearts, with
this memorable declaration: “If your lordships shall pro-
cede to pass this bill against me, I shall discontinue myself
quietly, and tacitly submit to what you do; God’s will be
done; naked came I out of my mother’s womb, and naked shall
I return; and whether he gives or takes away, blessed be the
name of the Lord!” At length, however, after a long and
very warm debate, the bill passed into a law, and the bishop
was condemned to the deprivation of all his offices and
benefices, and to perpetual exile. The justice of this sen-
tence, though much litigated at and immediately after the
time when it was passed, has been since generally al-
lowed. Of his attachment to the pretender, the following
striking instance is related by the author of the Memoirs
of lord Chesterfield, from Dr. Birch’s MS. papers. “Lord
Harcourt, leaving the old ministry, provoked Atterbury’s
abusive tongue. He, in return, declared, that, on the
queen’s death, the bishop came to him and to lord Boling-
broke, and said, nothing remained but immediately to pro-
claim king James. He further offered, if they would give
him a guard, to put on his lawn sleeves, and head the pro-
cession.” Of his disaffection to the existing government, and
particularly his con-
duct towards Mr. Giblin, a worthy clergyman, and curate
of Gravelend, whom he supsended for allowing the use of
his church to the chaplain of the Dutch troops, who were
called over in 1715 to suppress the rebellion. Atterbury,
in consequence of his sentence, left the country in June,
1723, accompanied by his daughter, Mrs. Morrice, to whom
he was affectionately attached, and landed at Calais. From
thence he went to Brussels; but being obliged to leave that
place, he removed to Paris, where he resided till his death,
lengthening the rigours of exile by study, and conversation
and correspondence with learned men. It appears how-
ever, by some letters published at Edinburgh in 1768, of
unquestionable authenticity, that he was actively engaged,
in 1725, in fomenting discontents in the highlands of Scot-
land, with a view of encouraging another rebellion. In
1729 he lost his daughter, and this afflictive event, which
he bore with resignation, is nevertheless thought to have
hardened his own disposition, which happened at Paris, in
February 1731. His remains were brought over to Eng-
land, and privately interred in Wathamstede-albany. We
cannot forbear inferring, in this place, Mr. Pope’s fine
epitaph on the bishop, written in the form of a dialogue
between his daughter, supposed to be expiring in his arms,
immediately after her arrival in France to see him, and him-
1776.
As to the justice of the compliment, which it pays to his
political sentiments, the reader must judge.

Dialogue.

She. “Yes, we have lived,—one pang, and then we part!
May heaven, dear father! now have all thy heart.
Yet, ah! how much we loved, remember still,
’Till you are dust like me.”

He. “Dear shade! I will:
Then mix this dust with thine—O spotless ghost!
O more than fortune, friends, or country lost!
Is there on earth, one care, one wish beside!
Yes, Save my country, Heav’n’s, he said, and
died.”

Bishop Atterbury had four children, two sons and two
daugthers. His son Olbreal alone survived him.

Some time before his death the bishop published a vindi-
cation of himself, bishop Smalridge, and Dr. Aldrich, from
a charge brought against them by Mr. Oldmixon, of having
altered and interpolated the copy of lord Clarendon’s 17th
History of the Rebellion.” His sermons are extant in four
volumes 8vo.: those contained in the first two were published
by himself, and dedicated to his great patron, sir Jonathan
Trelawny, bishop of Winchester: those in the last two were
published after his death by Dr. Thomas Moore, his
lordship’s chaplain. His epitaphic correspondence with
Mr. Pope is extant in the collection of that poet’s Letters.”
Mr. Nichols has lately published in three volumes, 8vo.
The Epitaphic Correspondence, Vitiations, Charges, Speeches,
and Miscellaneous, of the right reverend Francis Atterbury,
D. D. lord bishop of Rochester,” with historical notes; the
greater part of these volumes is entirely new. From
the General Dictionary (vol. ii. 445.) we learn, that Dr.
Atterbury is said to have translated Virgil’s Georgies in
English, and to have written an “Harmonia Evangelica.”
In an elegant dissertation on the fictitious person of Japys,
or Japis in the Aenid, he attempted to prove that Virgil
meant by this person to allude to Antonius Mafa, an emi-
nent physician and polite scholar at Rome, in the reign of
Augustus; but the attempt does not honor to his critical
erudition, and has been deemed futile by judicious commen-
tators. His translations of two odes of Horace, are re-
puted by a competent judge to have received more than
their due share of applause.

As to this prelate’s character, however the moral and po-
itical part of it may have been differently appreciated by
opposite
opposite parties, it is universally agreed, that he was a man of great learning and uncommon abilities, a fine writer, and a most excellent preacher. With respect to Atterbury's public and political character, it is marked with that turbulent ambition and contentious violence which animated the Becketts and Laud's of former times, and which was ill disguised by the affected mildness and moderation of his episcopal writings. "The turbulent and imperious temper of this haughty prelate," says Dr. Wharton (Effay on the Writings and Genius of Pope, vol. ii. p. 432, 433), "was long felt and remembered by the college over which he presided. It was with difficulty Queen Anne was persuaded to make him a bishop; which she did on the repeated importunities of Lord Harcourt. After his decease, Atterbury occasionally urged his friends to proclaim the Pretender; and on their refusal, upbraided them for their timidity, with many oaths; for he was accustomed to swear on any strong provocation." From an anecdote related by lord Chesterfield to Dr. Matty, and recorded in "Matty's Memoirs" of that nobleman (p. 279), it has been inferred, that Dr. Atterbury had been long known, among his friends, to be a skeptic, or an unbeliever, with regard to revelation. The anecdote is as follows. "I went to Mr. Pope one morning at Twickenham, and found a large folio bible with gilt clasps living before him on his table; and, as I knew his way of thinking upon that book, I asked him jocously, if he was going to write an answer to it? It is a present, sai d he, or rather a legacy, from my old friend the bishop of Rochester. I went to take my leave of him yesterday in the Tower, where I saw this bible upon his table. After the first compliments, the bishop said to me, my friend Pope, considering your inimitable, and my age and exile, it is not likely that we should ever meet again, and therefore I give you this legacy to remember me by it.—Does your lordship abide by it yourself?—I do. If you do, my lord, it is but lately. May I beg to know, what new light or arguments have prevailed with you now, to entertain an opinion so contrary to that which you entertained of that book all the former part of your life?—The bishop replied, we have not time to talk of these things; but take home the book; I will abide by it; and I recommend to you to do so too, and do God bless you!" This little story, however, not only uncorroborated, but contradicted by other facts, is not sufficient to warrant the charge of scepticism against his prelate. Whatever were his faults, he does not appear to have disbelieved or even doubted the truth of Christianity. His actions and writings exhibit the fiery zealot and bigot rather than the infidel; though it must be acknowledged, that these characters may be united in the same person. His sermons on the miraculous propagation of the gospel, and on a standing revelation's being the best means of conviction, besides other discourses, furnish important and pleasing evidences of his attachment to the Christian religion. It ought also to be considered, that he generally treats unbelievers with contempt, as an ignorant, superficial, and conceited set of men; which he would scarcely have done if he had been of the same sentiments. For though a man may conceal, or deny, or even pervert the opinions which he himself holds, it is not very likely that he should appear to despise the retainers of them. Besides, there is an ardour of affectionsake eftem in Mr. Pope's two last letters to Dr. Atterbury (Pope's Works, vol. v. p. 351—355.), written to him when he was in the tower, where that eminent poet, who valued himself upon his moral character, could not well have expressed to the bishop, if he had known that he had acted the base and hypocritical part of publicly professing and defending that religion which he privately disavowed. Not to add, that he actually derived much of his consolation in adversity from his religious opinions. His correspondence with Dr. Wall and bishop Potter, preserved in Nichols's publication, fully proves his belief in, and his zeal for the honour of the Christian revelation; and the testimony, derived from his private correspondence and from the uniform tenour of his life and writings, ought surely, with impartial and candid judges, to outweigh the evidence deduced from a single story, however well authenticated. In his letters to Mr. Pope, and to his other correspondents, bishop Atterbury appears in a very pleasing light, both as a writer and a man. In safe and elegant, these letters are superior to those of Mr. Pope, which are more florid. If we were to form our judgment of him, as a man, from these letters, we should incline to think that it was his fate with to spend his life in a learned and elegant social intercourse with a few private friends; and yet numerous facts sufficiently shew, that nothing could be more distant from his real disposition and character, and that he was actuated in early life and in the progress of his years by a rebellious and turbulent spirit. His panegyrick, bishop Smalridge, in the speech which he made, upon preferring him to the upper house of convocation, as Proctor, represents him as "Vir in solo literaturam generis holopes, in plerisque artibus et stildis in electus curiosis, in maxime perfectis literarum disciplinis perficiens; i.e. "one, who is well acquainted with all parts of literature, long and successfully exercised in most arts and studies, and most accomplished in those sciences which admit of the greatest perfection." Although it is allowed, that he was sometimes too severe upon his adversary, and dealt rather too much in satire and invective, yet this is imputed by his panegyrist more to the natural favour of his wit, than to any bitternesses of temper, or prepotent malice. As a composer of sermons and a preacher, he excelled his contemporaries, and in this respect few English authors have attained to so high a rank. Of his character, as a preacher, the following encomium is bestowed upon him by the author of the "Tatler" (N. 66); who, having observed that the English clergy too much neglect the art of speaking, makes a particular exception with regard to this prelate. "Atterbury," says he, "has so particular a regard to his congregation, that he commits to his memory what he has to say to them; and has so soft and graceful a behavior, that it must attract your attention. He never ceases to be so considerate, to give no small recommendation, but he is to be highly recommended for not losing that advantage, and adding to the propriety of speech (which might pass the criticism of Longinus), an action which would have been approved by Demosthenes. He has a peculiar force in his way, and has many of his audience, who could not be intelligent hearers of his discourse, were there not explanation as well as grace in his action. This art of his is used with the most exact and honest skill. He never attempts your passions, till he has convinced your reason. All the objections, which you can form, are laid open and dispersed, before he uses the least vehemence in his sermon; but when he thinks he has your head, he very soon wins your heart, and never pretends to shew the beauty of holiness, till he has convinced you of the truth of it." Dr. Blair (Lectures on Rhetoric, &c. vol. ii. p. 127—155). says of this prelate, that he is defervingly accounted one of our most elegant writers of sermons. "At the same time," he adds, "he is more distinguished for elegance and purity of expression, than for profundity of thought: his style, though sometimes careless, is, upon the whole, neat and chaste; and more beautiful than that of most writers of sermons.
ATT

fermons. In his sentiments, he is not only rational, but pious and devotional, which is a great excellence. Dr. Wardropper (ibi lippa, p. 435;) thinks, that Atterbury was, on the whole, rather a man of ability, than a genius; and that he writes more with elegance and correctness, than with any force of thinking or reasoning. Biog. Brit. Gen. Dict.

Atterbury, Lewis, the elder brother of the bishop, was born at Calcott, in the parish of Newport-pagnel in 1656, and after finishing his grammatical education under Dr. Bully at Westminster school, removed to Christ church college, Oxford, in 1674. In 1695, he was elected preacher to the chapel at Highgate, in the neighbourhood of London; and in 1707, he was presented by the queen to the rectory of Shepperton, in Middlesex. In 1719, he was collocated to the rectory of Hornsey, in Middlesex, in which parish the chapel of Highgate is situated. Upon application to his brother for the archdeaconry of Rochester, he was refused; probably more from a mean opinion of his talents, than from delicacy. However, he obtained the character of an useful parish priest, annexing the profession of physic, which he studied for the benefit of his poor parishioners, to the clerical character; and he acquired the reputation of a plain, solid, useful preacher. At the age of seventy he had a stroke of the palsy, and died at Bath in the year 1731. He published several sermons, which formed two volumes, and other pieces; and after his death, two volumes of his sermons have been published, in consequence of his testamentary directions, by Mr. E. Yardley, archdeacon of Cardigan. Dr. Atterbury was intimately acquainted with archbishop Tillotson, formed his style of preaching on his model, and published a defence of him against the attack of an Irish priest. Biog. Brit.

Atterklaa, in Geography, a town of Germany, in the archduchy of Austria, six miles north-west of Entzerloft.

Attemining, in our Old Writers, is used for a time or term granted for payment of a debt, according to Blount.

Attern, in Geography, a town of Hindustan, in the country of Agra, thirty-eight miles S. E. of Agra, and thirty-nine north-east of Gwalior.

Attestation, compounded of ad, to, and text, or witness, the giving testimony or evidence of the truth of any thing; especially in writing.

Attestation of Deeds, in Law. See Deed.

Attestation of Deeds, in devise. See Devise.

Atthis, in Ornithology, a species of Gracula, called by Haffiield cornus Egyptian; and by Latham, the Egyptian grackle. The colour of this bird is greenish; belly ferruginous; legs fawn-coloured. Gmelin. It inhabits Egypt, as the synonymous names imply; and is believed to live on centipedes, scorpions, and other insects, the remains of which having been found in the stomach.

It is about the size of a lark; bill dull black, reddish at the base; eye bluish; head rather flattened at the top; upper parts of the plumage deep green, spotted with blue-green on the crown, hind part of the neck, and the shoulders; neck and back of the same deep green, but not spotted. On each side of the neck and back is a longitudinal broad line, the fore-part of which is ferruginous, the rest of a whitish lucid blue; throat whitish; tail nearly even at the end, and of a deep blue colour; claws blackish. Lath. Gen. Syn.

Among the ancients, the name of atlas was given to some bird at present not very accurately known. By Aldrovandus, and other naturalists, the fame name has been also assigned to birds altogether different from the present species.

ATTIA, in Geography, a town of Persia, ten leagues south of Kin.

Attic, something relating to Attica, or the city of Athens. In matters of Philology, we use, Attic, juxta Attic, meaning a delicate, poignant kind of wit and humour, peculiar to the Athenian writers. Attic witneses, was a witnes incapable of corruption; so an Attic muse was an excellent one, &c.

Attic Dialect, in Grammar, one of the four Grecian dialects, which was used in Athens and the adjoining country. Those who have chiefly distinguished themselves in this dialect, are Thucydides, Aristophanes, Plato, Iocrates, Xenophon, and Democritus. Its general properties are that it affects contractions of syllables in the same word, and also the joining of words; it often changes ε into η, and ϊ, as ευέλογος for ουελογος, prudent, ηαμερός for ηαμερον, to consult, and ηεφίαλε for πρεπειαρ, to do; it calls away α from ηα and ηι, as ηθμελα for αλκημα, to steep, and ηπξανο for πνευξανο, more; it changes η into ν, as νες for νης, a temple; it joins ηι to the end of words, giving it a circumflex accent, as ησιος for ηηισιος, a temple; and it annexes to the end of adverbs, as νενινις, now. Besides, the Attics have several phrases peculiar to themselves. Port Royal Greek Grammar, vol. ii. p. 322, &c.

Attic, or Attic Story, in Architecture, a low story erected over an order of architecture, to finish the upper part of a building. It is so called because supposed to have been first used in Attica; but whether it was originally employed to conceal the roof, or from some reasons of convenience in the internal distribution, does not clearly appear; what has been mentioned respecting it by ancient authors being very obscure. There is no instance of an Attic among the existing antiquities of Athens. In Italy it is met with in the triumphal arches, and in the forum of Nerva.

It has been much employed by the moderns, and particularly by the Italian architects. But the rules which they give for its proportions are various, some making it in height equal to one half, and others to one third of the principal order. It is usually decorated with pilasters, and frequently with baffo-relievos, in the spaces between, or there are windowed in these spaces. The pilasters are sometimes plain, and sometimes have a trik, panneled, or other ornamentation. They have no diminution, nor have they any peculiar base or capital, the mouldings at the top and bottom of the Attic continuing round the pilasters. In the arch of Constantine at Rome there are statues placed over the columns of the principal order, immediately before the pilasters of the Attic; and this has frequently been imitated in modern buildings.

Attic Story is also frequently applied to the upper story of a house, constructed in the roof, when there is no order of architecture employed in its decoration.

Attic Order. This term has been by some authors used to denote the pilasters that are employed to decorate an Attic story. Pliny, after enumerating the other orders, says, "Prater habe canttur Atticae columnae quaternis angulis pariet interium intervallorum." But how these square columns were formed is very uncertain, since we have no remains of columns which are known to have been of the kind here described; and Vitruvius makes no mention of them. The Attic of the forum of Nerva corresponds most with Pliny's description, there being projections that come forward from the attic over the detached columns, faced with square pilasters, whose siles are nearly equal in width to their fronts. It seems improper, however, to call this an order of architecture, as it has no peculiar parts essentially
Attic or Attieurgic Base. Vitruvius, lib. iii. cap. 3. speaking of the bases of columns, says, "This done, the bases are fixed in their places, and are so proportioned that including their plinth, they have in height half the thickness of the column; and in projection, which the Greeks call \( \pi\varepsilon\varphi\omega\varsigma \), they should have one quarter of the thickness of the column; so that their breadth and length will be once and a half the thickness of the column. Their height, if they are to be in the Attic mode, is so divided, that the upper part is one third of the thickness of the column, and the remainder is left for the plinth. The plinth being excluded, the remaining part is divided into four parts, and the upper torus has one of them; the remaining three parts are equally halved, and one half makes the lower torus, and the other the scotia, which the Greeks call \( \tau\varepsilon\rho\sigma\omega\varsigma \), with its squares."

This kind of base is frequently found in the ancient examples of the Ionic and Corinthian orders, both Greek and Roman, but the proportion of its parts varies in almost every different example. We sometimes also meet with allusions between the tori and fillets, and all its mouldings are, in Roman architecture, frequently covered with ornaments. This base is extremely beautiful, and has been much employed by modern architects, who have, though very improperly applied it also to the Doric order, or rather to the order which has long been called Doric by the moderns. See Doric Order.

For an example of the Attie base we refer the reader to Plate X. of Architecture.

Attic or Attieurgic Door. Vitruvius, lib. iv. cap. 6, says, in speaking of doors, that "they are of three kinds, Doric, Ionic, and Attic." And he afterwards proceeds to describe the manner of forming the Attic door, concluding with this remarkable passage, "These rules, which are practiced in the composition of Doric, Ionic, and Corinthian temples, I have explained as well as I have been able, according to the approved methods;" intimating thereby that he has applied the term Attic only as relating to the Corinthian order.

Attic Year. See Year.

Attica, in Ancient Geography, one of the eight districts into which Achaia was divided, anciently called Atti, Alic, and Arbites. Plin. l. iv. c. 7. Paufan. in Attic, c. 11. Mela, l. ii. c. 3. This country is a kind of peninsula of a triangular form, bounded on the north by Boeotia and the gulf of Eupirus, on the west by Megaris, on the south by the Saronic gulf, and on the east by part of the Aegean sea; and extending from north-west to south-east about eighty miles with decreasing breadth, but at an average about forty miles, so that its area is considerably less than that of Yorkshire. This little country, every where intersected with rocks and mountains, is by nature extremely barren. The fertility of the soil requiring affluence to produce the common necessaries of life, rendered the territory much less inviting to plundering or conquering invaders than the fruitful lands in other parts of Greece. Hence Thucydides observes, in his Introduction to his History, that a much greater portion of its inhabitants was aboriginal than those of neighbouring divisions. The physical deficiencies of Attica tended to invigorate the intellectual and moral energies of the people; and a political establishment happily adapted to the circumstances and characters of the citizens, cherishing and improving the genius and spirit from which it sprang. A region less extensive and naturally productive than North Wales, was transcendent in the arts of war and of peace, and repelled the choicest myriads of the mod potent monarch. Informed by freedom, this little body made the gigantic depot of the East tremble on his throne, and left monuments of military achievements, springing from liberty and patriotism, and guided by wisdom, which have only been surpassed by the tranquil and pacific efforts of its genius in the various departments of the arts, literature, and philosophy.

Though in the early periods of their history, they were little subject to foreign invasions that fought to dispel them of their habitations, their maritime exposure opened the way to emigrations of sea-faring adventurers, who sought establishments, not by exterminating and enslaving the natives, but by conciliating them through an interchange of benefits. The first navigators recorded in history to have visited the Autochthones, or aboriginal possessors of Attica, came from the mother country of erudition and science. Cecrops, an Egyptian (B. C. 1556), led a colony of his countrymen into Greece. (See Strabo, lib. ix.) The colony of Cecrops derived its origin from the city of Sais, in Egypt. The adventurers who composed it had quitted the banks of the Nile, to withdraw themselves from the tyranny of an inexorable conqueror; and after a tedious voyage, reached the shores of Attica, at all times inhabited by a people whom the fierce nations of Greece had disdained to bring under the yoke. Their fertile fields offered no plunder, nor could their weakness inspire any dread. Habituated to the enjoyments of peace, free without knowing the value of independence, rude rather than barbarous, they must have united themselves without difficulty to strangers instructed by misfortune. In a short time, the Egyptians and the inhabitants of Attica formed but one people; the former, however, assumed over the latter that ascendency which sooner or later invariably attends superiority of knowledge; and Cecrops, placed at the head of the united people, conceived the noble design of bequelling happiness on his adopted country.

The ancient possessors of these lands yearly saw a regular succession of the wild fruits of the oak, and relied on nature for a reproduction which secured their annual subsistence. Cecrops first engaged the wandering hunters or shepherds of Attica to unite in villages of husbandmen. Corn, wine, and oil, rewarded their useful labours; and these productions being acquired by common toil, were regarded, with the ground itself, as a common property. The idea of an exclusive and permanent right to all the uses of a piece of land, whether belonging to communities or to individuals, is one of the most interesting steps in the progress of society. In Attica, this invaluable right was immediately followed by such institutions as tended to secure its enjoyment, and to check the injustice of man, who is seldom willing to acquire by flow labour what he can ravish by sudden violence. The indulgent influence of religion was employed on this important occasion. With a religious property religious rites were introduced, and Cecrops instituted sacrifices to the attributes of wisdom and of power under the names and semblable representations of Minerva and Jupiter. He is also by some historians said to have taught his subjects the art of navigation; to have instituted the areopagus, and to the institution of civil rights to have added the punishment of crimes. Aware of the advantages which might be derived from union of effort, Cecrops professed to facilitate it by constancy of residence; he induced his subjects to collect and secure themselves within a wall, and laid the foundation of Athens. He placed this new city on a hill in the midst of a large plain, and built the citadel on the rock in which the hill terminated; this
ATT

The chief city of Attica, next to Athens, was Eleusis. Rhamnus was famous for the temple of Amphitaurous and the statue of Nemesis. The principal river was Asopus; as to the Hissus, Eridanus, and Cephisus, they were rather brooks than rivers; but Attica, having a number of havens, was left in want of rivers. The riches of this kingdom, according to the Thucydides (I. 16), occasioned by its frugality and commerce, are said to have amounted to 12,000 Attic talents a year; hence it was enabled to maintain a powerful army and navy, and thus to extend its possessions. The coin of Attica was commonly flamped with the figure of an ox, and this circumstance gave occasion to the phrase frequent among the Greeks, of a thing being worth 10 or 100 oxen; and hence also arose the common proverb "bovem habit in linguam," when a man was thought bribed to speak contrary to his own sentiments. But the wealth, strength, and populosiues of Attica, were principally displayed in the number of tribes, amounting to thirteen, into which it was divided, and the great number of cities and towns belonging to each tribe.

ATTICUS, HERODES TIBERIUS CLAUDIUS, in Biography, was descended of a noble family, which traced their pedigreed as high as Cimon and Miltiades, and born at Marathon in the territory of Athens. His father, Julius Atticus, was reduced to a low condition by the proscription of his father; but by the accidental discovery of a treasure in his house, he was unexpectedly raised to the possession of affluence. Dreading the event of this discovery, he communicated it to the emperor Nerva, who empowered him to use it at his pleasure; and on a second representation, that it was too large for a private person, the emperor renewed his licence, adding that if it was too large for use, he might abuse it, if he pleased, for it was his own. Atticus having inreased his wealth by marriage, lived at Athens with very singular magnificence, giving to the people frequent largesses, and offering to the gods very splendid sacrifices. Whilst he had the command of the free cities in Aia, in the time of Adrian, he perceived that the city of Troas wanted water, and he obtained of this emperor a grant of three millions of drachmas, in order to defray the expense of procuring the necessary supply; but the charge of executing his project for this purpose amounted to seven millions of drachmas instead of three, and the additional expense he defrayed out of his own fortune. The great wealth of Atticus enabled him to make very liberal provision for the education of his son, Herodes; and accordingly he employed Secelius, one of the most eminent orators of the age, as his instructor, and rewarded him liberally for his services. Herodes professed distinguished talents, which he cultivated with diligence; and his attention was principally directed to the study of rhetoric. In this science, as it was then practised, he made great proficiency; and such was the ardour of his pursuit, and his ambition of gaining applause, that when he was deputed at an early age to address a speech to the emperor Adrian, who was then in Pannonia, the young orator is said to have failed in the attempt, and to have been almost urged by flame and despair to throw himself into the Danube. This misfortune, however, served only as an incitement to future diligence. Having finished his attendance in the schools of rhetoric, Herodes returned to his own country, and delivered public lectures, which were popular and much frequented by the sophists, philosophers, and rhetoricians of the age, who were munificently rewarded for their attendance and applause.

The liberality of Herodes was, however, sometimes imposed upon and abused. Aulus Gallus, who was himself a disciple of Herodes, mentions, one instance to this purpose. A man with a cloak, long hair, and a beard down to his waist, presented himself to the orator, and supplicated alms. Being interrogated who he was, the pretended philosopher indignantly replied, that he was a philosopher, and expressed surprise at the question. "I see," replied Herodes, "the cloak and the beard, but I do not see the philosopher." One of the company interpolated, and observed, that this person was an impudent beggar, who spent his time in the tavern, and inflected those who refused to relieve him. "Well then," said Herodes, "let us give as men, though not as to a man:" thus acknowledged on his own head the sin the young Marcus and Cicero. When he attained maturity, the republic was disturbed by the factions of Cinna and

ATT
and Sulla; but endowed with a peculiar facility of manners, which made him uniformly averse from civil contempts, he retired to Athens with a great part of his property, and there devoted himself to study, and particularly to Grecian literature, in which he excelled his contemporaries of his own country. At Athens he became popular by his conciliatory disposition and conduct, by the liberal distribution of his money, and by his charity to the poor and distressed. The Athenians wished to confer on him the honour of a citizen, which he declined; and though during his abode with them, he would not suffer them to erect statues to him, they testified their respect in this way immediately on his departure, an event which occasioned a general mourning through the city. The fame of Atticus, which he acquired from his attachment to this city, and his familiarity with its language and manners, became his usual appellation during his life, and continued to distinguish him in after ages. At a distance from the scene of political contention, he interred himself in the welfare of his friends; and at the risk of displeasing the triumphant party, he formed a friend in difficlys, for he affiled young Marius, when declared a public enemy, by supplying him with money to escape from his enemies. He even occasionally made journeys to Rome to support his friends in contested elections, and embraced every opportunity that occurred of serving those who needed his assistance. To Cicero he was particularly attached, partly from affinity, as his sister Pomponia was married to Quintus Cicero, but chiefly from similarity of disposition; and he supplied him with money in the time of his exile; and also intimate with Hortenius, the rhetorical rival of Cicero, he exerted himself in preserving a good understanding between them. When Rome was in a tranquil state, it was the place in which Atticus chose to reside; but he never engaged in public business. He avoided himself of none of the opportunities that occurred of increasing his fortune; whilst he was honoured with a nomination to public offices, he disregarded the emoluments accruing from them. He never engaged in a law-court, nor was ever concerned in an accusation as the principal or second. He never bid for statues at public auctions, or in any way partook of the spoils of the unfortunate. When the war broke out between Caesar and Pompey, Atticus was sixty years old; and his age was a plea of which he availed himself for not taking part with either; and by his subsequent conduct he offended neither the one nor the other. After the death of Caesar, whilc favour he had conciliated, he successfully opposed the establishment of a private treasure for the use of the party which had taken him off, though he was upon very intimate terms with Brutus. Nevertheless, when Brutus and Cassius were obliged to leave Italy, he supplied Brutus with a large sum of money. He afterwards exerted himself to the utmost of his power in favour of Antony and his family. Upon the return of Antony from his retreat, and when every friend of the republican party was exposed to great danger, Atticus withdrew into a place of refuge; and though Antony was urged to destroy him, he remembered his obligations to his benefactor, affured him by a letter written with his own hand of his faith, and appointed a guard for his protection. In this season of difficlys, Atticus succoured the fallen party, and supplied the necessities of those who, under proscription, had fled to Epirus, out of his own elaits; and he owed no less respect to Servilia the mother of Brutus, after the death of this patriot, than he had done during his prosperity. His family afterwards became allied to the imperial family by the marriage of his daughter with M. Agrippa, the friend and favourite of Octavius, who formed with Atticus an intimate acquaintance, and communicated to him all his movements and delusions. While Antony lived, an intimate correspondence was carried on between him and Atticus. Thus from the first to the last, he maintained the character of "the general friend of all parties, in all fortunes." The conduct by which this character was acquired and maintained has not escaped censure; and Atticus has been charged with a neutrality and indifferency, with regard to public concerns, which was dishonourable and criminal. To his Epicurean principles, which he imbibed at Athens under Phaedrus and Zeno the Sidonian, some have ascribed the peculiarities of his temper, and the resolution by which he seems to have been actuated, that amidst the fluctuations and vicissitudes of political events, he would maintain a composed and tranquil mind. But others have attributed his determining character to nature disposition and early habits, more than to any speculative principles. In domestic life, as well as in the more extended circle of social intercourse, he possessed a degree of self-command, which, all circumstances considered, appears to have been very extraordinary and singular. The temper of his uncle Cæcilius was intolerably perverse, and yet Atticus humourd it in such a manner that he retained his favour to the last, and inherited the greatest part of his very large fortune. With his mother, who died at the age of 50, when he was 67 years old, and with his sister, who was nearly of the same age with himself, he lived in a harmony so uninterrupted, that he never had occasion to be reconciled to the former, nor ever had any quarrel with the latter. By his own patrimony and his uncle's bequest, he was master of a large fortune, which he expended with liberality. His mode of living corresponded to his affluence, and to his taste and habits, as a man of literature and philosophy. His domestics were select, but not numerous; several of them had been born and brought up in his own family; and many of them were in one way or other as readers or copyists, employed to the purposes of literature. His table was elegant, but not costly. Reading was always an accomplishment of the upper; and he had no guests to whom such an entertainment was not acceptable. In his enjoyments he was moderate; in his studies, which formed a great part of his occupation, he was particularly attached to inquiries relative to the antiquities of his country: his laws, treaties, customs, and the genealogies of its illustrious families. On these subjects he wrote several treatises, which were held in high estimation. His poetical talents were employed in concise descriptions of the characters and actions of illustrious men, which were placed under their statues. He wrote in Greek a history of the confidant of his friend Cicero. Of the writings of Atticus, none remain; but we have a large number of the letters of Cicero, addressed to him, and written from the year of his confidant almost to the time of his death. These letters are confidential, and contain a variety of curious particulars; both political and literary. Atticus having attained to the age of 77, with little interruption of health, was seized with a disorder of the intestines, which terminated in a painful and incurable ulcer. Apprized of the danger of his case, he communicated to his son-in-law Agrippa, and other friends, his resolution of putting a period to a life that was no longer valuable to himself and others. Unmoved by their remonstrances, he determined to abstain from food, and though his fever left him and his pain abated, after an abstinence of two days, he perished in his purpose, and on the fifth day, death closed the scene, in the year of Rome 721, B. C. 33. Corn. Nepos in Vit. Atticis. Gen. Dict. Gen. Biog.
ATTICUS, a Platonic philosopher, lived under the emperor M. Aurelius, and took pains in ascertaining the precise difference between the doctrines of Plato and those of Aristotles. Eusebius has preserved several fragments of his works, in which he argues against Arisotle, concerning the ultimate end of man, providence, the origin of things, the immortality of the soul, and other topics. Plutarch, of the Eclectic school, held the writings of Atticus in high estimation, and recommended them as very useful for obtaining an accurate knowledge of the Platonic system. Atticus pronounced it impossible for those who had imbibed the Peripatetic notions, to elevate their minds to a capacity of understanding and relishing the sublime conceptions of Plato. Euseb. Chron. sub. Aurel. A. 179. Prep. l. xv. c. 4, &c. Fab. Bib. Grec. vii. p. 54.

ATTICUS, a patriarch of Constantinople in the fifth century, was a native of Scæfia in Armenia, and having received his education among the Macedonian monks, became first prebendary, and afterwards, viz. in 496, patriarch of the church of Constantinople. But having seized this see while John Chrysofolus was living, he was excommunicated by pope Innocent I. and the western bishops. However, on the death of Chrysofolus he was again restored, on condition of replacing his name in the diptychs, or list of the archbishops of Constantinople, whose names were recited at the altar, as having died in the communion of the church. Atticus is extolled for his learning, prudence, and piety; for the gentleness of his temper and manners; for his zeal against the Nestorians; and for his charity to the poor, without discrimination of religious party and profecution. He died in the year 427. Whilst he was prebendary, he committed his fermoens to memory; but when he became a bishop he preached extempore. Of his writings there are extant, "A Letter to Cyril of Alexandria," on the restoration of the name of Chrysofolus in the diptychs (esp. in Niceph. Hist. Eccl. l. xiv. c. 26); "A Letter to Calliopus, prebendary of the church at Nice," accompanying 300 crowns sent to the poor of that city (Socrat. l. vii. c. 23); and another (in Niceph. hist. sup.) addressed to the deacons of the church of Alexandria, concerning the means of restoring peace to the church. He also wrote a book "On Faith and Virginity," dedicated to the daughters of Arcadius, and cited by Cyril in his book to the empresses. Socrat. H. E. l. viii. c. 2. Sozom. H. E. l. viii. c. 27. Cave, H. L. vol. i. p. 384.

ATTIDIIUM, now Attilio, in Ancient Geography, a city of Umbria, situated between Sentinum, Camerinum, and Matilia, near the sources of the river Æsis. Pliny calls the inhabitants Attidii. Several ancient inscriptions have been found in the vicinity of Attilio.

ATTIGNY, in Geography, a town of France, and seat of a tribunal, in the department of Ardenne; two leagues north-west of Vozières, and fix fouth of Mezières.

ATTILA, in Biography and Historvy, king of the Huns, and by the modern Hungarians denominated "The Scourge of God," was the son of Mundzuk, and deduced his descent from the ancient Huns, who had formerly contended with the monarchs of China. Indeed the modern Hungarians have traced his genealogy upwards, in the thirty-fifth degree, to Ham, the son of Noah. At the death of Rugilas, A. D. 433, his two nephews, Attila and Bleda, succeeded to the throne of their ancestors. Having concluded an humiliating peace with the emperor Theodosius II., they extended their arms towards the north with so much success, as to reduce all the nations between the Danube and the Euxine under their dominion. Under pretence of an offence given them by the Romans, they made an irruption into the eastern empire, took several towns on the south of the Danube by force, defeated several imperial armies, and laid waste the whole adjacent country with fire and sword. Theodosius, thinking himself secure at Constantinople, retired into Asia, and was glad to purchase an inglorious peace. At this time the two nephews of Rugilas shared the government of the Huns; but Attila, whose ambition admitted of no partnership in power, caused Bleda to relinquish both his sceptre and his life, and acquired the sole sovereignty of the nation and its dependent territories. The extent of his empire affords the only evidence of the number and importance of his victories. If a line of separation were drawn between the civilized and the savage climates of the globe; between the inhabitants of cities, who cultivated the earth, and the hunters and shepherds who dwelt in tents; Attila might aspire to the title of supreme and sole monarch of the Barbarians. He alone, among the conquerors of ancient and modern times, united the two mighty kingdoms of Germany and Scythia, in their most ample latitude; Thuringia, extending to the Danube, was in the number of his provinces; he interposed with the authority of a powerful neighbour, in the domestic affairs of the Franks; and one of his lieutenants chaffuated, and almost exterminated, the Burgundians of the Rhine. He subdued the islands of the ocean, the kingdoms of Scandinavia, encompassed and divided by the waters of the Baltic; towards the east his dominion extended over the Scythian Æsars to the banks of the Volga; and he sent ambassadors to negotiate an equal alliance with the empire of China. He also reckoned among his subjects the numerous and warlike tribes of the Gepidæ and Ostrogoths. "The crowd of vulgar kings, the leaders of so many martial tribes, who served under the standard of Attila, were ranged in the submiffive order of guards and domestics, round the person of their master. They watched his nod; they trembled at his frown; and, at the first signal of his will, they executed, without murmur or hesitation, his stern and absolute commands. In time of peace, the dependent princes, with their national troops, attended the royal camp in regular succession; but when Attila collected his military force, he was able to bring into the field an army of five, or, according to another account, of 700,000 Barbarians." The portrait of Attila, says Jornandes, a Gothic historian, exhibits the genuine deformity of a modern Calmuck; with a large head, a swarthy complexion, small deep-set eyes, a flat nose, a few hairs in the place of a beard, broad shoulders, and a short square body, of nervous strength, though of a disproportionate form. His haughty step and demeanour expressed conscious superiority; and by freely rolling his eyes, he seemed to enjoy the terror which he inspire. Nevertheless, this savage hero was not inaccessible to pity; his rebellious enemies might confide in the assurance of pardon and peace; and Attila was regarded by his subjects as a just and indulgent master. His delight was war, and he indulged his passion for it to the destruction of myriads. Apprized of the influence of superstition over ignorant and savage minds, he availed himself of it, as a collateral and useful instrument for the accomplishment of his purposes. Accordingly he pretended to have discovered, by means of a shepheard, the famous sword of the Scythian Mars; and being in possession of this, he allerted his divine and indefeasible claim to the dominion of the earth. As the favourite of Mars, whom he propitiatted by bloody rites and sacrifices, Attila soon acquired a sacred character, which rendered his conquests more easy and more permanent; and the Barbarian princes confessed, in the language of devotion or of Jatroty, that they could not presume to gaze, with
with a steady eye, on the divine majesty of the king of the Huns. In his garb and mode of living, the king of the Huns affected no peculiar distin
tion, but rigidly adhered to the simplicity of his Scythian ancestors. His dress, his arms, and the furniture of his horse, were plain, without ornament, and of a single colour. The royal table was
served in wooden cups and platters; fish was his only food; and the conqueror of the north never tasted the luxury of bread. His palace, though it surpassed all other
houses in his dominions, was built entirely of wood; and it contained, within a palisaded enclosure, a variety of separate
buildings, appropriated to his numerous wives. When
the Roman ambassadors were introduced into the private
apartment of Cerca, the principal queen, she received their
visit, reclining on a couch; her domestics formed a circle
round her; and her damoils, seated on the ground, were
employed in working the variegated embroidery which
adorned the dress of the Barbare warrior. The other
wives of Attila politely admitted them to their presence and
table, nor was there any appearance among them of the
rigid and illogical confinement imposed by Attila's jealousy.
When these ambassadors had audience of Attila himself, he
was surrounded by a formidable guard; and when they
were invited to the royal feast, they had reason to praise
his politeness and hospitality. On this occasion the
company were diverted by a variety of buffooneries, which
produced loud and licentious peals of laughter; but Attila
himself maintained an inflexible gravity, and never relaxed
his features except on the reception of his favourite son,
Irmæ, who, by the assurance of his prophets, was to be the
future support of his family and empire. Thus did this
powerful monarch live familiarly among his people, and
pride himself in trampling upon the pomp and parade of
kings and emperors.

After the brief peace with Theodosius, Attila sent various
embassies, with complaints and threats, to Constantinople;
and, to the displeasure of the imperial court, a base
design was formed, with the privity and function of the emperor,
of murdering Attila, under the disguise of a solemn
embassy. The conspiracy was discovered, and the king of the
Huns, with a singular moderation, contented himself with
exacting a large ransom for the immediate agent in the
business, and with severely reprimanding Theodosius. The
treasure with the eastern emperor was renewed, at the expense of
fresh payments. On the accession of Marcian, in 453,
Attila's demand of tribute was refuted; upon which he sent
a threatening message to the emperors of the east and west,
which was delivered by his envoys in these terms: "Attila,
my lord, and thy lord, commands thee to provide a palace
for his immediate reception." He proceeded, however, to
direct his arms, in the first instance, against Valentinian III.,
a weak and unwarlike prince. The pretext of this hostility
was founded on the following circumstance. Honoria, the
fifheretofore Valentinian, having dishonoured herself by an
in
ter
game with her chamberlain, was banished to the court of
Constantinople. Here she found means to send an offer of
her person to Attila, with a ring, and an urgent request that
he would march and claim her for his spouse. These
overtures were at first received with coolness on the part of
Attila, but afterwards conceiving that he might derive ad-
vantage from them, he made a formal demand of Honoria,
with an equal share of the imperial patrimony, before he
proceeded on his intended irruption into Gaul. His demand
was refused, and Honoria was married to an obscure prince
in Italy, and there confined to perpetual imprisonment.
Attila, professing to be satisfied with respect to Honoria,
entered Gaul, under a pretence of making war upon Theo-
doric, king of the Vlæns, in Southern Britain. With this
view he assembled, in 453, an immense army of northern
Barbarians, and without opposition crossed the Rhine. In
his progress through Gaul, he defeated the country, laid
and burnt several cities, and at length arrived before
Orléans. Here he was overthrown by the arms of Theo-
doric, and of the empire, under count Theudric, who obliged
him to retire. After the bloody battle of Chalons, however,
without molestation to the confines of Thuringia, where he passthe Rhine, and continued his progress to
Pannonia. At the commencement of the following year,
Attila, having recruited his forces, passed the Alps, entered
Italy, and invested Aquileia, which he utterly destroyed.
He then ravaged Lombardy, sacked and reduced to
many of their towns; and thus, by means of the furs, which
who fled from the terror of his name, was unintentionally,
instrumental in laying the foundation of the Venetian republic. Valentinian, incapable of subsistence, fled to Ravenna.
To Rome, and sent a deputation to Attila, at the head of
which was Leo, bishop of Rome, for the purpose of decrees"ing his wrath, and proposing terms of accommodation.
Attila consented to leave Italy, on the payment of a very
large sum, as the dowry of the princess Honorina, and an
annual tribute. But this was only a temporary truce; he threatened to return the next year, if Honorina and her
dowry were not punctually transferred to him. Attila,
however, did not long forgive his return into his own
country. Having added to the number of his wives a beautiful young virgin whose name was Ildeo, he celebrated his marriage with great pomp and festivity at his
wooden palace beyond the Danube; and, oppressed by wine
and sleep, he retired at a late hour to the nuptial bed.
In the night a blood-vomiting burst, and as he lay in a
fainting posture, he was suffocated by a torrent of blood. His attendants found the trembling bride sitting by the side
of the bed, hiding her face with a veil, and lamenting the
death of the king, as well as her own danger. His body was
exposed in the midst of the plain, under a talaria pavilion;
and "the chosen squadrons of the Huns, wheeling round in
measured evolutions, haunted a funeral long to the memory of
a hero glorious in his life, invisible in his death, the
father of his people, the scourge of his enemies, and the
terror of the world. According to their national custom,
the Barbarians cut off a part of their hair, gashed their
faces with uncouth wounds, and bewailed their valiant
leader as he departed, not with the tears of women, but
with the blood of warriors. The remains of Attila were
inclosed within three coffins, of gold, of iron, and of stone,
and privately buried in the night; the spoils of nations were
thrown into the grave; the captives who had on the night
were inhumanly massacred; and the fate Bleda,
who had indulged such execrable grief, feasted with a
bloody and intemperate mirth about the recent sepulchre of their king." The death of Attila is commonly dated in
the year 454; by some, in 453.
With him the empire of the Huns terminated; for after his death, his numerous feuds either deserted one another by
their mutual contest, or were disposed of by those bold bishops, who aspire to the rank of kings. Anc. Hist. vol. xvi. p. 144—159.
Gibbon's Hist. vol. vi. p. 120—115.

ATTILA, ATTILIUS, in Lituus, denotes the rigging
or decoration of a ship. Fleta, l. c. 25.

ATTILUS, in Latinus, a term synonymous with
addox, adanç, and adalju Attinus; and applied by Pliny
and Rondelius to the variety of the Linnæan Amperis
florin, or common luteana.

ATTINGA AMERICANA, in Crinitol, 12, a name by
which
which Brief, calls the pinnated grous of the Arctic Zoology, and tertio capito of Gmelin.

ATTIRE, in Botany, is used by some to denote the third part or division of the flower of a plant; the other two being the entalpament and the foliation.

The attire is of two kinds, semiform and florid. — The semiform attire consists of two parts; chives or flaminia, and summits or spires, one upon each flamen.

The florid attire is usually called the thrums, as in the flowers of marigold, tansy, &c. Those thrums are called ferts, which consist of two, but most times of three pieces. And the outer part of the furt is the floret, whose body is divided at the top like a cowpflower, into five parts, or different leaves.

ATTIRE, in Heraldry, signifies a single horn of a flag.

ATTIRE, in Hunting, denotes the head or horns of a deer. The attire of a flag, if perfect, consists of horn, pearls, beam, getters, antler, fur-antler, royal, fur-royal, and croches: — of a buck, of the horn, beam, brow-antler, advance, palm, and spingles.

ATTIRED, in Heraldry, a term used in speaking of the horns of a flag, hart, or buck.

ATTIRES, are both the horns of a flag, hart, or buck.

ATTITUDE, in Painting and Sculpture, the posture or guile of a figure or statue; or such a disposition of their parts, as seems to express the action and the sentiments of the person represented. See MECHANICAL MOTION of the Human Figure, and Composition, and Contour, under the article SCULPTURE.

ATTIUM, in Ancient Geography, a promontory on the western coast of the island of Corica; now called Punta di Aticiolo.

ATTLEBOROUGH, in Geography, a township in America, in Bristol county, Massachusetts, eighty-two miles south from Boston, and nine north from Providence.

ATTLEBURGH, a town of England, in Norfolk, distant N.N.E. from London ninety-four miles.

ATTMELLA. See Acemella.

ATTNANG, in Geography, a town of Germany, in the archduchy of Austria, one mile W.S.W. of Schwannafadt.

ATTACK, a city and fortress of Hindostan, on the eastern bank of the Indus, built by Abar, in 1581, to command the passes that leads from Cabul to Lahore. This farts is so confined, either by the nature of the banks, or of the channel of the river, or both, that the passage from the landing place leads through the very forterfis itself. The ancient Taxila, where Alexander crossed the Indus, flood on or near to the site of Attack, N. lat. 33° 6'. E. long. 71° 15'; that part of the river Indus, called also Niah and Sinde, that separates the province of Lahore from Panthawur, is denominated the Attack, probably from the city founded on its banks. At Attack, the river Cabul, after receiving the rivers of Seward, Bipore, &c. joins the Indus, and very considerably increases it. For though the Indus is sometimes fordable above Attack, and Mr. Forster actually forded it at twenty miles above this place, July 12th, 1783; we never hear of its having been ford below that point.

From Attack downwards to Moultan, or to the confluence of the Panjub waters, this river (says Major Rennell) has obtained the name of Attack; but spoken of generally, it is called Sinde.

ATTOLLENS, Mucilagus Aurem, is a thin broad muscle connected at its upper part to the tendon of the fronto-occipitalis, and at the lower to the pina of the ear opposite to the anhelicus. Its use is to draw the external ear upwards, and to render it tene. This muscle is called superior auris by Winlow.

ATTOMBISSEUR, in Ornithology, a term by which the French falconers distinguish those falcons which will attack the honon in its flight; such a bird they call un bon atombisser.

ATTORE, in Geography, a town of Hindostan, in the Myloore country, fifty-four miles north of Titchinopoly, and twenty-nine N. N. W. of Rajanagur.

ATTORNARE, in the original sense, signified to turn over money and goods, that is, to assign and appropriate them to certain persons, or uses. This is properly called attornare rem. Attornare persona denotes to deprive a representative, or proxy, to appear and act for another.

ATTORNATO faciendo vel recipiendo, in the Common Law, a writ to command a sheriff, or steward, of a county-court, or hundred-court, to receive and admit an attorney to appear for the person that owes suit to court. F. N. B. 156. Every person that owes suit to the county-courts, court-baron, &c. may make an attorney to do his suit. Stat. 20 H. III. c. 10.

ATTORNEY, ATTORNATUS, in Law, a person appointed by another to do something in his stead, particularly to solicit and carry on a law-suit.

The word is compounded of the Latin ad, to, and the French tourner, to turn, q. d. to turn a business over to another. The ancient Latin name, according to Bracon, is responfulis.

An attorney is either public, in the courts of records, the king's bench, common pleas, &c. and made by warrant from his client; or private, upon occasion for any particular business, who is commonly made by letter of attorney.

Attorneys, in Common Law, are much the same with procurators, proctors, or synodes, in the Civil and Canon Law.

Attorneys are properly those who sue out writings, or procures, or commence, carry on, and defend actions, or other proceedings, in the names of other persons, in any of the courts of common law. — They are distinguished from solicitors, who do the like business in courts of equity, and the chancery, equity-court in the exchequer, chamber-court of the duchy, or the like.

Formerly every suitor was obliged to appear in person to prosecute or defend his suit, according to the old Gothic constution, unless by special licence under the king's letters patent. F. N. B. 25. This is still the law in criminal cases. Nor can an idiot appear to this day by attorney, but in person; because he is supposed not to have sufficient discretion for appointing a proper substitute; and upon his being brought before the court in his defence he will, the judges are bound to take care of his interest, and they shall admit the best plea in his behalf that any one present can suggest. But as in the Roman law "cum soli in iu fuo justi, alius non nomine agi non possit, sed quia loco non minimum circumstatis habeat, equester bonum per procuratores ligatur" (Inf. 4, tit. 10); so with us, upon the same principle of convenience, it is now permitted, in general, by divers ancient statutes, of which the first is flat. Weltm. 2 c. 10. (13 Ed. I. A. D. 1285.) that attorneys may be made, as if they had letters patent, to prosecute or defend any action in the absence of the parties to the suit. These attorneys are now formed into a regular corps; they are admitted to the execution of their office by the superior courts
ATT

of Westminster-hall; and are in all points officers of the respective courts in which they are admitted; and as they have many privileges on account of their attendance there, so they are peculiarly subject to the censure and animadversion of the judges. No man can practice as an attorney in any of those courts, but such as is admitted and sworn an attorney of that particular court; an attorney of the king's bench cannot practice in the court of common pleas; nor vice versa. To practice in the court of chancery, it is also necessary to be admitted a solicitor therein; and by the flat. 22 Geo. II. c. 46, no person shall act as an attorney at the court of quarter sessions, but such as has been regularly admitted in some superior court of record. With respect to the several courts, there are attorneys at large, and attorneys special, belonging to this or that court only. An attorney may be a solicitor in other courts by a special retainer; one may be an attorney on record, and another do the business; and there are also attorneys who manage the business out of the courts. So early as the statute 4 Hen. IV. c. 18. it was enacted that attorneys should be examined by the judges, and none admitted but such as were virtuous, learned, and sworn to do their duty. And many subsequent statutes have laid them under further regulations. By 3 Jac. I. c. 7, attorneys, &c. shall not be allowed any fees laid out for counsel, or otherwise, unless they have tickets thereof signed by them that receive such fees, and they shall give in true bills to their clients of all the charges of suits under their hands, before the clients shall be charged with the payment thereof. If they delay their client's suit for gain, or demand more than their due fees or disbursements, the client shall recover costs and treble damages; and they shall for ever after be disabled to be attorneys. None shall be admitted attorneys in courts of record, but such as have been brought up in the said courts, or are well skilled, and honest; and no attorney shall suffer any other to follow a suit in his name, on pain of forfeiting 20l. to be divided between the king and the party aggrieved. By 12 Geo. I. c. 29. if any person who hath been convicted of forgery, perjury, subornation of perjury, or common barratry, shall practice as an attorney or solicitor in any suit or action in any court, the judge where such action shall be brought hath power to transport the offender for seven years, by such ways and under such penalties as felons. The act 2 Geo. II. c. 23. ordains, that all attorneys shall be sworn, admitted, and enrolled, before they sue out writs in the courts at Westminster; and they are required to have served a clerkship of five years, and to be examined, sworn, and admitted in open court; and attorneys shall not have more than two clerks at one time, except the prothonotaries in the common pleas, and the secondary in the king's bench, and the several prothonotaries in the counties palatine and great sessions in Wales, each of whom may have three. Attorneys, upon being sworn and admitted, shall pay a famp-duty, by several acts, of 161. When the attorney's bills are taxed, he is to pay the costs of taxation, if the bill be reduced a fift part. A penalty of 50l. and disbarment to practice, are the consequnences of acting contrary to this statute. By flat. 6 Geo. II. c. 27, attorneys of the courts at Westminster may practice in inferior courts. By 12 Geo. II. c. 13, attorneys, &c. that act in any county-court, without admission according to the statute 2 Geo. II. c. 23, shall forfeit 20l. and no attorney, who is a prothonotary, shall sue out any writ, or proseute suits; if he doth, the proceedings, &c. shall be void, and such attorney, &c. shall be struck off the roll. By 22 Geo. II. c. 26, persons bound clerks to attorneys or solicitors are to cause affidavits to be made and filed of the execution of the articles, names, and places of abode of attorney or solicitor, and clerk; and none to be admitted till the affidavits be produced and read in court. Clerks are actually to serve during their whole time, and make affidavits thereof. Persons admitted attorneys, and clerks in chancery, or being a clerkship to fuch, may be admitted solicitors. By 23 Geo. II. c. 26, any person duly admitted a solicitor, may be admitted an attorney, without any fee for the oath, or any famp; and by flat. 2 G. II. c. 25, § 20. attorneys may be admitted solicitors. By 25 Geo. III. c. 80 every admitted attorney, solicitor, notary, proctor, agent, or procurator, shall annually take out a diploma certificate, with a five pound diploma within the bills of mortality, and three pound elsewhere, from the courts in which they practice, on penalty of 50l. and incapacity of practicing. By 3 Geo. III. c. 14, every person who shall become bound to serve as a clerk in order to his admission as a solicitor or attorney in any of the courts at Westminster, shall be charged an additional famp-duty of 200l. And in any of the courts of great session in Wales, or in the counties of Chester, Lancaster, or Durham, or in any court of record in England holding pleas, where the debt or damage shall amount to 40s. and not in any of the said courts at Westminster, a famp duty of 50l. And by the several famp acts, if the consideration money given with such clerk or appearance be under 10l., a famp duty of 10s. If above 10l. be given by 37 G. III. c. 5. 10s. more. The indemnity shall be intrusted, and affidavit shall be made within six weeks. Persons who have paid the duty of 100l. in any of the courts at Westminster, may be admitted in any of the other courts without payment of any further duty. New contracts with other makers are subject to no further duty. The privileges belonging to attorneys are as follows: an attorney, in respect of his attendance at the court, cannot be pressed for a sol- dier; but he is not privileged from serving in the militia, or finding a substituté: an attorney shall not be made constable, nor be elected into any other office against his will; as to the office of overseer of the poor, or churchwarden, or any office within a borough. Attorneys have the privilege to sue and be sued only in the courts at Westminster, where they practice; they are not obliged to put in special bail, when defendants; but when they are plaintiffs, they may infilt upon special bail in all bailable cases. 1 Vent. 299. Wood's Inl. 450. But an attorney of one court may, in that court, hold an attorney of another court to bail. Payment to the attorney is payment to the principal. Doug. 625. 1 Black. R. 8. An attorney has a lien in the money recovered by his client, for his bill of costs; if the money come to his hands, he may retain the amount of his bill. He may float it in transitu, if he can lay hold of it; if he apply to the court, they will prevent its being paid over until his demand is satisfied. If the attorney give notice to the defendant not to pay till his bill be disbarred, a payment by the defendant after such notice would be in his own wrong, and he paying a debt which has been assigned after notice. Doug. 238.

Attorneys are liable to be punished in a summary way, either by attachment, or having their names struck out of the roll, for ill practice, attended with fraud and corruptness, and committed against the obvious rules of justice and common honesty; but the court will not easily be prevailed upon to proceed in this manner, if it appears, that the matter complained of was rather owing to neglect or accident than design, or if the party injured has other remedy by act of parliament, or action at law. 12 Mod. 251. 318. 423. 583. 657. 4 Mod. 357. If an attorney, defendant in an action, does not appear in due time, the plaintiff may file a "forswearing," which enables him to strike the defendant
off the roll, and then he may be sued as a common person (Ch. 2 Hen. IV. c. 8), and cannot be proceeded against by bill. On making satisfaction to the plaintiff, an attorney so forbadged may be restored. Impey's Instructor Clericus, C. P. 521.

Attorneys are sometimes struck off the roll for their own application, for the purpose of being called to the bar, &c.; and in this case, they must be deliv'red by their name, before they are re-admitted attorneys. Doug. 144. An attorney convicted of felony is struck off the roll. Comp. 920.

Attorneys are also liable to be punished for false and unfair dealings towards their clients in the way of business, as for procuring suits by false titles and devices, and putting the parties to unnecessary expenses, in order to raise their bills; or demanding fees for business that was never done; or for refusing to deliver up their clients' writings with which they had been intrusted in the way of business, or money which has been recovered and received by them to their clients' use, and for other like gross and palpable abuse. 2 Hawk. P. C. 144. 8 Mec. 366. 12 Mod. 576.

Attorney of the Duchy of Lancaster, attornatus curie deinstante Lancastrie, is the second officer in that court; being there, for his skill in law, placed as advisor to the chancellor of the court, and chosen for some special trust repose in him, to deal between the king and his tenants.

Counsel.

ATTORNEY-GENERAL, is a great officer under the king, made by letters patent. It is his province to exhibit informations, and prosecute for the crown, in matters criminal; and to file bills in the Exchequer, for any thing concerning the king in inheritance or profits; and others may bring bills against the king's attorney. His proper place in court, upon any special matters of a criminal nature, in which his attendance is required, is under the judges, on the left hand of the clerk of the crown; but this is only upon solemn and extraordinary occasions; for usually he does not sit there, but within the bar in the face of the court.

Attorney, Letter of. See Letter.

Attorney, Warrant of. See Warrant.

ATTORNEMENT, or ATTORNMENT, a transferring of duty and service to another lord; or an acknowledgment which a tenant makes of homage and service to a new lord.

By the nature of the feudal connection, it was not thought reasonable nor allowed, that a servient should transfer his lord's gift to another, and substitute a new tenant to do the service in his own stead, without the consent of the lord; and, as the feudal obligation was considered as reciprocal, the lord also could not alienate his feigny without the consent of his tenant, which consent of his was called an "attornment." This doctrine of attornment was afterwards extended to all leffees for life or years. For if one bought an estate with any lease for life or years flanding out thereon, and the lease or tenant refused to attorn to the purchaser, and to become his tenant, the grant or contract was in null cates void, or at least incomplete (LT. 5. 571): which was an additional cog upon alienations. But after the statute "quia emortise terrarun" (18 Ed. I. II. i.), was passed, by which subinfeudation was prohibited, it became necessary that when the reveree or remainder-man after an estate for years, for life or in tail, granted his reveree or remainder, the particular tenant should attorn to the grantee. The necessity of attornment was, in some measure, avoided by the statute of uses (27 Hen. VIII. c. 12.), as by that statute, the possession was immediately executed to the use; and by the statute of "Wills" (35 & 35 Hen. VIII. c. 5.), by which the legal estate is immediately vested in the devisee.

Attornments, however, still continued to be necessary in many cases; but both their necessity and efficacy are now almost wholly taken away; for by Stat. 4 & 5 Ann. c. 16. it is enacted, that all grants and conveyances of manors, lands, rents, and reversionary, &c., by the king or others, shall be good, without the attornment of the tenant; but notice must be given of the grant to the tenant, before which he shall not be prejudged by the payment of any rent to the grantor, or for breach of the condition for non-payment. And by Stat. 11 Geo. II. c. 10. attornments of lands, &c., made by tenants to strangers claiming title to the estate of their landlords shall be null and void, and their landlord's possessioll not affected thereby; though this shall not extend to vacate any attornment made pursuant to a judgment at law, or with consent of the landlord; or to a mortgage; see on a forfeited mortgage. Till then, attornments were passed, the doctrine of attornment was one of the most copious and abridgment points of the law. But these acts having made attornment both unnecessary and inoperative, the learning upon it may be deemed almost entirely useless. 1 Inst. 529. Jacob's Law Dict. by Tomlins, tit. Attornment.

ATTOWAL, in Geography. See Attowal.

ATTRACTION, in Natural Philosophy, a general term used to denote the power or principle, by which all bodies mutually tend towards each other, regardless of the cause or kind of action that may be the means of producing this effect.
