Bey of Tunis, denotes a prince, or king thereof; answering to what at Algiers is called the bey. He is chosen out of the army; each order, even the most inferior, having an equal right and title to that dignity with the highest.

In the kingdom of Algiers, each province is governed by a bey or vice-roy; who is appointed and removed at pleasure by the bey; but has a despotic power within his jurisdiction; and at the pleasure for collecting the tribute from the Arabs, is assisted by a body of troops from Algiers.

The kingdom of Tunis is not divided into provinces, like that of Algiers, and governed by provincial beys, or vice-roys; but the whole is under the immediate inspection of the bey himself, who collects the tribute in person. For this purpose, he visits, with a flying camp, once every year, the principal parts of it; traversing, in the summer season, the fertile country in the neighbourhood of Kef and Bajiah; and in the winter, the several districts between Kairwan and the Jered.

BEYAH, in Geography, anciently called BESOFDA, and the HAPHAH, or HAPHAH of Alexander, a river of Hindostan, that rises in the great chain of snowy mountains, extending from Sirinagur, to the north of Cashmere, or the ancient Imaus; and after traversing the Panjab, it joins the Sutlej at Ferofepour; about 24 miles below the confluence, a separation again takes place, and four different streams are formed; the northmost and most considerable of which, receives the name of Beyah, and is a deep and rapid river. The others are named Herri, Doud, and Nooney; and near Moultan they unite again, and bear the name of Sutlej, until both the sublimity and the name are lost in the Indus, about 80 miles, or three days’ sailing, by the course of the river, below the mouth of the Chunaub. Rennell’s Mem. p. 102.

BEYENDORF, or BIESBERG, a town of Germany, in
the circle of Westphalia, and duchy of Berg, on the Wupper, 3 miles north of Leipzig.

BEYERLAND, an island belonging to Holand, situated on the Meuse, with a town of the same name; 4 leagues west of Dort.

BEYERN, a town of Germany, in the circle of Swabia, and county of Tullaenberg, situated on the Danube, 4 leagues from DATINGEN.

BEYHARTING, a town of Germany, in the circle of Bavaria, 24 miles E.S.E. of Munich.

BEYKE. See DERK.

BEYLA, a town and district of Abyssinia, in Senmar, about 11 miles west of Tecoma, and 316 miles due south, in Lat. 31° 42' 4'. Between Tecoma and Beyla there is no water. Imagededama, and a number of villages, were supplied with water from wells, and had large crops of Indian corn grown upon their pinnacles. But the Arabs Davome have destroyed these places, filled up their wells, burnt their crops, and expelled all the inhabitants to die by famine.

BEYMOND, or BEYWORT, a town of Germany, in the bishopric of Liege, 8 miles south of Liege.

BEYNAT, the chief place of a canton in the district of Drives, and department of Correze, containing 1426 inhabitants; thofe of the canton being 5488. The territory comprehends 135 kilometres and 6 communes.

BEYS, GILLES, in Biogrophy, a printer at Paris, in the 16th century, who first introduced into his editions the distinction foggeled by Ramus in his grammar between j and s, over comformers, and the vowels j and w. He died in 1595.

BESZYLER, (Graf. Therb.) in Jidobalogy, a name of the cubita flexibilis. Guido.

BEZA, THODORE, or THEODORE DE BEZA, in Biography, an eminent divine among the first reformers in Geneva, was born of parents nobly defended, in 1519, at Vezelai in Burgundy, and sent by his uncle, who was a counsellor in the parliament of Paris, to Orleans, in 1528, to be educated by Melchior Wolmar, a protestant and an excellent teacher. Having continued seven years under his tuition, he commenced the study of the law at Orleans; but his taste led him to the cultivation of polite literature, and he composed several Latin poems, which were considered by the learned as a promising specimen of his talents. After taking a law-degree, he returned, in 1539, to Paris, where his parents, who had intended him for the ecclesiastical profession, had procured for him a valuable abbotcy. Addicted to the delights of an easy and voluptuous life, he remained for some years at Paris; but under the influence of sentiments imbibed in his youth from his protestant preceptor, he determined sooner or later to break his letters. A marriage contracted from conjunctive motives rendered it necessary for him to renounce his benefices, and hailened in the execution of his purpose by the reflections attending a severe illness, he and his female companion fled, in 1548, to Geneva. In the following year he accepted the office of a Greek professorship at Laufanee, in the exercise of which he continued with reputation for nine or ten years. Here he read lectures in French on the New Testament, and published several books; one of which was a tragi-comedy, in French, entitled "Abraham's Sacrifice," which passed through several impressions. Having frequent opportunities of visiting Calvin at Geneva, he was induced by his persuasion to finish the version of the Psalms, which had been begun by Marot. During his residence at Laufanee, he published a treatise, "De Hereticis à Magistratu puniendis," in reply to a book written by Caflato, after the execution of Servetus; and in this treatise he maintained a doctrine no less dangerous in its tendency than inconsistent with his principles as a reformer and a protestant, that it was the duty of the civil magistrate to punish heresy. He also wrote on predestination, and the eschatid, in opposition to the Lutherans, and others, and in a style ofAILLERY which a masterly judgment and after-reflection led him to correct. In 1558, he was elected as one of the deputies commissioned by the protestants, to engage the German princes in favour of their brethren imprisoned at Paris, and of the perfecuted inhabitants of the valies of Piedmont. In the following year he removed to Geneva, where he became the colleague of Calvin, both in the church and university, and where by his abilities, learning, and zeal, he co-operated with him in advancing the reformation. In 1561, he did indignify himself by his eloquence on behalf of the Protestant party, at the conference of Poiffy; although he gave offence by his declared opposition to the doctrine of the real presence. Continuing in France, he attended the prince of Condé as a minister, when the civil war broke out, and accompanied him to the battle of Dreux. Upon his return to Geneva, in 1565, he wrote several books in theological controversy, with an acrimony that cannot be justified byPersonmoderation and candour. In 1571, he officiated as moderator in the national synod of Rochelle; and in the following year elected in that of Nîmes. In 1576, he held a disputation with Andreas, a Lutheran divine of Tubingen; and through the whole course of his life, the party to which he belonged availed itself, on many occasionsthis his talents and reputation. Having lost his first wife in 1588, he soon married another. Although the infirmities of his advanced age required his withdrawing from the duties of public instruction, the ardour of his genius remained to the close of his life, and he wrote Latin verfa a few years before his death, which happened in October 1605, after he had pasd his 86th year. Of his singular natural talents and literary acquirements no doubt can be entertained: nor need we wonder that bigotted Catholics should have calumniated him whilst he lived, and reviled his memory after his death. He has indeed, by his enemies, been unjustly traduced as a hypocrite, and a perfon of lax morals; but charges of this kind are refuted by the uniform tenour of his life. His partial advocates, however, must regret that, as a disputant, he was violent, impetuous, and dogmatical, and deficient in candour and charity. His juvenile pieces, in Latin poetry, in which critics have detected many numbers deviations from classical purity, were first printed in 1548. Some of these, with corrections, together with others of a more serious cast, were printed by the Stephenes at Paris, in 1577, 4to, under the title of "Theod. Bezae Poemata varia." His French works are of an inferior kind. His theological works are numerous. Of these, the most generally read, and the most highly esteemed, is his "Latin version of the New Testament," with critical and theological remarks. For an account of the MS. in his possession, see Cambridge MS. Gen. Diet.

BEZABA, in Geography, a river of Spain, which runs into Orlo, in the province of Guipeuscoa.

BEZABA, or GOZERTA, Gezeret che-Qnem, in Ancient Geography, a town of Aia, on the right bank of the Tigris, south-wellaTigranocerta, in the country called Zabili-

BEZANT, reprebents, in Heraldry, round flat pieces of gold. They were first borne by theolders of the holy wars, being the current coin of Byzantium (the modern Constantinople) with which the standards of the army were discharged, and from whence they took their name. They are always embazoned gold, but the foreign heralds make them both gold and silver.

BEZANTIE, in Heraldry, is when the field is powerfull with bezants, or when supporters, or crests, are frayed with them. The proper heraldic term is bezantie. When a bordure
bordure is charged with eight bezants, that being the limited number, you need not express the number, but say, a bordure fable bordure.

BEZANTILIER, signifies the second branch of the horn of an hart or buck, that shoots from the main beam, and is the next above the brow-antler.

BEZARA, in Ancient Geography, a town of Galilee near the sea, south of Ptolemais.

BEZDELKINO, in Geography, a town of Siberia, 80 miles north of Balaganskoi.

BEZDZIEZ, a town of Lithuania, in the palatinate of Brzece, 24 miles west of Pulk.

BEZE', a town of France, situate near the th the source of a river of the same name, in the department of the Côte d'Or, and chief place of a canton, in the district of Is-sur-Tille, 24 leagues E.S.E. of it.

BEZEK, or BEZAKA, in Ancient Geography, the place where Saul reviewed his army, before he marched against Gath-Gilead.

BEZENSTEIN, or PETZENSTEIN, in Geography, a town of Germany, in the circle of Bavaria, and territory of Nuremberg, 19 miles N.E. of Nuremberg.

BEZER, in Ancient Geography, a city beyond Jordan, over against Jericho, in the wilderness assigned by Moes the tribe of Reuben by Joshua to be a city of refuge, and given to the Levites of Gershon's family. Deut. iv. 43. Josh. xx. 8. The vultures in both places denominate it Bofer. Euefibius confounds it with Bobera of Arabia, which lay much farther to the east. See Bostra.

BEZETH, a city of Palestine, on this side Jordan, in the vicinity of Jerusalen, which Bechahides surprised, and the inhabitants of which he threw into a pit; probably the same with Bezekath. 1 Macab. vii. 19.

BEZETHA, or BETZETA, a division or part of Jerusalen, situate on a mountain, and encompassed with walls, being, as Josephus says, a new city attached to the old one, and called in Greek Betaetha, Camopolis. It lay north of Jerusalen and the temple.

BEZTIZ, in Geography. See BESHTZ.

BEZHLEN, a town of Transylvania, 12 miles N.N.E. of Bitiriz.

BEZIERS, a city of France, and principal place of a district, in the department of the Herault, feated on the left bank of the Orbé, not far from the grand canal. Before the revolution, it was the residence of a governor, and the see of a bishop, suffragan of Narbonne; its cathedral was small, but beautiful; it had besides a collegiate church, several religious houses, two hospitals, a college founded by the inhabitants in 1599, and an academy of sciences and belles lettres. It is surrounded by a wall, flanked with old towers, and decayed battlements. The number of inhabitants in both its districts is estimated at 14,211, and the population is small in proportion to its extent. The canton of the first division has 17,708, and that of the second 13,147 persons. The former canton has 9, and the latter 7 communes. The territorial extent of both comprehends 560 kilometres. The situation is beautiful, and it commands a view of several lakes of the grand canal of Languedoc. In the Not. Imp. it is called "Civitas Biterefium, Bitetra Septimunorum." In the 15th century it was ravaged by the Vandals; by the Saracens, in 720; by Charles Martel, in 739; and by Simon, count Montfort, in 1209; who, in the crusade against the Albigenes, took it by assault, and put more than 50,000 of the inhabitants to the sword. Since this time it has not recovered its ancient lustre. It was re-united to the crown by S. Louis, in 1247.

Its territory is fertile in corn, oil, and wine. It has also mineral waters. N. int. 43° 20' 41" E. long. 3° 12' 35".

BEZIRA, S. BEZIRA.

BEZOAER, BEZOAER, primarily denotes an antidote, or counter-poison. The word is formed from the Persian pazarah, which denotes the same, σα διαγινόμενος ἑαυτῷ; and zahar, pozon.

BEZOAER, Lapid B ezoaericae, is a term applied in a general way to various substances found in the stomach, intestines, and other internal cavities of the bodies of quadrupeds.

The true bezoar, however, is a calculous concretion, usually formed in the stomach of some of those animals which ruminate, or chew the cud. There are two sorts of the bezoar stones; one is brought from the East Indies, and Persia, and thence known under the name of Oriental bezoar. The other kind comes from the Spanish West Indies, or South America, and is called Occidental bezoar. The Oriental is considered by far the more valuable kind, and is exceedingly scarce, even in India. The larger the stone the more highly it is esteemed; its price increasing, like that of the diamond, in proportion to its size. A stone of one ounce has been sold in India for 100 livres, and one of four ounces and a quarter for 2000 livres. The price of the smaller stones, in Germany, in the year 1660, was from 16 to 32 ducats the ounce; but it had then much declined. The larger bezoars had no regular price, being often enormously dear. As long as it retained its fancied reputation, as an antidote to every kind of poison, and as a cordial for the support of life under the most trying circumstances of life, its price was advanced beyond its weight in gold, and it found a high place for many centuries among the most costly collections of precious stones. The size varied from that of a pea to a hen's egg, or even larger. Boeotius relates, that in his time the emperor Redolph II. presented one of the size of a goose's egg, which he ordered to be hollowed out into a cup, when the nucleus was found to be a small mass of herbs full strongly aromatic. The most anciently known bezoar stones were procured from the stomachs of goats feeding in the mountains of Persia, and those from the mountain goat were in such high request, that the emperor Shah-Abbas (who died in 1628) claimed all above a certain standard as a royalty, and appointed collectors for the purpose. The Oriental bezoars passed through the hands of the Armenian and Persian merchants, and were formerly brought to Europe in considerable quantities. In the east, those were the most esteemed that were obtained from goats feeding in the mountains, as the aromatic herbs found there were supposed to add much to the virtues of the calculus.

Authors disapprove with respect to the animal in which the genuine oriental bezoar is found; some attribute it to a species of goat, others to the antelope genus. Most naturalists allow this substance to belong to the gazelle, (Antilope Genella, Gmel.) Alberovandus calls this species of antelope, hircus bezoaericae; Linnaeus, capra bezoaerica; and Pennant, the bezoar antelope. Pallas, however, in his Spielegia Zoologiæ, gives the same name to the Egyptian antelope, (Antilope Oryx, Gmel.) Cuvier describes the oriental bezoar as being found in the intestines of the capra aggrus of the Linnaean sylymen, and Gmelin ascribes it to the capricorne goat. By the account of Clufius, the animal furnishing this concretion would seem to be larger than the goat, and more resembling the Nylyhua. There can be little question but similar substances have been occasionally met with in each of these animals, and in several other species.

The bezoar stone, when genuine, varies much in its form; this depending upon the figure of the nucleus, upon which the calculous matter is deposited, there being generally some foreign
foreign body in the centre of the bezoar. The substances which usually serve for nuclei to these concretions are straw, hair, small pebbles, nuts, hard seeds, stones of fruit, &c. but the most frequent nucleus of the real oriental bezoar, is the pod of a fruit, much like that of the Acacia vera Egyptian: though it at first sight resembles a coffee, or tamarind stone. In some of the bezoar stones formed on this fruit, the outer membrane of the bean having perished, and the bean shrunk in drying, there remains a cavity between it and the inner surface of the bezoar, so that it rattles within it, when shaken, in the manner of an attic, or eagle stone. It is of little moment what the figure or nature of the body may be, which is to serve the purpose of a nucleus, as it cannot in the slightest degree affect the quality of the calculous substance which is to be collected on its surface; any extraneous matter will suffice for this purpose, which may happen by any accident to be long enough detained in the flomach or intestines. The formation of bezoars appears to be effected in a manner similar to that observed in the production of the calculi of the urinary bladder of the human subject. We may presume that the bezoar is only formed when there is a tendency in the animal to generate an extraordinary quantity of calculous matter; for if it were otherwise, as that these substances were produced by such combination of the ordinary contents of the flomach and intestines, what animal, that is liable to such collections, could ever be without them? whereas, on the contrary, they are so scarce in the East Indies, that those which are brought into this country are supposed to be in general artificial compositions; aye, some have doubted if we ever meet with a genuine oriental bezoar in this country.

The season of the year also appears to influence their production. Camerarius remarks, that these bodies begin to form towards the month of November: and when the Parian anatomists discovered a bezoar in the stomach of the Chamois (Antilope Rupicapra,) it was the month of December.

The number of bezoar stones varies, in different animals, from one to six; hence, it is said to be pulmonary, previous to purging a bezoar animal, to reckon the number of stones it contains, which can be ascertained by feeling externally, and by this the price of the animal is regulated.

Velchius affirms, that the Bezoar is only found in the first, or second stomachs of ruminant animals, but the anatomists of the French academy state, that they met with it in the third stomach; and others have mentioned its being sometimes found in the intestines.

All bezoars are made of concentric layers, or by stratum super stratum, after the manner of the common urinary calculi. This proves their formation to be gradual; and as this mode of increase cannot be easily imitated, it is probably one of the best marks for distinguishing the genuine bezoar from that which is counterfeited.

The Oriental bezoar is smooth and glossy on the surface, the colour a dark green or olive; on removing the outer coat, that which lies next it appears likewise smooth and shining; it is generally less than a walnut; it is most esteemed for its medicinal properties, and is the only one kept by the London college. The Edinburgh college, in some of the former editions of their pharmacopoeia, directed both this and the oriental bezoar, but they now seem to allow them to be used promiscuously, retaining in their catalogue only the name of ligia bezoar.

The imitations of this stone have been carried to such perfection, that as far as respects form, colour, or other external characters, the deception cannot well be detected. Mr. Neumann supposes that those which come nearest the genuine bezoar, are a composition of plaster of Paris, chalk, or other earths stained of the proper colour by some vegetable tincture. Those which are palpably counterfeited, are composed chiefly of some retenus substance, and may be easily discovered by their liquefying in the fire, and being soluble in spirits of wine; he never could discover any mark of an animal nature in any of these. Chemical works, by Dr. Lewis, p. 533, &c.

The modes of trying if bezoar be genuine are, 1st. To immerse a portion of it, for some hours, in moderately warm water, when the water ought to remain untinted, and the stone undiminished in its weight: 2d. to apply to it a sharp red hot iron, which it should refill without trying or thriving: the 3d. which is considered the most certain experiment, is to rub the bezoar over a paper which has been previously scoured with chalk or quicklime; if it leave a yellow tint on the former, or a green one on the latter, there is no doubt of its being genuine.

The accidental bezoar is uneven on the surface; of a dirty green colour; it is heavier and more brittle than the oriental, to which it is considered much inferior in value; it is of a looser texture, and when fractured, the layers appear thicker, and exhibit a number of flake curiously interwoven. It is also found of a much greater size; sometimes being as large as a goose's egg.

The accidental bezoar has been found in some of the camel tribe, especially the guanaco (Camelus Huannanus) and the Vicuna (Camelus Vicugna,) which are inhabitants of South America.

This kind of bezoar, Mr. Neumann apprehends, is more likely to be an animal production than the other, because it yielded, on distillation, a small portion of volatile unrisuous matter. Chem. Works, p. 537.

The analysis of bezoar stones, as related by different chemists, is very contradictory, which has given rise to the opinion of the speciments which they submitted to experiment, being phalrous. Thofe stones examined by Slare, as oriental bezoar, did not diffuse in acids. Thofe which Grew and Boyle made trial of, did. Thofe employed by Geoffroy (in some experiments related in the French Memoirs, 1710,) did not seem to be acted on by spirits of wine, whilst those specimens examined by Neumann, at Berlin, almost entirely diffused in spirits. For an account of the analysis and chemical properties of the bezoar and similar substances; see Calculus.

In the early ages, when a knowledge of difeases was considered an occult and mysterious science, rare and unknown plants, or unnatural, and what were considered wonderful animal productions, were chiefly employed in the way of medicines; at this period we accordingly find the bezoar-tic stone posessed great reputation as a remedy for many difeases; it owed, no doubt, much of its fame to the fabulous accounts which were related with respect to its origin.

It was not known to the Greeks. The first person who has mentioned it was Aeneas, an Arabian physitian. He describes it to be generated of the tears, or gum, of the eyes of toads, who, after eating serpents, were accustom to run into the water up to the nose, where they stood till their eyes began to ooze a humour, which collecting under their eye-lids, gradually thickened and coagulated, and when it became quite hard was thrown off by the animal rubbing itself against the trees. Other stories concerning the history of the bezoar, equally wonderful and ludicrous, were credited, until the time of Garcia al Horto, physician to the Portuguese vicery of the Indies, who gave the first true account of the origin of this substance. Kempfcr afterwards gave a description of it with some new particulars.

The bezoar was first employed to prevent the fatal consequences of poison. This is expressed by the very name which
which is derived from the Persian word beznsher, or bezech, antidote, or from passahar, of which pa signifies against, and xabar, a poifon. Others derive the term bezoar from the Persian panzar, a goat.

It was afterwards given in vertigo, epilepsy, palpitations of the heart, jaundice, colic, and a great many other diseases; so that if its real virtues were answerable to its reputed ones, it would be a panacea. Even later writers have bestowed extraordinary commendations on it, as a sudorific and alexipharmic; but there is every reason to doubt its poifoning any such virtues. It is an earthy sublimate, devoid of tafte or smell. The history of its formation proves that it is not digestible, or otherwise affected by the juices of the intestinal canal. If it can ever be employed as a medicine, it should be on account of its absorbent quality, which, however, it appears to poffefs but in a very slight degree. It has been administered to patients in the quantity of half a drachm, and in some instances a drachm has been taken, without producing any fible effect; the dose has been generally flated at a few grains, which was probably on account of its fcarcity and great price. While it retained its medical reputation, it was faid to act as an antidote to every poison, vegetable or mineral, and to the bite or fling of all poisonous animals, in the dose of about 8 grains; but it would equally prove a counter-poifon when taken regularly in the quantity of two grains daily, in a glafs of wine, or especially of distilled water of cardus beneficus. To prepare a youthful constitution and vigour, an oriental's recipe is to take twice a year (purging being premifed) ten grains of bezoar daily, for five fuccedent days, with a cup of rofe-water. Bezoartic productions are at prefent fo little regarded for their medicinal properties, that few druggifts now think it necessary to have them in their poffeffion.

Bezoar, Equinum, is the name given to the calculous concretions occasionally met with in horses. They appear to be formed in the fame manner as the bezoar of the antelope or camel genus. They grow to a considerable fize; have usually an irregular fform, fomewhat between a comprifed fphere and a rhomboidal figure; when divided they exhibit the ufual fuccifion of ftrata, of which they are compofed, but which are not fo difficult as in the other bezoars; each layer is formed of excentric ftrata, which are in many places more evident than the divifion into ftrata; confequently the fection of the bezoar gives the appearance of its having been made of medallions, rather than concentric layers. The surface of the calculus bears a great refeemance to a piece of polifhed live-flone.

Bezoar, German, is called by some calf's eye, from the circumjance of its being occasionally found in the stomacas of cows, but the animal from which it is most commonly obtained is the chamois (Antilope Rupicapra). The nucleus of the German bezoar is either the hair which the animal may have swallowed, when licking itself, or the fubflance of undigefed vegetables, which are rolled into a round smooth ball. The quantity of calculous fubflance which is collected upon this ball is in general very trifling, often being merely a thin fivelule.

The bezoar which was found in the chamois by the Parthenian academicians, was made up of the woody fibres of the plants the animal had eaten; it was fMOOTH and bejmered with mucus on the furface; and was broken at one end, expofing a cavity in the centre of the ball, which had formerly, no doubt, been occupied by some folid fubflance, fuch as a pebble, or flone of some fruit. German bezoars have been found, according to Bartholin, and others, in horses and fheep, in which laft they are chiefly compofed of wool, which these animals accidentally fwallow.

From these fpecies of bezoar having little, if any, calculous matter in their compofition, they have been called by some writers, with propriety, Ergagropile; which feethe, and Balls.

Besides what have been already defcribed, there are concretions found in the gall bladder of animals, to which the term bezoar has been applied; these appear to be no other than biliary calculi.

The Huz or Bear Bezoars, called by the Dutch Pedro de pors, and by the Portuguese, who firfl brought it into Europe, Pedro de voitans, is found in the gall bag of an East India boar; in form and magnitude it resembles a fifter, though more irregular; it is most commonly white, with a tinge of green; the surface is smooth and fhininig, and is valued at ten times its weight in gold.

The Indians attribute extraordinary medicinal powers to this bezoar. They call it Medicina de jofs, and prefer it to that obtained from the Gazette; they confider it a sovereign remedy for the colica, a disease to which they are liable, and which is not less dangerous than the plague in Europe. They allow it to have great efficacy also in malignant fevers, small-pox, and most difeafes of women not with child, it being fuppos'd to produce abortion in those who are pregnant, if they ufe it indifferently. When it is to be ufed as a medicine, it is infufed in water or wine, until it has commininated a little bitterness to it. To facilitate the infusion, and at the fame time preferve fo precious a ftonc, they ufually infole it in a gold cafe, which is pierced with holes.

The Porcupine and Monkey Bezoars, are also the biliary calculi of these animals. Tavernier afferts, that they are not taken from the gall bladder, but the heads of the ape and the porcupine, which is highly improbable, and contrary to general analysis; he calls them Malaca flones, and fays that they are held in fuch estimation by the inhabitants of Malacca, that they never part with them, except as presents to ambassadors, or the great princes of the cafe.

According to Neumann, single ftones, taken from the porcupine or monkey, have been fold for eighty and eighty pounds flering.

It is not impossible but that thofe bezoars which are formed in the gall bladder may poffefs fome power as medicines; perhaps afo folutions might be employed with advantage in frurgery, but their great reputation amongst the Indian feems to arise altogether from ignorance and superflition.

Bezoar, bezoanum, is a yellow flone, found in the gall bags of the ox. It has been ufed by miniature-painters: in feveral cafes of yellow.

Bezoar, in Cnology, a fpecies of Bucchinum, that inhabits China. This flone is fubftrud and rufifhe: anterior part of the whors lamellated: pillar perforated. Gmelin. The colour is dark ochraceous, varied with brown: within yellow: coarfe, decufated with wrinkles, or frize: tall folid, bent, rufifhe with imbriacated fcales: sfree angular with flatfeld fides: anterior part flatfifh, plated, or drontated above.

Bezoara, or Buzzara, in Geography, a town with a fort in the peninsula of India, fitate on the north fide of the Kilna river, diftant 40, 3 geographical miles from Malafhipatam. N. lat. 16° 3'. E. long. 80° 39'. In the town is a magnificent pagoda, and another ftands on an eminence without it; which attract a great number of pilgrims, whose contributions are distributed in aids to the poor.

Bezoardies. The peculiar virtue of the bezoar being that of refilling and expelling poifons; the term bezoaric (now, however, nearly obfolute) has come to be almost synonymous with antidote. Thus, when a bezoaric medicine is mentioned, it implies, with the older writers, either a

FP

medicine.
BEZ

medicines into which bezoar enters, or one that resembles the bezoar in its supposed power of counteracting poisons, or afterwards, simply, a cordial. A few metallic preparations have had this application.

BEZARDICA TERRA, a name used by some authors for a medical earth dug in the pope's territories, and more frequently called TERRA NOVARES.

BEZOARDICUM MINERAL. or Mineral BEZOAR, is a perfect oxyd of antimony, made by adding nitric acid to the butter of antimony, and described under the article Antimony.

BEZOARDICUM Joviale, is a mixed oxyd of antimony and tin, formed by fusing together these metals, distilling with corrosive sublimate to convert both metals of the alloy into a butter, or marinated oxyd, and adding nitric acid to reduce them both to a perfect simple oxyd. It is entirely diffused.

BEZOLA, in Ichthyology, the name of a kind of Salmo, called by Gefner, Alburna caruela, and supposed to be in no respect different from Salmo Lascarius.

BEZOUT, STEPHEN, in Biography, a celebrated mathematician of France, was born at Neumours, March 19, 1736, and, at an astonishingly early period on the part of his father, devoted himself to the dissection of the mathematical sciences, to which his taste strongly inclined him. In 1758, he was appointed adjunct mechanic to the Paris academy of sciences, after having communicated two memoirs on the integral calculus, and affording other proofs of his proficiency in the mathematics; in 1763, he was nominated examiner to the marine, and was finally admitted into the academy in 1768; and, in the same year, member of the academy of marine affairs, and examiner of the pupils of the royal corps of artillery; and, in 1776, royal censor. His particular attention was directed to the solution of algebraic equations, and he had the honour of first discovering a method of resolving a particular class of equations of all degrees. In this work of investigating the roots of such equations, he was occasionally engaged from 1762 till 1779, when he published his treatise on the subject. To distinguish talents, and elaborate researches in the abstruser parts of mathematics, Bezout added an auxiliary discharge of the duties of the public position which he occupied, and a private character which was deservedly elevated. His following anecdotes furnish an interesting specimen of his regard to justice in the exercise of his office, and at the same time of the benignity and consideration of his temper. When two of his pupils were confined by the small-pox, and incapable of attending for the purpose of an examination, the want of which would have delayed their advancement for a whole year, he ventured, though he had never had that disorder, to visit them in person, and ascertain their proficiency, by which he was enabled to make a report in their favour. His constitution was at length impaired by his unremitting application, the fatigue of his various offices, and some personal chagrin; and he fell a sacrifice to a malignant fever, September 27, 1783, in the 51st year of his age. His publications were " A Course of Mathematics for the Ufe of the Marine, with a Treatise on Navigation," 6 vols. 8vo. Paris, 1764; a " Course of Mathematics for the Corps of Artillery," 4 vols. 8vo. 1779; and General Theory of Algebraic Equations," 4to. 1779; with a considerable number of Memoirs, chiefly mathematical, in the volumes of the French Academy, Montels, Hist. des Math. vol. i. p. 473. 298. Hutton's Math. Dict. Art. BEZOUT.

BEZOLZI, ALEXANDER and JERON, brothers in the service of the king of Sardinia, at Turin, the most celebrated performers of their time; the one on the hautbois, and the other on the bassoon. These kindred instruments were rendered famous all over Italy during the middle of the 18th century, not only by the exquisite performance, but by the amiable singular character of these two brothers. Their long and uninterrupted affection and fidelity together, were as remarkable as their performance. They were brothers; the eldest, when we heard them in 1770, was 75, and the youngest 60. The idem velle et idem volle were as perfectly in tune as their instruments; so that they had always lived together in the utmost harmony, carrying their similarity of taste to their very dress, which was the same in every particular, even to buckles and buttons. They had lived so long, and in such a cordial manner together, that it was thought, whenever one of them died, the other would not long survive him; which was exactly the case, both dying in 1782, within a few months of each other.

The compositions of these exquisite performers generally consisted of select and detached passages, yet so highly polished, that like apothegms or maxims in literature, each was not a fragment but a whole; their pieces being in a peculiar manner contrived to display the genius of their several instruments and powers of performance. The eldest played the hautbois, and the youngest the bassoon; but it is difficult to describe their peculiarities of expression. Their compositions, which printed, gave but an imperfect idea of its sweetnefs and delicacy: such a perfect acquaintance and agreement together, that many of the passages seemed heart-felt sighs breathed through the same reed. No brilliancy of execution was aimed at; all were notes of meaning. The imitations were exact; the melody equally divided between the two instruments; each forte, piano, cefando, diminuendo, and appoggiatura (see all these terms in their places), were observed with a minute exactness that could be attained only by a long residence and study together. The eldest brother had lost his under-front-teeth, and complained of age; and it was natural to suppose that the performance of each had been better; however, to me (says Dr. Burney), who heard them now, for the full time, it was delightful! If there was anything to lament in so exquisite performance, it arrove from the equal perfection of the two parts; which distracted the attention, except when in dialogue, so much as to render it impossible to listen to both, when both had diffarlner melodies equally pleading.

They were born at Parma, and had been upwards of 50 years in the service of his Sardinian majesty, without ever quitting Italy, (except one short excursion to Paris, in 1755,) or even Turin, but for that journey, and another to visit the place of their nativity. They were men of a sober, regular, and moral character; in easy circumstances; had a town and country house, and in the former many good pictures by the first masters.

The Bezozzi family has furnished many admirable musicians to Italy, and other parts of Europe. Gaetano Bezozzi, a celebrated performer on the hautbois in the king of France's service, was born at Parma, in 1727, entered into the service of the king of Naples in 1736, and into that of the king of France in 1765. We heard him perform a concerto at the concert spirituel at Paris in 1771, with great pleasure; and thought him superior to all whom we had then heard on the hautbois, except Fichter. His father, Joseph Bezozzi, had taught the celebrated brothers at Turin, Alexander and Jeron, his brothers, to play on the hautbois and bassoon. "M. Bezozzi of Paris," says Laberte, "in 1780, had during 25 years merited and enjoyed the highest reputation, as well as the esteem of all who knew him. His fon
was then lately received into the king's band, and his brother, Anthony Bezzafi, attached to the court of the king of Poland, had also a fun in the service of that of Dresden, where we heard him perform in 1772, and found him a truly great performer. His suifia di voce, or swell, was prodigious; indeed he continued to augment the force of a tone so much, and so long, that it was hardly possible not to fear for his lungs. His taille and ear were exceedingly delicate and refined; and he seemed to possess a happy and peculiar faculty of tempering a continued tone to different bases, according to their several relations: upon the whole, his performance was so capital, that a hearer must be extremely fatisfid not to receive from it a great degree of pleasure.

BEZZAMA, MARELLA, in Geography, a town of Italy, in the kingdom of Naples, and country of Otranto, 10 miles N. E. of Tarento.

BHAGNAGUR, a name formerly given to Hydrabad, which fee.

BIAKOR. See Bekeh.

BHARATA, a name given in the Sanskrit language to Hindostan.

BHATGAN, a city of Afia, in the kingdom of Nepal; the capital of an independent kingdom. It contains about 12,000 families, extends towards the east to the distance of five or six days' journey, and borders upon another nation, else independent, called "Crates," who profess no religion. See BHAGAN.

BHAVANI, the name of an ancient festival, annually celebrated on the full of May by the Copes, and all other Hindoos who keep horted cattle for use or profit. On this feast, they visit gardens, erect a pole in the fields, and adorn it with pendants and garlands. Similar rites are performed by the same classes of people in England, where it is known to be a relic of ancient superstition in that country. Hence it should seem, says Colonel Pearse, that the religion of the East, and the old religion of Britain, had a strong affinity.

BHEERAH, a place in Hindostan, on the east side of the Behut river, where is a pass over it, a little to the N. of W. from Lahore, about 11 minutes north of its parallel, and distant from it 85' geographical miles. N. lat. 32° 5'. E. long. 72° 12'.

B1, or BIA, a river of Russia, which, by uniting with the Katnusia, forms the river Oby.

BIA, in Conchology, a name given by the Siamefe, for a sort of little white shell, brought in vast numbers from the Madive islands, and used throughout most part of the East Indies for small money. Nine of these are equal to the French denier; they are called coris or cowries, and belong to the Cyprae genus of Lamellae.

BIBANAA, in Ancient Geography, a town placed by Ptolemy in the interior part of Arabia Felix.

BIACULA EATUS, in Ichthyology, a species of Balistes, having two ventral spines. Bloch, Gen. &c. This is pizcis coramnis of Willoughby. It inhabits India, and is of an elongated form, white, cinceros above, and rough to the touch, being covered with very short, biretute, or brilly hairs. It is a native of the East Indies, and, from the structure of the mouth, is a voracious kind, feeding probably on marine worms and crabs. The Dutch call it Hoven-chel; and the French, Balifie a deux piquans, in allusion to the two ventral spines, which constitute the specific character of the fish.

BIAEM, from BIA, opposition, in Rhetoric, denotes a kind of counter-argument, whereby something alleged for the adversary is retorted against him, and made to conclude a different way; for instance, "Occiditini,quia aditusilli interfecit non occidit; nam si id effe, in fugam me concepicis, " "You killed the perfon, because you were found standing by his body." (Bizz."

Rather I did not kill him, because I was found standing by his body; since, in the other case, I should have fled away."

BIFAM, in the Greek Laen, was an aifon brought against those who ravihi women, or used violence to any man's person. Potter, Archzol. lib. i. c. 24.

BIFAN also denotes a kind of saltne or sea-wine, used by the ancien Greeks in various disorders. It was made of grapes gathered a little before ripe, and dried in the sun; then preffed, the juice put up in casks, and mixed with a large proportion of sea-water; though Dioscorides seems to describe it as made of grapes steeped in sea-water, and then preffed. Gorr. Def. Med. p. 75.

BIFAFAR, or BIFARA, in Geography, a populous and powerful kingdom of Africa, situate west of Media and east and south call of Benin, from which it is separated by a chain of mountains; and extending beyond the fourth degree of north latitude, to the coast of the Gulf of Guinea. It has a capital of the same name; and the bay on its coast is called the lighthouse of Bifara. The natives of this country, the interior of which is little known, are idolaters, and much addicted to magic. They are said to be zealous in their worship, and to sacrifice their children to the devil. Bifara is also a small district of Africa, extending along the sea-coast, S.S.E. of the river Gambia, over-against the islands of Bifagos.

BIFABRA, in the Cynons of the Middle Age, a form of cry, or alarm to arms; on the hearing whereof, the inhabitants of towns or villages were to fly forth, and attend their prince. The word seems originally from Gascony; and the Italians even now, on a sudden insurrection of the people, commonly cry, Fia fora, by an usual change of the letter B into V.

BIAIO, St. in Geography, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, 31 miles W.S.W. of Nicalforo.—Alfo, a town in the same kingdom, in the county of Molife, 8 miles N. E. of Molife.

BIAJOS, the name by which the inhabitants of the Island of Borneo are distinguished. They are said to offer sacrifices of sweet-flavored wood to one supreme beneficent deity, and these sentiments of piety are accompanied by laudable morals. See Banjermessing and Borneo.

BIALA, a part of Prussian Silefsia, in the circle of Zulz.—Alfo, a small town in the duchy of Lithuania, belonging to Prufis, feated on the government of Johannesburg, which obtained its privileges in 1723.—Alfo, a town and river of Poland, which runs into the Vistula, S. W. of Cracow. N. lat. 49° 52'. E. long. 19° 20'.

BIALCERKIEW, a small town of Poland, in the Ukraine, feated on the Rofa, a river of the palatinate of Kiev, which discharges itself into the Dnieper; distant 60 miles S.S.W. from Kiev. Here the Tartars were entirely defeated in 1626.

BIALACRODKO, a small town of Poland, in the palatinate of Kiev, feated on the Irpian, 14 miles S. W. of Kiev.

BIALA, or BIALA, a town of Poland, in the palatinate of Brzezk or Biriefska, 16 miles S. W. of Brzezk or Birfels. N. lat. 52° 10'. E. long. 23° 25'.

BIALLOSTOCK, or BIALLSTOK, a neat and well built town of Poland, in the palatinate of Podalcalsia, north of Bielfk, in N. lat. 53° 5'. E. long. 23° 32'. The streets are broad, and the houses, which are in general platered, stand detached at uniform distances. The superior meeting

P 3 of
of this town is owing to the illustrious family of Bruni, whose palace adjoins the town, and who have contributed to ornament their place of residence. This palace is a large building, in the Italian style, and, on account of its magnificence, generally called the Verailles of Poland. It was formerly only a royal hunting seat, but given by John Calvin, together with Balhlock, and other estates, to Czarnecki, a general highly distinguished by his victories over the Swedes, when Poland was acutely crushed by her enemies. Czarnecki left one daughter, who married Bruni, the father of the late great general, and conveyed the estate into that family.

BIALOBOKY, a town of Poland, in the palatinate of Lemberg, 48 miles S. W. of Lemberg.

Biana, a town of Hindoostan, 26 leagues from Agra, which was formerly a large city, and included Agra among its dependencies. The town is still considerable, and contains many large stone houses. It was formerly the residence of a powerful rajah; but his principal city and fort were seated on the top of an adjoining hill, and the present town was only a suburb. The whole ridge of the hill is covered with the remains of large buildings, among which, the most remarkable is a fort, called "Bijey-Munday," containing a lofty pillar of stone, called "Bheemlat," or the Teak or olmian's lat or staff. This pillar is conspicuous at a great distance. The town and district now belong to "Ranjath Sing," the rajah of Bhirtoor. This place is famous for its excellent indigo. N. lat. 26° 20'. E. long. 77°. 6

Bianca, La, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra, 12 miles N. E. of Bova.

Bianca, Ital. for the note in music, which we denominate a minim: and the Fr. une blanche. This, though now almost the longest note in use, three or four hundred years ago, was the shortest. See Time-Table, and Musical Characters.

Bianchi, Francesco, called Il Frari, in Biography, an historical painter, was born at Modena, and was the disciple of the celebrated Antonio Correggio. His colouring was delicately fine, his attitudes graceful, and his invention very grand. His works possessed an astonishing beauty, and are prized as highly as even those of Correggio. He died in 1520. Pilkginton.

Bianchi, Peter, a painter of the Roman school, was born in Rome in 1694, and united with his talents as a painter the accomplishments of literature. He painted historical subjects, portraits, rural and naval scenes, animals, plants, and flowers, in fresco, oil, and ditamper. His reputation caused him to be employed in painting a picture in the church of St. Peter. He is said to have been a severe judge of his own performances, and to have destroyed many of his works after they were finished, because they did not please him. He died at Rome in 1730. Encyclopaedia.

Bianchi, John Baptist, born at Turin, Sept. 12th 1681, of an ancient and respectable family. After being educated with the greatest care, and under the ablest masters at home, he was sent early to the university, and made such progress in his studies, that at the age of 17, he was admitted doctor in medicine, and was soon after made physician to the hospital, a situation for which he was peculiarly qualified; for being fond of anatomical pursuits, he had here opportunity, from the number of subjects a large establishment of that kind necessarily furnished, of diffusing and examining the human body at every age, and labouring under every species of disease or deformity. He had the happiness also of finding his talents properly estimated by his brethren, and his labours rewarded, as he was advanced to be public teacher of anatomy at Turin, where his sovereign built for him, in the year 1715, a spacious and convenient amphitheatre. He also read lectures in philosophy, in pharmacy, chemistry, and on the practice of medicine. These honours were not however entirely without alloy, as he had the mortification to find his doctrine controverted by Morgagni, and by Hailer on even the existence of some parts he suppos'd he had discovered, disputed. The principal of his works are "Historia hepatica, seu de hepatitis structura, usibus, et morbis," 1710, 8vo. Morgagni has published some severe strictures on this work, in his "Anatomo Anatomica." It was passed, however, through several editions, and in 1725, was re-published in 2 vols. 4to with figures. "Deputas laryngales novi, eorum usus, morbis, curatione," 1740. also confuted by Morgagni. "Storia de monstro, di duo corp.," 8vo. 1749, the most labour'd and perfect, Hailer says, of all his works. He wrote also an history of the generation of man, with figures, in which he attempts to delineate the fœtus in its different stages, but the figures, Hailer says, are principally fictitious. Many of his disfutations are inflected by Mangetti in his "Theatrum Anatomia." Hailer. Bib. Anat. et Chirurg. Eroy. Dict. Hist.

Bianchi, John, born at Rimini, Jan. 3, 1693. After receiving a liberal education, he went to Bologna, where, in 1719, he was admitted doctor in medicine. Returning the following year to Rimini, he practised medicine there with success for many years. He revived the academy of Lynxen, a philosophical society, collecting the members together at first at his own house. In gratitude for this, a medal was struck, with his figure on the face, and on the reverse, a lynx, with the motto "Lincnis rertitus." His works and articles are various, of which the principal are: "A Tractate on the Cataract," 1720 in Italian; "Epitola anatomica, ad Josephum Putznium," 1726. "De monbris, et rebus monstrosis," 1749, and in 1751, an account of an im-potence of the right hemisphere of the brain, occasioning paralysis on the opposite side of the body. Eroy. Dict. Hist.

Bianchini, Francis, a mathematician and philosopher, was born at Verona, Dec. 13, 1602, and devoting himself to the church, became a doctor in theology, and distinguished by his unfeigned piety. But his principal celebrity was acquired by his literary and scientific performances. In early life he contributed to the establishment of the academy of the "Aktes, or the lovers of truth, and in the progress of his studies rendered it considerable service. His literary reputation attracted that notice to which the rank of his family also in some measure entitled him. Cardinal Ottoboni, afterwards pope Alexander VIII, appointed him his librarian; and he was promoted first to the dignity of canon in the church of Santa Maria della Rotunda, and also to that of St. Laurence, in Darasafo. He was also secretary to the congregation for the reform of the calendar, to which office he was nominated by pope Clement XI. The senate created him one of the nobility of Rome, and after his death the citizens of Verona placed his bust in their cathedral. He died of the plague March 2, 1729, with a character distinguished for the benevolence and candour of his manners, as well as for his piety and universal learning. Fontenelle honoured his memory with an eulogy, as one of the foreign members of the academy of sciences at Paris. His first work was "An Universal History," on a new plan, tending to give perplicity to the chronological distribution. The first part of this work was published in 1697, under the title of "La Historia Universale provata con monumenti et figurata con Simboli de gli Antichi." It extends, from the creation
creation of the world, to the destruction of the great Assyrian empire, and is held in high estimation for industry of research, and ingenuity of disquisition with regard to the genuine monuments of antiquity. The succeeding parts were never written. Of occasion of the reform of the calendar, Bianchini wrote two learned and scientific treatises, published in 1703, and entitled "De Calendario et Cyclo Caele- si ac de canone Paschalii Sancti Hippolyti Martyris, Dissertations dua." Of his astronomic skill and labour in tracing the meridian line, in the church of the Chartreux at Rome, he published an account in a dissertation "De nummo et gnomone Clementino." In 1777, he published "Camera ed Inserzioni Sepolcrati di Liberti, Servi ed Officiali della Caia di Augufo," on occasion of the discovery of a subterraneous sepulchral building, in 1726, on the Appian way. His observations on Venus, were published in 1728, under the title of "Hepseri et Phosphori Nova Phenomena, five Observations circa Planetam Venecius." The results of his observations on the rotation of Venus, and the position of its axes, though very interesting to astronomers, at the time of their publication, have since, however, been confirmed by others of a later date, made by Herschel and Schroetter, with instruments of much greater power than any which were known in his time, and inferred in the Philosophical Transactions. The cause of this difference has not yet been ascertained, and deserves investigation. (See Venus.) Bianchini was employed for eight years in preparatory measures for tracing a meridian line through the whole extent of Italy, but his death prevented the commencement of this enterprise. His edition of "Annales of the Lives of the Popes," in 4 vols. folio, with notes, dissertations, faces, &c. displays much genius and erudition; but it is said to abound with typographical errors. He left an unedited dissertation in Latin, on the three kinds of musical instruments of the ancients, which was published at Rome 1742, in 4to, under the following title: "Francisci Bian- chinii Veronensis utrque signaniere referendaris, & prefai domelicci, de tribus generaibus instrumentorum musicce ve- terum organice dissertatio." In dividing ancient musical instruments into three classes, namely, wind instruments, stringed instruments, and instruments of percussion, the first class includes flutes, trumpets, horns, the syrinx, and hydraulicon; the second, the monochord, the lyra trichordis, tetrachordum, the seven-stringed lyre, the cithara, the psaltery, harp, &c.; the third class comprises the tym- panum, cymbalum, crotalum, syrinx, and the tinninabalum. Of all these, the author has given descriptions and representations well engraved on plates. Fontenelle Eloge des Academicien. Nouv. Dict. Hist.

BIANDRATE, in Geography, a town of Piedmont, in the Navarre, 6 miles N.W. of Novara.

BIANDRONA, a town of Italy, in the duchy of Milan, 15 miles W.S.W. of Como.

BIANOR, in Entomology, a species of Papilio, nearly allied to P. Paris, and a native of the East Indies. The wings are above and beneath of the same black colour, with five rufous lunules on the posterior pair. Fabricius, &c. It may be doubted whether this is a distinct species from Paris; perhaps only a sexual difference.

BIAR, a small town of Valencia, in Spain, seated on a river which runs into the Elda, on the confines of New Catalonia. It is chiefly remarkable for its honey, which is distinguished by its whiteness and solidity, unaffected by any change of weather; distant two leagues call of Villena.

BIARCHUS, formed from Βλαρχος, annone, withals, and τιμίας, chief; an officer in the court of the emperors of Con-

stantinople, intrusted with the care and inspection of the provisons of the soldiery. The biarchus was the same with what the Latins call prefettus annone. His function was called biarchia; by the Latins, prefettura rei clariae. He belonged to the fedeia agentium in rebus. See ACHERENT.

BIARMIA, in Geography, a name given by the Scandi- navian navigators, in the Middle ages, to the whole country between the White Sea and the Ural. See PERMIA.

BIARUM, in Botany, a name by which the people of Egypt at this time called the root of the nilfuar, or falsa Egyptian, growing on the Nile.

BIAS, or Biasse, in a general sense, denotes the tendency or propensity of a thing towards one side more than the other; particularly the deviation of a body, or a plane, from its rectilinear course, or its level. See Inclination. It signifies also the inclination of a person's mind to one thing more than to another. The word is French, bias, which signifies the fame.

Bias of a bowl, is a piece of lead put into one side, to load and make it incline towards that side.

BIAS, in Biography, one of the seven wise men of Greece, was a native of Priene, in Ionia, and flourished in the reign of Alexicuses II. king of Lydia, about 608, according to some, but according to Blair's tables, about 565 years before Christ. He was eminently distinguished not only by his wisdom, but by his generosity and public spirit, and for these qualifications held in the highest veneration by his countrymen. Alyattes was obliged by a stratagem of his contrivance to raise the siege of his native town, when it was reduced to the utmost distress from famine. He first sent two fattened mules into the enemy's camp; and the king, observing with astonishment their good condition, sent deputies into the city under a pretence of offering terms of peace, but with a real intention of observing the state of the town and of the people. Bias, suspecting their design, ordered the granaries to be filled with large heaps of sand, and these heaps to be covered with corn; upon which, when the deputies returned, and reported the plenty of provision with which the city was furnished, the king no longer demurred, but concluded a treaty, and raised the siege. As an instance of his generosity, it is related of him, that when several young female captives were brought from Meflene to Priene, he redeemed them, educated them as his own daughters, and then restored them to their own as their parents. As an example of the low estimation in which he held the gifts of fortune, compared with the endowments of the mind, it is said, that when Priene was once threatened with a siege, and the inhabitants were leaving it, loaded with their most valuable effects, Bias took no pains to preserve any part of his property, alleging as a reason of his conduct to one who expressed his surprise at it, "I carry all my treasures with me." The following maxims of wisdom were ascribed to him. "It is a proof of a weak and disordered mind to desire impossibilities." "The greatest felicity is, not to be able to endure misfortunes patiently." "Great minds alone can support a sudden reverse of fortune." "The most pleasant state is to be always gaining." "Be not unkind- ful of the miseries of others." "If you are handesome, do handesome things; if deformed, supply the defects of nature by your virtues." "Be slow in undertaking, but resolute in executing." "Praise not a worthless man for the sake of his wealth." "Whatever good you do, or do all the good you can, and ascribe the glory of it to the gods." "Lay in wisdom as the store for your journey from youth to old age, for it is the most certain possession." "Many men are dissatisfied; therefore love your friend with caution, for
he may hereafter become your enemy." Bias is affected to have written more than 2000 verses concerning Ioia. His death was no less honourable than affecting; for he expired in the arms of a grandchild, while he was pleading a cause for a friend. Dog.-Laert. i. 82. Val. Max. l. iii. c. 2. vi. 2. Aus. Geil. i. c. r. 11. Cicer. de Amicit. c. 60. Plint. Conv. vii. 15. Artiol. Rhet. i. c. 13. 1. Stobaeus Scrm. 25. Drucker's Phil. by Enf. vol. 3. p. 145.

Bias, in Entomology, a species of Papilio (Pileh. Rusc.), that inhabits Cayenne. The wings are entire black, glossed with blue; beneath brown, with a white posterior margin. Fabricius.

BIASI, S. r. in Geography, a town of Italy, in the kingdom of Naples, and province of Principato ciria, 15 miles W. N.W. of PisaUtra.

BIATIANATLI. Saxonia, from Sax. violence, and Saxo, death; the name of hunchards, or those who kill themselves.

BIB, in Ichthyology, the English name of a fish of the Gadus tribe, called basta by Linnaeus.

BIBAN, in Geography, a town of Egypt, in Bahira, the residence of a kamesh. Once a week, on Monday, a fair for camels and other cattle is held in the fields adjoining to this place.

BIBONA, a town of Italy, in the duchy of Tuscany, 50 miles north of Arezzo.

BIBBS, Bins, or Brackets, in Rural Architecture, are made of elm plank, and bolted to the hounds of mats, as supports to the trellis trees. They are from three to five inches thick, and nine eleventh of the hounds in length, and in breadth five sixeighth their length. The after edge is first laid straight, and the upper part square from that, and the fore part tapered by a moulding to four or six inches of breadth at the lower ends. The after edge is fayed on the cheeks, and the upper part against the under side of the trellis trees on the fore side of the mast: viz. in the middle of the after edge, set up one inch and a half, and line straight from that to nothing at the lower end, which makes a butt in the middle; then place the bibbs on the mast, their thickness within the sides of the cheeks, and their upper parts to the outsides of the trellis trees; then let one inch and a half be raked by the lower edge of the bibbs upon the cheeks, and the wood taken out to that depth, and the thickness of the bibbs, that they may bed firm therein; they are then bolted edgeway through the checks with four bolts driven from the fore side and clenched on a ring on the aft-side. The bolts are to be in diameter from one inch to seven eighths, or three quarters in small ships' mats, and only three in number. The lower end of the bibb is rounded off to the surface of the cheek, and the edges chamfered.

BIBEN, in Geography, a town of Peria, in the Irak Agami, 140 miles south of Erghan.

Biben, otherwise called Pischem, and in Latin Peleno, or Petina, a town of Carnia, seated in a very fertile spot, on a high mountain; and the fee of a bishop, to whose jurisdiction belong two towns and eleven villages, in which are fourteen parishes, suffragan to the prelate of Gorz.

BIBER, a town or village of Germany, in the circle of the lower Rhine, the electorate of Mentz, and prefecture of Steinhelm, 5 miles E.S.E. of Francefort on the Main. This is one of eleven villages which are poissed in a common wood named the "Biber Mark." At Biber, all things relating to it are managed by the sheriffs of the Mark; and before the village, under a great lime-tree, lies the sheriffs' bench, where the Mark court is fenced in, and transgressors are openly cited and punished.

BIBER, in Zoology, a name given by Ridinger, &c. to the beaver, orater fur, Linnaeus.

Biber, Henry John Francis, in Biography, vice-chaplain to the archbishop of Salzburg, seems to have been the greatest performer on the violin of the 17th century. Balafter from Lubec, about the middle of that century, had so astonished the Oxoniens by his execution on the violin, that according to Ant. Wood, Dr. Willem, the music professor, after hearing him, stooped down to examine his feet, whether they were not cloven; that is, "whether he was a devil, or not, because his performance was beyond the faculties of man." But if we may now judge of his performance by his compositions that are still extant, it was very inferior to that of Biber, who published in 1681, solos for a violin and bass, the most difficult and the most fanciful of any music of the same period. One of the solos is written on three separate flaves, as if a score for two violins and a bass; but the trebles are to be played in double flaves. Others are played in different tunings of fourths and fifths, as for a treble viol. A second work by this musician, intitled, fiderum facies perfamum, confits of twelve sonatas in four and five parts, to be played on three instruments; and a third, harmonia artificios a artibus, published at Nuremberg, consisting of pieces in seven parts, to be played on three instruments. In this last work he is styled Biber, in knowledge of the finger-board, double flaves, and use of the bow, as well as composition, he seems to have surpassed all preceding violinists.

BIDERACH, in Geography, an imperial city of Germany, in the circle of Swabia, situate in a valley, watered by the Ries, near the Danube. The magistrates and people are partly protestants and partly catholicks; and the church, as well as the hospital, are common to both. The treaty of Weilphalia requires that it should have as many catholicks as Lutherans in the senate. It is governed, as to its offices, like the city of Augsburg. It has a large manufacture of faustians. The number of houses is estimated at 900, of inhabitants at 6,600, and of burghers at 900. This city is very ancient, and was known in the year 751, under Pepin. By the plan of indentities agreed upon by France and Ruffia, this imperial town was conceded to the maravgre of Baden. N. lat. 48° 47'. E. long. 10° 2'.

BIBERSTEIN, a small town of Swizerland, in the canton of Bern, seated on the north-west side of the Aar. N. lat. 47° 17'. E. long. 7° 56'.—Alio, a bailliwick, with a castle, in the circle of the Upper Rhine, and bishopric of Fidula, 8 miles east of Fidula.

BIBIENA, Bernardo Da, Cardinal, whose proper name was Daviz, or Diviz, was born of an obscure family at Bibiena, in the Celentine, in 1470, and entered into the service of the family of Lorenzo di Medici. He attached himself to cardinal John, afterwards pope Leo X., whom he accompanied in his exile and served with affection and fidelity. At Rome he ingratiated himself with pope Julius II, by whom he was employed in some concern of importance, and by whom his services were approved. On the death of Julius, he artfully persuaded the cardinals, that his master, though only 36 years of age, was not likely to live long, and by this artifice obtained his election. Leo was not insensible of his obligation, and made him his first treasurer, and in 1513, cardinal. In the direction of the works of the holy house of Loretto, in which he was employed, he encouraged men of literature, and engaged the best artists, particularly Raphael. Leo also deputed him as legate to the pontifical army against the duke of Urbino, then to the emperor Maximilian, and afterwards, in 1518, to Franc-
BIB

BIBLIA, in Geography, a market-town of Italy, in the duchy of Tuscany, and district of Cafentino.

BIBIG, a town of Egypt, two miles south of Feium.

BIBLIO, in Entomology, one of the Fabricius genera of Aniliata, and which in the Linnaean system forms a section of the Musca genus. Fabricius defines the generic character of Bibio from the sucker, feelers, and antennae.

The sucker consists of three bristles, and is a sheath of a single valve; feelers very short; antennae connected at the base, and pointed at the tip. Ent. Syll. See Musca.

BIBLITORY Muscle. See ADDUCTOR OWL.

BIBLE, a book, by way of eminence is called, containing the Scriptures, i.e. the writings of the Old and New Testament; or the whole collection of those which are received among Christians as of divine authority.

The word Bible comes from the Greek βιβλίον, or βιβλία, used to denote any book; but, by way of eminence, applied to the book of Scripture, which is "the book," or "book of books," as being superior in excellence to all other books.

Bibl. again comes from βιβλία, the Egyptian reed, from which the ancient paper was procured. See BIBLUS.

The word Bible seems to be used in the sense now specified by Chrysostom (In Col. H. g. tom. xi. p. 301.): "I therefore exhort all of you to procure to yourselves Bibles (βιβλία). If you have nothing else, take care to have the New Testament, particularly the Acts of the Apostles, and the Gospels, for your constant instructors. And Jerome (In 11. c. 20. tom. iii. p. 246,). "that the Scriptures being all written by one Spirit, are one book." Augustin also informs us (Enarr. in Phil. n. 2. tom. iv.), "that some called all the canonical Scriptures one book, on account of their wonderful harmony and unity of design throughout." It is not improbable, that this mode of speaking gradually introduced the general use of the word "Bible" for the whole collection of the Scriptures, or the books of the Old and New Testament.

The Bible is known by various other appellations, as the "Sacred Books," the "Inspired Writings," "Holy Writ," "Sacred Text," &c. By the Jews the Bible, i.e. the Old Testament, is called "Mikvah," that is, letters or reading; by the Christians the Bible, comprising the Old and New Testament, is usually denominated "Scripture," q. d. writing; sometimes also the "Book of God," the "Canon," "Rule of Faith," &c. These, and similar appellations, are derived from the opinion that has been entertained, in successive ages, of the divine original and authority of the Bible, and of its importance and utility as a rule of faith and directory of conduct. As it contains an authentic and connected history of the divine dispensations with regard to mankind; as it lays claim to divine inspiration; as its chief subject is religion; and as the doctrines it teaches, and the duties it inculcates, pertain to the conduct of men, as rational, moral, and accountable beings, and conduct by their natural influence, as well as by a divine constitution and promise, to their present and future happiness; the Bible deserves to be held in high estimation, and amply justifies the sentiments of veneration with which it has been regarded, and the peculiar and honourable appellations by which it has been denominated. See the sequel of this article.

The list of the books contained in the Bible, is called the canon of Scripture. See CANON. Those books that are contained in the catalogue to which the name of canon has been appropriated, are called canonical, by way of contradistinction from others called deuterocanonical, or apocryphal, pseudocanonical, &c., which either are not acknowledged as divine books, or are rejected as heretical and impious. See APOCRYPHAL.

The

BIBLIA, Ferdinand Galli, celebrated painter and architect, was born at Bologna, in 1657; and losing his father when very young, was placed under the direction of Carlo Cignani, who, observing his taste for architecture, obtained for him the instruction of Paradoffo, Aldrovandini, and Manini, the bell masters of that period for perspective and architecture. In consequence of the recommendation of Cignani, he was patronized by the prince of Parma, who employed him in executing a variety of decorations, and settled upon him an annual pension. For the dukes of Parma, he painted the scenes for Hiera, tyrant of Syracuse; in 1685; for Isidoria in love with Alexander, 1694; for Demetrio tiranno, 1645; for Erasto, 1700; and for Ifacoli generoso, in 1701. From Parma he went to Milan, where, in 1704, he painted the scenes for L'Innanzo Contesa, and thence went to Vienna, and was appointed painter and architect to the emperor Charles VI., by whom he was highly honoured and rewarded. He was the inventor of those wonderful and magnificent scenes which still decorate many theatres in Italy; and published a book of instructions for embellishing theatres in general. He also built several palaces. He was also an excellent machinist, and the sole inventor and director of the solemn festival machinery exhibited for the birth of the archduke of Austria, celebrated at La Favorite, near Vienna.

He had a brother, Francis, of equal genius and fame, and two sons worthy of such a father. It was Ferdinand Bibiena Galli, who, quitting mythology and fantastical forms, gave true representations of nature; rapidity of change, intelligent disposition of lights, and above all, that great help to illusion, the leaving something to the spectator's imagination. At length he left his light by cataracts in his eyes, and obtained leave to return to Italy, where he composed two volumes upon architecture for the instruction of young perfons. He had several children, whom he educated to his own art, and a considerable number of scholars. Bibiena died at Bologna, as some say, in 1741, and according to others, in 1743. His cabinet pictures exhibit a noble and elegant ornamentation, and an uncommonly beautiful tone of colour. His perspectives have an astonishing effect by judicious masses of light and shadow; and the vediges of magnificent buildings, which he happily introduces in his compositions, add a richness and grandeur to all his performances.
The first canon or catalogue of the sacred books was made by the Jews; but the original author of it is not satisfactorily ascertained. It is certain, however, that the five books of Moses, called the Pentateuch, were collected into one body within a short time after his death: since Deuteronomy, which is, at it were, the abridgment and recapitulation of the other four, was laid in the tabernacle near the ark, according to the order which he gave to the Levites. (ch. xxxi. v. 24.) Hence it appears, that the first canon of the sacred writings confided only of the five books of Moses; for a further account of which, see Pentateuch. It does not appear that any other books were added to these, till the division of the ten tribes, as the Samaritans acknowledged no others. However, after the time of Moses, several prophets, and other writers divinely inspired, composed either the history of their own times, or prophetic books and divine writings, or psalms appropriated to the praise of God. But these books do not seem to have been collected into one body, or comprised under one and the same canon, before the Babylonian captivity. This was not done till after their return from the captivity, about which time the Jews had a certain number of books digested into a canon, which comprehended none of those books which were written since the time of Nehemiah. The book of Eclesiasticus affords sufficient evidence, that the canon of the sacred books was completed when that tract was composed: for that author, in chap. xxxix. having mentioned among the famous men and sacred writers, Isaiah, Jeremiah, Ezekiel, adds the twelve minor prophets, who follow those three in the Jewish canon; and from this circumstance we may infer, that the prophecies of these twelve were already collected and digested into one body. It is farther evident, that in the time of our Saviour the canon of the holy Scriptures was drawn up, since he cites the Law of Moses, the Prophets, and the Psalms, which are the three kinds of books of which that canon is composed, and which he often styles “the Scripture,” or “the Holy Scripture.” Matt. xxi. 42. xxii. 29. xxxvi. 54. John, v. 39. This flows that they were distinguished from others, and formed a separate body. The person who compiled this canon is generally allowed to be Ezra. According to the invariable tradition of Jews and Christians, the honour is ascribed to him of having collected together and perfected a complete edition of the Holy Scriptures. The original of the Pentateuch had been carefully preserved in the holy of the ark, and had been probably introduced with the ark into the temple at Jerusalem. After having been concealed in the dangerous days of the idolatrous kings of Judah, and particularly in the impious reigns of Manasseh and Amon, it was found in the days of Josiah, the succeeding prince, by Hilkiah the priest, in the temple. Prideaux says, that during the preceding reigns, the book of the Law was so destroyed and lost, that, besides this copy of it, there was then no other to be obtained. To this purpose he adds, that the surplice expressed by Josiah and the people, at his reading the copy found by Hilkiah, may be accounted for by advertising to the history of the preceding reigns, and by collecting what a very idolatrous king Manasseh had been for 55 years, and that he wanted neither power nor inclination to destroy the copies of the Law, if they had not been secured by the fervants of God. The Law, after being so long concealed, would be unknown almost to all the Jews; and thus the solemn reading of it by Josiah would awaken his own and the people's earnest attention; more especially, as the copy produced was probably the original written by Moses. From this time copies of the Law were extensively multiplied among the people; and though within a few years, the autograph, or original copy of the Law, was burnt with the city and temple by the Babylonians, yet many copies of the Law and the Prophets, and of all the other sacred writings, were circulated in the hands of private persons, who carried them with them into their captivity. It is certain that Daniel had a copy of the Holy Scriptures with him at Babylon; for he quotes the Law, and mentions the prophecies of Jeremiah. Dan. xii. 13. ix. 2. It appears also, from the sixth chapter of Ezra, and from the ninth chapter of Nehemiah, that copies of the Law were dispersed among the people. It is unnecessary, therefore, to suppose, with some of the ancient fathers, such as Tertullian, Clemens Alexandrinus, Bashi, &c. that Ezra restored the scriptures by a divine revelation, after they had been lost and destroyed in the Babylonian captivity. For this opinion they had no other authority than the fabulous relation which occurs in the 14th chapter of the second apocryphal book of Esdras: a book too absurd for the Romanists themselves to admit into their canon. The whole which Ezra did may be comprised in the following particulars. He collected as many copies of the sacred writings as he could find, and compared them together, and out of them all, formed one complete copy, adjusted the various readings, corrected the errors of transcribers, and, as some say, annexed the “Keri chethim,” which are found in the margins of the ancient MSS. He likewise made additions in several parts of the different books which appeared to be necessary for the illustration, correction, and completion of them. To this class of additions, we may refer the last chapter of Deuteronomy, which, as it gives an account of the death and burial of Moses, and of the succession of Josiah after him, could not have been written by Moses himself. Under the same head have also been included many other interpolations in the Bible, which create difficulties that can never be solved without allowing them; as in Gen. xii. 6. xxii. 14. xxxvi. 5. Exod. xvi. 35. Deut. ii. 12. iii. 11, 14. Prov. xxxv. 1. The interpolations in these passages are ascribed by Pridaux to Ezra; and others which were afterwards added he attributes to Simon the Jull. Ezra also changed the old names of several places that were become obsolete, putting instead of them the new names by which they were at that time called; instances of which occur in Gen. xiv. 4. where Dan is substituted for Laith, and in several places in Genesis, and also in Numbers, where Hebron is put for Kirjath Arba, &c. He likewise wrote out the whole in the Chaldee character, changing for it the old Hebrew character, which hath since that time been retained only by the Samaritans, and among whom it is preferred even to this day. In the church of Dominic, in Bononia, there is paid to be a copy of the Hebrew Scriptures, preferred with great care, which they pretend to be the original copy written by Ezra himself, and for which great sums have been occasionally borrowed by the Bononians upon the pledge of it, and which have again been paid for its redemption. This copy is written in a very
very fair character upon a sort of leather, and made up in a roll, according to the ancient manner; but as it has the vowel points annulled, and the writing is fresh and fair, without any visible decay, its antiquity is very justly denied, and its novelty is not unanswerable. Bishop Pococke, in his Travels, vol. i. p. 23, mentions a MS. Bible, preferred at Cairo, in Egypt, which is said to be written by Ezra.

Dupin says, that Nehemiah had a great hand in compiling this canon; for proof of which we refers to the letter to the Jews of Jerusalem written to the Jews of Egypt, mentioned in the beginning of the second book of Maccabees, in which, it is said, that Nehemiah had collected the books of the Kings, of the Prophets, and of David. It is said, that this canon was then approved by the grand sanhedran, the great sanhedran, or council of seventy, and published by its authority. It is, however, says Dupin, more apparent, that about that time the number of the sacred books was fixed among the Jews by a canon, which the whole Jewish nation received and followed; so that they looked no longer upon such books as sacred and divinely inspired, which were not contained in this canon. The canon of the whole Hebrew bible seems, says Kennicott, to have been closed by Malachi, the latest of the Jewish prophets: about 50 years after Ezra had collected together all the sacred books which had been composed before and during his time. Prideaux supposes the canon was closed by Simon the Just, about 150 years after Malachi. But, as his opinion is founded merely on a few proper names at the end of two genealogies (1 Chron. iii. 19 & Neh. xii. 21), which few names might very easily be added by a transcriber afterwards; it is more probable, as Kennicott thinks, that the canon was finished by the help of the prophets, about 400 years before Christ. The books of the Old Testament having been settled by Ezra, Nehemiah, Haggai, Zechariah, and Malachi, were probably left perfect. Completely repaired after the injuries of time during the captivity; and corrected from such errors as might have crept in from want of care in the transcribers. But the Hebrew text, thus left to posterity, does not seem to have continued long in the same condition. For the celebrated text, relative to mount Gerizim, was without doubt altered soon after the temple upon Gerizim was built. And as that corruption has been proved upon the Jews, the Jews therefore corrupted their Pentateuch, in this instance, probably between the years 400 and 300 before Christ. See Pentateuch.

It is an enquiry of considerable importance, in its relation to the subject of this article, what books were contained in the canon of the Jews. In the arrangement of Ezra these books were divided into three parts; i. The Law; ii. The Prophets; and iii. The Cetubim, or Hagiorapha, i.e. the holy writings; which division our Saviour himself has taken notice of (Luke xxiv. 44); meaning by the Psalms the whole third part, called the Hagiorapha. In conformity to this division, Josephus (Contra Apion. i. 8. tom. ii. p. 441.) distributes the canonical books of the Jews into three classes. The first contains the five books of Moses; the second, thirteen historical and prophetical books, written from the time of the death of Moses to Artaxerxes; and the third, four books of hymns and of morality; the whole number amounting to twenty-two. The first class comprehends Genesis, Exodus, Leviticus, Numbers, and Deuteronomy; the second includes Joshua, Judges, Ruth, Samuel, Kings, Chronicles, Ezra with Nehemiah, Esther, I Esdras, Jeremiah with Lamentations, Ezekiel, Daniel, and the twelve minor prophets; and the third class contains Job, the Psalms, Proverbs, and Ecclesiastes. It appears that the Song of Solomon had no place in the list of the sacred writings drawn up by Josephus. Others, however, have joined Ruth with Judges, referred Job to the second class, and introduced the Song of Solomon into the third class. Origen, Athanasius, Thallus, Gregory Nazianzen, Epiphanius, and Jerome, speaking of the books that are allowed by the Jews as sacred and canonical, agree in saying, that they are the same in number with the letters in the Hebrew alphabet, i.e. twenty-two, and reckon particularly those books which we have already mentioned; with respect to which they all concur, except in relation to the book of Esther. All of them place the book of Job and the Lamentations among the books contained in the canon of the Jews; but Athanasius and Gregory Nazianzen do not reckon the book of Esther among them, and differing from others form the books of Judges; whereas Origen, Hilary, Epiphanius, and Jerome, make only one volume of Ruth and Judges, and introduce the book of Esther into the number of the twenty-two books reckoned by the Jews as canonical. They who distinguished Ruth from the book of Judges, and the Lamentations from the prophecies of Jeremiah, reckoned up twenty-four of them. These books are disposed of in the following order; viz. i. The Law, containing Genesis, Exodus, Leviticus, Numbers, Deuteronomy; ii. The writings of the prophets, divided into the former prophets and the latter prophets; those of the former being Joshua, Judges, Samuel, Kings, and the latter Isaiah, Jeremiah, Ezekiel, and the twelve minor prophets; iii. The Hagiorapha, which are the Psalms, the Proverbs, Job, the Song of Solomon, or Song of Songs, or Canticles, Ruth, the Lamentations, Ecclesiastes, Esther, Daniel, Ezra, and the Chronicles. Under the name of Ezra is comprehended Nehemiah. However, this order hath not always been observed among the Jews, neither is it so now in all places; for in this respect there has been a great variety, not only among the Jews, but also among the Christians, Greeks as well as Latins. All these books were received into the canon of the Holy Scriptures in the time of Ezra, for Malachi lived after him, and mention is made in Nehemiah of Jaddua as high priest, and of Darius Codomannus as king of Persia, who lived at least 100 years after his time; and in the third chapter of the first book of Chronicles, the genealogy of the sons of Zerubbabel is extended to so many generations as will bring it to the time of Alexander the Great, so that this book could not have been inserted in the canon till after his time. Accordingly, Prideaux supposes, that the two books of Chronicles, Ezra, Nehemiah, and Esther, as well as Malachi, were added in the time of Simon the Just, when he conceives the canon of the Holy Scriptures was completed. (See above).

The five books of the Law are divided into 54 sections, which division is attributed to Ezra, and was intended for the use of their synagogues, and for the better instruction of the people in the law of God. For every sabbath one of these sections was read in their synagogues. They ended the last section with the last words of Deuteronomy on the sabbath of the feast of the tabernacles, and began again with the first section from the beginning of Genesis the next sabbath after, and so went round in this circle every year. The number of these sections was 54, because in their intercalated years (a month being then added), there were 52 sabbaths. On other years they reduced them to the number of the sabbaths which were in these years, by joining two short ones several times into one. For they held themselves obliged to have the whole law thus read over in their synagogues every year. Till the time of the persecution of Antiochus Epiphanes, they read only the Law; but being then prohibited from reading it any more, they substituted in the room of the 54 sections of the Law, 54 sections out of the
the Prophecies, the reading of which they ever after continued. Thus, when the reading of the Law was restored by the Maccabees, the section which was read every Sabbath out of the Law served for their first lection, and the section out of the Prophecies for their second lection; and this practice was continued in the time of the apostles, Acts xiii. 15. xiii. 27. These sections were divided into verses, called by the Jews "Pefukim," and they are marked out in the Hebrew Bible by two great points at the end of them, called from hence "Sopha-Pafuk," i.e. the end of the verse. This division, if not made by Experience, is very ancient; for when the Chaldee came into use in the room of the Hebrew language, after the return of the Jews from their captivity in Babylonia, the Law was read to the people first in the Hebrew language, and then rendered by an interpreter into the Chaldee language; and this was done period by period. To distinguish these periods was an object of importance; and hence arose the division into verses, which was first applied to the Law, and afterwards to the Prophets and Hagiographa. The manner by which these divisions, or verses, are now distinguished is by the "Sopha-Pafuk," but it is not certain that this was the ancient method. Prideaux apprehends, that the Pefukim, or verses of the Heb. w bibles, were anciently distinguished in the same manner as the "Stiches" afterwards used in the Greek Bibles. The manner of their writing these Stiches at first was to allow a line to every Stichus, and there to end the writing, where they ended the Stichus, leaving the rest of the line a void break. But this mode occasioning a want of punctum at which their books were written, and making their bulk too heavy; in order to avoid these inconveniences, they afterwards put a point at the end of every Stichus, and continued the writing without leaving any blank. In the Hebrew Bibles they adopted the same mode, and put the two points, called "Sopha-Pafuk," at the place where one verse ended, and continued the writing of the next verse in the same line, without leaving any void space. The division of the holy Scriptures into chapters is of a much later date. The Psalms, indeed, appear to have been always divided as they are at present. Acts xiii. 53. 

But as to the rest of the Bible, the present division into chapters was unknown to the ancients. See Chapter and Concordance.

Besides three books which were received into the canon of the books of the Old Testament, and those of which have been deemed apocryphal, there are several others which are cited in the Old, and also in the New Testament, which seem either to have been lost, or excluded by Ezra from his canon. Of such books are the books of the wars of the Lord," cited Numb. xxi. 4. but it does not appear that in this place any book is mentioned, "of the Covenant," of which it is said mention is made Exod. xxiv. 7, but evidently referring to the laws received by Moses from the hand of God, related in the preceding chapters; the "book of the Lord," mentioned II. xxxiv. 16 which does not seem to be any particular book; "the book of Jasher, or the upright," cited in Josua. x. 13, and 2 Sam. i. 18. supposed by some to be an historical book, but more probably consisting of hymns and songs; and "the books of Nathan (1 Chron. xxix. 29. 2 Chron. ix. 27.) of Gad, (1 Chron. xxix. 29.) of Shemaiah, (2 Chron. xxii. 15.) of Iddo, (2 Chron. ix. 29. xii. 15. xiii. 22.) of Ahijah, (2 Chron. ix. 29.) and of Jehu, (2 Chron. xx. 34.) which were memoirs composed by those prophets, or rather prophecies, which contained a part of the history. The same may be said of the book of the "Journal of Chronicles" of the kings of Judah or of Israel, which are different from the Paralipomena, or Chronicles; the book of "Samuel the Scribe," cited in the last chapter of the first book of Chronicles; the discourses of Hosea, cited 2 Chron. xxxiii. 18. 19. the "Acts of Uzziah," mentioned 2 Chron. xxvi. 22. the "three thousand and Proverbs, written by Solomon, (see 1 Kings iv. 32.) a thousand and five Songs," etc. composed by the same author, and mentioned in the same place. Jeremiah speaks of a volume of prophecies which he had dictated to Baruch, supposed by some to be the Lamentations. (See Baruch.)

Besides these books that are lost, there are others, not included in the canon of the Old Testament, which are still extant; such as the "Prayer of king Manasseh, when captive at Babylon," cited 2 Chron. ch. xxxiii. "the third and fourth books of Efras;" "the third and fourth books of the Maccabees;" "the genealogy of Job," and "a speech of Job's wife," annexed to the Greek edition of the book of Job; "a Psalm," affixed to the Greek edition of the Psalms; "the book of Enoch," not entire, cited by several of the fathers, and regarded by them as apocryphal, and referred to by Jude, v. 14. the book of the "Assumption of Moses," and his "Testament," placed by St. Athanasius among the apocryphal books; "the Assumption, Apocalypse, or Secrets of Elias," cited by Origen; and a number of others forged by the Jews, and fathered on the Patriarchs. See New Testament.

It may not be improper to refer, in one view, the books of the Old and New Testaments to their proper authors. We may suppose then, without ascending to the region of conjecture, and tracing the origin of any books, or parts of books of the Bible to patriarchal times, that the Pentateuch consists of the writings of Moses, put together, perhaps, by Samuel, with a few additional; that the books of Joshua and Judges were, in like manner, collected by him; and the book of Ruth, with the first part of the first book of Samuel, written by him; that the latter part of the first book of Samuel, and the second book, were written by the prophets who succeeded Samuel, viz. Nathan and Gad; that the books of Kings and Chronicles are extracts from the records of the succeeding prophets, concerning their own times, and from the public genealogical tables, made by Ezra; that the books of Ezra and Nehemiah are collections of like records, some written by Ezra and Nehemiah, and some by their predecessors; that the book of Elish was written by some eminent Jew, in or near the times of the transctions there recorded, perhaps Mordecai; the book of Job by Moses, or a Jew of an uncertain period; the Psalms by David and other persons; the books of Paralipomena and Canticles by Solomon; the book of Ecclesiastes by Solomon, or perhaps by a Jew of later times, fpeaking in his person, but not with an intention to make him pass for the author; the Prophecies by the prophets, whose names they bear; and the books of the New Testament by the persons to whom they are usually ascribed. See New Testament.

There are many internal evidences, and in the case of the New Testament, many external evidences also, by which these books may be known to belong to the authors here named. Or, if there be any doubts, they are merely of a critical nature, and do not at all affect the genuineness of the books, or not alter, at least materially, the arguments that may be adduced in favour of their authenticity and authority. It is readily allowed, that objections have been made to the alleged authors of several of these books. Abenazer, followed by Hobbes, Pereira, Spinosa, and some others, deny the first five books to have been written by Moses. F. Simon, in particular, affirms, that the books, as we now have them, are not the originals written by the inspired penmen, but abridgments of them, made in after-times by a kind of college, or order of public auctories, or scribes,
BIB

scribes, appointed for that purpose. See Pentateuch, and each of the books of the Bible, under its proper title. See also New Testament.

The original language of the Old Testament was, without doubt, the old Hebrew, at least the greatest part of it; for all the books do not appear to have been written in the same language. Some chapters of Ezra and Daniel, (see Ezra and Daniel,) are judged to have been composed in Chaldee; and it has been supposed, that other chapters of this latter writer, and also the apocryphal books of Maccabees, Wisdom, &c. were written in Greek; Tobit and Ecclesiasticus, either in Greek or Syriac. As for the New Testament, it was written in Greek, except the Gospel of St. Matthew, which is thought by some to have been composed in Hebrew. Some few have thought that the Gospel of St. Mark was written in Latin, and also the epistle to the Hebrews. See the Title of each Book, and Testament.

With regard to the style of the several writers of the Old and New Testament, there is a very considerable diversity. The style of Paul may be easily distinguished by its peculiarity from that of any other writer. A discerning reader will not easily confound the style of Luke with that of either of the evangelists, who preceded him, Matthew or Mark; nor would he be in any danger of mistake the apostle John’s dictation for that of any other penman of the New Testament. The same diversity of style will be discovered by one who is but moderately conversant with the Hebrew, in the writers of the Old Testament. In this we have a greater variety than in the New. Some of the books are written in prose, and some in verse; and in each the differences between one book and another are considerable. In the book of Job, for instance, the character of the style is remarkably peculiar. What can be more dissimilar in this respect, though both are excellent in their kind, than the towering flights of the sublime Hiaiah, and the plaintive strains of the pathetic Jeremiah? In the several books of Scripture we can specify the concise style and the copious, the elevated and the simple, the apohoritic and the diffuse. This diversity in the dictation of the sacred penmen is perfectly reconciled with the idea of their inspiration; and in speaking on this subject, we should duly advert to the difference between the expression and the sentiment, and avoid confounding these two, as if they were the same; whereas they are widely different. The truths implied in the sentiments are essential, immutable, and have an intrinsic value; the words which compose the expression are in their nature circumstantial, changeable, and have no other value than what they derive from the arbitrary conventions of men.

That the Holy Spirit would guide the minds of the sacred penmen in such a manner as to prevent their adopting terms unsuitable to his design, or which might obstruct his purpose; and that in other respects he would accommodate himself to their manner and dictation, is both reasonable in itself, and rendered unquestionable by the works themselves, which have the like characteristic differences of style which we find in other compositions. Can it be accounted more strange that the Holy Spirit should, by the prophet Amos, address us in the style of a prophet, and by Daniel, in that of a courtier, than that by the one he should speak to us in Hebrew, and by the other in Chaldee? It is as reasonable to think that the Spirit of God would accommodate himself to the pluriformity and dictation, as to the tone of voice and pronunciation of those whom he was pleased to enlighten; for it cannot be denied, that the pronunciation of one person in uttering a prophecy, might be more articulate, more audible, and more affecting than that of another; and in like manner, as one style has more harmony, elegance, and peripetie than another. Catullus says judly, (Def. cont. Beazam.)

BIB

“Et dicit Spiritus, verba quidem et lingua loquenti aut seribenti liberant permittit; i.e. the Spirit dictates the things, leaving the words or language free to the speaker or writer. Jerom also observed a thousand years before, (Comment. in Epill. ad Gal. cap. i.) “ Nec putemus in verbo Scripturatum evangelii effe, sed in sensu;” i.e. let us not imagine that the Gospel conflits in the words of Scripture, but in the sense. To the same purpose is the observation of the ingenious and learned bishop Lowth, (De Sacra Poet. Heb. Prol. xvi.) “Hoc its facris variis tribuimus, ut nihil derogamus Divini Spiritus aliafuit; eti suam interea vim propriam ejusque coniugio, qua exiguissimam fuperficitur naturae ingenii consecutam; neque enim infirmus divino eius concitatur vatis animus, ut potius ordinatur hominis inodores: attoflltur et enguatur, non exemptur aut occultatur naturales ingenii fagacitates; et quamquam Mofis, Davidis, et Hier, scripta fempem fpiratur quiddam tam excelfum tam caerule, ut plane videantur divinitus edita, nihil tamen minus in his Molem, Davidem, Isaiam, famer agnoequus;” i.e. we shall detract nothing from the dignity of that inspiration, which proceeds from higher causes, while we allow to the genius of each writer his own peculiar excellence and accomplishments. The Divine Spirit by no means takes an entire possession of the mind of the prophet as to subdue or extinguish the character and genius of the man; the natural powers of the mind arc in general elevated and refined, they are neither eradicated, nor totally obscured; and though the writings of Mose, of David, and of Isaiah, always bear the marks of a divine and celestial impulse, we may nevertheless plainly discover in them the particular characters of their respective authors. See Inspiration.

It must be allowed, that many circumstances concur to render the style both of the New Testament and of the Old, of the historical books, as well as of the prophetical and argumentative, generally obscure, and often ambiguous; although we ought not to admit the exaggerated representation of father Simon, (Hist. Crit. des V. T. liv. iii. c. 2.) with regard to the greater part of the Hebrew words, which, he says, are equivocal, and of course their signification altogether uncertain. The origin of this kind of flatness must be sought in the author’s attachment to tradition, rather than to that kind of scepticism with which he is charged by Bollucc, bishop of Meaux, and which tended to undermine Christianity itself. To any person who duly reflects, this father’s representation must appear to be unfounded, or beyond all bounds hyperbolical. It is not just in its reference to the prophetical writings; and as to the historical books, they are, in general, remarkable for peripetie. The first quality by which the sacred history is distinguished is simplicity, which arises from this property of the Hebrew language, the verbs of which have not, like Greek and Latin, a variety of moods and tenses, nor do they abound, like the modern languages, in auxiliaries and conjunctions. This quality very much conduces to the peripetie of its style. Of this simplicity we have an example in the first paragraph of Genesis, consisting of five, not long, verses, and containing not fewer than eleven sentences, which are singularly simple; the subjunctives not being attended by adjectives, or the verbs by adverbs, without synonyms, or superlatives, or any effort towards expressing things in a bold, emphatical, or uncommon manner. In the Pentateuch, there is also a simplicity of sentiment, arising from the very nature of the early and uncultivated state of society, about which its books are conversant, and this renders the narrative, in general, extremely clear and engaging. Besides the simplicity of structure, and the simplicity of sentiment, there is another species of simplicity, for which Scripture history is more remarkable than any
other compositions of any language. This may be denominated simplicity of design. The subject of the narrative so engrosses the attention of the writer, that he disappears, as it were, from the view of the reader. He introduces nothing as from himself; no opinions of his own, no remarks, conjectures, doubts, or inferences; no reasoning about the cause or the effects of what is related. He never interrupts his reader with the display, either of his talents or his passion: he makes no digressions; he draws no characters; he supplies us merely with naked facts, from which we are left to collect the character. We observe no attempt to shine by means of the expression, composition, or sentiment. Plainness of language is usually preferred, because it is the most natural, the most obvious, and the best adapted to all capacities.

In this last feat of singularity, for which Xenophon among the Greeks, and Caesar among the Latins, have been recommended, our Lord's biographers particularly excel. With respect to the first species of simplicity, or that of structure, the difference of the genius of the Greek language from that of the Hebrew muse, without doubt, occasion a difference in the manner of Matthew, Mark, Luke, and John, from that of Moses; but the identity of idiom still occasions a strong resemblance between them. If Genesis, therefore, may be justly said to possess the first rank for simplicity of composition in the sentences, the Gospels are certainly entitled to the second: and John and Matthew have it in a higher degree than Mark and Luke. As to the second species, or simplicity of sentiment, the change of times, which is very great, as well as the difference of subjects, would necessarily confer the first degree of it upon the former. But in simplicity of object or design, the evangelists, of all writers, faced and prophane, appear the foremost. Their manner is indeed, in some respects peculiar and unrivalled. If we divert our attention from the historical, or narrative parts of the Bible, to the writings of the poets and prophets, we shall discover the animated, elegant, and sublime intermixed, as the subjects suggest, and the occasions require, with the simple and picturesque. But for other particulars, in reference to this subject, see Style and Testament. See also the titles of the several books of the Bible, for the distinguishing character of their writers.

Having considered the appellations by which the Bible is distinguished, the books of which it consists, the time, and manner in which they were collected, their respective authors, and the language and style in which they were written, it may not be improper to subjoin a few observations on the genuineness and authenticity of the Scriptures, on their high original and divine authority, and on their great importance and utility.

It should here be considered, that the genuineness of the Scriptures proves the truth of the principal facts contained in them; to which purpose we may observe, that it is very rare to meet with any genuine writings of the historical kind, in which the principal facts are not true, unless it be in instances where both the motives which engaged the author to falsify, and the circumstances which gave some plausibility to the fiction, are apparent; neither of which can be alluded in the present case with any colour of reason. As this is rare in general, it is more rare, when the writer treats of things that happened in his own time, and under his own cognizance and direction, and communicates his history to persons under the same circumstances, all which may be said of the writers of the Scripture history. Besides, the great importance of the facts mentioned in the Scriptures makes it more improbable, that the several authors should either have attempted to falsify, or have succeeded in such an attempt. This is an argument for the truth of the facts, which proves the genuineness of the books at the same time. However, the truth of the facts is inferred more directly from their importance, if the genuineness of the Scriptures be previously allowed. The same observation may be applied to the great number of particular circumstances of time, place, persons, &c. mentioned in the Scriptures, and to the harmony of the books with themselves, and with each other. These are arguments both for the genuineness of the books, and truth of the facts distinctly considered, and also arguments for deducing the truth from the genuineness. Moreover, if the books of the Old and New Testaments were written by the persons to whom they have been ascribed, i.e. if they be genuine, the moral characters of these writers afford the strongest assurance, that the facts ascribed to them are true. The sufferings which several of the writers underwent both in life and in death, in attestation of the facts delivered by them, furnish a particular argument in favour of these facts. Again, the arguments here alluded for proving the truth of the Scripture history from the genuineness of the books, are as conclusive in respect of the miraculous facts, as of the common ones. It may also be observed, that if we allow the genuineness of the books to be a sufficient evidence of the common facts which they record, the miraculous facts must also be allowed, from their close connexion with the others. It is necessary to admit both or neither. We cannot conceive, that Moses should have delivered the Israelites from their slavery in Egypt, or conducted them through the wilderness for forty years, at all, in such manner as the common history represents, unless we suppose the miraculous facts intermixed with it to be true also. In like manner, the fame of Christ's miracles, the multitudes which followed him, the adherence of his disciples, the jealousy and hatred of the chief priests, scribes, and Pharisees, with many other facts of a common nature, are impossible to be accounted for, unless we allow, that he did really work miracles. And the same observations hold, in general, of the other parts of the Scripture history. We might urge a particular argument in favour of the miraculous part of the Scripture history, that may be deduced from the reluctance of mankind to receive miraculous facts; which would put the writers and readers very much upon their guard, and would operate as a strong check upon the publication of a miraculous history at or near the time when the miracles were said to be performed; and thus it would serve as a strong confirmation of such an history, if its genuineness be previously granted. The converse of the proposition, now stated and explained, is also true: i.e. if the principal facts mentioned in the Scriptures be true, they must be genuine writings.

In connection with the preceding proposition we may observe, that the genuineness of the Scriptures proves their divine authority. Porphyry in effect acknowledges the truth of this proposition, in its reference to the book of Daniel, by being unable to devise a method of intimidating its divine authority implied in the accomplishment of the prophecies which it contains, without affecting, that they were written after the event, or that they were forgeries. Many of the other books of the O. and N. Testaments have unquestionable evidences of the divine foreknowledge, if they be allowed genuine: such are those supplied by Moses's prophecy concerning the captivity of the Egyptians, or of a flate not yet erected; Haaah's concerning Cyrus; Jeremiah's concerning the duration of the Babylonish captivity; Christ's concerning the destruction of Jerusalem, and the captivity that was to follow; St. John's concerning the great corruption of the Christian church; and Daniel's concerning the fourth empire in its dedication; which last was extant in the time of Porphyry, at least, that is, before the events which
it represents. The truth of the proposition might also be
argued from the sublimity and excellence of the doctrines
contained in the Scriptures; in no respect unfitting the sup-
poused authors, or the ages in which they lived, their educa-
tion or occupation; so that, if they were the real authors,
we are under the necessity of admitting the Divine assis-
tance. The converse of this proposition, viz. that the Divine authority of the Scriptures infers their genuineness, will be readily and
universally acknowledged. And there are several evidences for
the Divine authority of the Scriptures, which are direct and
immediate, and prior to the consideration both of their gen-
uineness, and of the truth of the facts contained in them.
Moreover, the truth of the principal facts contained in the
Scriptures proves their Divine authority. Such is the frame
of the human mind, that the Scripture history, allowed to
be true, must convince us that Christ, the prophets, and the
apostles, were endowed with a power greater than human, and
acted by the authority of a Being of the highest wisdom and
goodness. But if natural religion be previously established,
the truth of the principal facts of the Scriptures proves their
divine authority in a more easy and more convincing man-
er: for the knowledge and power manifested by Christ, the
prophets, and apostles, and also their good moral charac-
ters, showed them to be in an eminent manner the children, ser-
vants, and messengers of him, who is previously acknowledged
to be infallible in power, knowledge, and goodness; and they
actually lay claim to a divine mission, which claim cannot be
thought a false one, if we admit their credentials: or, in other
words, the truth of the principal facts mentioned in the Scrip-
tures proves the divine mission of Christ, the prophets, and
apostles, that is, the divine authority of the Scriptures.
By such mode of reasoning it is shown, that the genuine-
ness of the Scriptures, the truth of the principal facts con-
tained in them, and their divine authority, appear to be so
connected with each other, that any one being established
upon independent principles, the other two may be inferred
from it. On the subject of the inspiration of the Scriptures;
see INSPIRATION.
Another argument in proof of the genuineness of the
books of the Old and New Testaments, and of the truth of the
principal facts contained in them, may be deduced from the
manner in which they have been transmitted down from
ancest to another; refembling that, in which all other genuine
books and true histories have been conveyed down to poche-
ricy. As the writings of the Greek and Roman writers were
eleemed by those nations to be transmitted to them by their
ancestors in a continued succession, from the times when the
respective authors lived, so have the books of the Old Testa-
ment by the Jewish nation, and the New by the New by
the Christians; and it is an additional evidence in the last
cafe, that the primitive Christians were not a distinct nation,
but a great multitude of people dispersed through all the na-
tions of the Roman empire, and even extending itself beyond
the bounds of that empire. As the Greeks and Romans always believed the principal facts of their historical books,
so the Jews and Christians did more, and never seem to have
doubted of the truth of any part of theirs. In short, whatever
can be said of the traditional authority due to the Greek
and Roman writers, something analogous to this, and for the
most part of greater weight, may be urged for the Jewish and
Christian. Now, as all sober-minded persons admit the
books usually acribed to the Greek and Roman historians,
philosophers, &c. to be genuine, and the principal facts re-
lated or alluded to in them to be true, and that one chief
evidence for this is the general traditionary one here recited;
they ought, therefore, to pay the same regard to the books
of the Old and New Testaments, since there are the same,
or greater reasons for it. Besides, these traditional evidence are sufficient, and we thus gain a real argument, as
well as one "ad hominem," for receiving books thus handed
to us. For it is not conceivable, that whole nations
should either be imposed upon themselves, or concur to de-
ceive others, by forgeries of books or of facts. These books
and facts must, therefore, in general, be genuine and true;
and it is a strong additional evidence of this, that all nations
must be jealous of forgeries for the same reasons that we are.
On the conclusion of this argument, as it relates to mir-
acles; see MIRACLE.
We may proceed to observe further, that the great im-
portance of the histories, precepts, promises, threatenings,
and predictions contained in the Scriptures, are evidences
both of their genuineness, and of the truth of the principal
facts mentioned in them. The history of the creation, fall,
deluge, longevity of the patriarchs, dispersion of mankind,
calling of Abraham, descent of Jacob with his family into
Egypt, and the precepts of abstaining from blood, and of
circumcision, were of such concern, either to mankind in
general, or to the Israelites in particular, and some of them
of so extraordinary a nature, as that it could not be a matter
of indifference to the people amongst whom the account
given of them in Genesis was first published, whether they
received them or not. On the supposition that this account
was first published amongst the Israelites by Moses, and then
confirmed by clear, universal, uninterrupted tradition, it
will be easy to conceive, how it should be handed down from
age to age amongst the Jews, and received by them as indis-
tible. But supposing the account to be false, or that there
were no such velliges and evidences of these histories and
precepts, it will be difficult to conceive how this could
have happened, let the time of publication be what it may.
If early, the people would reject at once the account for want
of a clear tradition; if late, it would be natural to enquire how
the author was informed of things never known before to
others. If the account was delivered, as having been com-
municated to Moses by divine revelation, which is not very
costifuent with the numerous references that occur in Genesis
to the existing velliges of the things related, his fictitious
credentials would thus be embarrased, and his contemporaries
would be induced very particularly to examine them.
As to other cosmogonies and theogonies current among Pa-
gans, which are evident fictions; they furnish no just ob-
jection against the Mosaic history; because they were gene-
ally regarded merely as amusing fictions; and yet they con-
ceived in figures, or exprest in platte words some truths,
which agree with the book of Genesis, and afford a strong
premptive evidence in favour of this book. With respect
to the law of Moses, this was extremely burdensome, ex-
pensive, and severe, particularly in its reference to the crime
of idolatry, to which mankind were then extravagately prone;
and it was absurd, according to human judgment, in the in-
fances of prohibiting their furnishing themselves with horses
for war, and of commanding all the males of the whole na-
tion to appear at Jerusalem three times a year. Neverthe-
less, it claims a divine authority, and appeals to facts of the
most notorious kind, and to customs and ceremonies of the
most peculiar nature, as the memorials of these facts. Can
we then conceive, that any nation, with such motives to rej-
ounce, and such opportunities of detecting, the forgery of the
books of Exodus, Leviticus, Numbers, and Deuteronomy,
should yet receive them, and submit to this heavy yoke:
That the Jews did submit to the law of Moses in these cir-
cumstances, is evident from the books of the Old and New
Testaments, if we allow them the least truth and genuinen-
ness, or even from profane writers; and from the profet ob-
ference
The importance of its by the Jews scattered through all the kingdoms of the world. Should it be said, that other nations have ascribed divine authority to their lawgivers, and submitted to very severe laws, it may be alleged in reply, that the pretences of lawgivers amongst the Pagans to inspiration, and the submission of the people, may be accounted for from their peculiar circumstances at the time, without recurring to real inspiration; and more especially, if we admit the patriarchal revolutions related by Moses, and his own divine legislation, as heathen lawgivers copied after them, and hence we derive a strong argument in their favour. Besides, no influence occurs amongst the Pagans, of a body of laws framed at once and remaining invariable; whereas the body politic of the Israelites assumed a complete form at once, and has preferred it, with little variation, to the present time, and under many external disadvantages; thus supplying us with an influence altogether without parallel, and shewing the high opinion which they entertained of the great importance of their law. In short, of all the fictions or forgeries, that can happen among any people, the most improbable is that of the Jewish body of civil laws, and it seems to be utterly impossible in the case of the law of Moses.

If we further examine the history contained in the books of Joshua, Judges, Ruth, Samuel, Kings, Chronicles, Ezra, and Nehemiah, and extending from the death of Moses to the re-establishment of the Jews after the Babylonish captivity by Ezra and Nehemiah, we shall find a variety of important facts, most of which must be supposed to have furnished an occasion, either external and visible, or internal in the minds and memories of the people, as would verify them if true, or cause them to be rejected, if false. The conquest of the land of Canaan, the division of it, and the appointment of cities for the priests and Levites by Joshua; the frequent slaveries of the Israelites to the neighbouring kings, and their deliverance by the judges; the creation of a kingdom by Samuel; the translation of this kingdom from Saul's family to David, with his conquests; the glory of Solomon's kingdom; the building of the temple; the division of the kingdom; the idolatrous worship set up at Dan and Bethel; the captivity of the Israelites by the kings of Assyria; the captivity of the Jews by Nebuchadnezzar; the defection of their temple; their return under Cyrus, rebuilding the temple under Darius Hystaspis, and re-establishment under Artaxerxes Longimanus, by Ezra and Nehemiah; these events are some of them the most glorious, and some of them the most reproachful, that can happen to any people. How can we reconcile forgeries of such opposite kinds, and especially as they are interwoven together by various complicated and necessary connections, which do not admit of separation? The facts, indeed, are of such importance, notoriety, and permanency in their effects, that no particular persons among the Israelites could first project the design of forguing them, that their own people would not concur with such a design, and that neighbouring nations would not permit the fiction to pass. Nothing but the invincible evidence of the facts, here alleged, could induce a jealous multitude amongst the Israelites or neighbouring nations to acquiesce. This must be acknowledged upon the supposition that the several books were published in or near the times when the facts that are recorded in them happened. But suppose all these historical books forged by Ezra; the hypothesis is evidently impossible. Things so important and notoriety, so honourable and so reproachful to the people, for whose fake they were forged, would have been rejected with the utmost indignation, unless there were the strangest and most genuine traces of these things already amongst the people. They must therefore, in part at least, be true. If it be said that additions were made by Ezra; these additions must have been either of important or trivial matters. On the first supposition, the difficulty already stated recurs; and if the important facts are true, what possible motive could have induced Ezra to make additions of no importance? Besides, if any ancient writings were extant, Ezra must either copy after them, which destroys the present supposition; or differ from and oppose them, which would betray him. If there were no such ancient writings, the people would be led to enquire with regard to matters of importance, for what reason Ezra was so particular in things of which there was neither any memory, nor account in writing. Should it be said, that the people did not regard what Ezra had thus forged, this reduces the subject in question to matters of small, or of no importance. Besides, why should Ezra write, if no one would read, or regard? Further, Ezra must have had, like other men, friends, enemies, and rivals; and some, or all of these, would have been a check upon him, and a security against him in matters of importance. If we suppose these books, instead of having been forged at once, to have been forged successively, at the interval of one, two, or three centuries after the facts related, we shall involve ourselves in circumstances of time or other difficulties. Upon the whole, then, we may conclude, that the forgery of the annals of the Israelites appears to be impossible, as well as that of the body of their civil laws. It is needless to examine the books of Esther, Job, the Psalms, Proverbs, Ecclesiastes, and Canticles; and we might proceed to the Prophecies. But this subject will be resumed under the article Prophecy. For the importance of the subjects, comprehended in the books of the New Testament; see Testament, and Christianity.

We shall here subjoin some general evidences in attestation to the importance of the books of Scripture. That Jews and Christians have thought their sacred books very highly important, most genuine, and true, appears from the perjuries and sufferings which they have undergone on account of their attachment to them, and because they would not be prevailed upon to surrender them. The preservation of the law of Moses, probably the first book written in any language, whilst many others of a later date have been lost, marks the great regard that has been paid to it; and from this circumstance we may infer, that this and the other books of the Old Testament have been preferred on account of their importance, or from some other causes, equally evincing their genuineness and truth. The great importance of these books appears also from the many early translations and paraphrases of them; and these translations and paraphrases seem to correct errors that are unavoidable in the lapse of time, and to secure their integrity and purity. The hesitation and difficulty with which some few books of the New Testament were received into the canon, shew the great care and concern of the primitive Christians about the canon, and the high importance of the books admitted into it; and afford a strong evidence of their genuineness and truth. The same observation is in a degree applicable to the Jewish canon. Moreover, the religious hatred and animosity which subsisted between the Jews and Samaritans, and between several of the ancient sects among the Christians, convince us of what importance they all thought their sacred books, and disposed them to watch over one another with a jealous eye.

Further, the genuineness of the books of the Old and New Testaments may be evinced from the language, style, and manner of writing used in them. The Hebrew language, in which the Old Testament was written, being the language of an ancient people, who had little intercourse with their neighbours, would not change so fast as modern languages have.
have done, since different nations have been variously blended with one another by the extension of trade, arts, and sciences; and yet some changes must have occurred in the interval that elapsed between the time of Moses and that of Malachi. The Biblical Hebrew corresponds so exactly to this criterion, as to afford a considerabie argument in favour of the genuineness of the books of the Old Testament. Besides, these books have too great a diversity of style to be the work of either one Jew, or of any set of contemporary Jews. If they be forgeries, there must have been a facsimile of impo\(\text{i}o\)rs in different ages, who concurred in the same iniquitous design. Again, the Hebrew language ceased to be spoken, as a living language, soon after the time of the Babylonish captivity; and it would be difficult or impossible to forge anything in it, after it became a dead language. Hence it appears, that all the books of the Old Testament must be nearly as ancient as the Babylonish captivity; and as they could not all be written in the same age, none must be much more ancient, and this would reduce us to the necessity of supposing a facsimile of conspiring impo\(\text{i}o\)rs. Moreover, there is, as we have already observed, a simplicity of style, and an unaffected manner of writing, in all the books of the Old Testament, which is a strong evidence of their genuineness. The style of the New Testament, in particular, is not only simple and unaffected, but perfectly adapted to the time, places, and persons. To which we may add, that the narrations and precepts of both the Old and New Testament are delivered without hesitation; the writers teaching as having authority; and this circumstance is peculiar to those, who unite with a clear knowledge of what they deliver, a perfect integrity of heart.

Another argument for the genuineness and truth of the Scriptures, is supplied by the very great number of particular circumstances of time, place, persons, &c. mentioned in them. It is needless to recount these; but they are incompatible with forged and false accounts, which do not abound in such particularities, and the want of which furnishes a falipion to their discred. Compare, in this respect, Manetho's account of the dynasties of Egypt, Ctesias's of the Assyrian kings, and those which the technical chronologers have given of the ancient kingdoms of Greece, which are defective in such particulars, with Thucydides's history of the Peloponnesian war, and Cæsar's of the war in Gaul, in which they occur, and the difference will be sufficiently apparent. Dr. Pau\(\text{l}e\)y's admirable treatise, entitled "Horæ Pauline," affords very valuable illustrations of this argument as it respects the genuineness of the books of the New Testament.

The agreement of the Scriptures with history, natural and civil, is a farther proof of their genuineness and truth. The history of the fall agrees in an eminent manner both with the obvious facts of labour, sorrow, pain, and death, with what we see and feel every day, and with all our philosophical enquiries into the frame of the human mind, the nature of social life, and the origin of evil. Natural history bears a strong testimony to Moses's account of the deluge. Civil history affords many evidences, which corroborate the same account. (See DELUGE.) The Mosaic account of the confusion of languages, of the dispersion of Noah's sons, and of the fate of religion in the ancient polis\(\text{h}i\)an world, is not only rendered probable, but in a very high degree established, by many collateral arguments. See CONSPIRACIES OF LANGUAGE, DISPERSION OF MANKIND, IDOLATRY, SACRIFICE, &c.

The agreement of the books of the Old and New Testaments, with themselves and with each other, affords an argument both of their genuineness and truth. The laws of the Israelites are contained in the Pentateuch, and referred to, in a great variety of ways, direct and indirect, in the historical books, in the Psalms, and in the Prophecies. The historical facts also in the preceding books are often referred to in those that succeed, and in the Psalms and Prophecies. In like manner, the gospels have the greatest harmony with each other, and the epistles of St. Paul with the Acts of the Apostles; and, indeed, there is scarcely any book of either the Old or New Testament, which may not be referred to in many of the rest, in one way or other. For the illustration of this argument, let us suppose that no more remained of the Roman writers than Livy, Tully, and Horace, would they not by their references to the same facts and customs, by the likeness of style in the same writer, and difference in the different ages, and numberless other such like circumnstances of critical consideration, prove themselves, and one another to be genuine, and the principal facts related, or alluded to, to be true? Whenever we apply this reasoning to the present case will perceive, that the numberless minute, direct, and indirect agreements and coincidences, that present themselves to all diligent readers of the scriptures, prove their truth and genuineness beyond all contradiction. See ACTS, EPISTLES, AND TESTAMENT.

The harmony and agreement of the several writers of the Old and New Testament appear the more remarkable, when it is considered that their various parts were penned by several hands in very different conditions of life, from the throne and sceptre down to the lowest degree, and in very distant ages, through a long interval of time; which would naturally have led a spirit of impatience to have varied its schemes, and to have adapted them to different situations in the world, and to the different vicissitudes of every age. David wrote about 400 years after Moses, and Isaiah about 250 after David, and Matthew more than 700 years after Isaiah. And yet these authors, with all the other prophets and apostles, write in perfect harmony, confirming the authority of their predecessors, labouring to reduce the people to the observance of their instructions, and loudly exclamming against the neglect and contempt of them, and denouncing the severest judgments against such as continued disobedient. Consequently, as the writers of the Holy Scriptures, though they all claim a divine authority, yet write in perfect connection and harmony, mutually confirming the doctrine and testimony of each other, and concouring to establish the very same religious truths and principles, it is a strong proof that they all derived their instructions from the same fountain, the wisdom of God, and were indeed under the direction and illumination of the same spirit. This leads us to add, that the unity of design, which appears in the different recorded in the Scriptures, is an argument not only of their truth and genuineness, but also of their divine authority. In order to perceive the force of this argument, it is only necessary to inquire what this design is, and how it is purveyed by the series of events and divine interpositions, recorded in the Scriptures. (See DISPENSATION.) We may further add, that divine communications, miracles, and prophecies, recorded in Scripture, are agreeable to natural religion, and even seem to be necessary in the infancy of the world. (See MIRACLE, PROPHECY, AND REVELATION.) It should also be considered, that the historical evidences in favour of the genuineness, truth, and divine authority of the Scriptures, do not become ifs from age to age; but, on the contrary, it may rather be presumed, that they increase. Since the three great concursing events of printing, the reformation of religion in these western parts, and the restoration of letters, so many more evidences and coincidences have been discovered in favour of the Jewish and Christian histories, as may serve, in some measure, to supply the want of those
those that have been lost in the preceding times; and as this
improvement of the historical evidences is likely to continue,
there is great reason to hope, that they will grow every day
more and more incurable to all critical, serious inquirers.

The moral characters of Christ, the prophets, and the
apostles, prove the truth and divine authority of the Scrip-
tures.

The characters of the persons who are said in the
Scriptures to have had divine communications, and a divine
illumination, are so much superior to the characters that occur in
common life, that we can scarcely account for the more emi-
nent single ones, and much less for so large a succession of
them, continued through so many ages, without allowing the
divine communications and affiance, which they allege.

Notwithstanding considerable imperfections that pertained to
many of these eminent persons, and the human occasional
offences chargeable upon some of them, yet the impartial
reader should consider, whether the prophets, apostles, &c.,
were not so much inferior, not only to mankind at an average,
but even to the best men among the Greeks and Romans, as
is not fairly to be accounted for by the mere powers of hu-
man nature.
If this statement should be disputed, their charac-
ters, however, are too good to allow the supposition of an
impious fraud and falsehood, which must have been the case
if they had not divine authority. Besides, it should be re-
collected, that the undisguised and impartial manner in which
the imperfections and faults of the eminent persons mentioned
in Scripture are related, furnishes a remarkable additional evi-
dence for the truth of such parts of the Scripture history in
which such relations occur, besides such evidences as extend
to the whole.

The excellence of the doctrine contained in the Scriptures
is an additional evidence of their authority. This argument
has great force independently of all other considerations.
Suppose, for instance, that the author of the gospel, which
goes under the name of St. Matthew, was not known, and
that it was unsupported by the writers of the primitive times;
yet such are the unaffected simplicity of the narratives, the
purity of the doctrine, and the sincere piety and goodness of
the sentiments, that it carries its own authority with it.
The same observation is applicable in general to all the books
of the Old and New Testament, so that if there was no
other book in the world besides the Bible, a man could not
reasonably doubt of the truth of revealed religion. If all
other arguments were set aside, we may conclude from this
first consideration, that the authors of the books of the
Old and New Testament, whoever they were, cannot have
made a false claim to divine authority. The Scriptures con-
tain doctrines concerning God, Providence, a future state, the
duty of man, &c., far more pure and sublime than can in any
way be accounted for from the natural powers of men, so
circumstantial as the sacred writers were. Let the reader
consider whether it can be reasonably supposed, that Jewish
shepherds, fishermen, &c., should, both before and after the
rise of the heathen philosophy, so far exceed men of the
greatest abilities and accomplishments in other nations, by
any other means than divine communications. Indeed, no
writers, from the invention of letters to the present times,
are equal to the penmen of the books of the Old and New
Testaments in true excellence, utility, and dignity; and this
is surely such an internal criterion of their divine authority,
as ought not to be ridiculed.

The many and great advantages which have accrued to
the world from the Patriarchal, Judaical, and Christian re-
velations, prove the divine authority of the Scriptures. These
advantages relate partly to the knowledge, and partly to the
practice of religion. The internal worth and excellence of
the Scriptures, as containing the best principles of know-
ledge, holiness, consolation and hope, and their consequent
utility and importance in a moral and practical view, fully
and directly demonstrate their divine original. The wonder-
ful nature, and superior excellence, of the attempt made by
Christ and his apostles, for reforming mankind, and making
them happy in a future state, are evidences of their divine
authority; which is farther illustrated and confirmed by the
manner in which the love of God and of our neighbour is
taught and manifested in the Scriptures. This may also be
inferred from the doctrine of the necessary subordination of
pain to pleasure, and from the mutual influence of be-
ings to the happiness and misery of each other, unfolded in
the Scriptures. The divine authority of the Scriptures may
be farther deduced from the superior wisdom of the Jewish
law, considered in a political light, and from the exquisite
workmanship manifested in the tabernacle and the temple.

The time and manner in which the Scriptures were written
and delivered to the world, furnish arguments for their
divine authority; nor is the want of universality in the pub-
lication of revealed religion any just objection to it. The
exclusion of all great degrees of enthusiasm and imposture
from the characters of Christ, the prophets, and apostles,
prove their divine authority; and it may be also inferred,
from the reception which Christ, his forerunners and fol-
lowers, with their doctrines, have met with in all ages.
See these arguments stated, illustrated, and applied at large
in Hartley's Observations on man, p. 350—421. See also
on the subject of this article. Prideaux's Conn. vol. ii. 475—
497, 8to. Dupin's Hist. of the Canon, ch. i. and ii.
Kennicott's State of the printed Hebrew text of the Old Testa-
ment, diff. p. 295, 8to. &c. and Dissertatio Generalis, annexed
to the second volume of his Hebrew Bible. Taylor's Scheme
of Scripture Divinity, ch. 39. ch. 40.

The Jews, at first, were very reflex in communicating
their Scriptures to strangers; defiling and dimming the Gen-
tiles, they would not dispense to them any of the treasures
concealed in the Bible. We may add, that the people bor-
dering on the Jews, as the Egyptians, Phœnicians, Arabs,
&c., were not very curious to know the laws or history of
a people, whom in their turn they hated and defiled.

Their first acquaintance with these books was not till after
the several captivities of the Jews, when the singularity of
the Hebrew laws and ceremonies induced several to define
a more particular knowledge of them. Josphus (Conr.
Apion. p. 1033.) seems surprized to find such faithful footstuds
of the Scripture history interpersed in the Egyptian, Chal-
dean, Phœnician, and Grecian histories; and accounts for it
from this circumstance, that the sacred books were not as yet
translated into Greek, or other languages, and consequently
not known to the writers of those nations. The first version
of the Bible was that of the LXX into Greek, in the time of
Ptolemy Philadephus, about 280 years before Christ;
though some maintain that the whole was not then trans-
lated, but only the Pentateuch; between which and the
other books in the version of the LXX, critics find a great
diversity in point of style and expression, as well as of accu-

caly. See Scripture.

Various kinds of books have been composed on the Bible,
either to explain the fentre, or make its doctrine more obvious,
to facilitate the remembrance of it, or to establish particular
opinions from it; such as Introductions, Apparatuses, Sum-
maries, Manuals, Histories, Expositions, Commentaries,
Harmonies, &c.

Bibles are distinguished, according to their language, into
Hebrew, Greek, Latin, Chaldee, Syrac, Arabic, Coptic,
&c.; some account of each, and their several editions, &c., we
shall here subjoin.
BIBLE, Hebrew, are either manuscript or printed. The
both manuscripts Bibles are those copied by the Jews of
Spain. Tho' copied by the Jews of Germany are also
exceed, but more common. The two kinds are easily distin-
guished from each other; the former being in beautiful
characters, like the Hebrew Bibles of Bomberg, Stephens,
and Plantin; the latter in characters, like those of Munster
and Guemphus. F. Simon observes, that the oldest manu-
script Hebrew Bibles are not above six or seven hundred
years old; nor does rabbi Menahem, who quotes a vast
number of them, pretend that any of them exceed six hundred
years.

Dr. Kennicott, in his Dissertatio Generalis, annexed to his
Hebrew Bible, p. 21, observes, that the most ancient MSS.
were written between the years 900 and 1100; but though
those are the most ancient are not more than 800 or 900
years old, they were transferred from others of a much more
ancient date. The MS. preferred in the Bodleian library is
not less than 800 years old. Another MS. not less ancient, is
preferred in the Cufsehen library at Vienna. The same
learned writer informs us, that almost all the Hebrew
MSS. of the Old Testament, which are known at present,
were written between the years 1000 and 1157; and hence
he infers, that all the MSS. written before the years 700 or
800, were destroyed by some decree of the Jewish senate, on
account of their many differences from the copies then
declared genuine. This circumstance is also alleged by Walton
(Prolegomena, 4. 6), as the reason why we have so few
copies of the age of 600 years, and why even the copies of
700 or 800 years are very rare.

The Hebrew distinctions and denominations of the various
parts of the Hebrew Bible, as they occur in the titles of the
ancient MSS. will be easily understood by the following
table of distribution.

PENTATEUCH,

Prior

Dr. Kennicott, by the industry of his research, has formed
a catalogue of the titles and places of above 400 different
MSS. of the whole, or of parts of the Hebrew Bible: a
number about three times as great as that of the Greek MSS.
of the New Testament, which have been collected at a vast
expense, and collated with a truly laudable zeal. (See TEST
AMENT.) Of these MSS. 54 are preferred in the
Bodleian library at Oxford, and 13 in different colleges of
the University; 9 are repolished in the public library at Cam-
bridge, and 3 in different colleges; 27 are found in the
British Museum; one in the Lambeth library; and one
in the library of the Royal Society. The preceding
MSS., with 7 copies of the Samaritan Pentateuch, amount
to 110 copies, making 125 volumes. Other MS. copies are
preferred at Alcala, and Complutum in Spain, Altorf
in Swabia, Amsterdam, Anhalt-Delfau, Augsburg, Baden,
Vol. IV.
use for this edition. At the same time that this edition of
the Hebrew Bible was preparing at Venice, another edition
of equal fame was preparing by cardinal Ximenes, at Com-
putium in Spain; and as these two capital editions were
thus in the press at once, neither of them could be printed
from the other. But as they were both printed by men
who either were, or had been Jews, (see Wolfin, tom. ii.
p. 339.) from such MSS. as were uniformly corrected by
the fame Mafora, they would exhibit almost universally the
same text. And that the Hebrew MSS. here used, had
suffered this Maforatical execution, is plain from the words
of Ximenes in his dedication to pope Leo. This famous
Bible was begun in 1502, and finished in 1507, but not
published till 1522, and not for several years, first by Michaels,
(Lect. New Tnt. vol. ii.) till 1524. In 1526 or 1528, the
fame Bomberg printed the folio Bible of the celebrated
Rabbi Jacob Ben Chaim, with his preface, the Maforatical
divisions, a preface of Aben Ezra, a double Mafora, and
several various readings. No one who duly considers the
preface of this editor (printed by Kennicott, Diff. vol. ii.
p. 229.) can possibly doubt his having published it, according
to the copies most exactly corrected by that Mafora, which
he profoundly revered. In 1549, was published the
second edition of B. Chaim’s Bible, with the famous pre-
face at the beginning; and of this edition Le Long says,
“praed tintiffima efft et omnium optima, jueta qua praefir-
ti tempus proderunt.” Wolfin gives it precisely the same
character; but adds, that Conrado Zeitner blames B. Chaim for being so excessively devoted to the Mafora.
In 1572, was published the Royal, or Spanish Polyglott, in
8 volumes, printed at Antwerp; principally under the di-
rection of Arius Montanus. It is not pretended, that the
leaf correction was made in this edition of the Hebrew text; (nor could it be expected of one editor who believed the per-
fecition of the Hebrew text.) The third edition of B. Chaim’s
Bible was printed in 1618; it is the fame with the second, but
much more correct. From the former editions it was, that
Buxtorf, the father, printed his rabbinical Hebrew Bible at
Bâbil, in 1619; which, though there are many faults in it,
is more correct than any of the former. This was the fifth
edition of B. Chaim’s Bible, in which the Hebrew text was
copied exactly from B. Chaim’s second edition. In 1534,
Sebastian Munster published a Hebrew and Latin Bible, in
2 vols. fol. at Bâbil, with the commentaries of the Rabbins,
and some notes; and Elias Hutter printed a Hebrew Bible
in large letters, at Hamburgh, in 1587, fol. Robert Ste-
phen’s Hebrew Bible, with the Greek version from the
Complutenian edition, the Latin vulgate, and another new
Latin version, commonly called Vatablus’s Bible, was printed
in 1545. In 1623, appeared at Venice a new edition of the
rabbinical Bible, by Leo of Modena, a rabbin of that city,
who pretended to have corrected a great number of faults
in the former edition; but, besides that it is much inferior
to the other Hebrew Bibles of Venice with regard to paper
and print, it has passed through the hands of the inquiritors,
who have altered many passages in the commentaries of the
rabbins. The rabbinical Bible of Bomberg and Buxtorf has
been superceded by that of rabbi Mofes, published at Amster-
dam in 4 volumes folio, in 1724—1727. In 1641, was pub-
lished, in 10 folio volumes, the Paris Polyglott, which, though
it claims no merit from correcting the Hebrew text, will
ever be honored by men of true learning, for containing
(besides the Syriac and Arabic versions) the first edition of
the Samaritan pentateuch and its version, printed from
MSS. brought into Europe between the years 1620 and
1630, and published by the learned Morius, to whom the
world is also indebted for many excellent remarks on the
Hebrew text, as well as on the Samaritan pentateuch. In
1657, was published the London Polyglott, under the direc-
tion of the eminently learned Brian Walton, in which, how-
ever, the Hebrew text is printed Maforetically; almost in
an absolute agreement with the many former editions, and
with the latest and work MSS. Although the editor has
thrown clearly, that the Jewish transcribers have made many
mistakes, and that the MSS. have many true readings, where
the printed text is erroneous; and though he speaks (Pro-
leg. 4, 12.) of having supplied some things which were not
in the Venice or Bâbil editions, yet the only supplement which
he has made is restoring the two verses in Johina, which had
been arbitrarily expelled by Maforetical authority. See Poly-
glott.

As to Hebrew Bibles in 4to. that of R. Stephens, in 4
vols. Paris, 1539—1544, is esteemed for the beauty of the
characters; but it is very incorrect. Plantin also printed
several beautiful Hebrew Bibles at Antwerp; one in eight
volumes, with a preface by Arius Montanus, in 1571, which
far exceeds the Complutenian in paper and print, and con-
tents; this is called the Royal Bible, Biblia Regia, because
it was printed at the expense of Philip II. of Spain; an-
other at Geneva, in 1619; besides many more of different
sizes, with and without points. Manaffeh Ben Israel,
a learned Portuguese Jew, published two editions of the
Hebrew Bible at Amsterdam; the one in 4to. in 1635, who
tells us in the preface, that he had altered a few letters; and
where the most corrected copies differed, he took refuge in
grammar rules and the Mafora; the other in 8vo. in 1639:
the first has two columns, and for that reason is commodi-
fous for the reader. It is printed with points, in an elegant
trpe, and has the Keri and Chetib in the margin. The
8vo. edition has vowel points and accents, and the marginal
notes. In 1639, R. Jac. Lomandro published a new edition
in 4to. at Venice, with small literal notes at the bottom of
each page, where he explains the Hebrew words by Spanish
words. This Bible is much esteemed by the Jews at Con-
stantinople: in the text they have distinguished between
words where the point kamats is to be read with a kamets-
katuphas, that is, by ә, and not an a.

Of all the editions of the Hebrew Bible in 8vo. the most
beautiful and correct are the two of Jo. Athias, a Jew of
Amsterdam. The first, of 1661, is the best paper, which,
notwithstanding its being corrected according to ancient
MSS. is certainly (so far as letters and words are concerned)
agreeable only to the last, as the other printed copies were
before it; but that of 1667, is the most exact. This
was published by Leufden, who tells the reader, “Tihi damus
Biblia, impreca per Athiam, quibus correctiora nunquam
fol aspexit.” And yet, though the fun never faw fo much
implicit obedience paid to the Mafora before the, the Rabbins
affire us, in their prefatory recommendation, that some
whole words were here corrected ex Mafora & a Mafor-
tica, in dupem legem frerent.” This supreme Maforeti-
cal edition appeared to their high mightiness the States-
general, fo particularly meritorious, that Athias, the typog-
rapher, was presented with a chain of gold, and a gold meda-
1l pendant. But it is somewhat extraordinary, that a Jew
should thus be rewarded for an edition, in which Leufden
(though a Chriftian) confesses, that he permitted the Latin
contents, here added in the margin, to explain away some
of the prophecyes relating to the Mefiah. Le Long, in loc.
Leufden’s laft edition of Athias, was followed in 1705,
by Vander Hooght’s very elegant edition. No corrections
can be expected from this editor, who considered every
letter in his book, howsoever it was introduced, as abolutely
genuine, and maintained the Mafora to be infallible.

After
After Athias, three Hebraizing protestants engaged in revising and publishing the Hebrew Bible; viz. Clodius, Jablonfski, and Opitius.—Clodius’s edition was published at Frankfort in 1677, in 4to. At the bottom of the page it has the various readings of the former editions; but the author does not appear sufficiently versed in the accenting, especially in the poetical books; besides, it was not published under his eye, many faults have crept in. That of Daniel Ernst Jablonfski in 1699, in 4to. at Berlin, is very beautiful as to letter and print: but, though the editor pretends he made use of the editions of Athias and Clodius, some critics find it scarcely in any thing different from the 4to. edition of Bomberg. For this man of eminent learning it was referred to lay the foundation for a reformation of the printed Hebrew text. This he has done in the preface, by making several excellent observations on the nature of the present Hebrew MSS. with the proper marks of their antiquity, and the great advancement of the Hebrew language from them.

He has satisfactorily shown, that the Jewish transcribers have committed many mistakes; that the Keri is various readings arising from the mistakes of transcribers; that the older MSS. have them in the text, but the later in the margin; and consequently, that the Masora, which considers the Keri as in the margin, must be founded on the later copies; that one of the Hebrew MSS. at Berlin contains some thousands of various readings, and that the other old Hebrew MSS. have numerous differences from the printed text; and that these old MSS. have suffered many alterations from the late correcting Masorets. He also states the possibility of procuring, by due zeal and exertion, very ancient MSS. from such of the Jews as have been settled for many ages in China, Ethiopia, Constantinople, Thelidanon, and other distant parts of the world. Jablonfski is the first author, who, after announcing the actual existence of many various readings in the Hebrew MSS., has recommended both an accurate examination of these MSS. now known, and a diligent search after others, at present unknown, through the several quarters of the world. To him, therefore, belongs the honour of having planned the noble scheme for correcting the many corruptions of the printed Hebrew text of the Old Testament; and yet not daring to practice what he recommends, he republished the Hebrew text almost the same as it was adjusted masoretically in Leufden’s edition of 1667. His corrections have been confined almost entirely to the vowel-points and accents. The edition of Opitius was published in 4to. at Kell, in 1709; the character is large and good, but the paper bad: it is done with a great deal of care; but the editor made use of no manuscripts but those of the German libraries; neglecting the French ones, which is an omission common to all three. Opitius copied from Leufden’s Athias, though, he says, he collated several MSS. in Berlin, and other places; but he idolized the Masora, and held all readings inconsistent with it, however recommended by any MSS., in sovereign contempt. Hence it follows, that if this edition was conformable to the late MSS., as regulated by the Masora, the fame Masoretic influence must have regulated the very early copy, printed at Brefcia, in 1494; because that edition is recommended by Opitius. Wolf. Bib. Heb. ii. p. 375. The three last mentioned editions have this advantage, however, that besides the divisions used by the Jews, both general and particular, into parables and psalms, they have also those of the Chaldaeans, or of the Latin Bibles, into chapters and verses; the keri kethib, or various readings, Latin summaries, &c. which made them of considerable use with respect to the Latin editions, and the concordances. See Chapters.

The little Bible of R. Stephens, in 1602, is very much prized for the beauty of the character. It was printed in 7 vols. at Paris, in 1544—1546. Care, however, must be taken; there being another edition of Geneva, exceedingly like it excepting that the print is worse, and the text left correct. To these may be added some other Hebrew Bibles, without points, in 8vo. and 24to. which are much coveted by the Jews; not that they are more exact, but more portable than the rest; and are used in their synagogues and schools; of these there are two beautiful editions, the one of Plantin, in 8vo. with two columns, and the other in 24to. reprinted by Raphalengius at Leyden, in 1610. There is also an edition of them by Laurens at Amsterdam, in 1631, in a larger character; and another in 12mo. at Frankfort, in 1604, full of faults, with a preface of M. Leufden at the head of it.

In 1720, an Hebrew Bible was published at Hall, by the learned professor John Henry Michaelis; being the first edition, which contained any various readings, collected from Hebrew MSS. by a Christian editor. The text is taken from Jablonfski’s edition, with some few emendations. There were collated for this Bible most of the printed editions, and also five Hebrew MSS. belonging to the library at Erfurt. The propriety of selecting various readings from Hebrew MSS. and ancient versions, is set forth in the preface; and the editor has inferred here and there some variations of words and letters; but the variations, chiefly noted, relate to the minutiae of criticism, confuting only in points and accents.

Charles Francis Houbigant, one of the subiects of the oratory at Paris, published an elegant edition of the Hebrew Bible at Paris, in 1753, contained in four volumes, folio. The text is that of Vander Hoocht, without points, to which he has added marginal notes, correcting that text by the Samaritan pentateuch, Hebrew MSS. and ancient versions; and also a new Latin version, made by himself, expressive of such a text as his critical emendations appeared to justify and recommend. This celebrated edition, (says Dr. Kennicott, than whom there could not be a more competent judge) seems to proceed upon so just a plan, as to its main principles, and to be executed (in the general) with so much skill and judgment, as to claim for its worthy author the applause of all the friends of religion and learning. He expresses, however, a wish, that the author had spared some of his bolder criticisms, when they are unsupported by MSS., or ancient versions; especially, where the proposed emendations are not clearly and strongly recommended by the context. Some learned men have wished, that, instead of inferring only a few select various readings from the Hebrew MSS., all the various readings had been noted by the author after each chapter. But the labour of such a work would have been immense; and we have great reason to be satisfied with what the learned and industrious editor has actually done. It has, indeed, been objected by Dr. Hodges, in his preface to the work entitled "The Christian Plan," that Houbigant intended to alter the Hebrew text; to make it conformable to the Vulgate; whereas, it was the editor’s professed intention to set aside the Vulgate, as being faulty, and not answering his purpose, and to publish a new Latin version of his own. T. Houbigant obtained from the pope two gold medals, in testimony of his approbation of this edition.

Dr. Kennicott, after almost twenty years’ laborious collation of 694 copies, manuscript and printed, of which about 630 are MSS. either of the whole, or of particular parts of the Bible, and nine years more spent in examining the Hebrew MSS., and recommending a collation of them, published, in 1776, the first volume of his Hebrew Bible, in folio;
entitled "Vetus Testamentum Hebraicum, cum variis Lectionibus." The second volume, with the general dissertation, was published in 1780. The text is that of Everard Van der Hoogh, in 1705, already mentioned, which is very correctly printed, with the similar Hebrew letters, remarkably sharp and well defined; differing from it only in the disposition of the poetical parts, which Dr. Kennicott has printed in hieroforms, into which they naturally divide themselves; however, the words follow one another in the same order as they do in the edition of Van der Hoogh; so that any person may read these passages as prose, if he is so inclined; or may divide the hieroforms differently, according to his own judgment. This edition is printed on an excellent type; the Samaritan text, according to the copy in the London Polyglott, is exhibited in a column parallel with the Hebrew text; those parts of it only being introduced, in which it differs from the Hebrew; and the rest of the Samaritan column being left blank, so that the eye perceives at once, with the utmost ease, the variations of the Hebrew and Samaritan texts. The numerous variations, both of the Samaritan manuscripts from the printed copy of the Samaritan text, and of the Hebrew manuscripts from the printed text of Van der Hoogh, are placed separately at the bottom of the page, and marked with numbers referring to the copies from which they are taken.

We shall subjoin to this article a brief account of the life and proffes of that highly interesting and meritorious undertaking, for the completion of which we are indebted to the indefatigable industry and perseverance of the late Dr. Kennicott. A very general opinion seemed to have prevailed among learned men, till about the middle of the last century, in favour of the integrity of the Hebrew text: and Dr. Kennicott ingeniously confees, that he was misled by the common error. The Rabbins boldly afferted, and the Chriftians implicitly believed, that the Hebrew text was free from error, and that in all the MSS. of it, no infall of any various reading of importance could be produced. The hint persons, who seems to have combatted this notion in the way of a regular attack, was Ludovicus Capellus. From the differences he observed between the Hebrew text and the version of the LXX, and between the Hebrew Pentateuch and the Samaritan pentateuch, from the palpable and manifest corruptions, which he thought he saw in the text itself, and from the many reasons which induced him to suppose that the vowel points and the Mafaora were both a modern and an unfafs invention, he was led to question the general integrity of the text; and his enemies allowed, that in his attack upon it, he discovered much learning and ingenuity. Still, however, he acquifed and admitted the uniformity of the MSS. But the matter was not brought to the test of an actual collation of any number of MSS. and versions, and little was done, till Dr. Kennicott's attention was directed in 1748, by the late learned Dr. Lowth, bishop of London, to an examination of 2 Sam. xxiii. 8. This circumstance convinced him of his former error, and he was soon satisfied that the Hebrew text was far from being perfect, and that it was impossible to understand this finge verfe, without allowing that there were in it four divisions. Kennicott's explanation of this verse having been approved by Dr. Lowth, he was requested to examine the fubfleuent parts of the fame chapter; which was likewise performed, and the whole was published in 1753. He proceeded to examine two parallel chapters in the first book of Chronicles, and the second book of Samuel, and found an omission in the former of no less than 33 Hebrew words. Although such great corruptions were proved from the printed text itself, and from the ancient versions, yet it had not at that time been suspected, that there were now extant any Hebrew MSS. which would at all afift in correcting the faulty passages of the Old Testament. In the sequel, however, this was found to be actually the case, for Dr. Kennicott, on examining some of the Hebrew MSS. in the Bodleian library, found that they contained, in the chapters above cited, several of the readings which he had recommended as genuine, before he had inspected their MSS. A discovery so important to sacred literature being thus begun in 1753, and extended to 50 Hebrew and Samaritan MSS. in Oxford, it was soon much improved by consulting a number of other at Cambridge and in London. The inquiry was promoted by means of a catalogue of all the other Hebrew and Samaritan MSS. which were then known to exist in different parts of the world, published by Dr. Kennicott in 1760, in a second dissertation on the Hebrew text. In this work he endeavored to produce a general conviction, as to the certainty of the Hebrew printed copies being much corrupted, and the great advantage that might be derived from MSS., by furnishing many various readings of consequence, which are the true ones; and by confirming the ancient version in a multitude of instances of little moment in themselves, and therefore not likely to have originated from design. It was also proved, that the Samaritan Pentateuch was of great importance; that its MSS. would serve to correct a variety of typographical errors, which disfigured the two printed editions; and that the Samaritan copies were frequently confirmed even by the Hebrew MSS.

In consequence of these interesting discoveries, Dr. Ken- nicott was solicited by the late archbishop Secker, and many other learned persons, and by several societies of literary men, particularly by the university of Oxford, to whole counte- nance and encouragement the undertaking was recommended by the late Dr. Hunt, professor of Hebrew and Arabic in that university, to undertake a collation of all the Hebrew and Samaritan MSS. in our own country. Discouraged at first by the prospect of so arduous an undertaking, he at last, in 1760, consented to engage in it. Of his progress, and the circumstances that attended it, we have a detailed account in the "Dissertatio Generalis," published with the second volume of his Bible. Having proposed ten years as the time which, he thought, would be necessary for collating the Hebrew and Samaritan MSS., he was enabled by his singular affability to fulfill his own expectations and those of the public. Patronized by his Majesty, and by a great number of liberal friends and well-wishers to the undertaking, both at home and in foreign countries, in the list of whom are no fewer than seven crowned heads, several princes, cardinals, archbishops, and bishops, besides universities, public libraries, and many of the most eminent literary in various parts of Europe; Dr. Kennicott instituted various and extensive inquiries after MSS. at Conflantinople, Warsaw, Venice, Bologna, Mantua, Pavia, Genoa, Liffen, Geneva, Utrecht, Erfurt, Berlin, Stockholm, and Hamburg. The numerous Hebrew MSS. of the latter place were collated by the cele- brated Reimarus, who not only concurred in, but applaudet the undertaking. In the prosecution of this work, it was found that the printed editions of the Hebrew Bible, which had been suppos'd to agree, and on the agreement of which the notion of the integrity of that text had been founded, very much differed from one another; and particularly, that the old editions agreed most with the oldest and best MSS., and the modern editions with the latest and worst MSS. As one proof of this, it is alleged, that the variations in the first edition (1488) from Vander Hoogh (in 1705) amount to twelve thousand. In the year 1767, Dr. Ken- nicott derived great advantage from his own examination of the Paris MSS., both Hebrew and Samaritan, and from Dr.
Dr. Gill's collection of all the passages quoted in the Talmud. An Hebrew MS., which once belonged to a synagogue at Jerusalem, was at this time purchased by his Britannic majesty; and our author himself, hoping to obtain other treasures from the East, sent to Canton, and had nearly succeeded in procuring a MS. from the Jews at Cali-long-fu, in the province of Honan. But though he failed in China, he succeeded in America, and procured a complete Hebrew MS. from a Jew at New York. During the tenth and last year of this collection, eight Danish MSS. were sent to Oxford for the author's own examination, as were also six others from Toledo, by Dr. Bayer. Collations of other MSS. were furnished, at the same time, from Sileia, Cologne, Stralsburg, Konigsburgh, Upsai, Leyden, and Ireland. The indefatigable author, having thus collected materials for his noble undertaking, an undertaking so lefs honourable to his country than to himself, proceeded to diget the variations, with which he was furnished, under their several books, chapters, and verses. During this operation, he formed a plan for a more complete feruency of the butt MSS., through Europe, by sending some well-qualified person to re-examine the MSS. already collated, and to examine the rest in passages of greater moment, and where success seemed at all doubtful, Mr. (afterwards Dr.) Bruns, a learned German, was selected for this embasy; and he was honoured with letters from the secretaries of state here, to all our foreign ambassadors, as well as from the rulers of the two synagogues in London. The places in which he thus examined MSS., during a tour of three years, were Paris, Louvain, Cologne, Mentz, Worms, Manheim, Nuremberg, Augsburg, Stuttgart, Carlsruhe, Stralsburg, Bafie, Zutic, Berne, Geneva, Turin, Caffa, Veruli, Milan, Genoa, Leoghum, Sicma, Rome, Florence, Bologna, Cefena, Modena, Reggio, Parma, Mantua, Padua, Venice, Udine, Gorizia, Gradicina, Trieste, Vienna, Drefden, Leipzic, Erfurt, Lena, Delfau, Berlin, Hamburg, Helmbadt, Caffel, Amsterdam, Utrecht, Leyden, and the Hague.

The variations contained in nearly 700 bundles of papers, being at last digested, including the collections made by Dr. Bruns; and the whole, when put together, being corrected by the original collations, and these again translated into 50 folio volumes, the work was put to the press in 1773; and both volumes (as we have already said), with the general dissertation, were issued in July 1780.

In order to have the necessity as well as the utility of this work, Dr. Kennicott has presented us with a surprizing detail of testimonies, which exhibit the opinions both of the Jews and Christiania, as to the Hebrew text, from the earliest times down to the present. The Jewish testimonies are arranged under five distinct periods, viz. from the time of Malachi, about 420 years before the birth of Christ, to the commencement of the Christian era; from Christ to the year 500 after Christ; from the year 500 after Christ to the year 1000; from this year to the invention of printing, about 1450; and from the invention of printing to the year 1780. The first Jewish testimonies are those of Jofephus and Philo, who speak of the Greek version as perfectly agreeing with the Hebrew text in their time; whereas Dr. Kennicott afferts the corruption of the Hebrew text before the time of these Jews, and also the very great importance of the Greek version. For the Pentateuch of this version being made about 180 years before Christ, and the other books being also translated into Greek about 100 years before Christ (as is inferred from the prologue to Ecclesiasth in this version), we must have had many true readings, where the Hebrew was afterwards corrupted. Although in Pf. xvi. 10, the word for "thy holy one," which is now plural in the text of every copy expressed maforetically, yet in the Greek version it is singular, which is the case in no less than 180 copies, agreeably to the quotations of St. Peter and St. Paul. And because the argument of these apostles urged upon the Jews, in the effect of this corruption, depends on this word's being truly singular, Dr. Kennicott considers this various reading as of greater moment than any other which was ever drawn forth from MSS. He observes, that as the Greek version thus helps to prove the Hebrew text corrupted when it differs from it, so where the Hebrew text is corrupted, and that version agrees, it proves the corruption to be older than the version, unless the version has since been affiliated to the Hebrew. Such very early corruptions occur, as he conceives, in Deut. x. 6. Gen. xi. 32. and Gen. xxxvi. 31—43. The third influence contains 13 verses, which, being written by Moses, were probably inserted from Chronicles, i. 43—54, in some MS. of Genesis, into the margin, and thence taken into the text. This interpolation is found as to be found in all the versions, and likewise in the Samaritan text. In the first instance, many words are omitted in the Hebrew text, and in all the versions, which are preferred only in the Samaritan text. In the second instance, the number 145 is corrupted into 205 in the Hebrew text, and in all the versions, and it is right only in the Samaritan text. Dr. Kennicott afterwards specifies two great corruptions: one, where the Greek version has been affiliated to the Hebrew, by addition; and another, in which the Syriac version has been thus accommodated, by change. The first relates to 20 verses, probably interpolated in 1 Sam. xviii.; and the second, to the word for body altered to the word for ears, in Psalm xvii. 3; on which word, body, the argument is grounded, in the 15th chapter of the epistle to the Hebrews: and a very old Syriac MS. in the royal library of Paris, translated from the Hebrew, has preferred the true word for body; and another has proved, that the Jews have altered their ancient copies, wilfully, from the Hebrew text and Greek version of Isaiah, xix. 18, respecting the temple at Helipolis; and also from their turning Moses into Manafis, in Judges xviii. 30. Many other influences occur in the period now under consideration.

In the interval between the birth of our Saviour and the year 500, Dr. Kennicott remarks, that though the present Mafora separates our tenth commandment into two, agreeing to the division now made by the Roman Catholics; yet the muty of this commandment, as made by Protestants, is expressly confirmed by Philo and Josephus; and the Maforet mark of separation (at Exodus xx. 17.) is absent from at least 234 Hebrew copies. Josephus is farther cited, as confirming the ancient chronology in the Greek version against that now in the Hebrew text; and likewise, as having a number much more credible as to the gold and silver left by David. The fame historian also confirms the reading in the epistle to the Hebrews, chap. vii. 4, from Genesis xiv. 20. He confirms, too, the Syriac version, and the edition of Sixtus, reading four in 2 Sam. xvii. 7., and the Vatican MS. reading four in 1 Sam. xvii. 4. And through the later Jews have taken Daniel out of their prophetical books, yet Josephus calls him a prophet, in the strongest terms. It appears further under this period, that the Hebrew MSS. differed at the time of the composition of the Talmud; and that some of the true readings may still be found in this work. This is confirmed by several instances, and particularly by Psalm xxi.

Under the third period Dr. Kennicott considers the subject of the Keri, which fec. This period also includes a collection of 216 variations between the oriental and occidental MSS. Proofs of differences are likewise deduced from the old Jewish books,
books, Rabboth, Pirke Eliezer, and Cozri. Saadias, who flourished about the year 1000, is also referred to as having read differently from the printed text; and Hai, about the same period, is said to have followed those MSS., which were defective in Jellina, chap. xxi., where two whole verses, absolutely necessary, though expunged by the Maforra, have been found in 149 Hebrew MSS. at this time.

At the end of this period, Dr. Kennicott introduces the Arabic version, generally ascribed to R. Saadias, which has hitherto been reputed only secondary, as if it had been always taken from the Greek or the Syriac; whereas, it is honoured with the title of a primary version in several places; because it is found to agree with the Hebrew MSS, where both Greek and Syriac diverged from it. This Arabic version has some very important readings, particularly in preferring that word which expresses the cause of God's anger against Balaam, Numb. xxii. 22. It is also important where it is only secondary; because it helps to determine the true reading of the Greek version, where the Greek MSS. are now at variance; as in Psalm xvi. 14, lxvii. 9, Mechef v. 1, and Zechariah xii. 7.

To the close of this period, Dr. Kennicott refers the two oldest and best Hebrew MSS. now extant, one at Oxford, and the other at Vienna. Of the Bodleian MS., supposed to be 800 years old, he observes, that it contains about 15,000 variations. In the pentateuch of this MS. the Greek version is confirmed by 109 various readings; the Syriac, by 98; the Arabic, by 82; the Vulgate by 88; and the Chaldee paraphrase, by 42. It also agrees with the Samaritan version, against the Hebrew, in 750 instances. This, it is added, is the only one which has preferred a word of great importance for understanding, 2 Sam. xxiii. 3-7, in which word is confirmed by the Greek version, and recovers to us a prophecy of the Messiah.

The fourth period, from 1200 to 1450, is introduced with an observation, that the oldest Hebrew MS. which has a certain date (1166), though containing only 9120 verses, has above 6000 variations. The testimonies of Aben-Ezra, Jarchi, Maimonides, and Kimchi, who all flourished between 1150 and 1250, belong to this period. After taking notice of several true readings preferred by these four Rabbies, Dr. Kennicott introduces Mei Hallewi, who died in 1244, with his pathetic lamentation over the many variations in the Hebrew MSS.

Under the fifth and last period, from 1450 to 1780, including the printed Hebrew text, Dr. Kennicott takes particular notice of the five first editions of different parts, and of the first edition of the whole together. He adds, that the Paltms, as first printed in 1457, contain about 600 variations; and that the Hebrew Bible, as first printed in 1498, contains above 12,000. These, and some other very early editions, agree with the older MSS. much more than the editions after the year 1500, but full more than that by Jacob Ben Chaim, in 1526, which has been in general the standard down to the present time. About the year 1500, began the superflitious regard for the Maforra; and such MSS. as had been maforically corrected, were preferred for the editions of Cardinal Ximenes and Felix Pratensis. But the Maforra being highly venerated by Ben Chaim, he chose for his text such MSS. as had the Maforra most perfect; which MSS. were the latest and the worst: and yet, unfortunately, this text became the general standard for the Antwerp, Paris, and London Polyglotts, as well as for other editions of lefs note afterwards. The Jews have not, however, been satisfied with the correctness of Chaim's edition. For Rabbi Lonzano was afterwards encouraged to visit many countries, and to collate ten MSS. in order to render the text more perfect; and yet this complaint of errors was again renewed in 1537, by Manafth Ben-Israel. These testimonies are concluded with the Mantuan edition, called Minchat Shai, in which are about 2000 various readings, collected from MSS. and early editions, by Solomon Neorzi, in the last century; but it was not printed till 1714.

So that, at the time when Christians were generally inflicting on the perfection of the Hebrew text, the Jews were labouring to correct it, and lamenting its great imperfection in the following terms: "Quis refertluct decus? Quis ejicet raphanos et spinas? Horor confertit me: quum viderem multitudinem variuntium, quix occurrit in libros! Editores sunt obcurati, neque iix eis; neque oif quixut ceflacion hujus diversitatia! Ecce nos palmates tanquam cacci, in obfuscitate diversitatum! Deus auferat tenebras nostrar!"

On examining the testimonies of Christian writers with regard to the state of the Hebrew text, Dr. Kennicott begins with the Evangelists and Apollos; and here he adverts to the quotations made in the New Testament from the Old; on which subject, see Quotation. It appears, by unquestionable evidence, that the Old Testament has been corrupted, in many instances; and that a full correction of the Hebrew text, grounded on the authorities of Hebrew MSS., the Samaritan pentateuch, and the ancient versions, will, in many places, restore to the Old Testament that harmony with the New which it has long wanted. Instances occur in Gen. xvi. 24.: Phil. vii. xxxiv. 22., compared with John xix. 26, 27, and xl. compared with Hebrew xvi. 4: Amos iv. 2 compared with Acts xv.: Hahab vili. 14. lii. Psalm lxvii. 19. Hose. xi. 14. Amos v. 26. Deut. xxxi. 5 and 6: Habakkuk ii. 4. Many arguments are adduced by Dr. Kennicott to shew, that the Jews have corrupted the chronology, from the creation to Abraham, either by subtracting or by adding 1500 years; and this great corruption is not in the Greek version, but in the Hebrew text; and that it was introduced in the second century. As it was a very ancient tradition, that the Messiah was to come in the sixth chilid, because he was to come in "the last days," (found on a mystical application of the six days' creation), it was contrived to shorten the age of the world from about 5500 to 3760, and thence to prove that Jesus could not be the Messiah, because at the era of his birth the time for the advent of the Messiah was not yet come. The time of this great corruption is shewn to have between the years 175 and 200. The old Italic version, made from the Greek about the year 1000, is adduced to confirm some ancient readings of the Greek version, particularly as to the more extended chronology. Dr. Kennicott, after various pertinent quotations from Ignatius, Justin Martyr, and Irenæus, refers more particularly to Tertullian, with a view of proving that, in his time, the passage in Hahab liii. 4. expressed the sense ascribed to it in the 8th chapter of St. Matthew, where the Evangelist quotes it as foretelling, that "the Messiah should heal bodily diseases." The Hebrew words, it is shewn, admit this sense: Tertullian fo expresses them; and so did the old Greek version, which has been strangely altered in this place, out of opposition to the gospel. Origen is cited, as affording many interesting particulars, with regard to the differences in the Hebrew copies, and the true readings of the Greek versions; and Eunebius, Théophras Antiochenus, Ephraim Synus, Jerom, Epiphanius, Augustin, and Sulcius Severus, are quoted to the same purpose. The 1st period of the Christian writers terminates with the oldest MSS. of the Greek version, particularly the Vatican and Alexandrian MSS. written about the year 400, which see. Dr. Kennicott proceeds to the period that elapsed between the years 500 and 1000, and avails himself of
BIB

of the Syriac versions (see Syriac) for introducing some useful observations on several passages, particularly Psalm xi.
6, 7, 9, and 2 Kings viii. 16.; in which last passage three words are now interpolated in the Hebrew text, which, though they are also found in the Vatican and Alexandrian MSS., are not in the Complutian and Aldine editions; nor are they in an ancient MS. of Kings, nor in some of the best MSS. and earliest editions of the Vulgate. See Vulgate.

From the year 1000 to 1450, the testimonies of Christians are very few. Yet soon after the Jews fled from the East into Europe, in 1240, the Hebrew language was studied by several Christians, particularly by Lukanfric and Anfelm, Grothald and Robert Bacon; and this last learned man, with his Franciscan brethren at Oxford, bought many Hebrew MSS. when the Jews were expelled from England in 1289. In the 15th century, Raymond Martini accused the Jews of corrupting the Hebrew text; and he speaks of MSS. differing in Zech. xii. 10., with respect to which Dr. Kennicott observes, that forty copies have here the reading expreseed in John xix. 37. Dr. Kennicott also cites Nic. Lyra, Radulphus Armachamus, Tolstus, Perez de Valensi, and Marullus Vicinus.

Under the last period, from 1450 to 1780, Zeuhlins takes the lead; and he extols the Greek version, and remarks the corrupt addition of Jer. chap. iii. Luther is also mentioned; and Bibilander is celebrated on account of his excellent criticism on Ezekiel xiii. 21. As it is very improbable that the news of the capture of Jerusalem should be nearly eighteen months in reaching Babylon, it will be satisfactory to know, on the authority of the Syriac version and eight Hebrew MSS., that this period was not more than six months. Having described the editions of Sixtus and Clement, Dr. Kennicott observes, that the present English version frequently expresses, not what the translators found in their Hebrew text, but what they thought should have been there; and that the 14th psalm, inferred in the liturgy of the Church of England, contains three verses not found at present in the Hebrew text of that psalm, but which are probably genuine. We have already mentioned Capellus's opinion on this subject; and yet, though he proved the corruption of the Hebrew text by every argument, except that of MSS. Buxtorf, the ion, following his father, who asserted the absolute agreement of all the ancient MSS., affirmed that no Hebrew MS. in the world contains any various reading which agreed with either of the ancient versions. It is needless to recite the opinions of Mede, Morin, Beveridge, Walton, Hammond, Bochart, Huetius, Pocock, Le Clerc, &c. on this subject. We shall here only observe, with Dr. Kennicott, that Jablonski was the first editor of an Hebrew bible who spoke of any Hebrew MSS.; and he names four, by the help of which he made a few corrections. Nevertheless, he omitted the two necessary verses in Joshua, chap. 21., though Dr. Kennicott has established them, in consequence of the examination of 149 copies. Opitius declares that he, in his edition, obeyed the Mafora, in defiance of all the MSS. and editions of the world united. Vitringa has shewn, according to Dr. Kennicott, how a mistake in one MS. may afterwards have been introduced into many, from the practice of correcting many MSS. by one as their standard. The conjectural emendation made by this eminent biblical critic, in 2 Chron. xxvi. 5., is confirmed by fifty copies; and his reading of Hab. xix. 18. is established by the Talmud and sixteen Hebrew copies. J. H. Michaelis, although he published some various readings, omitted many variations of great moment, probably from an undue deference to the advocates of the integrity of the Hebrew text. Among these advocates we may reckon Wolffus, who maintained that mistakes might exist in some MS. copies, but not in all; because some one MS., or some one edition, always had the true reading. Carpzovius contended, that the Hebrew text has descended to us in the same fframe of purity in which it was first found; not indeed in all the copies, but in those of the better sort; nor in these separately, but in such altogether: and he thought it needful to collect these from every quarter of the world, because, in his opinion, those which are near at hand will be sufficient: a concession which abhires his former doctrine. The learned Halcy, in his Notes on the Holy Scriptures, published in 1729, alludes, as a reason why the quotations in the New Testament differ from those of the Old, that the Hebrew copies have been altered since the days of the apostles. Bishop Hare, with whole testimonies Dr. Kennicott concludes his catalogue of Christian writers, contends earnestly for admitting the corruption of the Hebrew text. He rejects the titles of many of the psalms, as not given by the authors of these psalms. He condemns the practice of vanishing over, instead of correcting, the corrupted readings; and he laments that Hebrew MSS., the chief support of criticism, were wanting.

Dr. Kennicott closes his account of his laudable undertaking, with evincing the great use to be derived from the Hebrew MSS. and ancient versions, for amending the printed Hebrew text; and with exhorting persons in power to render such corrections sutficient to the public good, by procuring a more correct and a more intelligible English translation, or rather a revival of the present English translation of the Old Testament. These MSS., he says, strongly confirm the ancient versions, and enable us to ascend to the times of Jerom, of the Apostles, and even of Ptolemy Philadelphia; and he adds, it now remains to be seen in what kingdom or country, through Europe, will be manifested the greater zeal, for correcting the modern translations of the Old Testament.

The work of which, for the gratification of our readers, and with a view of recording and transmitting the honour of our country, where it was undertaken, and of the age in which we live, we have given a copious account, will appear in its pre-eminent importance and utility, whenever it shall be applied to the desirable purpose of aiding a public and authoritative new translation of the Bible, or, at least, an efficient revision of the common version. In the translation of particular books of Scripture, by Bishops Lowth and Newcome, and by others of inferior rank in the church, &c. we observe the advantage resulting from Dr. Kennicott's labours; but their full benefit can only be enjoyed, when the translation is complete, and authoritatively introduced into common use. It has contributed eminently to the honour of the king of Sweden, that he has been the first prince in Europe who has infused his royal commands for executing a purpose of this kind; and Dr. Kennicott thinks, it would be criminal to suppose that Great Britain, which has enjoyed such distinguished blessings of Providence, will be backward in fo pious a design. No person, whatever be their rank either in the church or state, can more laudably testify their veneration for the Holy Scriptures, and their concern for the information and benefit of the world, than by adopting and accomplishing a measure of this kind. It would serve also to obviate many objections against the truth and authority of divine revelation. It has been urged by Lord Bolingbroke, and by other writers on the side of scepticism or infidelity, "that if the Scriptures had been from God, they would always have been preferred in their primitive purity." In opposition to suggestions of this kind, Dr. Kennicott shews, that neither the wisdom nor the
the good of the Supreme Being can be justly imputed, from the supposition that many errors have crept into the present text; because the most important matters are full secure and certain, and men have always been able to derive from the Bible a rule both of faith and practice. For the illustration of this position, he appeals to the ancient churches, both Greek and Italian, and the modern churches of both Protestants and Roman Catholics; since, amongst all these, their faceted books taught them "what they must do to be saved!" though they contained many errors. The correction of which was very definable. Indeed, the integrity of the faceted books could not have been preferred without a "miracle," perpetual as to time and universal as to place, which would consequently be a greater miracle than any in the Bible; nevertheless, as many corruptions, in transcripts made from transcripts, even since the year 420 before Christ, were available, it is happy that several versions, made 1500 or 2000 years ago, will correct some of these corruptions; and that the Hebrew MSS. still extant, will correct others. Upon the whole, it is of great importance, that the effect of these corrections should appear in its whole extent, and as speedily as possible, not only to Christians in particular, but to the world in general.

The learned Dr. John Bernard Roffi, professor of divinity and the oriental languages in the Royal Academy of Parma, undertook to make a collection of the various readings of the Old Testament, in imitation of that of Oxford; and for this purpose he examined, by himself, or his friends, 1470 MSS. or printed copies. Of foreign MSS. 210, which had been omitted by Dr. Kennicott, were collated in the most important passages; and of ancient editions, either in his own possession, or to which he had access, the number amounted to 288, of which 250 are such as had not been collated by Dr. Kennicott. M. de Roffi announced his design in a tract, entitled, "Apparatus Hebræo-Biblicus," and published at Parma in 1753, &c.; and he proposed to compile four volumes, in 4 vols. 4to. The first volume was published at Parma in 1758, under the title of "Variae Lectiones Veteris Testamenti, &c." or the various readings of the Old Testament, drawn from an immense number of MSS. and printed editions, compared with the Samaritan text and the ancient versions, and examined and appreciated by the most accurate rules and principles of faceted criticism. This volume contains the "Prolégomènes," and a clavis of the books of Genesis, Exodus, and Leviticus. In the introduction we have several curious critical discussions, from which we learn that this collection averts, as Dr. Kennicott's valuable and judicious labours had before done, instead of invalidating, the integrity of the faceted text in matters of the greatest importance; as all the MSS. notwithstanding the diversity of their dates, and of the places where they were transcribed, agree with respect to that which constitutes the proper elegance and sublimity of divine revelation, namely, its doctrines, moral precepts, and historical relations. M. Roffi charges the variations not merely on the copyists, but on the ignorance and temerity of the critics, who have, in all ages, been so ambitious of correcting the text to their authors, and who, instead of correcting the pretended errors of others, frequently substitute in their place real errors of their own. This author is of opinion, that the common reading of an ancient text ought never to be changed but by the authority of MSS. and if there be any exceptions to this general rule, they are very rare: and the conjectural alterations of critics should be thrown into the notes. M. Roffi, however, observes, that we must not confound the alterations introduced into the faceted text by the injuries of time, the negligence of transcribers, or the boldness of critics, with those which have been made by public authority. The faceted writers of ancient times left, as he says, their records to other writers, who were often their disciples, as also to public scribes, and to magistrates, who revised them. In this revision, which was executed either by faceted authors, or by the public authority of the fynagogue, corrections and rearrangements were made, where they were judged necessary. This, M. de Roffi thinks, appears evident from the present state of the faceted writings; and in confirmation of his opinion, he quotes the Syrian Interpreter, who, in a note placed at the end of the pentateuch, says, that this work was composed by Moses, but was afterwards digested and finished by Judah. He gives his conjectures, that Moses himself made use of ancient records, both in his history of the creation, and in that of the deluge. He thinks that the frequent repetitions and anachronisms, which are discoverable in the book of Genesis, ought rather to be attributed to a writer anterior to Moses, than to scribes in after-times; or to the confusion of the ancient records themselves, as some have imagined. This opinion was proposed and maintained with singular ingenuity and erudition, before the time of Roffi, in a French work published at Brussels in 1753, entitled, "Conjectures concerning the original memoirs, which Moses appears to have made use of in composing the book of Genesis, together with remarks designed to confirm or illustrate the several conjectures." The revision, says Roffi, which Ezra made of the faceted writings, with the assistance of MSS. and according to the rules of criticism, both on his own authority as a faceted writer, and that of the council of which he was a member, did not annul the MSS. that were anterior to his time, either in the hands of the Samaritans, or in those of the Jews, from which thofe of the Cuthites or Samaritans had been taken, or in the hands of the Egyptians, or in those of the Babylonian Jews, who did not return to the holy land. The edition of Ezra remained entire till the destruction of Jerusalem; but it underwent several alterations before the time of the Masorites, whose critical labours or attempts, with a view of securing the faceted code against future injuries, are well known. Yet, notwithstanding these attempts and labours, some faults, which were anterior to their time, still remained; and others, though of little consequence, afterwards crept into the faceted text. The only forces from which we can derive warrantable corrections of these faults are, according to this author, the MSS., the ancient editions, the Samaritan text, the ancient versions, the parallel places, the analogy of the text or of the history, the testimonies of ancient writers, critical conjectures, and the Masorah, which De Roffi treats with more respect than Dr. Kennicott, of whom he complains on that account. He fuses many learned and judicious observations on the various forces, from which materials are to be derived for the necessary corrections. As to the MSS. he lays down rules for ascertaining their age, of which the most obvious is the date; and in order to understand their dates, he takes notice of the various methods of computing time employed by the Jews, and the different eras from which they reckon. When the dates are wanting, it becomes difficult to ascertain the time of a MS., if it be anterior to the thirteenth century. Those which are anterior to the twelfth century are very rare; and the author minutely indicates the marks that distinguish them. The rarity of the ancient Hebrew MSS. has been occasioned by the Jewish custom of depositing their books and phylacteries in public places, from whence, to make place for others, they have been taken and buried in wells, or under ground, where they soon rot. Thofe of a very remote antiquity, which are no longer ex-
tant, are often restored, in part, by copies which fill sub-
fill. With regard to ancient editions, De Rossi distin-
guishes the Masoretic from those editions without the Ma-
sor, which are anterior to the year 1525, when the rab-
biblical Bible of Jacob Ben Chaim was published. Of 242
which he has collected, he reckons 50 which belong to the
fifteenth century, and above 60 which are anterior to the
first Masoretic Bible. The ancient versions enumerated by
the author are the Greek, Chaldeic, Syriac, Arabic, and Per-
ian; and among these, the Greek version of the Pent-
touch, yet unpublished, which is in the library of St. Mark
at Venice, and which he supposes to have been made in the
twelfth or thirteenth century, by an Hellenist, from the
Hebrew of Ezra or of Palestine; and not as the Septuagint,
from the Egyptian or Ethiopic text. The differences that
are found in these versions must not be considered as various
readings; since many of these diversities are to be attribu-
ted, says De Rossi, to the translators themselves, who have
sometimes taken great liberties with the original text,
by altering it in their versions. For other particulars, we
refer the learned reader to the work itself. The second
volume was published at Parma, in 1585, and contains the
books of Kings included in the Hebrew, Joshua, Judges, Samuel,
and Kings. The third comprehends Isaiah, Jeremiah, Ezekiel,
the twelve lesser prophets, with the Song of Solomon,
Ruth, Lamentations, Ecclesiastes, and Esther. And in the
fourth, or last, are the Psalms, Proverbs, Job, Daniel, Ezra,
Nehemiah, and Chronicles. Parma, 1586. The high price
of Kennicott's and De Rossi's valuable works, induced
M. Breitkopf to employ Dr. Docenlein and Professor
Meijer, to collect the most interesting various readings
from the above works, and to print them under the text of
his new edition of Reineccius's bible, printed at Leipsic in
1725, and again in 1739, under the title of "Biblia He-
braica, olim a Christiano Reineccio edita, nunc denuo, cum
varis lectionibus, ex ingenti codicum copia, a B. Kenni-
cotto & J. B. de Rossi collatorum," Lipsiae, 8vo, 1795.

**Bibles, Greek.** The most ancient Greek version is the
Septuagint: for an account of which, the manner in which
it was found, the collation of its MSS., and other circum-
cstances relating to it, see **Septuagint; see also Alex-
andria, and Vatican.** The number of editions of the
Bible in Greek is very considerable; but they may be all
reduced to three or four principal ones, namely, that of
Complutum or Alcala de Henares, that of Venice, that of
Rome, and that of Oxford. The first or Complutenian
edition was undertaken by the divines of Complutum, under
the direction and at the expense of Cardinal Ximenes,
and finished in 1514, but not allowed by Leo to be published
till 1520; nor were the copies of it distributed to the world
at large before the year 1522. It was inserted in the Poly-
glot Bible, usually called the "Complutenian Bible." In
this edition the Greek of the LXX. is said to be altered in
many places, in order to accommodate it to the Hebrew
text, and to the Vulgate. For a more particular account of
it, see **Complutensian, and Polyglott.** It has been
reprinted in the Polyglott Bible of Antwerp, called
"Biblia Regia," by Arias Montanus, in 1572; in that of
the Commentaries, commonly called "Vatiafius's Bible," in
1599; and in De Jovy's Polyglott of Paris, in 1645. See
**Polyglott.**

The second Greek Bible is that of Venice, formed from
many ancient copies by Andrea Ascanius, and printed by
Aleus Manutius in 1518, and hence called the "Aldine
edition." This edition approaches nearly to the Roman,
and is said to be purer than the Complutensian. Malus
says of it, that it is a copy of the simpler interpretation
of the ancient LXX.; but not pure, nor free from all inter-
mixture of the words of Theodotion. Usher observes, that
it sometimes deviates from the LXX. and adopts the read-
ings of Aquila; and that various glosses have crept into it.
From this Aldine edition all the German copies have been
derived, which generally adopt the words of it, but differ
from it in the order of the books, chapters, and some verses.
The apocryphal books are printed separately after the text.
This edition was reprinted, with the Complutenian Latin
version, in 1520, by Aud. Cratandrus; and again, in 1550,
by Rich. Brylingerus; at Straubing, in 1526; at Ham-
burgh, in 1526; at Frankfurt, by the Wecheliani, in 1577;
and in other places, with some alterations, to bring it nearer
to the Hebrew. The most commodious is that of Frank-
fort, in which are published, from the Complutenian
edition, the four last chapters of Exodus, and a great part of
the 24th chapter of the Proverbs. There are also added
little Scholia, which shew the different interpretations of
the old Greek translation. The author of this collection
has not annexed his name, but it is commonly ascribed to
Francis Janius.

The third Greek Bible is that of Rome, or the Vatican
(fac Vatican), formed from the Vatican copy by cardinal
Carafa, and other learned personages, who were employed
in this work for nine years, by the order and under the au-
nipces of Pope Sixtus V. It was printed at Rome in 1588,
with the Greek Scholia, collected from the MSS. in
the Roman libraries. It was afterwards printed in Latin,
with learned and useful notes, by Flaminius Nobiliss, at
Rome, in 1588. The Greek edition, with the Latin annexed,
the distinction of verses, according to the Vulgate, the Greek
Scholia, and the Notes of Nobiliss, was printed at Paris,
in 1628, by J. Morin, priest of the Oratory. In forming
this edition, Carafa made use of several ancient MSS. be-
sides the Vatican, and particularly one procured from the
library of Cardinal Bellarinus, written in large letters, and
another from Magna Graecia, agreeing with the Vatican;
and Carafa professed that it was his design, not to accom-
mmodate this edition to the Latin Vulgate, or the Hebrew,
but to the ancient LXX. Notwithstanding some few tri-
val objections, this edition has been extolled for its purity,
its freedom from any material corruptions, and its superi-
ority to all other editions. From this all the English
editions have been derived. The Greek edition of Rome,
or as Grabe says in his Prolegomena, that of Paris, has been
printed in the Polyglott Bible of London, in 1657; to
which Walton has added, at bottom, the various readings
of the Aldine and Complutensian editions, and of the Alex-
andria MS., as well as of Marchianus's and Card, Bar-
berie's. It was printed at London, in 1653, in 8vo.,
with some deviations with regard to the order of the books,
the number of the psalms, &c.; at Cambridge, in 2 vols.
12mo., with a preface by the learned Pearson, in 1665;
at Amsterdam, with the same preface, in 1683; by Leuf-
den, 8vo.; and at Leipsic, in 1697, 8vo. with the Greek
Scholia of the Roman edition, the parallel places and va-
rious readings, and a preface by J. Frickius of Ulm. An
other Greek Bible was published at Franqueur, in 1709,
by Lambert Bos, who professed to adhere to the Roman edi-
tion of the Vatican copy, and to subjoin at the bottom of
the page, besides the Scholia of the Roman edition, all the
various readings he could find, together with fragments of
the versions of Aquila, Symmachus, and Theodotion.
Breitinger, however, observes, that Bos, instead of adher-
ing to the Roman edition, has followed that of Paris by
Morinus, or the text in Walton's polyglott. This edition
of Bos has been long the common text-book of biblical
scholars.
scholars, who cannot safely purchase the Roman edition; although it is far from being a correct copy of its prototype.

The fourth Greek Bible is that done from the Alexandrian MS., begun at Oxford by Dr. Grabe, in 1707. An edition of a similar kind had been undertaken by Patricius Junius, or Patrick Young, who proceeded no farther than the 17th chapter of the Book of Numbers, and also proposed by Vossius, but not undertaken. In Grabe's edition, the Alexandrian manuscript is not printed such as it is, but such as it was thought it should be; i.e. it is altered wherever there appeared any fault of the copyists, or any word inferred from any particular dialect. This some think an excellence, but others a fault; urging, that the manuscript should have been given absolutely and entirely of itself, and all conjectures, as to the readings, should have been thrown into the notes. For the plan of this work, and the mode of its execution, we refer to the author's Preliminary. A valuable edition of this work, enriched with various readings from the Vatican copy, and other manuscripts, and illustrated by critical disquisitions, was published by Jof. Jac. Beringer, in 4 vols. 4to., in 1730. Tigur-Helvet. A collection of the MSS. of the most ancient Greek version of the Septuagint has, within these few years past, been undertaken by Dr. Holmes, canon of Christchurch, Oxford; and the first volume was published at Oxford in 1798, folio, for an account of which, see Septuagint. Walton's Pre-legalman. I. Grabe's Preliminary. Hodii de Bibliorum Textibus originalibus, &c. p. 638, &c. Fabr. Bib. Græc. l. iii. c. xi. § 6. Tom. II. p. 324, &c. See Septuagint, and Testament.

Bibles, Latin, how numerous formerly, may be all reduced to three classes; the ancient Vulgate, called also "the old Italic," or "Vulgar Latin," (see Italic Version,) translated from the Greek Septuagint, for the use of the Latins, soon after their conversion to Christianity; which version was allowed to be superior to all the rest, being, as St. Auffin calls it, "tenacior verborum cum perpliciatu fenticia": which version being corrupt, Jerome, between the years 370 and 380, made a new Latin version from the Hexaplar Greek; the modern Vulgate, the greatest part of which is done from the Hebrew text; and the new Latin translations, done also from the Hebrew text in the sixteenth century. We have nothing remaining of the ancient Vulgate, used in the primitive times in the Western churches, but the Psalms, Wisdum, and Ecclesiastes. Nothius has endeavoured to retrieve it from the works of the ancient Latin fathers; but it was impossible to do it exactly, because most of the fathers did not keep close to it in their citations.

As to the modern Vulgate, there are numerous editions very different from each other. Cardinal Ximenes has inserted one in the Bible of Complutus, corrected and altered in many places. R. Stephens, and the doctors of Louvain, have taken great pains in correcting the modern Vulgate. See Vulgate.

The best edition of Stephen's Latin Bible is that of 1540, reprinted in 1545, in which are added, on the margin, the various readings of several Latin manuscripts, which he had consulted. The doctors of Louvain revised the modern Vulgate after R. Stephens; and added the various readings of several Latin manuscripts. The best of the Louvain editions are those, at the end of which are added the critical notes of Francis Lucas of Bruges.

All these re-formations of the Latin Bible were made before the time of pope Sixtus V. and Clement VIII. since which people have not dared to make any alterations, excepting in comments, and separate notes. Sixtus V. who was advanced to the papal see in 1585, although the Latin Bible of Gregory XIII. was declared to have been restored to its primitive integrity, formed, by the assent of learned person, another edition; and issued a bull in 1589, revoking and declaring that this was to be deemed, without doubt or controversy, that which was acknowledged as authentic by the council of Trent, and to be maintained as true, legitimate, authentic, and unquestionable; forbidding the alteration, addition, or subtraction of the least tittle of it, and declaring such a mutilated edition delinquent of credit or authority. Nevertheless, after the death of Sixtus V. this edition was suppreased by succeeding popes, as inaccurate and imperfect. A new edition was undertaken by pope Gregory XIV. and completed and announced by Clement VIII. in 1592, which, though different from that of Sixtus, and even repugnant to it, is received as authentic, under the name of Sixtus V.; and it is now the standard throughout all the Roman churches. That pontiff made two re-formations; but it is the fault of them that is followed. See Vulgate. From this the Bibles of Plantin were done, and from those of Plantin all the rest; so that the common Bibles have none of the after-corrections of the same Clement VIII. It is a heavy charge that lies on the editions of pope Clement, viz. that they have some new texts added, and many old ones altered, to countenance and confirm what they call the Catholic doctrine: witnesses that celebrated passage of St. John, tres sunt, &c. Mr. James, an English protestant, has collected above 2000 articles, some of which are indeed of no great consequence, in which Clement's edition differs from that of Sixtus. Clement has adhered more closely to the Hebrew text: and his edition, says Dupin, is much more correct than that of Sixtus. He adds, though the vulgar version be not altogether free from errors and defects, it must nevertheless be confessed that the council of Trent had sufficient reason to prefer this before all the other Latin versions, as Theodore Beza, P. Pugiuss, L. de Dicus, Caflabon, Grotius, Walton, and some other protestants, have allowed. This version was the most ancient of all that were extant at the time of this council; the greater part of it was done by Jerome, a very exact and faithful interpreter. It had been used for many ages in the Latin church; it was written in a simple and natural style, and yet occasionally heightened by noble expressions; and upon the whole, says Dupin, it was the best and most perfect version.

There is a great number of Latin Bibles of the third class, comprehending the versions from the originals of the sacred books made within three hundred years. The first is that of Sanctus Pagninus, a Dominican, under the patronage of pope Leo X. printed at Lyons, in 1520. In 1528, authorized by two letters of pope Adrian VI. and pope Clement VII. prefixed to it, the former dated in 1523, and the latter in 1526, and much censured by the Jews. He employed 25 years in the execution of this work, and finished it before the year 1518. This the author improved in a second edition. In 1542, there was a beautiful edition of the same at Lyons, in folio, with fcelosis, published under the name of Michael Villanovanus, i.e. Michael Servetus, author of the fcelosi. Thoe of Zurich have likewise published an edition of Pagninus's Bible in 4to. And R. Stephens reprinted it in folio, with the Vulgate, in 1557, pretending to give it more correctness than the former editions. There is also another edition in 1558, in four columns, under the name of Vetulobus; and we find it again in the Hamburg edition of the Bible in four languages.
In the number of Latin Bibles is also usually ranked the version of the same Pagninus corrected, or rather rendered literal, by Aris Montanus; which correction being approved of by the doctors of Louvain, &c. was inserted in the Polyglott Bible of Philip II., and since in that of London. The chief aim of Montanus has been to translate the Hebrew words by the name number of Latin ones; so that he has accommodated his whole translation to the most ferupulous tastes of grammar, without duly adverting to his Latin, and therefore this version may be considered rather as a grammatical commentary than a true version, and adapted to instruct young beginners in the Hebrew, rather than to be read separately. There have been various editions of this in folio, quarto, and octavo; to which have been added the Hebrew text of the Old Testament, and the Greek of the New. The belt of them all is the first, which is in folio, 1571. The translation of Thomas Malvenda, a Spanish Dominican, is more grammatical and barbarous than that of Montanus, and not much esteemed.

Since the Reformation, there have been several Latin versions of the Bible from the original Hebrew by Protestant. The most esteemed are those of Munster, Leo Juda, Caftalio, and Tremellius; the three last of which have been reprinted various times. Munster published his version at Basle in 1534, which he afterwards revised; he published a correct edition in 1546. Without rigidly adhering to the grammatical signification of the words, like Pagninus and Montanus, he has given a more free and intelligible version; but by not deviating from the sense of the Hebrew text, he has retained some of its idioms. He has also avoided himself of the commentaries of the bell Rabbinis. Huetius gives him the character of a translator well versed in the Hebrew language, whose style is very exact and conformable to the original. Caftalio's fine Latin pleases most people; but there are some who think it too much affected, and defective of that noble simplicity and natural grandeur, and of that incomparable energy of style, belonging to the originals, and some other versions: the best edition of it is that in 1573. Leo Juda's version, altered a little by the divines of Salamanca, was added to the ancient Latin edition, as published by R. Stephens, with notes, under the name of "Vatablus's Bible," in 1555. It was printed at Zurich in 1543, and is more elegantly written than Munster's, but sometimes recedes too far from the literal sense. It was condemned by the Parisian divines, but printed, with some alterations, by the Spanish divines of Salamanca. That of Junius and Tremellius is preferred, especially by the Calvinists, and has undergone a great number of editions. It possesses much more of the true natural simplicity. The chief Hebraists are preferred, and the whole is exactly conformable to the Hebrew text, without the leaf obscurity or barbarity. Nevertheless, it is not without defects; relative pronouns are introduced, without attention to the Hebrew text, and they are charged with adding some words to express their own sense.

We may add a fourth class of Latin Bibles, comprehending the Vulgate edition, corrected from the originals. The Bible of Iodorus Calixtus is of this number: that author, not being content with restoring the ancient Latin copy, has corrected the translator in a great number of places, which he thought ill rendered, so as to make them conformable to the Hebrew text. Although he corrected about 2000 places, he has omitted some to avoid giving offense to the catholics, by making too many alterations in the vulgar version. Some protestants have followed the same method, and, among others, Andrew and Luke Osiander, who have each published a new edition of the "Vulgate," corrected from the originals, according to the Hebrew text. They have inflected their emendations in a character different from the text of the vulgar version, instead of throwing them into the margin, and thus they have occasioned some confusion.

Bibles, Oriental. At the head of the Oriental versions of the Bible, must be placed the Samaritan, as being the most ancient of all, though neither its age nor author have been yet ascertained, and admitting no more for Scripture but the Pentateuch, or five books of Moses. This translation is made from the Samaritan Hebrew text, which is a little different from the Hebrew text of the Jews. This version has never been printed alone; nor any where but in the Polyglots of London and Paris. See Pentateuch, and Samaritans.

Bibles, Chaldee, are only the glosses or expositions made by the Jews in the time when they spake the Chaldee tongue. Those they call by the name of Targumim, or paraphrases, as not being any strict versions of the Scripture. They have been inflected entire in the large Hebrew Bibles of Venice and Basle; but are read more commodiously in the Polyglot, being there attended with a Latin translation. See Chaldee Paraphrase.

Bibles, Syriac. There are extant two versions of the Old Testament in the Syriac language; one from the Septuagint, which is ancient, and made probably about the time of Conlangite; the other, called antiqua & simplex, made from the Hebrew, as some suppose, about the time of the apostles. This version is printed in the Polyglots of London and Paris.

In the year 1555, Widmanstadt printed the whole New Testament in Syriac, at Vienna, in a beautiful character. After him there were several other editions; and it was inserted in the Bible of Philip II. with a Latin translation. The best edition of the Syriac New Testament is unquestionably that of Leyden, published by Schaal in 1705, and reprinted, much improved, at Leyden in 1717. The New Syriac and Arabic Testament was printed at Rome, in 1703, by the Propaganda, for the use of the Maronite Christians in Syria. Gabriel Sionita also published a beautiful Syriac edition of the Psalms, at Paris, in 1525, with a Latin interpretation. See Syriac Version.

Bibles, Arabic. Although the Christian religion was preached in Arabia, as well as in other countries of the East, at an early period, it never was the established religion of the country, as in Syria and in Egypt; for even the temple of Mecca was a heathen temple till the time of Mahomet. A translation of the Bible into Arabic was therefore wholly unnecessary before the conquests of the Saracens, when the Arabic became the vernacular language of Christian countries. Historical evidence on this subject extends no further than the tenth century, when Rabbi Saadis Gaon published an Arabic version of the Pentateuch; and if conjecture may be allowed (fays Marsh, in his edition of Michaelis's Introduction, vol. iii. p. 599.), we may suppose that most of the Arabic versions were made during the period that elapsed between the conquests of the Saracens in the 7th century, and the crusades in the 11th, especially about the middle of this period, when the Syriac and the Coptic, though they had ceased to be living languages, were still understood by men of education; and Arabic literature, under the patronage of Almamon and his successors, arrived at its highest pitch. The age in which the Arabic printed version, or version from the Syriac, was written with the Arabic wholly uncorrected, for we have no knowledge of the MSS. from which the Roman edition of the four Gospels (mentioned below) was printed; and all that we know of the MSS. used by Gabriel Sionita in his edition of the Paris Polyglot, and by Erpenius in his edition of the Arabic New Testament, is, that the former used a MS. brought from Aleppo, and written in Egypt in the 14th century, and the latter a manu-

script
script brought from Egypt, in which the gospels were written in the 13th, and the Acts, Epistles, and Revelation in the 14th century. But we are left wholly in the dark with respect to the century in which the versions themselves were made. The Arabic versions may be divided into four classes; viz. those taken immediately from the Syriac, from the Coptic, from the Greek, and from the Latin. That various Arabic versions have been made from the Latin in modern times by oriental monks residing at Rome, who, being instructed by the Romish clergy to regard the Vulgate as the standard by which all other versions should be regulated, proposed essentially to serve their brethren in the East, by translating it into their native language, is evident from what is related by professor Adler in his Biblical and Critical Journey to Rome, p. 175; and an Arabic version of this kind was actually published at Rome, in 1752, by Raphael Tuki, bishop of Arakan. As for those versions which are written in parallel columns with the Syriac and Coptic, of which copies exist in the royal library at Paris, it is reasonable to suppose that they were not made from the Greek, but immediately from the ancient versions with which they are connected, as the means of understanding them, after the languages in which they were written had ceased to be spoken. For the same reason, those annexed to the Greek text were probably taken immediately from the Greek; but of these Greek Arabic MSS. only one has been discovered, namely, that in the university library at Leyden. Walton (Prolegomena, p. 96) says, that there are two kinds of Arabic versions in use among the eastern Christians; one called the Syriac, and the other the Egyptian, from the countries in which they are used. Both these versions, according to A. Jullianin, bishop of Nbo, were translated from the Greek. In the year 1516, Aug. Jullianin printed at Genoa an Arabic version of the Psalter, with the Hebrew text and Chaldee paraphrase, adding Latin interpretations, which, he says, were taken from the Syriac or Antiochian version. There are also Arabic versions of the whole Scriptures in the Polyglotts of London and Paris, said by Jullianin to be taken from the Egyptian or Alexandrian versions; and we have an edition of the Old Testament entire, printed at Rome in 1671, by order of the congregation de propaganda fide; but it is of little esteem, as having been altered agreeably to the Vulgate edition. The Arabic Bibles among us are not the same with those used by the Christians in the East. Some learned men take the Arabic version of the Old Testament, printed in the Polyglott, to be, at least in part, that of Saadia, who died in the year 942, and who translated the whole Old Testament from the Hebrew into the Arabic, expressing the Arabic in Hebrew characters. Their reason is, that Aben Ezra, a great antagonist of Saadia, quotes some passages of his version, which are the same with those in the Arabic version of the Polyglott; yet others are of opinion that Sadia's version is not extant. For though the whole Hebrew Bible was thus translated by him, the Pentateuch only has been, as yet, published from his version. The other books, now in Arabic, in the Paris and London Polyglotts, were translated at different times by different authors; partly from the Greek, and partly from the Syriac versions; and few parts, if any, excepting the Pentateuch, were translated from the Hebrew text. The Arabic version is the latest of all the ancient versions of the Old Testament; however, that part of it which has been translated from the Hebrew, will assist in detecting some corruptions that have crept into the Hebrew text since, and those parts that are made from the ancient versions will assist in elucidating the true readings of those versions. In 1622, Erpenius printed an Arabic Pentateuch, called also the Pentateuch of Malew, as being made by the Jews of Barbary, and for their use. This version is very literal, and esteemed very exact. The four evangelists have also been published in Arabic, without and with a Latin version, at Rome, in 1591, folio. The Latin translation is printed under each line of the Arabic text, and is taken from the Vulgate, though the Latin text is in some measure altered, so as to make it correspond to the Arabic. In a representation of the baptism of Christ, annexed to it, the date appears to be performed, not according to the oriental custom of immersing, but according to the northern practice of sprinkling; for our Saviour is placed, not in Jordan, but at the brink of the river, with his feet only immered, while John the Baptist, kneeling on a rock, pours water on his head. The MS. from which this edition proceeds of the Arabic gospels is taken, is wholly unknown. Michaelis observes, that upon comparing it with the catechism of the Druses, the passages there quoted from the gospels coincide with this edition; whence he infers that this version must have been long and generally known in Asia. But from this coincidence no other inference can be justly drawn, except that the Arabic version of the gospels, printed at Rome in 1591, was made before the 11th century; for to that age the origin of the Druses is referred. Erpenius observes, in the preface to his Arabic New Testament, that this edition bears a great resemblance to the MS. from which he printed the four gospels, except the first thirteen chapters of St. Matthew. The version, says Michaelis, was certainly taken from the Greek; but father Simon (Hist. Crit. des Verfions du N. T. ch. 18.) says, that upon comparing the Arabic version of the four gospels printed at Rome, and afterwards reprinted in the Polyglotts, with an Arabic translation of the Coptic version, he found them dissimilar; but that on comparing it with an Arabic translation of the Syriac version, he perceived a great resemblance. Hence he concluded, that it was taken, not from the Greek, but from the Syriac text. This version has since been reprinted in the Polyglotts of London and Paris, with some little alteration of Gabriel Sioni. This Gabriel Sioni, a Maronite by birth, from the neighbourhood of Libanus, and one of the principal editors of the Paris Polyglott, relates, that he made use of a manuscript written in Egypt in the 14th century; but he seems to have been unacquainted both with the name of the author, and with the age in which he lived. Le Long relates, that it was brought immediately from Aleppo to Paris. From this MS. the Arabic version of the Acts and of the Epistles was taken, which was first in the Paris, and reprinted with additions in the London Polylott. But this version of the Acts and Epistles can lay no claim to high antiquity; and though it was probably not taken from the Syriac, yet it is not certain whether it was taken from the Greek or the Coptic. Erpenius published an Arabic New Testament entire, as he found it in his manuscript copy, at Leyden, in 1616, from a manuscript written in the Upper Egypt, in 1342. From two dates, which Erpenius seems to have confounded, it is probable, that the manuscript used by him was a compound of two different manuscripts, one written in the 13th, and the other in the 14th century; and this is very consistent with the opinion, that the gospels in this manuscript were translated either from the Coptic or from the Greek, and the Acts and Epistles from the Syriac. There are some other Arabic versions of late date mentioned by Walton in his Prolegomena; particularly a version of the Psalms preferred in Sion College, London, and another of the prophets at Oxford; neither of which has been published. The English society for promoting Christian knowledge published, in 1727, an Arabic New Testament, for the use of the Chaldeans in Asia. Ten thousand copies were printed, but none sold in Europe, so that this edition is very scarce. Two
Two copies are preferred at Cambridge, one in the university library, and another in the library of St. John's College. The text is taken from the Polyglot; but the editor Solomon Negri, by order of the society, altered it in those passages which vary from the reading of our present Greek text. The editor, says Michaelis, has taken the liberty of differing 1 John v. 7, without cautioning the reader that it was not taken from any MS.

An Arabic Bible is said to have been printed at Bukhæræ, in 1706, and the gospels at Aleppo, in 1706. Of these, as well as of the complete editions of the Arabic version, a description is given in Le Long's Bibli. Sacr. ed Mach. P. ii. vol. 1. p. 110—137. For an account of the MSS. of the Arabic in which the N. T. is preferred in the different libraries of Europe, see Bœmer's edition of Le Long's Biblical Sacr. P. ii. p. 234—240, or vol. i. p. 120—122. Paris ed. 1723; Uri's Catalogue, N. 22—34, of the Arabic MSS.; and Note 111 to § 3. ch. vii. in Marth's edition of Michaelis's Introduction to the N. T. In the university library are two Arabic manuscripts of the gospels, which formerly belonged to Cyrilus Lucaris.

Bibles, Coptic. There are several manuscript copies of the Coptic Bible in one of the great libraries, especially in the library of Paris. The Coptic version of the New Testament must be regarded as a principal version of considerable antiquity, because it has given birth to several others in the Arabic language; for since Egypt was invaded by the Saracens, who extinguished the old language, the Egyptians have generally annexed to the Coptic N. T. an Arabic translation, which has almost supersed the original. Nebhur, in his Description of Arabia (p. 86.), relates, that though the gospels are still read in the Coptic version in the public service, it is not understood even by the priests; and that immediately after the lefions have been read in Coptic, the same are read in Arabic, which is the present language both of the Upper and the Lower Egypt. Thomas Marshall had once intended to print the Coptic version, and had even prepared the four gospels for the press, but he died before they were printed. Upon which the publication was referred for Dr. D. Wilkins, a native of Memel in Prussia, who, after having studied the Coptic, made a journey to Amsterdam with this view; but induced by some ingenious circumstances, he removed to Oxford, where his Coptic New Testament was printed in 1716, at the expense of the university. Besides a long preface, he added a Latin translation of the Coptic text, which Jablonoffi and La Croix have criticized with some severity. It is said, however, that Wilkins took great pains to present the world with a faithful copy, and that his intentions were not unsuccessful. He also printed the Pentateuch, with a Latin translation, in 1731. Since his time a great variety of MSS. have been collated; and if Woide had undertaken the task, a more complete edition of the Coptic version might have been expected. The title of Wilkin's edition is "Novum Testamentum Aegyptium vulgo Copticum, ex MSS. Bodleianis declarifit, cum Vaticanis et Parifibinis contulit, et in Latinum feromonem convertit, David Wilkins, Ecclefiae Anglicane Prebener," Oxon. 1716, 4to. Maj. Montfaucon, in his Palæographia Graeca (l. iv. c. 7. p. 31.), says, that the Coptic MSS. which remain, are not very ancient, and that he has not seen any older than 500 years. Wilkins, in his preface, supports the antiquity of the Coptic version by several arguments, the chief of which is drawn from Antio- nius, who began to lead an ascetic life about the year 271, and who, though an Egyptian, and ignorant of Greek, read the New Testament in the same purpose Woide (p. 97. of his Essay, mentioned below) maintains, that the Egyptian version used by Antonius in the third century, was written in Coptic, because he actually read an Egyptian version of the Bible, and as he understood only the dialect of his own country, he concludes that the Coptic version existed before the middle of the third century. Ludovicus Pickius, or Lous Piqueus, who was acquainted with the Coptic language, refers this version to the fifth century. See Mill's Prolegomena, § 1520.

The readings of the Coptic have a striking affinity with those of the Latin version, and sometimes with those of the Codex Cantabrigiensis. The story of the adulteress is found in some copies, and omitted in others; but 1 John v. 7, is omitted in all. Wette has also observed, that the Coptic New Testament has a very great similarity to the quotations of Origen, Eusebius, Cyril, and to the Alexandrine manuscripts. The best accounts of the Coptic version are given in Simon's Histoire Critique des Versions du Nouveau Testament, ed. 16.; in the Preface to Wilkins's edition of the Coptic New Testament; in Le Long's Biblical Sacr. ed. Mach. P. ii. vol. i. § 10.; and particularly by the learned Woide, in a German essay printed in 1778, in vol. iii. of the Kritische Beiträge, p. 1—100. See Coptic.

Bibles, Sahidic. The Sahidic version of the Old and New Testament, or that of Upper Egypt, existed only till of late in MSS.; but in 1728, the learned Woide published proposals for an edition of several fragments of this version, comprehending about a third part of the New Testament, under the following title, "Fragmenta Novi Testamenti, quae Thebaïdiæ, et Coptâæ, et Ethiopice, et Egyptianæ, et Syrianæ, et Arabice, et Graecæ, et Latinæ, vel Latinae, vel declarent, cum libellis, et collationibus, et argumentis, quae hic et alibi, etc."

The learned editor lived to continue the work so far as to print the fragments of St. Luke's gospel, and to prepare for the press the manuscripts of the fragments of St. John's gospel, but he died in May 1780. After his decease, the delegates of the Clarendon press entrusted the completion of the work to Dr. Ford; and under his care it made its appearance, entitled, "Fragmenta Novi Testamenti, et versiones Coptice, Thebaïdæ, Sahidæ, et Syriæ, et Egyptianæ," Oxon. large folio. In an elaborate dissertation prefixed to this work, Dr. Woide treat[s] of the Coptic version of the Old Testament; of the Sahidic version of the Old Testament; and of the original texts from which those versions were made. In his opinion both the versions were made from the Greek; they express the phrasing of the version of the LXX.; and most of the additions, omissions, and transpositions, which distinguish the LXX. from the Hebrew, are discoverable in both the Coptic and the Sahidic version. In a second section the author treats of the Coptic version of the New Testament, and Wilkins's edition of it; of the Sahidic version of the New Testament; and of the antiquity of the versions of the Old and New Testament in both dialects. And in a third section, Dr. Woide gives an account of the versions, in both dialects, of the apocryphal books of the Old and New Testament. From his observations and account, we may conclude, that the Coptic and Sahidic are distinct and independent versions; that the Copic inclines more to the Alexandrian or Western edition, than the Sahidic; that no remarkable coincidence is to be found between the Coptic or Sahidic version and the Vulgate; and that we have no reason to suspect the former to have been altered or made to conform to the latter; and that the age of the Sahidic version is not yet ascertained. Dr. Woide supposes, that it was made in the second century; and in proof of this opinion, he allege[s] three arguments. The first argument, deduced from the use made of an Egyptian version by St. Anthony, who is said by St. Athanasius to have been ignorant of the Greek language, and yet to have constantly read the Scripture, has been mentioned under the preceding article.
article. His second argument is deduced from a Sahidic MS. which is probably of the second century, and which contains various passages both of the Old and New Testaments, coinciding with some of the fragments of the Sahidic versions. His third argument is founded on an apparent coincidence of some passages in the fragments, with a manuscript containing two books of the fabrication of the Gnostics, and evidently written in the second century. It appears then, if no objections can be made to these arguments, that proofs may be alleged of a higher antiquity in favour of the Sahidic version than can be produced in favour of any other version of the New Testament; and it must of course be of the greatest importance in the criticism of the Greek Testament. At the same time it must be acknowledged, that the oldest historical evidence for the high antiquity of an Egyptian version is that of Epiphanius and Theodore; the former quoted by Semler in his "Apparatus ad Novi Testamenti interpretationem," p. 64.; the latter by Wilkins, in the "Prolegomena" to his Coptic New Testament, p. 6. From an examination of the various readings furnished by the above-mentioned fragments, it appears, that the story of the adulteress, John, vii. 1—12, is not among them; in the Acts of the Apostles, ch. xx. 28, the Sahidic version coincides with those Greek MSS. which have &eγνων, not έγνων; in 1 Tim. iii. 16, they coincide with those which read ὁδιαίνεσθαι αἰδως; and 1 John ch. v. has the sixth and eighth verses; but the seventh, which contains the testimony of the three heavenly witnesees, is absent. We have an account of the Sahidic version of the New Testament in "Friederici Münterii Commentatio de indeo versionis N. T. Sahidicis, &c." Hafniae, 1789, 4to. to which are annexed some fragments of the New Testament from manuscripts in the possession of cardinal Borgia. Some fragments of the Sahidic version of the gospels of St. Matthew and St. John have been likewise published by Mingarelli in his "Ægyptiorum codicis reliquiae, Venetis in bibliotheca Nanana affervata," Bonon. 1785, 4to. MSS. or rather fragments of MSS. of the Sahidic version are preserved in the libraries of Rome, Paris, Oxford, Berlin, and Venice.

BIB

The Ethiopians have also translated the Bible into their language. Chrysofom, cited by Michaelis, says, that the Ethiopians had in his time a version of the Bible; but his evidence is unsatisfactory. Ludolf, in his history of Ethiopia, relates, that the Scripture was translated into that idiom of the Ethiopic language, which was at that time more natural to the inhabitants of Africa, from the Greek version of the LXX., according to a certain copy used in the church of Alexandria, which the innumerable various readings that are inserted in the English Polyglott Bible from one of the same copies, plainly prove. As for the author, and time of the translation, he is unable to ascertain either; but thinks it most probable that it was begun at the time when the Habelines, or Abyssinians, were converted, or soon after, and that it was gradually perfected. Mr. Bruce, in his "Travels," vol. i. p. 490, says, that the Abyssinian copy of the Holy Scriptures was, in Mr. Ludolf's opinion, translated by Frumentius, a bishop in the 4th century, who first preached Christianity in Ethiopia; but Ludolf has left the matter undecided. See Hill of Ethiopia, p. 262. ed. 1682. Mr. Bruce himself inclines to this opinion. They divide the Old Testament, says Ludolf, containing 46 books, into four principal parts, and mix the apocryphal with the canonical. Walton, (Proleg. xv. p. 102.) says, that Gaunim had an ancient MS. of the whole Ethiopic Old Testament, which was deposited in the royal library of Sweden. Mr. Bruce informs us, (vol. i. p. 485.) that he brought with him a copy of the Ethiopic version of the O. T. which he has deposited in the British Museum; but it does not appear that he brought a copy of any part of the New. Indeed he says, (vol. i. p. 493.) that copies of the whole N. T. are in that country very scarce; that, except in the churches, he had never seen a single MS. which comprehended all the parts of it; and that even the transcripts of the Gospels were in the hands only of men of the first distinction. The Ethiopic version of the N. T. contains the whole of it, divided, according to Ludolf, into four separate parts, viz. the Gospels, the Acts, the fourteen Epistles of St. Paul, and the seven Catholic Epistles. The Apocalypse is added as an appendix, and entitled "Abakhailadis." Scagler refers the Ethiopic version to the time of Juliusian, at which period he dates the conversion of the Abyssinians: but Walton refers it to a much earlier period, and not far distant from the times of the Apostles. Whoever was the translator of it, it appears to have been taken immediately from the Greek: from the frequent confusion of words which found alike in the Greek, but which have not been confounded by any other translator, and from its agreement in many of its readings with the Alexandrine MS., and with the quotations of Origen. Neither of these circumstances can appear extraordinary, as it was natural for the inhabitants of Abyssinia to procure their copies of the Greek Testament from Egypt. The translation of the Gospels is much superior to that of the Epistles. This version was first published at Rome, in 1548 and 1549, under the pontificate of Paul III. but the editors, who were natives of Ethiopia, had a very imperfect MS. of the Acts, the chasms of which they were obliged to supply from the Vulgate. To this purpose, Ludolf observes, that the Acts of the Apostles, for the most part, were translated at Rome, out of the Latin and Greek, for want of the Ethiopic original. This original seems to have been the source from which our editions of the Ethiopic version of the N. T. have flowed; and it is probably preferred in the Vatican, though it has not yet been described. Walton reprinted this Roman edition in the London Polyglott; but his copy, being in some places illegible, the editors filled up the deficiencies according to their own judgment, so that the Roman edition retains the same value, as if no other were extant. The Latin translation was made by Dudley Loftus, and corrected by Callell; but it is of little worth, and has led Mill, and other collectors of various readings, into error. A more accurate Latin translation of the Ethiopic version has been published by professor Bode, under the following title, "Novum Testamentum ex versione Ethiopic interpreta in Biblis polyglottis Anglicanis edition ed Ethipioc lingua in Latinum translatum," Brunsvigii, 1752, 1755. 2 tomi, 4to. The best extracts from the Ethiopic version, says Michaelis, are and must be uncertain, because we have no accurate impression of the version itself; however, his editor (Dr. Marth) observes, that if the Ethiopic version was made immediately from the Greek, and in an early age; if its readings coincide with the quotations of Origen, and the Greek MSS. of the Alexandrine edition, it seems to be entitled to the same privileges, as other versions of equal antiquity. The principal objection applies not so much to the version itself, as to our printed text, which is probably incorrect, as not being the result of a collation of different MSS. But the same objection may be made to the old Syriac version, in which, though various MSS. have been used since the original edition of Widmanstadt, the alterations that have been made deferse rather the name of corrections than of improvements. Of all the books of the O. T. there never was any printed, but the Psalms and the Song of Solomon, in the Ethiopic language at Rome, in 1513; at Cologne, in 1518, and since that time, with
with corrections and emendations, by Walton, in the London Polyglott.

Bibles, Armenian. There is a very ancient Armenian version of the whole Bible, done from the Greek of the LXX, by some of their doctors, about the time of St. Chrysostom. See Armenian version. The first printed edition of the Armenian version was published in the 17th century by Ufcan, bishop of Erivan; because the Bible was at that time become scarce in Armenia, that a single copy cost 1200 livres. Hence a council of Armenian bishops assembled in 1662, ordered the Bible to be printed in Europe. Accordingly, three distinct editions were printed at Amsterdam; the first in 1666, containing both the O. and N. T. in 4to. a second, in 1668, including only the N. T. in 8vo. and a third, in 1698, in 12mo. The two first were printed under the direction of Ufcan; but the last is the most beautiful edition. A complete description, particularly of the first of these editions, is given in Le Long, Bib. sacra, ed. Mafch. P. H. vol. i. p. 173–176, 180. A lift of Armenian MSS. of the N. T. is given in Dr. Baer's edition of this work, P. i. p. 286, or vol. i. p. 135, of the Paris edition of 1725; see also vol. i. p. 76, of the Catalogus MSS. Bib. Regia, and note 11 to § 3, chap. viii. of Marsh's Michaelis. La Croze and G. Whiston have accused the editor of the above-mentioned edition of having corrupted, in some places, the Armenian text. It is certain, however, says Michaelis, that John v. 7, was not in his MS.; for Sandius declares, that he had seen the MS. from which the Amsterdam edition was printed, and that it wanted that verse. Sandius, in the place referred to by Michaelis, speaks of one ancient MS. which he had seen, in possession of the bishop of the Armenian church, and which had been collated at Amsterdam, in which this passage did not occur. It is possible, however, and even probable, that Ufcan had more than one MS. and the words of Sandius do not imply the contrary. Nevertheless, we have positive evidence, that Armenian MSS. written before the time of the council at Cis, in 1307, have not this verse. In like manner, John v. 4, is wanting in the Armenian MS. but inserted in Ufcan's edition; and La Croze observes, that Ufcan himself acknowledges, in his preface, that he had altered some passages from the Vulgate; not, as he candidly allows, with an intention to deceive, but from ignorance and superstition.

Bible, Georgian. The Georgian version was first printed at Moscow, in 1743, fol. and a description of it is given by the learned Eichhorn, in his "Allgemeine Bibliothek," or Universal History of Biblical Literature, vol. i. p. 153—169. From the description it appears, that the Georgian text was altered from the Slavonian, in the edition of Moscow, and it would therefore be of little value in the criticism of the N. T. Two MSS. of the Georgian version of the Gospels are preferred in the Vatican. See Le Long, Bib. Sacr. tom. i. p. 140. ed. Paris, 1723.

Bibles, Persian. Some of the Fathers seem to say, that all the Scripture was formerly translated into the language of the Persians; but we have nothing now remaining of the ancient version, which was, certainly, done from the Septuagint. The Persian Pentateuch, printed in the London Polyglott, is, without doubt, the work of Rabbi Jacob, a Persian Jew, familiarized Tavosius, Tavusius, or Tufus, from the city Tus, where the Jews had a famous academy. It was translated from the Hebrew text, for the use of the Jews, who lived in Persia, and printed in the Hebrew character, with the Hebrew text, and with the version of Onkelos and Saadia, at Constantinople, in 1551. From the collation of this, with other versions, we may deduce a satisfactory explanation of the famous prophecy of Jacob concerning the advent of the Messiah, unperturbed by the glosses of the Rabbins. We have likewise two Parthic versions of the four Gospels, of which the most ancient, and that which is of course the most valued by the learned, is printed in the London Polyglott, accompanied with a Latin translation by Dr. Sam. Clarke, and notes by Dr. Thomas Greaves, contained in the appendix. This Parthian version of the four Gospels, which is the only part of the N. T. hitherto printed, was taken from a MS. in the possession of Dr. Pococke, and written in the year 1341, as appears by a declaration annexed to it. A new Parthian translation has been published by professor Bode, at Helmstadt, in 1750, 1751, with a preface containing historical and critical remarks on the Parthian version. Dr. Greaves has very justly observed, that the Parthian is a translation of the Syriac, for it sometimes retains even Syriac words, and subjoins a Parthian interpretation; and in other places confounds the meaning of words, that have a similar sound only in the Syriac. This is likewise probable in itself; for the Chaldaeans, who lived scattered in the Persian empire, made use of Syriac as the language of the church, and as the language of literature; and it was common for the Persians to study in the schools of Syria, especially at Edessa. The principal use then of the Parthian version is in discovering the false readings that have crept, from that version into the Syriac. It might be added, that the Parthian omits passages, that are wanting in no MS., or version except the Syriac; as Matt. xxvii. 46, Mark. vii. 34. There is another Parthian version of the Gospels, which Abraham Wheeloe began to print in 1652, and which was finished after his death by Pierion, in 1657. It was published in London, and three MSS. were used by the editors. Walton, in his "Prolegomena," xvi. p. 102, informs us, that he knew of only three MSS. of the Parthian Gospels, one in the possession of Dr. Pococke, which he used, and the other two in the libraries of Oxford and Cambridge, different from the other, and less ancient. If this be the case, Wheeloe must have used MSS. containing distinct versions, and his text must be of a mixed nature, and of less value in that respect, as well as in point of antiquity, than that of the Polyglott. Wheeloe, or rather Pierion, whose name is prefixed to the second title page, was of opinion, that this Parthian version was made from the Greek; but Renaudet believed it to have been taken from the Syriac. Walton mentions two Parthian versions of the Psalms, that were made in the 17th century from the vulgar Latin.

Bibles, Gothic. It is generally said, that Ulphilas, a Gothic bishop, who lived in the fourth century, made a version of the whole Bible, for the use of his countrymen. Philostorgius (Hist. Eccles. i. ii. c. 5) afferts, that Ulphilas omitted the book of Kings, from an apprehension, that the maternal spirit of his nation might be rooted by the relations of the Jewish wars; yet this opinion has been confuted by Knittel, in his learned commentary, § 255. Michaelis, who was once a strenuous advocate for the opinion, that this was a Frankish version, has since changed his mind, and in the last edition of his Int. to N. T. vol. ii. p. 130. ed. Marth, expresses his conviction, that it was Gothic. For an account of the author, see Ulphilas; and to the account already given of this version under the article Argenteus Codes, we shall here subjoin the following particulars. From the martyrology of Nicetas, preferred by Simeon Metaphrastes, it appears, that this version was made immediately from the Greek. Besides, independently of this evidence, it is natural to conclude, that a native Cappadocian, who was bishop of a nation in the neighbourhood of Constantinople, and was sent ambassador to the Greek emperor, would translate from the original Greek, with which he was much bet-
BIB

BIB

ter acquired than with the Latin version, from which some writers have erroneously supposed its version was taken. Moreover, from a passage quoted by Blenchi in the “Prolegomena,” to the first volume of his, “Evangeliarium quadruplex,” p. 8, from a MS. preferred at Brictia, containing the old Latin version of the Gospels, we may infer, that the Greek version was known in Italy, and that a diffucion was made between it and the Italian. Of this important version we have few remains. The principal of these are contained in the Codex Argenteus; which has the four Gospels, though not without considerable changes. It was first printed in Gothic letters, at Dort, in 1665, 4to.; and reprinted at Amsterdam, in 1684, (Michaels) and another edition was printed in Latin letters, at Stockhol, accompanied with the Ilandish, Swedish, and Latin vulgate. In 1750, it was printed at Oxford, by Lye, after the corrections and emendations of archbishop Benezel; and in 1752 and 1755, the learned Hare published two small essays, under the title of “Uphilas illustratus,” in which the erroneous passages of the former editions are correctly printed in Latin letters, accompanied with a Latin translation, and notes.

Bibles, Moscovites, Russian, or Slavonian. The Russian or Slavonian version was taken from the Greek by two brothers, Methodius and Cyril, natives of Thessalonica, and apostles of the Slavonians, who lived in the 9th century. According to the account given by Poletika, a learned person of Russia, and formerly Greek translator to the holy synod, in answer to inquiries proposed by Michaelis, it appears, that the holy synod ordered a complete copy of the Bible to be taken, in 1499, which is preferred in the library of that Synod; but from the same testimony it appears, that MSS. of the New Testament are extant from the 11th to the 14th century, some on vellum, others on paper, which are also preferred at Moscow, in the library of the holy synod. The oldest known edition is that of Prague, published by Francis Securin, in 1501; but Poletika is not certain whether it contains the whole Bible complete. It was revived in 1570, altered in several passages from an ancient MS. written in the title of the grand duke Vladimiro, given to Czarabunda, secretary to the duchy of Lithuania, and used in the edition of the Bible, printed at Olrog, in 1581, at the expense of Con. Basil, duke of Olrog, for the common service of all Christians who spoke the Slavonic language. Other editions were printed at Moscow, in 1603, 1751, 1756, 1757, and 1766, in folio, in 1759 in large 8vo, and in 1783, in 4to. It was also printed at Kiev, in 1758, folio; and at Supral in Poland, in small folio. A copy of the edition of 1581, and another of that of 1603, both which are scarce, are preferred in the university library of Gottingen. A particular edition of the Acts of the Apostles, and the Epistles, was printed in 1653. The passage 1 John v. 7, is found of their in the Olrog edition, the ancient MSS. nor in these editions of the Acts and Epistles, which are prior to 1653. That of 1653 contains it; that of 1603 has it in the margin, and that of 1751, and other modern editions, in the text. Poletika thinks this interpolation was made in the time of the patriarch Nicon, in 1653, when an edition was published of the Acts and Epistles. A very excellent description of the Slavonian version has been communicated to the public by Dubrowitsky, a very learned critic, in the “Neue Orientalische Bibliothek,” vol. vii. p. 153—167. From this work the following particulars, relating to this version, are extracted, by Marsh, in his edition of Michaelis’ notes to ch. vi. § 37. The Slavonian version is very literally translated from the Greek, the Greek construction being frequently retained where it is contrary to the genius of the Slavonian; and resembles, in general, the most ancient MSS. In the Gospels it agrees with the Codex Stephani more frequently than with any other Greek MS. In the catechical epistles it agrees, in general, with the Codex Alexandrinus, and frequently in the Revelation. In the Acts and in the Epistles, in the Paul, it agrees, in general, with the most ancient MSS., but sometimes with one, sometimes with another. It most frequently with Wetstein’s Codex E. Of the readings adopted by Griesbach in the text of his Greek Testament, the Slavonian version has at least three-fourths. Where the united evidence of ancient MSS. is against the common printed reading, the Slavonian version agrees with the ancient MSS. It has not been altered from the Vulgate, as some have supposed, though the fact is in itself almost incredible. It varies from the text of Theophylact, in as many instances as they agree: and their coincidence is to be ascribed, not to an alteration from Theophylact, but to the circumstances, that both Theophylact and the authors of the Slavonian version used the Greek edition. The Slavonian version has few or no readings peculiar to itself, or what the critics call “lectiones singulares.”

Bibles, Spanish. There are two translations of the Bible into this language; one done by the Jews, from the Hebrew, and first printed at Ferrara, in 1553, and at Amsterdam, in 1661; the other by Caiffodore Reina, printed at Basel, in 1599. A corrected edition of it was printed at Amsterdam, in 1622, and at Frankfort, in 1622. This translation was made from the Hebrew, or rather from the version of Pagninus, and the New Testament from the Greek. There is a translation of the N. T. in Spanish, done by Francisco Estpresin, and dedicated to Charles V., of which there are several editions; and another, yet different Spanish translation of the N. T. printed in 1546.

Bibles, Italian. There are four Italian versions: the first towards the clofe of the 13th century, by James de Voria, archbishop of Genoa, who translated the whole Bible into Italian, from the Vulgate; which ancient version is quite lost; the second by Bruciolus, in 1530, who translated the Bible from the Hebrew, or rather from the version of Pagninus, and dedicated it to Francis I. king of France; the third by Malherbi, a Venetian and Benedictine monk, abbot of St. Michael de Lemo, translated from the vulgar Latin towards the end of the 15th century; the first edition of which was published in 1471; one of them, in 1477, revived by friar Martin, a Dominican; and afterwards printed at Venice in 1541; and the 4th by Diodati, a Protestant, which is much esteemed, and has been often printed. This edition, which was conformable to the French edition of Geneva, was first published in 1607, and again a second time in 1614. The New Testament was translated by father Zachary, a Dominican friar of Florence, and printed apart at Venice, in 1542. An Italian edition of the Epistles and Gospels was printed in 1533.

Bibles, French. The most ancient translation of the Bible into French is that of Guiards de Moulins, a canon of St. Peter d’Aire, in the diocese of Tournaine, who was employed in translating the historical books of the O, and N. T. from the year 1291 till 1294. Of this translation there are several editions in the Paris library. Some historians affirm, that Charles V. king of France, caused the Bible to be translated into French by Nicholas Orimo, superior of the house of Navarre, and doctor of Paris. These, and some other translations of parts of the Bible, are extant in MS. in the Paris library. The first French Bible was printed by order of Charles VIII. and dedicated to him, and consequently before the year 1498; being the translation of Guiards de Moulins. The New Testament was printed in French by Colin, printer of Paris, in 1523. But the
the first edition of the whole Bible, translated from the vulgar text into French, was printed, in 1530, at Antwerp, by Martin Lempereur, with privilege from Charles V. The first edition of this Bible, in 1530, is in the Paris library; and the second, in 1531, which is larger, is extant in the libraries of St. Germain des Prez, and of St. Genevieve. These two editions precede that of Robert Olivetan, the first published by the Protestants, in 1535. The translation above-mentioned was printed the third time at Antwerp, in 1530, and is preferred in the Jefuits' library of the college of Levis le Grand. This translation was revised by the divines of Louvain, and was the foundation of all the French Bibles, since published either by the Catholics or Protestants. The first is that of Robert Olivetan, a.k.naman of Calvin, who has copied the Antwerp translation, and merely corrected such passages as differed from the Hebrew text. A new edition was given by Calvin, which comes nearer to the vulgar Latin 1 and of this Bible many editions were published between the years 1550 and 1561. In 1560 was published a new edition of the Bible, revised by Theodore Beza. In the following year another French translation of the Bible, from the Italian version of Diodati, was published, and held for some time in estimation by the Calvinists. In 1588, the Geneva translation was again corrected, and rendered more conformable to the Hebrew and Greek text. This was revised by M. de Dalmare, ministers of Groningen, and printed with notes at Amsterdam, in 1609. In the year 1555, Sebastian Calaholo published another French translation of the Bible from the Latin, the style of which is affected and obscure.

A reformation of the French Geneva Bible, by Renatus Benedict, professor of divinity in the college of Navarre, was published in 1566. This was condemned by a brief of Gregory XIII, in 1575. A new edition was undertaken some time after, altogether conformable to the Latin, and free from the errors of the Calvinists, by the doctors of Louvain, who followed the old Antwerp translation, and that of Olivetan, which they corrected: which was printed by privilege from the king of Spain, and under the sanction of the licence of the prelates at Antwerp, in 1578; at Lyons, in 1585; and in several other places. The unfavourable Bibles were for some time copies of the Louvain edition, with some corrections: such were that of Peter Beri, printed at Paris, in 1668, and that of Peter Frison, printed at Paris, in 1620. Corbin's Bible, printed in 1641, and approved by the doctors of Poitiers, recedes more than the rest from the Bible of Louvain, and adheres more closely to the literal sense of the text of the vulgar Latin. A new edition of the version of the doctors of Louvain, revised and corrected agreeably to the text of the ancient Vulgate, was published by father Veron, in 1647, and dedicated to the clergy of France. The translation of Abbot de Marolles, is done from the Greek text, or rather from the version of Erasmus, and was first published in 1469, again in 1633, and a third time in 1655. The edition of the N. T. called the edition of Mons, was published in 1667, under the name of Jasper Migent, printer at Mons. Father Abelt's translation of the N. T. was first printed at Paris, in 1666. God cann's translation was printed at Paris, in 1668. The whole Bible was also translated by Isaac de Maître, of Sax, from the Vulgate, and partly published in his life, and afterwards continued by Peter Thomas, lord of Fofe, in 1670. Quefeul's translation of the N. T. differs little from that of Mons; otherwise than by being more conformable to the vulgar Latin. Father Benhommes has also published a translation of the N. T. and many others have in later times translated either the whole or various parts of the Bible.

Bibles, German. Luther's translation of the Bible into German, was done with the affiance of Melanthon, and others of his disciples, the Old Testament from the Hebrew, and the New from the Greek, in 1524, and the publication of it, in several succeeding editions, very much contributed to the progress of the reformation. This was soon followed by a German translation by Jerom Emker, a catholic, who in his notes criticises that of Luther; and by another translation, done by John of Dietenbergh, from the vulgar Latin, in opposition to that of Luther. Luther's edition, reformed by the Zuinglians and Calvinists, in various editions, was published at Newaid in 1588, and at Herborn in 1595, to the dissatisfaction of the Lutherans. The German translation of Paul Eber, a Lutheran, was printed at Wittenberg in 1564; and German translations were also printed by Leon Juda, and John Picantor, both Calvinists. A new translation in German, by Jasper Ulenberg, a Catholic, not to mention many others, was printed at Cologn in 1650, and was much used in Germany.

Bibles, Flemish. The Catholics in the Netherlands had several Flemish translations of the Bible in the 16th century. One was printed in 1548, which was translated by Nicholas Van Winghe, who says that he followed a Flemish translation printed in Holland 70 years before, i.e. long before the reformation. This Bible was revised by the doctors of Louvain, and printed afterwards at Antwerp in 1599, and often since. The Protestants in the Low Countries had for a long time only a translation made after the German Bible of Luther, till in pursuance of an order issued by the synod of Dort, in 1618, they had a new translation printed in 1637, exactly conformable to the Hebrew text of the Old, and the Greek of the New Testament. The Armenians, dissatisfied with this, made another Dutch translation from the Greek, which was printed at Amsterdam in 1630.

The northern nations, who embraced the doctrines of Luther, have no other translations of the Bible besides those done in the vulgar tongue after the German of Luther. The Swedish translation was made by Laurence Petri, archbishop of Upsal, a disciple of Luther, and printed at Stockholm in 1646. The Danes have also one in their language, published first in 1524, and since revised and reprinted in 1635.

There is also a translation of the Bible in the Icelandic tongue, which some pretend to be the ancient language of the Norwegians or Goths, and another Finnish translation in 1648. The Lappish have also the Psalms, and some other books of the Bible, translated into their own language. In the Polich language, the Socinians have a Bible printed in 1653, and they have likewise a Polich Bible in Lithuania, printed in 1652, done from the Greek and Hebrew by Simon Budni. Sands also mentions a translation of the New Testament by Martin Cechovius, a Socinian, printed with notes in 1777. Pope Gregory XIII, employed the Jefuit Vicki to make a new translation of the Bible in the Polish language, which was printed at Cracow in 1599, with the approbation of Clement VIII. The Bohemians have a Bible in their language, with notes, printed in Germany from 1579 till 1601. The Hungarians have a translation done by George Caldi, a Jefuit, and printed at Vienna in 1626. They have also another more ancient, printed at Frankfort in 1638, and at Oppenheim in 1642.

Bibles, Indian. A translation of the Bible into the North American Indian language, by Elliott, was published in 1660, at Cambridge, in 1661.

Bibles, Saxan. After the Saxon inhabitants of this country were converted to Chriftianity, we have reason to believe that they soon had the whole Bible in the characters of their own country, and that the four Gospels in the

Vol. IV.
fame language were read in their religious affections. The whole scripture is said to have been translated into the Anglo-Saxon by Bede, about the year 701; though others contend that he only translated the Gospels; and others ascribe to him only the gospel of St. John.

We have certain books, or parts of the Bible, by several other translators; as 1. The Psalms, by Alcerv, bishop of Shireborn, contemporary with Bale, about the year 1665; though by others this version is attributed to King Alfred, who lived near two hundred years after, and who is said by Mr. Fox (ultra infra) to have translated both the Old and New Testament into his native language, and by others to have translated the greatest part of the New Testament: but the authority on which these affirmations is too precarious to claim any great degree of confidence. On equally uncertain authority it has been said, that the whole Bible was translated into the Saxon language in the reign of Athelstan. Bale, however, "Script. Brit. cen. 2. c. 27," cites the testimony of Malcolm for this purpose; and archbishop Usher refers this to the year 920. Some books of the Bible were translated by Eadred, or Egbert, bishop of Lindisfarne, about the year 680, according to the conjecture of Mr. Sel- den. A celebrated version of the four Gospels in the Saxon language, said to be made by one Alfred, a priest, is reported to have been found in the celebrated code of bishop Eadred. Adem is said to have written a letter to Eadred, extant in "Wharton's Aud. Hift. Dogm. Ufher," p. 351; in which he exhorts him, for the common benefit and use of all people, to put the scriptures into the vulgar language, which Butler, in his book against the vulgar translation, says he did. And archbishop Usher, in his "Hift. Dogm." c. 5 tells us, that the former translation of the Evangelists, done by Eadred, without distribution of chapters, was in the possession of Mr. Rob. Bower. In the Cotton library is a book of the four Gospels, said by Wharton, in his "Anglia Sacra," part i. p. 695, to be written by bishop Eadred himself, and which had been adorned with pictures, gold, and jewels, by Ethelwold, bishop of Winchester. Eadred, or Egbert, died in 721. But some have doubted the existence of such an Anglo-Saxon MS. A version of the Psalms in Anglo-Saxon was published by Spelman in 1640. 2. The Evangelists, extant done, from the ancient Vulgate, before it was revised by St. Jerome, by an author unknown, and published by Muth. Parker in 1671. This was printed from a MS. now in the Bodleian library, under the direction of the archbishop Parker, by John Fox the martyrologist, with the following title, "The Gospels of the four Evangelists, translated in the olde Saxons' tyme out of the Latin into the vulgar tongue of the Saxons, and now published for telumonic of the same," at London, by John Daye, 1571. This edition has a preface by John Fox, and is dedicated to queen Elizabeth. Another edition of this version was published at Dort in 1665, by Dr. Thomas Marshall, who tells us that he could ascertain neither its author nor age. An old Saxon version of several books of the Bible, was made by Elfric, abbot of Malmesbury, and afterward, viz. in 965, archbishop of Canterbury; several fragments of it were published by Will. Lilly, or W. L'Ifle, in 1638, the genuine copy by Ead. Thwaites, in 1699, at Oxford.

Wm. L'Ifle observes, on occasion of this publication, that "if that good ordinance first created by God," Deut. x. 5, for the preservation of the book of the law, by keeping a copy of it in the a.k., had been continued, and standard Bibles had been preferred in our cathedral churches, as it has been since appointed by king Alfred, we might now have shewed the whole book of God, or the entire Old and New Testament in Saxon, which was the English of those times, translated both by that king, and the archbishop of Canterbury, Elfric. Elfric translated the Pentateuch, Job, Judges, Ruth, four books of Samuel, entitled in Latin, liber regum, a fifth book called Verba Dierum, or Chronicles, the Psalter, three books of Solomon, viz. Proverbs, Ezechiel, the chief of all fongs, the books of Wisdom and Ecclesiastes, the prophets Th., Jerem., Ezekiel, Daniel, the Prophets, Ezra, Job, Tobin, Esther, Judith, and Maccebees. Hence we may conclude, with little doubt, that the books of the Testament were before translated into Saxon, and commonly read in that language. The Pentateuch, Job, and Judges, of Elric's translation, are preserved, says Usher, in Cotton's library; where is also a Psalter, with several hymns of the Old and New Testament, with the Apostles' and Athanasian creed, with an English interlinear translation. The book appears, by a note at the end of it, to have been written in the year 1649. The Anglo-Saxon version, above-mentioned, is divided into sections, over each of which is placed a rubric, directing when it should be read; and this circumstance knew, that at this time the Holy Scriptures were read in the public service of the church in a language which the people understood. Various readings from this version of the four Gospels were first quoted by Mill (Proleg. § 1462), who took them from the papers of Marshall. With respect to its antiquity, the learned are not agreed: some have referred it to the fifth or seventh century, since Bede died A.D. 735; but others, more generally, to some part of the eighth century. For an account of the MSS. of the Anglo-Saxon version, see Le Long, Bib. Sacr. tom. i. p. 422, 423, ed. 1735; and for a complete cata-logue of Anglo-Saxon MSS., in general, Wanley's Appendix to Hicken's Thesaurus, published at Oxford in 1755, folio. Lewis's Hift. Eng. Transl. of the Bible, p. 5, &c.

Bibles, English. The first English Bible we read of was that translated by J. Wickliffe, about the year 1370, according to some, and 1380, according to others; but never printed, though there are MS. copies of it in several public and private libraries. The MS. of the Old Testament, ending with the second book of the Maccabees, in St. John's college Oxford, is said to have been written by Wickliffe himself. This translation, though expressed on the top of the leaf before Genesis, is very doubtful. This translation was made from the Latin Bibles then in common use, not be-cause Wickliffe thought the Latin to be the original, or of the same authority with the Hebrew and Greek text, but because he did not understand those languages well enough to translate from them. He likewise chose to translate word for word, as had been before done in the Anglo-Saxon transla-tion, without observing the idiom of the several languages, so that this translation is in some places not very intelligible to those who do not understand Latin. Before the invention of printing, transcripts were obtained with difficulty, and copies were so rare, that the price of one of Wickliffe's twelve English New Testaments appears, from the regality of Wil-liam Alnewich, bishop of Norwich, in 1429, to have been four marks and forty pence, or 2l. 16s. 8d. This translation gave such offence, that a bill was brought into the House of Lords, 15 Ric. II. A.D. 1530, for suppressing it. But by the opposition of the duke of Lancaster, the king's uncle, the bill was thrown out of the house. Wickliffe's followers were encouraged, by this favourable circumstance, to revive the translation of their master, or rather to make another not so literal and verbal, but more free and accommodated to the sense. The MS. copies of this translation are more rare than those of the other; but they are found in the Bodleian library, and in other libraries both of Oxford and Cambridge. J. de Trevifs, vicar of Berkley in Gloucestershire, who died about
about the year 1530, is also said to have translated the whole Bible; but if this be true, it does not appear that any copies of his translation are now remaining. It is probable, that Treviss merely translated certain sentences of the Bible, that occur in his writings, and some of which are said to have been painted upon the walls of the chapel in Berkley castle. Another English translation has been erroneously ascribed to Reginald Pecock, bishop of Chichester, A.D. 1522; in consequence of his having translated some passages of scripture, cited in his works. Richard Fitz-Ralph, archbishop of Armagh, is said to have translated the Bible into Irish. He died in 1520. Dr. James, relying on a vague declaration of Sir Thomas More, in his account of the continuations of Arundel, affirms, that the Bible has been twice translated into English; and that one of these translations is much more ancient (some hundred years) than Wickliffe's. But Lewis has shown this to be a mistake. (Hill. Eng. Trans. p. 44.)

The zealots of those times were alarmed by these English translations; and in order to prevent their misuse, they urged the necessity of restoring the use of Latin Bibles; and to this purpose Chaucer represents the religious as collecting and depositing them in their libraries, and thus withdrawing them from secular priests and curates, and thus hindering them from preaching the gospel to the people. In 1537, when some secular priests were lent from the diocese of Armagh in Ireland, to study divinity at Oxford, they were obliged soon to return, because they were not able to purchase a Bible. Eneas Sylvius, afterwards pope Pius II, obsevered in 1548, concerning the Italian priests, that they did not seem to have ever so much as read the New Testament; and Robert Stephens, speaking of the Sorbonists, says, that when they are asked in what place of the New Testament anything was written, they replied, that they had read it in Jerum, or in the Decrees, but what the New Testament was they did not know. (See Holy de Bible. Textibus, p. 454.) Indeed, at that time, if copies of the Bible had been more frequent, the clergy were generally so ignorant as not to be able to read or understand Latin. The Latin Bibles were not only scarce, but much corrupted by the carelessness of transcribers, and the interference of presumptuous critics. In 1537, Wickliffe's followers were become so numerous, and copies of his English translation of the New Testament so common, that an English Bible was sold for 20s., whereas the price of a portuine, or breviary, was 6 marks. After the art of printing was introduced into England, Latin, Hebrew, and Greek Bibles, and particularly copies of the New Testament, became much more common; and accordingly a vicar of Croydon in Surrey, is said to have expressed himself to this purpose, in a sermon preached at Paul's Cross about this time: "We must root out printing, or printing will root us out."

Bible, Tindal's. For the first printed English translation of the scriptures we are indebted to William Tindal, who, having formed a design of translating the New Testament from the original Greek into English, removed to Antwerp in Flanders, for this purpose. Here, with the assistance of the learned John Try, or Fryth, burnt for heresy in Smithfield, in 1552, and a friar, called William Roys, who suffered death on the same account in Portugal, he finished it, and in the year 1526, it was printed either at Antwerp or Hamburgh, without a name, in a middle sized 8vo. volume, and without either calendar, concordances in the margin, or table at the end. Tindal annexed a pillic at the clofe of it, in which he "defied them that were leamed to amend if ought were found amifs." Le Long calls this "the New Testament translated into English, from the German version of Luther." But for this degrading application he seems to have too much authority besides a story related by one Caschius (in Adelis Martiani Lutheri ad an. 1526, p. 152), with a view of depreciating Tindal's translation. Many copies of this translation found their way into England; and to prevent their dissemination among the people, and the more effectually to enforce the prohibition enacted in all the decrees against reading them, Tindall, bishop of London, purchased all the remaining copies of this edition, and all which he could collect from private hands, and committed them to the flames at St. Paul's cross. The first impressions of Tindal's translation being thus disposed of, several other numerous editions were published in Holland, before the year 1530, in which Tindal seems to have had no interest, but which formed a ready sale, and those which were imported into England, were ordered to be burned. On one of these occasions, Sir Thomas More, who was then chancellor, and who occurred with the bishop in the execution of this measure, enquired of a person, who was accursed of heresy, and to whom he promised indemnity on confideration of an explicit and fait faftory answer, how Tindal fled abroad, and who were the persons in London, that abetted and supported him; to which inquiry the heretical convert replied, "It was the bishop of London who maintained him, by lending him a sum of money to buy up the impression of his Testament." The chancellor replied, admitted the truth of the declaration, and suffered the accused person to escape. The people formed a very unfavourable opinion of those who ordered the word of God to be burned, and concluded, that there must be an obvious repugnance between the New Testament and the doctrines of those who treated it with this indignity. Those who were suspected of importing and conciliating any of these books, were adjudged by Sir T. More to ride with their faces to the tails of their horses, with papers on their heads, and the New Testaments, and other books which they had dispersed, hung about their cloaks, and at the standard in Cheapside to throw them into a fire prepared for that purpose, and to be fixed at the king's pleasure.

When Tindal's purchase served only to benefit, Tindal, and those who were employed in printing and selling successive editions of his Testament, and other measures for restraining their dissemination seemed to have little or no effect, the pen of the witty, eloquent, and learned Sir Thomas More, was employed against the translator; and the bishop granted him a licence, or faculty, dated March 7, 1527, to have and to read the several books which Tindal and others published; and at his desire Sir Thomas composed a dialogue, written with much humour, and designed to expose Tindal's translation, which was published in 1530. In this dialogue he alleges, among other charges, that Tindal had translated three words of great importance, viz. the words 'priests,' 'church,' and 'charity,' calling the first fems, the second congregation, and the third love. He also charges him with changing commonly the term grace into faviour, confusion into knowledge, penance into repentance, and a contrite heart into a troubled heart. The bishop of London had, indeed, in a sermon, declared, that he had found in it no less than 2000 errors, or mistranslations; and Sir Thomas More discovered above 1000 texts by tale, falsely translated. In 1532, a royal proclamation was issued, by the advice of the prelates and clerks, and of the universities, for totally suppressing the translation of the scripture, corrupted by William Tindal. The proclamation set forth, that it was not necessary to have the scriptures in the English tongue, and in the hands of the common people;
people; that the distribution of them, as to allowing or denying it, depended on the discretion of their superiors; and that, considering the malignity of the time, an English translation of the Bible would rather occasion the continuance, or increase of errors, than any benefit to their souls. However, the proclamation announced the king's intention, if the present translation were abandoned, at a proper season, to provide that the Holy Scriptures should be by great, learned, and catholic persons, translated into the English tongue, if it should then seem convenient. In the mean time, Tindal was chiefly employed in translating from the Hebrew into the English the five books of Moses, in which he was assisted by Miles Coverdale. But his papers being lost by shipwreck in his voyage to Hamburgh, where he designed to print it, a delay occurred, and it was not put to press till the year 1532. It is a manuscript dedicated at different presses, and with different types. In the preface he complained, that there was not so much as one in his New Testament, if it lacked a little over its head, but it had been noted, and numbered to the ignorant people for an heresy, who were made to believe, that there were many thousand heretics in it, and that it was so faulty as to be incapable of amendment or correction. In this year he published an answer to Sir Thomas More's dialogue, containing his reasons for the changes which he had introduced into the translation. The three former editions of Tindal's English New Testament being all sold out, the Dutch bookellers printed a fourth in this year, in a smaller volume and letter. In 1531, Tindal published an English version of the prophet Jonah, with a prologue, full of invective against the church of Rome. Strype supposes that before his death he finished all the Bible but the Apocalypse, which was translated by Rogers; but it seems more probable that he translated only the historical parts. In 1534, was published a fourth Dutch edition, or the fifth in all, of Tindal's New Testament, in 12mo. In this same year, Tindal printed his own edition of the New Testament in English, which he had diligently revised and corrected; to which is prefixed a prologue; and at the end are the pills of the Old Testament, closing with the following advertisement, "Imprinted at Antwerp, by Marten Empour, anno M.D. XXXIV." Another edition was published this year, in 16to, and printed in a German letter. Hall says, in his Chronicle, printed during the reign of Henry VIII. by Richard Grafton, the benefactor and friend of Tindal. 

"William Tindal translated the New Testament, and first put it into print; and he likewise translated the five books of Moses, Joshua, Judicum, Ruth, the books of Kings, and books of Paralipomenon, Nehemiah, and the first of Eldras, and the prophet Jonas; and no more of the Holy Scriptures." Upon his return to Antwerp, in 1532, king Henry VIII. and his council, contrived means to have him seized and imprisoned. After long confinement he was condemned to death by the emperor's decree in an assembly at Augsburg; and in 1536, he was strangled at Vellefort, near Brussells, the place of his imprisonment, after which his body was reduced to ashes. He expired, praying repeatedly and earnestly, "Lord, open the king of England's eyes." Several editions of his Testament were printed in the year of his death. Tindal had little or no skill in the Hebrew, and therefore he probably translated the Old Testament from the Latin. The knowledge of languages was in its infancy; nor was our English tongue arrived at that degree of improvement, which it has since attained; it is not, therefore, surprizing, that there should be many faults in this translation which need amendment. This, indeed, was a talk, not for a single person, but requiring the concurrence of many, in circumstances much more favourable for the execution of it than those of an exile. Nevertheless, although this translation is far from being perfect, few first translations, says Dr. Gellaeus (Prospectus, p. 88.), will be found preferable to it. It is astonishing, says this writer, how little obsolete the language of it is, even at this day; and in point of peripety, and noble simplicity, propriety of idiom, and purity of style, no English version has yet surpassed it.

Bible. Coverdale's. In 1535 the whole Bible, translated into English, was printed in folio, and dedicated to the king by Miles Coverdale, a man greatly esteemed for piety, knowledge of the scriptures, and diligent preaching; on account of which qualities king Edward VI. advanced him to the see of Exeter. In his dedication and preface, he observes to this purpose, that, as to the present translation, it was neither his labour nor his desire to have this work put into his hand; but when others were moved by the Holy Ghost to undertake the cost of it, he was the more bold to engage in the execution of it. Agreeably, therefore, to desire, he set forth this "special" translation, not in contempt of other men's translations, or by way of reproving them, but humbly and faithfully following his interpreters, and that under correction. Of these, he said, he used five different ones, who had translated the scriptures not only into Latin, but also into Dutch. He further declared, that he had neither wrested nor altered so much as one word for the maintenance of any manner of sect, but had with a clear conscience purely and faithfully translated out of the foregoing interpreters, having only before his eyes the manifest truth of the scripture. But because such different translations, he said, were apt to offend weak minds, he added, that there came more understanding and knowledge of the scripture by these fundy translations, than by all the glosses of sophistical doctors; and he therefore desires, that offence might not be taken, because one translated "scribe," and another "lawyer," one "repentance," and another "penance," or "amendment." This is the first English Bible allowed by royal authority; and also the first translation of the whole Bible printed in our language. It was called a "special" translation, because it was different from the former English translations; as Lewis has shewn (Hill, Eng. Transl. p. 98,) by comparing it with Tindal's. It is divided into six volumes, adorned with wooden cuts, and furnished with scripture references in the margin. The last page has these words: "Printed in the yeare of our Lorde M.D. XXXV. and latned the fourth day of October." Of this Bible there was another edition in a large folio in 1550, which was re-published, with a new title, 1553; and these, according to Lewis, were all the editions of it. Coverdale, in this edition of the English Bible, prefixed to every book the contents of the several chapters, and not to the particular chapters, which was afterwards the case; and he likewise omitted all Tindal's prologues and notes. Soon after this Bible was finished, in 1536, lord Cromwell, keeper of the privy-seal, and the king's vicar-general and vicegerent in ecclesiastical matters, published injunctions to the clergy by the king's authority, the seventh of which was, that every parson, or proprietary of any parish church within this realm, should, before the 1st of August, provide a book of the whole Bible, both in Latin and in English, and lay it in the choir, for every man that would to look and read therein; and should discourage no man from reading any part of the Bible either in Latin or English, but rather comfort, exhort, and admonish every man, to read it, as the very word of God, and the spiritual food of a man's soul, &c.

Bible, Matthew's. Matthew's. In 1537, another edition of the English Bible was printed by Grafton and Whit-
Whitechurch, at Hamburgh, as some think, or, as others feppofe, at Malburow, or Marpurg in Helfo, or Marbeck in the duchy of Wutenberg, where Rogers was superintendant. It bore the name of Thomas Matthew, and it was set forth with the king's most gracious licence. Mr. Wanley is of opinion, that, to the end of the book of Chronicles, this edition is Tindal's translation; but from thence to the end of the apocrypha, Coverdale's: but Lewis (p. 107.) thinks it probable that the prologue of Jonah should be excepted, which Tindal finished in his lifetime, and which is the same in this edition, and in Coverdale's Bible of 1535. Mr. Wanley also observed, that the whole New Testament was Tindal's. Dale says, Rogers translated the Bible into English, from Genesis to the end of Revelation, making use of the Hebrew, Greek, Latin, German, and English (i.e. Tindal's) copies. This book contained Tindal's prologue and notes; and, as Heylin says (Hist. Ref. fol. 20.), it was no other than the translation of Tindal and Coverdale somewhat altered. The name of Matthew is allowed to have been fictitious, for reasons of prudence; one of which was, that the memory of Tindal had become odious to many. It may well be admitted, that John Rogers, a learned academic, and the first who was condemned to the flames in the reign of queen Mary, was employed by Cranmer to superintend this edition, and to furnish the few emendations and additions that were thought necessary. This must have been the general permission in 1535; as the condemning sentence preferred by Fox (Acts, &c. vol. iii. 125.), is "against Rogers, priest, alias called Matthew." Cranmer presented a copy of this book to lord Cromwell, deferring his interference with the king for the royal licence, that it might be purchased and used by all. There are exact two letters (Strype's Life of Cranmer, p. 58.) from the archbishop, on the subject of lord Cromwell's interference, expressing warm approbation and acknowledgement. "I doubt not," says he, "but that hereby such fruit of good knowledge shall ensue, that it shall well appear hereafter what high and excellent service you have done unto God and the king; which shall so much redound to your honour, that, besides God's reward, you shall obtain perpetual memory for the same within this realm."—"This deed you shall hear of at the great day, when all things shall be opened and made manifest." In the year 1538, an injunction was published by the vicar-general of the kingdom, ordaining the clergy to provide, before a certain festival, one book of the whole Bible, of the largest volume in English, and to let it up in some convenient place within their churches, where their parishioners might most commodiously resort to read it. A royal declaration was also published, which the curates were to read in their several churches, informing the people, that it had pleased the king's majesty to permit and command the Bible, being translated into their mother-tongue, to be sincerely taught by them, and to be openly and candidly read in every parish church. But the curates were very cold in this affair (says Lewis, p. 168.), and read the king's injunctions and declarations in such a manner, that scarcely any body could know or understand what they read. Johnian (Hist. Account, &c. in bishop Watton's Collection, p. 94.) adds, that they also read the word of God confusedly; and that they bade their parishioners, notwithstanding what they read, which they were compelled to read, "to do as they did in times past, and to live as their fathers, the old fashion being the best." Fox observes (Acts, &c. vol. iii. 516.), that the setting forth of this book much offended Gardiner and his fellow bishops, both for the prologues, and especially because there was a table in the book chiefly about the Lord's supper, the marriage of priests, and the mafs, which there was fid not to be found in scripture. Strype, however, says, (Life of Cranmer, p. 64.), it was wonderful to see with what joy this book was received, not only among the more learned, and those who were noted lovers of the reformation, but generally all over England, among all the common people; and with what greediness God's word was read, and what refreshment there was to the places appointed for reading it. Every one that could, bought the book, and hastily read it, or heard it read; and many elderly persons learned to read on purpose. During a vacancy in the see of Hereford, it was visited by Cranmer, who enjoined the clergy to procure, by the 11th of Augilt, a whole Bible in Latin and English, or, at least, a New Testament in these languages; to study every day one chapter of these books, conferring the Latin and English together, from the beginning to the end; and not to discourage any layman from reading them, but encourage them to it, and to read them for the reformation of their lives and knowledge of their duty. In the course of the year 1538, a quarto edition of the New Testament, in the vulgate Latin, and Coverdale's English, bearing the name of Hollyboufe, was printed, with the king's licence, by James Nicolson. Of this another more correct edition was published in 1539, in 8vo., and dedicated to lord Cromwell. In 1538, an edition in 4to. of the New Testament, in English, with Erasmus's Latin translation, was printed, with the king's licence, by Redman. In this year it was resolved to revise Matthew's Bible, and to print a correct edition of it. With this view Grafton went to France, where the workmen were more skillful, and the paper was both better and cheaper than in England, and obtained permission from Francis I. at the request of king Henry VIII. to print his Bible at Paris. But, notwithstanding the royal licence, the Inquisition interfered, and robbed the work of all its beauty; and the impulsion, confiling of 2500 copies, was seized, confiscated, and condemned to the flames. Some copies, however, of these books, escaped the fire, by the care of those who were appointed to superintend the burning of them; and the English proctors, who had fled on the first alarm, returned to Paris as soon as it subsided, and not only recovered some of these books, but brought with them to London the preces, types, and printers, and, refuming the work, finished it in the following year.

Bible, Cranmer's, or the Great. As soon as the papal power was abolished in England, and the king's supremacy settled by parliament in 1534, Cranmer was very ambitious in promoting translations of the Holy Scriptures into the vulgar tongue; well knowing how much the progress of the reformation depended upon this measure. Accordingly, he moved in convocation, that a petition should be presented to the king for leave to procure a new translation of the Bible. This motion was vigorously opposed by Gardiner, bishop of Winchester, and his party; but Cranmer prevailed. The arguments for a new translation, urged by Cranmer, and enforced by queen Anne Bullen, who had then great interest in the king's affections, were so much considered by him, that, notwithstanding the opposition, public and private, on the part of Gardiner and his adherents, Henry gave orders for setting about it immediately. To prevent any revocation of the order, Cranmer, whose mind was intent on introducing a free use of the English Scriptures by faithful and able translators, proceeded without delay to divide an old English translation of the New Testament into
nine or ten parts, which he caused to be transcribed into paper-books, and to be distributed among the most learned bishops, and other such requiring that they would perfectly correct their respective parishes, and return them to him at a limited time. When the appointed day came, every man sent his appropriate portion to Lambeth, except Stokesley, bishop of London. This laudable design of the archbishop failed; but the business was executed by other persons, whom he counseled and encouraged, as we have already stated in the preceding pages. In April 1539, Grafton and Whitchurch printed the Bible (called the "Great Bible") in large folio, "cum privilegio ad impressum folum." A beautiful frontispiece, designed by Holben, and particularly described and exhibited in an engraving by Lewis, p. 122, &c. was prefixed to it: and in the text, those parts of the Latin version, which are not found in the Hebrew or Greek, are inserted in a smaller letter; such, for instance, as the three verses of the 14th psalm, which are the 5th, 6th, and 7th, in the translation of the English language, and the controvcrsed words, 1 John v. 7, 8, 11, and a mark is used to denote a difference of reading between the Hebrew and Chaldee, afterwards explained in a separate treatise. In this edition Matthew's Bible was revised, and several alterations and corrections were made in the translation, especially in the book of Psalms. Tindal's prefaces and notes, and the notes added by others, in the edition of 1537, were wholly omitted. Pointing hands, placed in the margin and in the text, shew the passages on which the notes were to have been written. Johnson (ubi supra, p. 76.) calls this third edition of the Scriptures the Bible in the large or great volume, attributes it to the year 1539, and supposed it to have been the same which Grafton obtained leave to print at Paris. He says, that Miles Coverdale compared the translation with the Hebrew, mended it in many places, and was the chief director of the work. Agreeably to this, Coverdale, in a letter to Paul's crofs, defended his translation from some scandalous reports which were then railed against it, confessing "that he himself now saw some faults, which, if he might review the book once again, as he had twice before, he doubted not he should amend; but for any heresy, he was sure that there was none maintained in his translation." This is related by Dr. Tulk, who was one of Coverdale's auditors. A second edition of this Bible seems to have been printed either this or the next year, by Edward Whitchurch; but the copy is imperfect, and has no date.

In the course of the year 1539, another Bible was printed by John Ryddell, called "Taverner's Bible," from the name of its conductor, Richard Taverner, who was educated at Christchurch, Oxford, patronized by lord Cromwell, and probably encouraged by him to undertake the work, on account of his skill in the Greek tongue. This is neither a bare re-vision of the English Bible, but described, nor a new version; but a kind of intermediate work, being a correction of what is called "Matthew's Bible," many of whose marginal notes are adopted, and many omitted, and others inserted by the editors. It is dedicated to the king. After his patron's death, Taverner was imprisoned in the Tower for this work: but he had the address to re-ignite himself in the king's favour. Wood (Hist. et Ant. Univ. Oxon. fol. 1674, l. ii. p. 264.) gives a particular account of Taverner; attributes his imprisonment to the influence of those bishops who were attached to the Romish religion; and informs us, that his version was read in churches by royal authority; in November 1539, the king, at the intercession of Cranmer, appointed lord Cromwell to take special care that no person, within the realm, should attempt to print any English Bible for five years, but such as should be admitted by lord Cromwell; and affirms this reason for the prohibition, that the Bible should be considered and perused in one translation, in order to avoid the manifold inconveniences to which human frailty might be subject from a diversity of translations, and the ill use that might be made of it. In the year 1539, two privileged editions of the Bible, which had been printed in the preceding year, issued from the press of Edward Whitechurch. Lewis mentions three other impressions of the "Great Bible," which appeared in the course of this year; two printed by Whitchurch, and one by Petyt and Redman. Cranmer wrote a preface for the editions of the year 1539, from which we learn the opinions and practice of those times. In May of this year, the curates and parishioners of every parish were required, by royal proclamation, to provide themselves with the Bible of the largest volume before the feast of All-Saints, under the penalty of 50s. for every month during which they should be without it. The king charged all ordinaries to enforce the observance of this proclamation; and he apprized the people, that his allowing them the Scriptures in their mother-tongue was not his duty, but an evidence of his goodness and liberality to them, of which he exhorted them not to make any ill use. In May 1539, one edition of Cranmer's Bible was finished by Richard Grafton; who, in the November following, completed also another Bible of the largest volume, which was superintended, at the king's command, by Tonftal, bishop of Durham, and Heath, bishop of Rochester.

In consequence of the king's settled judgment, "that his subjects should be nursed in Christ by reading the Scriptures," he again, on the 7th of May, published a brief, or decree, for setting up the Bible of the great volume in every parish church throughout England. However, this decree appears to have been very partially and reluctantly observed; and the bishops were charged, by a writer in 1540, with attempting to suppress the Bible, under pretence of preparing a version of it for publication within seven years. After the death of Cromwell in 1540, the bishops inclined to popery gained strength; and the English translation was represented to the king as very erroneous and heretical, and destructive of the harmony and peace of the kingdom. In the convocation, assembled in Feb. 1542, the archbishop, in the king's name, required the bishops and clergy to revise the translation of the New Testament, which, for that purpose, was divided into fourteen parts, and portioned out to fifteen bishops; the Apocalypse, on account of its difficulty, being assigned to two. Gardiner clogged this business with embarrassing instructions; and Cranmer clearly perceiving the resolution of the bishops to defeat the proposed translation, procured the king's consent to refer the matter to the two universities, against which the bishops protested; but the archbishop declared his purpose to adhere to the will of the king his master. With this contest the business terminated; and the convocation soon after dissolved. The Romish party prevailed also in parliament, which enacted a law that condemned and abolished Tindal's translation, and allowed other translations to remain in force, under certain restrictions. After the passing of this act, Grafton, the king's printer, was imprisoned; nor was he released without giving a bond of 300l. neither to print nor sell any more English Bibles, till the king and the clergy should agree on a translation. In 1544, the Pentateuch was printed by John Day and William Sires; and in 1546, the king prohibited by proclamation having and reading Wickliffe's, Tindal's, and Coverdale's translations, and forbade the use of any other than what was allowed by parliament.
liament. From the history of English translations, during the reign of Henry VIII, we learn, that the friends to the reformation conducted themselves with zeal and prudence in the great work of introducing and improving English translations of the Bible; that they encountered many difficulties from the dangerous insolvency of a despotic prince, and from the inconstant prejudices of a Jacobin party; and that the English scriptures were fought after and read with avidity by the bulk of the people.

Upon the accession of Edward VI, the fierce stat. 32 & 35 Henry VIII. c. 1. was repealed, and a royal injunction was issued, that not only the whole English Bible should be placed in churches, but also the paraphrase of Erasmus in English to the end of the four Evangelists. It was likewise ordered by this injunction, that every parson, vicar, curate, &c. under the degree of a bachelor of divinity, should profess the New Testament, both in Latin and English, with the paraphrase of Erasmus upon it; and that the bishops, &c. in their visitations and synods should examine them, how they had profited in the study of the Holy Scriptures. It was also appointed, that the epistle and gospel of the mass should be read in English; and that on every Sunday and holiday, one chapter of the New Testament in English should be plainly and distinctly read at matins, and one chapter of the Old Testament at evensong. But in the year 1549, when the book of common prayer, &c. was finished, what nearly resembles our present common version was enjoined, that after reading the Psalms in order at morning and evening prayer, two lessons, the first from the Old Testament, and the second from the New Testament, should be read distinctly with a loud voice. During the course of this reign, that is, in less than 7 years and 6 months, eleven imprentions of the whole English Bible were published, and six of the English New Testament; besides an English translation of the whole New Testament, paraphrased by Erasmus. The Bibles were reprinted, according to the preceding editions, whether Tindal's, Coverdale's, Matthew's, Cranmer's, or Taverner's; that is, with a different text, and different notes. But it is doubted by the writer of the preface to king James's translation, whether there were any translation, or correction of a translation, in the course of this reign.

In 1552, the "Great Bible," viz. that of Coverdale's translation, that had been printed in the time of Henry VIII. and also in the time of king Edward, was reviewed by archbishop Parker, and reprinted for the use of the church; and this was to serve till that projected by his grace was ready for publication. See Bishop's Bible.

Bible, Geneva. Many of the principal reformers having been driven to Geneva during the persecutions of queen Mary's reign, they published, in 1557, an English New Testament, printed by Conrad Bodius; the first in our language which contained the divisions of verses by numerical figures, after the manner of the Greek Testament, which had been published by Robert Stephens in 1551. R. Stephens, indeed, published his figures in the margin; whereas the Geneva editors prefixed theirs to the beginning of minute subdivisions with breaks, after our present manner. When queen Elizabeth passed through London from the Tower to her coronation, a pageant was erected in Cheapside, representing time coming out of a cave, and leading a perfon clothed in white, who represented Truth, her daughter. Truth had the English Bible in her hand, on which was written "Verbum veritatis." Truth addressed the queen, and presented her with the book. She kissed it, held it in her hands, laid it on her breast, greatly thanked the city for their present, and added, that she would often and diligently read it. Upon a royal visitation in 1559, the Bible and Erasmus's paraphrase, were referred to churches; and articles of enquiry were exhibited whether the clergy discouraged any from reading any part of the scriptures. "Ministers were also enjoined to read every day one chapter of the Bible; and at least 15 in number, were allotted to select men of learning and abilities, appointed, as Fac-sfaus, by the queen's command; and, accordingly, at the conclusion of each part, the edition of 1562 has the initial letters of each man's name to the end of the first epistle to the Corinthians; e.g. at the end of the Pentateuch,

W. E.
W. E. for William, bishop of Exeter, whose allotment ended there; at the end of Ruth, R. M. for Richard Menevius, or bishop of St. David's, to whom pertained the second allotment; and so of the rest. But it still remains uncertain, who, and whether one or more, reviled the rest of the N. T. Eight of the persons employed were bishops; whence the book was called the "Bishop's Bible," and the "Great English Bible." The archbishop employed other critics to compare this Bible with the original languages, and with the former translations; one of whom was Laurence, a man famous in those times for his knowledge of Greek, who first collatig the bishop's Bible followed exactly. His grace also sent instructions concerning the method which his translators were to observe; and recommended the addition of some short marginal notes, for the illustration or correction of the text. But the particulars of these instructions are not known. The archbishop, however, directed, reviewed, and fulfilled the whole; which was printed and published in 1568, in a large folio, and with a beautiful English letter, on royal paper; and embellished with several cuts of the most remarkable things in the O. and N. T. and Apocrypha, maps cut in wood, and other draughts engraved on copper. It has many marginal references and notes, and many useful tables. It has numerous interjections between brackets, and in a smaller character; which are equivalent to the italics afterwards used by James's translators. Dr. Goddes is of opinion, (Letter to the Bishop of London, p. 33.) that italic supplements were first used by Arians Montanists, who died in 1598. The several additions from the vulgar Latin, inserted in the "Great Bible," are omitted; and verse 7 of 1 John v, which was before distinguished by its being printed in a different letter, is here printed without any distinction; and the chapters are divided into verses. In the following year, 1569, it was again published in large 8vo. for the use of private families. This Bible was reprinted in 1572, in large folio, with several corrections and amendments, and several prologomena; this is called "Matthew Parker's Bible." With regard to this Bible, Lewis (p. 61.) observes, that the editions of it are mortly in folio and 4to., and that he never heard but of one in 8vo.; for which he supposes this to be the reason, that it was principally prefixed for the use of churches. In the convocation of the province of Canterbury, which met in April, 1571, a canon was made, enjoining the church-wards to see, that the Holy Bible be in every church in the largest volumes, if convenient; and it was likewise ordered, that every archbishop and bishop, every dean and chief rectiatory, and every archdeacon, should have one of these Bibles in their cathedrals and families. This translation was used in the churches for forty years; though the Geneva Bible was more read in private houses. For king James's opinion of it, see King James's Bible.

**Bible, Rheims.—**After the translation of the Bible by the bishops, two other private versions had been made of the New Testament, the first by Laur. Tomson, under-secretary to Sir Francis Walsingham, made from Beza's Latin, printed together with the notes of Beza, published in 1576, in 8vo. and afterwards in 1599, varying very little from the Geneva Bible; the second, by the papists at Rheims, in 1582, in 4to. called the "Rheims Bible," or "Rheims Testament." Those finding it impossible to keep the people from having the scriptures in the vulgar tongue, resolved to give a version of their own, as favourable to their cause as might be. It was printed on a large paper, with a fair letter and margin. One complaint against it was, its being translated from the vulgate Latin, and retaining a multitude of Hebrew and Greek words untranslated, for want, as the editors express it, of proper and adequate terms in the English to render them by; as the words *asympt, tunker, rational, holocaust*, *prepunct, passekle,* &c. whence Fuller called it, in his quaint manner, "a translation which needed to be translated," and Fuller says that "by all means they laboured to suppress the light of truth under one pretence or other." They added large annotations, to flew, as they say, the modern reader, in molt places pertaining to the controversies of those times, both the heretical corruptions, and false deductions, and also the apostolic traditions, the explications of the holy fathers, the decrees of the Catholic church, and most ancient councils. Some have said, that it was printed in a most cobby manner, in order to put it out of the power of common people to purchase it; but if any of the laity secretly procured one of these Rheims Testaments, he durst not own that he had read it, without previously obtaining from his superior a licence for this purpose. Many of the copies were seized by the queen's searchers, and confiscated; and Th. Cartwright was solicited by secretary Walsingham to refute it; but, after a good progress made therein, archbishop Whitgift prohibited his farther proceedings therein, as judging it improper the doctrine of the church of England should be committed to the defence of a puritan, and appointed Dr. Fulck in his place, who refuted the Rheims with great spirit and learning. Cartwright's refutation was also afterwards published in 1678, under archbishop Abbot, together with the Rheims translation. This procedure was much more agreeable to the true spirit of protestantism, than the act of feizing and burning the copies; "argument being the only weapon (says the truly excellent private Newcomen), which should be wielded to defend Christlikeness, or any mode of proseling it." Other editions were printed at Antwerp, in 1600, and in 12mo. at the same place, in 1630, and at Paris, in 4to. in 1637. Within 30 years after their New Testament, the Roman Catholics published a translation of the Old, at Doway, hence called the "Doway Bible," in two 4to. volumes, the former in 1609, the other in 1612, from the Vulgate, with annotations. It is said that the translators were William Allyn, afterwards cardinal, Gregory Martin, and Richard Brilhow; and that the annotator was Thomas Worthington. But some (Le Long. 418.) ascribes the version of the New Testament chiefly to William Raynold.

**Bible, King James's.—**The last English Bible was that which proceeded from the Hampton-court conference, in 1603, where many exceptions being made to the Bishop's Bible, king James gave order for a new one; not as the preface expresses it, for a translation altogether new, nor yet to make of a bad one a good one, but to make a good one better, or of many good one best. On the second day of this conference, Dr. Reynolds, the speaker of the Puritans, moved his majesty, that a new translation of the Bible might be undertaken; because those which were allowed in the regins of Henry VIII. and Edward VI., were corrupt, and such versions as were extant were not answerable to the truth of the original. It has been observed by learned men with regard to the translators in the reign of Henry VIII. that they followed Erasmus and Sebastian Muller too closely; of the Geneva version, that it was formed too faithfully on the model of Beza; and of the Bishop's Bible, that it was not sufficiently exact, but full of errors, because its conductors departed from the Hebrew, and trod too exactly in the foot-steps of the Greek. In reply to Dr. Reynolds, the king said, that he had never yet seen a Bible well translated into English; though he considered the Geneva translations as the worst. On the suggestion of Bancroft, bishop of London, he forbade marginal notes; some of the Geneva
notes having been, in his opinion, "very partial, untrue,
editious, and favouring too much of dangerous and trai-
titious conceits." In 1642, the king commissioned fifty-four
learned men of the two universities, and of other places,
to confer together, so that nothing should pass without a general
conformity, in order to make a new and more correct tran-
slalion of the Bible. Such of these as survived till the com-
mencement of the work were divided into six classes. Ten
were to meet at Welminster, and to translate from the Pen-
tateuch to the end of the second book of Kings. Eight,
affiliated at Cambridge, were to finish the rest of the histo-
rical books, and the Psalms. At Oxford, seven were
undertaken by the four greater prophets, with the laments-
tations of Jeremiah, and the twelve minor prophets. The
epistles of St. Paul, and the remaining canonical epistles,
were allotted to another company of seven, at Welminster.
Another company of eight, at Oxford, were to translate the
gospels, the Acts of the Apostles, and the Apocalypse.
Lastly, another company of seven, at Cambridge, had assigned
to them the Apocrypha, including the prayer of Manasseh.
The King prefcribed certain rules, which the translato-
ners were required carefully to observe. The Bishop's Bible
was to be the standard, from which as few deviations as pos-
sible were to be allowed; the names of the prophets, and the
correct writers, with the other names in the text, were
to be retained as nearly as possible to their vulgar use; the old
cacchialical words were to be retained, as the word "church,"
which was not to be translated "congregation," &c.; of
words admitting divers significations, those were to be retained
which had been most commonly used by the most eminent,
or most ancient fathers, being agreeable to the propriety of the
place, and the analogy of fact; the division of the chapters
was to remain with as little alteration as possible; no marginal
notes were to be introduced, except for the explanation of He-
brew or Greek words, which could not without circumlocution
be duly expressed; quotations were to be annexed in the mar-
gin, for the sake of referring from one scripture to another;
every particular person of each company was to take the same
chapter or chapters, and having separately translated his
appropriate part, all were to meet, to compare what they
had done, and to agree as to that which should remain; when
any part was finished by the company, it was to be referred
to the rest for their various and judicious consideration; if
any doubt or difference occurred, it was to be settled at a
general meeting; with respect to places of special obscurity,
the opinion of learned persons was to be obtained by letters
addressed to them for this purpose; and skilful persons were
required to transmit any observations that might be of use
to the company, either at Welminster, Cambridge, or Ox-
ford; the directors in each company were to be the deans of
Welminster and Cheltenham, for that place, and the king's pro-
secutors in the Hebrew and Greek, in each university; and
the following translations, if they agreed better with the
text than the Bishop's Bible, were to be used, viz. To-
ald's, Matthew's, Coverdale's, Whitchurch's, or the Great
Bible, printed in 1539 and 1540, by Whitchurch and Glat-
ton, and the Geneva Bible. The king also instructed his
prosecutors, that three or four of the most eminent and grave
divines of the university, assigned by the vice-chancellor, upon
conference with the rest of the heads, should be overseers of the
translations, as well Hebrew as Greek. The transla-
tion was begun in the spring of 1669, and the completion of
it occupied almost three years. When the whole was
completed, and three copies of it were sent to London, one
from Cambridge, a second from Oxford, and a third from
Welminster, two were chosen from the joint companies
which had assembled at those places, to review and polish it.

The two from the Cambridge companies were Mr. John
Bois, fellow of St. John's college, and Mr. Andrew Downes,
professor of Greek. These daily met their fellow-labourers in
Stationers' hall, London; where, in nine months, they
completed their task, and received, each of them, by the
week 33l. from the Company of Stationers, whereas, "be-
fore they had nothing." The whole was, at last, reviewed by
Bilbop, bishop of Winchester, and Dr. Mykles Smyth, after-
wards bishop of Gloucester, who prefixed arguments to the
different books; and the latter was ordered to write the pre-
face. This edition of the Bible, with the preface and a dedi-
cation to the King, was first published in London, in the
year 1671; and is commonly called "King James's Bible." Several
editions of it were published in 1674, and in 1675; and
particularly one by R. Barker, in 1674. In some
editions of this Bible, between 1638 and 1665, an alteration
is introduced in Acts vi. 3, where, instead of "He may ap-
poinl," it is inserted "He may appoint," which has been
charged on the Independents. But as the first Bible in
which it was observed is that printed at Cambridge by Buck
and Daniel, in 1638, it is probably an error of the press,
without any design to favour any particular party. In 1660,
a beautiful edition of this Bible in folio, with correct bibli-
cal cuts, engraved by Ogilby, was printed at Cambridge,
by John Field; and another edition was printed in 1664, at
Amsterdam, in 1664, by John Carne, a leader of the Eng-
lish Brownists, with marginal notes, showing Scripture to
be the best interpreter of Scripture. The editor has pre-
fixed a preface; and the Apocrypha is omitted. A very
fine edition of this Bible was published in a large folio, in 1701,
under the direction of Dr. Tenison, archbishop of Canter-
bury, with chronological dates, and an index, by bishop Llo-
yd, and tables of scripture measures by bishop Cumberland;
but this edition abounds with typographical errors. After this
translalion, all the other versions dropped, and fell into obscu-
try; the Epistles and Gospels in the Common Prayer Book,
which were still continued, according to the Bishop's tran-
slation, till the alteration of the liturgy in 1661, and the
Psalms and hymns, which are to this day as in the old
version.

About the time when king James resolved on a new trans-
lation of the Bible, another translation was finished by Mr.
Ambrose Usher, elder brother of the learned primate of
Armagh of the name. It was never printed; but it
preffered in MS. in 3 vols. 4to. in the library of Trinity
college at Dublin. In 1764, Mr. Anthony Purver published
We have also had several translations of the New Testament,
(fee Testament) and of particular books and parts of the
Old and New Testament, the principal of which will be
noticed in their proper places.

Learned persons have entertained very different opinions
concerning the accuracy and value of the translation, made
by order of king James, and now in common use. Bishop New-
tcome, the late much respected primate of Ireland, has given an
abstract of those opinions. Selden recommends it as the "best
translation in the world." The committee for religion in the
time of Cromwell, A. D. 1656, whilst they pretended to dis-
cover some mistakes in it, allowed it to be the "best extant";
Walton in his "Prolegomena," highly commends it; and
Poole in his "Synopsis," says, that "in this royal
version occur very numerous specimens of great learning and
skill in the original languages, and of uncommon ac-
tlemen and judgment." In the "Bibliales Litterarum,"
A. D. 1723, it is observed, that "it made its way by general
acceptance and approbation, without the interference of aut-
ocracy to enforce it. A pure argument that it is generally
learned the bell we have; though it has still many en-
U n fiderable
fiderable faults, and very much needs another review." Dr. Wells, in his general preface to the O. T. professes to cor-
ext it, " either where it does not give the true sense of the original, or where the true sense is not well expressed," ac-
ting to the modern idiom. The author of an " Essay for a New Translation of the Bible, &c." 1728, after speaking in praise of this version, recommends the attempt to give a
more exact translation than that which has hitherto appeared; and he adds, " it were indeed to be wished, that those who
are in power did employ men of true learning, and solid
piety, free from bigotry and blind zeal, in so noble and neces-
sary a work." J. N. Blackwall in his " Sacred Classics," might be made (in the English Bible) of faulty translations of the divine original; which either weaken its sense, or debauch and taint the beauty of its language. He also observs, that " a new translation can give no offence to people of sound judgment and confideration; because every body, conversant in these matters, and unprejudiced, must acknowledge, that there was lefts occasion
to change the old version into the present, than to change the present into a new one."— Such an accurate and admirable translation, proved and supported by sound criticism, would quash and silence most of the objections of pert and profane cavillers, which chiefly proceed from their want of penetration and discernment of the connection of the argu-
ment, and their ignorance of the manner and phrase, of the
divine writings. It would likewise remove the scrupules of
many pious and conscientious Christians." A new divi-

tion of the sacred books into chapters, sections, and periods, might be so contrivd and managed as to make a new edition
very commodious and beautiful; which would overbalance all inconveniences which superfluitv and weakness could pre-
tend might arise from alterations, and make a victorious and speedy way to the favour and full approbation of the world.
There is hardly one chapter in the N. T., says this author, that is not fruitfully divided, in consequence of which, the
connection and meaning of particular passages are rendered
confused and obscure; whilst the style is materially injured.
It is, with pleasure and just veneration, he continues,
"to the memory of our learned and judicious translators, that I acknowledge their version in the main, to be faithful, clear, and solid. But no man can be so superfluitvously devo-
ted to them, but must own that a considerable number of
passages are weakly and imperfectly, and not a few falsely,
rendered. And no wonder; for since their time there have been
great improvements in the knowledge of antiquity, and
advancements in critical learning, &c." If ever (says Dr.
Waterland, Scripture Vindicated,) " a proper time should come of revising and correcting our old English translation,
which, though a very good one, and upon the whole scarce inferior to any, yet is undoubtedly capable of very great
improvements. &c." Doddridge, Welbye, Wynne, Elking-
ton, Purver, Worlsey, Priestley, &c. &c. express themselves
to the same purpose. " To confirm and illustrate the holy
scriptures," says the eminently ingenious and learned bishop
Loth (Vilification Sermon at Durham, 1758,) "to evince their truth, to shew their confidence, to explain their mean-
ing, to make them more generally known and fluided, more
casily and perfectly understood by all; to remove the diffi-
culties, that discourage the honest endeavours of the un-
learned, and provoke the malicious cavils of the half-learned:
this is the most worthy object that can engage our attention;
the most important end to which our labours in the search
of truth can be directed. And here I cannot but mention
that nothing would more effectually conduce to this end,
than the exhibiting of the holy scriptures themselves to the
people in a more advantageous and judicious light, by an accu-
rate revivis of our vulgar translation by public authority.
This hath often been represented; and, I hope, will not always be represented in vain." The late archbishop
Secker delivers similar sentiments in his " New Testa-
ment to have been made at the opening of the Convoca-
tion in 1761," printed at the end of his charges; " London,
To the same purpose are the declarations of Dr. Dorell, in his " Critical Remarks on Job, &c." Oxf. 1772, pref. p. 6.; of bishop Lowth, in his " Prelim.
Diff. to Heilsh," 4to. Lond. 1778, p. 69.; of Dr. White,
in his " Revival of the English Translation of the O. T. rec-
commended," Oxf. 1779, p. 8, 9, &c. &c. Dr. Kemmott,
Green, and Blayney, excellent judges on this subject, have
courncred in the same opinion, of the necessity and utility
of either a new translation or a revivis of the old one. The
late Dr. Geddes, in his " Pr. specus of a New Translation of
the Holy Bible," 4to. Glasc. 1786, p. 2, expresses himself
in the following language. " The highest eulogiums have
been made on the translation of James I., both by our
own writers, and by foreigners; and indeed, if accuracy,
 fidelity, and the strictest attention to the letter of the text,
be supposed to constitute the qualities of an excellent ver-
ion, this, of all versions, must, in general, be accounted the most
excellent. Every sentence, every word, every syllable, every
letter and point, seem to have been weighed with the most ex-
cactitude, and expressed, either in the text or the margin, with
the greatest precision. Poginus himself is hardly more literal;
and it was well remarked by Robertson, above 100 years
ago, that it may serve for a lexicon of the Hebrew language,
as well as for a translation. It is, however, confinedly, not
without its faults. Besides those that are common to it with
every version of that age, arising from faulty originals, and
Mafonic prepositions; it has its own intrinsic and peculi-
ary blemishes, which Dr. Geddes enumerates. From a su-
perfluitvous attention to render the Hebrew and Greek into
literal English, its authors adopted modes of expression which
are abhorrent from the English idiom; and perhaps from
that of all other modern tongues. There is a also a most
want of uniformity in the mode of translating, which is
owing to the variety of persons employed. The books called
apocrypha are, in Dr. Geddes's opinion, generally trans-
lated better than the rest of the Bible; for which one rea-
on may be, that the translators of them were not cramped
by the fetters of the Mafors. The translators of this ver-
sion mistook the true meaning of a great many words and
sentences by depending too much on modern lexicons, and
by paying too little attention to the ancient versions. For
various reasons they encumbered their version with a load of
vulgar Italic; often without the least necessity, and almost
always to the detriment of the text. Like other translators
of their day, they were too much guided by theological
fictions, and leem, on some occasions, to have allowed their
religious prejudices to have gotten the better of their judg-
ment. Besides, through the constant fluctuation and pro-
gress of living languages, there are many words and phrases,
in the vulgar version, now become obsolete, of which mo-

dern writers have selected a great variety. The construction
also is less grammatical than the present state of our language
seems to allow; and the arrangement of the words and sen-
tences is often such as produces obscurity and ambiguity.
Dr. Campbell, in his preface to " The Four Gospels tran-
lated;" Dr. Symonds, in his " Observations on the Ex-
pedience of reviving the present English version of the Four
Gospels, and of the Acts of the Apostles;" Mr. Wakefield,
in his " Translation of the N. T. ;" and Mr. Ormerod, in his
" Short Specimen for an Improvement in some parts of the
prent Translation of the O. T.;" unite in recommend-
ing a revival of our present translation. Dr. Symonds, in particular, examines the grounds of an opinion, advanced by Lowth, in his "English Grammar," p. 97, and also by many others, which is, that the vulgar translation of the Bible is the best standard of the English language. Distinguishing between the terms one of the standards, and the left standard, which are very different, he allows that the plain and simple turn of expression, resulting from the choice of old English words, may entitle our version to the former appellation, and yet many other circumstances must be united to confirm its claim to the latter. Accordingly, he suggests the following inquiries: "Are the words and phrases, employed by our translator, generally placed in their proper order? Are they so arranged as to preclude all obscurity and ambiguity? Do we always find the antecedent to which the relatives refer? Hath a right attention been paid to the modes and times ofverbs? And is there a due propriety observed in the use of particles, upon which the clearness of a sentence chiefly depends?" The want of conformity to these rules, or to the greater part of them, will not allow our version of the Bible to lay claim to the appellation of the left standard of our language. Many other opinions of very respectable writers, decided in favour of an improved version of the Bible, might be added to those that are above cited. Objections, however, have been urged against it, by Dr. Vicevims Know, in his "Effays Moral and Literary," and also by others; and they have been examined and obviated by the late primate of Ireland, Dr. Newcome, who avows his opinion, that nothing would be more beneficial to the cause of religion, or more honourable to the reign and age in which it was patronised and executed, than an improved English version of the Scriptures.

It has been said, that a new version of the Bible is quite unnecessary. But although our English translation, or any translation extant, contains all things necessary to salvation, yet in common language a measure is said to be necessary, when it is highly expedient. Let any competent scholar study the Bible in the original languages, and then pronounce whether our authorized version is not capable of amendment and improvement, in numberless places, many of which must be considered as very important. If every part of Scripture be intended to answer some important purpose, as it certainly is, or it would not have been given to us, every part ought to be put into the hands of Christians as free as possible from obscurity and error. Some mistakes, among many that may be deemed small, are so considerable as to deprive Christianity of much solid evidence, and furnish the Sceptic with his most formidable weapons. Whilst it is acknowledged that our present version contains every thing necessary to salvation, it may be alleged, that if this be a sufficient reason for not correcting those faulty passages which admit of correction, it would be a sufficient reason for throwing them out of it altogether. But as our heavenly Father has been pleased to favour his creatures with additional light, it would ill become us to permit any of this light to be obscured, or to pretend that it is not wanted. If, according to the constructions of some of the objectors to a new version, the faith and practice of illustrious persons are sometimes affected by the present version, and if, in some instances, its obscurity would be removed; religion is a matter of such great concern as to demand from those who watch over its interests, that even these defects should be rectified. It is dangerous to retain any known errors in our national version; they operate differently on different minds; nor is it easy to estimate their degree or effects. The opinions and conduct not only of the unlearned, but of the learned themselves, who do not carefully examine the Scriptures, have in fact been strongly influenced in matters of acknowledged importance, by corrupt readings or misinterpretations of a very few texts. It has again been objected, that a new translation is an extremely dangerous attempt; that nothing would more immediately tend to shake the basis of the establishment; and that it would be imprudent to shock the minds of some very devout and well-meaning people, by an innovation which they could not help considering as an insult on heaven. A measure of this kind would tend to shake the faith of thousands, to whom it was impossible to demonstrate the necessity of a change, or the principles on which it was conducted. Persons of this class would lose their veneration for the old version, without acquiring sufficient confidence in the new: and the benefits must be great indeed, that can compensate even for the remotest possibility of such an evil. To this mode of objecting it has been replied, that it does not immediately affect the merits of the question, but it arranges the prudence of introducing a correct version, as a measure from which dangerous effects, and not solid advantages, will be apt to arise on the whole. Whatever tends, it has been said, to the perfection of an establishment, would not shake it, but give it splendour, strength, and security. An accurate version would reflect the highest honour on our national church, and may be ranked in an eminent degree among those measures, which would fix it on a basis as firm as truth, virtue, and Christianity. Such a work would be as natural a subject for the praise of all Protestant countries, as King James's Bible was for the honourable testimony born to it by the synod of Dort. It ought also to be recollected, that after Coverdale's translation had received the sanction of authority, the Bibles of Matthew, Cranmer, Taverner, archbishop Parker, and James I. were all innovations in their day; and yet that, considered as different versions, they produced no civil or ecclesiastical commotion, no violent agitation in the minds of men, resembling those which are now apprehended and predicted. Besides, a translation by authority ought to supersede all others from its intrinsic excellence; and it would of course supersede them by the frequency, correctness, and cheapness of its editions, as King James's did that of Geneva, notwithstanding the preference given to it by the Calvinists. Moreover, it is hard to conceive, how the faith of thousands can be shaken by removing stumbling-blocks, instead of retaining them. Aburd belief and corrupt practice arise from an ignorance of the Scriptures; nor from the best human inducements and affinities to search and understand them. It is the nature of truth, and especially of divine truth, to captivate those who contemplate it, in proportion as the veil is withdrawn, and its genuine features appear. Ill-founded prejudices should exist among the people, their teachers should seriously labour to remove them. These prejudices are such, as far as they exist, which might be easily removed, or which would not deserve to be regarded. Besides, the public mind might be prepared for it, and disposed to acquiesce in it by previous and frequent recommendations of it on the part of ecclesiastics, who derive weight from their rank, and, which is the height of all ranks, says a primate of Ireland, from their reputation. A repeated diffusion of the topics, that involved the necessity, expediency, and utility of a new version, in discourse, in the pulpit, and from the press, and the concurrence of the bell, the wiflet, the most learned, and the greatest, in the recommendation, patronage, and conduct of an amended version, would give the bulk of the community as great a confidence in it as they ever reposed in any preceding one. Some, indeed, may say "Let us introduce no change; for we cannot tell what further change may be required of us." Had this kind of lukewarm and timid reasoning been U u 2 regarded,
regarded, neither the reformation, nor the revolution, could have taken place; and we should have been still subject to Romish superstition, and to episcopal power. It is certainly not less the part of wisdom and common sense to give up what is wrong, than absolutely to maintain what is right.

It has been further argued, that the present translation derives an advantage from its antiquity, greatly superior to any which could arise from a correction of its inaccuracies. Hence it would follow, that the versions of Tindal, Wick-cliffe, and Jerom, rise in excellence. But no age or precept can authorize error; and it is obliquity to defend in any version, however ancient or venerable, what cannot be ration-ally defended. Although it be desirable that the grave ancient edd should prevail in an English translation of the Bible, a translation may nevertheless become too antiquated; and in fact our own Bible retains words and forms of such remote use, that some of them are not understood, even by in-telligent readers, and many of them are rather harsh and uncouth, than venerable and majestic.

But it has been said, that the present translation ought to be retained in our churches, on account of its intrinsic beauty and excellence. The language, though simple and natural, is rich and expressive. Even in the literal translation of the Psalms, there are passages exquisitely beautiful and irresistibly tranporting; and where the sense is not clear nor the connect-ion of ideas obvious at first sight, the mind is foothed, and the ear ravished with the powerful yet unaffected charms of the style. These beauties, it is alleged, on the other hand, are found, in an equal, or partly in a superior degree, in our first version; and must be more or less found in every version of the Hebrew Scriptures, that is not a mere paraphrase. King James's translators found it in their prototype; the diaion and phrasing they borrowed from their predece-sors in translation. What is beautiful, what is excellent, what is melodious and ravishing in the present version, should unquestionably be retained by all future translators; but is there any reason for retaining its corruptions, its mistrans-la-tions, its obscurities, and its other acknowledged imperfections?

The correcting translators, it will be again urged, differ among themselves. Differences must necessarily arise among interpreters of the Scriptures. King James's translators often disagreed as individuals; and adopted in a body what seemed to be most agreeable to the found rules of interpreta-tion. Let a like number of able judges decide, on the same principles, between biblical critics of the present age. But the new translators recede too far from the common version. This, however, in a new version, is not necessary, nor would it be proper; whilst they recede from its errors and imperfections, they should retain its general diction and manner, nor ever allow themselves to deviate from it without a sat-isfactory reason.

It has been further intimated, by those who are averee from a new version, that such as with for additional information may have recourse to those authors, who have explained obs-ecire and erroneous passages. But have all Christians, who meet with difficulties, time and ability to consult these writers? Or if they had, is it in any respect decent or fit that the public Scriptures, confided to want affilience, should be suffered to depend for support on these extraneous props? The national Bible is the great record of our reli-gion; it is this which the Delit attacks, and this must sup-ply us with our defence.

The objections proceed with observing, that no translation, even of a single book, has yet appeared, preferable on the whole, to the received one. Let it be considered, however, that the attempts of individuals necessarily labour under great comparative imperfections; and yet these should be promot-ed by the natural patrons of sacred learning, and parts of the Scriptures should be aligned to such as are best qualified for the honourable task of translating and explaining them; be-cause these private versions and explications will form a most useful groundwork for a revised version of the whole Bible by public authority.

After all, it will be said by some, who are convinced that our present Bible should be revised, that this is not a proper time for the undertaking; and that we should wait till, by the further incease of light and progres of improvement, we shall be able to carry the work to a greater degree of perfection, and, if possible, make future revisions unnecessary. This argument may be always urged; because religious knowledge will encrease, in proportion as human learning improves, and as new light is obtained from versions and MSS. that are already known, and that may yet be discov-ered, fully examined and compared. "But shall we, in the mean time, prolong the difficulties of the Christian, and the fancied triumph of the Infidel? The mistakes already discovered are well worthy of correction. Should others of importance be brought to light in the next, or subsequent generation, let them also be corrected. The true rule in this case is, to revile as often as revision is necessary. To defer this longer, is an injury to religion; to put it off till it can be done in such a way as to preclude the necessity of future revisions, is in fact to put it off for ever."

"The tale of the age for found logic, found criticism, and found philo-sophy, has acquired sufficient strength to triumph over their opponents."

In favour of an improved version of the Bible, for national use, it has been argued, that such a translation becomes ne-cessary by the unavoidable fluctuation of living languages. The style of Wickciffe's version, and of Tindal's, very widely differs in the course of 148 years, and the English language underwent also a great change between the publication of Tindal's Bible and that of King James's, in an interval of 68 years. Since the year 1611, when the present version first appeared, our language has acquired a great degree of copi-ouines, of elegance, of accuracy, and perhaps of fluidity. Many words and phrases which occur in the revised version are become unintelligible to the generality of readers; and many, which are intelligible, are so antiquated and debased, as to excite disgust among the serious, and contempt and derision among libertines. Hakluyt (Remarks on several passages of Scriptures, Camb. Svo. 1759); Purver (Translation of the Bible); Dr. Symonds (Observations on the expediency of revising the present English version, &c. Camb. 4to. 1789); Dr. Wells (Pref. to Comment on the O. T.); Dr. Camb-bell (Four Gospels translated from the Greek. 4to. Lond. 1789); and Dr. Geddes (Prospectus); have selected many words and phrases that require correction, and that admit of obvious improvement. The style of a biblical version is a matter of importance; both as it invites the perusal of a book which the Spirit of God inspired, and as it influences the national language and taste. Whatever merit be allowed to the version now in use, with regard both to its inter-pretations as well as its style, it must be allowed that, since the period in which it was executed, the biblical apparatus has been much enriched by the publications of polyglotts; of the Samaritan pentateuch; of ancient and modern ver-sions; of lexicons, concordances, critical dissertations, and sermons; books of eastern travels; discussions on the geo-graphy, customs, and natural history of the East; accurate tables of chronology, coins, weights, and measures. Many Hebrew and Samaritan MSS. many early printed editions of the Hebrew Scriptures, have been collated by Kennicott and
and De Rossi; the Eastern languages, which have so cloe an affinity with the Hebrew, have been industriously cultivated at home and abroad; the Masoretic punctuation is now ranked among useful affinities, but no longer implicitly followed; and the Hebrew text itself is generally allowed to be corrupt in many places, and therefore capable of emendation by the same methods which are used in restoring the integrity of all other ancient books. With such an accession of helps, with light poured in from every part of the literary world, with such important principles, and with the advancement of critical skill to apply them, it is natural to conclude, that many mistakes and absurdities may be removed from the present version, and that the precision, beauty, and excellencies of the original, may be communicated to it in various places. The present state of the Hebrew text, in its reference to a new version of the O.T. has been already represented in the commencement of this article; and that of the text of the New Testament will be the subject of a future article; See Testament.

Dr. Newcome, in his "Attempt towards an improved version, &c. of the Minor Prophets," published in 1785, proposed a variety of rules for conducting a new translation of the Bible. These have been since corrected and enlarged (ubi infra); and in order to render this article, the subject of which is highly important and interesting; as complete and as satisfactory to biblical readers as our limits will allow, we shall here subjoin the most material parts of them. The learned prelate proposes, in the first place, that a plan, resembling the regulations preferred to King James's translators, should be deliberately adjuted by a large committee of judicious and learned men. A more select committee, well acquainted with the original tongues in which the Bible is written, should then be appointed by proper authority, who should invite every scholar to contribute his remarks; who should have their respective parts assigned them; and who, after the performance of their allotted tasks, should amicably unite in advancing the whole to its proper degree of perfection. The fifth of his rules is, that a translation of the Bible should express every word in the original by a literal, verbal, or close rendering, where the English idiom admits of it. This rule admits of some few exceptions; but it excludes unnecessary deviation from the grammatical form of the original words; unnecessary paraphrase, which enervates the force of the original, disfigures its manner, and sometimes suggests a wrong idea; sentential renderings; and such as are defective. The second rule directs the translator, where the English idiom requires a paraphrase, to endeavour so to form it as to comprehend the original word or phrase; and to express the supplemental part in Latin, except where harshness of language results from the adoption of this method. The third rule recommends, in cases where a verbal translation cannot thus be interwoven, the subtitution of one equivalent to it, and which implies the reading in the original; but the idiom in the text should be literally rendered in the margin. By observing the second and third rules, the utmost fidelity to the original will be shewn, which is the primary duty of a biblical translator; the customs and manners of the ancient nations will be explained; the peculiar genius of the original languages will be exhibited; and the reader unskilled in them will be best enabled to interpret for himself. The fourth rule requires, that the language of a biblical translation should be pure, or conformable to the rules of grammar. The fifth rule directs, that propriety should be a prevailing character in the words and phrases of a biblical translation; that is, they should have the function of use, and the signification given to them should be warranted by the best speakers and writers. In order to preserve the venerable turn of our present version, some few exceptions may be allowed under this general rule. The sixth rule enjoins the translators to retain the simplicity of the present version; for which purpose they should exclude foreign words, and the pomp and elegance of modernized diction. The seventh rule inclinates periphrasis. The eighth rule recommends the same original word, and its derivatives, according to the different leading senses, and also the same phrase, to be respectively translated by the same corresponding English word or phrase; except where a distinct representation of a general idea, or the nature of the English language, or the avoiding of an ambiguity, or elegance of style, or harmony of sound, requires a different mode of expression. In conformity to this rule, it is proposed, that translators should previously agree on the rendering of certain words and phrases. Accordingly, the original word "Jehovah," which expresses the self-existence of the deity, and which, so far from being barbarous, is a grand and magnificent term, should be retained; that it should be considered, by the help of concordances, whether the same word can always be rendered in the same manner; and that when an English word suits every place, it should invariably be used; that if the original word cannot always admit of the same rendering, of which many examples occur, the different renderings may be reduced to as few as possible, and those the fittest which the English language affords; that different words, which have the same, or nearly the same sense, should be distinguished in translating them, when the English tongue furnishes distinct and proper terms; and that parallel passages should be rendered in the same words. The ninth rule requires that the collocation of words should never be harsh and unskilfully fitted to an English ear. The tenth rule recommends to translators of the Bible a suitable degree of beauty and elegance. This beauty, in its prevailing character, must be easy and natural, simple and severe; free from laboured ornament and artful variety of phrase. The style, like that of the original, must be raised in the poetical parts, but not inflated, and plain in the historical parts, but not abject. "Let nothing," says Dr. Symonds (ubi supra) "be admitted into the text, which we cannot read with pleasure, as well as with advantage." In the eleventh rule it is required, that dignity should characterize a version of the Bible. The opposite extreme results from the introduction of debased and offensive terms or phrases; of which some are degraded by familiar use, others are colloquial and vulgar Anglicisms; and modern phraseology, as such, is undignified in a translation of the Bible. The twelfth rule prefers energy as another characteristic of a biblical translation. This quality is obtained, in a great degree, by simplicity and propriety in the terms that are selected to represent the peculiar notions conveyed by the sacred writers, and by expelling the clausules contained in the original with the conciends. The forcible style of the Scriptures is enfeebled by epithets and paraphrase; nor does their majesty more disdain the defect of ornament, than the excess of it. A version of the Bible will derive much force by retaining those Hebrewisms which the English language badly admits, or to which an English ear can now accustomed. Obscure Hebrewisms, such as weaken the signification of the original, and those which misrepresent its meaning, should be avoided. In the thirteenth rule it is recommended to continue the old ecclesiastical terms, such as repentance, mystery, elect, predestined, &c. which are now part of our theological language, and of which explanations perpetually occur. Rule fourteenth. Metaphors are, in general, to be retained. By observing this rule, the genius of a language, and the nature and customs of a country, will often appear.
Rule fifteenth. Proper names should remain as they are now written in those places where they are most correctly represented. Rule sixteenth. The bulk known geographical terms should be inserted in the text; and those of the original in the margin; e.g. Syria, marg. Axam; Ethiopia, marg. Cufa. Rule seventeenth. The language, tense, and punctuation of our present version should be retained, unless when a sufficient reason can be assigned for departing from them. Rule eighteenth. The critical tense of passages should be considered, and not the opinions of any denomination of Christians whatever; so that the translators should be philologists, and not controversialists. Rule nineteenth. Passages already admitted into the common version, but which are allowed to be marginal glosses, or about the authenticity of which critics have reason to be doubtful, should be placed in the text between brackets. Rule twentieth. In the best editions of the Bible, the poetical parts should be divided into lines answering to the metre of the original; or some other method should be used to distinguish them from prose. But if it should be thought advisable to exclude the poetical distribution from our Bibles, and confine it to the prohibitions of the scholar, some proper mark of distinction for metrical parts, as the Hebrew Rechiah or two horizontal points placed over a word, may be admitted into the authorized impressions of the Old Testament; or, at last, the contents prefixed may advertise the reader of the passages generally allowed to assume the tone and form of poetry. Rule twenty-first. Of dark passages, which exhibit no meaning as they stand in our present version, an intelligible rendering should be made on the principles of sound criticism. Under this head of sound criticism, Newcome includes that which is conjectural, the sober use of which he frequently recommends. But it admits of doubt, whether conjecture can ever be authorized in a translation which is intended for general use; for if it be exercised on flight occasions, it must be in some degree superfluous; if on material ones, it must ever be indecisive. The learned prelate, however, lays down the following canons for this kind of criticism. Never suppose that the text is corrupted, without the most cogent and convincing reasons. Never have recourse to conjectural criticism, until every other source has been tried and exhausted. Let all corrections be consistent with the text, and with one another. Invert no correction, however plausible or even certain, in the text, without warning the reader, and distinguishing it by a proper note. For other infractions of the rule, more immediately desirable for the editor of such a new version, we refer to the editor himself; as well as to his appendix, for a list of the various editions of the Bible, together with an account of the libraries public or private, in which they are to be found. Another more complete list of this kind is prefixed to bishop Wilson's Bible. See Lewis's Translations of the Bible, 8vo. 1739. Johnstone's Historical Account of the several English translations of the Bible, in bishop Watson's Collection of Theological Tracts, vol. iii. p. 60–100. Newcome's Historical View of the English Biblical Translations, &c. 8vo. Dublin, 1792.

Bibles, Welsh. There was a Welsh translation of the Bible made from the original in the time of queen Elizabeth, in consequence of a bill brought into the house of commons for this purpose in 1563. The act 5 Eliz. c. 28, reciting, that in Wales the people were popishly inclined, and very ignorant, put the direction of this work into the hands of the bishops of Hereford, St. David, Bangor, Landaff, and St. Asaph, who were to inspect the translation, and take care that such a number should be printed as would provide every cathedral, collegiate, and parochial church, and chapel of ease, within their respective dioceses, where Welch was commonly spoken, with one copy. It was printed in folio, in 1588. Another version, which is the standard translation for that language, was printed in 1620. It is called Parry's Bible. An impression of this was printed in 1690, called Bishop Lloyd's Bible. These were in folio. The first octavo impression of the Welsh Bible was made in 1650.

Bibles, Irish. The New Testament having been translated into Irish by William Daniel, archbishop of Tuam, Bedell, who was advanced to the see of Kilmore and Ardagh, in 1629, first procured the Old Testament to be translated by one King; but the translator being ignorant of the original languages, and having done it from the English, the bishop himself revised and compared it with the Hebrew, the Septuagint, and the Italian version of Diodati. He supported Mr. King to the utmost of his ability, whilst he was engaged in this work; and when the translation was finished, he would have printed it in his own house, and at his own charge, if the troubles in Ireland had not prevented it. The execution of his benevolent design was also impeded in consequence of the notice that was given of it to the lord lieutenant and the archbishop of Canterbury, who thought it disrespectful for a nation to have a Bible published, which had been translated by such a dubious person as King. However, the translation escaped the hands of the rebels, and it was afterwards, viz. in 1685, printed at the expense of the Hon. Robert Boyle.

Bibles, Gaelic. The Bible was translated and published by the society in Scotland for promoting Christian knowledge, in the Gaelic language, for the use of their schools, and of the people in the Highlands, at different periods, and in detached portions, as the funds of the society allowed. In 1767, the New Testament in Gaelic was published by itself; and in various successive years, and in separate volumes, the several books of the Old Testament were published. In 1796, the first edition of the New Testament being exhausted, the society published another, consisting of 20,000 copies. And as some of the first printed volumes of the Old Testament have been so much reduced in number, as to be insufficient to supply the urgent demands of the Highlanders in general, and of the society's own school in particular, a new edition of 20,000 copies has been lately undertaken (in 1803), at an expense of 2284l. 16s. defrayed by voluntary subscription. An act of charity, highly important and laudable, as the persons, for whose accommodation it is designed, amount to no less than 355,000; of whom, it is computed, that 500,000 underlie no other language than the Gaelic, or at least cannot comprehend a book written, or a continued discourse spoken, in any other.

Bible-Doctors, in Ecclesiastical History, a denomination by which the schoolmen of the twelfth and thirteenth centuries were distinguished, who made the Scriptures the chief subject of their studies, and text of their lectures. However, in the course of the thirteenth century, the holy Scriptures, together with those who studied and explained them, fell into great neglect and even contempit. The Bible-Doctors were flighted as men of little learning or acumen; they had few scholars, and were not allowed an apartment, or a servant to attend them, or even a slated time for reading their lectures, in any of the famous universities of Europe. The illustrious Roger Bacon inveighed very bitterly against this abuse; and his excellent friend, Robert Groschead, bishop of Lincoln, wrote a pathetic letter to the regents in theology in the university of Oxford, on this subject; earnestly instigating them to lay the foundations of theological learning in the study of the Scriptures, and to devote the morning-hours to lectures on the Old and New Testaments. But
But all these remonstrances and exhortations had little or no effect.

BIBLIA, or Biblia Petrina, in a military sense, denotes a machine used by the ancients for throwing stones or darts.

BIBLIANDER, Theodore, in Biographies, whose true name was Boucherman, a learned Protestant divine, was born in 1504, at Bâle, near St. Gall, in Switzerland. He officiated as professor of divinity at Zurich from 1532 to 1560, when he was declared emeritus, or past service, not because he was incapable of executing his office, but because he had advanced opinions that deviated from the standard of orthodoxy with regard to the doctrine of predestination. He died of the plague, at Zurich, in 1561. He was well acquainted with the Oriental languages, and published, in 1550, an edition of the Koran; the text of which, by Bayle, was corrected by a collection of the Arabic and Latin copies; and he added marginal notes, pointing out and refuting its absurdities. But others say, that this edition is faulty, and disputes Bibliander's skill in the Oriental languages. To this edition he subjoined the lives of Mahomet and his successors, and prefixed an apology, by way of preface, which gave great offence by maintaining the lawfulness and utility of a free perusal of books adverse to true religion. He also wrote several other books on theological subjects, some of which are printed, and others remain in MS. in the library at Zurich. He likewise published the Bible of Leo Judaeus, called the "Zurich Bible," and printed in 1543, and translated from the Hebrew into Latin the last 8 chapters of Ezekiel, Daniel, Job, Ecclesiastes, the Canticles, and the last 48 Psalms. Gen. Diff.

BIBLIOGRAPHIA, a branch of archi-geography, employed in the judging and perusing of ancient manuscripts, whether written in books, paper, or parchment. The sense of it is now extended, and it signifies a work intended to give information concerning the first, or best editions of books; and the ways of selecting and distinguishing them properly. In short, it is used for a notice, or description of printed books, either in the order of the alphabet, of the times when printed, or of the subject-matters. In which sense, bibliography amounts to much the same with what is otherwise called bibliotheke.

BIBLIOLOGY, a kind of divination performed by means of the Bible. This amounts to much the same with what is otherwise called fortunec Tibles, or fortunec faciendum. See Sortes. It consisted in taking passages of Scripture at hazard, and drawing indications therefrom concerning things future; as in Augülinus, toto a utile. It was much used at the consecration of bishops. F. J. Davidius, a Jesuit, has published a bibliography, under the borrowed name of Pseudus Christiannus.

BIBLIOLOGY, an extravagant passion for books, to a degree of madness; or a desire of accumulating them beyond all reason and necessity.

BIBLIOTHECA, from grieci, book, and Saxon, repository, from saxon, I lay up, properly signifies a library, or repository of books. See Library. It is also used for a compilation of all that has been written on a certain subject; or a digression of all the authors who have treated of it. In this sense, we have bibliographical, as that of Dioscorus Siculus; mythological bibliography, as that of Apollodorus; theological and sacred bibliography, as those of Ravanaelius, &c. It is also used for a catalogue of the books in a library; such as the Bibliotheca Cappellana, Bibliotheca Cordofana, Biblioteca Thiene, Bibliotheca Byzantiana, Bibliotheca du Bas, &c.

L'Abbé has published a bibliotheca bibliotheca, or a catalogue of the names of those who have written bibliography, which has since been continued and improved under another title by Teller, from 800 writers to the number of no less than 2500. Schramius has also published a programma on the writers of theological bibliography.

BIBLIOTHECA is a name given to the books of the Old and New Testament, in regard of their excellency, and sufficiency for the uses of the Christian life; and it is also a title given to divers journals, or periodical accounts in French of new books.

BIBLIOTHECA Patrum, or of the Fathers, is a collection of the writings of the elder fathers, printed in one or more volumes. The first of this kind was published at Paris by Marg., de la Bigne in 1596.

BIBLIOTHECARIAN, a library keeper, otherwise called librarians.

The word is also used for the author of a bibliotheca, or a catalogue of books.

In this sense, P. L'Abbé has given a bibliotheca, or catalogue of bibliothecarians. Geffen, Lipenius, Struvius, Fabricius, &c. are celebrated bibliothecarians.

BIBLIOTHEQUE Musica. See Musical Library.

BILIS, in Entomology, a species of Papilio, with black dentated wings, and a band of fanguincous spots on the posterior ones. It is a native of America, and called papilio hyperia by Cramer. Olf. This must not be confounded with papilio biblis of Cramer, which is a very different insect, and seems to be a variety of papilio penicillata of Fabricius.

BIBLIS, or Biblis, in Ancient Geography, a celebrated fountain of Ionia, situated E. S. E. of Milectus. It is mentioned by Paunianis and Ovid.

BIBLISTS, biblistes, an appellation given by some Romish writers to those who profess to adhere to Scripture alone as the sole rule of faith, exclusive of all tradition and the supposed authority of the church. In which sense, all protestants are, or ought to be, biblistes. Biblistes, among Christians, answer nearly to Caristics or Texturaries among the Jews. The Christian doctors were divided, towards the close of the twelfth century, into two classes; viz. the biblici, and the scholastics: the former were called doctors of the sacred page, because they explained the doctrines of Christianity in their manner by the sacred writings; however, their reputation declined, and the scholastic theology prevailed in all the European colleges till the time of Luther. See Bible-Doktoren.

BIBLIS, in Botany, an aquatic plant in Egypt, called also papyrus; of the skin whereof the ancient Egyptians made their paper. See Papyrus, and Paper.

Hence also the Greeks gave the denomination βιβλία to books made of it. See Bible.

BIBLIS, in Ancient Geography, a river in the island of Naxia. BIBONA, a place of Gallia Aquitania, in the route from Burgundia to Sepulchra.

BIBORA River and Bay, in Geography, lie to the east of Cartago bay, on the main land of Honduras, about N. lat. 14° 26'. W. long. 82° 45'.

BIBRA, Bebra, or Biebra, a town of Germany, in the circle of Upper Saxony, in Thuringia, 10 miles west of Naumburg, and 8 south of Querfurt.

BIBRACE, in Ancient Geography, a city of the Alani, according to Strabo, but according to Cæsar, a fortified town of Gaul, the capital of which was large and populous, now defolate: about 4 miles to the north-west of Autun, and called Beuret, Bevray, and Bray.

BIBRAX, Bievra, a town of Belfrica, in Gaul, in the country of the Rhemi, north-west of Durocortorum. This town was attacked with great fury by the other Belgic nations, because it had declared for Cæsar. Cæs. Bel. Gal. l. 2. c. 7.
BIC

BIBRICH, in Geography, a town of Germany, in the circle of the Upper Rhine, and principality of Nassau Saarbruck Uffingen, 3 miles S.S.W. of Wiesbaden.

BIBROCII, in Ancient Geography, an ancient people of Britain, who are supposed to have occupied the south-eastern part of Berkshire, from the Loddon on the west to the Thames on the east. These people undoubtedly came from that part of Gaul, where the town Bibra was situated, and their name leads us to the discovery of their origin, as well as of the place of their residence in this island. It is not certainly known when this colony settled the Bibraci left their native country, and settled in Britain, though it is probable that it was not long before Caesar's invasion, to whom, perhaps, they were engaged to submit by the influence and example of their friends and countrymen in Gaul. As the Bibraci were but a small nation, they seem to have been subjugated by some of their neighbours before the invasion of Claudius, and therefore they are not further mentioned in history. The name of the hundred of Bray, on the Thames, near Maidenhead, is evidently derived from the name of these ancient inhabitants; as the ancient Plibras, in France, now bears the name of Bray.

BICALCARATUS, in Zoology, a species of Pavo, of a brown colour, with the head slightly crested, and two spots on each leg. Guerin. This is Para Cinnamopterus of Buffon; et poio de Montacur of Sontear; pavo cinnamopterus of Edwards; and pavo cinnamopterus of Latham.

This splendid bird is a native of China; in point of size it rather exceeds the common peafant, and has a blackish bill, with the base of the upper mandible red from the nostrils; the feathers are yellow; crest small, though composed of fine; the tail long feathers, and of a dull brown colour; the face is marked; sides of the head white; neck brown, frizzled across with dull; upper parts of the back, capularis, and wing-coverts dull brown, dotted with pale brown, and yellowish; and near the end of each feather a rich and glossy purple spot, changeable to green, to blue, or gold, in different points of view; lower part of the back and rump brown, spotted with white, and body beneath brown, frizzled transversely with black; upper tail coverts longer than the tail, and each marked with a fine purple spot near the end, encircled with black and orange; legs and claws brown. This is the description of the male. The female is one third smaller; head, neck, and upper parts brown; head smooth; feathers on the upper parts marked with a dull blue spot, encircled with dull orange; and the legs have no spots.

BICARI, in Geography, a river of Sicily, which runs into the Termini, 2 miles west of Belfanti.

BICARINATA, in Zoology, a species of Lacerta, with compressed tail of moderate length, and erininfurated; on the back four rows of erininfurated scales. This is of a greyish colour, and inhabits South America and India. Gen. &c.

BICAUDALIS, in Anatomy, an appellation given by some anatomists to a muscle of the external ear, usually denominated the retroversor, or retrorsor auris, which see.

BICUALIS, in Teleology, a species of Ostracion, of a triangular form, with two sub-caudal spines, and ten rays in the dorsal fin. Guerin. There is a supposed variety of this fish found in India, and described by Artedi, in which the body is entirely covered with spots and tubercles.

BICE, or Bise, among Painters, a blue colour, prepared from the lapis lapis, formerly brought from Armenia, but now from the silver mines in Germany. Phil. Trans. N. 179. p. 26. Dufay, v. 5. p. 95. Bice is small reduced to a fine powder by levigation. See SALT.

The word comes from the barbarian Latin lapis, or lapis; and that, perhaps, from the French bis, gris, gris.e.; whence

Bice bears the belly body of all bright blues, used in common work; but is the palest in colour. It works indifferent well; but inclines a little to be fatty, and therefore requires good grinding on a very hard stone, and should be washed before it is used. It lies blue near the eye of any blue more fat, except ultramarine. Its goodnes lies in the brightness and coolness. It was formerly used in oil, and more frequently in water colours; but it is now much out of use. We have also a green bice, made of the blue, with the addition of orpiment; and several compositions of indigo and verditer, with chalk and other cheap substances, are sold under the name of bice.

BICE, in the Mythology of the Hindus, the name of one of their Gods, proceeding from Brahma, the immediate agent of the creation, under the supreme power. It derives its appellation from the belly or thighs, and denotes nourishment, and it was defined by its founder to provide the necessaries of life by agriculture and traffic.

BICEPS, from bis and caput, in Anatomy, is a name common to several muscles, which consist of two distinct portions, called heads. Those which are commonly known at present by that appellation are the following.

BICEPS FLOOR CUBITI. The longer portion, or head, of this muscle, arises by a tendon from the upper part of the glenoid cavity of the scapula; it then passes through the shoulder joint, and descends in the groove in the upper part of the os brachii, afterwards the fibrous fibres begin to attach to it. The shorter portion arises tendinously and flabbly from the coracoid process of the scapula, in common with the coraco-brachialis muscle; a little below the middle of the os brachii, the heads unite and form a bulky muscle, the fibres of which terminate below in a strong roundish tendon, which is inserted into a tubercle, at the upper end of the radius, at that part which is next to the ulna. At the commencement of the lower tendon of this muscle, an aponeurosis is sent off from it, which soon expands into the fascia of the fore-arm.

The use of this muscle is numerous, and the consideration of them affords a good demonstration of the impropriety of denominating a muscle from any single office which it may serve, as it tends to limit our ideas of its utility. The action of this muscle tightens the fascia of the fore arm; it turns the hand supine; it bends the joint of the elbow; it raises the arm towards the shoulder; and occasionally it brings the bones of the shoulder to the arm.

BICEPS FLOOR CRUDE. The long portion, or head, of this muscle arises, in common with the semi-tendinosus, from the upper and back part of the tuberosity of the os ischium; the short portion arises from the linea aspera on the back part of the thigh bone. These two portions having conjunctly, produced a strong tendon a little above the external condyle of the os femoris, which forms the outer ham string, and which is attached to the upper part or head of the fibula. The chief use of this muscle is to bend the leg upon the thigh, and when it is brought into that situation, to turn the leg backwards.

BICESTER, in Geography, a market-town of Oxfordshire, England, is situated in a valley on the banks of a small river, which falls into the Cherwell, at Urt. It is a large respectable town, divided into two parts, called Market-end, a parish, and Kings-end, a hamlet. This place, and its vicinage have been possessed by the Romans, as its name implies; and many Roman coins, and other memorials of that people, have been discovered here and at Alcester, or Old Chestert, at different times. The embankments at the latter place are nearly obliterated by the plough; but from the name, and the antiquities that have been found, it seems evidently
CIC

**BIC**

dently to have been a Roman station. "Alchester, Alceir, or Car-Allec," says Dr. Plot, "was a walled town that stood in the north-east parts of Oxfordshire, built, as may be coll-cted from many probabilities, by Caius Allectus, one of the thirty tyrants, who, by slaying his dear friend and emperor Carausius, obtained the sole government of Britain."

The Oxford canal passes through Lower Reyford, near this town, and conveys many articles of trade to and from it. Here are a large weekly market on Fridays, and six fairs annually, besides two annual marts in spring and autumn for the sale of sheep and cattle. The town has a well established charity school for 30 boys; and a charity, called the focolaes. This is endowed with lands, of about 1283 yearly rent, which is applied towards the relief of decayed tradesmen. The principal manufacture of this town is common flippers; and it is feepsofed that there are more made here than in any other town in England. Many females are employed in lace-making. The church is a large handsome building, with a lofty tower, and ornamented with many costly monuments. Here is a handsome meeting-house for the dissenters. The parish of Market-end, and hamlet of Kings-end, contain 410 houses and 1946 inhabitants. Plot's History of Oxfordshire. Camden's Britannia.

**BICHE, BICHE DE GUIANE, in Zoology, a name assigned by one French writer (des March. Voy.) to the Brazilian myg of Parnass, rapheius Americanus of Gmelin. Biche des Bois is also the name of cerus Mexicano (Gmelin) in Barran. Fr. Equin. 151.**

**BICHET, a corn measure, containing about a Paris not, chiefly used in Burgundy and the Lyonnais. Bichere denotes also a certain quantity of land, as much as may be found by a bichet of corn.**

**BICHNI, in Geography, a town of Peria, in the province of Erivan, 30 miles N.N.E. of Erivan.**

**BICHON, in Zoology, the name given by Buffon to canis maliteau of Ray.**

**BICHONNOY, in Geography, a town of Ruffia, in the government of Mohilie, seated on the Dnieper, 32 miles south of Mohilie. N. lat. 53° 20'. E. long. 35° 50'. This is one of the districts of the government, called allo Storie Biakof, or Bicehor Starov.**

**BICINCTA, in Entomology, a species of Apis, described by Schrank in Aufi. It is black and villous; mouth and abdomen glossy, with two white belts on the latter. Inhabits Upper Aulria.**

**BICNTA, a species of Vespa, of a black colour, with a spotted thorax, and two yellow bands on the abdomen. A small insect, and inhabits the cape of Good Hope. Fabricius.**

**BICNTA, a species of Tenbered, with a black body; belts on the abdomen, vent, mouth, and thanks yellow. A native of Europe. Fabricius. Abdominal yellow belts two, from which it is specifically named bicincta.**

**BICNTA, a species of Musca (Syphus), found in the north of Europe. It is black; antennae elongated; fides, dut, and two abdominal belts yellow. Linn. Fr. Suec. &c.**

**BICNTA, a species of Scolla, of a black colour, and hairy; abdomen with two yellow bands; wings blue-black. A native of America. Fabric. Mael. &c. This insect is ibex radulae of Sulzer.**

**BICNTA, in Geography, a town of Norway, 70 miles S.S.W. of Drontheim.**

**BICKFANEB, BICANEER, or BIZANEIER, a town of Vol. IV.**

**BICLINIUM, from bis and cane, I sing, in Church Mufie, the hanging of two, either together or alternately, in which sense, the word ilands opposed to melody.**

**BICKAOER, in Geography, a town of Norway, 70 miles.**

**BICLAN, the capital of a cirer or district of the same name in Marwan, the north division of Atrimere. This country is sandy and desert, and in great want of water. Of this country little is known; it is governed by a rajah, and inhabited by Rajpoos. The town is situated about 42 miles west of Nagore, and 90 W.N.W. of Atrimere. N. lat. 27° 12'. E. long. 74°.**

**BICKERN'S ISLAND, in Geography, a name given by Capt. Edwards, in 1791, to an island in the South Sea, near the Friendly islands, called by the natives Lattay, and discovered by Maurelle in 1781. It consists chiefly of a vast conical mountain, the summit of which appeared to be burnt, but the sides were covered with trees; and it is surrounded with a lower border, which is very fertile, and affords fresh water. This island supplies cocoa-nuts and bananas. S. lat. 18° 47' 20". W. long. 174° 48'.**

**BICCOCA, a town of Italy, in the duchy of Milan, near which the French were defeated by the Imperialists in 1552; 2 miles N.E. of Milan.**

**BICOLOR, in Conchology, a species of Donax, with an ovate shell marked with elevated flirix, which decussate a few transverse ones; rufous, with a white ray on one side. Gual. Mael. &c.**

**BICOLOR, a species of Pinka found in the Red Sea. This kind is thin, inflected at the lateral margin; yellowish, with black brown rays, and a few longitudinal flirix. Chemnitz. This shell is thorny, elongated, with curved flrnx at the curved margin; the largest end rounded.**

**BICOLOR, in Entomology, a species of Apis that inhabits Denmark. The thorax villous and ferruginous; abdomen black and immaculate. Fabricius.**

**BICOLOR, also an Indian species of Apis, of a black colour, with the abdomen hairy; fulvous above, and snowy-white beneath. Fabricius. This bears some resemblance to apis centuncularis, but is larger.**

**BICOLOR, a species of Attelabus found in Europe. It is of a black colour, with the thorax and wing-cafes reddish; feutel, thighs, and thanks at the base, and tip black. Linnaeus Fr. Suec.**

**BICOLOR, a species of Duprestis, with pointed wing-cafes, of a braly-green colour, with a yellow spot; breath and abdomen yellow. Fabricius. Inhabits South America.**

**BICOLOR, a species of Cantharis, of a yellow colour, with half of the wing-cafes blue. Thumberg. Inhabits the cape of Good Hope.**

**BICOLOR, a species of Carabus that inhabits North America. It is black above, and ferruginous beneath. Fabricius.**

**BICOLOR, a species of Cerambyx that inhabits Cayenne. This is ferruginous; thorax with two spines and tubercles; wing-cafes beyond the middle, with the abdomen black. Fabricius.**

**BICOLOR, a species of Chrysina, of a braly-green above, and violaceous beneath. Fabricius. Inhabits Alexandria.**

**BICOLOR, a species of Cicada (Ceropis), of a griseous colour, with the upper part of the thorax fangulous. Linn. Muf. Leis. A native of Europe.**

**BICOLOR, a species of Cryptoccephalus (Erathia). This insect is of a black colour, and brafly above; l'abricius. A native of New Holland.**

**BICOLOR, a species of Curculio found in America.**

**This**
This is of a black colour, with a rufous thorax and wing-cases. Fabricius.

**Bicolor**, a species of *Hemnostes*, of an oblong form and black colour; beneath tawny; wing-cases rufous. Fabricius. Inhabits Germany.

**Bicolor**, a species of *Elater*, of a brownish ferruginous colour; head and thorax brown; wing-cases rufous. Inhabits Europe. Linn. Muf. Linn.

**Bicolor**, a species of *Glytta* (*Locustula*), described by Linnaeus. It is grizzled, aperturnal, with the hinder thighs rufous beneath.

**Bicolor**, an African species of *Ichneumon*, of a ferruginous colour; tip of the abdomen, breast, and end of the upper wings black. Gmelin.

**Bicolor**, a species of *Lamyris* (*Pyralus*), of a ferruginous colour with the posterior part violaceous. Fabricius. This is *Cambrinus bicolor* of Anecoc. acad. It inhabits America, and has the antennae flattened.

**Bicolor**, a species of *Leptura*, of a pale ferruginous colour, with the eyes, wing-cases, wings, and upper part of the thorax and abdomen rufous. Fabricius.

**Bicolor**, a species of *Leptura* (*Dania*), that inhabits Europe. It is of a golden colour, with the upper part of the thorax and the wing-cases green; the latter rufous with impressed dots; posterior thighs destinated. Gmelin, &c.

**Bicolor**, a species of *Lyta*, of a tawnycoloured; wing-cases black at the tip. Geoffroy. Inhabits France.

**Bicolor**, a species of *Mordella*, described by Forster (Nov. Ins.). It is of a black colour; wing-cases tawny, with the tip ferruginous and beneath. It is found and is in the middle band. Very small. Inhabits England.

**Bicolor**, a species of *Nitidula* found in Europe. This insect is rufous, with black wing-cases, having a ferruginous band at the base, and a spot of the same colour near the apex. Fabricius.

**Bicolor**, a species of *Phalæna* (*Bombbyx*), found in Saxony. The wings are white, with a large yellow spot, with black marks. Fabricius.

**Bicolor**, a species of *Searabæus*, with the thorax very slightly armed, and on the head a single tubercle; wing-cases black; abdomen rufous. Fabricius.

**Bicolor**, a species of *Sispa*, of a brown colour, with rufous legs. Linn. &c. A native of Europe.

**Bicolor**, a species of *Smyx* that inhabits New Holland. This is of a black colour; head, abdomen at the tip, and wings yellow; the latter brown at the tip. Gmel. This insect was first described by Fabricius from a specimen in the collection of Sir Joseph Banks, under the specific name *Li. donata*.

**Bicolor**, a species of *Stephanus*, of a black colour, with the antennae, wing-cases, and legs ferruginous. Linn. A native of Europe.

**Bicolor**, a species of *Tentheado*, of a brilliant black, with the abdomen and base of the wings yellow; a band of black. Schrank. Inhabits Autria.

**Bicolor**, a species of *Vespa* that inhabits China; and in size and appearance resembles the common wasp. It is yellowish; antennæ above, crown, thorax, and vent brown. Fabricius, &c.

**Bicolor**, in *Ichthyology*, a species of *Gobius*, found in the Mediterranean sea. It is of a brown colour, with all the fins black. Briin, pile.

**Bicolor**, in *Ornithology*, a species of *Alcedo*, of a green colour, and golden rufous beneath; a black and white waved band on the breast; wings and tail spotted with white. Gmelin. This bird is a native of Cayenne. Buffon calls it *Martin pêcheur vert et roux de Cayenne*; pl. e.l.; and Latham the rufous and green kingfisher. Length eight inches: bill black; legs reddish; breast of the female not banded.

**Bicolor**, a species of *Fringilla*, that inhabits the woods of Jamaica and Bahama islands, and is called by English writers the *Bahama starling*. The head and breast are black; back, wings, and tail, greenish. Gmelin. The length of this bird is four inches; its note very monotonous. Buffon calls it *Coloris Labanencis*; and Buffon *Verdinaire*.

**Bicolor**, a species of *Lanius*, of a blue colour; white beneath; front and black. Linn. &c. This is *Lania Madagas- garseina* of Linn. Syll. Nat. edit. 13; *Lania Madagascar* varicclus varicclus of Buffon; *Piagefriche bleu de Madagascar* of Buffon; and *Blue-fish* of Latham. It is about five inches and a half in length, and, as the luscinia impia, is a native of Madagascar.

The bill, head, margin of the quills feathers, two middle tail feathers, and inferior margin of the four next blue; legs and claws black. Female, forbbid white beneath.

**Bicolor**, a species of *Locias* found in the East Indies. Gmelin very briefly describes it as an habits a curious, and red beneath. This is *Fringilla rubra minor of Buffon*; *Bunus of Buffon*; *Little brown linch of Edwards*; and *orange-breasted greyback of Latham*. There is likewise a variety of this kind of a brownish colour, white beneath, and chin inclining to brownish. About three inches and a quarter in length; bill whitish; legs fuscous.

**Bicolor**, a species of *Musicipa*, of a black colour; front, space round the eyes, throat, rump, spurious wings, hand on the greater wing-coverts, tip of the tail, and under parts of the body, white. Gmelin. Buffon calls this *Gobe nonce à ventre blanc de Cayenne*; and Edwards and Latham black and white *fusycatcer*. A variety of this bird is white, except the hind part of the head, and neck, rump, wings, and tail, bill, and legs, which are black. The female is of an uniform grey colour. Inhabits the moist meadows of Guiana.

**Bicolor**, a species of *Picus*, called by Latham, after Buffon, the *Entenland woodpecker*; *Piépie ou pic varié de Entenland*, Buffon. This is varied with greyish and white; head crested, white on the sides; quill feathers brown, spotted with white. Gmelin, &c.

The length of this beautiful bird is about six inches; bill head colour; irides white; plumage brownish-grey and white finely blended; above, the colours are intermixed transversely, and beneath in a perpendicular direction; creet on the sides intermixed with crimmon; sides of the head white, verging to brown; legs head colour. The female has no crest, and is entirely brown.

**Bicolor**, a species of *Trogilus*, of a scarabæus-golden colour, with the head and throat blue. Gmelin. This is of the middle size, and inhabits Guadaloupe. It is *Colibri* Nr. 2. of Fermin. Surin. ; *Sophié-emande of Buffon*; and *Sophine and emerald humming-bird of Latham*.

**Bicolor**, a species of *Turdis*, of a brown colour, tinged with green; abdomen and vent white. This inhabits the cape of Good Hope; and is ten inches long. Buffon calls it *Mort brun du cap de bonne espérance*; and Latham the *White-rumped thrush*.

**Bicolora**, in *Ichthyology*, an African species of *Phalæna* (*Nudus*). Wings yellow, with a broad brown posterior margin.

**Bicolorata**, a species of *Phalæna* (*Geometra*) with the wings blueish and rufous; anterior black at the tip, and spotted with white. Inhabits Surinam. Cranes, &c.

**Bicolorata**, a species of *Searabæus* (*Melolontha*) found at the cape of Good Hope. It is glistens green, length
BIC

beneath teffaceous, legs tipped with gold. Fabricius, &c.

BICOLORATA, a species of Phalena (Geometra) with blueish fibrated wings; first pair black at the tips, with white spots. A large insect, and inhabits Surinam. Fabricius.

BICORDATA, a species of Cicada (Ranaatra), with black wing-cafes, both sides, and line in the middle, with the legs yellow. Scopoli. Inhabitit Carniola, on the nut-tree.

BICORDATUS, in Natural History, a species of Echinus, having the crown doubled. Leake apud Klein, &c.

BICORNE Os, in Anatomy, is a name which has been given to the os hyoides.

BICORNES, from bis, and cornu, horn, in Botany, plants whose anthers have the appearance of two horns. The term likewise expresses an order of plants of the Fragmenta Methodi Naturalis of Linnaeus.

BICORNICER, in Mythology, an appellation of Bacchus, who is sometimes represented with horns, as symbols of the rays of the sun, or of the virtue which be imparts to wine. The Arabians gave this name to Alexander the Great, either to express his having added the eastern to the western empire, or in allusion to medals on which he is represented with horns, under a pretence that he was the son of Ammon.

BICORNICUS, Musculus, in Anatomy, is an appellation formerly given to those muscles usually denominated Extensors carpi radiales; which see.

BICORNICUS, or Teleconis pollens manus, are terms formerly applied to designate the three extensor muscles of the thumb.

BICORNICUS, in Entomology, a species of Scarabaeus, with two horns on the thorax; a recurved, single-toothed horn on the head, and rufous wing-cafes. Aubert, Jablonoky. Inhabits South America; of a middle size among the horned kind of Scarabaei.

BICORNICUS, a species of Hispa, with pedicellated antennae; thorax and wing-cafes brayly-green; head two-horned. Inhabits North America. Fabricius.

BICORNICUS, a species of Curculio, with acutely dentated thighs, and two teeth on the head. Fabricius. Inhabitit New Zealand, and is varited with brown and cinerous.

BICORNICUS, a species of Cassio; that inhabits South America. It is of a cyanous blue colour, with a trunated spine on the anterior angle of the wing-cafes. Linn. Fabr. &c.

BICORNICUS, a species of Mantis, found in South America, and it is said also in India. The thorax is smooth; head bipartite and fabulate. Linn. &c. The legs are unarmed.

BICORNICUS, a species of Afis, with two horns in front; head black; abdomen hirsute and rufous. A native of Europe. Fabricius.

BICORNICUS, a species of Aranea, with two horns on the abdomen. Lepechin. It. Found in the woods of Siberia.

BICORNICUS, in Natural History, a species of Planaria, with an ovate-lanceolate body obtuse at both ends, of a greyish ash colour, dotted with black; and two very short divergent tubes on the fore-part. Gmelin. This is Pfeilbeo punctata of Pallis.

BICORNICUS, a species of Acantha, found in the North Sea. This kind is hemi-terrestrial, and glabrous with two horns. Mill. Zool. Dan.

BICORPORAL SIGMA, from bis, and corpus, body, in Afromony, those signs of the zodiac which have two bodies, or conflit of two figures. Such are gemini, or the twins; also pisces, or fagittarius, conflitting of a man and a horse.

BICOSTELLA, in Entomology, a species of Phalena (Tinea) found in Europe. This is cinereous, with a brown stripe on the anterior wings; feeders advanced; antennae downy. Linn. Fabr. &c.

BICOLELY, in Geography, a town of France, in the department of the Meute, and chief place of a canton in the district of Toul, 14 league south of Toul.

BICUSCULATA, in Botany. See Fumaria.

BICUSPIDES, denteo nolariis, in Anatomy, are the two small grinders, which are not the front teeth. See Teeth.

BIDA COLONIA, BLEEDA, in Ancient Geography, a town of Africa, mentioned by Ptolemy, and situated in the interior part of Mauritania Caledonica, S.W. of Iconium. See BLEUDA.

BIDACHE, in Geography, a town of France, in the department of the Lower Pyrennees, and chief place of a canton in the district of Ustaritz. 5 leagues east of Bayonne. The town contains 2,204 inhabitants, and the canton 9,766. Its territorial extent is 21.43 square kilometres, and it has 9 communes. N. lat. 41° 31'. W. long. 10°. BIDAL, or BIDALE, in our Ancient Cylirons, denotes the invitation of friends to drink ale at some poor man's house, who, in consideration hereof, expects some contribution for his relief. See ALE.

BIDALDI, an ancient kind of foot-folders mentioned by the French historians, armed with two darts.

Hence the origin of the word, which seems to be a corruption for "bidardi," or "a bimis cardis." They are also called bidiri, bidenu, bidemen, bidunis, and pituns.

BIDASSAOA, or VIDASSAO, in Geography, a river which rises in the Pyrenees, and runs into the bay of Biscay between Anday and FONTARRABIA, separating France from Spain. This river was for a long time a subject of dispute between France and Spain, each country laying an exclusive claim to it; but in the 15th century Louis XII., of France, and Ferdinand, king of Spain, agreed that it should be common between the two nations, and that the duties paid by those who pass from Spain to France should belong to the latter, and of those who pass the contrary way to the former. BUFFON observes, that the inhabitants of the environs of this river have ears of an uncommon size.

BIDBURG, a town of the Netherlands, in the duchy of Luxembourg, containing two parish churches, and a convent; 11 leagues N.N.E. of Luxembourg.

BIDDEFord, or BIDFORD, an ancient sea-port, market, and borough town of Devonshire, England, is situated near the southern coast on the eastern and western banks of the river Torridge, which is of considerable breadth here, and at spring tides rises to the height of eighteen feet. The greater part of the town is built on the declivity of a steep eminence, and many of the houses being composed of timber, brick, cob, and mudwalls, present rather a poor appearance. Bideford does not appear to be noticed in the Domesday survey, but soon after the conquest it was bellowed with Kilhampton in Cornwall, on Richard de Grenville, a Norman knight, who accompanied the conqueror into England, and was ancestor to the illustrious family of the Granville, who for upwards of five hundred years continued proprietors of the lordship. Some of this family have greatly signalised themselves in the public events of England; and the names of two, Sir Richard Grenville and Sir Edwin Granville, are honourably noticed in the historical annals of this country. This town, though described as a borough in a

Charter
B I D

charter of Edward I, and afterwards represented in several
parliaments, seems to have been greatly reduced at the time
when Leland visited it, for he merely mentions the river and
the bridge. Camden, however, speaks of it as "remarkable
for its populousness." At the time of the latter antiquary,
Bideford assumed a commercial importance, and carried
on some trade with America and Newfoundland. Queen
Elizabeth granted it a charter of incorporation, which withd
the government in a mayor, five aldermen, seven capital bur-
gesses, a recorder, town-clerk, and two surgeons at once.
By this charter the inhabitants are empowered to hold a
weekly market, and three annual fairs. Another charter was
however obtained in 1610, which confirmed the former, and
granted the townsmen some additional powers and liberties.
The patroonage and residence of Sir Richard Granville and Sir
Walter Raleigh proved highly favourable to Bideford; for
after these worthy knights had discovered Virginia and Caro-
olina, they returned to, and settled here. In the time of the
Civil Wars, the inhabitants of this place declared themselves
very early in favour of the parliament; but their success did
not prove equal to their zeal, for in attempting to relieve
Exeter, they experienced a severe and total defeat, and im-
immediately resigned Bideford, Barnstable, and their appen-
dages, to the royalists.

In the year 1646, Bideford was ravaged by a plague,
which appears to have been occasioned by the landing of
a cargo of Spanish wool; an article which at that period con-
stituted a principal part of the trade of the town. The cre-
duality and superstitition that characterized the English in
the seventeenth century are strikingly exemplified by an occurrence
which happened here in 1682. Three poor females were ac-
cused of witchcraft, and so direct and positive was the evidence
adduced against them, at several examinations before the
magistrates, that they were committed to Exeter gaol, and
soon afterwards tried, and executed for their alleged
crime.

About the middle of the last century, the export trade
of Bideford to Newfoundland was so considerable, that only two
other ports in the kingdom employed an equal number of
vessels, and in the export trade only one port excelled it.
During the unwise administration, and injurious wars of queen
Anne's reign, these commercial transactions materially suf-
f ered, and the French privateers obtained so valuable
prizes from Bideford bay, that it was emphatically termed the
Golden bay. The number of vessels now belonging to this
port is almost one hundred; these vary in burthen from
twenty to two hundred and fifty tons, and are chiefly em-
ployed in the conveyance of coal and culm; in the exporta-
tion of oak bark to Ireland and Scotland; in the herring
trade; and in the importation of fish from Newfoundland.
The quay is conveniently situated near the centre of the
town, and the body of the water at high tides will bring up
vessels of 500 tons burthen. The chief manufacture of this
place is that of coarse brown earthenware, which is made
with clay brought from Fremington near Barnstaple.
The price of this is only two shillings and sixpence per ton.
The bridge at Bideford, built of stone, consists of twenty-four
irregular arches, and was constructed about the middle of
the fourteenth century. It is 677 feet in length, and was con-
structed at the expense of Sir Thobald Granville, kn.t. and at
the instigation of the bishop of the dioceze, who granted indul-
gences to such persons as gave money in aid of the work. The
court, a spacious building, was erected in the form of a
cross about the middle of the fourteenth century. A house
industry has lately been erected here; and a free school,
and a free grammar school are ranked among the charitable
foundations of the town. The market-place is spacious, and
the town hall is a large convenient building with two prions
beneath it. In the peri the of Bideford are 626 houses and
2587 inhabitants. This town is 211 miles S.W. from
London.

Thomas Stukeley, a defendent of the celebrated chaplin
to Oliver Cromwell, was a native of Bideford, and was distin-
cuted for many eccentricities of character. John Shub-
beare M.D., an author of some eminence, was also born here
in the year 1709.

About five miles east of this town is Tawstock, the seat of
Sir Bouchier Wrey, Bart. This place is mentioned by dif-
ferent authors as remarkable for embracing at one view
"the belt manor, belt manse, finial church, and richet
rectory in the county." Bishop's Tawton, near Tawstock,
is said to have been the first feat of the bishop of this diocese.
Watkin's History of Bideford. Maton's Tour through the
western counties. Prince's Worthies of Devonshire. Beauties

Bideford, a port of entry and port-town of America,
in York county, and district of Mayne, on the south-west side
of Saco river, on the sea-coast, 14 miles S.W. from Port-
land, 24 N.E. from York, and 105 from Boston. It con-
tains 1618 inhabitants, and the county-courts are held here
and at York. N. lat. 43° 26'. W. long. 70° 25'. The bay of
Bideford lies at the mouth of the river Saco, and has
Black point for the N.E. point, and cape Porpoise for the
S.W. point.

BIDDING, is used for proclaiming or notifying; also for
offering a price for goods put up for auction.

BIDDING of the beads, a charge or warning which the
priest priec gave to his parishioners at certain special times,
to say many pater-nollers, &c. on their beads.

Bishop Burnet (Hist. Ref. vol. ii. p. 20.) has preferred
the form, as it was in use before the reformation, which was
this: after the preacher had named and opened his text, he
called on the people to go to their prayers, telling them what
they were to pray for; "Ye shall pray (says he) for the king,
for the pope, for the holy catholic church, &c." When this
was done, all the people paid their beads in a general silence,
and the minister knelt down and likewise said his: they
were to say a pater-noster, an ave-maria, Deus misereat
nostri, dome salum fac regem, gloria patri, &c., and then
the sermon proceeded.

BIDDLE, John, in Biography, a distinguished peron
among the Sotamians, and reckoned the father of the English
seets bearing this denomination, and lately assuming that of
Unitarians, was born at Wotton-under-Edge in Gloucester-
shire, in 1615; and after a previous grammatical education,
in the course of which he exhibited specimens of his talents
and improvement, admitted, in 1632, a student at Mag-
dalen-Hall, in the university of Oxford. Here he acquired
great reputation for learning and prudence, both as a stu-
dent and a tutor: and having taken his degrees of bache-
lor of arts in 1634, and of master of arts in 1641, he was,
in this latter year, recommended by the principal perons in
the university to the magistrates of Gloucester, and apponted
by them master of the free school of St. Mary de Crypt, in
that city. In this office he completely answered the expec-
tations of his constituents, and gave great satisfaction to the
parents of the young persons who were entrusted to his care.
But he did not long enjoy, without moleltation, the advan-
tages of this situation; for he was led, by a diligent study
of the scriptures, to adopt notions that were deemed hereti-
cal, concerning the Trinity, and more particularly to deny
the deity of the Holy Spirit. Failing to give satisfaction
to the magistrates, before whom he was summoned, by his
confession in 1644, he drew up a more explicit account and
defence
defence of his sentiments on this subject in a tract, entitled, "Twelve arguments, drawn out of the scriptures, wherein the commonly received opinion touching the deity of the Holy Spirit is clearly and fully refuted." A copy of this treatise, which he had shown to some of his friends, having been, by the treachery of an acquaintance, delivered to the magistrates of the city, and to the parliament committee then sitting there, he was committed, in December 1645, to the common gaol. He was released, however, on giving security for his appearance when called for. Six months after he had obtained his liberty, he was summoned to appear before the parliament at Westminster, and examined by a committee. As he freely professed his disbelief of the commonly received opinion concerning the divinity of the Holy Spirit, he was committed to the custody of one of the officers, and kept in that state of restraint for five years.

In the mean while, his book entitled "Twelve arguments, &c." was published, and being declared blasphemous against the divinity of Christ, the house, in 1647, ordered it to be burnt by the common hangman. In the following year, the author, perceiving in his opinions, and avowing his fear of their importance, published two other tracts of a similar nature; one entitled, "A confession of Faith touching the holy Trinity, according to the scripture:" and another entitled, "The testimonies of Irenæus, Justin Martyr, Tertullian," and of several other early writers, relating to the same subject. These books excited an alarm, and were the means of procuring a severe ordinance of parliament, inflicted in May 1648, at the solicitations of the Assembly of divines, who acted in this instance in a manner that entails disgrace on their memory, and denouncing the penalty of death against those who held opinions contrary to those that were established respecting the Trinity, and some other doctrines, accounted blasphemous and heretical; and severe penalties on those who differed in letter matters. By this infamous and execrable decree the fate of Biddle seemed to be inevitable. But he escaped in consequence of a difference in parliament, supported by a party in the army, to whose care this ordinance would have extended. After the death of the king, the Independents acquired influence, and introduced a kind of general toleration, under which Biddle was allowed to go to Staffordshire, where he was hospitably received by a judge of the peace, who, at his death, left him a legacy. From this retired asylum, however, he was remanded by president Bradshaw to closer confinement, in which state he continued for several years, under an imputation of blasphemy and heresy, which deprived him of all society, and reduced him to such lamentable indigence, that his whole support for a considerable time was a draught of milk morning and evening. The only divine who visited him, during this period, was Mr. Peter Gunning, afterwards bishop of Ely. In these circumstances he obtained temporary relief by being employed in correcting the press for a Greek Septuagint, printed in London by Roger Daniel; and in 1654, he regained his liberty by the general act of oblivion, published by the parliament in this year. Of this liberty he availed himself, by instituting a Sunday's lecture for reading and expounding the scripture, and thus propagating his opinions. The Presbyterian ministers were rendered uneasy by his zeal and successes, more especially as they could derive no assistance for restraining him from the secular power. Not satisfied with the opportunities he enjoyed of disseminating his sentiments from the pulpit, and in the intercourse of private friendship, he had again recourse to the press, and in 1654, published his "Two-fold Scripture catechism," one larger and more comprehensive, and the other more brief, for the use of children. For this publication he was called to the bar of Cromwell's parliament, and committed to the Gate-house, where he was debarred the use of pen and ink, and the access of any visitor; and his books were also ordered to be burnt. Although a bill was brought into parliament for punishing him, he obtained his liberty after six months' confinement, by due course of law. Some time after, he had a dispute with a baptist teacher; in the course of which he made use of some expressions, for which he was thrown into Newgate, and tried for his life at the next sessions, on the ordinance above-mentioned. On this occasion counsel was at first denied him, but afterwards granted, and the trial deferred. In the mean while Cromwell interfered, and disapproving of this kind of intolerance, contented himself at first with detaining him in prison; but afterwards, in order to silence the clamours and petitions that were prefered against him, banished him for his life to St. Mary's castle in the island of Scilly, assigning him an annual subsistence of 100 crowns. In this place of exile Biddle continued three years, applying himself to close study, and particularly to that of the Apocalypse. His friends at length prevailed with Cromwell to recall him; and in 1658, as no charge appeared against him, he was liberated. He then became pastor of an independent society in London, and propagated his opinions without molestation, till the fear of the presbyterian parliament assembled by Richard Cromwell, and the advice of his friends, induced him to retire into the country. On the dissolution of that parliament, he returned to his former station. After the restoration of Charles II. he withdrew from public service, and exercised his ministry in private assemblies with his select friends. However, in June 1662, their meeting was discovered, and both he and his friends were apprehended and committed to prison; and at length, by process of law, each of his hearers was fined 20l. and Biddle himself 100l.; and they were ordered to remain in prison till these fines were paid. The close confinement and foul air of a prison, within five weeks, brought upon him a distemper, which terminated his life September 22, 1662, in the 47th year of his age: and thus was his death hastened by the intolerance which perverted him during the greatest part of his life. Mr. Biddle professed a considerable degree of learning, and with the Scriptures he was so conversant, that he could repeat the New Testament from memory, both in English and in Greek, as far as the 4th chapter of the revelation of St. John. He professed also, with this retentiveness of memory, powers of reasoning, which eminently qualified him for discriminating his peculiar opinions, and gaining preachers.

In his private character he was distinguished by his piety and devotion, by his moderation and temperance, by his constancy and benevolence, and by his irreproachable virtue. As he differed in some respects from Socinians and the foreign Unitarians, his followers were for some time denominated "Biddellians;" but the name did not subsist after his death (1658). Biddulphs Life of Biddle, in Unitarian tracts, vol. iv. 1791. Neal's Hist. of the Puritans, vol. ii. p. 476, 490.

BIDDLES, in Geography, a settlement-on a branch of Licking river, in Bourbon county, Kentucky, about 6 miles N.W. from Millers on the N.E. side of the same branch; and 32 miles N.N.E. from Lexington.

equal, oblong, channelled, concave. Cor. compound, uniform, tubular; corollas hermaphrodite, tubular. Proper, one-petalled, funnel-form; border five-chief, crested. Stam. filaments five, capillary, very flut., anther cylindrical, tubular. Pet. fl. oblong; style simple, the length of the flaments; ligulas two, oblong, reflex. Per. none: calyx un-changed. Sepals solitary, obtuse, angular; down with two or more awns, oblong, straight, acute, rough-hooked backwards. Rec. flat, flabby; chaffs deciduous, flatish. Oval. In most of the species an expanding five-leaved calyx surrounds the compound flowers. *Verbeia* differs from *Bidens* only in having a ray. Sometimes the corolla has one or two radial florets. Reich. Eff. char. Cal. imbricate. Cor. sometimes but seldom with a floccle or two in the ray. Seed crowned with erect, furrowed awns. Recept. flabby.

Species, 1. *B. tripartita*, trifid water-hemp-agrimony, or bur-marigold. Lin. sp. pl. 1165. Hud. 355. With. 706. Hull. 181. Rheyl. 308. Sibth. 238. Abbot 177. Curt. Lond. f. 4. t. 57. Smith. Fl. Brit. 357. 1. Verbeia feu cannabis aquatica, flore minus pulchro, elator et magis frequens. Rau Synop. 187. Eupatorium cannabinum ternaria. Ger. et. 711. B. Conyza pallutris, fol. tripartita divisa. Loes. prulf. 53. 180. "Leaves trifid; calyx ribbed, with opposite, red, hairy, rough hairs, which the calyx causes to curl from the base towards the ends of the leaflets. Calyx three-cornered. Root annual; stem from one to three feet high, with opposite, reddish branches, patent, leafy, obtusely quadrangular, furrowed, and smooth; leaves opposite, smooth, deep ferr., trifid or quinquefid; flowers terminating, solitary, somewhat erect, with undivided patent leaflets; leaflets of the calyx unequal, plane, smooth, break'd with brown; the floccles uniform, tubulose, yellow; seeds compyfere, two or three-angled, the angles backward rough, two or three awns, terminating; form what eret, yellow, three-cornered, prickly backward; the chaffs of the receptacle resembling the leaflets of the calyx, but narrower. It frequent in places inundated, and on the banks of ditches; flowers in August and September. This plant dyes a deep yellow; for which purpose the thread or yarn must be first steeped in slim water, then dried and steeped in a decoction of the plant, and afterwards boiled in the decoction. As by a chemical analysis it is found to possess much the same qualities as verbeia acumella, it may probably have the same good effects in expelling the stone and gravel. 2. *B. minima*, nodding bur-marigold. Lin. sp. pl. 1165. Reich. 297. Hull. ed. 310. Fl. Dan. t. 121. Abbot 177. With. 883. Curt. Lond. 5. 55. B. tripartita. B. Hud. 355. B. Cernua. 7. Smith. Fl. Brit. 357. Verbeia minima. Dill. in Rau Syn. 188. t. 7. f. 2. Diff. 167. App. 66. "Leaves lanceolate; flowers and seeds erect." This was first marked by Dillenius for a distinct species. Haller thought it to be no more than a variety of the *cornus*, in which he has been followed by all our British botanists. Found in dried marshes. 3. *B. nodiflora*, feathery-flowered bidens. Lin. spec. 1165. Dill. eith. t. 44. f. 52. Reich. 357. "Leaves oblong, quite entire, one-toothed, fem dichotomous, flowers solitary, flabby." An annual plant, rising with stems eight or nine inches high, roundish, rough, with white hairs, purple at the base. A native of the East Indies; cultivated at Eltham by Dr. Sherard, in 1732. 4. B. tenella. Lin. Spec. 1165. Reich. 3572. Amon. 6. str. 47. "Leaves linear, peduncles capillary, calyxes mostly four-leaved, seeds erect five-fold." Stem stiff, leaf-traces concolorous, six or seven inches in height. An annual plant, and a native of the Cape of Good Hope. 5. *B. cornua*, drooping water-hermaphroditism, or bur-marygold. Sp. pl. 1165. Hud. 356. With. 705. Hall. 151. Relh. 359. Siibth. 238. Abbot 177. Curt. Lond. f. 3. t. 55. Fl. Dan. t. 121. Smith. Fl. Brit. 357. 2. Pet. herba. t. 20. f. 6. Rau him. 357. 2. 3. Verbeia pulchrior Loreus. Rau Syn. 157. Baus. hiil. v. 2. 1074. Coreopsis bidens. Sp. pl. 1281. Chrysanthenum cannabinum bidens, foliis integris. Morf. hill. 1. 6. t. 5. f. 22. Eupatorium cannabinum chrysanthenum. Barc. et. 1209. Conyza palutziris, foliis ferratis. Le. prulf. 54. t. 11. "Leaves lanceolate, filaments clasping, flowers nodding, seeds erect." Root annual; stem from one to two feet high or more, upright, branched, a little hairy, purplish, dotted with red, round at bottom, ariated at top, with branches opposite, nearly upright, leaves opposite, moderately conate, undivided or with flat serratures, spreading, smooth on both sides; peduncles risen; flowers yellowish-green, finally drooping, generally radulate; calyx consisting of about seven leaves, finely serrate at the edge, ribbed, turning back, and longer than the corolla; with eight corollas in the circumference, hermaphroditic like the central one, but with the tube more tumid and depressed. In places overflowed for a long time, they change into ligulate narrow corollas: receptacle pyramidal, four-cornered; seeds with four awns, two of which are large; the prickles pouenting downwards. This flowers a month later than the *tripliaria* and in the state it has a strong smell, not very disagreeable. A native of most parts of Europe. Haller observes, that *coreopsis bidens* of Linnaeus differs in so respect from *B. cornua*, except in having radicate florets in the circumference; hence Dr. Stokes concludes, that bidens and *coreopsis* form one genus. Found at Ditchingham in Norfolk, and Tarporley in Cheshire; frequent in Ireland. 6. *B. fendleri*, smooth-flaked bidens. Lin. Spec. 1166. Curt. fruct. 2. 412. Reich. 3704. Berka. diff. t. 5. f. 5. Chrysanthenum, &c. Mor. hill. 3. 17. f. 6. t. 5. f. 20. "Leaves pinnate, serrate, marked with lines, smooth; seeds erect; calyxes leafy; stem pilifer." The stem rises about three feet high, sending out many horizontal branches, from the ends of which are produced clusters of yellow flowers. It grows naturally in Virginia, Maryland, and Canada, where it is often a troublesome weed. It was cultivated by Mr. Miller in 1752. 7. *B. palaestina*, hairy bidens. Lin. Spec. 1166. Syll. 732. Reich. 3705. Dill. eith. t. 43. f. 51. Thum. jep. 379. Lour. cochin. 488. Gerant. Fruct. 2. 412. B. Chinensis. Agrimonia Moleca. Rump. Amb. d. 38. t. 15. f. 2. "Leaves pinnate, somewhat hairy, stem with bearded joints, calyxes with a simple involucre, seeds diverging." A native of America, and of Tongataboo in the South Seas. B. of China resembles the American; but in the latter the leaflets are united, in the former they are distinct; and the seeds of the American have from two to five awns, and in the Chinese always four. The American was cultivated in 1752 by Dr. Sherard. 8. *bipinnata*, hemlock-leaved bidens. Lin. Spec. 1166. Reich. 3705. Lour. cochin. 488. Chrysanthenum. frem. par. t. 123. Mor. hill. 17. d. 24. f. 6. t. 7. f. 23. "Leaves bipinnata, gilded, calyxes involucrate, corollas half-radiated, seeds diverging." An annual plant; a native of Virginia; cultivated in Kew garden in 1699. Laurinco says, it is a native of China and Cochinchina. 9. *B. nivea*, snowy bidens. Lin. Spec. 1167. Reich. 3766. Dill. eith. t. 47. f. 55. Swartz obs. 256. B. Dill. eith. t. 47. f. 55. 3. 7. Diff. eith. t. 46. f. 54. "Leaves simple, cordate-ovate, acuminate, branches tri-chotomous, ferrate, flowers hemispherical, peduncles elongated." A native of Jamaica, in elevated pastures, and on the sea-coast of the southern parts. Mr. Miller says, it grows naturally in South Carolina, and also at Camppehly; cultivated at Eltham in 1732.

Most of the species are herbaceous annuals; some, however, are shrubs; leaves generally opposite, some pinnate; flowers axillary or terminal.

Propagation and culture. The first, second, and fifth, being common weeds in many parts of Europe, are seldom cultivated in our gardens, but readily propagate themselves by seeds, in wet situations. The third, fourth, seventh, and twelfth, must be grown upon a moderate hot-bed in the spring, and afterwards treated like other hardy annual plants, planting them into the full ground the latter end of May. They will flower in June; soon afterwards the plants will decay. The fifth and eighth are easily propagated by seeds sown in the spring, in an open situation, where, if they be allowed to clatter, the plants will come up the following spring, and two or three of them may be planted where they are to grow; and after they are rooted, they will require no further care. Being annual plants, they decay soon after the seeds are ripe. The ninth, tenth, eleventh, thirteenth, and fourteenth species are propagated also by seeds, sown on a cold-bed in the spring; and when the plants are fit to remove, they must be each planted into a separate small pot, plunged into a fresh hot-bed, and treated like other tender plants from the same hot countries. In autumn they must be placed in the bark-stove. Properly managed they will mostly abide for some years.

Bidentes. See Coreopsis, Elephantopus, Splanthus, Verbesina, and Zinnia.

Bidentes, in Coneyology, a species of Myrtus, with a straited and slightly curved shell, having the posterior margin inflected, and the hinge at the end bidentated. Gmelin. A native of the Mediterranean, Ethipic, African, and American seas. The colour of this shell under the epidermis is black or blue, about an inch in length, and straited longitudinally.

Bidentes, a species of Nerita, with a smooth shell, and inner lip bidentate. Liern. Nat. Hist. Utr. Country unknown. This shell is black or reddish, with obsolete fimbriae, and the size of a pea. Sometimes it is yellow, clouded with whitish, with three black bands.

Bidentes, in Entomology, a species of Scarabaeus, found in America. The head and thorax are brassy-green and downy; wing-cases teataceous, glossed with green. Fabricius.

Bidentes, a species of Cassida, of a black colour. Wing-cases protruded in front, with an erect spine on the spine of each. This is of a large size, and is an inhabitant of Brazil.

Bidentes, a species of Curculio, that inhabits New Zealand. It is black; posterior thighs dentated, with a single spine on each of the wing-cases. Fabricius.

Bidentes, a species of Cerambyx (Lamia), found in New Holland, and described by Fabricius. It is grizeous; thorax acutely spinous; wing-cases bidentated at the tip.

Bidentes, a species of Mantis, that inhabits America. The thorax is lacubor; wing-cases green, fasciculated with black; wings brown, deep black in the disk.

Bidentes, a species of Gymnus (Spinifera), the thorax of which is obtusely spinous; inner and posterior margin, and bidentated vent, sognumose; wing-cases pale. A native of Europe. Linn. and Gmelin. There is also another species in this section, described by Linnaeus and Gmelin, under the name of bidens. It is of an ovate shape, and grizeous, with the thorax acutely spinous, and the antennae rufous. This inhabits Europe.

Bidentes, a species of Spina, of a black colour, with two spines on the thorax, and third segment of the abdomen, with a yellow margin. Fabricius. It inhabits the north of Europe.

Bidentes, a species of Formica, that inhabits Surinam. Thorax with a bidentated tubercle; head ovate; antennae ferruginous; lower joint black. Fabricius. Sp. Inf.

Bidentales, in Antiquity, a place struck with a thunder-bolt, and on that account consecrated to the gods, and to Jupiter in particular, and forbidden to be trod on, and to remove its bounds was deemed sacrilege. Bidental only differed from putul, as in the latter, the thunderbolt was supposed to be hidden or buried with ceremony under the ground. The fall of lightning, or a thunderbolt, on any place, was judged by the Romans an indication that Jupiter demanded it for himself. Hence, they surrounded it with a wall, rail, itakes, or even a rope; and expiated it, by the sacrifice of a bidentes, or sheep of two years old. Peltus represents the bidental as a temple, where sheep of two years old were offered in sacrifice. But by temple, he here means no more than a place inclosed, and consecrated to the gods. The appellation was extended to thunder itself, and to persons destroyed by it.

Bidentales, priests among the ancient Romans, instituted for the performance of the ceremonies of a bidental. The bidentales conduced a college, or decury, who had the service and proclamation, or interpretation of thunder and lightning. The first, and principal part of their office was, the sacrificing a sheep of two years old, which, in their language, was called bidentes, as having only two teeth, one on each side; or rather from bidenis, anciently written for bidentis, two years old.

Bidentata, in Coneyology, a species of Helix, found in the botanic garden at Stratford, and figured by Chemnitz. The shell is pyramidal, somewhat carinated, broad, and very finely straited, with a reflected, bidentated lip.

Bidentata, in Entomology, a species of Arpis (Andrena) that
BID

BIDLOO, GODFREY, in Biography, a celebrated Dutch anatomist, born at Amsterdam, 1649, applied early to the study of surgery, which he practiced several years at his native city; he was also surgeon to the army, and at length physician to William III, with whom he continued in great favour to the time of his death, which happened in 1702. In 1694, he was made professor of anatomy and surgery at Leyden. He was a man of considerable learning, Haller says, but more attached to the pleasures of the table, than to study, to which he attributes the numerous errors and inaccuracies in his otherwise splendid and valuable anatomical tables, which were criticized, perhaps, with too much severity by Ruyssch, who had been his pupil. Our countryman, William Cowper, purchased 300 copies of the plates, in the lifetime of Bidloo, and published them as his own, only giving new explanations, of which our author, with reason, complained in his "Guilem Cwper ctitatam curam tribunal," Leyden, 1725, 4to. Besides his great anatomical work, consisting of 165 tables, with explanations, fol. 1685, and his controversial papers, he published, "Observationes de animalibus in hepate villi detectae," 1698, 4to. "De oculis et viso variarum animalium," 1712, 4to. "Exercitiones anatomica-chirurgicae," 1730, 4to. These, with various other dissertations, were collected, and published in 1781, 4to, two years after his death. Haller, Bib. Anat. Chirurg. et Med. His nephew, Nicholas Bidloo, was physician to the great Czar Peter I.

BIDON, a liquid measure of about five quarts English measure; seldom used except among ship's crews.

BIDOURLE, in Geography, a river of France, which passes by S. Hippolyte, Sauer, Sommieres, &c. and runs into the lake of Peraut, 3 leagues east of Montpellier.

BIDOURE, a river of France, which runs into the Adour, near the junction of that river with the gaves of Paced and Olare.

BIDUMI, a country of Asiatic Turkey, the south part of Syria, bounded on the north by Palestine, on the west by Egypt, and on the east and south by Arabia; it is nearly desert, and has only a few scattered villages.

BIE, ADRIAN de, in Biography, a painter of portraits and ornamental architecture, was born at Liere, in 1554, and after being initiated in the rudiments of his art by Wouter Aths, became the disciple of Rodolph Schoof, a painter of considerable reputation at Paris. He perfected himself at Rome, where he spent six years in the study of the best masters, and there received great encouragement from persons of the first distinction. He so much excelled in the mezzetins of his penelling, and in the delicacy of his touch and colouring, that he was frequently employed to paint on jasper, agates, porphyry, and other precious materials. The place and time of his death are not ascertained. Pilkington. See BIE.

BIEBER, in Geography, a town of Germany, in the cir- cle of the Upper Rhine, and county of Hanau Munzenberg, 16 miles east of Hanau. Near this town are a mine of copper and silver, and some works of iron and cobalt, in which the latter is prepared into a beautiful smalt.

BIEBERICH, a small but handsomf town of Germany, seated on the borders of the Rhine, and in the vicinity of Mentz. It belongs to a prince of the same name.

BIERERSBACH, a town of Germany, in the circle of Franconia, and principality of Bayreuth.

BIEBRA, a river of Poland, which runs into the Narew, near Wiezna, in Masovia.

BIECZ, a town of Poland, in the patinamate of Cracow, seated on the river Wisloake, and famous for its mines of vitriol. N. lat. 49° 50'. E. long. 21° 40'.

BIEDA,
BIE

BIEDA, a town of Italy, in the late of the church, and province of Patrimonio, 10 miles W. of Sutri.

BIEDEBURG, anciently Bede, a small town of Germany, in the circle of Burgundy, and duchy of Luxembourg, which was flourishing till the year 1663, but soon afterwards laid waste by the French.

BIEDEKOPF, or BIEDEKAP, a small town of Germany, in the circle of the Upper Rhine, and principality of Upper Hesse, seated on the Aulbs, 16 miles N. W. of Marburg, and formerly famous for its iron-works and founders.

BIEFVERSKOW, a district of Zealand, belonging to Denmark, including 12 churches.

BIEKA, BIEQUE, BORIQUEN, or CAB'S ISLAND, one of the Virgin Islands in the West Indies, about 23 miles in length, and not 6 in breadth, where it is widest. It is distant about 6 miles S.S.E. from Porto Rico. The soil is rich, and it has a good road on the south side, called Great Harbour. It is claimed by the Spaniards, whose interest it is to let it remain defolate. N. lat. 18° 2', W. long. 64°. See Virginia Islands.

BIEKOW, or Jezow, a town of Poland, in the patinate of Lencicz. 24 miles S. E. of Lencicz.

BIEL, a town of Spain, in Aragon, 6 leagues S. W. of Jaca.—Alto, a river of Spain, which joins the Ores at Exca. See Bienne.

BIELA, a town of Bohemia, in the circle of Czaffau, 6 miles N. E. of Teutsch Brod.

BIELA, or BIEL, a town of Italy, in Piedmont; the capital of a small country, bounded on the north by the Alps, on the west by the duchy of Aosta, on the east by the Vercellus and the Malferan, and on the south by the Canaves; the town is rich and populous, containing about 7,000 inhabitants, and is divided into the Upper and Lower, and has four churches and four monasteries. It is famous for an image of the Virgin Mary; distant 13 miles N. from Ivrea, and 24 N. W. from Vercelli. N. lat. 45° 27'. E. long. 8° 3'.

BIELACH, a river of Germany, in the archduchy of Austria, which runs into the Danube, near Melek.

BIELAILA, a river of Russia, which rises in the Uralian mountains, and after traversing the government of Ufa, discharges itself into the Kama, on the borders of the government of Cafan.

BIELASTENA, a town of Croatia, 10 miles north of Bihae.

BIELAY, a town of Bohemia, in the circle of Koninigratz, 4 miles S. W. of Branau.

BIELSKO, a town of Siberia, 40 miles south of Enchef.

BIELCOPOL, a town of Poland, in the patinate of Kiov, 48 miles west of Balacercik.

BIELEF, a town and district of Russia, in the government of Tula, seated on the Oeca, 50 miles W.S.W. of Tula.

BIELEFELD, a town of Germany, in the circle of Westphalia, and county of Ravenberg, divided by the Lutterbach into the old and new town, seated at the foot of a mountain, and containing about 800 houses. The inhabitants are partly Lutherans, and partly Roman Catholics. The old town has two churches, the new a convent and a chapel. This town received municipal privileges in 1287, and was formerly Hanseatic; it is distant 22 miles north of Lippstadt.

BIELGORD, a town formerly called Sarkel, and district of Russia, in the government of Kursk, seated on the Donetz; 50 miles S.S.W. from Kurik. N. lat. 50° 55'. E. long. 46°. This town was built in 902, by the great Vol. IV.

BIED, a town formerly called Sarkel, and district of Russia, in the government of Kursk, seated on the Donetz; 50 miles S.S.W. from Kurik. N. lat. 50° 55'. E. long. 46°. This town was built in 902, by the great Duke Wladimir, and is an archbishop's see; it submitted to the arms of Potemkin, in 1790.

BIELGORD. See Akerman and Moscow.

BIELGRAD, a town of Croatia, 46 miles S. E. of Bihae.

BIELIAN, a town of Russian Tartary. N. lat. 43° 20'. E. long. 66° 4'.

BIELICA, or Bilizin, a town of Lithuania, in the province of Vilna, seated on the Niemen, 10 miles south of Lithuania. N. lat. 53° 35'. E. long. 55° 40'.

BIELISKA, a town of Poland, in the patinate of Kiof, 41 miles S.W. of Koif.

BIELITZY. See BIELTY.

BIELE, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Chaumont, 6 miles E.S.E. of Chaumont.—Allo, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Oleron, 14 miles south of Oleron.

BIELOI, a town and district of Russia, in the government of Smolenske, on the small river Vobilha, falling into the Meha or Meza, which discharges itself into the Duna; 56 miles N.N.E. of Smolenske. N. lat. 55° 40'. E. long. 30° 40'.—Allo, an island in the Karkoji sea, about 70 miles in circumference, 20 miles from the continent of Russia. N. lat. 73° 40'. E. long. 69° 14'.

BIELOKAMIESKOI, a fortress of Russia, in Siberia, on the eait side of the Irith, 12 miles S. E. of Sempolatnoi.

BIELO-OZERO, or White Lake, a lake of Russia, in the government of Novgorod, about 50 versts long, and 30 broad, which receives into it several small streams. The only one that flows out of it, is the Sheksina, which falls into the Volga. The water of this lake is clear, having a bottom partly of clay, and partly of stone. The clay is generally of a white colour, and in stormy weather causes a strong white foam upon the surface of the water. From this circumstance, the lake first obtained its name Biello, or White. It contains plenty of fish and crabs. N. lat. 59° 42'. E. long. 36° 30' to 35° 18'.

BIELOPOLIE, a town and district of Russia, in the government of Karkof, seated on a rivulet falling into the Smn, 85 miles N.N.W. of Karkof.

BIELOVITZ, a town of Croatia, 11 miles S. W. of Damianovitz.

BIELOVODSK, a town and district of Russia, in the government of Voronetz, seated on the Derkul, which falls into the Donoe, 130 miles south of Voronetz. N. lat. 49° 42'. E. long. 39° 10'.

BIELOW, a town of Poland, in the patinate of Volhina, 36 miles eait of Lucko.

BIELOZERSK, a town and district of Russia, in the government of Novgorod, on the south side of the lake Bieu-Ozero, near the euffix of the river Sheksina, 64 miles N. E. of Vologda. N. lat. 59° 45'. E. long. 37° 10'.

BIELSA, a town of Spain, in Aragon, 6 leagues from Aina.

BIELS, a town of Poland, and capital of the patinate of Podalach, where the dietue for the district is held. It is little better than a miserable village, though called in the geographical descriptions of Poland, a large town. N. lat. 52° 48'. E. long. 23° 28'.—Allo, a town of Poland, in the patinate of Plczeko, 10 miles N. E. of Plczeko.

BIELETSCH, a town of Bohemia, in the circle of Chrudim, 16 miles north of Chrudim.

BIELUGA, in Zespol, Delphines Lescus (Gmelin) in Steker's Kambtshakta, &c.

BIELENAIE, John, in Biograph, born in 1621, at Yy Mazer.
Maxeres, a city in France, where he practised surgery with such success, as to attract the notice of his sovereign, Lewis XIV., by whom he was made surgeon to the army in Flanders. He acquired great reputation; Haller says, by introducing the future of the tendon, and by curing a puncture of the brachial artery in a young nobleman. He gives excellent caution, on taking up the artery, after amputating a limb, to avoid including the nerve in the ligature. He performed the operation of the thorax successfully, and appears to have been a bold and expert operator, and to have made considerable improvements in his art. He died 1681, aged 80 years. A few years after his death, viz. in 1688, a pollitical work was published, containing an account of these operations, under the title of "Operations de Chirurgie, par une methode courte et facile," 12mo. Paris. Haller Bib. Anat. Eloc. Diet. Hill.

BIENENBUTTEL, in Geography, a town of Germany, in the circle of Lower Saxony, and Principality of Lunenburg, 10 miles S.S.E. of Lunenburg.

BIENNE, a small district of Swisserland, lies between a lake of the same name and a chain of the Jura mountains. It is surrounded by the cantons of Berne and Solouere, the bishopric of Bale, and the principality of Neufchatel. The bishop of Bale is the sovereign of this little state, but his power, even before the French revolution, was exceedingly limited; and its constitution was nothing but a limited monarchy, nor an independent republic, but a kind of mixed government, partaking in some degree of both. The bishop of Bale, upon his promotion to the see, received the homage of the citizens and militia of the town of Neuffatell, with attendant tokens of absolute submission, but at the same time he confirmed, in the strongest manner, all their privileges and franchises. The mayor appointed by him was his representative, to whom it belonged to convocate and preside in the little council, as the chief court of justice, to collect the summons, and to declare the sentence; but without giving any vote himself. Although justice was carried on, and executed in the name of the bishop, yet neither that prince, nor the mayor, had the prerogative of pardoning criminals, or of mitigating the sentence. All causes, civil and criminal, were brought before the council in the first instance; and in more important proceedings, an appeal lay to the sovereign council. In both cases, each party chose a member of the council to act as his advocate, which office he discharged without fee or recompense. The sovereign's council, at a general meeting, chose a year at a time, who should preside in the administration. The legislative authority resided in the great and little councils combined: the former consisting of 40 members, and the latter, to which the executive power belonged, being composed of 24; and it was required that the members of each council should be married men. Both councils elected their respective members; and therefore the constitution was altogether aristocratical. The burgomaster, or chief of the regency, was chosen by the two councils, and presided at their meeting, and retained his office during life; but it was necessary that he, as well as the several magistrates, should be confirmed annually by the two councils. The salaries annexed to these posts were small, and the general expenses of government so inconsiderable, that the revenues of the state were sufficiently ample.

This republic, though a Protestant one, under the sovereignty of a Catholic bishop, enjoyed in the fullest extent the power of imposing taxes, contracting alliances, declaring war and peace; and, in short, of exercising every other act of absolute and independent legislation. Its singular constitution was guaranteed by Berne, Friburg, and Solouere, with which the town was closely allied, having connected itself with the former in 1352, with the second in 1496, and with the latter in 1582; in consequence of which union it became a member of the Helvetic confederacy. This alliance between the cantons and the town of Bienne was paramount to that of the same cantons with the bishop of Bale: for the town enjoyed the right of sending deputies to every general diet, ordinary or extraordinary, a privilege not possessed by the bishop. The language of the country is a provincial German; but, as the territory borders on the principality of Neufchatel, the inhabitants speak also a corrupt French. The extent of the town and territory of Bienne is estimated at 144 square geographical miles, and its population at 5,500, or nearly 6,000 persons; the people are very active and industrious. Bienne forms an important post into the Swisserland territories; accordingly, it was occupied by the French on the 8th of February 1798, and annexed to France as subject to the bishop of Bale, whose rights they assumed in consequence of having seized his territories.

Bienne, called by the Germans Biel, the capital of the above district, is situated at the foot of mount Irn, and at a little distance from the lake of the same name. Between the town and the lake is a plain, which the sovereign council, by a kind of Agrarian law, that was honourable to the legislature, allotted, by distinct portions, to each burgher for his own distinct use: and it is entirely laid out in small kitchen gardens. Several manufactures have been established in the town, which, considering its size, carries on a tolerable trade. The government, by adopting the liberal policy of conferring the burgheip at an early rate, has contributed to increase the population of the town, and to extend its commerce. N. lat. 47° 8' E. long. 1° 4'.

Bienne, lake of, lies to the north-east of that of Neufchatel, with which it is connected by the Thijelle, which separates the country of Neufchatel from the canton of Berne. It is about 9 miles long, and 4 broad; its borders are pleasing and picturesque, as it is skirted with agreeable walks and country houses; and the town of Nidan forms a very beautiful object upon its eastern side. Towards the southern extremity of this lake is the island of St. Peter, sometimes called the island of La Motte, and sometimes Rousfield, on its having been the place of Rousfield's retirement and residence, when by the violence of the populace he was obliged to withdraw from Motier, where Frederick king of Prussia had ensnared him for protection. Mr. Coxe, when he visited this island, landed on the north side of it, and passed through an agreeable meadow, skirted with vineyards, to a large farm-house, formerly a convent, and secularized at the reformation, but inhabited, at the time of Mr. Coxe's visit, by the steward of the general hospital at Berne, to which the island belongs. "The island," says Mr. Coxe, "is about 2 miles in circumference, and richly wooded with various shrubs and trees, particularly with large oaks, beech, and Spanish chestnuts. Its surface is gently undulating; the southern slope, covered with herbage, forms a gradual slope to the lake; the remaining borders are steep and rocky; in a few places their summits are thinly fringed with shrubs; in others their perpendicular sides are clothed to the water's edge with hanging woods. The views from the different parts of the island are beautiful and diversified; that to the north is the most extensive and pleasing. It commands the lake of Bienne, which is of an oval form; its cultivated borders spotted with villages and castles, with the towns of Nidan and Bienne standing on the further extremity. Agreeable walks are carried through the woods, and terminate at a circular pavilion placed in the centre of the island. During vintage, particularly, and on Sunday, which is the usual day of fertility, the island is filled with parties, who take refreshment at the farm-house, stray about the woods, or dance in the circular building, and animate these romantic but solitary scenes."
feenes." " Roufieu occupied an apartment in the farm-house, the only dwelling in the island. He lived with the steward and his family, who are the present inhabitants (1785). The woman informed me, that he paid for his board and lodgings 40 shillings a mouth; that he usually rofe at six, dined with the family at twelve, and after a flight supper retired to rest at nine. She added, he was extremely cheerful and agreeable; conversed with the family with the greatest cafe and complacency, and conformed to their hours and manner of living; he amused himself entirely in wandering about the woods, and searching for plants, which he used to explain to them with singular satisfaction. Roufieu mentions his residence in this delightful island with the highest terms of rapture, and with his usual pronouns of exaggeration. "I was permitted," says he, "to remain only two months in this delightful island; but I could have passed there two years, two centuries, all eternity, without suffering a moment's ennui, although my whole society consisted of the steward and family, good, but plain people. I esteem those two months the most happy period of my life; and so happy, that I could have passed my whole existence without even a momentary wish for another situation." Cox's "Travels in Switzerland," &c. vol. ii. p. 152, &c.

**BIENNIAL PLANTS.** In Botany, denote such, as the epithet imports, that are of two years' duration. Of this tribe there are numerous plants, which, being raised one year from seed, generally attain perfection in the same year, or within about twelve months, flowering up stalks, producing flowers, and perfecting seeds in the following spring or summer; and soon after commonly perish, or apparently decay and dwindle, so that they soon die off. Biennials are, therefore, always in their prime the first or second summer. They confiib both of effulent and flower plants. Those of the former fort are the cabbage, savoy, carrot, parsnip, beet, onion, leek, &c.; and those of the latter are the Canterbury bell, French lily-flowered, wall-flower, Rock-flower, sweet-william, Chiaspinck, common-pink, matted-pink, carnation, feabious, holly-hock, tre-mallow, vervain-mallow, tree-prime-rose, honesty, or moonwort, &c.

**BIENTINA.** In Geography, a town of Italy, in the duchy of Tuscany, on the side of a lake, called the "lake of Bientina," or the "lake of Seffo;" which lake is about 6 miles long, and 5 wide; 12 miles cast of Pifa, and 28 west of Florence. The territory of Bientina lies in the middle of a marsh, in the centre of a valley, not very spacious, bounded by the high mountains of Pifa, and by those of Lucca and Valdinevo, which intercept the wind, and prevent a renewal of air; and it is, therefore, as one would imagine by its situation, peculiarly unhealthy and unfavourable for inhabitants. It is nevertheless very populous, and sufficiently healthful even in summer. The principal causes of this salubrity are said to be the numerous population, the extensive commerce, and the extreme attention that is paid to the continual discharge of the rain-waters, but, above all, the advantage of an abundant spring, which descends from the hills of St. Colomb, by means of long aqueducts, and supplies the inhabitants with excellent water. "The situation of Bientina, therefore, duly examined, shows how far the art of man is capable of rendering habitable, and even salubrious, places naturally pestilential." BIEVILLE, D. T. De, M.D., in "Biography," born in France, practiced medicine many years at the Hague, and is only known by the following works, which bear his name: " La Nymphomanie, ou Traité de la fureur utérine," 1717, 8vo.; "Recherches théoriques et pratiques sur la Petite verole," 1772, 8vo. "Traite des erreurs populaires, sur la fante," La Hague, 1775, 8vo.

**BIER.** A kind of wooden carriage, on which the bodies of the dead are borne to their grave. The word comes from the French biere, which signifies the fame. It is called in Latin feretrum, a ferenda. Among the Romans the common bier, upon which the poorer folk were carried, was called fandopila; that used for the richer folk, felatica, felatica funebris, sometimes letus. The former was only a sort of wooden shelf, volit area, which was burnt with the body: the latter was enriched and gilded for pomp. It was carried bare, or uncovered, when the person died a natural and easy death; when he was much disfigured or disintarted, it was veiled or covered over.

**BIER," in Geography," a herry, or dirric, of the diocese of Funen in Denmark, including 12 churches, and several noblemen's seats.

**BIERLING, GASPAN THEOPHILUS," in Biography, took his degree of doctor in medicine at Padua, about the middle of the 17th century, when he returned to Magdeburg, his native city, where he was in considerable estimation. He published "Adverfariorum curiourum Centuria prima," June, 1679, 4to. He describes the effects of eating the hylocyamus (henbane,) drowniness, and delirium, which are cured, he says, by taking the extract of caftor, and the effects from the bite of a viper, cured by eating the flesh of one of those reptiles. He had the merit of recommending the cool treatment, and even bleeding, in the small-pox, contrary to the then generally received opinion. For the remainder of his works, which are numerous, but in little estimation; see Haller's Bib. Med. Elog. Dict. Hist.

**BIERVERNIET, in Geography," a small town of Flanders, on the west side of the Scheldt, which has been much reduced by frequent inundations, and the fortifications of which were destroyed in 1688. William Beukeljamo, or as others have written his name, Beukelings, who taught the Dutch the art of curing hizzings, was a native of this place, and died here in 1597. The town is 7 leagues north of Ghent, and 4 E. N. E. of Sluis. N. lat. 51° 25'. E. long. 3° 42'.

**BIÉSBOOS," a large lake in the Merwe, between Dort and Gertrudenburg, formed by the irruption of the banks or dikes.

**BIESE, a river of Germany, which rises 8 miles south-west from Stendal, in the Old Mark of Brandenburg, and purifying its course to Sehauen, changes its name to Aland.

**BISENTHAL," a town of Germany, in the circle of Upper Saxony, and middle Mark of Brandenburg, 20 miles N. E. of Berlin.

**BIÉSUS, NICHOLAS," in Biography, born at Ghent in Flanders, March 27, 1516, studied medicine at Louvain; thence he went to Valencia in Spain, and afterwards to Sienna, in Italy, where he took his degree of doctor. Returning to Louvain he was advanced to the chair of profef- for in medicine, which he filled with credit several years, expounding to his pupils, as the cufom then was, the works of Galen. He was then called by the emperor Maximilian II. to Vienna, and appointed his physician, which post he held until April 1573, when he was suddenly cut off by a fit of apoplexy. His works are: "Theorica Medicina, libri sex," Ant. 1558, 4to. "In Artem medicam Galeni Commentarius," 1560, 8vo.; "De Methodo Medicina," 1564, 8vo.; "De Natura libri quinque," 1573, 8vo.; the two last works have been several times reprinted.

**BIÉSMES.** In Geography, a place of France, which is a paif across the Aine, from the department of the Meuse to
that of the Marne; 3 miles from St. Menchold, and 12 from Grand Pre.

BIELEN, a town of Poland, in the palatinate of Ploczko. N. lat. 5°. E. long. 20° E.

BIETICHGEM, a town of Germany, in the duchy of Wurttemberg, at the conflux of the Enz and Metterbach; 10 miles N. of Stuttgart, and 30 S. S. E. of Heidelberg.

BIEVRE, a river of France, which rives a little to the south of Verfailles, and passing towards Paris, changes its name for that of Gobelas, on account of its water being used in that manufacture, and soon after it joins the Seine.

BIEUZI, a town of France, in the department of Morbihan, and chief place of a canton, in the district of Pontivy; 2 leagues S. S. W. of Pontivy.

BIZHOW, or BINSCHOW, a town of Bohemia, in the circle of Konigigratz; 3 miles east of Konigigratz.

BIFARIA, FOLIA, in Botany, denote leaves that point two ways.

BIFASCIANA, in Entomology, a species of PHALANA (Tunetius). The anterior wings are tesselaceous; two oblique bands, spot, and arched mark at the apex brown. Linn. Muf. Left. &c. Inhabits Europe.

BIFASCIATA, in Conchology, a species of BULLA, the shell of which is somewhat tapering, erect, and white, with two broad reddish bands at the aperture. Lüter. Gmelin. Native place unknown.

BIFASCIATA, a species of Voluta, described by Lüter and Martini. This shell is thin, tranversely striated, and flesh coloured, with two white bands and a single tooth on the pillar. It is rather less than an inch in length; and has a long narrow aperture. Native country unknown.

BIFASCIATA, a species of Cypraea, of an oblong form and purplish, with a straw-coloured band, and a narrower white one, and brown border. Gmelin. Length nearly four inches. Country unknown.

BIFASCIATA, a species of Nerita, of a blackish colour, with two hoary bands and white tip. A native of India. Gmelin. Chenmitrua, &c.

BIFASCIATA, in Entomology, a species of Silpha, found in Saxony. This is black, with two bands and a spot at the apex of ferruginous colour. Fabricius. This is a small insect.

BIFASCIATA, a species of Cassidea, that inhabits South America. It is pale with two brown bands. Gmelin.

BIFASCIATA, a species of Coccinella, of a ferruginous colour, with two bands and four dots of black. Fabricius. This insect inhabits the Cape of Good Hope; and is Coccinella flexuosa of Thunberg.

BIFASCIATA, a species of Chrysomela of a large size, that is found in Cayenne. It is tellaceous: wing-cases brassy and shining: two spots and two bands of yellow. Fabricius, &c.

BIFASCIATA, a species of Cicada (Cerophii), of a yellowish colour, with brown wing cases, and two white bands. Fabricius. This is Cicada fulica, festiva alarum libris albis, of Linn. Syl. Nat. XII. and Cicada trilatissima, of Degeer. Inhabits the north of Europe.

BIFASCIATA, a species of Phaena (Gomphus), described by Linnaeus as a native of Europe. The anterior wings are cincere, clouded, with two bands; posterior pair white.

BIFASCIATA, a species of Libellula, that inhabits America. The wings are hyaline, with a brown spot at the base, and two bands of the same colour. Fabricius. Obs. This is Libellula trimaculata of Degeer; and Libellula pulchella of Dury.

BIFASCIATA, a species of Tenthredo, that inhabits Europe. The general colour is brown; thorax black; mouth,}

**BIFASCIATA, a species of Mutilla, that inhabits New York.** The colour is black; upper part of the head and thorax, and two bands on the abdomen red: wing-violaceous-black. Swederus. Nov. Act. Stockh. Entirely downy and twice the size of M. Europea.

**BIFASCIATA, a species of Tipula, of a yellowish colour, with transparent wings palely invested with brown. Schrannk Inf. Auct. Of the middle size, with the eyes black.**

**BIFASCIATA, a species of Musca, that inhabits South America.** It is rufous, with two golden bands on the abdomen. Fabricius, &c.

**BIFASCIATA, a species of Scolia, that inhabits New York.** This insect is of a black colour; two dots on the anterior part of the thorax, scutell, and two interrupted bands on the abdomen ferruginous. Swederus Nov. Act. Stockh.

**BIFASCIATUS, in Conchology, a species of Conus, figured by Born. This kind is white with angulated chief nut lines, and two orange bands: spire rather prominent: base surrounded with orange lines, and the intermediate spaces with tesselated spots. Country unknown.**

**BIFASCIATUS, in Entomology, a species of Scarabæus, that inhabits Coromandel: on the thorax is a triple protuberance, with an eretic horn on the head; wing-cases black, with two rufous bands. Fabricius.**

**BIFASCIATUS, a species of Dermestes, of a black colour, with two waved yellow bands: thorax tesselated with cinereous colour. Thunberg. A native of the Cape of Good Hope.**

**BIFASCIATUS, a species of Dostrichus, found in Siberia. It is of a black colour: wing-cases yellow, with two blueish-black denticulated bands. Gmelin. This is Dermestes bifasciatus of Lepech. it.**

**BIFASCIATUS, a species of Cryptocerus, that inhabits Africa.** It is rufous, with two spots on the thorax, and two bands on the wing-cases of black. Fabricius.

**BIFASCIATUS, a species of Cerambyx (Plicinus), found in South America. The thorax is denticulated: body black: wing-cases red, with two black bands: antennae short. Gronovius, Fabricius, &c.**

**BIFASCIATUS, a species of Attelasus (Cerus), of a brassy-green and downy: wing-cases blue, with two scarlet lines. Fabricius. A native of Siberia.**

**BIFASCIATUS, a species of Grullus (Bulla-Acritium), of afuscous brown with white spots, and two lateral ochre-coloured bands. Herkl. at Fuefli. Inhabits sandy places.**

**BIFASCIATA, a species of Phalena (Tineca), with fuscous glossy wings; with two bands of white, the hinder one interrupted: head rufous. Fabricius. Inhabits Denmark.**

**BIFERÆ, in Botany, denote plants that flower twice a year, or in spring and autumn.**

**BIFERNO, in Geography, a river of Italy, which runs into the Adriatic, nor far from Termini.**

**BIFFA, in Middle Age Writers, a machine for casting stones and stones, having a movable counterpoise, which turned round its yard.**

**BIFID LEAF, in Botany. See LEAF.**

**BIFIDUS, in Entomology, a species of Cimex (Reduvius) of a black colour: wing-cases with a rufous band; an erect blunt spine on the scutell. Inhabits China, and is of a large size. Fabricius. D. nov. Inf. China.**

**BIFOLIUM, in Botany. See OPHRYS.**

**BIFORIS, in Natural History, a species of Echinus, having at the base five furrows, and ten flexuous radiated lines;**
BIFORMIS, an appellation given to Bacchus, either because he is represented sometimes as a young man, sometimes as an old man; sometimes with a beard, and sometimes without one; or because wine, of which he is the symbol, renders men sorrowful and frantic, or gay and pleasurable.

BIFRONS, a perfom double-fronted, or two-faced.

BIFRONS is more peculiarly an appellation of Janus, who was represented by the ancients with two faces, as being supposed to look both backwards and forwards; though other reasons for it are reuted by Plutarch. Sometimes he was painted with four faces, quadrifrons, as representing the four-leon.

BIFRONS, in Entomology, a species of BENTUS, that inhabits Cayenne. This insect is black, with bristled wing-cases, having glabrous yellow spots. Fabricius.

BIFRONS, a species of ICNINEUM, described by LINNEUS: it is an European insect of a black colour, with the front white, and a black spot beneath the antennae; tip of the petiole, and the two first segments of the abdomen, with the legs reddish. LINNEUS.

BIFURCATUS, in Entomology, a species of CINEX (Oblongus), that inhabits Germany. It is blackish: abdomen pale yellow, and bifurcated. Scheffer. Antenna conflit of four joints.

BIGAMIA, a chariot for racing, drawn by two horses abreast. The word ought rather to be written biges, in the plural; q. d. biges, two horses being joined by a yoke.

BIGA, a chariot of ancient Rome, drawn by two horses abreast. They were first introduced in the Olympic games in the 93rd Olympiad, or about the year 408, B.C. It appears, however, that the Greek heroes who celebrated the first Nemean games in honour of Archemorus, were borne on biges. Bige were the chariots first used in the Crconian games; then triges, and afterwards quadriges. The moon, night, and the morning, are by mythologists supposed to be carried in biges, the fun in quadriges. Statues in biges were at first only allowed to the gods, then to conquerors in the Crconian games; under the Roman emperors, the horse statues, with biges, were decreed and granted to great and well-deferring men, as a kind of half triumph, being erected in most public places of the city.

BIGARELLA, in Botany. See PRUNUS.

BIGARELLA, in Geography, a town of Italy, in the duchy of Mantua, 7 miles E. N. E. of Mantua.

BIGATI, in Antiquity, a kind of ancient Roman silver coins, on one side whereof was represented a biga, or chariot, drawn by two horses. The biga as bigatus was properly the Roman denarius, whose impression, during the times of the common-wealth, was a chariot driven by Victory, and drawn either by two horses, or four, according to which it was either denominated bigatius, or quadrigatius. Bigati therefore were of different values, according to the species of denarius.

BIGBERRY, or Bigbury bay, in Geography, lies on the south coast of Devon, and is formed by the Bolt Tail on the sea, and Stoke-point on the west, in the direction nearly of N. W. by W. The entrance into Plymouth found is round Stoke point to the N. W.

BIGBONE CREEK, an American creek in Woodford county, Kentucky, which falls into the Ohio from the east, in about N. lat. 35° 17'. W. long. 85° 54'. It is small, but has three branches; the north-westernmost interlocks with Bank Lick creek, which falls into Licking river. It is noted on account of the large bones and soft licks in its vicinity.

BIGBONE LICKS lie on each side of the above-mentioned creek.
B I G

B I G

creek, a little below the junction of the two eastern branches, about 8 miles from the mouth of the creek. These, and also the other salt springs, in the western country, are called lick, because the earth about them is scorched up in a very curious manner, by the buffaloes and deer which lick the earth, on account of the saline particles with which it is impregnated. A stream of brackish water runs through these licks, the soil of which is of a soft clay. The large holes found here, and in several other places near salt licks, and in low soil grounds, thought to belong to the Mammoth, have perplexed naturalists, in their investigation of the animals to which they belong. See Bones, fossil, and Mammoth.

BIGEMINATE LEAF, in Botany. See Leaf.

BIGERRONES, a people of Gaul, so called by Caesar, and denominated by Pliny, Biggeris, and by Antonius, Degetiarchi. M. d'Avrille places them at the foot of the Pyrenees, to the west of the Conuenus. Their name excises in that of Bigorre.

BIGGAR, the name of a town and parish of Lanarkshire, in Scotland. The parish includes an area of land, measuring about 6 miles, by 31 in transverse diameter. The surface is partly hilly, and is appropriated, in nearly equal parts, to pasture and arable. The population of the parish in 1790 was 957, but this was 161 les than when a return was made 56 years anterior. From the improved state of the roads, and of agriculture, it was found to contain 1226 persons in the year 1800. The town of Biggar has 389 inhabitants. Here are three annual fairs. At the west end of the parish are the vestiges of a large tumulus, and three encampments. Tradition says, that a desperate battle was fought here between the Scots under Sir William Wallace, and the English army, when the daughter was very great. Sir John Sinclair's Statistical History of Scotland.

BIGGE, a river of Germany, which runs into the Lena, 3 miles north of Allendorn, in the duchy of Wettphalia.

BIGGI, in Zoology, Antelope Tragocamelus of Gmelin, in Mandelli's, it.

BIGGLESWADE, in Geography, is a large improving town of Bedfordshire, Engad, pleasantly situated in a fertile valley, on the eastern bank of the river Ivel. This has been rendered navigable to the town by act of parliament, and considerable quantities of coals, timber, corn, and some other commodities, are brought by this channel. An extensive weekly market, and four annual fairs, also attract various merchants to the town. The manor belongs to the king, and the parish includes, besides the town, the small hamlets of Stretton and Holme. These together contain a population of 1650 persons, who occupy 301 houses. The church, an ancient and strong edifice, was partly built in the year 1290, and was formerly collegiate. The inhabitants, being free tenants, have all equal rights in the church. In this town are two charity-schools; also a Baptist meeting-house; and being seated on a great public road, it contains several large inns. Biggleswade suffered very materially by fire, which happened on the 16th of June 187. In a few hours 150 dwelling-houses were reduced to ashes, besides some malt-houses, corn-chambers, &c. which were situated round the market-place, near the centre of the town. The damages sustained by this fire were estimated at 24,000l. Since the conflagration several new houses have been erected, and the town has assumed a more modern and improved appearance. On the 25th of February 1792, a shock of an earthquake greatly alarmed the inhabitants of this place, and its concussio was so powerful as to throw down some old houses. It halted several seconds, and was found to extend northward into Yorkshire, and towards the sea-coast of Lincolnshire. In the manor of Retton, at a short distance south of Biggleswade, as a cart was ploughing the land, he discovered a yellow earthen pot, which was found to contain about 300 gold coins of Henry VI. They were nearly the size of half crown pieces each, but being very thin did not equal the weight of a guinea.

About 4 miles west of Biggleswade, are the remains of Warden-abbey, which was formerly a very extensive and considerable foundation. It was founded in 1135, by Walter Espec, for Cistercian monks; and at the dissolution its revenues were valued at 309l. 16s. 6d. per annum. Leeland's Itinerary. Camden's Britannia. Beauties of England and Wales, vol. i.

BIGGS BAY, lies on the south side of Jamaica, and to the east of north from Portland-point, which is the most easterly point of the island.

BIG-HILL CREEK, an American creek, which runs west into the Kalkaflkas river, 25 miles below Beaver creek, 17 above Blind creek, and 26 northerly from the mouth of Kalkaflkas.

BIGGIN SWAMP, See Swander River.

BIGI, in Geography, a town of Sicily, in the valley of Mazara, 10 miles east of Mazara.

BIGIS, in Ancient Geography, a town of Acha, placed by Ptolemy in Drangiana.

BIGLA, in Geography, a town of Lithuania, in the patlinate of Wilna, 40 miles E. N. E. of Wilcohnir, near a lake from which the river Drifta issues. N. lat. 55° 26'. E. long. 29° 24'.

BIGLOBATUS, in Entomology, a species of Curculio, found at the Cape of Good Hope. This is of a black colour, with a cancellated scutum; thorax globose, very rough with punctured dots; wing-cases with scarious dots, and two rows of tubercles on each side. Sparrm. Nov. A. Stockh.

BIGLUMIS, a species of Vespa, with four dots on the scutel; margin of the abdominal segments white, with two white dots on the second. Gmelin. Vespa Rudispersis of Linn. Syll. Nat. is deemed a variety of this kind.

BIGNAN, in Geography, a town of France, in the department of Morbihan, and chief place of a canton, in the district of Joffelin, 3 leagues S. W. of Joffelin.

BIGN, in Conchology, a name under which Adanson describes Pala Tringa of Gmelin.

BIGNON, Jean, in Biography, was born at Paris in 1599, and educated by his father, who was an advocate in the parliament of Paris, and distingushing by his learning and character. Having made a surprizing progress under his father's tuition, he was placed, about the age of ten years, near the person of the young prince of Condé, and about this period published, "A Description of the Holy Land," more accurate than any extant. In 1604, he composed for the use of the young duke of Vendome, a "Treatise on Roman Antiquities." These works were compositions; but his work on the " Election of the Popes," said to be composed in his fourteenth year, but not published till 1668, was of a more original kind, and displayed a degree of erudition that surprized the most learned men of the age.
BIGNONIA, so named by Tournefort, in honour of the abbé Bignon, Eng. trumpet-flower, or scarlet jasmin, in Botan. Lin. gen. 1. 259. Reich. 817. Schr. 1018. Tourn. 72. Juff. 139. Garro. t. 52. Clas and Order, didymum angiosperma. Nat. Ord. Periconata. Bignoni. Jull. Gen. char. Cal. perianth one-leaved, erect, cup-form, five-cleft, Cor. monopetalous, campanulate; tube very small, the length of the calyx; throat very long, venticlole beneath, obovate-campanule; border five-parted, the two upper divisions reflex, lower patent. Stam. filaments four, subulate, shorter than the corolla; two longer than the other two; another reflex, oblong, as it were doubled. Pyll. germ oblong; stylo filiform, situation and form of the filaments; Higma copiate. Per. Silique two-celled, two-valved; partition membranaceous, parallel, thickened at the futures. Seeds very many, imbricate, compressed, membrane-winged on both sides. Obs. Catalpa has only two perfect flaments, and three very small rudiments of flaments, with a five-leaved calyx. Four, however, and even all five perfect, have been observed by Cyrilli. 'The form of the silique in this genus is indeterminate. The seeds are always winged, though some on one side only.

Species. 1. B. Catalpa, common Catalpa tree. Lin. spec. 868. Reich. 3. 155. Hort. cliss. 317. 1. Alit. Hort. Kew. 2. 346. Duhum. Arb. 1. 104. 1. 41. Catalph. Car. 1. 49. t. 29. "Leaves simple, coriace; item eretic; seeds winged with membraner. A deciduous tree, with an upright stem, covered with a smooth brown bark, 30 or 40 feet high; with lateral branches, ovate leaves placed opposite at every joint, flowers in branching panieles towards the end of the branches, of a dirty white colour, with a few purple spots, and faint stripes of yellow on their infide, which flowers are succeeded by long taper pods not yet produced in England. Found by Mr. Careby growing naturally on the back of South Carolina, brought into England about the year 1726, and now not uncommon in our nurseries and plantations. In our climate the leaves come out very late; and the tree requires a sheltered situation. It flowers in August, and is known in the nurseries by its Indian name "Catalpa." The branches dye wool a kind of cinnamon colour. Thunberg mentions that the Japanese lay the leaves on parts of the body affected with pains, on a supposition that they are beneficial to the nerves; and that a decoction of the pods is servicable in the althama. 2. B. tontometula. Lin. Syll. 562. Thunb. Jap. t. 252. "Leaves simple, coriace, tubuentule beneath; flowers axillary, paneled." A native of Japan. 3. B. japonica, Carolina yellow jasmine. Lin. spec. 869. Reich. 3. 155. Gelessumum. Park. 1465. n. 5. Rain hilt. 1769. Catalph. Car. 1. t. 53. Syringa. Pluk. Alm. t. 112. f. 5. "Leaves simple, lanceolate, item twining. Rising with slender stalks, that twilt themselves round the neighbouring plants, and mount to a considerable height, with single opposite leaves at every joint, that remain green throughout the year; growing naturally in South Carolina, where it spreads over the hedges, and, at the season of flowering, perfuming the air to a great distance; and also found in some parts of Virginia: called yellow jasmine, probably from the sweet odour of its flowers. Cultivated in 1640, in Kew garden, by Parkinson. 4. B. anguis. Lin. spec. 869. Reich. 3. 156. Apocyno affinis. Scon. jan. 1. 208. Clematis. Pluk. Amer. t. 94. Pluk. Alm. t. 163. f. 2. "Leaves conjugate; tendril very short, bowed, threeparted." A native of the West Indies. 5. B. equinquilis. Lin. spec. 869. Reich. 3. 156. Sapp. hort. 2. t. 85. Pluk. spec. 5. ic. 55. f. 1. "Leaves conjugate, cirehete; leaflets ovate and lingular; peduncules twinered; filiques linear." Received by Mr. Miller from La Vera Cruz, in New Spain. 6. B. paniculata. Lin. spec. 869. Sylit. 563. Reich. 3. 156. Jacq. am. t. 116. Pluk. 91. t. 175. Pluk. spec. 5. ic. 56. f. 1. "Leaves conjugate, cirehete; leaflets cordate-ovate; flowers racem med peduncules three-flowered." Sent to Mr. Miller from La Vera Cruz, by Dr. Houftoun. Observed about Carthagea by Jacquin. 7. B. cricgidera. Lin. spec. 869. Reich. 3. 157. Vir. cliss. 60. Hort. cliss. 317. 3. Gring. vrg. t. 73. 2. 95. Pluk. ic. 48. t. 58. Pseudo-Apocynum. Mur. hilt. 5. 612. n. 6. f. 1. 3. 16. "Leaves conjugate, cirehete; leaflets cordate; item unicate;" deriving its trivial name from a section of the Flem which represents a cross. Sent to Mr. Miller from Campsachy. 8. B. caperata, four-leaved trumpet-flower. Lin. spec. 870. Sylit. 593. Reich. 3. 157. Vir. cliss. 59. Hort. cliss. 317. Bryn. ic. 33. t. 25. Duhum. Arb. 1. 104. t. 40. Catelph. Car. 2. 82. Clematis. Bocc. ic. 31. t. 15. f. 3. Zan. hilt. 74. 2. ed. 2. 49. t. 33. Rain hilt. 1329. "Leaves conjugate, cirehete; leaflets cordate-lanceolate; bottom-leave simple." Sent to Mr. Miller from Camppeachy. A native of Virginia and Carolina; and cultivated in
in Kew garden in 1730. 9. B. pultescens. Lin. Spec. 870. Reich. 3. 159. "Leaves conjugate, circinose; leaflets carinate-ovate, pubescent beneath." Growing naturally in Virginia, and several other parts of America. 10. B. tripalliha, three-leaved trumpet-flower. Lin. Spec. 870. Reich. 3. 157. "Leaves ternate; leaflets ovate, acuminate; stem thrubby, erect." Sent to Mr. Miller from La Vera Cruz, by Dr. Houtouin. 11. B. pentaphylla, hairy five-leaved trumpet-flower. Lin. Spec. 870. Reich. 3. 158. Hort. clff. 497. 6 "Leaves digitate; leaflets quite entire, obovate." Sent to Mr. Miller from Jamaica, by Dr. Houtouin; and introduced into Kew garden before 1733. 12. B. leucyczylon, smooth five-leaved trumpet-flower, white-wood, or tulip-flower. Lin. Spec. 870. Reich. 3. 158. Swartz pl. 233. Pl. Pl. ind. t. 200. f. 4. Brown jam. 263. n. 1. Sloan, jan. 2. 62. n. 47. Raini diss. 114. 2. "Leaves digitate; leaflets quite entire, ovate, acuminate." According to Sir Hans Sloane, this tree is as large as any in the island of Jamaica, having a large flat-topped trunk covered with a smooth whitish bark, and a very hard white wood. According to Browne, it grows in a kind soil to a large size, and is considered as a good timber-wood; but when its growth is not luxuriant, it is fit only for smaller and subordinate implements. Its juice and tender buds are said to be an antidote to the poisonous juice of the manchineel. Mr. Miller says, that it rives with an upright stem to the height of 40 feet, in the natural country of its growth; and that the seeds, dispersed by the winds to neighbouring lands, supply plants in great plenty. Cultivated by Mr. Miller in Kew garden, in 1759; and received by him from Barbadoes under the denomination of "white wood." 13. B. radiata, ray-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 158. Fenzl. pl. 751. 22. "Leaves digitate; leaflets pinnatifid. Stem three inches high; corolla pale yellow, with red dots. A native of Peru, in very dry sand. 14. B. radiata, range or ash-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 158. Hort. clff. 317. 4. Upf. 178. Gron. virg. 73. 94. Duham. arb. 1. 103. 1. Sibb. hort. 2. 1. 84. Pleuro gelfominium ixioufoum. Riv. mon. 101. Pleundo Apocynum. Mor. hiff. 3. 612. n. 1. f. 15. t. 3. f. 1. Park. 1679. and 353. n. 6. Gelfominium hederaceum Indicum. Cen. can. t. 103. Raini hiff. 1768. B. fraxini fol. coccineo fl. minore. Catecb. car. 1. t. 65. Mill. fig. 43. t. 65. Duham. arb. 103. 2. "Leaves pinnate; leaflets gaffed; stem with rooting joints." Stems rough, branches trailing, festooning by the roots, issuing from their joints, to the trees in their natural place of growth, and climbing to a great height; in Europe, where it is generally planted against walls, flitting into the mortar of the joints, in order to support the branches, and rising to the height of 40 or 50 feet: flowers produced at the ends of the shoots of the same year, in large bunches, with long swelling tube, shaped somewhat like a trumpet, whence the plant has the appellation of " trumpet-flower," corolla of an orange colour, and opening at the beginning of August. Cultivated in Kew garden in 1640. The seeds of B. were sent from Carolina in 1724, by Mr. Catecb; and since that time many plants have been raised in England, by seeds sent from that country. 15. B. pultescens, branching-leaved trumpet-flower. Lin. Spec. 871. Reich. 3. 159. Jacq. Amer. pikt. 91. t. 176. Brown. jam. 264. 3. Pltn. Spec. 5. k. 54. Sloan, jan. 2. 63 n. 49. B. frutescens. Mill. dict. n. 3. "Leaves pinnate; leaflets serrate; stem erect, firm; flowers racemed." An upright shrub from four to eight feet in height; flowers yellow, with red lines on the inside of the tube; filices half a foot long, with winged seeds. A native of all the fugar islands in the West Indies, chiefly in a dry, rocky, or gravelly soil. Mr. Miller says, that he received this sort first in 1729, from La Vera Cruz, where Dr. Houtouin found it in great plenty; since which time he obtained the seed from the island of Bermuda, by the title of "candle-wood." 16. B. griffrisea. Lin. Spec. 564. Plnn. clff. 253. Kanz. p. 69. "Leaves pinnate; leaflets ovate, acuminate, serrate; stem twining; calyx fimbriate-acute." Stem thrubby, climbing, four-cornered; calyx five-cornered; corolla purple, the size of a rose; differing from the radicans in having a stem not at all rooting, a large flower, and a fimbriate-acute calyx. A native of Japan. 17. B. echloniadea. Lin. Syll. 564. Suppl. 182. Padr. Rheed. Mal. 6. 47. t. 26. "Leaves unequally pinnate; leaflets ovate, quite entire, acuminate, pubescent; corolla bearded, with the rudiment of a fifth lamen." A large tree, with a whitish ash-coloured bark; leaves spreading, petiolate; pedal terminating; pedicels opposite, dichotomous; flowers solitary, from the divisions; calyx hoary; border of the corolla a little arched, rough with hairs, red, five-cleft; the two upper segments yellow, with red dots; lower segments rough with hairs, curled at the edge, disk waved, white, veins red, throat rough with hairs; the rudiment of a fifth lamen, inserted into the tube of the corolla, barren; filices linear, flat, bent, streaked. The fresh flowers, immersed in water, give it a pleasant odour; and in the East Indies, of which it is a native, they sprinkle it over the temples in a morning, to correct the flagrant air. 18. B. johcathan. Lin. Syll. 564. Suppl. 283. Nrr Pongolong. Rheed. Mal. 6. 53. t. 29. "Leaves unequally pinnate; leaflets ovate, rough with hairs; calyx one-leaved, spotted; corolla falver-shaped. A large tree, differing in the structure of the flower from the other species, but having didymous flaments, and a pod filled with winged seeds. It is evidently of this genus. The timber is ash-coloured, or red, smooth, and much used for a variety of utensils in India. A native of Malabar, Java, and Ceylon, in woods near waters. 19. B. peruviana. Lin. Spec. 871. Reich. 3. 159. Hort. clff. 317. 5. "Leaves decompound; leaflets gaffed; stem with tendrils at the joints." A native of America. 20. B. indica, Indian trumpet-flower. Lin. Spec. 871. Reich. 3. 159. f. 8. zeyl. 236. Lour. cochinch. 379. Palega pajan. Rheed. Mal. 1. p. 77. t. 43. Raini hiff. 1741. B. pajan. Rheed. 79. t. 44. Raili hiff. 1741. n. 2. "Leaves bipinnate; leaflets quite entire, ovate, acuminate." A large tree, with ascending branches. A native of the East Indies, and Cochinchina. Introduced in 1795 by Dr. Solander. A variety occurs near Mozambique, in Africa. 21. P. corvola. Lin. Spec. 872. Reich. 3. 162. Catecb. car. 1. t. 42. "Leaves bipinnate; leaflets lanceolate, entire." Grows naturally in the Bahamas islands, whence Mr. Catecb sent the seeds, in 1724; and many of the plants were raised in the gardens near London. In the country where it grows naturally, it rives to the height of 20 feet. 22. B. longiflollma, waved-leaved trumpet-flower, Ait. Hort. Kew. 2. 247. Jacq. Amer. 192. t. 176. f. 78. Swartz. Prod. 91. Brown. jam. 264. 2. Pltn. ic. 47. t. 57. B. Quercus Lamarck Encycl. 1. 417. "Leaves simple, oblong, acuminate; stem erect: seeds woolly. An elegant upright tree, 40 feet high and upwards. A native of the West Indies; cultivated and growing luxuriantly in many parts of Jamaica, especially in the low lands and favannas, where it grows to a considerable size, and is considered as an excellent timber-tree. Its numerous flowers, and slender filices, add a peculiar grace to its growth. In Jamaica it is known by the name of " French oak," and in the French West India islands it is called " Chêne noir," 23. P. eleglinita. Gritt. fruct. 1. 240. t. 52. Jacq. Amer. 183. t. 176. f. 52. Aublet. Guian. 2. 468. t. 263. 264. Swartz
BIG

Swartz prodr. 97. "Climbing; lower leaves ternate; upper bijugous, ciriiform; fruit echinate." A rambling shrub climbing to the tops of trees by its very long and numerous branches. A native of the Weft Indies, Carthagea, and Guiana. 25. B. pentandra. Lour. Cochinch. 379. "Leaves bipinnate; filaments five, with two anthers in each; calyx flesh-coloured, five-toothed." A middle-sized tree, with ascending branches. A native of Cochinchina, near rivers. Loureiro has another species under the name of B. longiflora, which is a native of Cochinchina, by rivers, and which is not the B. longiflora of Jacquin (N° 22.); agreeing, according to Loureiro, with the "longiflorum" of Rumphius (vol. iii. p. 75. t. 46.); or B. fluminea of the younger Linnaeus, in the length and form of the corolla, but not in the spathe-like calyx and pinnate leaves. But Retzius observes, that Rumphius's plant is not the same with Linnaeus's, and it is very different from the "Nur-Pongcheon" of the Hortus Malabaricus. Loureiro also remarks, that the three Althea species which he has described can by no means be adapted to the generic character formed by Linnaeus from the American species, except in the fruit; and even that it is not always two-celled in the Althea species.

The Bigonias are trees or shrubs, inhabiting the hot climates, of the East and West Indies, and eminently beautiful. The leaves are opposite; in some species, unequally pinnate or ternate; in others, conjugate, with a two-leaved petiole between the leaflets, frequently furnished with a tendril for climbing. Flowers in panicles, large and handsome, of various colours, red, blue, yellow, or white. The calyx should be observed, whether it be simple or double; the corolla, whether it be regular or irregular; the stamens, whether they be fertile or barren; the fruit, whether it be bony or capsular, in form of a filique, or ovate. There are many species, particularly from Brazil, not yet sufficiently known to admit of arrangement under this genus. B. ferrugineus does not belong to this genus, says Mr. Martyn, but to that of lophium.

Propagation and culture. These are exotic trees or shrubs, and may be raised from seeds sown in a moderate hot-bed in the spring. They should be soon inured to the open air, to prevent them being drawn up weak. They may be also increased by cuttings, and formed into plants by layers. The seeds of the common Catalpa tree are annually brought over from South Carolina. The seedling plants should be placed abroad in the beginning of June, in a sheltered situation, till autumn, and then placed under a summer frame, to guard them from the winter frosts; exposing them in mild weather to the open air. In the following spring they should be taken out of the pots, and planted in a nursery-bed, in a warm situation, where they may remain two years, and then planted where they are to remain. This tree may be also propagated by cuttings, which, in the spring, should be planted in pots, and plunged into a moderate hot-bed, shading them from the mid-day sun, and occasionally, but sparingly, refreshing them with water. In about six weeks, when they have taken root, and made shoots above, they should have plenty of air, and accustomed to bear being exposed to the open air; and afterwards treated like the tender plants. The Catalpa delights in a rich moist soil, where, in a few years, it will produce flowers. The plants of the third species, not bearing cold, when young, should be sheltered in winter, planted against a warm wall, and protected from frosts by coverings of mats, and by tan covering the soil about their roots. The fourth and fifth species will live in the open air, when planted against a wall with a south aspect, and sheltered in a very severe frost. The sixth, seventh, eighth, tenth, eleventh, and twelfth sorts, are tender, and will not thrive in this country out of the bark-box. If the ninth species be planted in the full ground against a wall, the roots should be covered in the autumn with some old tanners' bark, to keep out the frost in winter; and in very severe frost they should be covered with mats. The twelfth sort will take root from cuttings planted during summer in pots, or plunged in a bark-bed: it has flowered several years in the Chelsea garden, in August. The fourteenth sort is so hardy as to thrive in the open air; but the trailing branches should be supported; and as they spread much and rife to a great height, they will serve to cover unlight buildings; and also trained against the limbs of trees, they make a fine appearance when in flower. It is propagated by seeds, but the young plants thus obtained will not flower in less than seven or eight years; and therefore those propagated by cuttings or layers are most esteemed, because they will flower in two or three years after planting. The necessary culture for these plants, after they are established, is to cut away all the small weak shoots of the former year in winter, and shorten the strong ones to the length of about two feet; and thus young shoots will be obtained for flowering in the following summer. These plants are of long duration: some of them remain vigorous after 60 years, and produce plenty of flowers every season. The fifteenth species is propagated by seeds sown on a hot-bed, and by transplanting the plants into separate small pots, filled with light fresh earth, and plunged into a fresh hot-bed; by removing them in autumn into the bark-box, giving them but little water during winter, and in summer refreshing them with it sparingly; and they should remain constantly in the bark-box, and be treated like other tender plants from the hot countries. The third year from seed they will flower; but they do not produce seeds in England. The other sorts have not been cultivated in England. Martyn.

BIGORNO, in Geography, a town of Corfica.

BIGORRE, a country of France, in the province of Gueyenne before the revolution, but now forming a part of the department of the Upper Pyrenees. Its capital was Tarbes. It is bounded on the N. E. by Armagnac and the country of the four valleys, Nebouran and Astarac, on the south, by the Pyrenees; and by Bear, on the west. It has been sometimes divided into the country of Ruffian, the Plain, and the Valleys; and estimated at 16 leagues in length from north to south; and in its greatest breadth at 7 leagues. From its general situation, this country might be expected to enjoy the same mild climate that is experienced in the neighbouring provinces, under the same latitude; but from local circumstances the climate is very different. The Pyrenees intercept the warmth of the more southerly country of Spain; while, from its elevated situation, it is exposed to the chilling blasts of the north. On this account, Bigorre is deprived of many fruits and vegetables, such as the orange and olive; however, the laurel, fig-tree, and myrtle, are not injured by the climate. The air of the mountains is cold and chilling, but that of the plains and valleys.
walls, more mild and substantial. This country produces wood in considerable quantities, excellent wine, rye, barley, and milk; but not much wheat. It has good pastures, quarries of marble, and medicinal springs. The mountains of Biggerrc confine of schist, marble, and granite. See Py-
reness.
The inhabitants of this district possess a peculiar and characteristic physiognomy, in which they all resemble one another: they are healthy and active, lively and cheerful, and unite impetuous courage with strength and agility. The impetuosity of their temper renders their language rapid, passionate, and full of protestations; and they sometimes lose the voice an octave below the natural key, that they may suddenly raise it to the shrill note. Their ideas abound with imagery; and their gestures are quick and violent. They are distinguished by their generosity and beneficence. They practice the fling from their infancy, and can draw a bow before they speak; and those persons are regarded as the most accomplished, who are most skilled in keeping, riding, and throwing the bar. The education of the Ercole, who are not husbandsmen, is conducted with a view to the church; and they boast of many eminent per-
sons in science and literature.

BIGOT, a person foolishly obstinate, or perverted at
ached to an opinion. The word is formed from the German big, and Gott, or the English by-God. Camden relates, that the Normans were first called Bigots, on occasion of their dusk Rolls; who receiving Gills, daugh-
ter of King Charls, in marriage, and with her the in-
vellir of the dukedom, refused to kifs the king's foot in token of submission, which he would hold it out for that purpose; and being urged to it by those present, answered haughtily, "No, by God!" whereby the king, turning around, called him Bigot; which name has passed from him to his people.

BIGOT, Emerit, in Biography, an eminent promoter of literature, was born at Rouen in 1629; and forming an early attachment to literature, he declined all public buil-
dings, and employed himself in augmenting a large library bequeathed to him by his father, and in correspondence and conversation with persons of learning. Few persons con-
culated, by the model of his temper, by the friendship and favoritism of his manners, and by his love of peace and en-
deavors to maintain it, a greater number of friends, who re
defected and esteemed him. In various parts of Europe through which he travelled, he formed connections with literary men; but his most intimate friends of this descrip-
tion were Menage and Nicholas Heinius. Although he distinguished himself by aiding others in their literary per-
fomances, the only work he published in his own name was the Greek text of Palladius's life of St. Chrysostom, found in the grand duke's library at Florence, to which he an-
nexed a Latin translation. Having enlisted his valuable library on his family, in order to prevent its dispersion, he died at Rouen in 1690. However, notwithstanding his precaution, his library was publicly sold at Paris in 1706. Gen. Dict.

BIGOT, in Italian Bigotta, in Commerce, is used to denote a Venetian liquid measure, containing the fourth part of the ducat, or half a galeon.

BIG RICK, in Geography, a large rock on the S.E.
bank of the Venerian in America; about 3 miles N.E. from its mouth in the Mississippi, and about 8 miles S.E. from Cape St. Antonio on that river.

Big Rock Branch, the north-eastern head branch of Alleghany river. The branch called Big Hole Town joins it, and forms the Alleghany, 85 miles N.E. from, and above, Venango fort.

BIG Salt Lick, a garrison in the state of Tenessee, near the Salt lick, on Cumberland river, 115 miles from Knoxville; 80 from S.W. point on Clinch river, 32 from Bledsoe lick, and 68 from Nashville.

BIG Sandy River, or Tatterson, rises near the source of Cumberland river, and separating Virginia from Kentucky, discharges itself into the Ohio, opposite to the French pur-
chase of Galopin, in about N.lat. 38° 37'. Vancouver's and Harmar's forts stand on this river. On its banks are several salt licks and springs. Little Sandy is a short small river, which falls into the Ohio, about 20 miles west of Big Sandy river, in the county of Mason, Kentucky.

BIGUBA, a town of North Africa, seated on the river Rio Grande. N. lat. 11° 30'. W. long. 34° 37'.

BIGUTTATA, in Entomology, a species of Silpha,
met with at Upfal. This is totally ferruginous, with a pale line and spot on the wing-cases. Thunberg, Nov. Act. Stockh.

BIGUTTATA, a species of Cassida, with a yellow thorax;
reddish wing-cases; black margin, and two yellow spots.
Fabricius. This insect inhabits Cayenne.

BIGUTTATA, a species of Coccinella, described by
Fabricius. It is rufous, with two yellow spots. The
country is unknown. Size small: thorax glossy and black, with the fides yellow.

BIGUTTATA, a species of Cantharis, found in gardens in
Europe. The thorax is black in the middle; wing-cases short, black, and yellow at the tip. Linn. Fr. Succ. 
Fabricius. This is Telephorus nigri, formosus flavus, elysius apicis Acidus of Degueur.

BIGUTTATA, a species of Buprestis, with very entire line,
green wing-cases, with a white dot; abdomen blue, with three white dots. Fabricius, &c. Inhabitats Eng-
land.

BIGUTTATA, a species of Cicada (Cercopis), of a black colour, spotted with yellow; wing-cases brown, with a white marginal spot. Inhabitats Germany. Fabricius.

BIGUTTATA, a species of Cicada (Rinaster l'abri), that
is found in Europe. It is black, with a patch of fangous red on each side of the thorax. Fabricius.

BIGUTTATA, a species of Vespa, of the small size, that
inhabitats China. Its black, and spotted with yellow; margin of the segments, and two dots of yellow on the second one. Fabricius.

BIGUTTATA, a species of Scodia, of a black colour, with two transverse white dots on the abdomen; wings black. A small species, and inhabits Spain. Fabricius.

BIGUTTATOR, a species of Ichneumon, described by
Thunberg. It is black, with two dots on the feutel. Found at Upfal.

BIGUTTATUS, a species of Curculio, that is found in
Germany. It is black, with elevated dots on the wing-
cases; abdomen and posterior legs yellow. Fabricius.

BIGUTTATUS, a species of Cryptcephalus, of a black colour, with the head, tip of the wing-cases, and legs yellow. Gmelin. A native of Austrlia.

BIGUTTATUS, a species of Carabus, that lives under the
bark of trees in Sweden, and is described by Thunberg. The head is roundish and brassy; wing-cases black, with a pale spot at the apex.

BIGUTTATUS, a species of Dytiscus, described by
Linnaeus as a native of Europe. This is black; legs, end of the abdomen, antennae, mouth, two dots between the eyes, thorax, and wing-cases tesselose, the latter spotted with brown; in the middle of the thorax two black spots.

BIGUT-
Bijore, called also Bijour and Bajour, the Bazira of Alexander, a province of Hindoostan, bounded on the south by Paishawur, on the north by Kutture, on the east by Seward and Beneer, which are separated from it by the Penjekorh river, and on the west by Guzaungool. This province, according to the dimensions flated in the Ayen Abarce (vol. ii. p. 192, &c.) extends 25 miles north and south, and 40 miles east and west; it contains about 500000 acres, and is of the main part of it, a mountainous, and abounds with paffes and strong situations; so that their inhabitants have not only held themselves generally independent of the Mogul emperors, but have occasionally made very serious infroads into their territories. In this province there is at this day a tribe of Afghans, denominated Yuzuf-zyces, which traces its origin to certain persons left there by Alexander the Great, when he passed through this country. Both Abul Fazi, the author of the Ayen Abarce, and Soojan Rae, an eminent historian of good reputation, report this tradition without any material alteration. The latter, indeed, adds, that these Europeans, if we may call them so, continued to preserve that ascendency over their neighbours which their ancestors may be supposed to have possessed, when they first settled here. Although we should reject this pedigree as fabulous, yet the bare statement argues the belief of the natives; for which there must have been some foundation, that Alexander not only conquered Bijore, but also transferred that conquest to some of his own countrymen. The people of Bijore had likewise an high idea of Alexander's exterminating authority; and they denominated him the "Two-horned," agreeably to the striking emblem of power in all the eastern languages. (Ayen Abarce, xi. 194.) These Yuzuf-zyces, says Mahomed Cazim, quitted their ancient habitations between Ghizini and Candhilar, and after various unsuccessful attempts to obtain a settlement in Cabul, at the time when Mirza Ulug Beg, surnamed Cabulc, ruled that kingdom, finally established themselves in Seward and Bijore; which at this period were governed by a dynasty of princes styled "Sultani," who derived their lineage from Alexander the Great. The Yuzuf-zyces possess, in addition to Seward and Bijore, the tracts situated between those provinces, and the rivers of Cabul and Indus; the greatest part of which is described as a desert in the Ayen Abarce, but by Berrouruli as a forest. In the time of Aechar, Zincthh Kus was sent to chastise them; and he overrun their whole territory, and even penetrated to the borders of Cagurgh, and took the strong fortress of Kusal, or Gutal, seated on a mountain 15 miles north of Bijore. About the year 1672, Aurungzebe found it necessary to chastise these Yuzuf-zyces; since which period the return of Nadir-Shah, in 1730, again brought them into notice. To him they appeared formidable; but he reduced them to submission; and if they really engaged to supply his army with 50000 men, the tribe must have increased since the time of Aechar, when Bijore contained only 30000 and Seward 20000 families. Rennell's Mem. p. 159, &c.

Bijore, the capital of the above-described province, situated about 6 miles, or about 60 geographical miles, from Nilab or Attock, and at 50 of the same mile, north a little east from Paishawur, and at the large distance east a little north from Ialalabad. N. lat. 34° 7'. E. long. 76° 44'.

Bijore, the name of a river which rises in the mountains, N.E. of Bijore, and passing by it, forms a junction with the Penjekorh, Seward, and Kameh, and falls into the Nilab, or Sinde, at Attock.

Bisik, a town and districk of Siberia, in the government of Kolyvan, seated on the river Bi, or Bia, which, by uniting with the Katunis, forms the river Ob; 150 miles S.S.E. of Kolyvan. N. lat. 53° 31'. E. long. 84° 14'.

Bijugum, Flora, in Botany, denotes a winged leaf, bearing two pair of folioli.

Bikulakova, in Geography, a town of Rousia, in the government of Ufa, on the river Ik, 80 miles N.E. of Orenburg.

Bikillum, or Beckilen, a small island in the Red sea, 8 leagues from the coast of Arabia. N. lat. 19°. E. long. 42° 25'.

Bikou, a town of Poland, in the palatinat of Brandaw, 50 miles north of Brachaw.

Bila, a river of Bohemia, which runs into the Moldau near Auffig.

Bila Alt, a town of Bohemia, in the circle of Leitmeritz, 10 miles W.S.W. of Kummiv.

Bilena, or Biliana, in Ancient Geography, a town of Arabia Felix. Pertum.

Bilun, in Geography, a town of Bohemia, in the circle of Churudin, 5 miles west of Churudin.

Bilandis Defendis, in L. a., a port directed to a corporation, for the carrying of weights to such a heaven, there to weigh the wool, which pertains by our ancient laws were licensed to transport. Reg. Otag. 272.

Bilandt, in Navigation, a small merchant-ship with two masts; distinguished from other vessels of the same kind by the form of the main-ail, which resembles a sattet-tail. The head is bent to a yard, similar to the mizen-yard of a ship, and hangs to the main-mast, as a ship's does to the mizen-mast. This method of rigging has proved inconvenient, and is now seldom used, except by the Dutch.

Bilunus,
BILANUS, in Botany. See CRATAEVA.

BILARIUS, Porus. See BILARII Poroi.

BILATERAL COAGULATION, denotes kinship, or kindred, on both sides; that of the father as well as mother.

Such is the relation of brothers, sisters. Bilateral hands contrasting unified to unilateral.

BILBA, in Ancient Geography, a town of Asia, in Babylonia.

Bilbao, sometimes called Bilbo, in Geography, a port-town of Spain, in the province of Biscay, seated on the banks of the river Ybazarabal, about 6 miles from the sea. On the water-side is a large square, well fringed with pleasant walks, extending to the outlets on the banks of the river, and containing a number of houses and gardens, which form an agreeable prospect, this particularly in falling up the river. The number of houses in this town is about 500, some of which are built on piles; they are solid and lofty; the streets are well paved and level; and as they may be washed at pleasure, Bilbao is one of the neatest towns in Europe. The tide that flows into the river forms a secure and much frequented harbour; and a considerable commerce is thus carried on in iron, wool, of which, it is said, 60,000 bags are annually exported to Great Britain, France, and Holland, saffron, and cheese.

Towards the close of the 13th century, the people of Biscay, having maintained their independence, together with their profession of Christianness, even when the Moors gained possession of the other parts of Spain, and having about this time obtained some advantages over them, began to direct their attention to the manufacture of their own excellent iron, not only for their own use, but for the supply of other nations; and their port of Bilbao began to have shipping, and to engage in foreign trade, perhaps before any other nation in the west of Mediterranean sea, at least in a very considerable degree.

In the latter part of the 13th century, this town was refounded, or new built, by Didacus Lopez, then prince, or lord of the province; and as it was the staple port for the iron and wool of Spain, its commerce rapidly increased; and it appears from Rymer’s Fœdera, that in the reign of king Edward IV. A.D. 1474, the merchants of Guipuzcoa carried on, probably by the port of Bilbao, a considerable trade with England. It appears, also, that the Biscayners, availing themselves of the advantage of their shipping and port, were concerned in the whale-fishery at an earlier period than any other nation of Europe, Norway excepted.

The town is supplied with flesh and poultry, and also with fish of various kinds, and particularly with a fort of eels in winter, which are small, of a pale colour, about three months long, and without a back bone, caught in prodigious quantities at low tides, and in summer with the cuttle-fish. The framiers are a Tuscan building, in the centre of the town, with an open court, and a fountain in the middle, by means of which it is kept clean, and free from offensive smells and scents. The environs abound in gardens, which are fertile in legumes and fruits. This town has five churches, and several religious houses; and in its police it has one law of a peculiar kind, which renders ingratitude criminal, and subject to a penalty. Although the air is generally damp, the town is remarkably healthy, and the inhabitants are robust, cheerful, and long-lived; so that the hospital is frequently without a patient. The women are capable of enduring labour as well as the men, and are employed in unloading the ships, carrying burdens, and performing the busines of porters. At the close of the day they return to their habitations, without any appearance of fatigue, dancing and singing to the pipe and tabor. Their music is defrayed at the expense of the town; and on holidays it is performed in the midst of a great concourse of persons under the trees in the great square. The women of Bilbao, though constantly exposed to the air, have good complexions, lively eyes, and fine black hair, which they customarily braid, and which they reekoon peculiarly ornamental. Married women wrap a white handkerchief round their heads, so fastened as to fall down in three plaits behind, and over this they wear the Montona cap. Those who understand their language say it is very soft and harmonious, as well as energetic. N. lat. 43° 15'. W. long. 2° 45'. See Biscay.

BILBOY, in Botany. See VACCINUM.

BILBILINEAE Aquif., in Ancient Geography, Alabama, mineral and medicinal waters of Spain, 24 miles from Bilbilis, according to the itinerary of Antonine. The name Allama, given by the Arabinians to this place, has the same meaning with the aque calide del of the Latin. See Allama.

BILBILIS, Bamhola, a town of Hispania Tarraconensis, belonging to the Celibus, south of Tarraconae; seated on a mountain surrounded by the waters of Salo or Xalon. Bilbilis was a municipal town, and bore the title of Augulla, which is found on several medals. The poet Martial was of this city, called by Ptolemy Bilhe.

"Municipis Augulli minis quo Bilbiliis acri
Monte creat, rapidis quo Salo cingit aqua."

Martial, l. 10, epig. 103.

On most of the medals of Bilbilis, we perceive, on one side a head of Augustus, and, on the other, a cavalier, armed with a lance and a helmet.—Alfo, a river of Spain, the waters of which were famous for tempering iron; called also Salo.

BILBOWS, in Scæphus, a punishment answering to the flocks at hand.

They confit of long bars, or bolts of iron, with thackles fiding on them, and a look at the end, used to confine the feet of prisoners, in a manner similar to the confinement of the hands in handcuffs. See Stocks.

BILCOCK, in Ornithology, one of the synonymous English names of Rallus australis, or water-rail.

BILDERWERTSCHEN, in Geography, a town of Pfuffia, in the province of Lithuania, 4 miles N.W. of Stalluponsch.

BILDESTON. See Bilston.

BILDEGE, or Bilge of a Ship, denotes the bottom of her floor; or the breadth of that part which she rests on, when she is a-ground.

Hence, when a ship receives a fracture in this place, by striking on a rock, or otherwise, she is said to be bilged, or bulged.

BILDEGE-Water, is that which, by reason of the flatness of the ship’s bottom, lies on her floor, and cannot go to the well of the pump. This water is always, if the ship does not leak, of a dirty colour, and disagreeable smell.

The Dutch, whose ships are often of this form, use a sort of pumps, called "bildege-pumps," or, as we call them "burp-pumps," to carry off the bilge-water. BILGE, in Physiog., is the fluid prepared from the blood by the liver of animals. The colour of healthy bile in the human subject is probably of a deep yellow brown. In oxen, it is frequently of a yellowish green. In the gall bladder, it is of a thickish consistence, of a nauseous feel, or like that of mucus, of a bitter taste, and peculiar smell. Its specific gravity is about 1.027. It readily mixes with water, but will not incorporate with oil, yet it takes grease out of cloths. Albumen may be precipitated from it by alcohol and acids; and Cadet ascertained its proportion in 100 parts of ox bile to be about 0.52. (Cadet, Mem. Par. 1767.) If a solution of bile in muriatic acid be concentrated by heat, a coagulated precipitate takes place, and the solution changes its colour from a

grafs
grafs green to a brown. This precipitate has the properties of a resin. From 100 parts of bile, 1.87 of crystallized soda has been obtained, and some was probably left in the process. Cadet also obtained from bile a bulk of a fivetith tale. There are other substances found in bile in small quantities: sulphurated hydrogen gas, which is emitted on the addition of muriatic acid; a little muriate of soda, phosphate of lime, and phosphate of soda and of iron. Of course water is the vehicle for all these substances, and forms the largest share of the ingredients in the composition of bile. For an account of the secretion of bile, see the article Liver, functions of.

Bile, in Chemistry. This fluid may justly be considered as equally important to the chemist as to the physiologist; and accordingly it has been examined with extreme minuteness by a great number of eminent chemists, in various countries, with a general parity of result which is highly satisfactory. Indeed the analysis of bile, as far as relates to the detection of its leading constituent parts, is neither very complicated nor remarkably difficult.

Chemists have not been able to detect any considerable difference between the bile immediately secreted from the liver, and that which is found in the gall-bladder, excepting that the latter appears on the whole to be somewhat less watery, more bitter and more viscid than the former. The age of the animal makes a greater difference, the bile of a cow or oxen being more viscid than that of calves. On account of the cafe with which ox-gall is procured in considerable quantity, this has generally been selected for experiment; but its analysis does not essentially differ from that of the bile of any other animal.

Bile is a homogenous fluid, in some animals of a deep yellowish brown, in others of various shades of green, so viscid as not to pour by drops; of a peculiar faint smell, but not ungrateful when fresh, and not from a dis eased animal; intensely bitter to the taste, even when very largely diluted with water, and somewhat pungent. It is considerably heavier than water; its specific gravity being from about 1.02 to 1.025, varying according to the age and health of the animal, and probably to the time that it has remained within the gall-bladder. When agitated, bile lathers like soap water.

When bile is gently heated, an aequous vapour arises, which, when condened, appears by the most delicate reagents to be nothing but water, though impregnated however with the odorous part of this fluid, and somewhat fetid. Bile loses about seven eighths of its bulk of mere water by this evaporation; and the residue gradually thickens in the confluence of a tenacious extract, which, on carefully drying, becomes a hard brittle tinfoil-like mass, of a dark colour, and intensely bitter.

If this extract of bile be slowly heated in a retort to decomposition, the products are, a watery fluid fetid with sulphurated hydrogen gas, a brown fetid liquor containing ammonia, a tenacious limking empyreumatic oil, with more carbonated ammonia, and a copious emission of carbonic acid, and carbonated with sulphurated hydrogen. The maf in the retort swells up prodigiously in the process, and leaves a pufy coaly mass to incinerate, the ashes of which contain a notable quantity of carbonated soda, with some muriate of soda, phosphen of soda and lime, and a little iron. Fontana obtained from a pound of ox-gall 43 grains of carbonated soda, and 6 grains of common salt.

The residue, therefore, of calcined bile contains alkali in excess; and hence water, with which it has been lixiviated, readily turns syrup of violets green. The same tett of an alkali is given with fresh bile, diluted with water, that the change of colour may be more apparent.

The action of acids on bile throws much light on its composition. Muriatic acid, strong or dilute, added to bile, immediately produces a coagulation, and, at the same time, renders the whole liquor a fine light green. The coagulum, however, is partly re dissolved, if the acid is concentrated. Examined chemically, it is found to be albumen, but intensely bitter. In the clear green liquor, though retaining the muriatic acid, the bitter taste also strongly predominates. Evaporated slowly, it departs in about an hour's time another precipitate, very green, intensely bitter, and soft and tenacious like turpentine. The clear liquor is now yellowish, and, on further evaporation, yields a number of cubic crystals of muriated soda, formed chiefly, if not entirely, by the soda originally contained in the bile and the acid added. As a proof that this is the case, if the experiment is made with nitrous or sulphuric acid, instead of the muriatic, the salt will be nitrated or sulphated soda. The above decomposition is more perfect, if bile and dilute muriatic acid are at first boiled together for a few minutes; the retort then is a total separation of a dark green glutinous bitter mass, and a liquid now colourless and feebly bitter, from which the muriated soda may be procured by evaporation.

This glutinous coagulum, when dry, burns like a resin. Alcohol, heated upon it dissolves one part, and leaves another untouched, thus entirely separating it into two distinct principles; the insoluble, which is albumen; and the soluble, which retains the colour and taste of bile, is totally precipitated from the spirit by water, is highly inflammable, insoluble in water, and has been considered as a species of resin or combustible oil, and is termed by some the resin of bile. Fourcroy, however, supposes it to be more of the nature of adipocere.

Alcohol alone is another important reagent for the analysis of bile. When these two fluids are mixed together, a coagulum is immediately formed of a whitish tenacious substance, feebly bitter when well washed, and exhibiting all the properties of albumen. The remaining liquor is green, and contains, mixed with the alcohol, the albuminous, saline, and colouring matter of the bile. Alcohol equally separates albumen from bile, insipidified by evaporation, and dissolves the remainder. The alcoholic solution of bile, not previously treated by an acid, differs considerably from that which has undergone this treatment. In the latter case, as before mentioned, the solution is decomposable by mere water, and by evaporation is converted into a very feebly productive fluid. In the former case, the solution mixes uniformly with water, yields by evaporation a transparent extract like gum-arabic, of a fivetith taste, a little mixed with the natural bitterness of bile, and easily soluble in water. The residue of this difference is doubtless owing to the separation of the soda from the resin of bile by the oxygen in one instance, whereas in the other they remain united in the form of a natural soap. Hence it is that the affusion of an acid upon the latter alcoholic solution decomposes it, and separates an unctionous substance, which again dissolved in alcohol is new precipitable from this solvent by simple water, and refembles a pure resinous solution.

Some chemists have thought that they could also detect a faccharine matter in bile, but the experiments to this purpose are not conclusive.

The oxygenized muriatic acid gas passed through bile diluted with a little water, soon destroys its yellow green colour, and precipitates the albumen in white flocculi; the laponaceous resin
B I L

refin continues in solution without colour or smell; but the bitternnes remains. A further quantity of this acid separates the refrinos oil as the muriatic acid does, but white and concrete. Any acid poured upon bile already bleached by the oxymuriatic acid, separates numerous white concrete matter much resembling adipocere. but the specific nature of the change produced by the oxymuriatic acid has not been properly ascertained.

Bile therefore may be inferred from the present state of chemical analysis to contain,
1. A large proportion of water.
2. A substantia closely resembling animal albumen.
3. A peculiar refrinos inflammable matter, naturally and intimately with
4. Soda, into a kind of soap, or faponaceous extract.
5. Some neutral salts.
6. A small quantity of oxyd of iron.

Besides these constituents, there is a colouring and odorant matter, but it is not yet ascertained whether these are properties of any of the above-mentioned ingredients, or whether they belong to a peculiar substance.

Some chemists have also supposed a kind of fæcearion mucilage, resembling the fugar of milk, but the existence of this, in recent unaltered bile, is very doubtful.

Bile has been supposed to be a powerful antiseptic, and its effects in the animal economy have been attributed to this quality, but without much foundation. Bile, left in itself in a moderate temperature soon becomes putrid (though not so speedily as blood); it then exhales a very fetid odour, but after this point it decomposes but very slowly, and at last affumes a ftrong, not very unpleasant musty smell. This partial resistiance to putrefaction is probably owing to the refrinos ingredient, which lasts, when separated by acids and alcohol, in the way already mentioned, is absolutely incapable of putrefaction. M. Cadet afferts, that at no time during this process is any acid generated.

The faponaceous quality of bile, which is very characteristic, and is owing to the intimate union of its refin with soda, renders it inefficile with milk, with oil, myrrh, aloes, and other gum-refins, by trituration, without curdling, or ready decomposition. It is also owing to this intimate mixture with this natural soap that the albumen which bile contains is not coagulable by heat; even if an additional quantity of albumen (white of egg for example) is mixed with bile, heat will not congregate it. Hence too, alcohol only partially separates the albumen, unless the acid is previously applied to engage the soda, and the alcholic solution of the refin retains the soda fo as to render the refin not separable by mere water.

Bile, or ox-gall, is employed in various ways as a cleaner of wool, cloth, &c. to get out greace spots, to take off the greasynefs of ivory in preparing it for receiving colours; and in China it is mixed with some of their varnish. Gail a little putrid may be preferred a long time from further alteration by being boiled for a few minutes.

M. Fourcroy afferts, that he has obtained a substantia, resembling bile in every property, by mixing blood with a third of water, coagulating it by heat, and slowly evaporating the ferment. This experiment has, however, been repeated by others without success. See Cadet in the Mem. of the Acad. des Sciences, for 1767 and 1769. Van Bochante, Professor at Louvain, in the Jour. de Phys. tom. 13. Suppli. An. Chim. tom. 4, 5, and 6. Fourcroy Systeme de Conn. Chim. &c.

Bile, in Medicine, a yellowish-green fluid, more or less viscid, and of a bitter taste, secreted in the liver, and conveyed from that organ, by the so-call'd ductus communis choledochus, into the duodenum. It is a yellow compound fluid, being resolved by chemical analysis into a variety of ingredients; such as water, albumen, refin, fats, muriate of soda, phosphat of soda, phosphat of lime and iron, besides a fæcearion matter analogous to fugar of milk. In its general properties, it may be said to partake of the nature of a soap, although it will not intimately mix with oil. The cylic bile, or that which is contained in the gall-bladder, possesses more viscidity and bitterness, (i.e. is more concentrated) than that which flows directly from the biliary ducts into the duodenum, and which is termed hepatic bile.

When we fix an organ of such magnitude as the liver, appropriated to the secretion of the bile, we are naturally led to infer that the fluid so secreted, must answer some useful purposes in the animal economy; but respecting the number and kind of purporses which it answers, physiologists do not exactly agree. It may, perhaps, concur with the pancreatic juice, to the separation of the refuse part of the alimentary pulp (chyme) from the proper chyle; but, as Dr. G. For-
dyce has remarked, in his treatise on the digestion of food, the bile does not unite with the chyle itself, and pass along with it, through the lacteals into the blood. Mixed with the feculent matter, and colouring it, the bile seems to prevent that matter from running into fermentation, by virtue of its alkaline nature; and perhaps, also, in consequence of the bitter principle which it contains, it may, in some degree, resist putrefaction; but its principal and most obvious use is, as a stimulus to the intestines, serving to keep up a due degree of peristaltic action, and thereby to produce a regular and natural evacuation of their contents. Hence a diminished secretion, or obstructed passage of the bile, is always accompanied with colicinenes.

From this view of the nature and composition of the biliary secretion, and of its action upon the living body in a state of health; we proceed to the consideration of its morbid conditions, which may be reduced to four heads: viz.
1. Deficiency.
2. Obstitution.
3. Excess.
4. Vifitation.

1. A deficiency of Bile. This is known by a pale and languid habit of body, indigelation, flatulency, acidity, colicinenes, and pale or clay-coloured stools. It is occasioned by a febrous state of life, by intemperance, and by depriving the aliment of its vegetable principles, and of some of the indigenous fermenta, which are necessary to the proper action of the alimentary organs. It occurs in chlorosis, hypochondrias, and chronic hepatitis. (See what is said of these diseases under their respective titles.) To whatsoever cause it may be owing, it is always attended with indigelation and colicinenes; two symptoms which should be especially attended to in the cure. A well regulated diet should be prescribed, wherein spirited drinks, high-seaoned meats, flintulent vegetables, and crude and acid fruits, should be forbidden. Much flesh should at the same time be laid on a plan of regular exercise; and the injurious effects of cold and damp upon the gall and hepatic systems, should be counteracted by suitable clothing. As a further aid to digestion, bitters and chalybeates (especially the chalybeate mineral waters), should be preferred; and colicinenes should be remedied by occasional doses of rhubarb, neutral salts, and aloeits; and some times by the stronger cathartics. Acidity should be counteracted by alkalis, among which, foda or natron preparatum answers well. Where the diminished secretion of bile has appeared to be connected with a diseased structure of the liver, and particularly where such a change of structure has arisen from inflammation, mercury (Dr. Saunders observes), has been found useful, even carried to the degree of producing a slight inflammation, and moderating the violence, however, of its operations by plentiful dilution, with
with gum arabic, and other vegetable demulcents. In these cases, the same author has found a tepid bath, of 90 degrees of Fahrenheit, to produce manifest good effects. 2. Obstruction of Bile. After it is secreted, the bile is sometimes prevented from passing into the duodenum. This may happen from various causes; viz. from an obliteration of the cavities of the bilary ducts, either by a thickening of their coats, or by a tuberculous state of the liver, the consequences of inflammation; from prepuce produced by enlargements of the neighbouring parts; and from a too vivid and efficient state of the bile itself; but, more than all, from gall-stones impacted in the common duct. Whenever in any of these ways, the bile, after been secreted, is hindered from passing into the duodenum, it is either taken into the circulatory system by what is termed regurgitation, or by absorption; producing great languor and oppression, together with a yellowness of the skin, and tumica conjunctiva of the eyes, &c. i.e. giving rise to jaundice. (See Gall-stones and Jaundice.) The treatment must be varied, according to the variety of conditions on which the obstruction depends. In this phase, it will be sufficient to remark, that saline purgatives, mercurials, fapomaceus and alkaline medicines, with tepid dilution, and warm bathing, will be found useful to the majority of these cases.

3. Excess, or redundancy of Bile, is a morbid affection, of very frequent occurrence. Among its exciting causes may be mentioned intemperance of living, the summer and autumnal heats of our own latitudes, and more especially, the high temperatures of the tropical climates; in a word, whatever produces a hurried circulation, or irritates the vascular and secreting system of the liver. A redundancy of bile makes itself known by a general languor of the body, together with naufea, foul tongue, loss of appetite, and indigestion; or, by being directed to the intestines, excites a painful diarrheas, ultimately tending to weaken their tone, and disturb their regular peristaltic motion. It generally happens, that, during the excess and prevalence of bile in the first passages, some absoption of it takes place into the habit, so that the skin becomes yellow, and the urine is febibly impregnated with it. The pulse is quicker than natural, and there is a considerable degree of thirst, with an increase of heat; the usual symptoms of fever. The body becomes emaciated, and the general aspect of the patient is extremely unhealthy. It may be added, that most of the fevers of hot climates, whether intermittent, remittent, or continued, are accompanied by an overflow of bile. (See Fevers.) When the increased secretion of bile affects the stomach and bowels in such manner as to excite both vomiting and purging to a violent degree, it gives rise to that form of diæsea which is termed cholera; of which a particular description will be found under that title; when it produces vomiting, joined with confusion and acute pains about the umbilical region, the diæsea is termed bilious colic (see Colic); and lastly, when the evacuation of bile is frequent and copious by flood only, without frequent vomiting, it constitutes bilious diarrheas. (See Diarrhoea.) It is the remark of that judicious writer to whose work we have more than once referred in this account of bilious disorders, that it is more difficult to supply a deficiency of bile, than to carry off its excess. In fact, little more is required for the fulfilment of this last intention, than to promote the discharge of the redundant bile by gentle saline evacuants, (for the bile has generally of itself a purgative tendency), and to prevent fresh accumulations, by diluting freely with water heated to a proper temperature. For this purpose, the patient should drink every morning, according to the excellent directions of Dr. Saunders, from half a pint to a pint of water, of a temperature from 90° to 114° of Fahrenheit's thermometer, and use moderate exercise before breakfast. With the same view, the Bath and Buxton waters, (provided their use be not contraindicated by viferal disease), and the Chelseham water also may be recommended. At the same time, a proper diet should be prescribed, consisting of food that is easy of digestion, not too hot, not too cold, and free from flatulence; and spirituous drinks and malt liquors should be forbidden. Paltry is particularly improper. Water, or wine and water, will be the best beverage. When the bile has been sufficiently evacuated, bitters and chalybates may be given with advantage. But where these complaints are the consequence of residing in the tropical regions, the only effectual remedy is to remove to a temperate climate. People, who have suffered in these respects from the heat of climate, and to whom it is necessary to return to this country for the recovery of their health, should endeavour (as Dr. Lind has recommended), to arrive in the beginning of summer, as they will find the winters of Great Britain, on their first arrival, too piercing and severe for their constitutions.

4. Vitiation of the Bile. In almost all cases wherein the secretion of bile exceeds the natural quantity, it is at the same time vitiated in its quality. Thus in bilious fevers, bilious diarrheas, bilious colic, and cholera morbus, it is often vitiated both in colour and taste, appearing wholly of a pure green colour, and posseing a sharpness or acridity which feats the teeth on edge, and produces a burning and corroding inflammation in the stomach, oesophagus and fauces, and at the same time violent twitchings in the intestinal canal. Such vitiations of the bile are common to infants, as well as to adults. The remedial treatment consists in evacuating the offending bile by the means specified under the preceding division (3), and correcting its vitiated qualities by the employment of alkalis, and by copious dilution with aquous and mucilaceous liquids. After due evacuations, the stomach and bowels may be protected from the irritating action of the remaining bile by opiate medicines. Lind, Clark, Winterbottom, and other writers on the diseases of hot climates, may be referred to for many excellent observations on bilious disorders; but the best and most comprehensive treatise on this subject is that of Dr. Saunders.

Biledgik, in Geography, a town of Atiic Turkey, in the province of Natolia, 32 miles N. W. of Elbi-Shehr.

Biledulgerid, a country of Africa, comprehending, according to some geographers, the southern part of Algiers, together with the whole tract of land that lies in this direction between the Atlantiue ocean and Egypt, and in this extent, including eight large tracts or provinces, viz. Barca, Biledulgerid proper, Segelmeina, or Sinmillis, Tafilet, Tigonarin, Zeb or Zab, Darka or Daras, and Tefef, besides several inferior districts, mentioned under the names of Oguela, or Augela, Paffan or Fezzan, and Gudamis or Gadames, &c. It was known to the ancients under the name of Nomida. But in a more confined and proper sense, according to the arrangement of De Lisle, and several modern geographers, Biledulgerid includes that tract of land which lies south of Algiers and Tunis, and is bounded on the east by a ridge of lofty mountains, which separates it from Tripoli and part of Gadames, on the west by the countries of Zab and Mezzab, and on the north by the province of Vergela, or Vergela. Its dimensions are not accurately ascertained; but it is somewhat of a square form, supposing it to extend about 60 or 80 leagues, every way, or from about 31° 15' to 34° 15'. N. lat. and from 5° 30' to 10° E. long. Some have derived the appellation Biledulgerid from Behd el Gerid, or the "land of dates," under which denomination it is designated in Remelli's map of North Africa; but others, with Dr.
Dr. Shaw, deduce it from Blaib el Jereid, or the "dry country." The whole province of Bledulgerid, bordering to the south on Sahara, or the Great Desert, is mountainous, sandy, and barren, producing little or no sustenance but dates, which grow in such abundance, that various parts of it are covered with palm-trees bearing this fruit. The climate is hot and unhealthy; the people are meagre, wantonly, and thrivelled in their complexion, and their eyes are inflamed by the reflection of the sun-beams, from the white hard soil, and by clouds of dust and sand driven by the high winds at some fountains in such abundance, as to bury men and cattle under their collected mists. They are all subject to a scurvy-like complaint, of which they can allay no probable causes, but to inveterate, that their teeth drop out, and their bodies become leathenome. In other respects they are healthy and vigorous, and live without sickness or dispute to a great age. The plague of Barbary is scarcely ever heard of in this province, notwithstanding the contiguity of the two countries, and the frequent intercourse of their inhabitants. Bledulgerid, properly so called, has few rivers and towns. The natives of Bledulgerid are represented as a lewd, treacherous, thievish, and savage people, that delight in murder, blood, and rapine. They are, in general, a mixture of old Africans and wild Arabs; the former of whom lived with some degree of regularity and civil order, in a kind of villages composed of a number of little huts, whilst the latter inhabited movable tents, and ranged from place to place in quest of food and plunder. These Arabs value themselves on their superiority with regard to birth and talents above the primitive inhabitants; and whilst they are wholly independent and free, they occasionally hire themselves to serve in the wars of the neighbouring princes, and hence arises the chief part of their public revenue. The reft pursue no other occupations besides plundering and hunting, and particularly hunting oritches, the flesh of which they dress for food, and the feathers they barter for corn, pulse, and other necessaries. The other parts of these birds they use in their religious rites, as ornaments of dress, or as pouches and knapsacks. Besides dates and oritches, they likewise subsist on the flesh of goats and camels; and for their drink, they use either the broth in which the flesh is boiled, or the milk of their camels, for they seldom have water, which is not only scarce, but brackish and unwholesome. For the character and manners of those who inhabit that part of Bledulgerid, taken in its former extent, and bordering on the Atlantic ocean, see MONSELEMINES and Mongearts.

BILfeld. See BILLED.

BILGE. See BIDGE.

BILGUER, JOHN ULLICK, in Biography, born at Coire, in the country of the Grisons, in Switzerland; after passing through the usual course of education, practised surgery at Berlin, where he soon acquired such reputation, as to engage the attention of king Frederic the Great, who made him surgeon to one of his regiments, and, in proportion, surgeon-general to the Prussian army. In the course of an extensive practice in this pil, he had an opportunity of observing how very small a proportion of the men recovered from fractures, where the soft parts were greatly bruised, and the bones shattered, when the limb had been amputated, which in such cases was the general practice. This induced him to try more lenient methods, which he practised with such success, as to enable him to reduce the cafes in which amputation should be declared to be necessary to a very small number. In 1761, he was admitted to the degree of doctor in medicine, by the university of Hall, in Saxony, when he read for his thesis "De membrorum amputatione rarissime admittandis, aut quasi abrogandis." This work was translated into French, and highly commended by Tiflot, then in the zenith of his reputation, which gave the work such credit, and so quick a circulation, that it was soon naturalized in every country of Europe, and its diffusion has been attended with most beneficial consequences. The methods recommended by the author for preferring retracted limbs, even in cafes that have been before thought hopeless, succeeded so often, as very much to diminish the frequency of the operation. He also published at Glogau, in 1763, "Instructions for Surgeons of Hospitals," in German. In this work, he further defends and illustrates the doctrine contained in the thesis. In cafes where amputation cannot be avoided, he advises leaving a portion of the integuments, a practice now become general. There are also other works published by this author on the practice of surgery, for the titles and accounts of which, see Haller's Bib. Chirurg. Ely. Diet. Hill.

BILGHY, in Geography, a town of Hindostan, in the Myce province, and in that district ceded to Britain in 1799, 38 miles W.S.W. from Harponully, and 35 N.N.W. from Bedmore. N.lat. 14° 8'. E.long. 74° 50'.

BILINARY Calehit. Some of the concretions found in the gall bladder or ducts, and which are generally of an oval form, are composed of a white substance like spermaceti, crystallized in brilliant plates or slices. These concretions float in water, and are inflammable. They dissolve in heated alcohol, in oil of turpentine, and in alkalies; in the latter case, the solution has the properties of a soap.

Other biliary concretions are of a polygonal form, and generally very numerous; they are of a brownish colour, and are formed of concentric layers, of a subfus like infusibl bile.

In some biliary concretions, there is a mixture of both the subfus above described.

There are also sometimes found in the gall bladder dark-coloured small brittle concretions, which are infusible in alcohol, or oil of turpentine, and which are not inflammable. (See GALL-STONES.) For a detail of experiments relative to Bile and these calculi, consult Cadet, Mem. Par. 1797. Fourcroy, Ann. de Chimie. Gren & Vanquan, ibid. Ramlay in the Thetaur. Med. Edin. and Macurg. See CALCULI, Biliary.

BILIARI Pari, the excretory ducts of the liver, now commonly termed sofa biliaria. See LIVER.

BILICH, a town of Siberia, 8 miles S.E. of Vercholensk.

BILIHAN, a town of Perlia, in the province of Irac, 100 miles S.S.W. of Amadan.

BILIKOWNK, a town of Poland, in the palatinate of Kiov, 50 miles west of Kiov.

BILIMBI, in Botany, a species of the Averrhoa (see AVERNHOA); which is carefully cultivated in the gardens of the East Indies, where it flowers throughout the year. The juice of the root is drank as a cure for fevers. The leaves boiled, and made into a cataplasm with rice, are famed in all sorts of tumors, and the juice of the fruit is used in almost all external complaints, dipping linen rags in it, and applying them to the parts. It is drank, mixed with arrack, to cure diarrhoea; and the dried leaves, mixed with betel leaves, and given in arrack, are said to promote delivery. The fruit is pleasant to the taste when fully ripe, and is commonly eaten; when smaller, and unripe, it makes a very pleasant pickle.

BILIN, in Geography, a town of Bohemia, in the circle of Leitmeritz, 14 miles west of Leitmeritz. This place has a fine citadel, and a spring of acid water; and holds annual fairs.
BIL

BILINEATA, in Entomology, a species of Leptura, of a blackish-brown, with two lines on the thorax, and scattered dots on the wing-cases yellowish. Scopoli, Gmelin. Inhabitats Carniola.

Bilineata, a species of Catharis, with a yellow thorax, with a spot, and four brown dots; wing-cases yellow, with a fulvous line. Thunberg, &c. This is a native of the cape of Good Hope.

Bilineata, a species of Chrysomela, that inhabits Scandinavia. It is green, glossed with gold; anterior part of the thorax excavated; and a double blue line on the wing-cases. Gmelin.

Bilineata, a species of Phalena (Geometra), with yellowish tellaceous wings, waved, with a broad stripe acrof, having a brown and a white margin. Linn. F. Suec. &c. A very common insect in hedges during the summer months; and is called in England sometimes the "fly moth."

Bilineata, a species of Phryganea, of a blackish colour, with brown wings, and two white lines on each margin. Inhabits the north of Europe.

Bilineatum, in Conchology, a species of Buccinum, described by Lillie. "The shell is very characteristically; spire obtuse; the whorls with a spotted band and two lines. Its native country is unknown.

Bilineatum, in Entomology, a species of Phalangium, of a pale colour, with two dorsal lines and black dots. Fabricius. Inhabits Norway.

BILINEATUS, a species of Curculio. This insect is brown, with two white lines on the wing-cases. Inhabitats Germany.

Bilineatus, a species of Cerambyx (Pristus), with erenate thorax, marked with two white lines; wing-cases ferruginous, speckled with white, and bordered with yellow. Inhabits America. Fabricius, &c.

Bilineatus, a species of Cryptoccephalus, of a minute size, that is found in Europe. This insect is black, with two yellowish lines on the wing-cases, and ferruginous legs. Gmelin. A native of Europe, and described by Linnaeus as Chrysmela bilineata.

Bilineatus, a species of Ichneumon. It is black, with two yellow lines in front; abdomen depressed; legs red; tips of the posterior ones brown. Linn. Mot. Left.

Bilineatus, in Ichthyology, a species of Pleuronectes, found in China. It is thin, long, above yellow, with a brown margin; beneath reddish-white; entirely covered with very small scales. This is specifically distinguished by having the lateral line double. Bloch.

Bilineatus, in Zoology, a species of Coluber, of a rufous colour, with two yellowish stripes; la double-racée of count de Cepede, and bilineated snake of Dr. Shaw. This kind, according to the former writer, measures two feet one inch in length, of which the tail is six inches and a half; colour rufous, each scale bordered with yellow; and from the back of the head are two bright golden-yellow stripes extending to the end of the tail; scales on the head large, those on the body smooth; native country unknown; abdominal fece 205; subocular fece 99.

Bilinguus, in Law. See Medietas Lingus.

Bilinguus, properly denotes a person who has two tongues in his mouth; an inference of which is given by Dolezal. It is also used for a person who speaks two languages.

Bilious Fever. See Fever.

BILIRIANS, in Geography, a denomination given to a class of inhabitants of the southern parts of Ruflia. In their origin they are Sarmates, who settled in their present habituations, and now exist under the name of Tchuvaches. See Belgarians.

Biltitz, a town of Silezia, in the principality of Tefchen, separated from Biala by the river of the same name, and at a small distance from it. N. lat. 49° 5'. E. long. 19° 6'.

Bilizin, a town of Poland, in the patinate of Novogrodek, about 18 miles N. E. of Novogrodek. N. lat. 53° 55'. E. long. 25° 45'.

Bills, in Agriculture, denotes an edge-tool, of the ax kind, with a hooked point, fitted to a handle, and used to chop bushes of trees, &c. When short, it is called a "hand-bill;" when long, a "hedge-bill."

Bill, in Common Language, denotes a written or printed paper, posted up in some public place, for the purpose of advertising the sale of any merchandise, ship, &c. or the failing of any vessel, &c.

Bill is also used among tradesmen and workmen for an account of goods sold and delivered, or of work done, with the charge annexed.

Bill, in Commerce, denotes a security for money under the hand, and sometimes seal of the debtor, without any condition or forfeiture, in case of non-performance.—In which it is distinguished from a bond or obligation. See Bond.

It has been usually defined a writing, wherein one man is bound to another to pay a sum of money, on a day that is future, or presently on demand, according to the agreement of the parties at the time when it is drawn, and the dealings between them.

Bill, in Law, denotes a declaration in writing, expressing a wrong or grievance, which the complainant hath suffered by the party complained of; or else some offence committed by him against some law or statute of the realm. This bill is commonly addressed to the lord chancellor, especially for unconfessable wrongs done to the complainant; and sometimes to others having jurisdiction, according to the law directs. It contains the fact complained of, the damages sustained, and the petition of process against the defendant for redress. This is used as well in criminal as in civil matters. In criminal cases, when the grand jury upon a presentment or indictment finds the same to be true, they indorse on it "billa vera," upon which the offender is liable to stand indicted of the crime, and is bound to make answer to it; and if the crime touch the life of the person indicted, it is then referred to the jury of life or death, viz. the petty jury, by whom, if he be found guilty, then he shall stand convicted of the crime, and is by the judge condemned to death.

Many of the proceedings in the king's bench are by bill; it is the ancient form of proceeding, and was, and yet should be, filed in parchment, in all suits, not by original. The declaration is a transcript of it, or supposed to be. See Amendment.

In Scots law, every summmary application in writing, by way of petition to the court of session, is called a "bill."

Bill of Appeal. See Appeal.

Bill of Attainder. See Attainder.

Bill, Crofts. See Cross-Bill, and Suit in Equity.

Bill in equity, is a kind of petition addressed to the lord chancellor, with which a suit in chancery commences. This in the nature of a declaration at common law, or a libel and allegation in the spiritual courts, sets forth the circumstances of the case at length, "in consideration of which," (for this is the usual language of the bill) "and for that reason"
is wholly without remedy at the common law;" relief is therefore prayed at the chancellor's hands, and also proceeds of subpoena against the defendant, to compel him to answer upon oath to all the matter charged in the bill. See Suit in Equity.

Bill of Exception to Evidence. See Exception.

Bill of Exchange, in Commerce and Law, a short note, or writing, ordering the payment of a sum of money in one place, to some person aligned by the drawer, or remitter, in consideration of the like value paid to him in another place. (See Remittance.) Or, it is an open letter of requisit from one man to another, defining him to pay a sum of money named in it to a third person, on his account, or to any other to whom that third person shall order it to be paid; or it may be made payable to bearer. This kind of negotiable security for money, invented among merchants in different countries, serves to facilitate the remittance of money from the one to the other, and of course the conduct of commercial transactiions; so that, since its first introduction, it has extended itself to almost all pecuniary negociations.

Bills of exchange were unknown in the ancient Roman commerce, as well as jurisprudence. According to the common opinion, they are said to have been brought into general use by the Jews and Lombards, when banished for their usury and other vices; who found means to withdraw their effects, which they had lodged in the hands of friends, both in France and England, by secret letters and bills conceived in short precise terms, like the modern bills of exchange, which they negociated by the affiance of merchants and travellers. The Jews were banished out of France by Philip Angulas, in 1143, and out of England, in 1290; but the use of paper credit was introduced in the Mogul empire in China, in 1235. It appears, that bills of exchange were negociated at Hamburg, in 1188; and it has been said, that the faction of the Gibellins, being expelled Italy by the Guelfs, towards the close of the 13th century, retired to Amsterdam, and used the fame means for the recovery of their effects in Italy as the Jews had done; and hence, as some have thought, the Dutch merchants took the hint of negotiating bills of exchange, and soon spread the practice throughout Europe. The name Gibellins is said to be the inventors of the re-change, or re-exchange, on account of damages, charges, and interest, when bills of exchange, which they called "polizoo di cambio," are not paid, but returned on protest. In 1307, bills of exchange seem to have been in use in England, though their nature was not well understood at a much later period; and the first reference to them in an act of parliament, occurs in 1384, when they were forbidden to be used without the king's licence. In 1394, an ordinance was fined by the city of Barcelona, that bills of exchange should be accepted within twenty-four hours after they were presented, and that the acceptance should be written on the back of the bill. Moreover, in 1403, the magistrates of Bruges requested those of Barcelona to inform them what was the common practice, in regard to bills of exchange, when the person who presented a bill raised money on it in an unusual manner, in the case of its not being paid, and by these means increased the expences so much, that the drawer would not consent to sustain the los. The form of the bill, such as is now used, is seen in the memorial, which also speaks of usance; and it also appears, that first and second bills were at that time drawn, and that when bills were not accepted, it was customary to protect them. Anderson's Hist. Com. vol. i. Beckman's Hist. of Invent. vol. iii. p. 462.

In common speech, a bill of exchange is frequently called a "draught"; but the former is the more legal, as well as mercurial expression. The person who makes or draws the bill is called the "drawer," and he to whom it is addressed is denominated the "acceptor." When he undertakes to pay the amount, he is called the "payee;" and if he appoint another to receive the money, this person is called the "indorser," as the payee is, with respect to him, the "indorser," and any one who happens for the time to be in possession of the bill is called the "holder" of it. The time at which the payment is limited to be made is various, according to the circumstances of the parties, and the dis-
a non. (1 Salk. 129. 2 Ed. Raym, 757. 96.) But at length the legislature recognized them and put them upon the same footing with inland bills of exchange; by statute 3 & 4 Ann. c. 9. made perpetual by stat. 7 Ann. c. 25. § 3; which enacts that promissory notes, payable to order or bearer, may be assigned and indorsed, and action maintained on them, as on inland bills of exchange. By stat. 15 Geo. III. c. 51, and 17 Geo. III. c. 30. made perpetual by stat. 27 Geo. III. c. 16. all negotiable notes and bills for less than 20s. are declared to be null and void; and notes or bills between that sum and 5l. must be made payable within 21 days after date, must particularize the name and description of the payees, must bear date at the time and place in which they are made, must be attested by a subscribing witnhes, and the indorsement of them must be attended with the same strictness in all respects, and made before the notes or bills become due. The omission of any one of these regulations and formalities vacates the security, and is penal to him that utters it. Bills of exchange and promissory notes must now be drawn on stamped paper; and the stamp is proportioned under stat. 31 Geo. III. c. 25. 37 G. III. and 41 G. III. c. 10. to the amount of the bill from sixpence to three shillings for such as are payable on demand; and for those payable after date from one shilling to four shillings. If foreign bills are drawn here, the whole fum must be stamped; but bills drawn abroad are not liable to any stamp duty. As bills of exchange were first introduced for the convenience of commerce, it was formerly thought that they could neither be drawn nor negociated by any person who was not actually a merchant; but it has been since decided, that any person capable of binding himself by a contract, may draw or accept, or negotiate a bill of exchange, and by stat. 3 & 4 Ann. c. 9. be a party to a promissory note. However, an infant cannot be sued on a bill of exchange, nor a feme-covert, except in such cases as he is allowed to act in as a feme-fsole. If a bill is drawn on two joint traders, the acceptance of one binds the other, if it concern the joint trade; but it is otherwise, if the bill concern the acceptor only, in a distinct interest and respect. On the subject of procuration with regard to bills; see Procuration.

A promissory note, when indorsed, begins to be transferable. A bill of exchange, for the indorser of the note corresponds to the drawer of the bill; the maker to the drawer or acceptor, and the indorser to the payee; and this resemblance being fixed, the law is precisely the same in bills of exchange and promissory notes. It is now a decided point of law, that bills and notes made payable to bearer are equally transferable with those payable to order; and the transfer in both cases equally confers the right of action on the bona fide holder. But the mode of transfer is different; as bills and notes payable to bearer are transferred by mere delivery, the others by indorsement. There are other bills and notes which differ from those already described, and which are securities for money, because they are considered as money itself. These are "Bank-notes," "Banker's calh-notes," and "drafts on Bankers," payable on demand. Bank-notes are regularized on ordinary transactions by common consent as cash, and they have the credit and currency of money to every effectual purpose, and feem to be as lawful a tender. (Stat. 5 W. & M. c. 20. § 28. 3 Term Rep. 554.) Banker's calh-notes, and drafts on bankers, are considered among merchants as money, and received in payment as ready cash; and if the party receiving them do not, within a reasonable time, demand the money, he must bear the loss in case of the bank's failure. The precise time is not absolutely determined; but it is held most advisable to carry such drafts on bankers, as are payable on demand, for payment on the day in which they are received, if the situation of the parties admit of it.

Bills of exchange and promissory notes, which, according to the general principles of law, are to be considered only as evidences of a simple contract, are however in one respect regarded as specialties, and on the same footing with bonds; for they are prefumed, unless the contrary be shown by the defendant, to have been made on a good consideration; nor is it incumbent on the plaintiff either to shew a consideration in his declaration, or to prove it at the trial.

Bills of exchange, and also notes, are assignable or negotiable without any fiction; and every person to whom they are transferred may maintain an action in his own name against any one, who has before him in the course of their negociation rendered himself responsible for the payment of them. But the instrument, or writing, which constitutes a good bill or note, must have certain essential qualities. One of these is, that the bill or note should be for the payment of money only, and not for the payment of money and the doing of some other act. Another requisite quality is, that the instrument must carry with it a personal and certain credit, given to the drawer or maker, not confined to any particular fund. But in the application of this principle, there is a material distinction between bills and notes. With regard to the former, where the fund is supposed to be in the hands of the drawee, the objection holds in its full force, not only because the productiveness of the fund is contingent and precarious, but because the credit is not given to the person of the drawer; but where the fund, on account of which the money is payable, either is in the hands of the drawer, or he is accountable for it, the objection will not hold, because the credit is personal to him, and the fund is only the consideration of his giving the bill. With respect to a note, if the drawer promises to pay out of a particular fund, then with his power, the note will be good under the statute; the payment does not depend on the circumstance of the fund's proving unproductive, or not, but there is an obligation upon his personal credit; the bare making of the note being an acknowledgment that he has money in his hands. Another essential quality of a good bill or note is, that it must be absolutely payable at all events, and not depend on any particular circumstances which may or may not happen in the common course of things. No præter form of words is necessary to make a bill of exchange or a note under the statute; any order, which cannot be complied with, or promis, which cannot be performed, without the payment of money, will make a good bill or note. As the words "value received," have been usually inferred in bills or notes, some doubt has occurred, whether they are essential. It is now understood, as a decided point, that these words are not necessary; for it has been held, that the word "value" is sufficient, and that it may be given to the person to whom the money is due, either at the time of delivery, or even after the receipt of the note.

Bills of exchange, and promissory notes, are considered as the security of the parties, and the injury sustained by their non-payment, is no less than the loss which would have been sustained by a direct demand. But the inaccuracy of law in this particular is now considerably remedied. It is now provided, that, if a bill or note be not paid, the party receiving it may retain it until the time appointed for payment; and if the person to whom it is drawn refuse to pay the principal sum, the party may take legal proceedings against him, and sue for damages, and for the interest which the loss has occasioned. These alterations in the law are not without effect; for they have militated against the use of bills of exchange, and have tended to increase the use of promissory notes. There are, however, still many cases in which bills of exchange are preferable to promissory notes, and in which the latter may be considered as a substitute only. In the first place, bills of exchange are more certain, and more proper for the purpose of contract; and it is difficult to doubt, that bills of exchange are generally more convenient for the purpose of negociation. In the second place, bills of exchange are more convenient for the purpose of negociation; and it is difficult to doubt, that bills of exchange are generally more convenient for the purpose of contract.
livery; if payable to A. B. or bearer, they are payable to bearer, as if A. B. were not mentioned. But to the transfer of those payable to order, it is necessary, in addition to delivery, there should be something, by which the payee may appear to express his order. This additional circumstance is called an "indorsement." See Indorsement.

By the very act of drawing a bill, the drawer comes under an implied engagement to the payee, and to every subsequent holder, fairly entitled to the performance that the person on whom he draws is capable of binding himself by his acceptance; that is, to be found at the place where he is described to be, if that description be mentioned in the bill; that if the bill be duly presented to him, he will accept in writing on the bill itself, according to its tenor; and that he will pay it when it becomes due, if presented in proper time for that purpose. In default of any of these particulars, the drawer is liable to an action at the suit of any of the parties before-mentioned, on due diligence being exercised on their parts, not only for the payment of the original sum mentioned in the bill, but also for the damages, interest, and costs; and he is equally answerable, whether the bill was drawn on his own account, or on that of a third person; for the holder of the bill is not to be affected by the circumstances that may exist between the drawer and another; the personal credit of the drawer being pledged for the due honour of the bill. If a man write his name on a blank piece of paper, and deliver it to another, with authority to draw on it a bill of exchange, and leave it to another to make his acceptance, and then to deliver it to a third party, he renders himself liable to be sued as the drawer of any bill so formed by the person to whom he has given the authority. If acceptance be refused, and the bill returned, this is notice to the drawer of the refusal of the drawee; and then the period, when the debt of the former is to be considered as contracted, is the moment when he draws the bill; and an action may be immediately commenced against him, though the regular time of payment, according to the tenor of the bill, be not arrived for the drawee, not having given credit, which was the ground of the contract, what the drawer had undertaken has not been performed. When a bill of exchange is indorsed by the person to whom it was made payable, as between the indorser and indorsee, it is a new bill of exchange; as it is also between every subsequent indorser and indorsee; the indorser, therefore, with respect to all the parties subsequent to him, stands in the place of the drawer, being a collateral security for the acceptance and payment of the bill by the drawee; his indorsement imposes on him the same engagement that the drawing of the bill does on the drawer; and the period when that engagement attaches, is the time of the indorsement. Nor will any thing discharge the indorser from his engagement, but the absolute payment of the money; not even a judgment recovered against the drawer or any previous indorser; neither is his engagement discharged by an ineffectual execution against the drawer, or any prior or subsequent indorser. The engagement of the drawer and indorsers depends on certain conditions to be performed by the holder of the bill, and without the performance of which he has no remedy against them.

When the payment of the bill is limited to a certain time after sight, the holder must present it for acceptance, otherwise the time of payment will never come. Although it has never been directly determined, whether the holder of a bill, payable at a certain time after date, be bound to present it for acceptance immediately on receiving it, or whether he may wait till it become due, and then present it for payment; yet in practice it often happens that a bill is negotiated and transferred through many hands, without acceptance, and not presented to the drawee till the time of payment; and no objection is ever made on that account. If, however, on the holder presenting the bill for acceptance, this be refused, he is bound to give regular notice to all the preceding parties to whom he intends to resort for non-payment; and if on account of the holder's delay, any loss be incurred by the failure of any of these parties, he must bear this loss. It is also the duty of the holder of a bill, whether accepted or not, to present it for payment within a limited time; otherwise the law will imply that payment has been made, and it would be prejudicial to commerce, if a bill might be produced to charge the drawee at any distance of time, when all accounts might be adjusted between him and the drawee. A presentment either for payment or acceptance must be made at reasonable hours, which are the common hours of business in the place where the party, to whom the bill is presented, resides. If acceptance or payment be refused, or the drawee of the bill, or the maker of the note, has become insolvent, or has absconded, notice from the holder himself must be given to the preceding parties, and in this notice it must be added, that the holder does not intend to give him credit. What may be considered as a reasonable time, within which notice must be given, either of non-acceptance or non-payment, has been subject to much doubt and uncertainty. It was once held, that a fortnight was a reasonable time; but that period is now much contracted. With respect to acceptance, it is usual to leave a bill for that purpose with the drawee till the next day; but if he, when called upon the next day, delay or refuse to accept according to the tenor of the bill, it is now an established rule, where the parties, to whom notice is to be given, reside at a different place from the holder and drawee, that notice should be sent by the next post; and the same rule obtains in cases of non-payment. Also in cases of the drawer of the bill, or maker of the note, having absconded, or not being found, notice of these circumstances, in case either of non-acceptance or non-payment, must be sent by the first post. Considerable difficulty has occurred in establishing a general rule in this respect, where the party entitled to notice resides in or near the place in which the holder lives. The court, however, has on several occasions laid it down as a principle, that what shall be considered as a reasonable time in case of notice, and also of demand of payment, is a question of law; and this seems to have been fully established, and it is understood generally, that a demand must be made, and notice given, as soon as under all the circumstances it is possible to do so. As to the manner in which notice is given, either of non-acceptance or non-payment, there is a remarkable difference between inland and foreign bills. In the former no particular form of words is necessary to entitle the holder to recover against the drawer or indorsers, the amount of the bill, on failure of the drawee or acceptor; it is sufficient if it appear that the holder means to give no credit to the latter, but to hold the former to their responsibility. But in foreign bills, other formalities are required. If the person to whom the bill is addressed, on presentment, will not accept it, the holder is to carry it to a person vested with a public character, who is to go to the drawee and demand acceptance; and if he then refuse, the officer is there to make a minute on the bill itself, confining of his initials, the month, the day, and the year, with his charges for minuting. He must afterwards draw up a folena declaration, that the bill has been presented for acceptance, which was refused, and that the holder intends to recover all damages which he, or the deliverer of the money to the drawer, or any other, may sustain on account of the non-accept
acceptance. This minute, in common language, is termed the “noting” of the bill; the solemn declaration, the “pro-
tell,” and the person whose office it is to do these acts called a “public notary”, and to his protestation all foreign courts give credit. If no such notary be resident in the place where the bill is negotiated, protest may be made by any Jewish inhabitant in the presence of two credible witnesses. For the circumstances attending this protest, and the difference in this respect between inland and foreign bills, see PROT\.

When a bill is once accepted absolutely, it cannot in any case be revoked, and the acceptor is at all events bound, though he hear of the drawer’s having failed the next mo-
ment, even if the failure was before the acceptance. The acceptor may however be discharged by an express declara-
tion of the holder, or by something equivalent to such de-
claration. But no circumstances of indulgence shown to the acceptor by the holder, nor an attempt on his part to re-
cover of the drawer, will amount to an express declaration of
discharge. Neither will any length of time short of the sta-
tute of limitations, nor the receipt of part of the money from the drawer or indorser, nor a promise by indorsement on the bill by the drawer to pay the residue, discharge the holder’s remedy against the acceptor. Although the receipt of part from the drawer or indorser be no discharge to the acceptor, yet the receipt of part from the acceptor of a bill, or the maker of a note, is a discharge to the drawer and in-
dorsers of the one, and to the indorsers in the other. Un-
less due notice be given of the non-payment of the residue; but where due notice is given, that the bill is not duly paid, the receipt of part of the money from an acceptor, or mak-
er, will not discharge the drawer or indorsers; because it is for their advantage, that as much should be received from others as may be. So the receipt of part from an indorser is no discharge of the drawer or preceding indorser. If the drawer of a note, or the acceptor of a bill, be fused by the indorser, and the bail pay the debt and costs, this absolutely discharges the indorser as much as if the principal had paid the note or bill; and the bill cannot afterwards recover against the indorser in the name of the indorser. On the principles of several cases it has been finally settled, that to entitle the indorser to recover against the indorser of an in-
land bill of exchange, it is not necessary to demand the mo-
ney of the first drawer.

By the 3 & 4 Ann. c. 9, § 7, it is enacted, that if any peron accept a bill of exchange for and in satisfaction of any former debt or sum of money formerly due to him, this shall be accounted and esteemed a full and complete pay-
ment of such debt; if such person, accepting any such bill for his debt, do not take his due course to obtain payment of it, by endeavouring to get the same accepted and paid, and make his protest according to the directions of the act, either for non-acceptance or non-payment.

Where a privity exits between the parties in a bill of ex-
change, an action of debt, or of “indebitatus assumpsit,” may be maintained; but where it does not exist, neither of these actions will lie. A privity exists between the payee and the drawer of a bill of exchange; the payee and drawer of a promissory note; the indorser and his immediate in-
dorser of either the one or the other; and perhaps between the drawer and acceptor of a bill; provided that, in all these cases, a consideration passed respectively between the parties. But no privity is supposed to exist between the in-
dorser and acceptor of a bill, or the maker of a note, or be-
tween an indorser and a remote indorser of either.

The action which is now brought on a bill of exchange, is a special action on the face, founded on the custom of merchants. This custom was not at first recognized by the court, unless it was specially set forth; but when this custom was recog-
nized by the judge as part of the law of the land, and they declared they would take notice of it “ex officio,” it became unnecessary to recite the custom at full length; a simple de-
claration that “the drawer, mentioning him by his name, according to the custom of merchants, drew his bill of exchange, which is sufficient.” If the plaintiff, adhering to former precedents, thought proper to recite the custom in general terms, and did not bring his case within the custom so set forth; yet if, by the law of merchants, as recognized by the court, the case was stated, entitled him to his action, he might recover; and the setting forth of the custom was reckoned surfluplage, and rejected. Whether the drawer of a bill, or the indorser of a bill or of a note, receiving the bill or note in the regular course of negotiation before it has become due, can maintain an action on it against the acceptor or maker, in the character of indorser, seems undecided; but there is a case which clearly shews that a drawer or indorser cannot maintain an action in the character of indorser, “where the indorsement is after the refusal of payment;” because when a bill is returned unpaid, either on the drawer or in-
dorser, its negotiability is at an end. The action, there-
fore, in which the drawer or indorser, after payment of the money in default of the acceptor, may recover, the first against the acceptor, and the latter against any of the pre-
ceding parties, must be brought in their original capacity as drawer or indorser, and not as indorser. If the drawer, without having effects of the drawer, accept and duly pay the bill without having it protested, he may recover back the money in action for money paid, laid out, and expended to the use of the drawer.

Instead of bringing an action on the custom, or on the statute, the plaintiff may in many cases use a bill or note only as evidence in another action; and if the instrument want some of the requisites for making it a good bill or note, the only use he can make of it is to give it in evidence.

The holder of the bill or note may sue all the parties who are liable to pay the money; either at the same time, or in succe\sion; and he may recover judgment against all, if sat-
isfaction be not made by the payment of the money before judgment obtained against all; and proceedings will not be staid in any one action, but on payment of the debt and costs in that action, and the costs in all the others in which he has not obtained judgment. But though he may have judgment against all, yet he can recover but one satisfac-
tion; and though he be paid by one, he may sue out execu-
tion for the costs in the several actions against the others. To this action the defendant may plead the statute of limita-
tions; and by the express provision of the statute of queen Anne, all actions on promissory notes must be brought within the same time as is limited by the statute of James, with respect to actions on the bill. And to this plea it is no good replication, that it was an account between merchants, where it appears to be for value received.

As the action on a bill of exchange is founded on the cus-
tom of merchants, so that on a promissory note is founded on the statute 3 & 4 Ann. c. 9. In both cases, however, it is necessary, that all those circumstances should be expressly staded, or clearly and inevitably implied, which, according to the character of the parties to the action, must necessarily concur, in order to entitle the plaintiff to recover. In flating the bill or note, regard must be had to the legal operation of each respectively. It has been decided, that the legal operation of a bill or of a note, payable to a fictitious payee, is, that it is payable to the bearer; and therefore it is pro-
per in the statement of such a bill, to allege that the drawer thereby requited the drawer to pay so much money to the
bearer; and in the statement of such a note, that the maker
thirty promised to pay such a sum to the bearer.

As to the proof that is necessary in actions on bills or notes, we
may observe, that the plaintiff must, in all cases, prove so
much of what is necessary to entitle him to his action, and of
what must be stated in his declaration, as is not, from
the nature of the thing, and the situation of the parties, neces-
sarily admitted. In an action against the acceptor, it is a gen-
eral rule that the drawer’s hand-writing is admitted; that
of the acceptor must of course be proved; and that of every
peron, through whom the plaintint, from the nature of the tran-
section, must necessarily derive his title. On a bill pay-
able to bearer, in an action against the acceptor, he has only
to prove the hand-writing of the acceptor himself; but in
case of a bill payable to the payee, or to the payee or endorse-
ner, the acceptor must prove the hand-writing of the very payee who must be the first indorser.

In case of a transfer by delivery, the plaintiff may be called
upon to prove that he gave a good consideration for the bill
or note, without the knowledge of its having been stolen, or
of any of the names of the blank indorsers having been
forged. In an action by the indorsee against the drawer, the
same rules obtain with respect to proof of the hand-writ-
ing of the indorsers, as in an action against the acceptors.
That of the drawer himself must of course be proved; and it
must also be proved that the plaintint has used due dili-
gence. From the rule, that in an action against the drawer
or acceptor of a bill payable to order, there must be proof of
the signature of the payee, first indorser, and all those to
whom an indorsement has been specially made, arose the
question, which long and greatly agitated the commercial
world, on the subject of indorsements in the name of "fi-
titious payees." A bill, payable to the order of a fictitious
person, and indorsed in a fictitious name, is not a novelty
among merchants and traders. But in the years 1786, 7,
and 8, two or three houses, by their mutual guilt, have
entered into engagements far beyond their capital, under an
apprehension that the credit of their own names would not
be sufficient to procure currency to their bills, adopted, to
a very extensive degree, a practice which had before been
found convenient on a smaller scale. For a considerable time,
whilst money could be procured for the payment of thes
bills by the acceptors or drawers, and they had sufficient cre-
dit with the holder to have them renewed, the subject of
these fictitious indorsements was not questioned. But when
credit failed, and a commination of bankruptcy became necce-
sary, the other creditors felt it their interest to refile the
claims of the holders of these bills, and inflicted that they
should not be allowed to prove their debts, because they
could not conform to the general rule of law, requiring proof
of the hand-writing of the first indorser. The chancellor,
when the question came before him by petition, directed trials
at law. From the decisions in consequence of these trials,
the principal of which was affirmed in the House of Lords,
and which had fetted that such bills are to be considered as
payable to bearer, it follows, that the name of the acceptor’s
hand only is sufficient to entitle the holder to recover on the
bill; and in a particular case, where the bill was drawn by
the defendant and others on the defendant, it was determined
that a bona fide holder for a valuable consideration might re-
cover the amount against the acceptor in an action for money
paid, or money bad and received. The effect of the determi-
nation of the judges in the House of Lords, with respect to
the principal case above alluded to, is as follows. If a bill of
exchange be drawn in favour of a fictitious payee, with the
knowledge as well of the acceptor as the drawer; and the
name of such payee be indorsed on it by the drawer, with
the knowledge of the acceptor, which fictitious indorsement
purports to be to the drawer himself or his order; and then
the drawer indorses the bill to an innocent indorser for a va-
iable consideration, and afterwards the bill is accepted;
but it does not appear that there was an intent to defraud
any particular person; such innocent indorse for a valuable
consideration may recover against the acceptor, as on a bill
payable to bearer. Perhaps also, in such case, the innocent
endorse might recover against the acceptor, as on a bill pay-
able to the order of the drawee, or on a count stating the
special circumstances. On other cases, afterwards brought
before the House of Lords on demurrers to evidence, the
guages gave their opinion, that it was not competent to the
defendants to demar; and that on the record, as flated, no
judgment could be given. The whole disproved a system of
bill-endorsement to the amount of a million a year, on ficti-
tious credit, which ended in the bankruptcy of many; but
which had at least the good effect of showing that the obli-
gations of law are not to easily eluded as those of honour and
confidence.

In an action by an indorsee against an indorser, it is not
necessary to prove either the hand of the drawer or of the
acceptor, or of any indorser before him against whom the
action is brought, every indorsee being, with respect to sub-
sequent indorsees or holders, a new drawer. Where an action
is by one indorser, who has paid the money, proof must be
given of the payment. In an action by the drawer against
the acceptor, where the bill has been paid away and returned,
it is necessary to prove the hand-writing of the latter, de-
mand of payment by him, and refusal, the return of the bill,
and payment by the plaintint. In an action on the cafe by
the acceptor against the drawer, the plaintiff must prove the
hand-writing of the defendant, and payment of the money
by himself; or something equivalent, as his being in prison
on execution. Where a bill is accepted, or a bill or note is
drawn or indorsed, by one of two or more partners, on the
partnership’s account, proof of the signature of the party
accepting, drawing, or indorsing, is sufficient to bind all the
rest. When a servant has a general authority to draw, accept,
or indorse bills or notes, proof of his signature is sufficient
against the master; but his authority must be proved, as
that it was a general custom for him to do so, &c. An ac-
tion on a bill of exchange being by an executor, and upon a
debt laid to be due to tellator, it was held necessary to prove
that the acceptance was in the lifetime of the tellator.
Where the defendant suffers judgment by default, and the
plaintiff executes a writ of inquiry, it is sufficient for the
latter to produce the note or bill, without any proof of the de-
fendant’s hand; and on such judgment, a writ of inquiry
feems now to be unnecessary.

As to the different subjects of dispute, with regard to
bills of exchange and notes, the most usual are those which
arise either from the total want of consideration, or from the
illegality of the consideration for which the bill or note was
given. See Consideration.

If a bank-bill, payable to A. B. or bearer, be lost, and
it is found by a stranger, payment to him would indemnify
the bank; yet A. B. may have trover against the finder,
though not against his allegiance for valuable consideration,
which creates a property. If the poiffessor of a bill acci-
dentally loses it, he must caste intimation to be made by a
notary public before witnesses, that the bill is lost on the public,
and requiring that payment be not made of the fame to any
person without his privity. And by flatt. 9 & 10 W. III. c. 17,
if any inland bill of exchange for 5l. or upwards shall be
lost, the drawer of the bill shall give another of the same
tenor, security being given to indemnify him, in case the
bill so lost be found again. If a bill lost by the poiffessor

Note, and Bill of Exchange.

Bill, to protest a. See PROTEST, and Bill of Exchange.

Bills, bank, are notes or obligations signed on behalf of the company of the bank, by one of their cashiers, for value received. See Note, and Bill of Exchange.

Bill of credits. See Credit.

Bill of entry, an account of goods entered at the custom-house, both inward and outward; in which are expressed, the name of the merchant importing or exporting, the quantity, number, and mark of the goods, and place from or to which they are imported, or to be exported.

Bill of Lad ing, an instrument signed by the master of a ship, acknowledging the receipt of a merchant's goods, and obliging himself to deliver them at the place to which they are consigned, in good condition. Of such bills there are usually three: the first, kept by the merchant; the second, sent to the factor to whom the goods are consigned; and the third, kept by the master of the ship. See CHARTER-PARTY.

Bills of mortality, are weekly lists compiled by the parish-clerks in and about London, containing the numbers of such as die of each disease, as well as of those that are born every week. See MORTALITY.

Bills of parcels, an account of the particular sorts and prices of goods bought, given by the seller to the buyer. See Rights.

Bill of sale, is an instrument or writing which a person, wanting a sum of money, and delivering goods as a security to the lender, gives to him, empowering him to sell the said goods, in case the sum borrowed is not repaid, with interest, at the time appointed. See Sale.

Bill of store, a licence granted at the custom-house to merchants, to carry such stores and provisions as are necessary for their voyage, custom-free. See Rights.

Bill of sufferance, a licence granted at the custom-house to a merchant, to suffer him to trade from one English port to another, without paying custom. See Rights.

Bill, or BEAK, asyrn, in Ornithology, the elongated horny processes or mandibles of birds. The form of the bill varies greatly in different kinds of birds, that they afford the most permanent character by which these creatures may be arranged. In the distribution of families, Linnaeus first notices the structure of the bill, the tongue, and nostrils; and these parts constitute almost exclusively (with the legs) the distinction of the genera likewise. See Ornithology, and Anatomy of Birds.

The PHOENICOPTER'S bill is a true hyperbola, pointed at the end like a sword; and what is remarkable, the upper bill of this bird moves in eating, the lower being fixed, which is the contrary of what is found in all other kinds. The wood-pecker's bill is strong, and sharp enough to dig holes, and build in the heart of the hardest timber. See PHOENICOPTERUS and PICUS. Phil. Trans. N° 251, p. 155. N° 350, p. 509.

In the island of Ferro, a fixed reward is given for the bills of ravenous birds. All watermen are obliged to bring a certain number yearly to the country courts, at the feast of St. Olaf; when they are thrown into a heap, and burnt in triumph. Plott gives divers inflances of monstrous irregularities
gularities in the bills of birds; particularly of a raven, whose mandibles crooked each other, the lower chip turning upwards, and the upper downwards. Plott's Nat. Hist. Stafford, ch. vii. § 4.

BILLA vera, the bill is true. The grand jury indorsing a bill whereby any crime punishable in that court, is presented to them, with the word, billa vera, signify thereby, that the prosecutor has furnished his preface with probable evidence, and worthy of farther consideration; whereupon the party presented is said to stand indicted of the crime, and bound to make answer thereto, either by confessing or traversing the indictment. See Bill in Law, supra.

BILLANCOURT, in Geography, a town of France, 4 miles S.W. from Paris.

BILLARD, or Bill, in Ichthyology, an English name, in some places, for the young coal-fish, gaius carbonarius, when a year old; meaning at that time from 8 to 10 or 15 inches in length.

BILLAU, in Geography, a river of Silezia, which runs into the Nevis, near the town of Nyae.

BILLY, a town of France, in the department of the Ille and Vilaine, and the chief place of a canton, in the district of Fougères, 14 league south of Fougères.

BILLEKA, a town of Poland, in the patinate of Lemberg, 10 miles east of Lemberg.

BILLERDECK, a town of Germany, in the patinate of Westphalia, and bishopric of Münster, 5 miles N.N.E. from Coesfeld.

BILLERICA, a township in Middlesex county, Massachusetts, in America, incorporated in 1635; containing 1200 inhabitants, lying 20 miles north of Boston, and watered by Concord and Shawsheen rivers, which run north-callyter into Merrimack river.

BILLERICAY, in Geography, a market-town of Essex, England; built on a fine eminence, commanding a view of a rich vale between the town and the river Thames. Though enjoying the advantage of a weekly market on Tuesdays, it is only a hamlet in the parish of Great Baddow, the church of which is situate about one mile and a half south of this place. For the accommodation of the inhabitants, a church is erected and supported in the town. Here are two annual fairs; and the whole parish contains 250 houses, and 1472 inhabitants. Billericay is 23 miles N.E. from London. Morant's history of Essex.

BILLESDON. See Bilston.

BILL. See Hatborough.

Billett, or Billette, in Heraldry, signifies a figure whose length exceeds its breadth; when the arms are charged with several of them, they are then called Billettes. The royal arms of Nassau, prince of Orange, is Jupiter Billette sol, a lion rampant of the left. Authors differ much in regard to the antiquity of the billet, which was evidently a piece of wood cut in the form of a parallelogram, and retains that name and shape to this day.

Billett, Billette, in the French Customs, a little sign in form of a cask, hung up at places where toll is to be paid, to advertice passengers and carriages, that before they advance farther, the dues are to be paid to the king, or the lord who is charged with the care of repairing the highways.

Billets for fuel, are small pieces of wood, which must be 3 feet 5 inches long, and 7½ in compass, &c. Judges of peace shall enquire, by the oaths of six men, of the affize of billets; and those which are under faze are forfeited to the poor. Stat. 43. Eliz. c. 14. 9. Ann. c. 15. 16. Ann. c. 6. See Fuel.

BILLES of gold, denote wedges or ingots of gold, mentioned in the flat. 27. Ed. 3. c. 27.

BILLETING of soldiers, in Military language, is the lodging or quartering of them in the houses of the inhabitants of a place. This is done by a ticket, called a billet, which entitles each folder, by act of parliament, to candles, vinegar, salt, and either small beer or cider, not exceeding five pints per day, gratis; with the use of fire, and the necessary utensils for dressing and eating their meat.

BILLETING, among Sportsmen, denotes the ordure and dung of a fox.

BILLETTINS. See Brothers of Charity.

BILLI, JAMES de, in Biography, a French Jesuit, was born in Compiégne in 1602, and entered the Society of Jefuits in 1619. He taught philosophy for three years, and was a preacher for more than twenty years. He was rector of Chalons, Langres, and Sens; but he is best known by his mathematical writings, which are as follow: "Nova Geometriae Clavis Algebrae," Paris, 1653, 4to.; "Tabulae Lodoice de doctrina eclipsium," Dijon, 1618, 4to.; "Tumulus Aetheris Judiciaria," Paris, 1659, 4to.; "Diophantus Geometria," Paris, 1660, 4to.; "Opus Alcmonticum, &c."

BILLIARDS, an ingenious kind of game played with two small ivory balls, on an oblong table, covered with green cloth, and placed exactly level; which balls are driven, by sticks made on purpose, alternately against each other, with a view to push the passive ball into hazards, or holes, on the edges and corners, according to certain laws or conditions of the game.

The word comes from the French billard, of bille, the ball made ufe of; and that from the Latin pile, a ball.

This game was invented by the French, and practised by the Germans, Dutch, and Italians; and is now a favourite diversion among persons of the first rank in many parts of England. The table on which it is played is about 12 feet long, and 6 wide; and not only covered with green cloth, but surrounded with cushions to prevent the balls from rolling off, and to make them rebound. It has fix holes, nets, or pockets, which are fixed on the four corners, and in the middle, opposite to each other, for receiving the balls, which, when put into these holes, are called hazards. The making of a hazard, or putting the adversary's ball into the hole at the usual game, is reckoned for two in favour of the player.

The game is played with sticks, called maces, or with cues. The mace is a long straight stick, with a head at the end, and is the most powerful instrument of the two: the cue is a thick stick decreasing gradually to a point of about half an inch in diameter; this instrument is played over the left hand, and supported by the forefinger and thumb. This is the only instrument in vogue abroad, and is used with addressing address by the Italians, and some of the Dutch; but in England the mace is the prevailing instrument, though regarded with some degree of contempt by foreigners, as the use of it does not require so much address as the cue; however, the mace is used for the peculiar advantage of "trailing," as it is called; or of following the ball with it such a convenient distance from the other ball as to make it an easy hazard. The several degrees of trailing are variously denominated by the connoisseurs; e.g. the shove, the sweep, the long stroke, the trail, and the dead trail.
trail or turn up, all which secure certain advantages to a good player; and even the butt-end of the cue becomes very powerful, when it is made use of by a good trailer. The varieties of this game are denominated the "white winning game," the "white losing game," the "red or carambole winning game," and the "red losing game." The game usually played is the first of these, and is the number. The rules for this game are as follow: 1. String for the lead and choice of balls; the person who does this must stand within the limits of the corner of the table, and not place his ball beyond the fringing nails or spots; the lead is won by him who brings his ball nearest the cushion. 2. If after the first person has thrum for the lead, the adversary should make his ball touch the other, he loses the lead; and if the player holds his own ball in thringing or leading, he loses the lead. 3. If the leader follows his ball with either mace or cue beyond the middle hole, it is no lead; and is it the option of his adversary to make him lead again. 4. The striker who plays at the lead must stand with both his feet within the limits of the corner of the table, and not place his ball beyond the fringing nails; and his adversary (only) is bound to see that he stands and plays fair; otherwise the striker wins all the points he made by the stroke. 5. When a hazard has been lost in either of the corner holes, the leader is obliged, if his adversary require it, to lead from the end of the table, where the hazard was lost; but if the hazard was lost in either of the middle holes, it is at the leader's option to lead from either end of the table. 6. If the striker does not hit his adversary's ball, he loses one point; and if by the said stroke his ball should go into a hole, over the table, or on a cushion, he loses three points; and he also loses the lead. 7. If the striker holds his adversary's ball, or forces it over the table, or on a cushion; or if he holds both balls, or forces them over the table, or on a cushion; in either case he loses two points. 8. No person has a right to take up his ball without permission from his adversary. 9. If the striker should touch or move his own ball, without intending to make a stroke, it is deemed an accident; and his adversary, if he require it, may put the ball back in the place in which it stood. 10. If the striker force his adversary's ball over the table, and his adversary should chance to drop it, so as to make it come on the table again, the striker wins two points; if the striker should force his own ball over the table, and his adversary should chance to drop it so as to make it come on the table again, the striker loses nothing by the stroke, and has the lead; but if the striker misfires the ball and forces it over the table, and it should be stopped by his adversary, he loses one point, and has the lead, if he chuses. 11. If the striker, in playing from a cushion or otherwise, by touching the ball, makes his mace or cue go over or beyond it, he loses one point; and, if his adversary require it, he may put the ball back, and make him pass the ball. 12. If the striker, in attempting to make a stroke, doth not touch his ball, it is no stroke; and he must make another trial; but if when the balls are near each other, the striker should accidentally make his ball touch the other, it is a stroke, though not intended. 13. If the striker who plays the stroke, should make his adversary's ball go near the brink of a hole, as to be judged it stand still, and afterwards fall into it, the striker wins nothing; and the ball must be put upon the same brink where it stood, for his adversary to play from the next stroke. 14. If the striker's ball should stand on the brink or edge of a hole, and if in playing it off he should make the ball go in, he loses three points. 15. If a ball should stand on the edge of a hole, and should fall into the hole, before or when the striker has delivered his ball from the mace or cue, so as to have no chance for his stroke, in that case the striker and his adversary's ball must be placed in the same position, as nearly as possible, and the striker must play again. 16. The striker is obliged to pass his adversary's ball, more especially if he misfires the ball on purpose; and it is at the option of his adversary to oblige him to place the ball where it stood, and play until he has passed. 17. If the striker plays both balls from his mace or cue, so that they touch at the same time, it is deemed a foul stroke; or if the adversary discover it, and a dispute should arise, an appeal may be made to the company present; and the marker, if required, must go round the table to each person separately, and ask if he has any bet depending, and if he understands the game and the disputed subject; and if the company and marker determine it to be a foul stroke, it is at the adversary's option (if not holed) either to play at the ball, or to take the lead; but if the adversary doth not discover it to be a foul stroke, the striker may reckon on all the points he made by the said stroke, and the marker is obliged to mark them; and no person has a right to discover to the player whether a stroke be fair or foul, unless he is asked. 18. If by a foul stroke the striker should lose his adversary's ball, he loses the lead; but if by such a stroke he loses his own or both balls, or forces his own or both over the table, or on a cushion, he loses two points. 19. If the striker plays on a ball when it is running or moving, it is deemed a foul stroke; and if he plays with both feet off the ground, without leave of his adversary, it is a foul stroke: if he plays with a wrong ball, he losles the lead, if his adversary require it. 20. If the ball should be changed in a hazard, or on a game, and it is not known by which party, the hazard must be played by each party with their different balls and then changed. 21. If the striker plays with his adversary's ball, and hole, or forces the ball at which he played over the table, &c. it is deemed a foul stroke. 22. If the striker plays with his adversary's ball, and holes, or forces the ball with which he played over the table, &c. he loses two points; and if he misses the ball, three points. 23. If the striker plays with his adversary's ball and misses it, he loses one point; and if his adversary discovers that he hath played with the wrong ball, he may part the balls, and take the lead if he pleases. 24. In all these cases of the striker's playing with the wrong ball (if discovered), his adversary must play with the ball at which the striker played throughout the hazard, or part the balls and take the lead. 25. Whoever stops a ball when running with hand, flick, or otherwise, loses the lead, if his adversary does not like the ball he has to play at the next stroke. 26. Whoever retains his adversary's flick when playing, it is deemed foul. 27. If the striker stops, or puts his ball out of his course, when running towards either of the holes, and, if adjudged by the marker and company to be going into a pocket, if he misfires the ball he loses one point, and if going into a hole by the same stroke, three points. 28. If the striker stops or puts his adversary's ball out of the course, when running towards or into a hole, or puts it into a hole, it is deemed a foul stroke. If the adversary does the same, as in the foregoing cases, he is subject to the same penalties as the striker. 29. He who makes the table when the ball is running, or throws his flick across the table, so as to occasion any detriment to his adversary, or blows on the ball when running, makes in either case a foul stroke; and if his own ball was running towards or near the hole, when he blows on it, he loses two points. 30. He who leaves the game before it is finished, and will not play it out, loses the game. 31. Any person, whilst playing, may change his mace or cue; and neither party has a right to object to either mace or cue being played within the said game; but when the parties agree to play mace against cue, Vol. IV.
The mace-player hath no right to use a cue, and vice versa, without leave of the adversary, 32. When a person agrees to play with the cue, he must play every ball within his reach with its point, and if he agrees to play with the butt of the cue, he must not use the point, without permission; when the parties agree to play point and point of the cue, neither has a right to use a butt during the match, without permission; but they have a right to play with a long cue over a mace, &c. and when they agree to play all points with the same cue, they have no right to use any other during the game. 33. If it be proposed to part the balls, the proposer, if the adversary agree to it, loses the lead. 34. Two milkings do not make a hazard, unless the contrary is previously settled. 35. The better are to abide by the players on the determination of the hazard, or on the game; and they have a right to demand their money, when their game is over, to prevent disputes. 36. The friker has a right to command his adversary not to stand facing him, or near him, so as to annoy or molest him in the stroke. 37. Each person is to attend to his own game, without asking questions. 38. No person in the room has a right to lay more than the odds on a hazard or game; and in questionable cases appeal should be made to the marker, or to the table of odds; hung up in the room. 39. When four persons play, the game is fifteen in number; and each party has a right to consult with and direct his partner in any matter respecting the game, &c.

The "white loosing-game" is the common winning-game, and twelve is the number. This depends entirely upon the defence, and the knowledge of the degree of strength with which each stroke should be played, either to defend or make a hazard; for if a person who has a competent knowledge of the game should not have a hazard to play at, he must endeavour to lay his own ball in such a position, that his adversary may not have one to play at the next stroke. In this game, if the friker misses the ball, he loses one, and if by the same stroke his ball goes into a hole, he loses three points; if he strikes his adversary's ball he loses two points; if either or both balls be forced over the table, or on a cushion, nothing is reckoned and the friker loses the lead, but if he misses his adversary's ball, and forces his own over the table, &c. he loses one point and the lead; if either of the parties forces either or both balls over the table, he reckons nothing, and the friker loses the lead; if the friker loses his own ball, he wins two points; if he holes both balls, he wins four points; if he holes either ball, and forces the other over the table, &c. he only loses the lead. The winning and loosing game is a combination of both games; in which all balls that are put in by striking first the adversary's ball, reckon towards game; and holing both balls reckons four. At this game and the loosing, knocking over, or forcing the balls over the cushion, goes for nothing; the friker only losing the lead. The "choice of balls" is choosing each time which ball the player pleases, which is without doubt a great advantage, and is generally played against loosing and winning.

"Bricole" is being obliged to hit a cushion, and make the ball rebound or return to hit the adversary's ball, otherwise the player loses a point. This is a great disadvantage, and is reckoned between even players to be equal to receiving about eight or nine points.

"Carambole," is a game newly introduced from France. It is played with three balls, one being red, which is neutral, and is placed upon a spot on a line with the stringing nail, (i.e. that part of the table from whence the player strikes his ball at first setting off, and which is generally marked with two brass nails). Each antagonist at the first stroke of a hazard, plays from a mark which is upon a line with it at the other end of the table. The chief object at this game is, for the player to hit with his own ball the two other balls which is called a carambole, and by which the player wins two. If he puts in the red ball he gets three, and when he holes his adversary's ball he gets two; so that even may be made at one stroke, by caramboling and putting in both balls. This game refurnishes the loosing, depending chiefly upon particular strengths, and is generally played with the cue. The game is fifteen up; nevertheless it is reckoned to be sooner over than the common game. The next object of this game, after making what we have distilled termed the carambole, is the bricole; that is, making the white ball, and bringing the player's own ball and the red one below the stringing nail, from whence the adversaries begin. By this means the opponent is obliged to play bricole from the opposite cushion; and it often happens that the game is determined by this situation.

The Russian carambole, is a game that has still more lately been introduced from abroad, and is played in the following manner: The red ball is placed as usual on the spot made for that purpose; but the player, when he begins, or after having been holed, never places his ball on any particular place or spot; being at liberty to put it where he pleases. When he begins to play, instead of striking at the red ball, he leads his own gently behind it, and his antagonist is to play at which he thinks proper; if he plays at the red ball and holes it, he scores three as usual towards the game, which is twenty-four instead of sixteen points; and the red ball is put upon the spot again; at which he may strike again, or take his choice which of the two balls to push at, always following his stroke till both balls are off the table. He is entitled to two points each time that he caramboles, the same as at the other game; but if he caramboles and puts his own ball into any hole, he loses as many as he might have got had he not holed himself; for example, if he strikes at the red ball, which he holes, and at the same time caramboles and holes himself, he loses five points; and if he holes both balls when he caramboles, and likewise his own, he loses seven, which he would have got if he had not holed his own ball. In other respects it is played like the common carambole game.

The "Bar-hole," is so called from the hole being barred which the ball should be played for, and the player striking for another hole; when this game is played against the common game, the advantage for the latter, between equal players, is reckoned to be about six.

The player at the one-hole, though it seems to those who are not judges of the game to be a great disadvantage, has in fact the best of it; for as all balls that go into the one hole reckon, the player endeavours to lay his ball constantly before that hole, and his antagonist frequently finds it very difficult to keep one or other ball out, particularly on the leads, when the one player lays his ball (which he does as often as he can) on the brink of the hole; leading for that purpose from the opposite end, which in reality he has no right to do; for the lead should be given from the end of the table at which the hazard is made; but when a person happens to be a novice, this advantage is often taken.

The four game, confines two partners on each side, as the common winning game; who play by succession after each hazard, or two points lost. The game is fifteen up; so that the point or hazard is an odd number, which makes a muffs at this game of more consequence than it is at another; being as much at four, six, or eight, as it is at five, seven, or nine, at the single game.

Hazards," are so called because they depend entirely upon the making of hazards, there being no account kept of
of any game. Any number of persons may play by having balls that are numbered; but the number seldom exceeds six, to avoid confusion. The person whose ball is put in pays so much to the player according to what is agreed to be played for each hazard; and the person who misses, pays half the price of a hazard to him whose ball he played at. The only general rule is, not to lay any ball a hazard for the next player, which may be in a great measure avoided, by always playing upon the next player, and either bringing him close to the cushion, or putting him at a distance from the rest of the balls. The table, when hazards are played, is always paid for by the hour.

BILLIAT, in Geography, a town of France, in the department of the Ain, and chief place of a canton, in the district of Nantua, 23 leagues S. E. of Nantua.

BILICHA, in Ancient Geography, a river of Asia in Mesopotamia, which rises in the mountains of Orofene, south of Edessa, and pursuing a south-easterly course, discharges itself into the Euphrates, at the town of Nicephorum.

BILLIGHEIM, in Geography, a town of Germany, in the palatinate of the Rhine, 4 miles S. of Landau, and 16 S. W. of Spire.

BILLIGRATZ, a town of Germany, in the duchy of Carniola, 14 leagues N. of Laubach.

BILLINGEN, a town of the Netherlands, in the duchy of Luxembourg, 20 miles E. of Spa.

BILLINGSGATE, a fish-market of London, kept every day, and the toll of which is appointed by statute. All persons buying fish in this market may sell the fame in any other market by retail, but none but fishmongers are allowed to sell it in shops; and if any person shall buy any quantity of fish at Billingsgate for others, or any fishmonger shall engross in the market, they incur a penalty of 20l. Fish imported by foreigners shall be forfeited, and the vessel &c. 10 & 11 Will. III. c. 24. 1 Geo. I. Stat. 2. c. 18. § 1. &c.

BILLINGSPORT, a place on the river Delaware, in America, situate 12 miles below Philadelphia, which was fortified in the late war, for the defence of the channel, and opposite to which were funk frames of timber, headed with iron spikes, called chevaux-de-frize, in order to prevent the British ships from passing. After the war they were raised by a curious machine, invented at Philadelphia for this purpose.

BILLIS, in Ancient Geography, a small river of Asia Minor, on the frontiers of Phaphagonia, on the borders of which was seated the town of Tcium, mentioned by Strabo.

BILLITON, in Geography, one of the Sunda islands in the Indian ocean, N. E. of the lower part of Sumatra, and E. of Banca. (See Straits of Banca.) S. lat. between 2° 30' and 3° 30'. E. long. between 107° 45' and 108° 20'.

BILLOM, a town of France, and principal place of a canton, in the district of Clermont, and department of Puy-de-Dome, 4 leagues E. S. E. from Clermont. The town contains 5,110 inhabitants, and the canton 13,711. The territorial extent comprehends 115 kilometres, and 10 communes. N. lat. 45° 43'. E. long. 3° 14'.

BILLON, BILLIO, in Coinage, a kind of base metal, either of gold or silver, in whose mixture copper predominates.

The word is French, formed according to Menage, from the Latin balio, or balio, bullion. According to N. Bout-tercous, billion of gold is any gold beneath standard, or twenty-one carats; and billion of silver, all below ten pennyweights. But, according to others, and among the rest, M. Boizard, gold and silver beneath the standard, as far as twelve carats, and six pennyweights, are properly base gold and silver, and all under those billion of gold, and billion of silver, base copper is the prevailing metal. The writers on numismatic science appropriate the term billion to signify metals of copper alloyed with a very small quantity of silver.

BILLS, in Geography, a rock in the Atlantic, near the west coast of Ireland, 6 miles N. W. from the island of Clare, and 6 S. S. E. from Achill-head.

BILLY, JAMES DE, in Biography, was born in 1559, at Guise in Picardy, and devoting himself to study, he entered the church, in which he passed some benefices. After suffering severely in the civil wars, he retired to Paris, and died in the house of his friend Gilbert Genebrane, in 1581. His works, both in prose and verse, were numerous; but the most valuable are his Latin translations of the Greek fathers: such are, "S. Gregorii Nazianzeni opera omnia," fol. 1569 and 1583; "Interpretatio Latina 18 prrorum libri S. Irenaei adv. Haeret. capitum," fol. 1577; "S. Joh. Damasceni opera," fol. 1577; "Hidori Pelusiac Epitome, Gr. & Lat. (3 hirt. books, fol. 1587;" and translations of some pieces of St. Chrysolomus, inserted in the Paris editions of his works, in 1581, &c. Moreci.

BILLY, in Geography, a town of France, in the department of the Allier; 43 leagues N. E. from Gannat.

BILMA, a desert country in the north of Africa, being a part of the Great Desert, or Sahara, and a prolongation of the Libyan desert to the S. W. bounded on the N. by the Tibesti mountains, and the desert of Bardoa, on the E. by Kavar or Kuur, on the S. by Bornou, and on the W. by Zegzeg, Agades, Afouda, Gannat, &c. N. lat. about 23° to 25°. W. long. about 20°. The salt lake of Dumboo, the Chelonides Palus of Ptolemy, is said to be situated in the desert of Bilma.

BILOBUS, in Entomology, a species of Scarabæus, with two prominent lobes on the thorax; a simple horn on the head, and wing-castes incrusted. Inhabits the south of Europe. Fabricius.

BILOBUS, a species of Dytiscus, of an oblong-ovate form and black; mouth, vertical two-lobed spot, thorax, futural line, base, and margin of the wing-castes yellow. Linn. Muf. Leib.

BILLOBUS, a species of Cimex (Spinifera), with an obtus- dentated thorax; wing-castes greyish or reddish; vent with two lobes. Linn. Muf. Leib. A native of Europe.

BILLOBUS, in Ornithology, a species of Charadrius, called the Wotted Plouer, by Latham. It is an inhabitant of the coast of the Malabar. The bill and legs are yellow; frontal skin naked, and pendulous in two pointed lobes; body above yellowish grey; beneath white. Gmelin, &c. The crown, hand on the tail, and quill feathers are black; band across the eyes, greater wing-coverts, and some of the tail feathers at the end white. This is Plouer à bandeaux of Buff. Hift. Off. and Plouer de la côte de Malabar of Pl. enl. of the fame author. Length nine inches and a half.

BILLOCULAR, in Botany, a term applied to a capsule, having two cells.

BILOYAR, in Geography, a town of Ruffia, in the government of Simbirk, on the east side of the Volga, 16 miles S.E. of Simbirk.

BILLS, or BILSUS, LEON DE, of Rotterdam, in Holland, in Biography, acquired much fame for a time, about the middle of the 17th century, for a suppos'd new method of preferring bodies from putrefaction, and of defeciting them without occasioning an effusion of blood. By his method of preparing the bodies, they were said to preserve their flexibility as well as freedom from putridity for ages; so that 3 B 2
they might be differted during the summer, and remain under the demonstrator's hands for weeks, months, or years, if necessary, without emitting any offensive smell. De Bils had the art of gaining so much credit to his profession, that he is said, by Haller, to have sold his secret to the university of Louvain for 22,000 florins. He had demanded a much larger sum, and certainly had his preparations asnered the high elogia bestowed on them by his favourers, the secret would have deferred it. Prior to the sale he had lent one of his bodies to the theatre at Leyden, at which Deuibus, one of his warmest admirers says, "sed fideam superat omnem, excelsus hortum sanzader, recentur mortuum decreas, tanto theatru digastrinum opus." De admiranda anatomie, nobilitati vir L. D. Bils, p. 352. But not contented with the fame, and money acquired by his secret, for he held his prepared bodies at high prices, he pretended to have made discoveries in the structure of the liver, and in the lymphatics, by which he exprest himself to deferred contemp, it appearing that he was totally ignorant of the art of anatomy, in which he affected to be a master. He is said to have died plinius from the effects of the putrid air inhaled while preparing his bodies, and in a few years his preparations, which were to have lasted for ages, were totally destroycd. His productions, which were numerous, and excited much interest at the time, were collected and published in 1692, in 4to. under the title of, "De Bils invinta anatomia antiqua nova cum chlorisnorum virorum epistolarum, et testimoniorum Joannis ab Hosorne, et Pauli Barbetoe, reformato, interprete Godeone Bueno. Amb." 

BILLS, in Geography, a city of Hindustan, and capital of a cirrur in the Malwa country; 416 miles S. W. of Benares, 867 N. W. of Calcutta, by Gunre Mundhah, 560 N. W. of Hydraabad, 657 S. W. of Lucknow, 249 N. W. of Nagpoour, 140 nearly E. of Ougcin, and 496 N. E. of Poona. Bills, which is almost in the heart of India, affords tobacco of the mott fragrant and delicious kind throughout that whole region, and which is distributed accordingly, N. lat. 23° 30’. E. long. 77° 53’.

BILSEN, a town of Germany, in the circle of Westphalia, and bishopric of Liege, chief place of a canton in the district of Macracht, and department of the Lower Maule, seated on the Demeer, poftooie the privileges of a city, but of no great consideratio, 14 miles N. of Liege. The town contains 1925 persons, and the population of the canton includes 6358. The territory comprehends 170 kilometres, and 46 communes.

BILSKOI, a town of Siberia, on the Bilaia, 96 miles N. W. of Irkutsh.

BILSON, THOMAS, in Biography, a learned prelate of the Endlich church, was born at Winchelsea, and educated at Wykehans school near his native city. In 1565, he was admitted fellow of New College, Oxford, after having served two years of probation. He took in due course his several degrees of bachelor and master of art, and also of bachelor and doctor of divinity; the last of which was conferred on him in 1580. In his earlier years he was fond of poetry, philophy, and physic; but after having entered into orders, he confined himself wholly to divinity, and became an excellent preacher. His first preferment was the mastership of Wincheihei school; and he afterwards became prebendary of Winchelsea, and at length warden of the college, in which office he was instrumental in preserving the revenues of it, when they were likely to have been lost by forgery. In 1583, he published a treatise entitled "The True Difference between Christian Subjection and unchristian Rebellion," dedicated to queen Elizabeth, and composed for the purpose of confusing those catholic writers who attacked her right to the throne, and to the allegiance of her subjects. In this treatise passages occur that are favourable to reluctance in certain cases, and which have not escaped the censtures of later advocates of passive obedience. This was succeeded, in 1593, by his "Perpetual Government of Christ's church, &c," designed to shew, that from the Mosaic institution to the modern ages of Christ, the church has been governed by patriarchs and teachers of different ranks, superior and subordiuate, and evidenced one of the best books in favour of episcopacy. In consequence of this publication he was promoted to the see of Worceser in 1596, from which he was translated in 1597 to that of Winchelsea, when he was also appointed a pryve counsellor. About this time he delivered a course of sermons at Paul's cross, against some of the tenets of the Puritans, on the subject of redemption, and the descent of Christ into hell, which occasioned a controversy with the leaders of that sect. In the course of this controversy the bishop maintained the actual descent of Christ into hell, or the place of the damned, an opinion which was then deemed orthodox, but which has since been rejected by the bell expsitors of the 39 articles, and by every rational divine. This prelate took a lead in the Hampton-court conference, where he was distinguished by his learning; and in general he was one of the most able advocates in favour of the church of England. To him, in conjunction with Dr. Smith, afterwards bishop of Gloucester, was committed the care of revising and finishing the new version of the Scriptures, called King James's Bible. He was also one of the delegates who pronounced the sentence of divorce between the earl of Essex and his countess. This learned bishop, whose life was a course of incessant labour for the public good, and whose private character uniformly corresponded with his high station, died in 1616, and was buried in Weftminster Abbey. Biog.-Brit.

BILSTEIN, in Geography, a town of Germany, in the circle of the Lower Rhine, and capital of a bailiwick, in the duchy of Westphalia, seated on a mountain; 42 miles E. of Cologne.

BILSTON, a large village, or chapelry, of Staffordshire, England, is remarkable for the number of its houses and inhabitants, without having the advantage of a chartered market or fair. From its proximity to Birmingham and Wolverhampton, and having the advantage of a navigable canal near it, Bilston abounds with manufactures, among which those for japanned and enamelled goods are the principal. Furnaces for smelting iron ore, forges and forging mills, mostly worked by steam engines, also abound here. In the vicinity of the town are several coal mines, which produce great quantities of that fofil. An orange coloured sand is also abundant, and is in much request by the artizans, as a fand to cast metals in. Here is a quarry of remarkable flones, lying horizontally in twelve strata, each progressively increasing in thickness from the top downwards. The stone is mostly appropriated to the making of citterns, troughs, &c. Bilston is in the parish of Wolverhampton, but is a distinct township for all parochial proceedings. There is a chapel of modern erection, also two meeting-houses, and a free-school. This chapelery is within the exempt jurisdiction of the dean of Wolverhampton, and is a perpetual curacy. Bilston is 127 miles N. W. from London; it contains 1355 houses, and 6914 inhabitants. Shaw's History of Staffordshire.

BILSTONE, or BILSTON, is a small manufacturing town of Staffordshire, England. The making of blue cloths, blankets, and yarn, give employ to most of the inhabitants. Here was formerly a considerable market on Wednesdays, but it is
is nearly deforted, and the whole town is much reduced. Here are two annually fairs. The parish contains 121 houses, and 744 inhabitants.

BILUR, in Natural History, a name given by many of the Arabian writers to a gem, which though they often mention, they have no where given us a description of. Some have imagined it the onyx, and others the beryl; but it appears more probable to have been a species of crysall; probably the prabbe crysall of the East Indies, which is considerably finer than the common sprig crysall, and is often sold under the name of the white sapphire; though considerably inferior, both in figure and hardness, to the true white sapphire.

BIMA, in Geography, a river of Hucodast, so called by Mr. Pennant. See BREHAM.

BIMACULARIS, in Entomology, a species of Phalæna (Pyralis, Gnem.), found in Europe. The anterior wings are griseous brown, with two brown spots. Linn.

BIMACULATA, in Conchology, a species of Tellina, found in the European and American seas. This shell is of a somewhat rounded triangular shape, rather broad, smooth, whitish, with two fangiousous spots within. It is a small shell, being usually half an inch in length, and sometimes, though rarely, of a yellowish colour. Linneus, Donovan Brit. Shells, &c. On the English coast this is a scarce species.

BIMACULATA, in Entomology, a species of Silpha, found in Barbary. It is ovate and black; head of the antenna, globose; legs ferruginous. Gmelin. The margin of the thorax is rather ferruginous, and the middle of each wing-cake is marked with a red spot.

BIMACULATA, a species of Chrysomela, of an oblong shape, and black; wing-cakes tesselaceous, with a black spot on each. Inhabits America. Fabricius.

BIMACULATA, a species of Lepurta, of a rusous colour, with cylindrical thorax; wing-cakes dotted, with a spot and undulated streak of white on each. Schaffer, &c.

BIMACULATA, a North American species of Caltharis, with a ferruginous thorax, having a black spot; wing-cakes tesselaceous, with a black spot at the tip. Fabricius.

BIMACULATA, a species of Mordella, of a large size, that is found in Hungary. It is ferruginous, with the breast black; wing-cakes tesselaceous, with a black spot on each. Fabricius. Mant. Inf.

BIMACULATA, a species of Buprestis, that inhabits India. The wings are very entire, fraterated, with a red spot; body brownish, green. Linn. Fabr. &c.

BIMACULATA, a species of Sphinx (Zygaena), of the middle size, that inhabits America. The wings are above and beneath black, with two yellow spots on the anterior wings. Gmel. Fabr. &c.

BIMACULATA, a species of Phryges, described by Degeer. The wings are brown, with a double yellow lateral spot. Linn. &c.

BIMACULATA, a species of Tipula, found in Europe. The wings are hyaline, with two brown spots; abdomen spotted, with ferruginous in the middle; antenna feathered. Linn. Fn. Suec. Ofb. This specific character is liable to some exception, for it is only the female which has the abdomen spotted with ferruginous; that of the male is immaculate.

BIMACULATA, a species of Musca, found in New Holland, and described by Svederus, Nov. Act. Stockh. The colour is light blue, with a whitish spot on each side of the breast: abdomen green, and blue at the base.

BIMACULATA, a species of Scoria, described by Fabricius. It is black, hairy, with two pale yellow spots; antennae yellow. A variety of this insect with fulvous, instead of yellow spots, is mentioned by Pelag. Inf. Calabr. The former inhabits North America.

BIMACULATA, a species of Aranea, of a small size, that is found in Europe. The abdomen is fabroutund, chesnut, with two white spots. Gmelin. Abdomen rather depressed.

BIMACULATA, a species of Textreto, of a pale colour, with the eyes, base of the abdomen above, and two spots on the breast, black. Linnæus Muf. Linn.

BIMACULATA, in Zoology, a species of Lacerta, described by Sparrmann. Nov. Act. Stockh. The tail is carinated, toothed, and twice the length of the body; all the toes lobated. Inhabits the woods of St. Eutlace and Pennsylvania, living under ground, or in the hollows of trees, and depositing its eggs in the earth. The body is blue, tinged with green, and thickly spotted with black, but having two larger than the rest on the shoulders, from whence it is specifically named bimaculata; on each foot are five toes.

BIMACULATUM, in Entomology, a species of Phalearium, with the abdomen black, and two white spots. A native of England and Norway. Gmelin.

BIMACULATUS, a species of Scarabæus, with three flight tubercles on the head; wing-cakes fraterated, with two red spots at the base. Inhabits Germany. Fabricius.

BIMACULATUS, a species of Hister, of a black colour, with the posterior end of the wing-cakes red. Linn. Fn. Suec. Found in the dung of oxen. This is Hister funebris of Scopoli; and Attelabusatus niger; chrysiris leviro nonnullis frisiatis; p.earbot noir de Geoffroy.

BIMACULATUS, a species of Curculio, of a brown colour; wing-cakes dotted with cincereous; frount and legs black. Inhabits Saxony; and resembles Curculio colon, but is rather smaller.

BIMACULATUS, a species of Cryptoraphalus, of a dusky black, with fulvous thorax, and tesselacous wing-cakes, with two spots of black. Fabricius. Obs. This is Chrysomela melanchephala of Schaller, &c. A native of Italy and Saxony.

BIMACULATUS, a species of Carabus, of a black colour, with a common interrupted band; antenna and feet tesselaceous. Mant. p. 532. Gmel. Inhabits India. The thorax of this insect is yellow, or black, and sometimes spotted in different specimens.

BIMACULATUS, a species of Gryllus (Bulla acidrium) found in Europe, and described by Herbst. The thorax is brown, with an ochraceous lunate on each side.

BIMACULATUS, a species of Ichneumon. Colour black; front, legs, antenna beneath, anterior part of the thorax, two spots on the wings, and posterior margin of the abdominal segments, except the second, yellow. Linn. Muf. Linn. Breeds in the larva of phalana limbata. Scutell raised behind. Inhabits Europe.

BIMACULATUS, is also a species of Ichneumon, that inhabits Aurora, and is described by Schrank. It is black, with a yellowish fusel; two lateral segments of the abdomen with a single gypieous spot on each above.

BIMACULATUS, in Ichthyology, a species of Salmo, the body of which is comprissed, and marked with two spots; anal fin with thirty-two rays. Gmehn. This is a native of South America. Seba calls it Tetragonopterus; and Aried Vorgenusse Ambiœntus.

BIMACULATUS, a species of Labea, found in the Mediterranean.
dittereean sea. The dorso fin is filamentous, body marked
with a brown spot in the middle, and another near the tail.
Gmel. &c.

BIMACULOSA, in Entomology, a species of Cocein
tella, with fulvous wing-cases, having two obsolete white
feminlari patches. Herbst and Fuekeli, &c.

BIMACULOSA, a species of Phalena, that inhabits Ger-
many. Colour whitish grey; anterior wings rather clouded;
posterior ones with two black spots. Fabricius, &c.

BIMATRA, in Ancient Geography, a town of Asa in
Medopotamia. Ptolemy.

BIMBLELE: ou fussse Linnet, in Orchidewy, a name
given by Buffon to a species of mustella, since called
by Latham the palm sower, and noriella palmarum by
Gmelin.

BIMEDIAL, in Mathematics. When two medial lines, as
A B and C D, are commensurable only in
power, and containing a rational
rectangle, are compounded; the A B C D
whole AC shall be irrational, with
respect to either of the two, and is called a first bimedial line.

But if two medial lines, commensurable only in power,
and containing a medial rectangle, he compounded, the
whole will be irrational, and is called a second bimedial line.

Eucl. lib. x. prop. 38 and 39.

BIMUCRONATUS, in Entomology, a species of Scara
beus, that inhabits Armenia. It is tettaceous; thanks of
the anterior legs large, and hearded; shield of the head
mucronated on both sides, and bordered with fine hairs.

BINA, in Geography, a town of Italy, in the Cremona,
10 miles N.E. from Cremona.

BINACLE, in Sea-Language. See BUTTACLE.

BINAGARA, in Ancient Geography, a town of India, on
this side the Ganges. Ptolemy.

BINARD ISLAND, in Geography, a long and narrow
island on the north coast of France, to the east of Rotentin
point, having entrances at both the end and west end, and
within it a found or bay. It lies to the east of St. Maloes,
towards Cancale.

BINAROS, or Vinaros, a town of Spain in Valencia,
on the confines of Catalonia, near the coast of the Medi-
terranean, at the mouth of a river, which forms a small harbour,
with anchorage at about a cannon shot from the town, in 6
to 9 fathoms. It is surrounded with walls, and defended by
some cannon; 5 miles north of Peniscola, and 20 south of
Tortosa.

BINARY NUMBER, that is compounded of two units.

BINARY Arithmetic, a method of computation first pro-
posed by M. Leibnitz; wherein, in lieu of the ten figures in
the common arithmetic, and the progression from 10 to 10,
he has only two figures, and uses the simple progression from
two to two.

Jof. Pelican, of Prague, has more largely explained the
principles and practice of the binary arithmetic, in a book enti-
tled, "Arithmeticus perfectus, qui tria numerare necsit," 1717.

All his characters used in this arithmetic are 0 and 1;
and the cipher, here, multiplies every thing by 2, as it does
in the common arithmetic by 10. Thus, 1 is one; 10,
Binding Books. See Book-Binding.

Binding-Notes, in Music, imply two or more sounds on the same line or space, that are linked together by a semi-circle; and which, though written or printed twice, are not to be separated, but fullained like a single found.

The first of these tied or binding-notes, as in preparing disords, is usually struck on the unaccented part of a bar, and continued on the accented part. See Ligature, and Syncopation.

Example.

BINETTA, in Geography, a town of Italy, in the kingdom of Naples, and country of Bari, 4 miles W.S.W. of Biceto.

BINGAZI. See Bengasi.

BINGE, a town of France, in the department of the Cote d'Or, and chief place of a canton in the district of Dijon, 10 miles east of Dijon.

BINGEN, a town of Germany, in the circle of the Lower Rhine, and electorate of Mayence, and by the French arrangement, the principal place of a canton, in the district of Mayence, and department of Mont-Tonnerre. The town is said to contain 2663 inhabitants, and the canton 5638. It includes 10 communes. The town is seated at the conflux of the Nahe and Rhine. The stone bridge over the former is a noble structure, and the adjoining country is delightful. Bingen is a very ancient town, and was once imperial. The fortifications were destroyed by Lewis XIV. in 1689. A great part of the corn, which is carried into the Rhinegau, the neighbouring palatinate, comes through this place, which, on the other hand, supplies the palatinate with drugs, and various foreign commodities. Besides this traffic, it has in its vicinity very fruitful vineyards, which produce excellent wine. Near this town the Rhine is compressed into a narrow channel, between two rocks; about a mile and a half below it is a kind of whirl-pool, called the "Bingen-loch," the passage of which is dangerous. At a small distance is also an island on the Rhine, denominated "Maulbrun," or tower of rats; from a tradition, that an archbishop of Mentz was there devoured by these animals, in the tenth century, as a judgment executed on him for his cruelty to the poor, whom he compared to rats eating up the substance of the rich. Bingen is 19 miles W. of Mentz, 30 S. of Coblenz, and 54 E. of Treves. N. lat. 49° 54'. E. long. 7° 33'.

BINGENHEIM, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse, 16 miles N.N.E. from Frankfort on the Main.

BINGHAM, Joseph, in Biography, a learned English divine, was born at Wakefield, in Yorkshire, in 1668. Having acquired the rudiments of classical learning at a school in his native town, he was admitted in 1683, into University-college at Oxford, and in 1687, became fellow. Having taken
taken his master's degree in 1695, he was soon after presented by Dr. Radcliffe, the celebrated physician, to the rectory of Headborn-Worthy, near Winchester; a prebend, which, though not exceeding in value 100L a year, afforded him access to the valuable library at Winchester, and enabled him to prosecute the arduous undertaking, to which, in this retirement, he devoted much of his time and labour. Accordingly, the first volume of his learned work, entitled "Origines Ecclesiasticæ, or the Antiquities of the Christian Church," appeared in 1768. It was completed in ten volumes. Svo. and contains a judicious and candid, as well as ample account of the Christian clergy and churches from the earliest times. Besides this work, which was the result of much reading and indefatigable application, he published, in 1756, "The French Church's Apology for the Church of England; or, the Objections of the Difunctors against the Articles, Homilies, Liturgy, and Canons of the English Church, considered and answered upon the principles of the Reformed Church of France," &c. Svo. His avowed design in this work was to reduce the various principles and practices as are common to all the churches of the reformation. However laudable the design, uniformity of sentiment is not likely to be produced by any reasoning, as long as men are allowed to exercise their right of private judgment, and the only practicable union that can be that which results from mutual forbearance and benevolence. Mr. Bingham likewise published "A Scholastic History of Lay-Baptism," in two parts, 1712, Svo.; and "A Discourse concerning the Mercy of God to Penitent Sinners." All his works were collected and published in 2 vols. fol. Lond. 1725. Notwithstanding the acknowledged learning and meritorious services of Mr. Bingham, he had no other prebendaries besides that above-mentioned, till the year 1712, when he was collated to the rectory of Havant near Portsmouth. He died in 1723, and was buried in the church-yard of Headborn-Worthy, without any monument, of which he declared his dislike in his last will. B i g h . B r i t .

Bingham, in Geography, a town of Nottinghamshire, in England, stands nearly in the centre of the vale of Belvoir. It consists principally of two streets, running nearly parallel to each other, with more smaller streets branching from them. Near the centre of the town is a spacious market-place, where a weekly market is held every Thursday; it has also three annual fairs, and a large fair fair yearly, for hiring of servants. Bingham is flated by Thoroton to be much reduced since the reformation, as it was, previously to that event, it contained three chapels, exclusive of the parish church. The latter was collegiate, and is still a large handsome structure, with a tower and spire, side aisles and chantry. It contains numerous monuments, among which is a plain one inscribed to the memory of Robert White, a native of this place, where he died, in 1773, at the advanced age of eighty. He was author of an annual publication, entitled "The celestial Atlas, or New Ephemerides." The rectory of Bingham is esteemed one of the most valuable in the county of Nottingham, and is in the gift of lord Chesterfield, who is lord of the manor. This town is 124 miles north from London. It contains 220 houses, and 1082 inhabitants.

At Allerton, about two miles south from Bingham, archbishop Cranmer was born. About two miles north from Bingham is Earl-Bridgeford, where are the remains of an entrenchment, and where some coins, urns, &c. have been found. Horley places the Roman lation, Margiduun, "near Earl Bridgeford," from its situation near the fossed, and from the agreement of distances, between this and the other actions named in the Itinerary. Thoroton's History of Nottinghamshire.

Bi n g i u m, in Ancient Geography, a town of Gaul, in Germany Prima, west of Moguntiacum; now Bingen, which fec.

Binglestein, in Geography, a town of Germany, in the circle of Westphalia, and bishopric of Paderborn, 3 miles south of Buren.

Bingo, a small country of Japan, in the island of Nipon, situated in N. lat. about 34° 30'. E. long. 134°.

Bincum, a town of Germany, in the circle of Westphalia, and county of East Frieland, one mile north-west of Ort.

Bingut Cape and Bay, lie about E. by N. from Algiers, on the coast of Africa, in the Mediterranean. The town of Bingen is at the bottom of the bay of its name, about 12 or 13 leagues from Algiers.

Binieszky, a town of Lithuania, in the palatinate of Wilna, 44 miles S.E. of Wilna.

B inf i a, in Geography, a town of Affyria, according to Polemey.

Binninger, John Nicholas, in Biography, born at Montebellard, in 1628, studied medicine at Padua, and then went to Bafle, where he was admitted to the degree of doctor in that art in 1652. Returning to his own country, he soon acquired so much fame for his skill in his profession, that he was appointed professor of medicine, and physician to the family of the duke, his sovereign. He left "Observationum et Curationum medicinalium, centuria quinque," Svo. 1673, Month. containing some curious and valuable observations. Haller. Bib. Med. Eloy, Dict. Hist.

Binniguet, in Geography, a small island near the west coast of France, about a league south-west of Le Conquet, and a mile west of St. Matthew's point. N. lat. 49° 19'. E. long. 1° 5'.

Binn-na-Baird, and Binn-na-Muir-buidh, are the names of two lofty mountains, in the parish of Crathy, in Aberdeenshire, in Scotland. These summits are constantly covered with snow, and extending in the same ridge with the Cairigorm mountain, contain the same species of topaz, which bears the name of Cairigorm stones. Emeralds have been sometimes discovered here; also a species of brown folicious stone, which bears a very fine polish.

 BINOCLE, or Binocular Telescope, from binas, double, and ocular, eye, in Optics, that to which both the eyes may be applied, and consequently the same object be observed at the same time by both. It consists of two tubes, with two fets of glasses of the fame power, and adjusted to the fame axis; and some have pretended that it represents objects much larger and clearer than a single or monocular glass. But this is perhaps only an illusion, occasioned by the stronger impression, which two equal images alike illuminated make upon the eyes. This method of construction was invented by father Rheita, and brought into use by father Cherubin of Orleans. There are also microscopes of the same kind, but very seldom used.

Binoalis, in Entomology, a species of Formica, des-cribed by Fabricius as a native of Egypt. It is black; head
head large and rufous; with two tubercles on the pedi-

cle.

**BINOMIAL, or Binomial**, from *bin, two, and

name, name*, in Algebra, a quantity consisting of two terms or

members, connected by the sign *+* or *−* minus.

Thus *a* + *b* and *a* − *b* are binomials, consisting of the sum

or difference of those quantities; though the latter is often

called *residual*, and by Euclid, *apotome*.

The terms binomial and residual are said to have been first

introduced by Robert Recorde. See *Algebra*.

The powers of a binomial are found by a continual multi-

plication of it by itself, as often as an unit is contained in the

index of the power required. Those of a residual, *a* − *b*, are

obtained in the same manner, only with this difference in the

result, that the terms in which the exponent of *b* is an odd

number, will be negative.

If a root have three parts, as *a* + *b* + *c*, it is called a trino-

mial; if more, a multinomial.

**Binomia...**
And \( a - b \frac{1}{3} = a \left[ 1 - \frac{1}{3} \left( \frac{b}{a} \right) - \frac{1}{3} \left( \frac{b}{a} \right)^2 - \frac{5}{3} \left( \frac{b}{a} \right)^3 \right] \), &c.

And, in the same manner, if \( a \), divided by the cube root of the square of \( a \), be converted into a series, we shall have

\[
\frac{1}{a + b} = \frac{1}{a} \left[ 1 - \frac{2}{3} \left( \frac{b}{a} \right) + \frac{2}{3} \left( \frac{b}{a} \right)^2 \right],
\]

But these series are only commodious in calculation, in proportion to their degree of convergence. For if \( N \) be made to represent the rank which any term holds in the series arising from the binomial \( a - b \) being raised to the \( n \)th power, then that term will be to the following one as \( b \times \frac{m - N + 1}{N} \); from which it is evident, that for the terms of the series to go on decreasing, \( b \times \frac{m - N + 1}{N} \), taken positively, must be always less than \( a N \).

With respect to the history of this theorem, the prevailing opinion, till within these few years, has been, that it was not originally invented by Newton, but first given by him in that state of perfection, in which the terms of the series, for any assigned power whatever, can be found, independently of the terms of the preceding powers; viz. the second term from the first, the second from the second, the fourth from the third, and so on, by a general rule. But it has since been found, that in the case of integral powers, the theorem had been described by Briggs, in his "Trigonometria Britannica," long before Newton was born; and that, by the general law of the terms, independently of those of the preceding powers. For, as far as regards the generation of the coefficients of the terms of one power from those of the former ones, successively one after another, it was remarked by Vieta, Oughtred, and many others; and was not unknown to much more early writers on arithmetic and algebra, as will be manifest by a close inspection of their works, as well as the gradual advance the property made, both in extent and perspicuity, under the hands of the latter authors, most of whom added something more towards its perfection.

The knowledge, indeed, of this property of the coefficients of the terms of the integral powers of a binomial, is, at least, as old as the practice of the extraction of roots, of which it is both the foundation and principle. And as the writers on arithmetic became acquainted with the nature of the coefficients in the higher powers, they extended the extraction of roots accordingly, still making use of this property. At first, they appear to have been only acquainted with the nature of the square, the coefficients of which are the three terms, 1, 2, 1; and, by their means, extracted the square roots of numbers, but went no farther. The nature of the cube next presented itself; which consists of the coefficients, 1, 3, 3, 1; and, by means of these, they extracted the cube roots of numbers, in the same way as is practised at present. And this was the extent of their extractions, in the time of Lucas de Burgo, who, from 1470 to 1500, wrote several tracts on arithmetic, containing the substance of what was then known of this science.

It was not long, however, before the nature of the coefficients of all the higher powers became known, and tables formed for constructing them indefinitely. For, in the year 1543, Michael Stifelius, a German, published an excellent work on arithmetic and algebra, under the title of Arithmetica Integra, in which he gives the following table, for constructing both figurate numbers and the coefficients of the terms of the various powers of a binomial, which, since his time, has been often used for these and other purposes; and, more than a century after, was, by Pafcal, otherwise called the arithmetical triangle, and of which he has commonly been called the inventor, though he only mentioned some of its additional properties.

In this table Stifelius observes, that the horizontal lines furnish the coefficients of the terms of the correspondent powers of a binomial; and teaches how to use them in extracting the roots of all powers whatever. The same table was also used, for a similar purpose, by Cardan, Stevin, and other writers on arithmetic; and it is highly probable that it was known much earlier than the time of Stifelius, at least as far as regards the progressions of figurate numbers, which had been amply treated of by Nicomachus, who lived, according to some, before Euclid, but not till long after him, according to others; and whose work on arithmetic was published at Paris in 1538, and is supposed to have been chiefly copied in the treatise on the same subject by Boethius.

The contemplation of this table has also, probably, been attended with the invention and extension of some of our most curious discoveries in mathematics, both with respect to the powers of a binomial, the consequent extraction of roots, the doctrine of angular sections by Vieta, and the differential method of Briggs, and others. For a few of the powers or sections being once known, the table would be of the greatest use in discovering and constructing the rest; and accordingly it appears to have been used, on many occasions of this kind, by Stifelius, Cardan, Stevin, Vieta, Briggs, Oughtred, Mercator, Pafcal, &c.

But although the nature and construction of this table were thus early known, and employed in raising powers and extracting roots, it was yet only by raising the numbers from one another, by continual additions, and taking them from the table, for use, when wanted; till Briggs first pointed out the way of raising any horizontal line in the table, by itself, without any of the preceding lines; and thus teaching to raise the terms of any integral powers of a binomial, independently of any other powers; which was, in fact, giving the substance of the binomial theorem in words, but wanting the notation in symbols.

It may, however, be fairly questioned, whether Briggs knew how, even in the case of an integral exponent, to exhibit the law of the formation of the coefficients, under the form \( \frac{m(m-1)...(m-n+1)}{n!} \); for, though his method of forming the successive coefficients amounts to nearly...
tically the same things, yet the advancement in analysis de-
pend on the circumstance of the law which they observe, 
being expressed by means of a general symbol (n) without 
which, its extension would never have been made to 
those cases in which the index is negative or fractional: so 
that Briggs, even in the case of integral powers, does not 
appear to be fully entitled to the invention of the binomial 
theorem, properly so called.

But however this may be, it is universally agreed that 
no one before Newton had ever thought of extracting roots by 
means of infinite series. He was the first who happily dis-
covered, that, by considering roots as powers having frac-
tional exponents, the same binomial series would equally 
serve for them all, whether the index should be fractional or 
integral, or the series finite or infinite; and from this ex-
tension of the theorem, some of the most important improve-
ments, in the higher departments of mathematics, have 
arisen; particularly in the construction of logarithms, and 
the doctrine of series in general, which have since been car-
ried to a great degree of perfection, and now form some of 
the most curious and interesting branches of analytics.

It may also be farther observed, with respect to the claim 
of Newton as an original inventor of this highly useful 
theorem, that he had probably never seen the *Arithmetica 
Logarithmica* of Briggs; for it is well known that he was 
not an extensive reader of mathematical works, depending 
more on the powers of his own genius than upon any helps of 
this kind: so that there can be but little doubt of his 
having made the discovery himself, without receiving any 
light from what had been done by Briggs: and that he 
conceived the theorem to be new for all powers in general, 
as it was for roots and quantities with fractional indices.

But though this appears to be the case with respect to 
Newton, it is yet surprising that Dr. Wallis, who was a 
general reader of mathematical works, and who had 
actually seen Briggs's *Arithmetica Logarithmica*, as he men-
tions it in page 66. ch. xii. of his *Algebra*, should not have 
attended enough to this curious treatise, to know that it 
contained such a new and excellent theorem, as it fully 
appears he did not; since, in the 57th chapter of the above-
mentioned work, he describes the invention entirely to 
Newton; and adds, that he himself had sought after such a rule, 
but without success. It is also no less singular, that John 
Bernoulli, not half a century since, should first dispute the 
invention of this theorem with Newton, and afterwards give 
the discovery of it to Pafcal, who was born not long 
after it had been taught by Briggs. (See Bernoulli's works, 
vol. iv. p. 175.)

Dr. Wallis's *Algebra* was published in the year 1685; 
and it was here, for the first time after Newton's discovery of 
it, that the binomial theorem, according to his general 
manner of expressing it, appeared in print, and was made 
known to the learned world; though Leibnitz, and prob-
ably Dr. Barrow (who was Newton's great friend and 
patron in his youth), as well as some other mathematicians of 
that time, had seen it, in a letter addressed to Mr. Oden-
burgh, of October 24th 1676, (which was given in the 
*Commercium Epistolicum*), soon after the said letter 
was written. But he nowhere tells us his manner of investigat-
ing it; nor is any demonstration of it to be found, even in 
the case where the index is a whole number, in any part of 
his works. He says, indeed, in his next letter to Oden-
burgh, to be found in the same work, that the occasion of 
its discovery was as follows:

"Not long (he observes) after I had ventured upon the 
study of the mathematical sciences, whilst I was perusing the 
works of the celebrated Dr. Wallis, and considering the series of 
universal roots, by the interpolation of which we exhibit the 
area of the circle and hyperbola: for instance, in this series of 
curves, whose common base or axis is x, and the respec-
tive ordinates 1, 1 - x, 1, 1 + x, 1, 1 - x, &c. I observed that if the areas of the alternate 
curves, which are x, x - 1, x - 1, x, x - 1, x, x - 1, &c. could be interpolated, we should by this 
means, obtain the areas of the intermediate ones, the first of 
which (1 - x) is the area of the circle. In order to this it 
was evident, that in each of these series the first term was x, 
and that the second terms 1, x - 1, x - 1, x - 1, &c. were in 
theorems of progression, and consequently the first three 
terms of the series to be interpolated must be 
\[ x - \frac{1}{3} \left( \frac{3x}{2} \right) \], 
\[ x - \frac{1}{3} \left( \frac{3x}{2} \right) - \frac{1}{3} + \frac{1}{3} x' \], &c.

"Now, for the interpolation of the rest, I considered that 
the denominators 1, 3, 5, 7, &c. were, in all of them, in 
arithmetical progression; and consequently the whole 
difficulty consisted in discovering the arithmetical prog-
progressions of the number 11, 11, 11, 11, 11, &c. that is, the 
first, i.e. the second, i.e. the third, i.e. the fourth, i.e. the 
fifth, i.e. the sixth, &c.

"I applied myself, therefore, to discover a method by 
which the first two figures of this series might be derived 
from the rest; and I found, that if for the second figure, 
or numeral term, I put \( m \), the rest of the terms would be 
produced by the continual multiplication of the terms of this 
series, 
\[ \frac{m - 1}{2} \times \frac{m - 1}{2} \times \frac{m - 2}{4} \times \frac{m - 3}{4} \times \frac{m - 4}{5} \], &c.

"For instance, if the second term be put for \( 4 \), there 
will arise \( 4 \times \frac{m - 1}{2} \), that is \( 6 \), which is the third term;

the fourth term will be \( 6 \times \frac{m - 2}{3} \), that is \( 4 \); the fifth term 
will be \( 4 \times \frac{m - 3}{4} \), that is \( 1 \); and the sixth term will be 
\( 4 \times \frac{m - 4}{5} \), that is \( 0 \), which shows the series is here termi-
nated, in this case.

"This being found, I applied it, as a rule, to interpo-
late the above-mentioned series. And since, in the series which 
expresses the circle, the second term was found to be 
\( \frac{1}{2} \left( \frac{3x}{2} \right) \), I therefore put \( m = 4 \), and there was produced 
the terms 
\[ \frac{1}{2} \times \frac{1}{2} \left( \frac{1}{2} - \frac{1}{2} \right) \] 
\[ \frac{1}{2} \times \frac{1}{2} \left( \frac{1}{2} - \frac{1}{2} \right) \] 
\[ \frac{1}{2} \times \frac{1}{2} \left( \frac{1}{2} - \frac{1}{2} \right) \] 
\[ \frac{1}{2} \times \frac{1}{2} \left( \frac{1}{2} - \frac{1}{2} \right) \]

Hence I found that the area of the segment of the circle 
fought is \( x - \frac{1}{3} \left( \frac{3x}{2} \right) - \frac{1}{5} \left( \frac{3x}{2} \right) - \frac{1}{10} \left( \frac{3x}{2} \right) - \frac{5}{12} \left( \frac{3x}{2} \right) \) &c.

"In the same manner, the areas to be interpolated of the 
other curves might be produced; as also the area of the 
hyperbola.
hyperbola, and the rest of the alternate curves in the series

\[ 1 + x^2, 1 - x^2, 1 + x^2, 1 - x^2, \ldots \]

and in a similar way might other series be likewise interpolated, and that even if they should be taken at two or more intervals.

This was the way by which I first opened an entrance into their speculations, which I should not have remembered, but that, in turning over my papers, a few weeks ago, I, by chance, call my eyes upon these relating to this matter.

After I had proceeded so far, it immediately occurred to me that the terms \( 1 - x^2, 1 - x^3, 1 - x^4, 1 - x^5, \ldots \)

might be interpolated in the same manner as I had done in the cafe of the areas generated by them; and for this, there required nothing more than to have out the denominators, \( 1, 5, 5, 7, \ldots \) in the terms that express the areas; then the coefficients of the terms to be interpolated \( (1 - x^2, 1 - x^3) \) or universally \( 1 - x^m \) will be had by the continual multiplications of the terms of the series \( m \times \frac{m-1}{2} - \frac{m-2}{3} \times m^3 \times \ldots \)

Thus, for example, \( 1 - x^2 = 1 - \frac{1}{2} x^2 - \frac{1}{8} x^4 - \ldots \)

\( \frac{1}{16} \) \&c.; and \( 1 - x^3 = 1 - \frac{3}{2} x^3 - \frac{3}{8} x^6 - \frac{3}{16} x^9 - \ldots \)

\( \frac{1}{16} \) \&c.

Thus, I discovered a general method of reducing radical quantities into infinite series, by the binomial theorem, which I sent in my last letter, before I observed that the fame thing might be obtained by the extraction of roots.

But after I had discovered this method, the other way could not long remain unknown; for, in order to prove the truth of these operations, I multiplied \( 1 - \frac{1}{2} x^2 - \frac{1}{8} x^4 - \ldots \)

by itself, and found the product to be \( 1 - x^2 \), all the terms after these \( ad \ infinitum \) vanishing: in like manner \( 1 - \frac{2}{3} x^3 - \frac{3}{9} x^6 - \ldots \)

being twice multiplied into itself, produced \( 1 - x^3 \). And as this was a certain proof of the truth of these conclusions, I was thereby naturally led to try the converse of it, viz. whether these series, that were now known to be the roots of the quantity \( 1 - x^m \), might not be produced by the rule for extraction of roots in arithmetic; and, upon trial, I found it succeed to my wishes.

This being found, I laid aside the method of interpolation, and assumed these operations, as a more genuine foundation to proceed upon. In the mean time, I was not ignorant of the way of reduction by division, which was so much cail'd.

From this account, as given by Newton himself, it appears that his discovery of the law for the areas, with irrational ordiates, preceded that of the law for the expansion of those ordinates; although the latter, as Montucla observes, might have been expected to precede the former, if inventive genius always pursued the most easy method. But, in tracing the progress of the human mind, it may generally be observed, that a collection of discoveries, in any branch of science, is seldom found to be a series of regular dedctions; but, on the contrary, we often discern therein many anticipations, and sometimes even a reversion of the natural and logical order of ideas.

It is worth while here to remark, that Newton had made these discoveries, as well as many others, several years before Mercator had published his "Logarithometria," which contains a particular case of this theory; but, from an excess of modesty and indifference for those fruits of his genius, he delayed making them known to the world: and, even after the above-mentioned work had appeared, which would have operated as a powerful motive with most other men, in exciting them to share in the glory of these brilliant inventions, he was still more confirmed in the resolution he had taken, of not making himself known as an author till he was of a more mature age. He conceived, that Mercator having discovered, as it was said, the series for the hyperbola, would not be long before he extended his method to the circle, and other curves; or, if this should not be done by him, the invention would be readily perceived by others. In short, it appears rather singular, that as Mercator had converted the expression \( \frac{1}{1+x} \) into an infinite series, by the ordinary method of division, he should not have tried to discover the series for \( \sqrt{1+x} \) by the known method of extracting the square root; but this, though extremely obvious, escaped his notice: and many circumstances, of a similar kind, are to be found in the history of the sciences.

Newton, as has been already observed, left no demonstration of this theorem; but appears to have formed it merely from an induction of particular cases; and though no doubt can be entertained of its truth, having been found to succeed in all the instances in which it has been applied; yet, agreeably to the rigour that ought to be observed in the establishment of every mathematical theory, and especially in a fundamental theorem of such general utility and application, it is necessary that as regular and strict a proof should be given of it as the nature of the subject, and the state of analysis, can afford.

One of the first demonstrations of this kind that appears to have been given, is that of James Bernoulli, which is to be found, among several other curious things, in a small treatise of his, entitled "Ars Conjectandi," which has been very improperly omitted in the collection of his works, published by his nephew, Nicholas Bernoulli. But this is only applied to the case of integral and affirmative powers, and is nearly the fame with that which was afterwards given by Mr. John Street, in his commentary on Sir Isaac Newton's quadrature of curves. It is founded on the doctrine of combinations, and the properties of figurate numbers, which are there shown to involve in them the generation of these coefficients; and in the instance before mentioned, where the index of the binomial is a whole positive number, it is clearly and satisfactorily explained.

Since that time, many attempts have been made to demonstrate the general case, or that where the index of the binomial is either a whole number or a fraction, positive or negative; but most of these demonstrations having been conducted, either by the method of increments, the binomial theorem of De Moivre, or by fluxions, are commonly thought to be unsatisfactory and imperfect; and it should seem not without reason; as, independently of other objections, it appears contrary to the principles of science, as well as to just reasoning, to employ, in a matter purely algebraical, notions and doctrines derived from other branches, or from an analysis which is in some sort transcendental.

For these reasons, several eminent mathematicians have endeavoured to investigate this formula on pure analytical principles,
principles, in a more natural and obvious way; one of the first of these attempts being that of London, in his "Dissertations concerning the radical analysis," and the next that of Eperius, in the eighth volume of the "New Peterburg Memoirs." But the legitimacy of the former may be objected to, as depending upon various fractions, and other con- 

1. \( \frac{1}{a \pm x} = a^{n-1} \pm a^{-n}x + \frac{1}{8} a^{-2n} x^2 \pm \frac{1}{16} a^{-3n} x^3 + \text{&c.} \)

2. \( \frac{1}{a \pm x} = a^{n-1} + 3a^{-n} x + 6a^{-2n} x^2 \pm \frac{1}{10} a^{-3n} x^3 + \text{&c.} \)

3. \( \frac{1}{a \pm x} = a^{n-1} \pm a^{-2n} x + 1 \frac{1}{8} a^{-3n} x^2 \pm \frac{1}{16} a^{-4n} x^3 + \text{&c.} \)

4. \( \frac{1}{a \pm x} = a^{n-1} \pm a^{-1} x + \frac{1}{2} a^{-2} x^2 \pm \frac{1}{8} a^{-3} x^3 + \text{&c.} \)

5. \( \frac{1}{a \pm x} = a^{n-1} \pm a^{-2} x - 1 \frac{1}{8} a^{-3} x^2 \pm \frac{1}{16} a^{-4} x^3 + \text{&c.} \)

6. \( \frac{1}{a \pm x} = a^{n-1} \pm a^{-1} x - \frac{1}{2} a^{-2} x^2 \pm \frac{1}{8} a^{-3} x^3 + \text{&c.} \)

In all the instances here given, it is apparent, that the first term of the series, in each of them, is the same as the power or root of the first term of the binomial quantity to which it belongs; and that the coefficient of \( x \) in the second term is always had by multiplying the index of the first term into that term, having its index diminished by 1; and as these cases are of the same kind with those that are designed to be expressed, in universal terms, by the general formula, it is in vain, as regards the two first terms of the expansion, to look for any other origin of them, than what may be derived from those and similar operations.

For this purpose, let \( m \) denote any number whatever, integral or fractional, positive, or negative; and let the coefficients of the 3d, 4th, 5th, \&c. terms of the \( m \)th power of any binomial be denoted by \( p', q', r', \&c. \)

Then for \( x \), in the above form, put \( y+z \), and there will be

\[ a + y \pm z = a + ma^m - (y + z) + p \left( y^2 + 2yz + z^2 \right) + q \left( y^3 + 3yz^2 \right) \quad \&c. \]

\( \text{(omitting to set down the powers of} x, \text{which are not wanted in the demonstration)} \]

\[ a + y \pm z = a + ma^m - (y + z) + p \left( y^2 + 2yz + z^2 \right) + q \left( y^3 + 3yz^2 \right) \quad \&c. \]

And

\[ \text{and} \quad a + y \pm z = a + ma^m - (y + z) + p \left( y^2 + 2yz + z^2 \right) + q \left( y^3 + 3yz^2 \right) \quad \&c. \]

Hence the two series being identical, \( a + ma^m - (y + z) + p \left( y^2 + 2yz + z^2 \right) + q \left( y^3 + 3yz^2 \right) \quad \&c. \]

And since the coefficients of the terms involving the same powers of the arbitrary quantities \( y \) and \( z \) must be the same, we shall have

\( 2p = m \cdot m - 1 \cdot a^{m-1} \quad \text{or} \quad p = \frac{m \cdot m - 1}{2} \quad a^{m-1} \quad \&c. \)

And hence \( p' = \frac{m \cdot m - 2}{2} a^{m-1} \quad \&c. \)
The mouth of this river is in S. lat. 36° 45', W. long. 73° 28'; and its entrance known by two remarkable hills, called the Teats of Biobio, which are situated at the north, betwixt it and the bay of Conception, and serve to both as land-marks for navigators.

The river is about one mile across at the mouth, has good depth of water in the middle, and the tide rises about seven feet and a half at the full and change of the moon.

BIOCOLOYTE, in the Byzantine Empire, an order of officers appointed to prevent the violences frequently committed by the soldiery. The word is compounded of Βίτος, violence, and ὑπότασσω, I bind; and should rather be written bicolectic.

The biocolyte appear to have been much the same with the French archers of the Marshalmen. They were suppressed by the emperor Julian.

BIOCULATA, in Entomology, a species of Ephemeræ, described by Geoffroy, Ioannæus, &c. The wings are white, reticulated; on the head two yellow tubercles. Fabr. Inhabitae wet places in Europe. The tail of this kind is furnished with two bristles as long as the body.

BIOCULATA, in Natural History, a species of Hirundo, of an elongated form and cinereous colour, with two eyes. Gmel. Mill. This is hirundo magallensis of Linneus. Fa. Succ. &c. Found in wet hollows and rivulets very common. Length of this creature is nine lines. The female bears about forty eggs at a time, which are surrounded by a pellucid circle; at first these are cinereous, afterwards brown; and the young, after exclusion, adhere by their tails to the belly of the female. Gmel.

BIOCULATIS, in Entomology, a species of Cryptophilus (Griseus), found at the cape of Good Hope. It is tesselaceous; thorax immaculate; on the wing-cases two ocular white spots. Fabricius.

BIOCZ, in Geography, a town of Poland, in the palatinate of Cracow, north of the Carpathian mountains. N. lat. 49° 48'. E. long. 21° 42'.

BIOEA, in Ancient Geography, a sea-port in the southern part of the island of Sardinia, according to Ptolemy.

BIOELIO, in Geography, a town of Italy, in the lordship of Vercelli, 21 miles N.W. of Vercelli.

BIOGRAPHER, formed from the Greek biographia, life, and γραφει, I describe, an author who writes a history, or life, of one or more persons. Such were Plutarch, Corn. Nepos, &c.

BIOGRAPHY, the art of describing or writing lives, is a branch or species of history more entertaining, as well as more useful in many respects, than general history, as it represents great men more diffusely, unincumbered with a crowd of other actors, and deferring into the detail of their actions and character, their virtues and failings, gives more light into human nature, and leads to a more intimate acquaintance with particular persons than general history allows. A writer of lives may, for example, in minute particular, and familiar incidents. From him it is expected to give the private as well as the public life of those whose whole actions he records; and it is from private life, from familiar, domestic, and seemingly trivial occurrences, that we often derive the most accurate knowledge of the real character. The subjects of biography are not only the lives of public or private persons, who have been eminent and beneficial to the world in their respective stations, but those also of persons notorious for their vice and profligacy; which may serve, when judiciously characterized, as warning to others, by exhibiting the fatal consequences which, sooner or later, generally follow licentious practices. As for those, who exposed their lives, or otherwise employed their time and labours for the

The new city of Mocha, peopled by inhabitants who removed from Conception twelve years ago, is situated on its north bank, about twelve miles from the sea, and is a depot for the silver from the mines of Nimba, and for the gold with which its bands abound.
SBIO

service of their fellow-creatures, it seems but a just debt, that their memories should be perpetuated after them, and that posterity should be made acquainted with their benefactors. This was no small incentive to virtue in the pagan world; and no one can be ignorant, on due reflection, how natural this passion is to mankind in general. For this reason, as they do, so do their prefaces (Orat. vol. ii. p. 232), Virgil has placed not only his heroes, but all the inventors of useful arts and sciences, and other persons of distinguished merit, in the Elysian fields, where he describes them (Aen. l. vi. v. 661.): "Here patriots live, who, for their country's good, in fighting fields were prodigal of blood; Priests of unblemished lives here make abode, and poets worthy their inspiring god; and searching wits of more mechanic parts, who gave their age with new invented arts; those who to worth their bounty did extend, and those who knew that bounty to commend: the heads of these with holy fillets bound, and all their temples were with garlands crown'd."

In the lives of public persons, their public characters are principally, but not solely, to be regarded. The world is inquisitive to know the conduct of princes and other great men, as well in private as in public; and both may be of service, considering the influence of their examples. But to be over-inquisitive in searching into the weaknesses and failings of the greatest or best men, is, to say no more of it, a needless curiosity.

In this species of writing Plutarch has no inconsiderable merit; and to him we are indebted for much of the knowledge which we posses concerning several of the most eminent monuments of antiquity. His matter, however, is better than his manner; as he cannot lay claim to any peculiar beauty or elegance. His judgment too, and his accuracy, have sometimes been taxed; but whatever may be his defects of this kind, his lives of eminent men will always be considered as a valuable treasure of instruction. He is remarkable for being one of the most humane writers of all antiquity; less dazzled than many of them are, with the exploits of valour and ambition; and fond of displaying his great men to us, in the more gentle lights of retirement and private life.

It has been a matter of dispute among the learned, whether any one ought to write his own history. No one, it may be said, can be so much master of the subject as the person himself; and besides, there are many instances, both ancient and modern, to justify this practice. But, on the other hand, it must be owned, that it is attended with many inconveniences, some of which are mentioned by Cicero: "If," says he (Ad Famili. l. epist. 12), "there is anything commendable, persons are obliged to speak of themselves with greater modesty, and to omit what is blamable in others. Besides, what is said is not so soon credited, and has less authority; and after all, many will not hesitate in confuting it." To the same purpose it is well observed by Pliny (l. viii. ep. 1.): "Those who proclaim their own virtues, are thought not so much to proclaim them, because they did them, as to have done them, that they might proclaim them. Hence, what would appear great, if told by another, is lost, when related by the party himself. For when men cannot deny the fact, they reflect upon the vanity of its author. Wherefore, if you do things not worth mentioning, the actions themselves are blamed; and if the things you do are commendable, you are blamed for mentioning them." The justice of these reflections will be allowed; and yet, considering how natural it is for men to love themselves, and to be inclined in their own favour, it seems to be a very difficult task for any one to write an impartial history of his own actions. There is scarcely any treatise of this kind that is more celebrated than Caesar's "Commentaries," and yet Suetonius tells us (In Vit. c. 56.), that "Aulus Fulvio, who lived at that time, thought that they were written neither with due care nor integrity; that Caesar was too often credulous in his accounts of what was done by other persons, and misrepresented his own actions, either deliberately, or through forgetfulness; and therefore he supposes he would have revised and corrected them." At some times, however, it may without doubt be justifiable for a person to be his own historian. Plutarch mentions two cases, in which it is allowable for a man to commend himself, and to be the publisher of his own merits. These are, "when the doing of it may be of considerable advantage, either to himself, or to others." "Anciently," says Tacitus (Vit. Agric. c. 1.), "many wrote their own lives, rather as a testimony of their conduct, than from pride;" remarking, "that the more virtuous abound, the sooner the reports of it are credited." But the ancient writers had a method of diverting the reader's attention from themselves, when they had occasion to record their own actions, and of thus rendering what they said less invidious, which was by speaking of themselves in the third person: thus Caesar never says, "I did," or "I said this or that," but always "Caesar did," or "said, so and so." Dr. Johnson has given an excellent paper on the subject of biography in the collection of papers called the "Idler." Volney, in his "Lectures on History," remarks, that biography is the only kind of history that is proper for young people. See History.

Dr. Priestley has constructed and published a "Biographical Chart," which is very useful to students in chronology, history, and biography. This chart, which is about three feet in length, and two feet in breadth, represents the interval of time between the year 1200 before the Christian era, and 1800 after Christ, divided by an equal scale into centuries. It contains about 2000 names of persons the most distinguished in the annals of fame, the length of whose lives is here represented by lines drawn in proportion to their real duration, and terminated in such a manner as to correspond to the dates of their births and deaths in universal time. These names are distinguished into several classes by lines running the whole length of the chart, the contents of each division being expressed at the end of it. The chronology is noted in the margin on the upper side, by the year before and after Christ, and on the lower by the fame era, and also by the succession of such kings as were the most distinguished in the whole period.

BIOLE, L.5, in Geography, the chief place of a canton, in the district of Chambray, and department of Mont Blanc. The population of the place is estimated at 1038, and of the canton at 5625 persons; the territorial extent contains 292 square kilometres, and 10 communes.

BIOLYCHNIUM, formed of BIOS, life, and NOXES, lights, a name given by some physiologists to a supposed principle of vitality inherent in the heart, or blood, and remaining there as long as life continues. Of this principle, or innate heat, different accounts have been given by different writers; as Galp. Hoffman, Cagnerius, &c.

Beguinus has described a process for preparing from human blood a vital balsam under this denomination; and I. Erm. Burgavius has written a tractate upon it.

BION, in Biography, a native of Proconnesus, was contemporary with Pherecydes, and flourished about the 59th Olympiad, or 544 years B.C. Clemens Alexandrinus informs us, that he copied the titles, and abridged the works of
Bion, the Bacchus, who is said to have been the first writer in prose, and to have lived before the Trojan War.

Bion, the Pheicctope, was a native of Dorylaienas, and flourished in the reign of Antigonus Gonatas, king of Macedon, and died about the last year of the 174th Olympiad, or the 241st year B.C. He was a person of mean extraction, being the son of a Macedonian hairdresser; and when young, was sold as a slave to an orator, who afterwards gave him his freedom, and left him large possessions. Thus endowed he went to Athens, and devoted himself to the study of philosophy. He was the first disciple of Crates, then of the Cynics, afterwards of Theodorus, and last of all of Thrasymachus; but he adopted and maintained the opinions of Theodorus, called the atheist. He was skilled in geometry and music, and also in poetry and rhetoric; and went about from one city to another, displaying his talents, several of his orations, for which he was famous, are preferred; and Horace is supposed to allude to him in his

"If Bionis fernemibus, et felic insigni," Epist. ii. lib. ii.

To a great talker, who asked him a favour, he said, "If you would have me grant it, let some other person ask it for you." Being on board a ship belonging to pirates, which was chased by another, the pirates exclaimed, "We are undone, if they discover who we are," and I," says Bion, "If they discover who I am." He ridiculed the contradiction of burning the dead as if they were infallible, and lamenting them as if they were still sensible. Some of his jests were offensive to morals and decency; for neither of these did he pay much regard. Notwithstanding his avowed irreligion, he recurred, when sick, to the practice of primitive superstitions, and submitted to death with great reluctance. Brucker's Hist. Phil. by Enfield, vol. i. p. 180, Gen. Dict. Lacttius, lib. iv. tom. i. Ed. Meib. p. 255, &c.

Bion, a celebrated Dacian poet, was a native of Smyrna, and a contemporary of Ptolemy Philadæus, about 282 years B.C. In Sicily or Magna Grecia, where he is supposed to have spent the last part of his life, Molchatus was his pupil; and from the beautiful elegy of this poet, we are led to infer, that he left his life in prison, and that the perpetuity of his name did not escape just punishment. As a poet he was highly esteemed; and his performances that are extant, though imperfectly preserved, serve as examples of the excellence to which the Greeks had attained in similar compositions. Nothing can be more sweet and tender than his "Elegy on the death of Adonis," nor any thing more elegantly ingenious than his "Cupid instructed." The works of Bion are usually printed with those of Molchatus; and the best editions are those of Paris, in 1686; of Venice, in 1746; Hefilin's, at Oxford, in 1748; Schein's, at Leipzig, in 1722; and Wakefield's, Lond. 1705. Gen. Dict. Ger. Biogr.

Bion, M. mathematical instrument maker to the French king, died at Paris in 1733, at the age of 78 years, and is known to mathematicians as the author of two works; one, "On the construction and principal uses of mathematical instruments," translated into English with additions, by Mr. Edmund Stone; and another, "On the use of the Globes;" the fifth edition of which was published at Paris, in 1728.

BIONCOURT, in Geography, a town of France, in the department of the Meurthe, and the chief place of a canton, in the district of Chateau-Salins, 2 leagues W.S.W. of Chateau-Salins.

BIORKA, in Ichthyology, a species of Cyprinus, having thirty five rays in the anal fin. Found in the lakes of Sweden. Linnaeus. This is Cyprinus quinquecantal., pinnæ ad orificium 25., of Artedi.

BIONDO, Flavio, (Lat. Flavio), in Biography, an antiquary and historian, and one of the first who illustrated the Roman antiquities, was born at Forli in 1388, and died at Cremona. Being deputed in his youth on public business to Milan, he there made the first copy of Cicero's treatise on famous orators. At Rome he became secretary to pope Eugenius IV., and served the three succeeding popes in the same office. He was employed in various delegations to Venice, where he had an opportunity of forming an acquaintance and friendship with many learned philosophers in that republic. Debaafed by his marriage from enjoying any church preferment, and devoted to study more than to the pursuit of wealth and honour, he preferred retirement to nobility, and devoted his literary labours till his death in 1447. His long residence at Rome enabled him accurately to describe its chief relics of antiquity in 3 books entitled Rona antiquata; which were followed by 10 books on the laws, government, customs, religion, &c. of the Romans, under the title of De Ruma triumplanta. Another work, on its history, antiquities, and geography, was entitled Italia illustrata. All these works display great reading and diligent research, though they are not free from many errors to which his ignorance of Greek literature must have contributed. Having undertaken to write a general history from the decline of the Roman empire to his own time, he finished three decades of it, and the first book of the fourth. He also wrote a book De Origine et Gestis Venetorum, and had planned an entire history of the Venetian republic; but he afterwards chose to infest the substance of it in his general history. He left several other writings in MS., which it is no dish to mention. His style wants purity and elegance, and his judgment in collecting materials was superior to his taste in using them. A collection of his works was published at Bâl, in 1531, Ed. Nou. Dict. Hist. Gen. Biog.

BIORKE, in Geography, a town of Sweden, in the province of Upland.

BIÖRNEBOOM, a town of Finland, on the east side of the gulf of Bothnia, seated on a lake, 80 miles north of Åbo. N. lat. 62° 6'. E. long. 23° 35'.

BIÖRNSE, a small island of Denmark, near the south coast of the island of Funen.

BIÖRNSTADHL, JAMES JONAS, in Biography, a learned Swedish traveller, was born at Rotarbo in 1731, and having finished his education in the university of Upfal, he became, in 1766, tutor to the son of baron Rudbec, with whom he travelled for eight years through France, Italy, part of Germany, Holland, and England. At Paris, where he improved himself in the oriental languages, he was elected, in 1770, a member of the academy of sciences, and upon the baron's return to Sweden, in 1777, Biörnstahl received orders from the king to travel at his expense through the Ottoman empire, Syria, Egypt, and the northern part of Africa, and in the same year he was appointed extraordinary professor of philosophy at Upfal. In the following year he commenced his travels; and having a rendezvous at Constantinople, he continued there two years, improving himself in the eastern languages. In 1770, he was appointed professor of the oriental languages at Lund; but he died this year of a putrid fever at Saloniche. The result of his observations in the course of his travels was communicated in a series of letters to C. C. Gjörwell, librarian to the king at Stockholm; and a complete collection of them appeared at Stockholm, in 1778, in three volumes, 8vo., under the title of F. J. Boornstahl's Brief rörande des utfärdiga Reis utgifaren C. C. Gjörwell. A German translation of this work was published at Stralund and Rollrock in 1783, in fix volumes, 8vo. The principal object of Biörnstahl's research was oriental MSS., from which he made many important and useful extracts. Gen. Biog.
BIP

BIOT, in Geography, a town of France, in the department of the Var, and chief place of a canton, in the district of Grasse, 3 miles north of Antibes.

BIOTA, in Zoology, a name introduced by Dr. Hill for the Polype genus called Hydra, by Linnaeus, as it is believed from the reproduction or regeneration of the parts when cut off; and this name biota is likewise given it on the same account, being derived from βιός, life. See HYDRA.

BIOTHANATI, from βιος, violence, and δάκρυα, death, in some Medical Writers, denote those who die a violent death. The word is also written, and with more propriety, biothanatia; sometimes biathanatia.

In a more particular sense, it denotes those who kill themselves, more properly called autothanatia. See Suicide. In this sense it is that the word is used both by Greek and Latin writers. By the ancient discipline of the church, they were punished by denying them burial, and refusing all commemoration of them in the prayers and offices of the church.

BIOTHANATIS, supposed by some to be derived from βιός, life, and δάκρυα, death, and alluding to the belief of a future life after death, was also a name of reproach given by the heathens to the primitive Chrislians, for their constancy and forwardness to lay down their lives in martyrdom.

BIOTHANATOS is also used in some writers of the barbarous age for wicked, damnable, or accursed. Du Cange.

BIOUAC, Biovac, or Biovac, in the Military Arts, a nightly guard performed by the whole army, when there is an apprehension of danger from the enemy. The word is formed by corruption from the German wegwachter, a double watch or guard. See Guard.

BIOULLE, in Geography, a town of France, in the department of the Loir, and chief place of a canton, in the district of Montauban, 3 leagues N.E. of Montauban.

BIPARTIENT, in Arithmetic, is a number that divides another into two equal parts without a remainder. Thus 2 is a bipartient to 4, &c.

BIPARTITA, in Entomology, a species of Lepidura, that inhabits Upper Austria. It is of a black colour; thorax ferruginous, with a longitudinal black line; a common ferruginous spot on the wing-cases.

BIPARTITE LEAF, in Botany. See LEAF.

BIPARTITION, signifies a division into two equal parts.

BIPED, in Zoology, an animal furnished with only two legs. Men and birds are bipeds. Apes occasionally walk on their hind legs, and seem to be of this tribe, but that is not a natural position for them, and they rest upon all their legs like other quadrupeds. The jervous are also of the latter description, jumping and leaping on their hind legs, but relying on the fore legs likewise.

Plato, we are told, once defined a man to be a biped without feathers; and Diogenes, in order to shew what he deemed the absurdity of this definition, plucked all the feathers off a cock, and placing it in the midst of the Academical school, exclaimed, "there is one of Plato's men!"

BIPED, Biped, Bipes, a genus of reptiles that belongs to the lizard family, in the family of La Cepede. These have, according to the character established by that author, a very long body covered with scales; and the toes of the two little feet, which are placed anteriorly, are armed with nails. La Cepede describes only one species of this genus, which he calls le cemmelle; it is a native of Mexico, and preferred in the museum at Paris. La Cepede, it appears, was the first writer who described this creature; but Dr. Shaw noticed it afterwards in the Naturalist's Miscellany, under the name of lacerta honda sideis, lumbado-sideris, lizard, which sees; and a specimen of it, about half the size of that in the museum at Paris, is preferred in the British museum. This must not be confounded with lacerta lupis of Linnaeus. Pallis has described another kind of biped lizard, which is called lacerta apor, but in that the legs are very small, monadaclylus; and placed far behind: some have almost doubted whether these may not rather be parts of the organs of generation than legs; and in general appearance, the creature approaches rather to the snake than lizard tribe. It is a native of the southern parts of Siberia, and also of Greece, and is of a ferruginous colour.

BIPENNIS, in Roman Antiquity, a two edged ax, used anciently by the Amazons in fight; as also by the sami, to cut adunder the ropes and cordage of the enemy's vessels. The bipennis was a weapon chiefly of the oriental nations, made like a double ax, or two axes joined back to back, with a short handle. Some compare it to a figure of a pen, and suppose it hence to have acquired the name bipennis; the tube or barrel of the pen representing the handle, and the point or nib the head. Modern writers usually compare it to our halbard, or partizan; from which it differed in that it had no point, and that its shaft or handle was much shorter. See HALBARD.

BIPES, in Zoology, a species of LACERTA, with the body subequal, rounded, imbricated, and pale; on each scale a brown dot; no anterior feet; posterior feet with two toes unarmed. Gmelin. Aegris lapes, with two abdominal, and 16 subcaudal plates. Linne. Hist. Ad. Frid. A native of South America and India. Length about five inches; body cylindrical and slender; colour pale yellow. Biped. Lizard.

Bipes, a species of COLUBER, described by Gmelin on the authority of Scopoli, as an inhabitant of the Tyrolean waters, where it is said to feed on frogs and fishes; it has two feet, fulvous eyes, whitish under-jaw, elliptic, marginate, dorsal scales; sixes spotted with white; abdominal plates white, with a brown spot in the middle. Gmelin describes it specifically as having 116 plates on the belly, and 58 subcaudal scales.

BIPINNULA, in Botany. See ARETHUSA.

BIPICLATA, in Conchology, a species of Voluta, figured by Martini only. It is of a tapering shape, smooth, white spotted with yellow, and dotted with black; lip acute; pillar with two plaits.

BIPUNCTARIA, in Entomology, a species of Phal- na (Geometry), the anterior wings of which are cinereous, undulated with brown; a dusky band in the middle, and two black dots. Fabricius, &c.

BIPUNCTATA, a species of Apis, that inhabits Siberia. This insect is hairy and black, with two yellow belts; the first with two lateral black dots. Lepelchin it. Gmel.

BIPUNCTATA, a species of Akanes, with a black, globose abdomen, marked with two excavated dots. Linn. Hist. Suec.

BIPUNCTATA, a species of CANTHARIS, with two black spots on the thorax; wing-cases black at the tip. Fabricius. Inhabitants Leipiz.

BIPUNCTATA, a species of Cassida, of a yellowish colour, with two black dots on the wing-cases. This is a native of India. Fabricius.

BIPUNCTATA, a species of Chrysomela, described by Fabricius as a native of the Cape of Good Hope. It is tussacous, with a brown spot on each of the wing-cases.

BIPUNCTATA, a species of Cicada, described by Lin- neus. It is yellow, with two brown spots in front; wing-cases white, veined with yellow. A native of Europe.
**BIP**

**BIPUNCATA.** is also a species of **Cicada (Duflexa)**, found in South America. The colour is white; wing-cases deflected, and griseous, with two impressed dots on the anterior part of the margin of the thorax. Fabricius, &c.

**BIPUNCATA.** a species of **Coccinella**, of a red colour, with two black dots. Linna. Fn. Suec. &c.

**BIPUNCATA.** a species of **Ferula**, that inhabits Italy. The head and legs brown; a white spot on the wing-cases. Fabricius. It has eleven joints in the antenna.

**BIPUNCATA.** a species of **Leptaena**, of a black colour, with a pointed thorax; abdomen with yellow bands, and two dots of the same colour on the first segment. Fabricius. Inhabits Germany.

**BIPUNCATUM.** a species of **Opatrion**, of a brown colour, with five black spots. Gmelin.

**BIPUNCATUM.** a species of **Brachis**, that inhabits Helvetia. It is cinereous; wing-cases brown with an ocular, black dot at the base of each. Fabricius.

**BIPUNCTATUS.** a species of **Carabus**, of a somewhat brassy colour, with two impressed dots on the wing-cases. Linna. Fn. Suec. This is defcribed by Fabricius as being brassy, with black antennae, and pale tints. This inhabits Europe.

**BIPUNCTATUS.** a species of **Cimex (Rotundatus)**, of a pale greenish colour, with a white dot on each side of the scutellum near the base. Linnaeus. Inhabits Syria.

**BIPUNCTATUS.** a species of **Cryptochephalus**, of a glossy black; wing-cases red with two black dots; antennæ length of the body. Fabricius. Gmelin, &c. *Cryptochephalus punctatus*. Linna. Inhabits the northern parts of Europe; on the Nut.

**BIPUNCTATUS.** a species of **Cercelio**, found in Europe. It is cinereous, with a black spot on the wing-cases; thanks yellow. Linnaeus. Fn. Suec.

**BIPUNCTATUS.** is likewise a species of **Cercelio**, with the thorax fuscous; wing-cases clouded, with two glossy black spots near the apex. Lepech. It. A native of Siberia.

**BIPUNCTATUS.** a species of **Gryllus** (*Arida. Tetrata, lita*), of a brownish colour; feutel as long as the abdomen. A native of Europe.

**BIPUNCTATUS.** a species of **Hemorrhous**, found in Europe. It is variegated with yellow and brown, and has two black spots on the wing. Fabricius.

**BIPUNCTATUS.** a species of *Ichneumon*, found in Europe. This insect is black; base of the antennæ brown; thorax dark, and face yellow, with two black marks on the latter; abdomen, feutel, and tips of the posterior feet ferruginous. Linna. Mus. Lepa.

**BIPUNCTATUS.** a species of *Papilio* (*Pap. Urb*.). The wings are entire; brown, on both sides of the first pair an oblique band, and two dots of silver; at the base of the posterior ones beneath a band and fringe of yellowish.

**BIPUNCTATUS.** a species of *Scarabaeus*, having a black thorax, bordered with red; and red wing-cases with a black spot on each. Lepech. It. Fabricius. This is the insect which Pallus names *Scarabaeus coccinelloides*; it is found in the southern parts of Russia under horse-dung.

**BIPUNCTATUS.** in *Ichneumology*, a species of *Cyprinus*, defribed by Bloch. The lateral line is red, with a double series of black spots; and sixteen rays in the anal fin. This kind is found in the handy rivers of Germany.

**BIPUNCTELLA, in Entomology**, a species of **Phalena** (*Tineco*), wings cinereous brown, with a marginal white spot. Fabricius.

**BIPUNCTELLA.** a species of **Phalena** (*Tineco*), with fuscous wings, with a continuous dentated white tinge; thorax ferruginous with two black spots. Fabricius. This is *Tinea obliqua* of Schmetterer.

**BIPUNCTULATA.** a species of **Cantharis** (*Malacochirus*), of a brassy-green colour with the apex of the wing-cases red. Linna. Fn. Suec. Geoffroy. This is *Telephorus ventriculosus nigritus*, of Degener. A very common insect in most parts of Europe.

**BIPUNCTULATA.** a species of **Cassida**, of a green colour; wing-cases with two lateral fuscous spots. Inhabits Ceylon. Linna. Fabricius, &c.

**BIPUNCTULATA.** a species of **Chrysomela**, described as a Swedish insect by Thunberg. The wing-cases are black, spotted at the tip, head and sides of the thorax yellow.

**BIPUNCTULATA.** a species of **Coccinella**, of a black colour, with red spots, and fuscous abdomen. Linna. Fn. Suec.

**BIPUNCTULATA.** a species of **Hispa**, with ferrated antennæ; black and hairy, with a rufous spot at the base of the wing-cases. This kind inhabits Italy. Fabricius.

**BIPUNCTULATA.** a species of **Leptaena**, that inhabits Upflal. The wing-cases are black, fruited with dots, and two tesselated spots. Thunberg, &c.

**BIPUNCTULATA.** a species of **Nidulina**, of an ovate form, and black colour, with a red spot on each of the wing-cases. Fabricius and Gmelin. This is **Silphia oblonga nigra**, &c. of Linna. Fn. Suec. and Synt. Nat. Silpho, of Degeer; Derringer, of Geoffroy; and Oylama bisululata, of Lattarh. Inhabits Europe, and feeds on carcases, meat, bacon, &c.

**BIPUNCTULATUM.** a species of **Opaterum**, that inhabits Pomerania, and is about the sixth part of an inch in length. Its form is narrow and elongated; colour fuscous; wing-cases slightly grooved.

**BIPUNCTULATUS.** a species of **Atelius**, met with in North America. It is black, with a rufous spot at the base of each of the wing-cases. Fabricius.

**BIPUNCTULATUS.** an insect of the genus **Carabus**, in Gmelin's edition of the *Systema naturae*. This is the true **Carabus crux major** of Linnaeus, which Fabricius misconceiving, describes as a new species, in his work entitled "Species Infaetorum," under the name of *Bipunctulatus*. By retaining at the same time the Linnean character of **Carabus crux major** under the proper name, he confines two species of the same insect. In the *Entomologia fylstematica* of Fabricius, this error is continued, and Gmelin, relying on the authority of this writer, describes them also as distinct species. See **Crux major** (Carabus.)

**BIPUNCTULATUS.** a species of *Cimex*, the general colour of which is black; thorax fuscous; wing-cases livid, and two fuscous spots on the head. Fabricius, Gmelin, &c. *Cimex calvus* of Degeer. Inhabits South America.

**BIPUNCTULATUS.** a species of **Cryptochephalus**, described by Fabricius as being of a black colour, with a rufous spot at the tip of the wing-cases. Obs. The figure referred to in Schäffer *Vierzehender Fallkäfer*, is not black, but of a light
light or azure blue, rufous at the apex of the wing-cases; and the antennae of the same colour. It is an European insect, and inhabits the flowers of the chrysanthemum. Gmelin confiders it as Crypsophalus pude of Laihart.

Bipustulatns, a species of Dermea, that is black and glossy, with the head, thorax, and spot at the base of the wing-cases red. Thunberg. This is &p; huncaria of Fabricius. Country unknown.

Bipustulatns, a species of Dytiscus, described by Fabricius. It is smooth and black, with two red spots on the posterior part of the head. This inhabits the north of Europe.

Bipustulatns, a species of Dytiscus, that inhabits Germany. This kind is black; thorax yellow, with two black spots; wing-cases yellow, varied with brown. Fabricius.

Bipustulatns, a small species of Elater, found in woods in England and other parts of Europe; the colour is black and shining, with a red spot at the base of each of the wing-cases. Linna. Marth. &c. Obf. By mistake this insect is thus described by Gmelin, Nigr. nitidus, dytris puncto beffr. nigr., with reference to the Fabrical Species Insectorum, in which the dot at the base of the wing-cases is said to be red. This is Elater paratus of Panzer; and Le Taupin noir à taches rouges of Geoffroy.

Bipustulatns, a species of Gyrillus, in the section locula, of a pale brown colour; sword at the extremity of the abdomen, and two spots on the thorax black; wing-cases yellowish, suffused with black, and shorter than the wings. Gmelin, &c. This insect is rather less than an inch in length according to Schaeffer's figure, exclusive of the antennæ, which are rather longer than the body. Inhabits Europe.

Bipustulatns, a species of Scarabeus, of a black colour, with a rufous spot on each of the wing-cases. A native of New Holland. Fabricius.

Bipustulatns, a species of Staphylinus, that inhabits the northern parts of Europe. Colour black, with a ferruginous dot on each of the wing-cases. Linna. 

Biquadrate, or Biquadratic power, in Algebra, and Arithmetic, is the next power above the cube, or the square multiplied by itself. Thus 16 is the biquadrate, or 4th power of 2, or it is the square of 4, which is the second power of 2, or 2² = 4; and 4² x 4 = 16.

Biquadrate Equation, an equation raised to the fourth power, or where the unknown quantity of one of the terms has four dimensions: thus x⁴ + ax³ + bx² + cx + d = 0 is a biquadratic equation. See Equation.

Biquadrate parabola, in Geometry, a curve line of the third order, having two infinite legs tending the same way. See Parabola.

Biquadrate root of any number, is the square root of the square root of that number: thus the biquadrate root of 81 is 3; for the square root of 81 is 9, and the square root of 9 is 3; the biquadrate root of 16 is 2.

Biquarial, in the Customs of the Algerines, a cook of the divan. The janizaries, whom the Algerines call adelachi, after serving a certain time as common soldiers, are preferred to be biquarals, or cooks of the divan, which is the first step towards arriving at higher preferments. Biquarals have the care of furnishing the officers and commanders of the Algerine beldiery with meat and drink in the camp, in garrison, &c. From biquarals they are made adelachi; that is, corporals of companies, or commanders of squadrons.

Biquintile, an aspect of the planets, when they are 144 degrees distant from each other. It is thus called, because they are distant from one another by twice the fifth part of the 360 degrees. See Aspect.

Bir, or Biradschik, in Geography, a town of Asiatick Turkey in Melopotamin, fected on a mountain near the ealt coast of the Euphrates, in a very fertile country, the residence of a bey; 100 miles S. W. of Dianbeck.

Birabetane, in the Botanical Writings of the Ancients, a name given to Verbena, or vervain, and to other herbs used in sacrifices. It is only the word bihebertane, as altered by the Æolick manner of writing and speaking it. Hierobotan is the common Greek name of vervain, and other sacrificial herbs, and it is probable that the Latin name verbena came from the Æolick manner of speaking this word. All those herbs, which were laid upon the altars on solemn occasions, such as making of peace, and other solemn contracts, and were to be taken up by the contracting parties as part of the ceremony, were called by the Greeks hierobota, that is, sacred plants, and verbena; but as the plant we now particularly know by the name verbena was more frequent in use than any other on this occasion, it was afterwards distinguished by that name. See Verbena.

Bir-al-Cadhi, in Geography, a town of Persia, in the province of Segellan, 80 miles west of Zireng.

Birboom, a town of Hindoostan in Bengal, 36 miles W. by S. W. of Moorabbad; 100 N. N. W. of Calcutta. N. lat. 24°. E. long. 87° 57' 37.

Birbusca. See Birrisca.

Birch, Thomas, in Biography, an English historical and biographical writer of extensive and indelible repute, was born in London, November 23, 1705. His parents were Quakers; and he was intended for his father's trade, which was that of a coffee-mill maker; but so strong was his inclination to literature, that he requested leave to indulge it on the condition of providing for himself. Accordingly he became assistant to the master of a school belonging to the Quakers at Hemel-Hempstead; and after a similar employment in other situations, he at length deserted the profession of his parents, and though he had not enjoyed the advantage of an university education, took orders in the church of England. In 1732, having been ordained deacon in 1730, and priest in 1731, he was preferred under the patronage of lord chancellor Hardwicke, who was then attorney-general, to the living of Ulting, in the county of Essex. Some time before he took orders, he married the daughter of a clergyman; but the bed within 12 months after their marriage. In 1735, he was admitted into the royal society, and also into the society of antiquaries; and of the former society he became secretary in 1752, which office his declining health obliged him to resign in 1762. In 1753, the degree of doctor in divinity was conferred upon him by the Marischal college of Aberdeen, and in the same year he received the same honour from Dr. Herring, archbishop of Canterbury. He was also a director of the society of antiquaries, and a trustee of the British Museum. His church preferments were various, and rapid in their succession; but the last of these was the rectory of Depley in Essex, which he held, together with the united rectories of St. Margaret Pattens and St. Gabriel, Fenchurch-Brect, till his death. This melancholy event happened in consequence of a fall from his horse betwixt London and Hampstead, January the 19th, 1766. Having, in the course of his life, generously allided his relations, he bequeathed his library of books and MSS. to the British museum, and the residue of his property, amounting to little more than 52l. for the purpose of augmenting the salaries of the assistent librarians.

Dr. Birch was distinguished by the simplicity of his manners, and the friendliness and benevolence of his disposition. He was eminently active and zealous in promoting literary and laudable undertakings of various kinds; and though he devoted much of his time and attention to pursuits of literature, he gained leisure by early rising for indulging himself.
in the pleasures of social intercourse with persons the most distinguished for their attachment to letters and science. With respect to theological subjects, his sentiments were rational and liberal, and he was a zealous friend to religious and civil liberty. In this respect his views and principles were conformable to those of the truly excellent bishop Hoadly.

In literary labour few persons have been more diligent and indefatigable than Dr. Birch. The first great work in which he engaged was, “The General Dictionary, Historical and Critical,” comprehending a new translation of that of Mr. Bayle, and several thousand new lives, never before published. This valuable work was completed, principally by himself, with the co-operation of the reverend Mr. John Peter Bernard, Mr. John Lockman, and Mr. George Sale, in 10 volumes, folio. The first volume appeared in 1734, and the last in 1741. In 1737, he published “Professor Greaves’s Miscellaneous Works,” 2 vols. 8vo.; and in 1742, “Thurlow’s State Papers,” in 7 vols. folio, with a dedication to lord chancellor Hardwicke. In 1743, he edited “Cudworth’s Intellectual System,” his “Discourse on the Lord’s Supper,” and “Two Sermons,” with a life of the writer, in 2 vols. 4to. His “Life of the Hon. Robert Boyle,” 8vo., which has been since prefixed to the 4th edition of that eminent philosopher’s works, appeared in 1744; and in the same year he began a series of biographical sketches of distinguished persons, designed to accompany his portraits by Bowkran and Vertue. The first volume of this work was completed in 1747, and the second in 1752. In 1747, he published in 8vo. “An Inquiry into the Vear which king Charles I. had in the Transactions of the Earl of Glamorgan, &c.” a fact which, however overlooked, or disputed by some of our historians, was confirmed by the evidence adduced in this interesting publication, and has been since further corroborated by the Clarendon state papers. In 1748, Dr. Birch was the editor, in 2 vols. 8vo., of the “Miscellaneous Works of Sir Walter Raleigh,” to which is prefixed a life of the author. His next publication was “An Historical View of the Negotiations between the Courts of England, France, and Brussels, from the year 1592 to 1617; extracted chiefly from the MS. state papers of sir Thomas Edmondes, and of Anthony Bacon, &c.; to which is added, a relation of the state of France, with the character of Henry IV, and the principal persons of his court, by sir George Carew,” 8vo. 1749. To this volume Dr. Birch has prefixed a discourse on the utility of declaimed persons, on the original letters and papers preserved of the persons who were the principal actors in public affairs, followed by a biographical account of the three negotiators above-mentioned. Mrs. Cockburn’s “Theological, moral, dramatic, and poetical works,” 2 vols. 8vo., with the life of that ingenious lady, were edited by Dr. Birch in 1751; and he also published an edition of “Speacer’s Fairy Queen,” in 3 vols. 4to. One of his most popular works, which was “The Life of Archbishop Tillotson, compiled chiefly from his original papers and letters,” and dedicated to archbishop Herring, in one volume, 8vo., appeared in 1752; and in the following year he revised an edition of “Milton’s Prose Works,” in 2 vols. 4to., to which is prefixed a new life of the author. In 1754, he published in 2 vols. 4to. “Memoirs of the reign of Queen Elizabeth, from the year 1581 till her death,” &c. from the papers of Anthony Bacon, &c., and other MSS. never before published; in which, besides a full display of the tenors and actions of the earl of Essex, much light is thrown on the characters of the Cecils, Bacons, and other eminent persons of that period. Dr. Birch’s next publication was “The History of the Royal Society of London, from its first rise; in which the most considerable of those Papers communicated to the Society, which have hitherto not been published, are inserted in their proper order, as a Supplement to the Philosophical Transactions.” The two first volumes of this work appeared in 1756, and the other two volumes in 1757; and they bring down the history to the end of the year 1687. This is unquestionably an useful book of reference, and contains many particulars which may be of occasional service both to the philosopher and the biographer. In 1760, Dr. Birch published “Letters between Colonel Robert Hammond, Governor of the Isle of Wight, and the Committee of Lords and Commons at Derby-house, &c. concerning the King’s department at Hampton Court, and in the Isle of Wight,” 8vo.; and he closed his voluminous labours with “Letters, Speeches, Charges, Advices, &c. of Francis Bacon, lord viscount St. Alban’s, &c. in one volume, 8vo. Soon after his death, Dr. Maty published, “The Life of Dr. Ward,” which he had just lived to finish; and he had also prepared for the press, “Historical Letters, written in the reign of James I. and Charles I.” which Mr. Aycough was proposed to publish. In the list of his printed works we might also comprehend some papers communicated to the Royal Society, and some accounts of books in the works of the learned; but besides such, this was his unvaried affiduity in collecting every fragment pertaining to literature, and deemed by him of importance, that he left behind him 24 volumes 4to. of various papers copied by himself from the Lambeth Library. Upon the whole, whatever may be thought of Dr. Birch’s judgment in his detection of materials, of the minuteness of his references, of the justice and fagacity of his inferences from the facts which he produces, and of the want of elegance and animation in his style, it must be allowed, that literature has already derived, and may yet further derive, great benefit from his labours. Biog. Brit.

**Bird, or sweet-meat grafs, in Agriculture, a species of grafs, which has been lately cultivated with a particular attention. It is a fine, sweet, silky gras, with a durable ver¬ture; throws out a great crop, and produces a large quantity of feed. One rood of ground yielded a hundred weight of feed, and a very large load of hay. It is most proper for upland meadow; the feed should be left uncovered on the ground.**

**Birds, Anatomy of.** The regard which has been bestowed upon this tribe of animals, by different descriptions of mankind, renders their organization one of the most interesting branches of general anatomy. The immense catalogue of the species of birds, and the variety and beauty of their external characters, have made them favourite objects of investigation with the natural historian. The extraordinary degree of instinct displayed in all their habits and economy, more especially in the attachment of the sexes, the contraction of their nests, the care of their young, and the conduct of their migrations, have called forth the admiration of the philosopher and the lover of nature. The splendid colouring of their plumage, the powers of melody, and the liveliness and facility of many species, have given them value as objects of beauty or entertainment; whilst others
are as highly prized from furnishing occupation to the
sportsman, or a delicacy to the epicure.

The anatomical characters of this class of animals, are not
less deserving of attention than their other properties. In the
scale of animated existence, birds can scarcely be considered
inferior to mammals; and yet many of their functions are
exercised upon a very different plan, and almost constantly
by organs differently constituted. It is in birds that we
perceive the first general deviations from the scheme of orga-
nization pursued in the human subject: this will be found
most remarkably exemplified in the apparatus for the prepa-
ration and digestion of food, the secretion of urine, the mode
of generation, and the growth and economy of the young
animal, the anatomy of the brain, the structure of the eye
and ear, the mechanism of the organs of sound, and the con-
fstruction of the instruments of loco-motion.

The anatomy of birds has been much professedly both by
the older authors and in modern times, as the means of phyl-
ological knowledge, and in aid of the several purposes for
which these animals are so much esteemed. The information,
however, communicated in this way, falls far short of a sys-
tematic account of the subject: to supply which, therefore,
many original matters are necessarily introduced into the pre-
cent article, more particularly in the descriptions of the blood-
veins, of the organs of motion, and of the minute struc-
ture and uses of parts. Many errors of the older writers are
also corrected; and wherever the descriptions of others are
followed, they have been, as far as it has been practicable, re-
vised by a comparison with the recent subject or authentic
preparations.

**Organs concerned in the Exercise of the Vital Functions.**

The **Mouth and its contained Parts.**

In the other classes of animals, these parts are con-
structed to effect the division of the food previous to its
passage into the stomach, but in birds the processes of mali-
tication is either imperfectly performed, or carried on
by a peculiar mechanism to be afterwards described. Birds
are provided with those soft and flexible parts called lips; the aperture of their mouth is made by the
prolongation of the two jaws, which are covered with a
hard and horny substance. These are named the upper and
the lower mandibles, and together form the beak or bill.
The bones which enter into the composition of the bill, will
be considered along with the other parts of the skeleton.
The external or horny part is produced, like other similar sub-
fances, from a vascular and spongy membrane, which is
interposed between it and the bones; it corresponds exactly
in shape with the jaws, which serve it as a mould.

The bill is designed for many different purposes, and con-
fsequently is subject to great variety in its composition. In
the birds of prey it is strong, hooked, sharp, and furnished
with a tooth-like process on its edge, to enable them to the
better to seize and lacerate their prey; those birds which
feed on small grain, are provided with short, pointed,
sharp-edged bills for picking up and breaking their food;
the parrots also use their bills for dividing their meat,
in those instances, therefore, the bill may be considered analog-
ous to the teeth of other animals; but it is only the inci-
encers with which it can be compared, as it is incapable both
from its thin edges, and from the nature of the articulation
of the lower jaw, of performing any thing like the grinding
motion in which properly mastication consists.

The **pigeons** birds have commonly large and extended
bills, which become necessary to them, in order to secure
their prey; these birds almost always swallow their food
without dividing it.

Swallows and goats-fishers have short bills, but opening
very wide, suitable to their mode of procuring their food,
which consists in taking flies while the bird is on the wing.
The **wood-peckers, wry-necks, nut-bashers, &c. use the bill
as an instrument for perforating the barks of trees, and break-
ing nuts; for which purpose it is constructed like a wedge.

It may, in fine, be given as a general observation, that
the form and structure of the bill indicate the proper habits
and economy of the birds; they have therefore been al-
ways employed by naturalists as characteristic distinctions, and to
their works we refer the reader for a more detailed account
of the peculiarities observed in the bills of birds.

In consequence of a particular mechanism, arising from
two additional bones, the upper jaw of birds is capable of a
certain degree of motion. In general this is very confined,
but the parrot tribe are able to move the upper jaw with
considerable freedom. The bones and muscles upon which
this peculiarity depends, will be described with the organs
of motion.

The **cavity of the mouth** is lined with a thick vascular mem-
brane, behind which are placed a great number of follicular
glands, which discharge a mucous liquor upon every part of
the surface of the mouth. They are, however, most abun-
dant in those parts which sustain most friction, as the com-
 mencement of the oesophagus, and surrounding the aperture
of the nares, in the upper and back part of the mouth.

A cuticular tunic is spread over the glandular membrane,
which is as usual so soft and delicate, that it cannot without
difficulty be detected.

The **tongue of birds** can hardly be considered an instru-
ment of mastication; its motions are very limited, in con-
sequence of its containing a bone which runs through its
whole length, and the lingual bone being articulated behind
with the os hyoïdes, which determines the extent of its move-
ments. The only birds, in which the tongue is immediately
concerned in the division of the food, are those **puffers** living
upon seeds that are inclosed by a shell. In such the tongue
is employed to convey the food between the edges of the
bill, and secure it there until it is broken, which is not un-
like the action of the tongue of mammals during mastication.

The tongue of the **wood-peckers and wry-necks** is an organ
of curious structure, and enables these birds to transfer
their prey at some distance from the mouth; the mechanism
by which this is accomplished, and the bones and muscles which
belong to the tongue in general, will be particularly described,
with the other organs of motion. The varieties in external
form, and the structure and integuments of the subinance
of the tongue, will be considered under the head of the organ
of taste.

**Salivary glands** have been ascribed by most authors to
birds; but as it would appear, without duly considering the
uses of these parts. Birds, as already observed, do not com-
minute their food by mastication in the mouth, for which
purposes the saliva is employed by other animals; and the
glandular bodies, which have been described as salivary, ap-
pear to yield a fluid of rather a mucous than an aqueous
nature. The internal surface of the mouth of birds is be-
smeared with mucus, in order to facilitate the passage of the
food, which would not be necessary, if the aliments were
softened by saliva.

The salivary glands of birds are situated within
the angle formed by the anterior part of the lower jaw, and
between the skin and the inner membrane of the mouth.
They are two in number, and appear to be composed of
granular masses, or follicles, closely connected to each other.
They discharge their secretion into the lower part of the
mouth, by means of some foramina arranged on each side of
the
the tongue. They would seem to be of the greatest size in proportion to the bird, where the food is hard and dry grain; they are larger in the common fowl than in the geese.

The Parian academicians observed these glands in almost every kind they dissected. In the ostrich they describe them as being situated towards the pharynx; and in the bustard, they found several glandular bodies.

Oesophagus.

The tube, which conveys the food into the stomch of birds, is not situated exactly on the fore part of the neck, but a little on the right side. It is partially covered by the trachea, and it is connected to all the neighboring parts by loose cellular substance; in consequence of which, and its inclination to one side, when the neck is much bent, it does not take the same degree of flexure, but falls a little off to the right side. This effect is best observed in some of the birds which have long and flexible necks, as the gralla and water birds.

The form of the oesophagus varies according to the habits of the bird, and the nature of its food. In the capacious birds, and those which feed on fish, it is of great capacity throughout its whole length, generally exceeding in depth the breadth of the bird, and being more and more compressed in its progress. The magnitude of the oesophagus not only enables these birds to swallow their prey whole, but answers the purpose of a reservoir for their food, and thus counterbalances the draf-t-cuttings arising from their precarious means of subsistence.

Herons, the cormorant, the spoon-bill, &c. will devour as much fish at once as will be sufficient to support them for a considerable time; and an eagle is often obliged to exist for days or weeks upon a rat or mouse, which being swallowed, is conveyed by degrees into the stomch, until the whole is digested.

All the pidgeonous birds have the oesophagus most capacious at its commencement, or next the fauces, for the more convenient swallowing of their prey, which is always gulped down.

The pelican furnishes a most remarkable instance of a dilatation of the fauces, in the pouch which is placed beneath the lower jaw. This bag, if full, is very conspicuous externally; but when it is empty, the bird has the power of contracting it very considerably; when completely distended, it is said to be capable of containing ten quarts of water. The internal part of the pouch is peculiar to itself. The form of the oesophagus, the skin covering it externally, is clothed with a short down, smooth and soft, like fowl.

The pelican derives a double advantage from this enlargement of the fauces; it enables it to provide a supply of food and water for future necessity, and to transport nourishment to its young, until they can acquire it for themselves; in disgorging the food for their family, the parent presses the bottom of the sac against her breast, and thus discharges its contents; from which probably arose the absurd fable of her opening her breast, and feeding young with her blood.

A very remarkable provision of this kind has been described in the bustard, by Dr. James Douglas. In this animal there is a membranous bag, extending for some way down the fore-part of the neck, capable of containing seven quarts of water; it communicates with the mouth by an aperture beneath the tongue. See Plate I. fig. 1. in the Anatomy of Birds, in which this part is represented, as it has been figured in Edwards' Natural History of Birds, vol. ii. p. 73.

The pouch, upon which a ligature is fastened near its connexion with the mouth, b the trachea, and c the oesophagus.

The pouch of the bustard is confined to the male bird, according to most authors; some have, however, ascribed it to the female, and others have doubted its existence altogether. The Parian academicians dissected six bustards, and do not describe the throat sac, although all their subjects were males.

The bustard is said to use the pouch, as a temporary reservoir of water, from which it supplies the female during the period of incubation, and likewise the young brood, until they can move from the nest. It has been also occasionally employed as the means of defence. Barrington relates in his Miscellanies, p. 555, that at Morocco, where it is usual to fly the hawk at the bustard, the latter has been known to eject the water contained in the sac against his assailant, who is not uncommonly by this means baffled in the pursuit.

The crop, or craves, is a term applied to another species of dilatation of the oesophagus of birds.

When this enlargement is small, it is situated upon the right side of the oesophagus, and placed so low on the neck, that a portion of the bag is accommodated in the space left at the upper part of the thorax, within the fork-shaped bone. Its form is in general globular, but rendered somewhat irregular, from its connexion with the oesophagus, which enters at the superior part, and appears again on the middle, by which means the greater part of the crop is formed into a cul de sac.

It is obvious, that the effect of this structure is not only to receive a greater quantity of food than can be digested, but also to detain it in the crop until it has suffered some change.

The birds in which the crop is found of the figure just described, feed usually upon grain or other hard substances, which require to be softened by maceration in the mucous secretion of the oesophagus. Of these we may mention as inclusions, the pheasant, the common fowl, the pintado, the turkey, the Indian cock, the peace-fowl, &c.

Fig. 2, of Plate I. in the Anatomy of Birds, exhibits the crop of the phasian; a the oesophagus above the crop, b the same going on to the stomch, c the dilated part forming the crop.

The Parian anatomists found the oesophagus very much enlarged in the ostrich, but so close to the gizzard that these two parts appeared to be confounded with each other; so that it was difficult to mark the superior orifice of the ventricle; the situation of the bag also was very unusual, being lower than the gizzard, into which the entrance was by the bottom, and thus what is commonly called the superior orifice, was really the inferior.

It is somewhat remarkable, that the bustard, which is a graminivorous bird, and in most respects resembles those which have crops, should be quite without this provision, its oesophagus consisting of an equal and regular tube.

The parrot has a dilatation of the lower part of the oesophagus, which is commonly reckoned to be a crop, though perhaps improperly, as the enlargement is neither so suddenly produced, nor in such a degree, as to obstruct the passage of the food into the stomch; the crop of the parrot is only calculated, therefore, to afford a temporary accommodation to its food.

Some carnivorous birds are furnished with a crop, which only serves the purpose of a reservoir, as their food does not stand in need of maceration to soften it, which is so necessary with hard and dry grain.

The most singular kind of crop is that found in the pigeon genus. The oesophagus in these birds is of great capacity, from its very commencement, and at its lower part it swells out into two large facks, between which and the stomch it fulfills a considerable contraction. See Plate I. of the Anatomy of Birds, fig. 3. a the upper portion of the oesophagus, b, c.
BIR

The Bulbus glandulosus, or the Zone of Gastric Glands.—This part is situated at the termination of the oesophagus, and appears in most instances to be the continuation of that tube. It has the same cellular and mucous coats, which obscure its real structure, when perceived externally, especially in the graminivorous birds, which have strong muscles upon the oesophagus, and a short crop. The outer tunics are removed, a number of small glandular bodies are exposed, and arranged with the most perfect regularity, and closely applied to each other. They assume an indistinct granular appearance in small birds generally, and even still more so in those which subsist on animal food, as the accipitrine and piziforous birds; but in the galline, and the large graminivorous water birds, as the swan, the goos?. &c. the gastric glands, when dissected of their coats, are readily discovered, by the naked eye, to be small cylinders, or tubes, placed horizontally with respect to the parities of the flomach; the external end is close of and of a round figure; the internal extremity of the tube is somewhat concave, and contains a small foramen, which is applied to a corresponding hole in the internal membrane of the bulbus glandulosus. See Plate II. in the Anatomy of Birds, fig. 1. a represents a number of the gastric glands, with their external extremity exposed, by a portion of the mucous coat being removed; and in fig. b biews the orifices of these glands upon the internal cost of the flomach, and c the cut edge of the bulbus, with the cylinders as they are placed between the mucous and internal coats. The subject of both the figures is the solid bow.

The gastric glands commonly encircle the beginning of the flomach as a perfect and equal zone. In some instances, however, where they are not large, as in the capacious and piziforous birds, they are more numerous at one part of the flomach than another; see Plate III. fig. 2. which exhibits the flomach of the heron, b b the gastric glands.

The form of the bulbus is not quite regular in the ostrich; the structure of the glands also is not the same as in other birds: instead of being placed in regular and close order, they are disposed in mazes of an unequal form and size, separated for some distance from each other. On making a section of the mazes, they are found divided or interrupted, by processes of strong white cellular substance; from which it would seem, that they are composed of several glands, although there is but one foramen belonging to each maze on the internal tunic of the bulbus. The magnitude of the orifices of the gastric glands, even exceeds the proportion to be expected from the size of the bird; being capable of receiving the head of a large pin, they stand at the distance of about the ½ of an inch longer, and do not open with perfect regularity upon the internal surface of the flomach, being most crowded towards the centre, where also their apertures are larger; the internal tunic of the ostrich, from these circumstances, exhibits a worm-eaten appearance.

The gastric glands in all birds, like other parts, which produce an important secretion, are endowed with an extreme degree of vascularity.

Some authors have described a cuticular coat, or the internal surface of the bulbus glandulosus, which they have compared to velvet on account of its soft and springy texture; it appears, however, very doubtful, whether this covering should be considered a tunic or not; we have observed that it is readily detached, and soluble in water; it certainly bears no resemblance to the epidermis of the oesophagus, and still less to the flumach which invests the remaining portion of the flomach, or gizzard.

No very satisfactory experiments have yet been made upon the nature of the digestive fluid of birds. When it is expressed from the gastric glands, which is the only mode of obtain-
obtaining it pure, it is observed to be of an ash or pale yellow colour, turbid, and of a tenacious consistence, like mucous. Spallanzani found it in several birds to have a bitter and salt taste, which he attributed to admixture with some of the fluids contained in the intestines; he discovered also, that the turbidity and the colour were produced by the existence of a number of yellow particles, too minute to be distinctly seen without the aid of the microscope, and which in a few hours subsiding to the bottom, left the supernatant liquor as transparent as water. He has remarked the yellow tinge to vary in intensity, according to the species; in the eagle, for instance, it is cinnibar, and in the crow a reddish yellow colour, like the yolk of an egg.

A number of the experiments performed by Spallanzani, although in many instances he failed, shew that the gastric fluid of carnivorous birds will act upon vegetable matters and upon the other hand, that granivorous birds can digest animal food: but his most interesting and important experiment on the properties of the gastric fluid, is that made to determine its powers of reflothing the operation of cold. "On a very cold day in winter," he says, "I exposed a small quantity (of the gastric juice of the eagle) in a glass, on a window, along with other two glasses containing water, in one of which was disposed a quantity of common salt, sufficient to give it a stronger taste than the gastric fluid had. The thermometers set beside the glasses stood at five degrees below o (twenty and three-fourths, Fahren.). Of the three liquors, the first that was frozen, was the common water, the next was the salt water, and the last was the gastric fluid. When I carried them into my apartment, where the temperature was three and a half deg. above o, the first that thawed was the gastric fluid, next the brine, and lastly the water." The conclusion which necessarily results from this experiment is, that the gastric juice of birds, and from analogy, that of other animals, is capable of reflothing the effects of cold more than common fluids, or even those impregnated with a great quantity of salt; and therefore it may be considered as possessing the degree of vitality. If this supposition be admitted, it determines the nature of the digestive processes, to long a question in physiology.

The gastric fluid of the crow has been submitted to chemical examination by Scopolii, by which he discovered that it contained a quantity of gelatine and faeces substance, some muriate of ammonia, and phosphatce of lime, with a large proportion of water.

The second part of the organ of digestion of birds, is not less singular than the structure just described; it immediately succeeds the zone of gastric glands, and when in the natural situation, occupies the left region of the abdominal cavity, in which position it is retained by the several reflexions of peritoneum, which constitute the air cells. From being the part into which the food is received in order to undergo the process of digestion, it has commonly received the distinctive appellation of stomach; but it would seem more confident, not only with the form of the digestive organ in some birds, and with its functions in other animals, to apply the term stomach, both to the gastric glands, and to the mucous bag which immediately receive their secretion, and the food; or for the greater convenience and清晰ness of description, the lower portion of the stomach might be distinguished from the bulbous glandulofus, by the name of ventriculus.

The greatest variety exists with respect to the structure of this part of the organ of digestion in birds: when it possesses a certain degree of mucularity, it is well known under the name of the gizzard; and when its muscles are so thin as to give it the appearance of a ample bag, it is commonly, though erroneously, called a membranous stomach.

Fourcroy attempted to establish two classes of birds, according to the formation of their stomachs, calling the one nyctogastriques, and the other hymenogastriques, but these terms were only applicable to the two extremes.

Vie d'Azir has admitted three distinctions in the structure of the ventricle: the first that of the true gizzard, of which he gives inclusions in the galline, the foau, the gogo, &c.; the second where the muscles which compose the gizzard are not distinct from the other parts, nor very strongly marked, as in the thryrs and way; the third is the membranous stomach, as it is called, which is found in the heron, eagle, corvornat, &c. See the introduction to Vie d'Azir's Great System of Anatomy.

These distinctions are not, however, just; the gradation from the most mucular gizzard to the thinnest ventricle, is regular and uninterrupted; in order to understand which, and the other variations in structure, it is necessary that the true gizzard, or muscular stomach, be first described.

The external form of this organ is usually an irregular oval, the two ends of which are made of the great lateral or digastric muscle.

This muscle constitutes the principal mass of the gizzard; its attitude with respect to the bulbus glandulofus is oblique. The two thick muscles are united by means of a strong flat tendon, on each side of the gizzard, which in the centre is distinct from the parietes of the ventricle.

The portion of the stomach, which appears between the two thick muscles of the digastric muscle, and which is crossed by the tendon, belongs to the cavity of the ventricle; it is composed of fleshy fibres, passing in several directions, as may be most convenient for diminishing the cavity. Many of these fibres are continued into the substance of the digastric muscle, and others run in its outer margin, thus giving integrity and connexion to these two portions of the ventricle. See Plate II. fig. 1. in the Anatomy of Birds, which represents the external appearance of the stomach of the wild foau, b, b, the fleshy parts of the digastric muscle, c, the tendon connecting them to each other, d, the parietes of the ventricle on the superior part, e, the fame, inferiorly, f, the margins of the digastric muscle, with fibres passing along them.

The disposition of the fibres in the interior of the digastric muscle is exceedingly curious. They appear, upon a superficial view, to be arranged in thin concentric laminae, separated from each other by the most delicate tendon. These layers pass to the lateral tendons on the circumference, so that their force is exerted upon them. See Plate III. fig. 1. which is the section of the gizzard of the foau, a, a, the two great muscles of the mucous substance, b, b, the tendons by which they are connected to each other. But if another section be made, parallel to the fides of the gizzard, or across the concentric layers, we have found each of the laminae to be divided by a great number of delicate tendinous processes which form with each other figures and triangles of various shales, producing a reticulation, not unlike a honeycomb. The extraordinary multiplication of muscular fasciculi, which arises from the lamellated and reticulated structure of the gizzard, creates a force which almost surpasses calculation.

On laying the gizzard open by cutting through the tendon, which is the thinnest part, it is observed to be covered internally with a rude, callous substance, of a dark brown colour: this is thin and pliable upon the portion of the ventricle, not included by the digastric muscle, and partakes of the motions of the cavity; but when it covers that muscule, it becomes as tough and inflexible as the hoof of a quadruped; two oval surfaces are seen to project beyond the other parts; they are raised upon the interior of the thickest portions of the digastric muscle, and the horny integument when
When passing over them, they acquire nearly the thickness of an eighth of an inch. Plate II., fig. 2, in the Anatomy of Birds, shews the gizzard of the wild fowl laid open, d, the divided tendon, e, the cuticular or horny covering of the gizzard, ending decidedly at the commencement of the intestine, and below the zone of gastric glands; at the latter place the edge is shewn detached, f, the two prominent oval surfaces, g, the origin of the intestine, which being cut off short on the outside permits the light to appear through it.

The cavity of the gizzard differs very much in shape and extent from what might be expected, from the external figure of that organ. When all foreign matters have been expelled, the two prominent oval surfaces approach each other, leaving only a slit between them; any thing that defies the name of a cavity, is situated above and below the place where the tendons cross (see Plate II., fig. 2), for just within the tendon there is not cavity sufficient to contain the end of a finger. See Plate III., fig. 1, which shews a section in which the two oval surfaces are applied to each other, leaving at either end the appearance of a round hole, by means of which the superior and inferior cavities of the ventricle have communication.

When the horny or inelastic lining is removed, there appears another coat to the gizzard. This is soft, somewhat pungent, and endowed with vescularity; it is intimately united to the muscular substance of the ventricle, on one side, and on the other affords a surface for the adhesion of the horny coat; the connexion with which appears to depend upon the mutual intertusion of villous processes, too fine to be distinctly perceived by the naked eye.

Such is the description of the muscular ventricle, or true gizzard, as it exists in the swan, the goose, the duck, the phaeton, and common fowl, the pouter, the turkey, and a few others. In by far the greater number of birds, there is a deviation from the structure of the gizzard. The digastric muscle is less powerful, its tendon is incorporated with the randicles of the ventricle; the oval, or grinding surfaces are little or not at all distinguishable from the rest of the cavity, which is therefore of larger capacity; and, lastly, the substance lining the ventricle is less tough, thick, and hard, approaching more to the nature of cuticle. It would be endless to enumerate all the various differences of intermediate structure, which we and others have observed; suffice it to say, that it exists in almost all the penguins, or small birds which subsist upon a mixed food, such as grain, worms, insects, and fruits; also in most of the order scapuloria, and in many of the quail and anseres, which are pursued as game. In all which instances the deviation from the true structure of the gizzard varies in degree according to the nature of the food used by the bird; nav, differs from this cause in the same degree. Thus the gull has a strong muscular ventricle, when fed upon grain, which, if the bird be supported by fish, becomes so thin as to approach the membranous stomach.

It is remarkable, that many birds which live upon grain and hard substances, have neither a very muscular ventricle, nor the horny integument very thick. This is the case with all the struthiors birds, and some gulls, as the black. The stomach of the otis is capacious; the digastric muscle is thin, confiding the size of the bird, and the nature of its food; and the cuticular coat is so soft, that it has been aptly compared by several authors to flannel. The Parian anatomists describe the stomach of the ostriches as being thinner than that of the gischus, and divided into two parts by a valvular projection of the inner coat.

When the digastric muscle becomes so thin as to form a mere layer of fibres, in clofe union with the other coats of the stomach, and its tendons only fine aponeuroses, expanded on each side, the ventricle is termed membranous; an improper appellation, as much as the very same parts exist, which belong to the powerful and mafly gizzard, although in a diguged and diminished form, and unequal to the same functions; affording thus a curious example of the uniformity with which nature copies her own works.

This species of stomach is almost confined to the accipitres, or rapacious birds, and those amongst the gallea and anseres, which feed on fish. The woodpecker also poiffeis it, and probably it may be found in some f conversal birds, which live on insects and soft fruits.

The substance lining the membranous stomach is much thicker than common cuticle. It is occasionally soft, and almost of a gelatinous consistence, and easily detached from the internal coat of the ventricle.

The shape of this kind of stomach is usually a semi-oval, or the section of an egg. Several of the pheasant bird, as the heron, citrinus, pelican, &c. have, however, a second chamber, through which the food pauses in its way to the intestine. See Plate III. in the Anatomy of Birds. Fig. 2, is the stomach of the heron; a the lower part of the esophagus, appearing smaller than it really is, from being thrown into folds; b the zone of gastric glands, distinctly seen through the coats of the stomach, in consequence of the cavity being diluted with a transparent fluid, and afterwards placed against the light. If Spallanzani had employed the same expedient, he could not have denied the existence of a distinct glandular structure to the heron; c the inferior part of the stomach, chiefly composed of muscular fibres, spreading in a radiated manner from the lateral appendages; d, which supplies the place of the great tendons of the digastric muscle; e the second stomach, furnished with circular muscular fibres; f the first intestine arising from the additional ventricle. The communication between the two stomachs is very strict in the pelican.

Having described the structure of the digestive organ of birds, it remains to consider its functions. In these cases where the muscular power of the stomach is incomparable, and the cuticular coat thin and soft, digestion is carried on in the same way as in man and other animals, with this difference only, that the gastric fluid is formed by a distinct apparatus of glands, instead of being secreted by the whole surface of the cavity. In the true gizzard, however, we perceive an extraordinary departure from the common structure of the organs of digestion. This part supplies the place of the teeth of other graminivorous animals. In its mechanical powers and action it resembles a mill; the upper part serves as the receptable for the grain; the two internal projecting oval surfaces correspond to the mill stones, and the first intestine receives the substances in the ground or divided state. The experiments made at the academy of Cimento, and those of Rennear, Spallanzani, and others, shew that the gizzard is a machine of no ordinary powers. These experiments consisted in compelling birds to swallow hard and unyielding substances, and, after some hours, examining what were the effects produced upon them.

When balls of glass, or other brittle substances, were employed, they were speedily reduced to powder; metals and precious stones were indented or studded. Spallanzani introduced into the gizzard of the turkey, and common fowl, leaden balls, armed in one instance with twelve sharp needles, one quarter of an inch long; and in another, set with as many lancet points. Upon destroying the birds 18 hours afterwards, the needles and lancets were found broken off, and marks of impression appeared even upon the balls themselves; and, what is considered more extraordinary, the coats of the gizzard were perfectly uninjured.

When we con-
BIRD

BIRD

consider the immense strength which is obtained by the arrangement of the muscular fibres in the gizzard, and the horny condensation of its inner coat, there appears nothing incredible in these effects. And there is still another circumstance, not before the proceeds of which fully accounts for such extraordinary powers of trituration: every muscular stomach or gizzard contains a number of small flumes or pebbles; the size of the flumes is proportioned to that of the bird. Their number is subject to vary from many accidental causes. Two hundred have been reckoned in a turkey-ben, and above a thousand have been taken from the gizzard of one goose.

Spallanzani denied that these flumes were at all required for the comminution of the food. He has endeavoured to support his opinion by several experiments, which are, however, not clear or convincing with each other, and in contradiction to general observation; for it is well known, that birds do not thrive when they cannot obtain small flumes, and that it is part of the duty of the parent to provide them for their young, before they leave the nest. Spallanzani acknowledges that he could not procure any bird to young, that it had not some flumes in its gizzard; and therefore he was obliged to rear pigeons and turkeys even from the shell, before he was able to succeed. Birds, so far from swallowing small flumes from kennels of appetite, or in mülake for food, forced out and select those most suitable to their purpose, which are almost all bits of quartz, of an equal size, and a roundish figure, with many small sharp angles.

Large birds, as the struthion kind, the buffaloe, &c. are in the habit of swallowing coins and pieces of metal, which necessarily suffer a reduction by the friction to which they are exposed; and hence has arisen the ridiculous notion of the gibrch digesting iron.

We have no hesitation in deciding, that the extraneous bodies found in the gizzard are absolutely required for the perfect division of the food used by those birds that employ them. In further proof of which opinion it may be mentioned, that they are proportioned in quantity to the degree of musculature polished by the ventricles, and the nutritive quality of the food; and that those birds which have thin stomachs, and live upon animal food, never digestedly swallow flumes, or other indigestible substances.

In order to ascertain the mode of operation of the gizzard in the living body, Rauaner opened several fowls during digestion, and saw every motion in the part, which was confirmed in alternate contractions and dilatations, swiftly and gradually performed. Spallanzani instituted similar experiments upon several birds, with no better success; being unable to detect the least motion; and when he did perceive any, it was irregular, partial, and indistinct. This he attributed to the violence committed by opening the animal's body, which no doubt causes the motions to be less strong and regular; but the gizzard's exhibiting externally so little action, depends upon the disposition of the fibres, in the interior of the digastric muscle, which are calculated, not for performing extensive motions, but for exerting an immense concentrated force upon whatever may come within their influence.

The most satisfactory, as well as convenient mode of examining the actions of the living gizzard, is to provide a very lean, young bird, which has thin paricles to the abdomen. The side of the belly being deprived of feathers, all the motions of the gizzard can be both felt and seen. We have thus observed them to contract in alternate contractions of the digastric muscle, and of the intermediate parts of the ventricle. When the muscle acts, its figure is not perceptibly changed, but it feels as hard as a flume upon its relaxation, the paricles of the ventricle urge their contents again between the two grinding surfaces, when the muscle repeats its powerful contractions, by which the substances interposed are submitted to a pressure like that of a vice, accompanied by a slath rolling motion of the surfaces upon each other. These alternate actions succeed each other very slowly, but with regularity.

When the food and flumes roll under the pressure of the digastric muscle, a sound is heard exactly like what is produced by the tide coming upon a shore, where there are many loose flumes. This occurs with the same intervals of time, also, which are observed between the flux and reflux of the tide; and if the ear be applied to the body of the bird, during the time that the gizzard is in action, the sound of the ebbing and flowing of the tide is imitated to perfectly in loudness, and every other respect, that it is difficult to conceive it is occasioned by any other cause.

During the time that the food is undergoing a very minute division, in the manner described, the gibrch juice is diluted from the bulbous glandulosus in greater quantity than usual, and a more intimate mixture is formed of the digestive fluid and the triturated food, than could be accomplished under any other circumstances; and therefore we may look upon the process of digestion in graminivorous birds, as not only more complicated, but more perfect than it is in animals in general.

Intestines.

These are divided in birds, as in other animals, into great and small, although the terms are not very appropriate; there not being in general any material difference in the magnitudes of each.

The small intestines exceed the large very much in length; they are tunited chiefly in the anterior and right side of the abdomen, where they are strictly confined by the peritoneum, which forms the air-cells. The convolutions of the intestines are very regular, and contract as successive doublings one shorter than another, which give the appearance, on opening the abdomen, of a coil of rope, particularly in those birds which have the small intestines of considerable length. This effect depends upon the figure of the meconium, which is not composed in quite the same manner as in mammals.

The distinction of the small intestines into duodenum, jejunum, and ilium, is at all times to a certain degree arbitrary, and is still less allowable in birds. The only portion which deserves to be distinguished from the rest of the tube, is the first coil, which ascends on the right side of the stomach, including in its reflection the pancreas, and receives the biliary and pancreatic ducts.

The length of the intestines is determined usually according to the nature of the food upon which the bird lives; they are longest in the graminivorous, and very short in the acute-pica. Many birds, however, which use a mixed food, or even live altogether upon fish, have the small intestines of great length; this is the case with the heron, and several others. The whole of the intestines of the cormorant, according to the Parilian anatomists, measured seven feet long; and what is difficult to explain, those of the buffaloe and seafowry, although large and graminivorous birds, were only four feet in length. The different Odriiis affected by the Academy, varied materially with respect to the length of the intestinal canal, one subject measuring fifty feet, another forty-two, a third thirty-three, and a fourth twenty-nine feet.

There is very little peculiar to be noticed in the structure of the small intestines. They are, as in other animals, covered externally by peri-toncum, have two layers of muscular fibres, and their internal surface is furnished with those innumerable fine vascular proceedes called villi. The graminivo-
BIR

eous birds have commonly the longest villi; in the goose and
swan they are singularly beautiful, floating a considerable
way into the cavity of the intestines. The birds of prey, and
those which feed on fish, have the villi in general so small
and indistinct, that on a slight inspection, the inner surface
of the intestines appears quite smooth. The owls, however, forms
a remarkable exception to this observation in having long and
pendulous villi.

The vacular procresses upon the internal surface of the
small intestines of the *ostrich* do not possess the usual villous
or hair-like form, but consist of very thin plates, or lamelle.
These are short, with the edges somewhat round, and placed
not in succession, but alternately one with respect to another,
so that each lamella stands opposite to the interface of the two
adjoining, by which means the surface of the intestine
pens upon very exactly the appearance of twisted cloth. The
structure producing this effect cannot be seen completely, as
may be supposéd, without a magnifying glass.

We have not observed in birds any thing analogous to
those projections of the internal coat of the small intestines,
which in other animals are called *volutæ convolutæ*. The
Academicians, however, relate that they found in these
the upper tunic of the ilium folded longitudinally, in the
manner of the larvach of ruminating animals, and that
the external to the extremity of this intestine there were some trans-
verse wrinkles, which supplied the place of the valve of the
colon.

Throughout the tract of the intestinal tube, we have dis-
covered several clusters of mucous glands: where these are
situated, the internal coat appears as if slightly ulcerated, or
not unlike a dysenteric intestine, instead of that regular
dotted figure which the mucous glands commonly exhibit in
mammalia.

The great intestines, as they are called, bear no part of pro-
portion to the small, in point of length: in many instances,
even where the latter are of considerable extent, they do not
exceed a few inches. They only admit of division into two
parts; the cecal appendages, and the continuation of the tube
until it terminates at the anus. The first correspond
with the cecum cecum of mammalia; and the other
takes the place of the colon and rectum; but which from
its extreme shortness and direct course to the anus, would
appear to deserve only the name of rectum.

The cecal appendages are subject to as much variety as
perhaps any other part of the structure of birds. Generally,
they are two in number; in which case, they arise rather ab-
ruptly from opposite sides of the intestinal tube, about the
place where the convolutions cææ, and the intestine becomes
straight.

It may be received as a general rule, to which, however,
there are some striking exceptions, that the magnitude of the
cææ is in proportion to the musculature of the ilomach; we
accordingly meet with this organ of the greater fize, and
the strongest character in the gallinæ and other *græmmivir-
rous* birds, from which it will be found most convenient tinct
to take the description.

The cææ in these birds commonly ascend for some way
quite close to each side of the intestines, from which they
rise; during which they are less than the other parts of the
intestinal canal; they then make a slight curve outwards, and
become somewhat enlarged, and towards the superior
extremity they again diminish their termination in the
cul de sac. These parts reach up in the abdomen to near the
liver, and often make a slight curve round the spleen; they
are connected to each other, and to the intestine between
them, and also retained in their relative situation in the ab-
domen, by reflections of peritoæum, of which some are ana-
logous to the meco-colon and meco-rectum, and others con-
tribute to the formation of the air-cells. See Plate III. in
the Anatomy of Birds. Fig. 3, represents those parts in the
pintada, or guinea-hen; a the last portion of the small intestine
placed between the two cææ, b the cææ, e the rectum, dded
the peritoæum connecting those parts, r a process of perito-
aeum passing across from the top of one cææ to another.
If the cææ be slit open, it is found that they communicate
with the rectum by an aperture which is smaller than their
own cavity at the place; and consequently, any substance
will pass with difficulty into them from the other intestines,
and likewise be obstructed in its return.

Just within the entrance of each cææ, there is a clus-
ter of mucous glands, which appear like two spots of ulcer-
ation. These are particularly useful in this situation to smooth
the passage of substances in and out of the cææ.

The contracted parts of the cææ are in some degree vil-
ous on the inner surface, and resemble in structure the rei-
of the intestinal canal; but the dilated parts are deprived of
villi, possess very little vascularity, appear to have few, if any,
mucular fibres, are without mucous glands, and are little
better than simple membranous tubes. These parts contain
the viscer of the fowes.

All the uces which the cææ serve to animals are certainly
not yet known; and the functions of these organs in birds
are amongst the least understood. The magnitude of their
caec is not always in proportion to the apparent necessity
for such receptacles; often, where they might be expected
large, they are small, or absent altogether, and sometimes,
where the nature of the food would not seem to need these
repositories, they are of considerable size. With the view of
determining their uses, they were removed from the living
hen, and the consequence is said to have been, that the ani-
mal would not admit any food from the crop into the gizz-
ard, from which it might be inferred, that their organs
serve other and more important purposes in the animal
economy, than mere receptacles of excrement; that, how-
ever, they are employed as a sort of temporary receivers, to
receive the undigested parts of the food, is obviously true;
and that in doing so, they answer an useful purpose, appears
to be proved, in despite of many exceptions, by the more
numerous instances of their bearing a decided relation to the
digestive organs, and the quality of the food.

The same structure which has been described in the *guinea
hen*, or pintada, is to be found with little variation in all the
gallinæ except the pigeon, and in the *herbivorous anseres*,
such as the fowen, the goose, &c.

Daudin describes the cææ of the heath-cock (*tetrao tro-
gallus*), and of the wattle-grous (*tetrao lagopus*), as grooved or
fluted longitudinally.

The cææ of the *ostrich* are different from those of other
birds; they are large where they commence, and diminish
gradually towards their termination; they suffer many con-
volutions in consequence of a longitudinal band upon the
poleside, which is only two thirds of their length; they
are facculated, or divided into locali, throughout their whole
extent, by means of a valvar projection of the internal
coat, which winds in a spiral manner, similar to the valve of the
cææ in the *hare and rabbit* in mammalia, or the *rat* and
*weasel* kind amongst fih.

The spiral lamina is about five lines in breadth, but be-
comes somewhat less towards the extremities of the cææ.
This lamellated structure is continued for some way into the
other great intestine, and even into the small intestines; not,
however, as one spiral valve, but in several transverse pro-
jections, which have a semilunar figure, and are placed al-
ternately, so that one lamella is received between two others,
in the manner of the denticles of the bivalve shells. Plate
III. fig. 4, is a portion of the first part of the great intestine
or colon of the \textit{officium}, reprezentable of the natural size and cut across to shew the femicircular lamina on the inside.

The effect of this structure is obviously the retention of the excrementitious part of the food for a longer time in the ceca; which is accomplished in other justices by the \textit{smallev} of the aperture through which those parts communicate with the other intestines. This organ is not similar in the other \textit{scitualtious} birds. According to the \textit{Parisi}an \textit{difficlters}, the \textit{coffinyary} is not provided with any ceca. In the \textit{coffinyary}, or (with mere propriety) \textit{officium}, of New Holland, we have found two \textit{ecal appendages}, which opened into the rectum by orifices not much larger than pin-holes. The internal surfaces had none of the laminae, or valvular projections, but were furnished with fine vacular flocculi, similar to those of the small intestines of the \textit{officium}; with this difference, that in the New Holland bird, they are placed longitudinally, and are more loose and pendulous, looking somewhat like laceneted portions or fronds of the inner coat of the intinlale.

In by far the greater number of birds the cecal appendages are too small to serve any purpose, and appear only as useless imitations of the structure describbed in the \textit{granum}-
vorous kinds. Many, that live on a mixt food, and whose \textit{flomaces} are of an intermediate strength, amongst the larger \textit{pafferes}, the \textit{fiez} of \textit{Linnæus}, the \textit{grafe}, and the \textit{aniera}, have two ceca measuring in length usually about twice or thrice the intestine from which they take their origin. See \textit{Plate III.}, fig. 5, which exhibits these parts in the gull. Ceca of this size have hardly any cavity, and seldom receive any of the contents of the other intestines; in the small \textit{pafferes}, which feed upon seeds, as the \textit{sparrow} and \textit{fneb} tribes, the ceca bear a still less proportion to the size of the rectal intestine; see fig. 6. of \textit{Plate III.} in which the ceca are represented as they are commonly found in those birds.

In the pigeon the cecal procusses are so small, that they escaped the notice of \textit{fico} an anatomist as \textit{Severius}, who described the pigeon as wanting them altogether. Fig. 7. of \textit{Plate III.} exhibits their appearance in the dove.

The carnivorous birds of all others have the ceca of the smallest dimensions; so much so, in many instances, that their existence has been often denied. Fig. 8. of \textit{Plate III.} is copied from the Memoirs of the Royal Academy of Paris; it shews the dilated situation which was found in the \textit{fald} \textit{bazzard} (\textit{fulo bazzard}, \textit{Linn.}) in place of the cecal procusses. On the internal side, however, this enlargement was furnished with a valvular membrane, by which a pouch was formed on each aide.

The \textit{oval} appears a very remarkable exception to the common structure of the \textit{acceperæ}, with respect to the formation of the ceca, which both in figure and magnitude are similar to those parts in the gallinule. It is difficult to account for this singularity, unless it be supposed necessary to receive the indigestible parts of the animals, which this bird swallows entire.

Some of the \textit{picaevorsus} birds, as the \textit{lron}, \&c. have only one cecal process; it is very short, and in the \textit{lron} terminates in a pointed manner. See \textit{Plate III.}, fig. 6.

There are infinaces of the cecal appendages being altogether wanting. They have not been found in the \textit{coffinyary}, the \textit{cornutant}, the \textit{bitter} (\textit{ardes flundarius}), the \textit{parrot}, and the \textit{wood-pecker}.

That portion of the intestinal canal which corresponds to the colon and rectum of mammalia, as already observed, is very florid in birds. In its external characters, it resembles the rect of the intestinal canal, of which it appears to be simply the continuation. The internal surface is provided with villi, which, however, are not so long and delicate as those of the small intestines. They are rather very minute eminences than villous procusses, especially towards the termination of the rectum, at which place they often assume a decided granular appearance. The inner surface of the rectum of the New Holland \textit{officium}, however, prefers an exception to this observation; it is covered with fine and truly hair-like procusses; in this bird also the internal coat of the great intinlale is slightly folded or wrinkled transversely, in a manner somewhat similar to the valvule conuinentes of the small intestines of the human subject.

The termination of the rectum in birds is very usually called the \textit{cloaca}, on account of its receiving, as a common fink or fervoir, both the excrements of the intestines and the urine. There is at this place a dilatation of the gut, which is often only a flight and gradual enlargement just within the margin of the anus; but sometimes it swells out suddenly into a pouch or fack. A remarkable example of which occurs in the parrot; see \textit{Plate IV.} in the \textit{Anatomy of Birds,} fig. 1. the rectum, b. the pouch.

The cloaca of the \textit{bifard} has been found large enough to contain an egg. It is of an oval form; it is situated about an inch from the anus, and the rectum again experiences a contraction previous to its termination in the vent. See fig. 2. of \textit{Plate IV.} in the \textit{Anatomy of Birds;} a, the rectum before it enters the pouch, b, b, the pouch laid open to expose its interior, e, the contraction within the anus.

In the \textit{officium}, this dilatation is of great size; being capable of receiving one's two fists, according to the report both of the anatomists of the French academy, and of Mr. \textit{Warren}, who published a description of this bird, in the \textit{Philosophical Transactions}, see No. 394. p. 113.

The use which the anal pouch answers is almost too obvious to be mentioned, which is that of a temporary accommodation to the excrements of the bird, and their excretion is rendered less frequent.

The cloaca is furnished with somewhat stronger muscular fibres than the slit of the intestine, and is invested with a reflexion of cuticle, which in the larger birds is very palpable. Connected with the cloaca, there is a bag, or purse, which, taking the name of the anatomist who first described it, is called \textit{burfa} \textit{Fabricii.}

The \textit{purse} of \textit{Fabricius} is usually of an oval or round figure, depressed on the anterior and posterior sides, and thence always appearing empty. It is furnished with a narrow procusses, or neck, which is most contracted about its middle. Its situation is on the back part of the cloaca, to which it is closely connected, being insofar in the same situation of peritonoeum which envelops the rectum. When the peritonoeum is dilated off, it is found to be a distinct bag or neck, united only to the rectum by means of its neck, which pulsating obliquely in the coats of the cloaca, opens into the intinlale by a slit-shaped aperture. The internal coat of the cloacas projects over the opening like a petticoat, and performs the office of a valve, readily allowing the contents of the bag to pass out, but standing in the way of any regurgitation from the intinlale. See \textit{Plate IV.} of fig. 2. and the purse of Fabricius in the \textit{bifard}, which is of an oblong shape in this bird; e, the slit by which it communicates with the cloaca.

The size of this bag is in general fairly proportioned to that of the bird in which it is found. In the \textit{bifard} it has been flated to be two inches long; in the \textit{goose}, it measures about an inch and a quarter in length, and half an inch in breadth; and in the \textit{sparrow}, it is about a quarter of an inch long, and half as broad.

The external side of the \textit{burfa} is smooth and equal, but the internal part is thrown into deep rude. The folds are disposed in an arboraceous form, and branch off with great regular...
regularity from a flem which it is lodged in the neck of the bag. See Plate IV., fig. 3, in which the purfe of the goofe is deduced, with its cavity laid open, to exhibit the folds upon the inner surface.

When more closely examined, the structure of this part is very curious. Under the peritoneal covering, it is surrounded by a very delicate expansion of muscle, the fibres of which take a transverse direction. The internal tunic of the purfe is made of a thin pellicular membrane, and the folds which have been described, consist entirely of glandular bodies, which are too minute to be distinguished with the naked eye. By employing a lens of common magnifying powers, we have discovered in them to bear a great resemblance to the gastric glands, being, like them, little cylinders, which are perforated at one extremity to give passage to their secreted fluid; indeed, the only difference which appears between them is, that the glands of the purfe are shorter, being so much compressed in some instances, that they are nearly of an annular form. Fig. 4. of Plate IV. exhibits a portion of the purfe of the goofe, highly magnified; a, a, the glands composing the folds; b, b, the spaces left between the folds, which consist only of the tunics of the purfe.

The fluid produced by these glands, and of which the purfe always contains a greater or less quantity, appears to differ in no respect from common mucus. The necessity, however, for so ample a supply of mucus, as these glands are capable of furnishing, does not seem very plain, especially when it is considered that the purfe of Fabricius is not met with in all birds. Among various others, the parrot is without it, as appears by fig. 1. of Plate IV. in the Anatomy of Birds; yet the parrot has a very large cloaca, and might hence be supposed to need this glandular apparatus, even more than many birds, admitting its use to be the secretion of a mucous fluid, to fill the cloaca against the acrimony of the excrement and urine.

Although the functions of the purfe of Fabricius cannot be flated with certainty, it may be conjectured that they are not unimportant, from the delicacy of its organization, and its being so rarely wanting. There are a number of black points to be seen within the anus of the parrot, which appear like the orifices of mucous glands: may not these supercede the necessity of the purfe in this bird? The excrements of birds have been ascertained by Vauquelin and others, to possess an acid. This is increased by fermentation, into which feculent matters rapidly tend, and as it proceeds, the acid gives place to ammonia, which is evolved, towards the end of the process, in great abundance. The dung of the pigeon is found to contain an acid of a peculiar kind, which is increased by the mixture of the feces with water. It is from its chemical properties that the dung of pigeons becomes so serviceable as a manure, and that it is employed in the processes of some manufactures, and for domestic purposes, such as cleaning clothes, &c.

Vauquelin has also analysed the fixed parts of the excrements of fowls, which being compared with those of the food, afforded some veryingular and important results.

For this purpose he fed a hen for ten days upon oats, of which the consumed during that period 11,111,843 grains Troy weight: they contained

135,509 grains of phosphate of lime,
210,538 silice,
336,577.

In the course of these ten days the hen laid four eggs; the shells of which yielded 98,776 grains of phosphate of lime, and 453,417 grains of carbonate of lime. The whole quantity of excrement ejected during the ten days contained 175,529 grains of phosphate of lime; 58,494 grains of carbonate of lime, and 185,256 grains of silice. The amount, therefore, of the fixed parts discharged from the system during this period were as follows:

\[
\begin{align*}
\text{Given out} & \quad 274,325 \text{ grains of phosphate of lime}, \\
& \quad 514,971 \text{ grains of carbonate of lime}, \\
& \quad 185,260 \text{ silice,} \\
\text{Taken in} & \quad 356,057 \\
\text{Surplus} & \quad 615,425 \\
\text{Consequently there disappeared, during ten days, 34,282 grains of silice.} \\
\text{The quantity of phosphate of lime} & \quad 136,509 \text{ grains,} \\
\text{taken in was} & \quad 274,325, \\
\text{That given out was} & \quad 135,509, \\
\text{Deficient} & \quad 34,282 \text{ grains.} \\
\end{align*}
\]

There must have been formed, by digestion in this fowl, no less than 137,796 grains of phosphate of lime, as well as 511,911 grains of the carbonate of lime. It may hence be presumed, that lime (and perhaps phosphorus) is not a simple substance, but compounded of ingredients which exist in oats, water, and air, which were the only matters that could be introduced into the body of this fowl; as a quantity of silice had disappeared, it might be supposed, that it had contributed to the formation of the additional products; but if so, it must have entered into combination with a great quantity of some other substance. See Annal. de Chim. xxix. 16.

Notwithstanding these experiments were conducted by the ablest chemists of the age, they ought not perhaps to be affented to without being repeated under every circumstance which could lead to the detection of any error that might possibly arise.

This is not only necessary on account of the extraordinary nature of the results, which could only be produced by a creative power in the assimilating organs of the animal; but from other analogous experiments yielding refults of a contrary kind. Dr. Fordyce, for instance, found that a certain quantity of calcareous matter was required by birds during the period of laying; and if the bird was deprived of this, the shell never was formed, and the bird frequently died from the eggs not coming properly forward. The method he adopted to prove this was simple and satisfactory: he took a number of canary birds, when about to lay; some he inclined, so that they could have no access to any calcareous matter; and to others he gave a piece of old molar, which they swallowed with avidity, and they laid their eggs as usual; whilst, on the other hand, these birds he had not furnished with the mortar were unable to produce eggs, and in several instancies died. See Fordyce on Digestion, p. 25 & 26.

Liver.

This viscus is situated about the middle of the common cavity of birds. Its form, as in other animals, is much influenced by the shape of the parts which are immediately adjacent. The left side lies on the ilomach, the right covers the
BIR

the intestines, and the apex of the heart is accommodated in the middle, and wherever the liver comes into contact with these parts, it receives in a degree an impression of their form.

Vis d’Azir, in his great sytem of anatomy, says, that the liver of birds is divided into only two lobes; and Cuvier has repeated the assertion in his Tableau Elementaire de l’Histoire Naturelle. The observation, nevertheless, is not in all cases strictly true. In many birds there is a third lobe, situated at the back of the liver, between the right and left lobes: this appears to be analogous to the lobulus sigillati of the human subject, both from its mottl usual figure, and from its position. See Plate IV. of the Anatomy of Birds. Fig. 5. represents the liver, Sec. of the goose reviewed on the posterior or reverse side; a the right lobe reaching lower down than the other, and exhibiting impressions corresponding to the convolutions of the intestines; b the left lobe, with two prominent parts, and a depression extending along the lobes between them; c the third, or intermediate lobe. In the common fowl, the left lobe is left on the anterior part to deeply as almost to form two lobes on the left side. The French academicians allow three lobes to the liver of the cormorant; they are all very small. A third lobe has been described also in the pigeon by Borrichius, and in the fowm by Bartholome. The liver of the fowl confists of four imperfect lobes.

There is considerable variety in the shape and relative size of the two principal lobes; generally the right lobe much exceeds the other in bulk, and is somewhat longer. This character of the lobes is to be seen in the liver of the goose, Plate IV. fig. 5. but is more remarkable in the caffowary, and even still more so in the buffard, in which the right lobe descends to the bottom of the belly; both lobes are short in the eagle, the Indian cock, the parrot, the owl, and many others; and in the eagle the left lobe has the greater bulk.

The two lobes are nearly of equal size in the beroon kind, and both long shaped. However much the livers of birds may differ in external forms, the internal structure is the same in all, as we have proved by numerous observations. The secretory vesel is produced from the veins of the neighbouring viscera, as in mammalia, and after entering the liver by the depression or fissure on the lower surface, which corresponds to the porhe or gates of the human liver, it is distributed throughout the substance of the organ, and terminates in the same manner as the ven. porhe, i.e. in fine radii, or penicilli towards the surface of the liver.

As there is no mucular septum between the thorax and abdomen of birds, their liver has not the advantage of that mode of connection, which is called in mammalia the coronary ligament: it is however amply supplied by the duplicature of peritoneum, which corresponds to the faliform ligament; this process divides the two principal lobes, passing deeply between them; it is connected to the peritoneum, which forms the air cells, in the sides and back part of the abdomen, is incorporated with the pericardium, and joins the sternum and the linea alba on the fore part of the abdomen, and then becomes reflected on each side of the common cavity, which is thus divided almost for its whole extent, in the same manner as the mediastinum divides the thorax in mammalia. The extended attachment, which is in this way procured for the liver, renders this viscus more steady in its situation than it is in other animals, which birds require on account of the rapid and violent motions of their bodies during the act of flying.

As the faliform ligament goes on to the fore part of the cavity, the margin which forms the round ligament is necessarily wanting, but the remains of the umbilical vein may be traced running between the duplicature of the peritneum.

The gall-bag, or reservoir of the secreted fluid of the liver, in almost every instance where it exists, is situated upon the lower surface of the right lobe, somewhat nearer its central than its external edge. It is commonly received into a slight depression of the liver, so that about one half of the bag is brought into contact with that viscus, nothing being interposed between them but the connecting cellular substance. The surface of attachment is occasionally less extensive; thus in the eagle, buffard, and caffowary; it measured in the latter bird only one inch in diameter, although it is seven inches in length.

The structure of the gall-bag appears to differ in no respect from that described in mammalia; its coats doseve no trace of mucular fibres, and its internal surface exhibits the same kind of reticulation or net-work which is found in the gall-bladder of the human subject. See Plate IV. and fig. 5. in the Anatomy of Birds; the letter d indicates the gall-bag of the goose viewed particularly in its natural position; the reticulated structure is visible on the outside, but to bring it more perfectly into view the cavity is exposed by the removal of a portion of the bag.

The bile does not flow into the gall-bag by regurgitation from the common duct, but is conveyed directly thither by means of a particular tube designed for that purpose. This duct arises from the right lobe, passes on the side of the bag which is in contact with the liver, then becomes involved in the coats of the cyst, which it perforates the distance of one-third from the posterior end.

The orifice by which the duct opens into the cavity of the bag, is very small, and is surrounded by a smooth projection of the inner membrane, which added to the obliquity of the duct, affords the effect of a valve, and entirely prevents any return of the fluid upon the liver; for the more the cyst is distended, the more pressure will be laid upon the duct, in its passage.

It would seem that the cypho-hepatic duct is situated nearly in the same way in all birds, where it exists, but the present description is taken from the goose. See Plate IV. and fig. 5. in which e points out the termination of the duct in the gall-bag, upon the papilla above-mentioned, and the course of the duct also is to be indistinctly seen behind the tunics of the cyst.

The ducts which carry the bile to the intestines, are two in number, the hepatic and the cyphic. The first arises by two branches, generally from the right and left lobes of the liver, and while within the liver or pancre as the liver, they unite to form the trunk which proceeds to its insertion in the intestines, and usually crosses the duct of the gall-bag in its way thither.

The hepatic duct comes forth abruptly from the most posterior part of the gall-bag, which is not prolonged into a neck, as in other animals. The duct makes a turn round the end of the bag, along the side of which it then proceeds fo closely applied, that upon a flight examination it might be supposed to commence from that part, or even from the anterior end of the cyst.

The hepatic and hepatic ducts never unite to form the ductus communis, as in many animals; but proceed directly to the intestines, into which they always enter separately; sometimes very near each other, and at others removed to a little distance. Two hepatic ducts have been found
found in the Indian cock, or curassow, which also had a distinct infection in the intestine.

The part of the intestines where the biliary ducts penetrate, is commonly at the conclusion of the first doubling or convolution, which occurs after the origin of the intestine from the liver; or, in other words, it might be said to be at the termination of the duodenum. The bile duct of the gfrich is very large and enters the intestine near the liver.

As in mammalia, the passage of the ducts through the coats of the duodenum is somewhat oblique, and they open upon a papilla or prominence of the internal coat, thus gaining the effect of a valve, and preventing the regurgitation of their fluid. In addition to which, the biliary duct is described as having a fold of the inner coat of the intestine projecting over the orifices of the biliary and pancreatic ducts.

Plate IV. and fig. 5. in the Anatomy of Birds, exhibits the origin, course, and termination of the biliary ducts in the goose: § the hepatic duct, formed of two branches in the fissure of the liver; g the origin of the cystic duct from the end of the bag, appearing internally like a punctured hole; h its course behind the hepatic duct, beyond which it terminates in the intestine; i the first convolution of the intestine; k the portion from which the gizzard has been cut away; l the commencement of the second fold of the intestines, or the beginning of the jejunum.

Both the cystic and hepatic ducts of the gull become slightly enlarged at their insertion in the intestine, which is produced not so much from a dilatation of their cavity as a thickening of their coats. The more minute structure and the functions of the bile ducts are in every respect analogous to those of the same parts in other animals. A very curious observation has been made on this subject by Borrichius, which deserves to be mentioned. He opened a pigeon while yet alive, and discovered in the hepatic duct a pulsory motion, by which it was alternately dilated and emptied of its contents, the intervals between each contraction were somewhat longer than they occur between the systole and diastole of the heart. If this had been related by a less accurate anatomist than Borrichius, one would be led to suppose that a blood-vein had been mistaken for the biliary duct; but he watched the moment that the action of the heart subsided, and still the duct was alternately emptied and filled with a green fluid as before.

The gall-bag is occasionally wanting in birds, and it should be remarked, that this irregularity is not governed by any general rules of structure, as two species which agree in every other respect, are observed to differ in this; nay, according to the French academicians, the gall-bag is not constantly found even amongst the individuals of the same species; thus in dissecting six demiselles of Numilia (ardea virgo), it was absent in two of them, and the others had it very small. Amongst ten pintados, also, they only met with the gall-bag twice, and differing very much both in size and shape; and in those instances where the bag was absent the hepatic duct was found very large.

The species known to be deprived of the gall-bag, are the gfrich, the parrot, the pigeon, the bittern, the crane, and the cuckoo; in some of these, dilatations of the ducts have been observed which may be supposed to supply in a degree the office of the gall-bag, which appears from this, as well as other circumstances, to be simply a reservoir for the bile, and not an organ for working any change in the properties of that fluid. Being, therefore, a convenient, rather than a necessary structure, its absence need not be expected to be marked with any clear relation to the other functions of the animal economy.

No experiments have yet been instituted with the design of procuring a chemical analysis of the bile of birds; it is, most probable, however, that these would discover nothing peculiar, as in tenable properties, such as colour, taste, &c., it perfectly resembles the bile of mammalia.

The Pancreas

Consists of two distinct glands, for the most part, in birds. Their common situation is between the coil of the first intestines, to which they are very firmly bound by their peritoneal coat; they have a very elongated figure, furnished with wide angles, and edges, which are irregularly notched or indented. These ducts mark out imperfectly the original lobules of which the glands are composed. They appear to pollich the same internal structure which is described in mammalia, though not so palpably as to be discovered without some pains; to a flight observation their substance seems to be a white homogenous mass, instead of that conglomer of lobules, cells, blood-veins, and ducts, which really enter into its composition. Each of the glands produces a principal duct, which separately runs in the refection of peritoneum, into which intestine they are inserted, at a variable distance from each other, in the manner of the two biliary ducts. Their entrance is, with few exceptions, adjacent to that of the bile ducts, and often so near that one projection of the internal coat of the intestine serves for the termination of all the ducts.

See Plate IV. in the Anatomy of Birds, in fig. 5. the letters nn indicate the two pancreatic glands of the goose, a little separated from each other, and their other peritoneal connections, to exhibit more clearly their figure; n the ducts from each gland curved in their passage to the intestine. The pancreatic and biliary ducts are at a considerable distance in the gfrich and the gull. In the first, as already mentioned, the hepatic duct enters the intestine near the liver; but the pancreatic duct passes as usual into the left portion of the duodenum. The pancreatic ducts of the gull penetrate the duodenum at its commencement, whilst the biliary preserve nearly the common situation. It is not very unusual for these ducts to enter the intestine alternately, or for the two pancreatic to pass between the two biliary; this may be observed in the eagle, the heron, &c.

Considerable varieties have been described in the number, external figure, and magnitude, &c. of the pancreas in different birds. The French academicians have represented it as a single gland, with only one duct in the gfrich and cafsoarv. In the latter it was extremely small in proportion to the size of the bird, being only two inches long, and its duct a line and a half in length. In the eagle it appeared to be single, although in one instance it sent forth two ducts, and in another three; it was enlarged and round at the head, at which place it was perforated by the hepatic duct in its way to the intestine. They also describe that this gland varies in different individuals of the same species; thus in one cafsoarv they found the pancreas double, and in another single. De Graef in molt fowl found three pancreatic ducts, and also in the pigeon, and Bartholin observed only one pancreatic duct in the peacock.

The Spleen

Has been described as occupying different situations by different authors. Thus Cuvier, and other anatomists, have flatted its common position to be the middle of the mesentery. The French academicians found it closely adhering to the side of the ventricle, in one species of eagle (ulcro chry-

fesitos); and in another (ulcro babaiatis), it was met with under the right lobe of the liver; and Severinus mentions the spleen of the crow being situated upon the first intestine. In every bird, however, which we have examined with the view of after-
ascertaining the situation of the spleen, it has been uniformly discovered underneath the left lobe of the liver, placed a good deal backwards, and on the right side of the zone of gastric glands. Its peritoneal connections to the neighbouring parts are loose and permit it to be displaced, when the other viscera are removed from their situations, which circumstance may have occasioned some difference in the observations made upon the subject. The situation we have described is the most convenient for its being supplied with blood, which it receives from the gastric artery, and is besides consistent with general analogy.

The figure of the spleen is most commonly round; it is, however, in some birds, a little different in form. The most usual deviation is the oval or kidney shape, which has been observed in the caraborns, the eagle, the jay, the common buzzard, &c. In the goshawk it is cylindrical, and in the cassowary it has been likened in figure to a foul fish. In the goshawk it is much elongated, and pointed at both ends, as it is shown in Plate IV. in the Anatomy of Birds, and fig. 6.

The spleen assumes rather an irregular form in the geese; it is slightly compressed and round on the one side, and flat on the other. The outline presented on either side is triangular, and one of the angles is prolonged as a mammary process, which is distinguished from the rest of the spleen by a blood clot or fissure. This is represented in fig. 7. of Plate IV. of the Anatomy of Birds; a; the body of the spleen viewed on the flat surface; b the papilla-shaped processes; c the entrance of the sphincter artery, upon the edge; d the vein penetrating the flat surface.

The texture of the spleen is so much more close and firm in birds than in mammals, that one might be easily led to suppose its structure was different; but when prepared by being injected with coloured substances, and submitted to examination through a lens, we have discovered, as in mammals, the splenic artery to terminate in numerous minute branches, and the veins to take their rise from cells. The only difference which exists, is with respect to the magnitude of the cells, which are extremely minute; and thence arise the peculiar compactness and density of the spleen of birds.

The structure of this organ being so very similar to that of the spleen in mammals, it is fair to conclude that their functions are also analogous. The situation of the viscera in birds might be considered, therefore, as affording an objection to that theory, which supposes this organ was designed to regulate the quantity of blood employed by the arteries of the stomach during the secretion of the gastric fluid; for, in birds, the spleen receives no pressure as occurs in mammals by the introduction of food into the stomach, and consequently, cannot affect the distribution of the blood in the collateral arteries, more under the circumference of a full stomach than an empty one. In order to put the spleen of birds in the same conditions to which it is subjected in man and quadrupeds, it should be placed under the crop in the gnaminivorous tribe, or between the ventricle and the ribs in the other kinds.

Although it would be often wrong to determine the site of an organ in one class of animals, from the circumstances in which it may be placed in another; yet no theory can be considered as well founded, unless it be framed in the contemplation of all the varieties of comparative structure.

Absorbs.

One of the most remarkable and inexplicable circumstances in the anatomy of birds is, that the nutritious fluid of the intestines, or the chyle, is as transparent as the lymph which is taken up from the common interlacies, or the surface of the body. The absorbers of the intestines, therefore, do not deserve to be called laeves, an appellation they have received in man and quadrupeds, in consequence of the opacity and milky appearance of their contents.

The discovery of the lymphatic sytem in birds may be reckoned amongst the modern improvements in anatomy. Before Mr. Hunter, about the middle of the 18th century, described the absorbers of the neck, it was generally supposed that the office of these vesels was fulfilled in birds by the minute branches of veins. This opinion was rendered the more probable as several able anatomists had fought in vain for those white vesels, and their glands, which are so easily detected in the m eateny of the smalles quadruped. It was not then known, however, that the lymphatic vesels of the intestines were always pelvic in birds, and unprovided with glands, and accordingly Mr. Hunter's discovery was not generally admitted as decisive on the question, until some years afterwards the whole of the lymphatic sytem had been described by Mr. Hewson; he employed for this purpose a young and very lean goose, which had been recently fed, and having secured it upon a table, he opened the abdomen whilst the bird was yet alive, and placing a ligature round its m eateny vesels, as near to the root of the m eateny as possible, the lymphatics of this part became apparent in a few minutes. The same method also was purposed to expose the absorbers of the neck. A ligature was placed round the jugular vein at the lower part of the neck; and to be more certain of inclosing the lymphatics which are near it, a sufficient quantity of the surrounding substanse was included by the ligature. In this way he succeeded in tracing the lymphatic sytem, in more instances than one, after having filled the vesels with quicksilver. He published a description of the absorbers, illustrated by two drawings, in the Philosophical Transactions for the year 1748, and in his Experimental Inquiries into the lymphatic sytem.

As no accounts or figures of the absorbers of birds have been offered to the public since Mr. Hewson's time, we cannot do better than adopt the description, and copy the representation left to us by that indefatigable anatomist; in doing which, we shall transcribe his own words.

"This sytem consits in birds, as it does in the human subject, of three parts, viz. the laeves, the lymphatic vesels, and their common trunk, the thoracic duct. The laeves indeed, in their strictest sense, are in birds, the lymphatics of the intestines, and like the other lymphatics, carry only a transparent lymph; and instead of one thoracic duct there are two, which go to the two jugular veins. In these circumstances, it would seem, that birds differ from the human subject, so far at least as I may judge from the dissection of a goose, which was the bird I chose as most proper for this inquiry, and from which I took the following description, after previously injecting its lymphatic sytem with quicksilver.

"The laeves run from the intestines upon the m eateny vesels. Those of the duodenum pass by the side of the pancreas, and probably receive its lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist they are upon this artery they are joined by lymphatics: afterwards they get upon the celiac artery. Whilist
the mesenteric artery. These last mentioned lac\-eals, before they join those from the duodenum, receive from the rectum a lymphatic, which runs with the blood-veil\-ls of that gut. Into this lymphatic from small branches from the kidneys seem to enter, which, coming from those glands upon the mesentry of the rectum, at last open into its lymphatics. At the root of the coeliac artery, the lymphatics of the lower extremities probably join those from the intestines. The former," he says, "I have not yet traced to their termination, though I have distinctly seen them on the blood-veils of the thigh; and in one subject which I injected, some vessels were filled, contrary to the course of the lymph, from the net-\-work near the root of the coeliac artery. These veils ran behind the cava, and down upon the aorta, near to the origin of the cranial arteries; and I presume they were the trunks of those branches which I had seen in the thigh. At the root of the coeliac artery, and upon the contiguous part of the aorta, a network is formed by the lac\-eals and lymphatics above-described. This net\-work consists of three or four transverse branches, which make a communication between those which are lateral.

In the subject from which this description was taken there were four. From this network arose the two thoracic ducts, of which one lies on each side of the spine, and runs upon the lungs obliquely up towards the jugular vein, into which it opens, not indeed into the angle be\-tween the jugular and subclavian vein, as in the human subje\-ct, but into the inside of the jugular vein, nearly opposite to the angle. The thoracic duct of the left side is joined by a large lymphatic which runs upon the esop\-hagus, and can be traced as far as the lower or gland\-ular part of that canal, from which part, or from the gizz\-ard, it seems to issue. The thoracic ducts are joined by the lymphatics of the neck (and probably by those of the wings), just where they open into the jugular veins.

The lymphatics of the neck generally consist of two pretty large branches on each side of the neck, accompa\-nying the blood-veils. Those two branches join near the lower part of the neck; and the trunk is in general as small, if not smaller, than either of the branches. This trunk runs close to the jugular vein, gets on its in\-side, and then opens into a lymphatic gland. From the opposite side of this gland a lymphatic comes out, which pours the lymph into the jugular vein. On the left side, the whole of this lymphatic joins the thoracic duct of the same side; but, on the right side, one part of it goes into the inside of the jugular vein a little above the angle, whilst another joins the thoracic duct, and, with that duct, forms a common trunk, which opens into the in\-side of the jugular vein, a little below the angle which that vein makes with the subclavian.

"To this description it may be necessary to add, that thought it be taken from one subject, yet in three others of the same species, which I examined carefully, I saw nothing which disagreed with it. I particularly attended to the number of the thoracic ducts, supposing that possibly in this subject the two that I had seen might be only a variety, which is a circumstance that, as we are told, has occurred even in the human body. But in three others of this species, which I likewise successfu\-elly injected, I still saw two ducts; and therefore I am in\-clined to believe, that this is the constant number. I likewise carefully attended to the vessels coming from the gland on the right side; and in the only two subjects in which the lymphatics of the neck were properly filled,
which is often prolonged for some way between the lobes of the liver. It deserves remark, that notwithstanding the great size of the pericardium, the air, which pervades almost all the cavities of birds, is not admitted into this. The Par

iian anatomists, it is true, observed the pericardium to swell when they inflated the lungs and air-cells of the pinta
do, and thence concluded that the air had diffused to the heart, for which they affixed some curious reasons; such as the heart requiring compression and evaporation from its surface. They appear, however, to have been equally in error with respect to the fact and the reasoning: for, in a great number of species we have examined for the purpose, the pericardium was uniformly found to contain a certain quantity of water, and had not the least communication with either the lungs or air-cells. The Parían anatomists must have been led into this mistake by the dilatation of the air-cells around the pericardium. 

The heart is of a longer figure in birds than in other ani

mals; and the outline of the right side is slightly concave, in consequence of the pectric of the right ventricle being relatively thin. In the left side, the heart has been described as nearly round; measuring six inches from the base to the apex, and five inches across.

Birds have, like mammals, four distinct cavities in the heart, which bear the usual proportions in magnitude with respect to each other. The auricles however, and especially the right, are commonly more muscular than in other ani

mals; and the left ventricle is always much stronger than the right.

The internal surface of the auricles is very irregular, in consequence of the shape and size of the muscular fasciculi. There is one very strong portion of muscle, which enters into the composition of the auricular part of both cavities, from which other fasciculi proceed in a regular and radiated manner, at least in the right auricle. See Plate V. in the Anatomy of Birds. Fig. 3. here the heart of the goose, with the auricle and ventricle of the right side laid open, e the principal muscular fasciculi of the auricular portion of the cavity passing backwards towards the left auricle; f the left

fer fasciculi, which depart from the other as branches from a trunk; g g the deep fossa which exist on each side of the large fasciculi.

The blood of the viscera and lower limbs is conveyed into the right auricle by a vein corresponding to the inferior vena cava of mammals. There is, however, no vein strictly analogous to the superior vena, the veins of the right wing and that side of the head and neck, form a distinct trunk, which enters the upper part of the auricle; while those of the op

piste side also produce another trunk, which pass along the posterior surface of the left auricle, to which it is closely united, and opens into the right auricle beside the inferior cava.

The anatomists of the French academy observed, in most of the birds they dissected, a valvar projection of the inner membrane of the heart, over the entrance of the inferior vena cava into the right auricle. This valve resembles in form most of the interior valves of the human heart, and by its means, the orifice of the cava, which is really very large, puts on the appearance of a narrow slit. A similar valve hangs over the entrance of the veins which return the blood of the wings and head to the auricle. See Plate V. in the Anatomy of Birds, fig. 3. a a point out the veins, which terminate in the right auricle with their valvar orifices, into each of which a bristle has been introduced.

The analogy between the valves of the veins entering the right auricle of birds, and the Eulachian valve of the human heart, is very obvious, and demonstrates, as far as analogous structure can, that the latter serves the purpose of a valve to the vena cava in the human subject.

There are commonly two or three orifices for the coro

nary veins in birds, one is always larger than the rest, and transmits the blood of the principal vein of the heart. They are each provided with a slight projection of the inner mem

brane, which acts imperfectly as a valve.

The right ventricle is of a triangular figure, and is quite smooth on the internal surface; there being none of those procencies of muscle which are called carneae columnae.

The valve, which is placed at the mouth of the right ventricle, is of a peculiar shape and structure in birds. Instead of those thin and membranous folds, which usually surround the orifice of the ventricle, and are moved by means of their connexion with the carneae columnae, and which from their figure in the human subject are called the trigusid valve; there is a single projection of the fillets of the heart, of a triangular figure, and nearly as thick as the parietes of the cavity in which it is contained. The triangular valve is joined by its superior edge to the margin of the orifice of the ventricle, and is united by another of its edges to the right side of the cavity almost to the bottom. The third edge is unconnected, except by a small process, which goes off near one of the superior angles to the parietes of the ventricle on the left side. See Plate V. in the Anatomy of Birds, fig. 3.

In the triangular valve, exposed by means of the anterior pa
cieties of the right ventricle being cut off, a bristle is passed under the valve from the auricle; d d d the external surface of the heart; e the process connecting the floating edge of the valve to the parietes of the ventricle, with a bristle lying under it.

The triangular valve, from its thickness and muscularity, would seem to operate chiefly by means of the contraction of its own fibres, changing its figure, and thus obstructing the return of the blood into the auricle. Borrichius discovered a foramen in the septum of the heart of the pigeo, large enough to admit a bristle, by which the two ventricles had a direct communication with each other. See Ac. Dan. ann. i. oberv. 96.; and we have observed the same foramen at the upper part of the septum of the heart of the goose in one instance; it was of sufficient size to receive a crow quill. Such a communication does not appear, however, to be an uniform or natural structure, as we failed to discover it in other geese, and in different species of birds examined for the purpose. Indeed, a ready communication between the ven

tricles of an adult bird, would be inconsistent with the mode in which the functions of respiration and circulation are car

ried on in this class of animals.

The pulmonary artery is provided with three semicircular valves, as in mammals. It divides also, as usual, into a ve

fcel for each lung, and that of the right side passes under the arch of the descending aorta.

The blood is returned from the lungs by two pulmonary veins, which open very near each other into the upper and posterior part of the left auricle.

The mechanism of the cavities of the left side of the heart more nearly resembles that which exists in mammals. The sinus, or membranous part of the left auricle, is however very small, and of an oblong shape; and at the place where the pulmonary veins enter into the auricle, there appears to be a projection of the internal membrane, which performs the office of a valve to their orifices.

The valve of the left ventricle is thin and membranous, and resembles so much the mitral valve of the human heart, that the same name might with propriety be given to it.
The tendinous cords, however, which are attached to the margins of the valve, are not moved by distinct muscular fasciculi, or _cordae tendineae_, but proceed immediately to be lost in the sides of the ventricle. The lower part of the cavity is fasciculated, although not so remarkably as the internal surface of the ventricle of man or quadrupeds.

The aortic or semicircular valves are to be found at the origin of the great arterial trunk from the L ventricle.

The above account of the mechanism of the heart of birds shows that this organ is calculated to exercise its functions precisely in the same manner in these animals as in mammals; and that the pulmonary and general circulations are maintained by different chambers of the heart; consequently every particle of blood is exposed to the influence of the air in the lungs, previous to its distribution throughout the system for the purposes of nutrition, excretion, &c. Before the description of the vessels of general circulation is entered upon, it is in order therefore to treat of the organs of respiration, or the _Lungs_.

These bodies are situated on each side of the dorsal spine, upon the surface of the ribs and intercostal spaces, usually reaching in length from the second rib to the last intercostal space but one, and extending in breadth from the spine to about that part of the ribs, where the processes are bent from one to the other. In the _girich_, the lungs were found to measure ten inches long, and three and an half broad, and were one inch and an half thick.

The lungs of birds never move from their position, as they adhere to the inside of the chest, and are covered over by a strong membrane or _aponeurosis_. They are smooth and even on the anterior part; but their figure posteriorly exactly corresponds with that of the parts upon which they are laid. The ribs and intercostal spaces serve as a mould, of which the lungs are the perfect cast, presenting a remarkable projection for each depression between the ribs. These eminences are of course most striking next the spine; and towards the anterior edge of the lungs, which is very thin, they are scarcely visible.

The lungs have two coverings; one is somewhat analogous to the _pleura_, though not exactly similar to it in structure, being more like condensed cellular substance. It closely invests each lung, and appears to be fluent on some parts of its surface, and to adhere to the piaeties of the chest. The other coat is common to both lungs; it is extended from each side of the chest to the dorsal spine across the anterior surface of the lungs. It is connected in a degree to the fore-part of the spine, and indoles at this place the trunk of the descending aorta, suffering the aortic artery to pass through it. It has no intimate union with the proper tissue of the lungs except at the openings of the air-cells, and around the entrance of the great vessels of the lungs. The texture of this coat appears to be tendinous; its fibres all run in the transverse direction; and in large birds they are evidently white. This aponeurosis is not equally strong upon every part of the lungs; at the upper part, and especially above where the vessels enter, it is so weak as often to be hardly visible.

In all birds there would appear to be some muscular fibres passing from the side of the chest upon the aponeurosis of the lungs. There are very diffusely to be seen in the larger species, in some of which the muscles of the lungs are of considerable strength. The anatomists of the French academy observed six strong slips of muscle on each side of the body in the _girich_ and taffinours. They arose from the ribs which come from the spine, near their junction with those which belong to the sternum, and terminated in the aponeurosis which covered the lungs. Mr. Ranby discovered eight muscular fasciculi to each lung of the _girich_. See Phil. Tranf. N° 386. p. 229. We have noticed only four broad thin slips of muscle in the _girich_, which proceed from the articular of as many vertebral ribs with the sterneal; in the common _fowl_, the muscles of the lungs do not present the appearance of distinct slips, as in other instances, but are spread as a single layer upon each lung.

It is difficult to speak with certainty of the uses of the pulmonary muscles. The effect of their contraction appears to be the tension of the aponeurosis, and consequently the elevation of it into a flat surface which is ordinarily concave or depressed. This would necessarily produce some dilatation of the lungs; and therefore these muscles might be reckoned amongst the agents of inspiration, although their operation in this way would be very trifling.

The Parilian anatomists attributed several uses to them; they supposed that these muscles had the power of depressing the anterior part of the thorax, in consequence of their attachment to the movable angle of the ribs, and their oblique course upward to the spine. If they are allowed to perform this effect, they must be considered as muscles of expiration.

They imagined also that they caused, when in action, a contraction of the foramina through which the air is admitted into the great air-cells of the thorax or upper part of the body, and thus enabled the bird to maintain a continued distention of these cells, in order to diminish the specific gravity of its body during the time it remained on wing; or (what the academicians thought more probable) furnished the bird with a supply of common air to carry with it into the regions of the atmosphere, in which the air would be too thin and light for respiration; in the last conjecture, however, they seem to have forgotten the effect that the temperature of the bird's body would produce in the rarefaction of the air contained in the cells.

When the lungs of birds are stripped of their coverings, there are still found to be a connected, uniform fibres, and not reducible into lobes or lobules as in mammals; they appear, to a superficial view, solid and fibrous, but if examined more clearly, are seen to be made up of the ramifications of the great blood-vessels, the branches, and very minute air-cells.

When the bronchi enter the lungs, their chief branches, instead of being regularly and equally distributed, pass directly to certain points upon the surface of the lungs, and there terminate in several foramina, which communicate with the great air-cells of the body; these branches also of the bronchi retain in their structure, almost throughout their extent, some cartilaginous rings. The ramifications of the air-tube which really supply the substance of the lungs, are but branches of those which go to the cells. They are comparatively small, and entirely composed of membranes. This structure accounts for the fibrous appearance and solid feel of the lungs, and explains why birds are able to fill their air-cells with so much ease and rapidity.

_Air-Cells._

Although physiologists are not agreed with respect to the uses which these parts serve in birds, yet as they are immediately connected with the lungs, it seems most proper to describe them in this place. It is one of the most remarkable and peculiar circumstances in the anatomy of birds, that the atmospheric air has a ready passage to almost every part of the interior of their bodies.

The air-cells, according to their situation, may be divided into 3 parts:—

1. The _basal_ air-cells, which are situated in the bottom of the chest, and are placed between the _aponeurosis_ and the body of the _girich_. These open at the root of the lungs, and are covered with a strong membrane, which is connected to the _aponeurosis_, and is supplied with blood-vessels.

2. The _intercostal_ air-cells, which open into the intervals, or intercostal spaces, and are extremely numerous.

3. The _subcostal_ air-cells, which are about the lower ribs, and are connected to the _aponeurosis_; the _intercostal_ air-cells communicate with them at the lower part of the thorax.
The Parian anatomists describe all these cells as being formed of distinct tunics, so that each is a separate bag, instead of being made by continuous and reflected membranes. They represent the bags to be distinct also from the great membranous partitions of the cavity. See Plate V. in the Anatomy of Birds; fig. 4, is copied from the memoirs of the French academy, and exhibits the air cells, &c. of the offrich; a the trachea; b b the two bronchiae passing to the lungs; e the heart; and d d the liver, seen in the superior division of the cavity; e the transverse membrane which separates, like the diaphragm, the common cavity into two parts; f the trachea; and g g the convolutions of the intestine, seen in the lower or abdominal portion of the cavity; b b b the lateral partitions which include the four superior cells; i 2 3 4 5 indicate the different cells; the air holes are apparent in each, except the inferior or abdominal cells, which cannot be brought into view, as they lie behind the fourth cells.

The air-cells of birds in general do not exactly accord with the description given of the offrich and coughvurry, by the members of the Royal Academy; we shall therefore proceed to give an account of what we have observed on this part of the anatomy of birds in the geese, duck, common fowl, pigeon, &c.; and in order to make this description more intelligible, we shall take the liberty of naming the cells according to their situation with respect to other parts, although some of the terms must be adopted upon the strength of analogy, as the distinctions of thorax and abdomen do not with strictness belong to birds.

The first is the superior thoracic, or jugular air cell. When it is distended with air, it becomes evident upon the outside of the thorax, between the two branches of the fork; it is large enough in the goose to contain an apple in its anterior part, and posteriorly it extends on each side of the basis of the heart, over the lungs. This cell contains the divisions of the trachea into the bronchi, and the trunks and primary branches of the blood-vessels which supply the wings and head. A great number of membranous fibres pass through it in various directions, which serve to connect and keep steady the different vellae, and also divide this cell into several chambers, which, however, have all a free communication with each other. The air is transmitted from the superior part of each lung by two openings which are placed in the posterior chambers of this cell. These chambers do not appear to extend so far upon the lungs in other birds as they do in the goose; it is from this cell that the air paffes into the cells of the axilla, and under the fork-shaped bone, into the deep seated cells of the neck, and to those about the shoulder.

The next cells may be called the intermediate thoracic. They are generally two in number, one to each side; they lie immediately upon the lungs, and are in a degree covered by the anterior thoracic cell. That of the right side is usually larger than the one on the left; the latter is proportionally small in the goose, being almost concealed by the two adjoining cells, and extending under the posterior part of the liver. The cell of the right side is of an oblong figure, and is prolonged under the termination of the inferior vena cava in the right auricle, as far as the left side of the thymus glandulose. The intermediate thoracic cells receive their air through a large foramen, situated upon the outer edge of each lung, just at the basis of the heart. At the upper and inner angle of these cells also there is an opening which appears to lead to some small cells under the pericardium and esophagus, and to communicate indirectly with the anterior thoracic cell.

The air-cells of birds in general do not exactly accord with the description given of the offrich and coughvurry, by the members of the Royal Academy; we shall therefore proceed to give an account of what we have observed on this part of the anatomy of birds in the geese, duck, common fowl, pigeon, &c.; and in order to make this description more intelligible, we shall take the liberty of naming the cells according to their situation with respect to other parts, although some of the terms must be adopted upon the strength of analogy, as the distinctions of thorax and abdomen do not with strictness belong to birds.

The first is the superior thoracic, or jugular air cell. When it is distended with air, it becomes evident upon the outside of the thorax, between the two branches of the fork; it is large enough in the goose to contain an apple in its anterior part, and posteriorly it extends on each side of the basis of the heart, over the lungs. This cell contains the divisions of the trachea into the bronchi, and the trunks and primary branches of the blood-vessels which supply the wings and head. A great number of membranous fibres pass through it in various directions, which serve to connect and keep steady the different vellae, and also divide this cell into several chambers, which, however, have all a free communication with each other. The air is transmitted from the superior part of each lung by two openings which are placed in the posterior chambers of this cell. These chambers do not appear to extend so far upon the lungs in other birds as they do in the goose; it is from this cell that the air passes into the cells of the axilla, and under the fork-shaped bone, into the deep seated cells of the neck, and to those about the shoulder.

The next cells may be called the intermediate thoracic. They are generally two in number, one to each side; they lie immediately upon the lungs, and are in a degree covered by the anterior thoracic cell. That of the right side is usually larger than the one on the left; the latter is proportionally small in the goose, being almost concealed by the two adjoining cells, and extending under the posterior part of the liver. The cell of the right side is of an oblong figure, and is prolonged under the termination of the inferior vena cava in the right auricle, as far as the left side of the thymus glandulose. The intermediate thoracic cells receive their air through a large foramen, situated upon the outer edge of each lung, just at the basis of the heart. At the upper and inner angle of these cells also there is an opening which appears to lead to some small cells under the pericardium and esophagus, and to communicate indirectly with the anterior thoracic cell.

The air-cells of birds in general do not exactly accord with the description given of the offrich and coughvurry, by the members of the Royal Academy; we shall therefore proceed to give an account of what we have observed on this part of the anatomy of birds in the geese, duck, common fowl, pigeon, &c.; and in order to make this description more intelligible, we shall take the liberty of naming the cells according to their situation with respect to other parts, although some of the terms must be adopted upon the strength of analogy, as the distinctions of thorax and abdomen do not with strictness belong to birds.

The first is the superior thoracic, or jugular air cell. When it is distended with air, it becomes evident upon the outside of the thorax, between the two branches of the fork; it is large enough in the goose to contain an apple in its anterior part, and posteriorly it extends on each side of the basis of the heart, over the lungs. This cell contains the divisions of the trachea into the bronchi, and the trunks and primary branches of the blood-vessels which supply the wings and head. A great number of membranous fibres pass through it in various directions, which serve to connect and keep steady the different vellae, and also divide this cell into several chambers, which, however, have all a free communication with each other. The air is transmitted from the superior part of each lung by two openings which are placed in the posterior chambers of this cell. These chambers do not appear to extend so far upon the lungs in other birds as they do in the goose; it is from this cell that the air passes into the cells of the axilla, and under the fork-shaped bone, into the deep seated cells of the neck, and to those about the shoulder.

The next cells may be called the intermediate thoracic. They are generally two in number, one to each side; they lie immediately upon the lungs, and are in a degree covered by the anterior thoracic cell. That of the right side is usually larger than the one on the left; the latter is proportionally small in the goose, being almost concealed by the two adjoining cells, and extending under the posterior part of the liver. The cell of the right side is of an oblong figure, and is prolonged under the termination of the inferior vena cava in the right auricle, as far as the left side of the thymus glandulose. The intermediate thoracic cells receive their air through a large foramen, situated upon the outer edge of each lung, just at the basis of the heart. At the upper and inner angle of these cells also there is an opening which appears to lead to some small cells under the pericardium and esophagus, and to communicate indirectly with the anterior thoracic cell.
The lateral thoracic cells are amongst the largest of the body. They are of a pyramidal figure, their bases being applied to the intermediate thoracic cells, and their point reaching as far down as the bones of the pelvis; they cover the inferior portion of the lungs, and occupy a space between the ribs and the lobes of the liver. They have a very free communication with the branches of the bronchus, at the external edge of the lungs.

As the intermediate thoracic cells are small on the left, and large on the right side, these cells are larger on the left side than on the right: this disproportion is most observable in the goose, and very trifling in the duck, in which the two intermediate thoracic cells are nearly of an equal magnitude.

The air-cells, which are found in the lower or abdominal portion of the cavity of birds, are composed of thinner membranes than the others; in some parts they are so tender, that they are ruptured with the slightest touch, from which they become very difficult to examine.

Underneath the lateral thoracic cells, at the very lowest part of the lungs, on each side of the spine, the branches of the bronchus open into the cavity of the abdomen, by which means air is conveyed directly into the two great lateral abdominal cells, and from these it would appear that it passes into the others.

The lateral abdominal cell of the right side is by much the largest in the body; it reaches from the last rib to the anus, and lies over and included almost all the small intestines, the rectal capsule, and the kidney. It appears in the goose to be divided from the opposite cell by a membrane which passes obliquely from the right side of the anus to the lower part of the gizzard.

The left lateral abdominal cell contains the intestines of that side; it is attached to the margin of the gizzard, under which it is prolonged as far as the lungs, where it is supplied with air, as already mentioned.

The lateral abdominal cells transmit air to the inguinal cells, and to several chambers formed by the most delicate membrane, amongst the intestines. One of these being somewhat stronger than the others, there was an opportunity of observing it more distinctly. It makes a circuit around the right side of the gizzard to which it is attached, and incloses the duodenum and pancreas; it might thence receive the name of the duodenal cell.

Interposed between the parietes of the belly and the lateral cells there is frequently found a considerable quantity of tender fat; especially in aquatic birds, such as the goose, &c. By this means a soft cushion is provided for the small intestines to press and move upon, thus supplying the use of the omentum, which is a part not met with in birds.

The structure of the air-cells of birds in general does not appear to be the same described in the offish and saurimentary by the academicians. The membranes composing them instead of being distinct bags, as they relate, resemble rather the pleura or the peritoneum, and like them, seem to produce all the different cavities by the means of reflection. It must be confessed, however, that the membranes of the cells, especially in the abdomen, are very easily separable into different lamina, or layers, which, it might be supposed, could be ultimately resolved into distinct fascs.

It deserves to be mentioned, that each of the air-holes in the surface of the lungs opens obliquely into the air-cells; there being a slight projection of thin membrane over the aperture. The Partition anatomists described a valuable effect to this structure, which they supposed of great consequence, as it would serve to continue the dilatation of the air-bags, after they were once inflated. The projection of the membrane over the air-holes does not however appear to be sufficient to cause any obstruction to the regurg of the air from the cells; nor would it seem necessary or convenient to interrupt in the least degree the expulsion of the air contained in the cells.

The membranes of which the air-cells are composed, are reflected into the apertures of the air-cells, and are there perforated by a great number of small foramina, which correspond to the termination of the ramifications of the bronchus, through which the air has a ready passage. When these foramina are brought into view, by dissecting of the coverings of the lungs, they give the anterior surface an appearance of being pricked by pins.

The air-cells which are found amongst the muscles and integuments of the external parts of the body, vary in number and magnitude, according to the structure and economy of the bird. In every instance, perhaps, the anterior thoracic or jugular cell is continued along with the vellous and nerves into the axilla, making what may be called an auxiliary cell, and in most birds others go off from this anteriorly under the pectoral muscle, and backwards under the muscles of the scapula, forming pectoral and subscapular cells. In the eagle, buzzard, fork, lark, and other high flying birds, these cells are very large, and in many of those birds there are still larger cells, ascending under the integuments of the neck, and passing beneath the skin of the side of the arm, and the back of the shoulder. In the fork we found these cells large enough to admit the finger to pass a considerable way down upon the inside and back of the wing. They are also large in the owl and other birds of prey.

Most birds of flight have a number of cells placed under the lateral muscles of the neck. These are opposite to the bodies of the cervical vertebrae, and communicate with one another. It is from the different cells about the axilla and neck, that the bones of the shoulder, the humerus, and the vertebrae, receive the air which they contain.

The inguinal and glutaeal cells are filled from the great lateral cells of the abdomen, with which they have a communication, where the blood vessels of the lower extremities pass out of the pelvis. The inguinal and glutaeal cells surround the neck of the femur; they are in most birds very small, but in those which are much employed in flight, especially if the thigh bones receive air, they are larger, extending for some way amongst the muscles behind the joint. Camper observed two air bags between the glutaei muscles of the genus <i>gallinula</i> (<i>platyrhynchos</i>), although no air was transmitted into the femur.

The subcutaneous air-cells of the pelican are very large, and were described long ago by Mery, in the early Memoirs of the Academy of Sciences of Paris.

Several means have been employed to prove that the air is permitted to enter the cavity of the bones in birds. The air-cells and the lungs have been inflated from the bones, and injection being thrown into the trachea, was found, after dilating the air-cells, to have passed into the interior of the bones. A still more decisive experiment (although a cruel one) is to cut the humerus across in a living bird, and introduce the extremity of the divided bone into water, in which some soap has been dissolved, when it is perceived that bubbles are produced by the exit of the air from the end of the bone. This expedient not only affirmt the existence of air in the bone, but shews that there is a motion or circulation of it, which is the effect of the actions of inspiration and expiration.

This subject has been very extensively investigated by Cam-
per; he discovered the communications between the cavities of the bones and the air-cells of the soft parts, and afterwards in a great number of species what bones were filled with air.

The result of both his observations and our own tends to show, that the bones of birds are supplied with air, according as they are employed in the locomotion of the animal’s body. In birds of flight, therefore, almost all the bones are hollow, and receive air; thus in the eagle Camper found the air-cells communicated with the thigh bones, those of the pelvis and coxys, all the vertebrae, the sternum, clavicles, scapulae, and fork-shaped bone, and the bones of the wing.

The air was also admitted into the bones of the head from the cavity of the tympanum. We have observed the bones in the brack and flark to want marrow in the same manner as those of the eagle. Most of the bones are hollow in the rudi; but the os femoris is filled with marrow. The pigeon kind in general also have no air in their thigh bones, although the crown pigeon has been observed by Camper to possess it.

Birds even of moderate powers of flight, receive some air into the femur and other bones of the trunk, and between the surface of their cranium; and all birds, whose wings are not incapable of flight, have the humerus filled with air, with the exception of the woodcock, which has been observed to possess marrow in the humerus; but to counterbalance this impediment to the velocity of its motion, it is provided with pectoral muscles of unusual strength.

Those birds which are unable to transport themselves for any distance by the effort of their wings, are deprived of air in the humerus; of these may be included all the Frugibous kind, the penguin, the pafiia, &c. It is worthy of remark, however, that the Frugibous birds, which run with great rapidity, have most of their other bones hollow; Camper discovered the air to pass into the thigh bones and lower jaw of the ofr ich, and we have observed that it fills not only those bones, but the sternum, the ribs, the vertebrae, and the bones of the pelvis, in both the common ofr ich and that from New Holland.

The internal surface of those bones which contain air have been described by Camper as being in some cases lined with periosteum, and in others entirely deprived of it; thus he states the internal part of the femur of the eagle to be cancellated and furnished with a periosteum, upon which several blood-vessels are ramified, and the humerus of the same bird to be a simple hollow tube, without membrane, vessels, or cancelli. It appears to us, however, that the membranes of which the air-cells are composed, are continued in every instance into the interior of the bone, to which they may serve, it is true, the purpose of a periosteum, although in structure they are much more fine and delicate, and when these membranes cease to be vascu lar, they become dry, and adhere so closely to the surface of the bone, that they are not easily perceived.

The internal parts of the bones of birds which are filled with air consist of cells, like those of other animals; the only difference that can be observed is, that the cancellated structure is less close, and that the tube of the cylindrical bodies, such as the humerus and femur, is larger than usual.

It has been already mentioned, that the bones derive their air in the internal cavities of cells which are placed next them among the muscles. Some, however, a filled immediately from the lungs, or the large internal air-cells, and the bones of the head and jaws have communications with the Eulalia chian tube, the cavity of the tympanum, and the sinuaxes of the n\ole.

The humerus is supplied with air by the axillary cell, by means of an opening situated at the inner and back part of the head of the bone. See Plate VI. in the Anatomy of Birds; fig. 1. represents the inferior half of the humerus of the American turkey (melagoceus); a the air hole, which like the air-holes of the lungs does not open immediately into the cavity of the bone, but contains a number of smaller foramina, that are produced by the cancelli, and have a direct communication with the internal part of the humerus.

The fork-shaped bone is filled from the jugular air-cells, from which also the superior dorazal, and the lowest cervical vertebrae, receive some air, through several small holes scattered upon their lateral and anterior parts. The air-hole of the fork is placed upon the side of its scalpel extremity, next the spine. See Plate VI. in the Anatomy of Birds; fig. 2. is the one half of the fork-shaped bone of the flark, viewed upon the inferior, a the air-hole.

The clavicle appears to obtain its chief supply of air from the cells which are continued from the jugular air-cells backwards upon the shoulder joint.

The principal foramina is found on the inferior of the clavicle, where that bone is connected to the branch of the fork. There are besides this, some very minute holes upon the outside of the clavicle, immediately above the shoulder joint; and on each side of the sternal extremity of the bone, there is a hole large enough to admit a bristle. See Plate VI. in the Anatomy of Birds. Fig. 3. shews an internal view of the clavicle of the flark; a, the larger air hole at the joint of the shoulder; b, one of the small foramina which opens into the chest, containing a bristle.

The fascia deriva air also from the procues of the jugular cell behind the joint. It is transmitted through several holes upon the very extremity of the bone. See fig. 4. of Plate VI. of the Anatomy of Birds, a the air holes.

We have discovered the openings by which the air is conveyed into the sternum, to be exceedingly numerous. The principal foramina are situated all along the middle line of the bone, upon the internal surface, which appears reticulated, or made of cancelli. Towards the anterior part there is one hole much larger than any of the rest; and in addition to those of the middle of the bone, there are many others passing into the edges of the sternum to which the ribs are articular. All these foramina would appear to communicate with the thoracic cells. See Plate VI. in the Anatomy of Birds; fig. 5. exhibits the internal surface of the sternum of the flark; a a a the small foramina in the middle of the bone, b the principal air-hole near the top of the sternum, c c c many little foramina seen between the sternal ribs which lead to the lateral parts of the bone.

The vertebrae of the back seem to procure air immediately from the lungs; the foramina are numerous, and placed along the sides of the bodies of the vertebrae and at the roots of their transverse processes. The foramina which conduct the air into the cervical vertebrae, occur with as little regularity; the three first have their largest holes upon the sides of their bodies, and in the rest they are to be found within the canal of the transverse process for lodging the vertebral artery, and along the course of the spinal canal, at least so they have appeared in the flark. See Plate VI. in the Anatomy of Birds. Fig. 6. shews one of the cervical vertebrae of that bird, a the body of the bone, b the spinous process, c c the transverse process forming a portion of the vertebral canal, on the inside of which are perceived several foramina leading into the sublimate of the bone, d the tube behind the body of the vertebra for containing the spinal marrow, exhibiting many small holes upon its internal
nal surface. The foramina of the cervical vertebrae have com-
unication with the lateral air-cells of the neck.

The air-holes of the anterior ribs are placed upon
the ends of these bones, where they are joined to the sternum.
They are supplied from the intermediate and lateral thoracic
air cells. See Plate VI. in the Anatomy of Birds, fig. 5. Thebby
refers to the opening upon the lateral ribs.

The air-pipes into the posterior or vertebral ribs by a num-
ber of foramina, situated upon the internal surface of their
extremities next the spine. These foramina appear to have
from their situation a direct communication with the poste-
rior surface of the lungs. See Plate VI. in the Anatomy of
Birds. Fig. 7, is a vertebral rib of the fork seen upon its
inner side, a the processes which articulate with the bodies
of the dorsal vertebrae, b the part joined to the transverse
processes, c e the several air-holes.

The air-holes of the bones of the pelvis are so numerous,
and occur with so much irregularity, that they do not ad-
mit of a particular description. They are all situated upon
the internal surface of the bones, and appear to be confined
to that space covered by the kidneys, under which the air
molts intimate itself from the abdominal cells, in order to
reach them.

The pilage of the air into the femur of the eagle and
fork is through an opening upon the fore part of the
bone, full within the process corresponding to the great
trochanter. It is a round depression, under the edge of
which the apertures leading to the cavity of the bone are
situated. See Plate VI. and fig. 8. of the Anatomy of Birds,
which represents the femur of the fork seen upon the an-
terior side a the air-hole, b the cavity of the bone laid open,
exhibiting a number of air-cells, c pone the bone on the inside into many irregular
cells; these are most numerous towards the extremities of the
femur, and are hardly to be seen in the centre; e an artery
distributing its branches to the membrane which lines the in-
ternal part of the bone. The air-hole of the femur in these
birds communicates with the gluteal cells.

In the pluvialis birds the air-holes of the femur are placed
upon the posterior part, and are found upon both the upper
and lower portions of the bone. See Plate VI. in the An-
tomy of Birds. Fig. 9. shows the posterior surface of the fe-
umur of a young geese a depression on the upper part of the
bone, containing a number of air-holes, b the inferior
depression with only three foramina.

The air-holes of the lower jaw have been observed in the
African and New Holland garies, the fork, the buceros na-
frus and buceros rhinoceros, and the crow; and in all these
they consist of two holes situated upon the two extremities
of the jaw behind the articulation. See Plate VI. in the
Anatomy of Birds. Fig. 10. is the lower jaw of the crow;
a e the two air-holes. These foramina communicate by a
tube with the cavity of the ear.

The air does not penetrate the bones of the head and
jaws in water fowls.

Having described the distribution of air, which takes
place throughout the bodies of birds, it remains to assign an
use to this most curious and peculiar circumstance in their
anatomy. It has been already stated, that the opinions of
anatomists upon this subject are different. The members of
the French academy supposed that the air-cells were neces-
sary to carry on the actions of respiration in birds. Cam-
per thought that air was admitted into the bodies of birds
for the purpose of diminishing their gravity in relation to
their bulk, and thus facilitate their motions; while Mr.
Hunter, the greatest physiologist of this or any other coun-
try, felt unwilling to confine the functions of the air cells
to any one purpose, and suspected they might be useful in
giving tone and strength to the song of birds.

The observations of the academicians appear to us per-
factly satisfactory, with respect to the connection between
the existence of the air-cells, and the office of the lungs. They
have related, that during the act of inspiration the sternum
was elevated, and the thoracic air-cells dilated at the same
moment with the lungs, and that when the air was expelled
from the lungs and thoracic cells, by the depression of the
sternum, one portion of it was expired by the trachea in the
usual way, and the rest was urged into the cells of the abdo-
men, the two parts of the cavity thus becoming alternately
enlarged and diminished. In order to ascertain with the
more certainty the condition of the air-cells during re-
spiration, the academicians subjected several large birds, such
as the turkey, goose, &c. to the experiment of having the
parietes of the belly dissected off without injuring the air-cells,
while the animal was still alive, by which they had an oppor-
tunity of observing, that the air-cells below the sternum were
removed tenfe during the time the thorax was diminished for
expiration, and that as soon as the sternum was raised to in-
nrçale the capacity of the thorax, the abdominal air-bags
became flexed. We have made an experiment of a similar
kind, with the same result; the abdomen of a living geese
was laid open, from which no air proceeded during inspira-
tion, but while the air was discharged from the lungs, it paled
into the abdominal cells and through the opening of the
belly with so much force as to blow out a candle. The
necessity of having the cavity filled with air in birds, ob-
viously arises from the circumstance of the lungs being con-
finned to the posterior part of the thorax, and consequently
not capable of suffering any compression from the contrac-
tion of the chest, but by the interposition of some other
parts.

Many have supposed that the air-cells were not only
mechanically subservient to the actions of respiration, but
answered another important purpose by collecting a quantity
of air, which in repelling the lungs effected a further change
upon the blood, thus producing a sort of double respiration;
but the free communication which exists between the lungs
and the cells, renders it probable that the air on its return
paees directly by the air-holes into the branches of the
bronchial, and, consequently, is never brought into contact
with the blood. It would therefore appear that the only
part the cells perform in the process of inspiration is to sup-
ply an elastic medium, by means of which the motion of the
sternum and ribs, equally and regularly affect every part of the
lungs.

The air-cells making part of the mechanism of the
organs of respiration, does not preclude them from answer-
ing other purposes in the animal economy. It is plain to
demonstration that the bodies of birds lose much of their rela-
tive weight by containing air in their cavities, and still more
from its admission into the external parts and the bones; the
advantages of which in transporting themselves through fo-
light a medium as the air, or even in locomotion upon a solid
surface, are too obvious to be inferred upon.

The air while it remains in the body, necessarily acquires
the temperature of the living bird, which renders it much
lighter even than atmospheric air, and therefore it acts like
that contained in the swimming bladder of fishes.

A comparison of the structure of one bird with another
proves that the quantity of air is in proportion to the ra-
pidity and continuance of the animal's motion, all other cir-
cumstances being the same; and that the air is distributed
always in preference to those members which are most em-
ployed in locomotion, as has been already pointed out.
It might be offered in objection to this opinion of the use of the air-cells in birds, that the bat, which is an animal very remarkable for the velocity of its flight, and its long continuance on the wing, is unfurnished with any apparatus except its lungs for containing air. The answer to this, however, is very easy: the extent of the wing of the bat is singularly large for the animal, and its membranous structure enables it to give impulsion to a larger volume of air than could be produced by a wing composed of feathers, even of an equal extent; and further, the pectoral muscles of the bat are larger in proportion to the animal than they are found in any species of birds, even those at the highest flight; so that the structure of the bat, instead of proving any objection to the uses affixed to the air-cells in birds, affords the strongest confirmation of the theory.

Notwithstanding the respect which is due to every physiological opinion of Mr. Hunter, we cannot perceive that there is the least relation between the air-cells and the organs of voice in birds. With a view of determining this, we have compared the structure of different birds, and have not found the air-cells larger in singing birds, than others. The nightingale, so eminent for its loud and protracted notes, is formed, with respect to the air-cells, exactly like the common sparrow.

Animal Heat.

Although it is not yet proved that the vital temperature of animals is the result of that process which is called respiration; yet, as it is generally supposed to be so, it would appear most proper to notice the animal heat of birds, immediately after the expiration of the lungs and their appendages. It is remarkable, that birds possess a higher standard of vital temperature than all other animals. Camper fluctuates it to vary from 104 to 107 degrees of Fahrenheit's scale. Mr. Hunter found the rectum of the common fowl to be 103, 103½, and 104 degrees; and in a young goose, we observed the thermomther to stand at 103 degrees in the rectum, and when inserted into the cavity of the body, to rise and remain at 104 degrees. It is difficult to explain either the cause or the necessity of the high temperature of birds. It has been accounted for by their respiration being more perfect from the air passing twice through their lungs; but even supposing this would alter their degree of animal heat, the occasion does not seem to exist, as birds have not that double respiration which is supposed, as has been already shown. It is to be presumed, that the warmth of birds may depend, in a degree, upon the structure of their skin, and the nature of their coverings, which are not so delicate as to admit of much evaporation from the surface of their bodies; but it can hardly be supposed, that this, of itself, would be sufficient to produce a temperature so much higher than is found in other animals, and maintain it so uniformly and permanently as it exists throughout the whole class of birds.

No experiments have yet been made to determine the powers which birds possess of refilling the influence of external temperature; but it is to be inferred from analogy, that they can sustain greater extremes of both heat and cold than other animals, without suffering an alteration in their proper degree of temperature; but that, at the same time, birds would soon yield to dilution upon any material charge in their natural standard, it being found that animals generally enjoy ind-pendence of temperature, in proportion as it exceeds that to which they are commonly exposed, and that the higher their natural standard, the more inconvenience arises from any alteration of it.

Blood Vessels.

The organs of circulation in birds have obtained but little of the attention of comparative anatomists. The larger branches of the arteries and veins, which lie near some of the viscera, have alone received any description; and that rather from being involved in the account of other parts, than for their own sake. The distribution of the blood vessels of birds, notwithstanding this, is not the least interesting part of their anatomy, as will appear from the ensuing description, which has been taken chiefly from the fowl, goose, duck, flib, and common fowl, in which it was found to much alike, that it may be prefumed the same arrangement of the blood vessels prevals with little variety in all birds.

The Arteries

Proceed from a single trunk which arises from the left ventricle of the heart. This trunk is so short, that it is concealed by the other parts on the basis of the heart, and is only brought into view after the reflections of the pericardium, and the adjoining vessels are detached by dissection. It is from thence, that as the parts are commonly beheld, there appear to be three great arteries issuing together from the middle of the heart, which are the primary branches into which the aorta is divided. The first branch is to the left side, and after it is sent off, the trunk affixes itself to turn over the aoorcle, before it gives the branch of the right side; these two branches pass in a curved manner from the heart towards the axillae, in the form of horns, and each is analogous to the arteiria innominate of the human subject, so that instead of one, there may be reckoned two arteiries innominate in birds. After these branches are parted with, the arterial trunk is continued over the aoorcles, and on reaching the back part of the heart, becomes the defendent aorta.

The arteiria innominate first sends off the common trunk of the carotid and vertebral arteries, which before its division gives off one or two small branches; one of these runs down upon the lungs in company with the par vagum, and appears to supply branches to the aponeuroses of the lungs, and the air-cells at the upper part of the thorax; the other branch, after supplying the lymphatic gland of the neck, with several small artery's, ascends upon the side of the esophagus, to which and the inner lungs, the divisions of the trachea are, and to the parts and integuments of the side of the neck, its branches are distributed, accomplish with the superior esophageal and tracheal arteries. This branch is often not sent off until the trunk divides into the vertebral and carotid, in which case it comes from the latter artery. Sometimes in the duck, the suprascapular artery, which is usually derived from the vertebral, is a branch of the common trunk.

The carotid artery, after parting from the vertebral, proceeds to the middle of the neck, and soon disappears; being covered by the muscles of the anterior part of the neck, under which it lies hidden, and in close contact with its fellow of the other side, to very near the head. If, during its course in this situation, it gives any branches, they are too insignificant to be noticed.

The carotid artery emerges from between the muscles of the neck, at about the third or fourth vertebra from the head; and after giving a branch downwards, amongst the lateral muscles of the neck, it runs along the outer edge of the rectus major anticus muscle, to behind the angle of the jaw, where it divides into its several branches.

An artery first goes off posteriory, which passes a little forwards under the branch of the os hyoides, and after sending...
ing some blood to the muscles of the neck, makes a turn backwards, enters the foramen in the transverse process of the second vertebra, and terminates by a singular anastomosis in the vertebral artery.

The next branch is analogous to the internal carotid; it goes forward also under the os hyoides, and passes behind the muscles of the jaw close upon the lower part of the skull, at which place it sends a branch upwards, which appears to penetrate the bones on the outside of the ear, and supplies the organ of hearing. It sends a branch into the skull, and another through the articulation of the jaw, to unite with the ophthalmic, and contribute to the plexus at the back of the orbit. The internal carotid then enters an osseous canal, which runs along the blosis of the cranium, between the tables of the bone, and at the lower and back part of the orbit, the artery receives a remarkable anastomosing branch of the internal maxillary, which almost equals in size the carotid itself; and these two vessels produce by their union, one, which passes almost directly into the cranium at the usual place for the entrance of the carotid artery. This vessel forms within the skull an anastomosis similar to the circle of Willis; but the branch which occupies the place of the bifurcate artery, is very small, and appears to be furnished entirely from the anastomosis of the carotids, and designed only to supply the medulla oblongata and spinal marrow.

The branches of the internal carotid are thickly spread in an arboraceous form upon the surfaces of the brain; some on the outside, and others on the internal surfaces of the ventricles, and the circumference between the two hemispheres.

The carotid also, as usual, sends off the ophthalmic artery, which, besides supplying the eye and the parts in the orbit, produces several anastomoses with the branches of the external carotid, which will be noticed hereafter. After the trunk of the carotid has parted with the two branches just described, it passes for a little way downwards and forwards behind the angle of the jaw, and divides at once into different branches, corresponding to those of the external carotid in mammal, the first of which might be called the opthalmal or laryngeal artery. This vessel sends a branch to the muscles upon the horn of the os hyoides, and then turns downwards and divides into two branches, one to the trachea, and the other to the cephalopagus, upon the side of which parts they descend to the throat, where they inoculate with the tracheal and cephalopagus branches of the common trunk of the carotid and vertebral arteries.

The external maxillary artery dips in between the pterygoid muscle, and that which is situated at the back of the lower jaw for opening the mouth; it then passes behind the articular bone, and gives twigs upwards to the muscles of the jaws, and to the plexus at the back of the orbit; upon emerging from behind the articular bone, it lies under the zygomatic processes of the jaw, and sends an artery upwards, which is distributed to the temporal and malleolar muscles; and proceeding under the triangular tendon, that forms from the inferior margin of the orbit to the lower jaw, it divides into two principal branches: one of these passes along the side of the upper jaw, gives a branch upwards to the front part of the orbit which unites with the ophthalmic artery, and is lost at the top of the head. This branch is very large in birds with combs, as in conjunction with the ophthalmic, it furnishes numerous vessels to these vascular parts. The artery then passes on and supplies branches to the sides of the head before the orbits, and to the integuments and substance of the upper mandible, inoculating with the palatine branches of the internal maxillary artery.

The second portion of the external maxillary proceeds to the lower jaw, to which, and the lower part of the malleol

muscles, it is distributed. The external maxillary supplies the place of the temporal, labial, angular, nasojugal, and mental arteries of mammalia.

The laryngeal, or posterior palatine artery is a little branch of the external carotid, which is sent off posteriorly opposite to the external maxillary artery. Its branches are exhausted upon the back part of the fauces, the muscles for moving the upper jaw, and posterior naris.

The lingual, or sub-maxillary artery passes under the muscles which connect the os hyoides to the lower jaw, and close upon the back of the membrane of the lower part of the mouth, it sends a branch to the cephalopagus and trachea, supplies the muscles of the os hyoides, the tongue, the lower surface of the mouth, and furnishes the artery which enters the submaxillary of the lower jaw.

Just at the origin of the sub-maxillary artery, there is another little branch of the carotid, which is lost upon the muscles of the os hyoides.

The internal maxillary artery is, as usual, the continuation of the trunk of the external carotid; it runs forwards between the pterygoid muscles, and the lining of the mouth, upon the side of the long muscle for moving the upper jaw, and divides into two principal branches; one of them proceeds under the tendon of the long muscle to get upon the palate, where it forms two branches, of which one runs along the external side of the palate, between the membrane and the bone of the mandible to the extremity of the bill, where it becomes united to the same branch of the opposite side, as also to the middle artery of the palate. The other branch lies also superficially under the membrane which lines the mouth. It passes forward to meet its corresponding vessel of the opposite side with which it becomes actually incorporated, and by their union a single artery is generated, which runs along the middle line of the palate to the end of the mandible, where it unites with the lateral branches as already mentioned. At the junction of the vessel of each side to form the middle palatine artery, two branches go off, which are lost upon the lining of the mouth, and the interior of the organ of smell.

The other branch of the internal maxillary artery is reflected upwards towards the orbit, below which it divides and unites again forming a triangle, through which the veins pass; at this place it produces a remarkable plexus of vessels, like the reticulum of the carotid artery of quadrupeds, which is increased by branches from the ophthalmic and the palatine arteries, and from which the back part of the organ of smell receives its supply of blood.

The internal maxillary artery then runs directly backwards below the orbit, passes between the radiated or fan-shaped muscles which move the upper jaw, and the pterygoid processes; and turning forwards round the bals of the cranium becomes incorporated with the internal carotid artery just as it enters the bony canal, which conduits it to the brain. The vertebral artery soon after it parts from the carotid, sends off a branch backwards, which passes over the neck of the scapula and is lost among the muscles on the posterior part of the shoulder, inoculating with the articular and other arteries about the joint; this branch might be called the supra-ocularis. In the duck we have observed it before it makes the turn over the scapula to send an artery upwards along the muscles of the neck.

The trunk of the vertebral artery proceeds obliquely upwards, and having entered the foramen in the transverse processes of the second cervical vertebra, gives off a large branch downwards, which is distributed between the vertebrae, and to the spinal canal in the manner of the intercostal arteries, with which it anastomoses upon arriving in the thorax.
The remainder of the vertebral artery is continued upwards in the canal formed in the transverse processes of the cervical vertebrae, diminishing gradually in consequence of branches it feeds off between each vertebra to the spinal marrow and the muscles of the neck. Near the head, the artery is found considerably reduced; and within the bony canals in the transverse processes, terminates entirely by involucration with the reflected branch of the carotid, as before noticed.

The extraordinary anastomoses and the platoento which are to be observed in the arteries of the head in birds are not easily accounted for. It seems possible that they may be required in consequence of the great length of the neck in these animals; it being well known that frequent communication amongst the vessels, although it diminishes the impetus of the circulation, infuses a free and uninterrupted motion of the blood.

After the common trunk of the carotid and vertebral is detached from the arteries iniminating, this vessel may assume the name of the subclavian. While passing under the clavicle, it sends off some important branches: the first might be called a pectoral artery; it proceeds upwards upon the internal surface of the pectoralis minimus muscle, which it supplies; and then dividing into two branches, one passes over the anterior edge of the clavicle, and under the pectoralis major, between which and the sternum it runs, detaching its branches to the musculature; the other sends first along the under side of the clavicle a branch which is again subdivided and distributed to the outside of the shoulder-joint and to the deltoid muscles, in which it involutes with the articular artery. The vein then passes between the clavicle and the fork-shaped bone, and on a ligament which connects the head of the clavicle to that of the scapula, and disperses its branches upon the upper part of the shoulder-joint forming anastomoses with the neighbouring arteries.

The next branch of the subclavian is the humeral artery; it arises from the upper side of the vessel, and makes a slight curve to reach its situation on the inside of the arm, in order to dispense its branches in the manner hereafter described.

The internal mammary artery is given off just as the subclavian leaves the chell. It divides into three branches, one ramifies upon the inner surface of the sternum; another upon the pectoral ribs, and the intercostal muscles; and the third runs along the anterior extremities of the vertebral ribs, supplying the intercostal muscles, &c.

The chief peculiarity of the arteries of the superior extremity in birds, consists in the great magnitude of the vessels which supply the pectoral muscles; these, instead of being inconsiderable branches of the axillary artery, are the continuations of the trunk of the subclavian, of which the humeral is only a branch.

The great pectoral or thoracic artery passes out of the chell over the first rib, and close to the sternum, and immediately divides into two branches. One of them ramifies in the superior part of the pectoralis major, and the other is exhausted in the lower part of the muscle, and sends off a branch analogous to the long thoracic artery of mammalia.

The humeral artery, while within the axilla, gives a small branch backwards to the mufcles, under the scapula, and upon reaching the inside of the arm produces an artery, that soon divides into the articular and the profunda humeri. The articular artery passes round the head of the humerus, underneath the extensors; its branches penetrate the deltoide muscle, and anastomose with the other small arteries around the joint.

The profunda humeri as usual turns under the extensor muscles, to reach the back of the bone, at which place, in birds, it separates into two branches, of which one descends upon the inside, and the other upon the outside of the articulation of the humerus with the radius and ulna, and there involutes with the recurrent branches of the arteries of the fore-arm.

After the humeral artery has sent off the profunda, it descends along the inner edge of the biceps muscle, detaching some branches to the neighbouring parts; upon arriving at the fall of the wing it divides into two branches, one of these is analogous to the ulnar artery, and the other from its position deferves to be called rather the interosseous than the radial artery.

At the place where the humeral produces the two arteries of the fore arm a small branch is sent off, which is lost upon the fore part of the joint, and in anastomoses with the recurrent of the ulnar, and the profunda humeri.

The ulnar artery is the principal division of the humeral; it proceeds superficially over the mufcles which are analogous to the pronator, sends a large recurrent branch under the flexor ulnaris to the back of the joint upon which it ramifies and forms anastomoses with the profunda humeri. The artery then proceeds along the inner edge of the ulnar muscles, to which it distributes branches. It is afterwards seen passing over the carpal bone of the ulnar side, and under the annular ligament, at which place it sends off some branches which spread upon the joint and involute with similar ones of the interosseous artery. Very soon after the ulnar artery gets upon the metacarpus it dips in between the bones and re-appears upon the opposite side lying under the roots of the quills, to each of which it sends an artery; it preserves this situation to the end of the metacarpal bones, where it passes between the flgy analogous to the little finger and the principal or fore finger, and pursues its course along the edge of the latter, to the extremity of the wing, supplying each of the true quills with an artery and sending at each joint of the finger, a croes branch to communicate with the accompanying branches on the opposite side.

The interosseous artery detaches first a branch of some size to the membrane which is spread in the fold of the wings, upon which it forms several ramifications. After this the artery dips down behind the promotor muscles to get into the space between the ulna and radius. It here gives a branch backwards to communicate with the others about the joint, and proceeds in the interosseous space as far as the carpal joint, during which course they become much diminished from giving off several branches which are distributed to the interosseus and the quills placed upon the outside of the ulna. The remainder of the interosseous artery is expanded in some branches upon the back of the carpal joint, the battard quills, and along the radial edge of the metacarpus and bones of the fore-finger, where it forms communications with the croes branches of the ulnar artery already mentioned.

From this description it will be perceived, that no artery exists in birds strictly analogous to the radial; that there are no palmar arches; and that the size of the interosseous artery, and the course of the ulnar along the outside of the metacarpus are peculiarities which arise from the necessity of affording a large supply of blood to the quills during their growth.

The descending aorta makes a curve round the right auricle in order to get upon the posterior surface of the heart, after which its course is close along the spine, in which situation it is bound down by cellular sublimate, and the strong membrane or aponeronous, which covers the lungs on their anterior part. The first branch which this vessel appears to send off is a bronchial arteries; they arise from the fore part of the aorta just when it arrives upon the spine; and having entered
entered the lungs, their ramifications accompany those of the pulmonary arteries. They appear also to send branches to the 
fine, and the spaces between the ribs.
The intercostal arteries do not take their origin from the 
aorta in numerous and regular branches as in mammalia, but 
confine originally of but few vessels, which are multiplied by 
analogous with each other, and with the arteries which come 
cut of the spinal canal. An arterial plexus is thus formed 
round the heads of the ribs, from which a vessels is sent to 
each of the intercostal spaces. Many of these branches be-
sides supplying the intercostal muscles and ribs, are continued 
to the muscles upon the outside of the body and the integu-
ments. The analogous of the intercostal arteries round the 
ribs is very similar to the plexus which is produced by the 
great sympathetic nerve in the same situation.

The aorta produces no branch which deserveth the name of 
the phrenic artery, as birds do not possess that muscular 
septum of the body, to which the artery of this name is distri-
buteth in other animals.
The celiac artery is a very large single trunk, and arifes 
from the fore part of the aorta, even higher than the zone of 
gastric glands. It descends obliquely for a short way and 
then gives off a branch which soon divides into two or three 
other vessels that are spread upon the lower part of the coeca, 
and the side of the zone of gastric glands, uniting with the 
other arteries of the coeca at the right side. The submedian 
and posterior arteries, answering to the anterior of the aorta, 
are distributed to the adjoining portion of the small intestine. 
The posterior gastric artery, almost as soon as it is formed, 
detaches the jejunal arteries; and very soon after, it furnishes 
from the posterior side of the vessel, the right hepatic artery.
This branch proceeds to the right lobe of the liver, which it 
enters on the side of the hepatic duct; after having divided 
to two or three minute arteries on its way to the liver, it 
supplies the hepatic duct with a branch which accompanies 
the duct to the intestine, and is there lost. The posterior 
gastric artery then runs down upon the back of the gizzard, 
and opposite to the origin of the first intestine it sends off 
an artery which proceeds directly to one of the coeca, upon 
which and the side of the next intestine it is expended, insul-
lating at the end of the csecum, with branches of the menef-
teric artery, which are distributed to the adjoining portion of 
the small intestine. The posterior gastric then furnishes a 
large vessel which runs upon the gizzard and divides into two 
chief branches, which penetrate the substance of the digastric 
muscle, in which they are lost.
The next branch of the posterior gastric artery is the pan-
creatic. It runs between the two pancreatic glands, dispelling 
branches to each, and to the duodenum. After this the 
trunk of the posterior gastric divides into two branches which 
run along the margins of the upper and lower portions of the 
digastrical muscle, supplying them with numerous twigs, and 
analogous with the ramifications of the other gastric 
arteries.
The anterior gastric artery descends to the angle formed by 
the bulbus glandulosus and the gizzard, and there sends off 
a small branch which spreads upon the zone of gastric glands, and 
insulates with the first ramifications of the celiac, and 
immediately afterwards it detaches a large artery, which runs 
round the inferior margin of the digastric muscle, which it 
feveth with many twigs, and communicates freely with the 
corresponding branch of the posterior gastric artery.
Three small hepatic arteries take their origin from this 
branch of the anterior gastric, just as it passes over the 
highest part of the margin of the gizzard; these ve-
selfs enter the fence in the left lobe of the liver. The anterior gastric artery now proceeds along the fore-part of 
the gizzard, feeding one or two branches into the muscular 
fibres, and near the tendon it terminates in two large vessels, one of which is distributed upon the left 
side of the digastric muscle and the other passes a little over 
the tendon and then divides into two arteries; which pro-
duce several branches that disappear in the substance of the 
gizzard, and between the digastric muscles and the parietes of 
the ventricle, anatomicosing with the vessels of the posterior 
side.
The superior mepenteric artery takes its origin from the fore 
part of the aorta a little below the celiac, and proceeds for 
some way without detaching any branches; after which it 
experiences the same kind of division and subdivision that 
takes place in mammalia; and the numerous arteries which 
are thus ultimately produced are sent upon the small in-
testines. One of the first and largest branches of the superior 
meenteric, however, is allotted to supply one of the coeca, and 
and establish a communication with the inferior meenteric, 
and gastric arteries. This branch, soon after it leaves the 
trunk of the superior meenteric, divides into two. One 
descends upon the rectum, where it meets with the inferior 
meenteric artery, with which it produces a very remarkable 
analogous to the meenteric arch in the human sub-
ject; this united artery supplies the rectum and origin of the 
coeca. The second portion of this branch of the superior 
meenteric, runs in the space between the left part of the 
small intestine, and the csecum of one side sending numerous 
brances to each, and at the end of the csecum, communicat-
es in a palpable manner with another branch of the su-
ior meenteric artery, which runs upon the adjoining part of 
the small intestine.

A branch arises from the anterior part of the aorta, just 
below the lungs; it is designed for the nutrition of the organs of generation, and except in the season for propa-
gation, is so small as to be discovered with difficulty; but 
when the testicles become enlarged, it is considerably in-
creased in size in the male bird, and much more so in the 
female, when the ovary and oviduct are developed for pro-
ducing eggs. It nearly equals the superior meenteric artery 
during the period of laying, in which state we shall describe 
it. It is a single artery like the celiac and the meenteric, 
proceeds at a right angle from the aorta, and soon sends off 
a branch which goes into the kidney of the left side, to 
which it gives some twigs, and afterwards emerging from the 
kidney, it runs in the membrane of the oviduct, upon which 
it is distributed. After this branch is detached, the artery 
projects a little farther forwards into the cavity and divides 
into two branches, one of these goes to the ovary, in which 
it ramifies, and furnishes an artery of some size to each of 
the vesicles containing the ovum. The other is distributed in 
numerous branches to the membrane and superior parts of the 
oviduct, and insulates with the other arteries of the ovi-
duct. It deserves to be remarked, that this and all the other 
arteries which are furnished to the oviduct, have a tortuous 
or undulating course, in the same manner as the vessels of the 
uterus of the human subject.

There are no regular emulgent arteries in birds; the kid-
nies deriving their blood from various sources, which will be 
painted out as they occur.
The inferior extremity is supplied with two arteries, which 
have a separate origin from the aorta. One corresponds 
with the femoral artery, and the other describes the name of 
the common artery.
The femoral artery is a small trunk which takes its origin from the side of the aorta, opposite to the notch in the bones of the pelvis immediately under the last rib. This notch is formed into a round hole in the recent subject, by a ligament which is extended from it to the rib; and it is through this hole that the femoral artery makes its exit from the pelvis; just before it passes out upon the thigh, it sends off a long branch which runs backwards the whole length of the margin of the pelvis, distributing arteries to the abdominal muscles on one side, and the obturator internus on the other. This branch also appears to supply one to the ovicul. The femoral artery, immediately after leaving the pelvis, separates into two branches; one goes upwards and outwards, ramifying amongst the muscles in that situation; the other turns downwards, and is distributed to the flexors of the limb, and round the joint, and sends an artery to the edge of the vastus internus, which can be traced as far as the knee. The kidnies appear to derive some irregular indescernible branches from the femoral artery while it is within the pelvis.

The ilhaciac artery is the principal trunk of the lower extremity, exceeding very much in size the femoral. When it is produced by the aorta, it appears to be the continuation of that trunk; the remaining part of the aorta becomes so much and so suddenly diminished, and seems as it were to proceed as a branch from the back part of the vessel.

The ilhaciac artery, while in the pelvis, is concealed by the kidnies, in which situation it gives a branch from its lower side, which divides into three others that are distributed to the funicle of the kidnies; one of these on the left side is continued out of the kidney to be lost upon the ovoidul. The artery leaves the pelvis by the ilhaciac foramen, in company with the great saphenous; while within the form, it gives a branch obliquely downwards under the biceps to the muscles lying on the pelvis; and as it passes over the adductor, it sends off another along the lower edge of that muscle, which is chiefly lost in the femoral fuscus.

It then detaches several small branches to the muscles on the outer and fore part of the thigh, some of which anastomose round the joint with the branches of the femoral artery. Just as the ilhaciac arrives in the ham, it furnishes a very large branch downwards, which divides into two; one goes under the gaitrocnemius, to which and the deep seated flexors its branches are distributed as far as the heel; the other is analogous to the peroneal artery; it goes to the outside of the leg, supplies the peroneal muscles posteriorly, and passes along the outer edge of the flexors of the toes to the heel, above which, and behind the flexor tendon, it divides, running on each side of the heel, and forming several articular arteries around the joint, and communicating with the other branch, and with the anterior tibial, and the metatarsal branch of the plantar artery.

The articular arteries go off next from the artery in the ham, these two principal ones being deep seated. One proceeds under the vastus internus to the external part of the joint; the other is large, and situated upon the inside. It forms two vessels, one is the true articular artery, and spreads upon the ligaments of the joint, the other is distributed in the subincision of the flexor of the heel, which is placed upon the inside and fore part of the leg, and comes out upon the edge of this muscle to be lost in the integuments.

The posterior tibial artery is extremely small; it only supplies muscular branches to the internal head of the gaitrocnemius, and some of the flexors of the toes; it is lost on the inside of the heel in anastomoses with the peroneal artery, and other small superficial branches.

The trunk of the artery of the leg now gets upon the posterior surface of the tibia, and sends off through the deficiency left between the tibia and fibula at the superior part, a branch, which is distributed to all the muscles upon the fore part of the leg. The artery then creeps along the back of the bones for some way, and passing between them as above, where the fibula is divided with the tibia, it re-appears on the anterior part of the leg in the situation of the anterior tibial artery: at this place it detaches some very small branches, which frequently divide and unite again, to produce a most singular reticulation or plexus of vessels, which closely adheres to the trunk of the artery, and is continued with it as far as the articulation of the tibia with the metatarsal bone, where it disappears without seeming to answer any useful design. This plexus resembles in appearance exactly the division of the arteries of the extremities, which has been described by Mr. Carlile in the tardigrade quadrupeds, but differs from it in this circumstance, that the trunk of the artery is preferred behind it, without suffering any material diminution of its size.

The anterior tibial artery furnishes no branch of any importance during the time it is proceeding along the fore part of the leg. It passes under the strong ligament which binds down the tendons of the anterior muscles of the leg, and over the fore part of the joint on the inside of the tendon of the tibialis anticus; at which place it distributes some branches which inculcate with the other arteries round the joint; it then pursues its course in the groove along the anterior surface of the metatarsal bone, and covered by the tendon of the flexor digitorum. On coming near the foot, it sends off an artery, which divides, behind the joint of the internal toe, into two branches; one goes between the internal and middle toes, ramifies upon both their joints, and unites with the artery in the sole of the foot; the other is distributed between the internal toe and the pollex or toe which occupies the place of the great toe; the main artery now passes to the sole of the foot through a hole in the metatarsal bone left for the purpose, where the original parts of this bone were united by ossification. In this situation the artery might receive the name of the plantar. It has fearfully passed through the bone, when it divides into three branches; three of these are distributed to the tendons and ligaments, &c. on the outside of the foot and the back of the metatarsus, anastomosing with the defending branches of the peroneal artery; the fourth branch supplies the pollex, and also sends a branch upon the metatarsus. The remaining branches are designed for the three principal toes; one dips in between the internal and middle toe, unites with the anterior branch of the metatarsal artery, and is distributed to the sides of these toes as far as their extremity. The other divides, between the external and middle toe, into two branches, which run upon the opposite side of each of these toes to the end.

When the feet are webbed, the digital arteries send off numerous branches, which, ramifying in the membrane between the toes, establish a communication with each other. The present description has been taken from birds which possess three principal toes, and the back toe, or pollex; but no material difference can be expected in those with a greater number of toes.

After the trunk of the aorta has detached the ilhaciac arteries, it is continued along the spine, sending small branches analogous to the lumbar arteries, one of which ascends upon the rectum, supplies the place of the inferior mesenteric, and unites with the superior mesenteric, as already mentioned. The aorta separates above the coxygeal vertebra into three branches; two of these proceed late-
latterly, and are distributed to the neighbouring parts; and to the kidneys and ovitac; the third branch descends to the very point of the tail, upon the muscles and quills of which its branches are exhausted.

The arterial system of birds differs from that of other animals chiefly in the frequent anastomoses, which exist more especially amongst the arteries of the head and the viscera. Similar communications occur between the veins, which are even in some instances more singular and unaccountable, as will be perceived by the following description, which has been taken principally from the 

Veins.

The venous system returns the blood to the heart by means of three trunks; two of these, for the convenience of description, we shall call the subclavian veins, although they do not correspond in every respect with the veins of this name in mammalia; the other trunk is analogous to the inferior vena cava.

The subclavian vein is composed of the jugular and vertebral, and the veins which belong to the superior extremity or wing.

The vertebral vein is lodged in the same canal with the vertebral artery; it anastomoses between the vertebrae with the veins upon the spine, of the medulla spinalis, which is the continuation of the sinuses of the brain; in conjunction with these, therefore, the vertebral vein may be considered as answering the purpose of the internal jugular of mammals. It appears also to form at the base of the cranium a free communication with the jugular vein, and to receive by occasional branches, blood from the muscles of the neck.

The jugular vein is a single trunk in birds, and does not admit of the distinction into external and internal; it proceeds superficially along the side of the neck in company with the par vagum nerve. The vein of the right side exceeds the other in size; it is often twice as large. The jugular vein receives several lateral branches from the muscles and integuments of the neck, the oesophageus, &c.; one of these near the head is much larger than the rest; it lies deep amongst the muscles, and appears to communicate with the vertebral vein. There is a branch of the jugular which goes amongst the muscles of the tongue and of the os hyoideum, and another for the muscles within the jaws and the integuments in the back of the mouth; these might be called the lingual and submaxillary veins.

The two jugular veins form a most remarkable communication with each other immediately below the cranium, by means of a crosa branch, generally of an equal size with the trunks themselves. From each side of the arch thus formed there issue a large vessel, which is made up of the veins of the external part of the head; one of these passes round the articular bone, and apparently penetrates the joint of that bone with the lower jaw; it appears in several branches upon the side of the check, and spreading from the ear, in the manner of the portio dura nerve of the human subject, and contributes to form a plexus of veins below the posterior part of the orbit, similar to the arterial plexus already described in that situation. The principal branch of the veins of the head passes obliquely round the inter-articular bone, and below the orbit divides into several large vessels; one of which belongs to the back part of the palate, another ascends in the orbit, and unites with the ophthalmic vein; and a third is distributed to the interior of the organ of smell, the palate, and the external parts of the upper and lower jaws. These branches produce plexuses along the bafe of the orbit and the external edge of the palate, which correspond to those of the arteries before described.

In all the subjects we dissected for the veins we failed to discover any direct communication between the jugular vein and the sinuses of the brain; and in every instance the external veins of the head appeared to be sufficiently large of themselves to produce the trunk of the jugular. It may therefore be presumed, that if any branch analogous to the internal jugular vein passes through the posterior foramen lacerum, it is very inconsiderable, and incapable of transmitting the blood of the brain.

The sinuses of the brain seem to discharge their contents principally into some veins, which lie in the membrane forming the sheath of the spinal canal, and these appear to discharge their blood gradually, as they descend in the neck, by means of lateral communication with the vertebral veins. The sinuses, which immediately open into the spinal veins, are situated upon the back of the cerebellum, and produce by anastomoses with each other, with the superior longitudinal sinuses, and with others along the sides of the brain, an union of vessels, of a diamond shape.

The sinuses of the brain in birds generally are irregular in form, and consist of flattened canals; and not only the sinuses on the back of the cerebellum, but the spinal veins appear so like extravasation, that accurate and repeated observations are necessary to discover them to be real vessels.

The principal sinuses, besides those upon the cerebellum, are the superior longitudinal, and one which runs along the lower edge of each hemisphere of the cerebrum; there appears to be also one upon the side of the cerebellum, corresponding to the lateral sinuses. All the sinuses communicate with each other on the back of the cerebellum as already mentioned. The superior longitudinal sinuses is continued at its anterior part under the frontal and nasal bones, and anastomoses with the ophthalmic and nasal veins. There are other sinuses in the several duplicatures of the dura mater, which are too small to be easily traced, or to deserve much regard.

The veins of the wing, or superior extremity, have a less curious distribution than those of the head. The branches which are derived from the parts within the shell, the muscles about the scapula, and the pectoral muscles, accompany the arteries of the same parts, so regularly that their course does not require description.

The vein lies considerably lower in the axilla than the artery, but still continues to receive corresponding branches. The trunk of the vein descends in the course of the humeral artery, but more superficially; in this situation it may be called the biceps, or more properly the humeral vein. There is no vein in birds which deferves the name of the cephalic; there are branches of the humeral vein accompanying the articular and profunda arteries, and at the middle of the humerus, a large branch of the vein enters the bone; there are also two very small branches which lie in close contact with the humeral artery, which they accompany nearly its whole length.

The principal vein of the wing divides into two, opposite to the joint of the humerus with the fore arm. One of these branches belongs to the sides of the radius; it receives blood from the muscles and skin on the upper part of the fore arm, but its chief vessels lie between the integuments of the fold of the wing. The other branch of the humeral vein crosses the fore arm, just below the articulation, in company with the nerve, and running along the inferior edge of the ulna, receives a branch from between the bases of each quill, is continued along the ligament which fulfills the role of
the quills to the extremity of the wing, receiving many
veins of the joints from the opposite side of the fingers.
Besides these large superficial veins of the fore-arm, there ap-
pears to be one, and sometimes two, small accompanying
veins to the ulnar and interosseous arteries.

The inferior vena cava, before it enters the auricle, re-
ceives as usual the hepatic veins; these are numerous, and
open into the vasa, as it passes behind the liver, or more fre-
cquently within the substance of that viscus in the back part.
We have reckoned in the cock two large and two small hepa-
tic veins from the right lobe, and one large branch from the
left lobe, besides six minute veins, which come indifferently
from both lobes.

The trunk of the vena cava is very short in the abdomen;
it separates into two great branches analogous to the primary
iliac veins, opposite to the renal capsules; these turn to each
side, and experience a very singular dilatation. On coming
near the edge of the pelvis each of these two veins forms
a trunk; one of which collects the blood of the lower
extremity, as hereafter described; the other pafles straight
downwards and forwards in the substance of the kidney, and
admits the several emunctory veins, which are very large, and
are seen to pass for some way obliquely in the kidney, before
their termination. The descending branch of the iliac also
receives the ovarian veins, and when arrived at the lower end
of the kidney, divides into three branches; one transmits
the blood of the muscles of the tail and parts adjacent; an-
other accompanies the ureter to the side of the rectum, and
is distributed about the anus and parts of generation, answer-
ing to the hemorhoidal veins; the third pafles inwards to
the middle line between the kidneys, and there unites with the
corresponding branch of the opposite side. The vein which
is in this manner produced, receives all the blood of the
rectum from the anus to the origin of the ceca, anastomos-
ing below with the branches of the hemorhoidal veins;
and at the upper part of the rectum, it becomes continuous
with the trunk of the veins of the small intellines, forming
the most remarkable anastomoses in the body, both on ac-
count of its consequences and the fize of the veins by which
it is composed. By means of this communication, the blood
of the vasa, and the external parts of the body, flows almost
independently into the vena cava and vena portae; for the anas-
tomosing vessels are sufficiently large to admit the ready pas-
sage of a considerabfe column of blood in proportion to the
whole mass which circulates in the body of the bird; for in-
fause, in the goaf, the communicating veins of the pelvis are
equal in fize to a goafe quilt, and in the oiferich and caffofory they are as thick as a finger. The advantage
which appears to result from this remarkable union of vessels,
is the prevention of congestion, or the overloading either the
heart or liver with blood, as the one organ has the power of
relieving the other. It would seem from this, as well as fe-
veral other provisions of the fame kind, that the circulation
would be more liable to obstruction in birds than other
animals. It is difficult to say, however, to what cause such
an effect ought to be ascribed. Is it from the comprefion
sustained by the heart and other vifera, by means of the
air-cells during inspiration? Or, is the mode of progres-
sion by flight capable of imped the motion of the blood?

The anastomoses of the pelvic veins, in being the means
of conveying common venous blood into the liver, goes to
prove, that the blood of the vena portae does not require
any peculiar preparation by circulation in the spleen or
other vifera, which has been conceived as neceffary by fome
physiologists to fit it for the secrefion of bile.

The vena portae belongs almost exclusively to the right or
principal lobe of the liver. It is formed by three branches.
The portal vein is the fmaltest, and is added to the vena
cava, just as it penetrates the liver on the side of the hepatic
duct. The next is made of two branches; of which one
returns the blood of the posterior gallar artery, and there-
fore may be called the posterior gallar vein; and the other
is furnished by the pancreas and duodenum, and therefore
is the pancreatic vein. The third and largest branch of
the vena portae is the mesenteric vein, which not only collect
the blood from all the small intellines, but likewise re-
cieves the inferior mesenteric, or vein of the rectum, which
forms the communication that has been described with the
pelvic veins.

The veins of the left lobe of the liver, are furnished in the
goaf by those which accompany the anterior gallar artery,
and some branches from the head of the duodenum.

The anterior gallar veins produce two fmall trunks,
which enter at the two extremities of the fissure, in the
coupage surface of the left lobe of the liver, as it lies upon
the edge of the gizzard; the veins from the head of the
duodenum furnish a small vesfel which pafles backwards
to penetrate the posterior part of the fissure in the left lobe.
In the cock, the veins that the left lobe of the liver derives
from the anterior gallar, are more numerous than in the
goaf.

The veins of the zone of gallar glande, and of the lower
portion of the esophagus, do not contribute to the secre-
tory vesfeis of the liver, but proceed to the superior par-
of that viscus, to terminate in the vena cava; and does also
the umbilical vein.

The vein which returns the blood of the inferior extre-
mities, is divided in the pelvis into two branches, which
reproduce with the femoral and ilfahalic arteries; the
one pafles through the iliadic foramen, and the other
through the hole upon the anterior margin of the pelvis;
but the proportion they bear to each other in magnitude,
is the very reverie of what occurs in the arteries; for the
anterlor vein is the principal one, whilst the other is not a
very considerable vessel, and receives its supply of blood
from the muscles at the posterior part of the joint.

The femoral vein, immediately without the pelvis, gives
branches on both sides, which receive the blood of the ex-
tenlor and adductor muscles at their superior part; the
trunk pafles obliquely under the accelfory muscle of the
flexor digitorum, and over the os femoris, where it lies
superficially; it then winds under the adductor muscles,
and gets into the ham, where it receives many muscular
branches, and comes into company with the artery and
nerves. It here divides into the bifid and peroncal veins.
The bifid is joined by some branches from the surface of the
joint anwering to the articular arteries; it also receives
the anterior bifid vein which accompanies the artery of the
same name. The bifid vein proceeds down the leg along
with the artery on the inside of the deep-feated flexors of
the heel; it turns over the fore part of the articulation of
the tibia with the metatarsal bone, in order to get upon the
inner side of the metatarsus; above the origin of the pollex,
it receives a communicating branch from the peroncal vein,
and immediately after, two branches from the toes; one of
them comes from the inside of the internal toe; the other
arifes from the inside of the external and middle toes, unite
at the root of the toes in the sole of the foot, and is joined
by a branch from the pollex, before its termination in the
internal vein of the metatarsus.

The peroncal vein derives its principal branches, along with
thole of the peroncal artery, from the muscles on the out-
side of the leg. The trunk of the vein comes out from the
peroncal
peroneal muscles, and pass superficially over the joint at
the heel, and along the outside of the metatarsus; near the
pollex, or great toe, it sends a branch round the back of
the leg, to communicate with the tibial vein; after which, it
is continued upon the outside of the external toe to the ex-
tremity, receiving anastomosing branches from the tibial
vein.

Where the veins run superficially upon the upper and
lower extremities, they seem to supply the place of the
branches of the cephalic, subclavie, and the two joplens; but
the analogy is lost upon the upper arm and thigh: these
branches forming deep-seated trunks; this constitutes the
greatest peculiarity in the distribution of the veins in the
extremeties of birds.

Kidneys.

These organs occupy the posterior part of the common
cavity of birds, from the last rib to near the coxalgic ver-
tebra; they fill all the cavities and depressions of the bones
of the pelvis; the posterior surface, therefore, of the kid-
nies is extremely irregular; their interior part is rather
flat, and they are notched upon the external edge, which
gives usually the appearance of their being composed of
three lobes; but the inequalities of the edge, seem to in-
fluence the position of those being larger at one place than
another, than from an original division into lobes; these
prominences correspond to the most depressed parts on the
pelvis; accordingly, the kidneys are observed to form a
projection at the upper end, where they lie on the depres-
sion of the offia ilia, again opposite to the hollow on the
inside of the iliacal foramen, and lastly, at the lower par-
part of the kidney, where it fills the concavity of the
ischium.

The kidneys have a covering of thin periurineum, and
under this, they seem to possess another thin membranous
tunic, which closely invests them, as well where they are
applied to the bones, as anteriorly; this coat also appears
to be reflected into the substance of the kidneys, and to form
the cellular connections of the different parts which com-
pone these organs. According to the anatomists, the kid-
nies of the cormorant are separated from the other parts
of the lower belly, by a distinct membrane, and instead of
being divided into three lobes, are toothed like a cock's
comb on their gibbous part.

The texture of the kidneys is very fragile; readily giving
way under the slightest injury. They yield to the pref-
sure of the finger a granular feel, as if composed of a
number of minute bodies, easily separable from each other:
the surface of the kidneys, also, presents the appearance of
an aggregation of small glands.

The trunks and larger branches of the blood-vessels of
the kidneys have been already described. The termination
of the minute ramifications of the artery cannot be so
clearly perceived as in mammalia. When coloured fluids
are thrown in by the artery, the whole substance of the
kidney appears to equally admit the injection: the minute
branches of the blood-vessels are too numerous, therefore,
to allow of a distinct view of the figure assumed by the
secretory extremity of the artery; but it is probable,
from the structure of the kidney differing in other circum-
stances, that it is not wound into a coil, as in man and
quadrupeds.

The kidneys of birds, in general, do not possess any
cavity for collecting the urine, previous to its expulsion by
the excretory duct; each of the little mafles which form
the original glands, produces a duct; these are joined by
the neighbouring ducts, and thus others are generated,
which terminate in the ureter or common excretory duct of
each kidney. The ureter lies upon the anterior surface of
the kidney, partially embedded in its substance, so that it
is visible along the whole gland, except at the upper
part.

The members of the academy describe the kidneys of the
gricbic as being evidently composed of distinct glands, and
that the ureter did not lie as in other birds, superficially,
but was concealed in the glandular substance; in which
situation it suffered a degree of dilatation, forming as it were,
a pelvis, the whole length of the kidney, into which the
different excretory ducts discharged their contents; not,
however, from papillae, as in mammalia, but by open and
plain orifices. Mr. Ray, in his account of the anatomy of
the gricbic, plates, that he found the ureters occupy their
usual situation on the middle line of the anterior surface
of the kidney; but that the superior branch of the ureter was
very conspicuous, and entered the middle of the kidney,
where it formed a very large pelvis.

The structure of the ureters appears to be exactly the
same fince these ducts present in the human subject.

The course of the ureters, after leaving the kidneys, is
behind the rectum, to which they become connected by the
peritoneum covering the intestine; they proceed, for a very
little way, involved in the coats of the back of the rectum,
and open usually upon two little papillae, which project into
the cloaca, or termination of the rectum. The orifices of
the ureters in the cloaca, are much less than the width of
the tube to which they belong; this, therefore, added to the
obliquity with which they perforate the cloaca, an-
swers all the purposes of a valve, and prevents any regurgi-
tation of the urine back upon the kidneys.

The parian dissectors observed in the cnoeacery and
demaeile of Numida (ardes vrgo), that the ureters became
united to the excretory duct of the telibike, at the lower
part of the kidney; the common duct produced by their
union terminated, as usual, in the back of the cloaca.
This structure certainly does not exist in the generality
of birds.

The above description anticipates the observation, that
birds are unprovided with any distinct reservoir for urine;
analogous to the bladder; it is the cale throughout the
whole clafs, without an exception, that the faces and
urine are expelled together; but the dilatation of the end
of the rectum or cloaca, in some species, supplies the want
of the urinary bladder in a great degree, and renders the
ejections of both the urine and faces less frequent than
they would otherwise be, by according a temporary accom-
modation to a considerable quantity of excrement. These
dilatations are remarkably large in the gricbic, ferroc, &c.
See that part of the article which treats of the great intelle-
tine of birds.

It is a matter of common observation, that the excre-
timents of birds are of a white colour, and appear as if they
contained some calcareous substances: this effect is uni-
versally attributed to an admixture with the urine, which is
supposed to be of this colour and consistence; it deserves to
be mentioned, however, that if the urine be expressed from
the kidney, or examined before it has passed into the rectum,
it is neither white, nor of a chalky consistence, but a
limpid aqueous fluid, which exhales an urinous smell, that
is very perceptible in the larger birds, from which some
quantity of the urine may be obtained, by compressing the
kidneys. It would seem more probable, that the white
and chalky appearance of the excrements of birds, depended
upon the quantity of calcareous matter contained in the
foed parts of the faces, than that it is derived from the
urine. In proof of this supposition, it may be remarked,
that
that upon one occasion, where we fed a fowl with madder for a different purpose, the cretaceous part of the excrement lost its usual whiteness, and became of the pale pink colour which madder is well known to communicate to calcareous earths.

**Renal Capilares.**

These bodies hold the same situation in birds as in mammals; they also usually poffefs an irregularly triangular figure. The proportion which they bear in fize to the kidney, is perhaps less than generally occurs in quadrupeds. In the *goose*, they are each about as large as a pea. The colour of the renal capilares is in every infufion more or less yellow. Several of the older anatomists have described a single renal capilare in some species of birds: the mistake seems to have arisen from their being occasionally fo closely applied to each other, that they appear as one body.

The renal capilares of birds do not poffefs any cavity or dilated part for venous blood, which renders it probable that the enlargement of the capular vein, which has attracted so much attention in the human subject, is no way concerned with the function of these bodies.

Having discussed the structure and operations of those organs which are more immediately concerned in supporting the life of the individual, we shall proceed to consider those which are subfervient to the second order of functions.

**Organs employed in the Exercise of the Generative Functions.**

*Male parts of Generation.*

The *tefticles* of birds are always two in number; they are situated on the under side of the body, high up in the loins, upon the superior edge of the kidneys; from which position they never descend at any period of life, as in mammals. Consequently, birds are not provided with a *seroum*, or any external pouch for the accommodation of those glands. The figure of the tefticles is most commonly oval; occasionally they are of an elongated form, as in the *coffinwary*. See *Plate VII.* in the *Anatomy of Birds*; fig. 1. Sometimes the tefticles are nearly round, as in the *coffinwary*, and other infufions.

The tefticles appear to receive a covering from the peritoneum; but their proper tunic is remarkably thin, dense, and inelastic.

It will always be a matter of great difficulty, to exhibit satisfactorily, the intimate structure of the tefticles of birds, as a successful injection from the vas deferens is nearly impossible. The seminiferous tubes are so tender, that they do not sustain the least force without being ruptured; and at the period when the tefticles are fully developed, they are loaded with their own secretion, a circumstance highly unfavourable to the exposition of the structure of these organs by the means of injection. The blood-veifels of the tefticle are easily traced; some of them pass in the usual manner directly from the back part, through the glandular substance, to the surface, where they unite with others which spread in an arborescent form, under the capilares of the tefticles. The great mass of these glands is evidently made up of tubes, which are convoluted in all directions, and are separated into bundles or packets, by very thin cellular membranes. Their connection with the secretory extremities of the tneumatic arteries, and their termination in the excretery duct, are, however, involved in obscurity, for the reasons above given.

The tefticles of birds differ very much in fize at different seasons of the year. When these organs are not exercised in the act of generation, they become remarkably diminished; but, during the period in which the female lays her eggs, they acquire a bulk even beyond what might be expected, from the fize of the bird to which they belong. This subject has been strikingly illustrated by Mr. Hunter, in a series of figures representing the variation of bulk which takes place every spring in the tefticles of the *common parrow*; by which it is shown, that the tefticles of this bird are ordinarily about the fize of pin-heads, but, during the season of propagation, acquire nearly the bulk of pilow balls. See *Plate VII.* in the *Anatomy of Birds*; No. 1. exhibits the tefticles as they exist in the month of January; No. 2. as they are in the middle of February; No. 3. as they are found in the beginning of March; No. 4. their fize in the latter end of March; and No. 5. the bulk they assume in the middle of April.

The *vas deferens*, or excretery duct, arises usually from the posterior part of the tefticle, and probably always suffers a certain degree of convulution or coiling upon itself, corresponding to the epididymis, which generally differs more or less in colour from the body of the gland. In the *coffinwary and buffard*, it has been observed to be black; in the *coffinwary yellow*; and in the *ardua virgo*, a pale yellow. The academicians represent the epidermis of the *coffinwary* as being extended for some way above the tefticle, and considerably enlarged at the top. See *Plate VII.* in the *Anatomy of Birds*. Fig. 1. a a the two tefticles; b b the epidermis of each side; c c the vasa deferentias; d d the urters coming from the kidney to unite with the vasa deferentias; e e the excretery ducts common to both the kidneys and the tefticles.

In the *offrich*, the epidermis turns up on the side of the tefticle; and in the *ardua virgo*, it pendulous from it, and only connected by one end. The vasa deferentias also in this bird, appears to arise from the body of the teftis, instead of the epidermis; and at its lower part, the duct unites with the urters, in the same way as is represented in the *coffinwary*. In the *coffinwary*, the epidermis is situated below the tefticle, which it almost equis in fize.

In most birds the vasa deferentias proceed to their termination, without undergoing any remarkable degree of convulution, or experiencing any dilatation analogous to the *vesicula feminina*; but in the *cock*, these ducts are composed of convolutions or reflections of a tube from side to side, which are so closely applied to each other, that a longitudinal section of the duct presents the appearance of a series of cells, which seem to communicate with each other in the middle. These become larger and more numerous towards the lower part of the vas deferens, and are capable of containing a considerable quantity of semen. It may be premised, therefore, that the *cock*, and other fabulous birds, are provided with these receptacles of semen to enable them to meet the exigency of frequent copulation; and it is also to be observed, that those birds which have the vasa deferentias more simply formed, do not perform the act of coition so rapidly as the gallinaceous fowl. See *Plate VII.* in the *Anatomy of Birds*. Fig. 2. exhibits the genital organs of the *common cock*; a a the tefticles of an oval shape; b b the epidermis at the posterior part of each; c c the vasa deferentias, one of which is cut open to expose the involution appearance it presents internally.

The penis in those birds where it has been observed to exist, is fixed upon the end of the rectum, immediately within the verge of the anus; it is usually of a pyramidal figure, and in its ordinary state is twisted like a screw; its external tunic is derived from the intefine, and is formed into a number of little ruge, or proc'lices, giving the edges of the penis, in its contracted state, a jagged or notched appearance. The body of the penis is composed of a white ligamentous
mentous subsance, which supplies the place of the corpora cavernosa, but does not seem to contain any cells or cavity internally.

There is a groove, corresponding to the urethra, along the side of the white ligament; it takes the spiral course of the penis, and in no instance could we discover that it formed a distinct canal, the external coat of the penis appearing always to dip into the groove, so that it was visible externally; and hence it might be said that the urethra of birds is situated upon the outside of the penis. See Plate VII. in the Anatomy of Birds. Fig. 5. represents these parts as they are found in the gander: a is the penis, shaped like a screw, with the edges denticulated or notched by the folding of the external coat; b is the urethra commencing upon the left side of the penis, and continued upon the same side around the spine or screw; and at the end of the penis the fulcrum gradually disappears.

The form of the ofirich's penis is not spiral; it is also smooth upon the surface, and in shape it has been likened to a calf's tongue. The Parianan anatomiits describe it as being composed of white thick membranes, and of two strong hard ligamentous substances. They appeared to consist of very compact transverse fibres; one of the membranes was thicker than the other, and afforded a covering to the penis; the other enveloped immediately each of the two ligaments, which were separated from each other, and united about two fingers from the extremity. One was longer than the other, and measured two inches. The origin of the penis was at the cartilaginous swelling, which is situated at the junction of the bones of the pubis; from thence it was turned downward, and contained in a little pouch, which was placed at the lower part of the cloaca, in which the penis was continued to the anus. This small pouch can be distinctly separated from the large bag of the cloaca, by the contraction of the margin of its foramen. The lateral pouch only permits the excrements to pass from the other occasionally, and when it is closed, forms a sort of sheath for the penis.

The penis of birds receives some distinct muscular fasciculi from the rectum, which are inserted into the root of the ligamentous body; they appear to have the power of retracting it, or rolling it into the spiral form, and may perhaps render it more ready during coition. The mucous of the penis are large in the ofirich. The academicians describe four of them, two on each side. The two first took their origin from the internal part of the os sacrum, and descended along the pouch of the rectum, for the space of two lines, which they penetrated near the extremity, and passing under the sphincter ani, were inserted at the base of the penis. The two other mucous went from the internal part of the os ilium towards the bottom of the kidneys, and defended by the sides of the ureters, and after perforating the rectum, were attached to the lateral parts of the penis.

The penis of birds is unfurnished with any structure similar to the glans or prepuce; from which it might be questioned whether it is capable of receiving any peculiar sensations during the act of copulation. It would seem probable, however, that the penis is the chief seat of pleasure in birds as well as mammals, because it changes its form during coition, and experiences a great degree of relaxation afterwards. The penis of the drake is protruded some inches out of the anus during the performance of the venereal act; and after the orgasm is concluded, it is so much relaxed, that the animal has not the power of retracting it for some minutes; in which condition the penis hangs from the anus, and so much resembles an earthworm, that the ducks might take it for one, and attempt to swallow it. It is remarkable, however, that the greater number of birds are either unprovided with a penis, or have merely a rudiment of it, which is incapable of conducting the semen into the organs of the female.

In those birds which want the penis, it is very easy to perceive the manner in which the vasa deferentia terminate: thus, in the common cock they can be readily traced passing along the sides of the ureters to the back of the cloaca, into which they open a little lower than the ureters upon two papilae, which are elevated upon a ridge formed by the internal coat of the intestine, just within the verge of the anus. These papilae are prominent and sharp pointed; and although the ducts are of some size immediately behind, the aperture on the point of the papilae is so extremely small, that it is discovered with difficulty, and will scarcely suffer the finest bristle to pass through it. See Plate VII. in the Anatomy of Birds, fig. 2. c is the two sharp papilae, upon the points of which the vasa deferentia terminate in the cock. A bristle is introduced into one of them, and above them, and nearer the centre of the intestine are seen the orifices of the ureters designated by the letters d, d.

As these birds have no means of conveying the semen into the body of the female, a mutual evisceration of the extremity of the intestine always takes place during the copulation of fowl.

The termination of the excretory ducts of the testicle are difficult to discover in most of the birds which are furnished with a penis. This arises partly from the coats of the ducts becoming extremely thin and delicate near the extremity, and partly from the papilae upon which they open into the gut being in those cases so small as very easily to escape observation. The academicians did not succeed in tracing the vasa deferentia to their termination in any of the birds they described. They relate, however, that the penis of the ofirich and cafferous had no communication with the ducts, nor did they contain any tube in the internal part by which they could give passage to the semen. In all the birds we have examined, we could not perceive the least appearance of a canal in the interior part of the penis, or any means of communication between it and the vasa deferentia.

In the gander we have been able to discover the mode in which the semen is discharged from the excretory ducts. At some distance behind the root of the penis there are two papilae, surmounted by a number of small follicular glands; they are not so far asunder as those of the cock, and so little prominent, that unless minutely examined, they are not distinguishable from the glandular parts of the surface of the intestine which lie next them, and might easily be mistaken for a prominent edge of one of the follicles: from the point of these papilae a duct can be traced, as in the cock, to the back of the intestine; but furnished with coats so thin that it is perfectly transparent. See Plate VII. in the Anatomy of Birds, fig. 5. c is the small papilae on which the vasa deferentia terminate in the gander. Some small follicular glands are seen around them, and farther within the intestine the ureters open, as indicated by the letters d, d; at these points also there are some small mucous glands.

Mr. Hume has described the penis of the drake as possessing a distinct canal analogous to the urethra of mammalia, into which the vasa deferentia enter close to its origin at the verge of the anus. He states the penis to measure, when pulled out to its full extent, fix inches long, but that when left to itself it disappars within the verge of the anus, in consequence of the contractile power of the urethra. (See Phil. Transact. vol. xxi. p. 541.) The representation of the penis of the drake is copied in Plate VII. of the Anatomy of Birds.
of Birds, fig. 4, at the verge of the fundament surrounded by feathers; is the urinaria or seminal canal had opened through its whole extent or the orifices of the vesic deferentia; of the external tunic of the penis had opened, and from its cavity thrown into serpentine folds.

It deserves to be mentioned, that Rhafus also suppofed the vasa deferentia of the dice terminats in the penis, although he spoke doubtingly, not having actually traced them tither. See Anatomia animalium Guaertii Blatti.

In the gender, fossa, caffovary, and other birds which we have examined, the channel that runs upon the external part of the penis supplies the place of the urethra, and, appears fully competent to assume the conduit of a conduit to the semen, when it is introduced into the organs of the female.

The serous follicles surrounding the termination of the urinaria and seminal ducts, there are some others much larger upon the margin of the anus, on each side of the face of the penis. In the gender we have noticed twelve of these, fix on each side. They appear like masses of fat lying under the inner membrane of the intestine. The three outer glands have wide orifices which lead to a cavity within of some size: they furnish specimens of fine mucus follicles, a greater size than are almost ever met with, even amongst the larger quadrupeds. See Plate VII. in the Anatomy of Birds, for the large follicular glands on the margin of the anus of the gender; it the smaller glands next the penis. The anal glands are very remarkable in the saffonary.

No chemical analysis of the semen of birds has yet been attempted. The undertaking will be attended with some difficulty, from the small quantity which can be collected for investigation.

Female Parts of Generation.

There are no parts of the structure of birds which deviate, more from that of mammalia, than the female organs of generation; not only their configuration, but their functions, differ so much, that the same names cannot be applied to each, without extending analogy beyond what is justifiable. The genital organs of the female bird strictly consist but of two parts, an ovary and ovarian tube; for the different portions of the latter, which have received the names of uteri and vagina, perform very different functions from the same parts in other animals.

The ovary of birds is always single, which is a peculiarity of birds, and hardly ever met with in the other classes of animals. It is situated over the descending aorta, above the kidneys. Instead of the ova being imbedded in a solid mass, as in mammalia, they are contained in membranous cysts, which are prolonged into peduncles, or footballs, that are attached to the braf of the ovary, thus precluding the appearance of a cluster, or bunch of fruit, from whence the older anatomists were in the habit of calling the ovari of birds, the racemosus ovulum. Before the ovary, however, is developed, the sediment of the eggs do not project beyond the surface, but lie in close contact with each other, and are inclosed by the external membrane of the ovary, something in the manner of the ova of fish, or amphibia. The capsules which invol the ova of birds in the mature state, appear therefore to be formed by the extension of the outer membrane of the ovary, just as the contents of a hermitoidi obtain during their protrusion a covering of peritoneum. The membranous bags, in which the ova are included, adhere to the proper tunic of the egg at the anterior part only: for, when fly they are distinctly, being prolonged into a funnel, or tube, which forms the peduncle to each ovum.

The blood-veffels are transmitted through this funnel, and ramify in the space left between the capsule and the back part of the ovum, distributing their branches in a similar way to the central artery of the eye upon the back of the crystalline lens in mammalia. The capsules are extremely valuable at every part, except a certain portion of the anterior surface, which appears like a white streak, or broad line. When the eruption of the ovum takes place, this part of the capsule gives way, after which the eyes appears like the cup of an acorn, when the nut has been filled. The older anatomists almost universally believed that the capsules of the ova were imperfect at their anterior part, and that the white streak was owing to the proper tunic of the ovum being actually exposed at this place; they defend the capsule as being extended upon the ovum in a manner similar to the internal coats of the eye, and, like them, terminating by a defined line at the anterior part. The celebrated Harvey, however, observed that the membrane comprising the capsules was continued over the anterior part of the ovum, at which place it became very thin. The observations we have made on this subject confirm the assertion of Harvey; we have always been able to detect a very fine pellicular membrane being extended over the white line, which has all the appearance of being the continuation of the capsule. The coat of the capsule consists of several indistinct layers; and it is one of these only which appears to pass over the white line. The separation of the tunic of the capsules into layers is probably not an original formation, but is produced by the increase which takes place in the number and size of the blood vessels, and therefore the part which lies over the white streak might be considered as more nearly resembling the membrane of the capsule as it first existed. There are many instances of parts, on changing their position, either acquiring or losing vascularity, and becoming so much altered in their structure and appearance, that separately they could not be recognized for the same. The tunic conjunctiva of the eye affords a well-known example of this sort.

The portion of the capsule corresponding to the white line, from being bereft of blood-veffels, becomes thin, is easily ruptured, and is incapable of supporting any internal actions, in consequence of injury; we accordingly find, that this part suffers laceration when the ovum is shed, without the least inflammation succeeding, or any proceeds similar to that which arises upon the rupture of the ovary in mammalia. There is no deposition of new substance in the cavity of the yolk, or corpus albumen, formed. The lacunated portion of the egg is more flimsy (probably by absorption), and the edges assume the appearance of being cut, the capsules become contracted and thickened, and remain hollow, presenting very exactly the resemblance of cups or the calyces of flowers, and thence they have been often called the calices.

The base of the ovary, in which all the pedicles of the ova terminate, is of a peculiar texture. It is porous and tough, and seems to be composed of an intermixture of vessels and sertularia substance; it adheres firmly to the parts upon which it is placed.

The ova, during the time they remain in the ovary, possess only the yolk and the tiscula; the whites and the shell being added to them during their passage through the oviduct. Many of the blood-vefells which are distributed between the capsule and the ovum, penetrate the membrane of the latter, in order to supply blood for the nutrition of the egg during its growth. But when the egg arrives at maturity, these branches degenerate, and disappear entirely before the egg is expelled from its cell.

For the illustration of the structure of these parts, see Plate
Plate VII. of the Anatomy of Birds. Fig. 5, exhibits the genital organs of the hen during the season for laying eggs; at the superior part is seen the ovary, or ovariius sacrum, or vitellarium. The ova are arranged according to their state of growth. The largest are most external and pendent from their footstalks; those left advanced are close upon the matrix or bursa of the ovary; many of them are as yet but imperfect rudiments of the ova, and appear but as white fpecks in the matrix. The capsules of the ova, near maturity, display a very beautiful and luxuriant distribution of blood-vessels upon every part of their surface, except where the ova are to come out; a point out the Trump on the anterior part of each capsule, which is devoid of blood vessels; b; a capsule which has had its ovum, exhibiting the appearance of a cup or calyx.

The ovarian tube, or oviduct, during the season of laying, fills the greater part of the lower belly; it forms a number of curves or convolutions similar to the intestines, which, however, are not permitted the same latitude of motion amongst each other, because the prolongation of peritoneum, which includes the oviduct, is remarkably long, and is not so long as the parts it contains, and therefore the convolutions are coiled close together, and even some of them are doubled up within the peritoneum. The disproportion between the oviduct and peritoneum, which invests it, arises from the additional bulk the ovary acquires when its functions are performed, whilst the peritoneum must preserve at its back part its original extent, i.e. the length of the left kidney, from the middle of which it is reflected.

There is no decided muscular coat belonging to the oviduct; there are, however, muscular fibres between the peritoneal and internal coats of those parts, which have received the names of utersus and vagina; upon the former they are transverse, and upon the vagina the course of the fibres appears to be longitudinal.

The internal cost of the oviduct is the most remarkable part of its structure; and upon it chiefly depends the dimensions which have been made of the tube into infundibulum, Fallopian tube, uterus, and vagina.

The infundibulum is the extreme part of the tube next the ovary; it is composed apparently of a single thin membrane; the peritoneum and the internal tunic becoming both delicately fine, and so closely united to each other, at this place, that they seem to be but one. This membrane is expanded beneath the ovary in a loose manner, like the folds of a garment, and is fastened by its superior edge to the bursa or matrix of the ovary; and inferiorly it is connected to the uterum; by which means the folds of the membrane are always kept spread out, ready to catch the ova as they are discharged from the rachemus or vitellarium. The passage from the membranous expansion of the tube into the oviduct is contracted, and thence occurs the dilatation of this part to a funnel, and the application of the term infundibulum.

The next portion of the oviduct, or Fallopian tube, is of considerable length, being several times coiled backwards and forwards upon itself. It is very nearly of the same width at every part; and the inner membrane is singularly soft, and forms numerous thick folds, which take an oblique or spiral course. The internal surface of this part of the tube resembles very much that of the digestive thomach in ruminating animals.

Where the part termed the uterus commences, there is a contraction of the tube, to which succeeds a dilatation of an oval or egg shape; in this the internal membrane acquires more firmness, and instead of the soft white spiral plane, produces an immense number of frong vacular prococies or flocculi, which give the internal part of the uterina the appearance of being fringed or foliated.

The tube again becomes diminished in capacity, and its structure changed, to form the portion considered analogous to the vagina. At the origin of this part from the oval dilatation there are several annular contractions; after which, the canal undergoes some degree of convolution, which is concealed by the peritoneal coat. The internal membrane produces longitudinal rugae, or folds, which do not project far into the cavity of the tube.

The oviduct finally opens into the cloaca on the left side, not by a simple aperture, but the extremity of the vagina is protruded for some way into the cavity of the intestine, appearing as if a portion of the oviduct were turned inside out; and to the puckered oramen thus produced, the older anatomists, who were always defirous of comparing the structure of other animals with that of the human subject, gave the name of culda. See Plate VII. in the Anatomy of Birds, fig. 5; c c c the membranous expansion of the oviduct, d d its attachments to the ovary and uterus, e the aperture leading from the infundibulum to the interior of the oviduct; f f f f the convoluted part of the oviduct, which is supposed to be analogous to the Fallopian tube, and a part of it broad open to exhibit the spiral folds of the internal membrane; h h the oval cavity or uterus cut open, and a part of it turned backward to expose the folded structure of the internal membrane; i i the vagina doubled in a degree from its peritoneal covering to bring it more into view; k k the cavity exposed, showing the longitudinal folds; j j the projection of the end of the oviduct into the cloaca, with the corrugated oramen by which it opens into the gut; m m a portion of the rectum, left to explain the connection these parts have to each other; n n the urethra, through which a britle is introduced.

The parts which the several parts of the oviduct of birds serve, are very peculiar, and can hardly be compared with the functions of the genital organs of other animals. When the ovum is shed from the vitellarium, it is but imperfectly formed; and in passing along that portion of the oviduct which has been called the Fallopian tube, it meets with an albuminous fluid, which is secreted in abundance from the plicated membrane; a certain quantity of this fluid attaches itself to the ovum, and constitutes the whites and the chalazae. The egg now assumes an oval figure, and while still soft, descends into the dilated part of the oviduct, in which it is detained for some time, and obtains the calcareous covering or shell; after which, the lower portion of the duct, or the vagina, suffures itself to be enlarged, and the egg is expelled from the body of the bird. For the further history of the formation of the ovum, we refer the reader to the artic\Ee Eeg. In birds, and all animals strictly oviparous, the evolution of the embryo, and the growth of the fetus, is carried on without the body of the parent, and therefore the functions of the organs of generations in these animals are confined to the development and perfection of the ovum, which, as already observed, is partly accomplished in birds, while the egg remains in the ovary, and partly while it traverses the ovarian tube. It therefore seems improper to borrow the terms applied to the organs of viviparous animals in the description of those which only minister to the formation and support of the ovum. The progress of the fetus in birds; its mode of existence while in the egg, and the provisions for its subsistence afterwards, will be treated of under the head of In\Ecuation, which see.

It is not easy to determine how far the male semen is conveyed into the organs of birds during copulation. The older anatomists ascertained, that the two papillae on which the vasa deferentia
deferentia terminate, were introduced into the orifice of the ovisduct within the cloaca; and it has been observed, that the hen, before ceasing, ejects the intestine so much, that the orifice of the vagina is filled with the outside of the body, which would render the infection of the male organ very practicable, especially in those birds which are provided with a penis. The impregnating liquor must be transmitted as far at least as the part in which the egg is clothed with the shell; for afterwards it would be incapable of exerting any influence upon it; and it is probable that it reaches the ovum even before it acquires the whites, otherwise the stimulus could not be immediately communicated to the splanchnics. Many have supposed, that the semen produced a vapour which was propagated to the ovary itself; but the existence and operation of the anaer BIR

the Tiiey correBonding point to the two lilies, the far birds, but they and whitefs, but the placed The is situated Remarkable, The consequence which practicable, the penis. This part, from its situation, is little exposed to agitation or friction in venereal congress, and from its covering, which is the common integument of the arms, cannot be elevated or made delicate function. It may therefore be looked upon as one of the examples of uniformity of plan which are so often displayed in the works of nature, without the accomplishment of any immediate or obvious effect.

The female organs of generation of birds suffer even a greater alteration than the male parts, in consequence of the effusion of their functions. Before and after the period of laying has commenced, the ovary and ovisduct, which in their developed condition are the largest of the viscera, are so diminutive, that they are hardly to be seen; the ovary is a very small mass, which appears to be composed of an aggregation of minute pale yellow grains; the ovisduct is a mere membranous lubriculous, with scarcely any cavity, like a degenerated blood-vein; and the aperture, which at one period permits the egg to pass through it, is so nearly obliterated, that it is perceived with difficulty, and is so close that it does not suffer the smallest instrument, or even air, to escape from it into the intestine.

Mr. Hunter, and others, have observed, that even the sexual characters of some female birds have entirely changed, after the time they ceased to lay. This phenomenon has been remarked most frequently in the sea fowl. Several hens of this genus have assumed the manners and plumage of the cock so nearly, that their real sex could only be decided by anatomical inspection.

Orgins Subservient to the Performance of the Animal Functions.

Bones.

The offiscus fabric of the bodies of birds constitutes one of the most curious and characteristic parts in the anatomy of this class of animals; being in many respects so curiously formed, that the analogy between them and the same organs of other animals can scarcely be traced.

The bones of birds have been observed to vary in their colour. The water birds have them of a duller white than the other species, in consequence of their abounding with marrow. The bones which contain air, are always of the finest colour, much exceeding in whiteness the bones of any quadrupeds: they are all of a harder and closer texture. Becconn, in the voyage of Dampier, has observed that the Black fowl of the isles of Cape-Verd, and other birds of these islands, had black bones, and Dabbenent reared some hens of this kind. The same peculiarity has been noticed in the pintado; but some preparations which were preferred by Mr. Hunter to illustrate this subject, shew that it is the period in which the blackness resides.

The chemical principles of the bones of birds, do not differ from those of mammalia, except in there being a greater proportion of the calcareous phosphat in the long bones, filled with air. The arrangement of the offiscus particles appears to be in layers, rather than fibres, successively formed, and closely applied to each other.

The bones of the hawks, as in the other animals with vertebra, consist of those of the cranion, or brain-case; and those which contain the organs of taste, or, as they are commonly termed, bones of the face.

The external form of the cranion differs according to the species: a longitudinal and vertical section of it usually exhibits the cavity to be somewhat of an oval shape, of which the end next the face is rather pointed. In the oval, the cavity of the cranion is an oval, with the axis nearly vertical. The fame bones enter into the composition of the cranion in birds, as in mammalia; but the futures are obliterated at the early age in the former, that their cranion commonly appears as a single bone, and therefore, in order to examine the bones of the head separately, a very young subject must be choson.

The oif frontis is originally made up of two portions: they form the principal parts of the roof of the orbits, and a portion of the septum which divides one orbit from the other. They bend down, on each side, a pointed process, almost to the base of the bill. The prominences which are seen upon the heads of the caffowary, bontbills, pintado, and curassaw, &c., are attached to the os frontis, but were originally formed by distinct ossifications, in the same manner as the bones on the tarsus, which serve as the mould for the spur. The caucus of the caffowary's head is filled with numerous cells: in the pintado, the texture is more like that of the other bones.

The parietal bones are also in two pieces at one period, although the disunion is but rarely seen. They resemble two semi-spheres, hollowed out on the inside, to receive the brain.

The temporal bones compose the posterior parts of the orbits, and exhibit a remarkable depressión between two projecting processes, for lodging the muscles employed in the motions of the lower jaw. The zygons is not joined to the temporal bone.

The occipital bone originally consists of four portions: one placed superiorly, another below, and two laterally. When these are united, the bone has an annular figure, incircling the foramen magnum. The surface by which it articulates with the first cervical vertebra, is a sifle spherical protuberance, which is placed upon the anterior edge of the great foramen, and is received into a corresponding depression of the atlas. The mobility of the head is much increased by this mode of articulation.

The sphenoidal bone forms the greatest part of the bafe of the cranion, its processes are less evident in general, than in mammalia, although it furnishes a remarkable one which proceeds anteriorly like a illet, and receives upon its edge the ends of the inter-articular bones, and the palatine bones and vomers, which are each adapted to fit this process, and to slip along it, as the upper jaw is moved. The sphenoid bone wants the pterygoid processes, these belonging to the palatine bones in birds.

The internal surface of the cranion exhibits a sharp ridge, which divides the cavity into two principal fosse. The one contains the hemispheres of the cerebrum, the other, which is situated in the posterior and inferior part of the cranion, accom-
accommodates the two thalami nervorum opticorum, the cerebellum, and medulla oblongata, &c. On the surface of the superior fossa there are two slight projections, produced by the back of the orbits, and a small sphenoid ridge along the top of the cranium, which marks the division of the hemispheres; the inferior fossa displays a number of depressions, corresponding to the several parts it contains. There are also two irregular projections on the side, formed by the internal organ of hearing, and anteriorly the eminence called the fissa turcica, is to be seen, with a deep round cell for lodging the pituitary gland. The depressions on the internal part of the cranium are deep in the parrot and accipitrine birds.

The foramina of the cranium vary in many respects from what occurs in mammalia. The foramina through which the olfactory nerves are transmitted are only two in number; they proceed from a little depression at the anterior part of the skull, and open upon the upper and posterior surface of the orbit, along the superior part of which they are continued, as a deep groove, or rather more than a semi-canal, to the upper and back part of the nose, where there is another foramen or slit, formed by the ethmoidal bone. The optic foramina arise close together on the inside of the cranium, being only separated from each other by the thin partition of the orbits; this is frequently found deficient at the posterior part, and in that case the two optic foramina are thrown into one. The sphenoidal sinus does not exist in birds. The parts which are transmitted through it in mammalia, pass by distinct holes: some of these are arranged round the optic foramina, and one is found on the basis of the skull. The foramen rotundum and foramen ovale, are supplied by a single hole. It is seen on the line dividing the optic and bacular fossae.

The canalis caroticus appears to commence far back, on the outside of the cranium, and as it turns up to open upon the fissa turcica, there is a small foramen for the transmission of the communicating branch of the internal maxillary artery. The foramen lacrymal anterior does not exist, and the posterior foramen lacrymal is small, and placed within and under the external nectus auditory.

The meatus auditorius externus, is a very palpable foramen in birds.

The bones of the face in birds, although they differ extremely in form from those of mammalia, still preserve in general a distant analogy, by which they can be distinguished and compared. The septum of the orbits, notwithstanding its structure, is so dissimilar, must be considered as analogous to the ethmoid bone. It is united to the os frontis superiorly, and to the sphenoidal bone below; it is at both but a lamina, or plate of bone, so thin that it is nearly transparent and in numerous instances is in part membranous. At the back of the organ of smell there is occasionally a process which projects a little from the septum, and then turns down forming a slit, through which the olfactory nerve passes. This process may be compared to the os planum, and the septum itself, although it is not continued far into the nose, may perhaps be thought analogous to the nasal lamella of the ethmoid bone.

There is a bone usually of a triangular shape, which is attached to the anterior, and outer angle of the os frontis. This bone Cuvier has called the lacrymal, and others the superciliary. It is in a certain degree moveable on the os frontis. Its two posterior angles form the superciliary or anterior edge of the orbit. The superior of them is continued further backwards in the invocal bone of prey than others, giving a considerable prominence to the upper edge of the orbit. In the grefich, the superciliary arch is made of a number of small bones, which are continued from the lacrymal bone, and are distinct from the os frontis. The lower of the posterior angles of the lacrymal bone is prolonged considerably in the duck, but much more in the parrot, in which it goes so far back as to join the projection of the temporal bones, and thus completes the frame of the orbit.

The remaining bones of the face either enter into the composition of the mandibles, or are provided for the motion of these parts. The superior mandible is made up of the gisia nasi, olfa maxillaris, and inter maxillaris, the vomer, the malar, and palatine bones; the extremity of the mandible appears to be formed originally by a distinct bone, which is added, as it were, to all the rest. The separate parts of the mandible are not to be distinguished in the adult bird, but in young subjects they come easily asunder.

The palatine bones are so thin at their connection with the posterior part of the mandible, that they readily bend. At the back part, they spread out into two wings or terygoid processes, leaving a slit-shaped aperture for the posterior nares, in which is seen the vomer; where the palatine bones are joined above, there is a groove or gutter formed, which receives the inferior edge of the septum of the orbits, and on which the palatine bones have a degree of motion when the upper mandible is raised.

The zygoma is one of the most remarkable parts of the head of birds. It is a very long delicate bone, extended in a straight line from the inferior and back part of the upper mandible to the outside of the articular bone immediately above the articulation of the lower jaw. It is, as in mammalia, originally composed of two pieces, which in large birds are always visible. The anterior portion has been commonly described as a process of the palatine bones, but it is really produced from the part of the mandible that corresponds to the os nasi or jugale, as it ought, in order to be confident with analogy. The junction of the zygoma to the articular bone, is in a degree movable; this, added to its general slender form and flexibility, allows it to yield to all the motions of the superior mandible.

There are two bones belonging to the head of birds, to which there are none analogous in mammalia. One of these has been called by Dumeril the flaver bone, but improperly, as it is in no instance exactly square, and when its parietal cells are eminent, it is rather of a triangular form. We have chosen, both from its office and situation, to call it the articular bone.

This bone is interposed between the articulation of the lower jaw, and the os temporis; with both of these it produces a true joint. The articular surface it presents to the temporal bone, is like the two conodes of the occiput of mammalia, and between these the end of the bone contributes to the formation of the cavity of the tympanum. The articular surface next the lower jaw is made of two irregular eminences, placed obliquely across, forming a double pulley. On the outside of this the temporal extremity of the zygoma is attached, and on the inside there is articulated another slender bone, which, from its situation, deserves to be named the inter-articular bone. There is a process from the anterior part of the articular bone, which passes up into the orbit, and receives the attachments of muscles.

The inter-articular bone is connected by a moveable joint to the articular. It is a small, straight, three-sided bone, slightly
BIR

lightly enlarged at the extremities. It is directed forwards and inwards, and at the anterior extremity touches the inter-articular bone of the opposite side; at this place the ends of both are placed against the posterior extremity of the palatine bone, and are hollowed so as to encompass the lower edge of the septum of the orbits, along which they have some degree of motion, when urged forwards by the articular bones.

The effect of this mechanism is, that whenever the inferior end of the articular bone is brought forwards, which is accomplished in a degree by the opening of the lower jaw, but still more by particular muscles, to be hereafter described, the superior articular bone presses against the extremity of the palatine bones, and they communicate the impulse to the whole superior mandible, which being very thin at its junction with the os frontis, suffers itself to be pushed up or elevated from the base it commonly holds, and in this manner the mouth of birds is dilated in part by the motion of the upper as well as the lower jaw.

The _upper _is remarkable for having a great degree of motion in the upper mandible; in this bird the superior mandible is at all times separate from the frontal bone, they being only connected to each other by a very flexible ligament.

The _inferior mandible appears to be formed originally of four pieces; two of these correspond with the bones of the inferior maxillii, and the others produce the mould on which the lower part of the bill grows. The formation of the inferior jaw, independent of its connection with the bill, differs very much from that of mammals. There are no condyles, nor any process deferring the name of cornu, and the angle of the jaw is the thickest and lowest part of it. The articulation is made by two depressed surfaces placed on the side of a cavity, into which the posterior pulley of the articular bone slips in the motions of the jaw.

The form of the bones of the mandibles is precisely the same of the horned bill, with which they are covered; except in some water birds, the bill assumes more or less of a conic figure; sometimes compressed, sometimes arched, in some cases elongated, in others short, and varying in the degree of sharpness, strength, and solidity. As the diversity, however, which occurs in the mandibles of birds, is an external appearance, and belongs rather to the science of natural history, than to comparative anatomy, it would be improper to discuss the subject in the present article.

The peculiarities of the _fossa _and _foramina _of the face in birds, depend chiefly upon the form and proportions of the bones.

The _orbitar fossae _are so large, that they appear to occupy the greatest part of the profile of the head of birds. They extend in the skeleton from the roof of the skull to the palate, and communicate with the posterior part of the organ of smell. Cuvier very aptly compares them to the imperfect branch which one would conceive might be left by pinching the knuckle between two fingers, provided it were in a soft flate.

The _nasal fossae _are continuous with the orbitar. They open upwards by the two external nares, or nostrils, and below by the posterior nares. The septum nasi proceeds so short a way in the nose, that the nasal fossae make but one cavity. The external apertures of the nares are found in the bone, at the bale of the convex surface of the bill.

The _temporal fossae _are not crossed by the zygoma. They vary in depth according to the strength of the muscles employed in raising the lower jaw; they are therefore most plain in the rapacious birds, and those with long or heavy bills.

The _pheno-maxillary foramen _can have no existence in birds from the figure and extent of their orbits; neither have they the _internal orbitar, _or _sub-orbitar foramina, _or the _pheno-palatine canal. _

The _os hyoideum _possesses a singular conformation in birds. The body of the bone is in general of a short round figure, somewhat enlarged at its posterior extremity, at which place it is articulated with the two corana. These resemble horns exactly, both in their shape and direction; they are terminated by additional pieces, which form a sort of joint with the principal part of the horn, and generally confit entirely of cartilage. To the posterior end of the body or middle bone of the hyoïdes, there is articulated a small tyloid or dagger-shaped bone, which proceeds directly backwards, and soon terminates in a point. There is also a bone articulated with the anterior extremity of the body of the hyoïdes, which penetrates the sublimity of the tongue, and parmates in a certain degree of the form of that organ; it is commonly terminated by a pointed cartilage, which is attached to it by a movable joint, and is continued to near the tip of the tongue. This bone we should choose to call the _lingual._

The _os hyoideum _and _lingual _bone are singularly formed in those birds which have the power of protruding their tongue to take their food. In the _woodpeckers, _for instance, the cartilaginous extremities of the horns of the hyoïdes are immensely long, and when the tongue is not projected, are lodged in a groove or furrow, which runs over the whole head, and terminates only at the root of the bill. The _lingual _bone in these birds also is not cartilaginous at its extremity, but is covered with a hard or horny sublimity, which protrudes beyond the soft parts of the tongue for the dislance of about the quarter of an inch, ending in a point, and furnished with a number of sharp bars, or pliculae, which are moveable in the posterior direction only; so that, like the teeth of some fish, they suffer the infectis on which the bird preys to be easily perforated by the end of this instrument, but render it impossible for them afterwards to retreat.

The _vertebrae _of the different regions of the spine of birds do not bear the same proportion to each other with respect to number that is usual in other animals. The _cervical _portion in this class is generally composed of a much greater number of vertebrae than any other division of the spine. The length of the neck is in most birds determined by the height of the legs. Thos. water birds, however, which procure their sublimity by flying, are provided with long necks, and at the same time short limbs, as in the _caracor, _duvres, &c. The dorsal vertebrae are usually less numerous than in quadrupeds. The vertebrae of the loins become anchylosed with the bones of the pelvis, and with each other at an early period, and consequently it is difficult to reckon them. The caudal vertebrae are most numerous in those birds which make the greatest use of the tail, such as the _swallow, _woodpecker, _offrich, _&c.

The following table, which is extracted from Cuvier's Lectures on Comparative Anatomy, exhibits the variety which exists with respect to the number of the vertebrae in many species.

</tbody>
</table>

The cervical vertebrae are joined to each other by a mode of articulation which admits of very free motion in two directions:—laterally, and backwards or forwards. This depends upon the form of the particular surfaces of the bodies of the vertebrae, which consist of two portions of a cylinder applied crossways with respect to each other, and both a little hollowed for their mutual accommodation. The cylinder on the inferior part of the vertebra performs by its revolution the motion to either side; and when that of the superior part revolves, the neck is bent either backwards or forwards. The cylinders at the top of the neck admit of motion forwards; but those of the middle and inferior part of the cervical spine are incapable of performing a free motion forwards, as one contains a slight depression on its anterior part, which receives the edge of the other. The neck of birds, therefore, possesses in the contracted state, or when at rest, somewhat of the figure of an S, which is accompanied with several advantages to these animals. They are enabled by it to throw the weight of the neck and the head more over their centre of gravity, without which some species would be unable to preserve their equilibrium; and by combining the S like motion with that to each side, birds acquire a greater degree of flexibility in the neck than is possessed by other animals; they can touch every point of their own body with the bill, and thus supply the want of the prehensile faculty of the superior extremity or the tail, of which they are deprived by their peculiar mode of progression.

The surfaces of the articular processes lie nearly in the direction of the bodies of the vertebrae, but in some parts enhance a degree of obliquity conformable to the S like shape of the neck.

The spinoïd processes are only to be observed on the superior and inferior portions of the cervical spine, where they exist both on the anterior and posterior parts of the vertebrae. In birds with long necks there is a fossa on each side of the posterior spinoïd processes, for the attachment of the cervical ligament, or ligamentum nuchae. This fibres is to be observed perhaps in all birds, but is very remarkable in the fowl, swan, cafferary, and ostrich. In the last bird it is nearly as strong as it exists in the larger quadrupeds; the same kind of ligament is also interpreted between the spinoïd processes of the dorsal vertebrae. The transverser processes of the vertebrae of the middle of the neck spread forwards, and lead down a flyloid process of some length. These give attachment to muscles, and form in some birds a sort of canal on the anterior part of the neck, which contains the two carotid arteries. The anterior flyloid processes are little observable in the rapinnis and pochinen tribes, the parrot, &c.; but are usually very marked in the long-necked birds.

The dorsal vertebrae of birds have scarcely any motion, in order
order that the trunk of the body may not be affected by the
terfs of the wings in flight.

Their spinal processes are commonly archylofsed with
each other, which sometimes occurs also with respect to
the transverse processes. In the eifrích and saffonary, the
processes of the dorsal vertebrae are distinct, and possess a
degree of motion from which however these birds cannot suffer
any inconvenience, as they do not fly.

The eentl vertebrœ have spinal processes on both the
anterior and posterior surfaces; and the transverse pro-
cesses are usually very prominent. The last bone of the
tail, is, in most birds, of a plough-share figure for the at-
tachment of the quills. It is small and come in the raps, to
land eifrích, and saffonary; and in the fowl, it is
thin, oval, and lintened horizontally. It is wanting in a
variety of the domestic cock found in America.

The fcrum forms one of the most characteristic bones in
the skeleton of birds. It is a very broad thin bone, that
covers the anterior part of the common cavity, like a buke-
ker, and produces from its middle line, in every bird which is
capable of flying, a thin plate of bone, which refemles
very much the keel of a ship; but it is mos prominent at
its anterior part. The upper edge of the fcrum presents
two narrow depressions, which receive the ends of the two
clavicles; and to the most anterior point of the keel the
fork-shaped bone is commonly attached. The posterior
edge is thin, and in most species, contains a space on each
side, which is filled with membranes. In the acelpiteres,
parrot, and most aquatic birds, this is an oval hole; but in
the galline it is an oblong vacancy. The keel appears to be
added to the fcrum, merely for the attachment of the
great pectoral muscle. Accordingly, we find its projec-
tion is proportioned to the necessity there is for using this
muscle during flight; and in the eifrích and saffonary,
which do not employ their wings as organs of locomotion,
the keel is abot the domestic cock found in America.

The ribs of birds have been divided, like thofe of mam-
malia, into true and false, or as Vie d'aiz has termed them,
the fcrum-vertebral and vertebral. The true ribs are made
of two pieces, which are each composed of bone: the po-
terior portion is affixed to the spine by means of two
branches, of which one is articulated with the body, and
the other with the transverse processes of the same dor-
ral vertebra. The anterior piece is articulated by one end,
with the lateral edge of the fcrum; and by the other, to
the end of the vertebral portion. The frcnal extremities
of the ribs, being distinct bones, defer to be calld frcnal
ribs, which term we have employed in other parts of this
article. Most of the true ribs are furnished, about their
middle, with a thin offenes process, which proceed ob-
lquely backwards from the posterior edge of one rib, and
over-lays the one next behind it, and sometimes even goes
on to cover two ribs, as in the common eifrích. The
frcnal and vertebral portions of the true ribs form, at their
junction, an angle which points backwards, and is very
acute in the first ribs, which proves that the thorax
of birds is chiefly dilated by the anterior part of the fcrum,
being carried forwards from the dorsal spine; at which
time, the moveable angles of all the ribs become very ob-
tsue. These angles are fearely observable in the frications
birds. Their ribs affime very much the figure of thofe of
mammalia.

The number of the fcrum-vertebral ribs is liable to vary.
There are, on each side, four in the euckos and the esaffonary;
two in the crow, africain eifrích, and ferk; six in the bitter;
seven in the eagle, the buoyard, the owl, the crane, and the
duck; eight in the crfited gres, and several other water-
ford; and nine in the fonan.

The vertebral, or false ribs, are in most birds placed at the
anterior part of the thorax, which is the reverse of what is
observed in mammalia. When there are any of these ribs
situated posteriorly, they are only one or two pair, and im-
perfectly formed; there are two pair in the frications, which
do not project far from the spine.

The bones of the frications become confladated together at
a very early period. Their original parts are therefore very
difficult to distinguish. The portion corresponding to the
crnion bears some resemblance to that bone in mammalia;
but the ilium and pubis cannot be recognised by their
figure, and are only to be known by their relation to the
different foramina. There is a very long, slender bone,
originally connected to the ilium, on the fore-part of the
acetabulum, which supplies the place of the pubis. This
bone runs parallel to the anterior part of the ilium, with
which it is occasionally joined towards its extremity, but
never unites with the bone of the opposite side, except in
the eifrích, in which bird the bones of the pubes are broad
at their symphysis, and send a little forwards, producing
something of the appearance of the pelvis of mammalia.
The pubis unites with the ilium in the aceltes for a con-
iderable way, and leaves a distinct hole analogous to the
foramen ovale; and the space between these bones possefes
in all birds, at the anterior part, the traces of this fora-
men.

The ifehium is commonly united to the facrum and back
of the ilium, by the part which corresponds to the ifeudic
spine; consequently, the ifeudic foramen is complete in
the skeleton of birds. In the eifrích and saffonary, how-
ever, the ifehium is separate from the facrum, and is a long,
slender, flyoid bone, like the pubis. There is no taber-
osity to the ifehium, that part being thin and extended, ex-
ccept in the eifrích, where it becomes somewhat elongated.
The ifehium appears to be joined to the pubis in the new,
holland eifrích, by the intervention of another short
bone.

The bones of the shouder are very peculiar in birds;
besides the clavicles and feapulus, there is an additional
single bone, called the ferk: it usually possesses the figure of
a V; the point is attached to the most anterior part of
the keel of the facrum, and the ends of the branches are
secured by a ligament on the inside of the dorval extremities
of the clavicles, and also to the posterior process of the
feapulus, which is analogous to the acromion. The ferk
frequently approaches more to the figure of an U than a
V. Its angle is also often at some distance from the facru-
num, to which it is bound by a ligament. In the galline,
this terminates in a thin plate, from which a ligament is ex-
tended to the keel of the fcrum. As a general observa-
tion, it may be stated, that the ferk is strong and elatic,
and its branches wide, arched, and carried forwards upon
the body, in proportion as the bird possesses strength and
rapidity of flight; and accordingly, the frications birds,
which are incapable of this mode of progress, have the
fork very imperfectly formed. The two branches are very
flat, and never unite in the africain eifrích, but are an-
chylised with the feapulus and clavicle. The esaffonary
has merely two little processes from the side of the clavicle
which are the rudiments of the branches of the fork. In
the new holland eifrích, there are two very small thin
bones, which are attached to the anterior edge of the dor-
dal end of the clavicles, by ligament; they are directed
upwards towards the neck, where they are fastened to each
other
other by means of a ligament, and have no connection whatever with the sternum.

The clavicle is a straight bone in birds; it does not lie in a transverse direction with respect to the trunk of the body, but proceeds upwards and forwards towards the lower part of the cervical spine; and in proportion to the length and projection of the clavicle, the bird possesses strength of wing and activity of flight. The clavicle at its articulation with the sternum is thin and broad; but the rest of the bone is of a round shape; it produces a process from the posterior part of its dorsal extremity, which is united to the head of the scapula, and in conjunction with it, forms a depression analogous to the glenoid cavity, although not of the same figure. The side of the extreme part of the dorsal end of the bone, is joined by ligament with the branch of the fork, as already mentioned.

The clavicles of the frithrie are remarkably short, and are anchyloed with the scapula at least.

The flatb is two long, plain bones, with sharp edges, resembling, in a great degree, the blade of a knife; they lie parallel to the dorsal spine, and have no processes, except the one which contributes with the clavicle to form the cavity for lodging the head of the humerus; and a little eminence opposite to this, which seems analogous to the acromion, and is joined to the end of the branch of the fork. The scapula, like all the other bones of the shoulder, are very short in the frithrie, not passing beyond the first two or three ribs; although in many other birds these bones reach as far as the pelvis.

The humerus is a round, smooth bone, more or less enlarged, and flattened at the extremities; the surface by which it articulates with the scapula in the frithrie and clavicle, is at the very end of the bone, and is formed of a portion of a cylinder, instead of a sphere, which is most suitable to the motions of the humerus in birds, they being almost confined to the elevation and depression of the wing. The external tuberosity of the humerus is very small; but the spine which leads from it is greatly elevated in most species of birds. The internal tuberosity is, on the other hand, remarkably large, and furnishes a process at its upper part, which corresponds, in some respects, with the coracoid processes of the scapula in mammalia. The humerus is long, in proportion to the other bones of the wing in the African gharlitch, and takes the curvature of the bird's body. It is extremely short and small, and without processes, in the New Holland gharlitch, and eclairyrich.

The humerus is connected to the bones of the forearm by an articular surface, similar to that of the human subject.

The radius is usually a much more slender bone than the ulna, with which it is never observed to be anchyloed.

The ulna exhibits no remarkable processes; it forms a pulley on its lower end. These two bones are flat in the manchot (aftened), and are joined by an articulation which permits motion in several directions, with two tubercles, one above, and the other below the anterior edge of the humerus. The wing of this bird, both in its structure and offices, resembles a fin. The ulna and radius are nearly of an equal size in the frithrie; they are both very small, and have but little motion on the humerus.

There are but two carpal bones in birds; one is applied to the end of the radius, and prevents the motion of the lower part of the wing beyond the line of the radius; the other moves a little upon the end of the ulna, to which its form is adapted. It has often a little process from its lower edge, which is analogous to the os pisiforme. The carpal bones are obliterated in the frithrie birds.

The metacarpus consists of two bones, which are united at their superior part by anchylosis for some way. At this place there are some eminences which appear like the remains of the second row of carpal bones folded together. The articulation of the metacarpus with the carpus is the segment of more than the half of a pulley, which is grooved in the middle, and revolves within a corresponding surface of the lower carpal bone. This motion, for the convenience of deflexion, is called flexion and extension; but it is in frithries a lateral movement back upon the ulna, and accompanied with a degree of rotation, by which the concave figure of the bone is left in the very action of folding it. There is a styloid process on the upper part of the radial side of the metacarpus, which gives attachment to a small pointed bone, supplying the place of the thumb. A similar bone is affixed to the extreme end of the small branch of the metacarpus, and corresponds to the little finger. The principal, or fore finger, which terminates the wing, is articulated with the large or radial branch of the metacarpus. It consists of two phalanges, and the first exhibits marks of having been originally two bones. The two pieces of the metacarpus are to be seen in the African gharlitch, as also the three fingers; each of which is furnished with a hook, which is covered with a horn, like a claw; but in the New Holland gharlitch the metacarpus is a single bone, and there is but one finger, which is also terminated with a claw. All the bones of the hand are compressed into thin plates in the manchot.

The thigh-bone of birds has nothing very peculiar in its form; it wants the trochanter; it is singularly short, in proportion to the other parts of the limb, in such birds as have long legs; it is longest in the accipitres, and shortest in some water-birds. The femur is strong in all the gallines; and in the frithrie it is of an immense thickness; it is bent in the cornorant and the little grebe.

There is a certain portion of the ligament of the extensor muscles of the leg converted very early into bone; and this seems in general to supply the place of the patella; it is not usually provided in skeletons.

The tibia resembles in its form the bone fame in mammalia. There are several prominent edges on the fore part of its head for the attachment of muscles. The lower end of the tibia forms a pulley with a groove along the middle. The head of the tibia is prolonged in a remarkable manner upon the thigh, in the grebes and the divers.

The fibula is a very small bone, and is soon anchyloed to the side of the tibia.

The tarus and metatarus consist, in the adult bird, but of one bone; it exhibits, however, a process corresponding to the divisions which existed between its several pieces when it was first formed. These are strongly marked in the long-legged birds, and shew that the metatarsus contained originally as many bones as there are principal toes. There is usually also a prominence on the posterior part of the head of the bone which represents the os calcis. The inferior extremity of the metatarsal bone produces a process shaped like a pulley for the articulation with each of the principal toes.

There are three bones in the composition of the tarus and metatarus of the manchot separate from each other in the middle; and therefore these birds are plantigrade, or walk upon the metatarsus as well as the toes.

The extraordinary length of limb which belongs to some kinds, as the frithrie and wading birds, depends upon the extent of the tibia and metatarsal bone.

The flocks, and some others of the gallines, which sleep flanding on one foot, possess a curious mechanism for preserving the leg in a state of extension, without any, or at least with little muscular effort. There arises from the fore part of the head of the metatarsal bone a round eminence, which piles up between the projections of the pulley on the
BIR

antler of the end of the tibia. This eminence affords a sufficient degree of resistance to the flexion of the leg to counteract the effect of the oscillations of the body, and would prove an insurmountable obstruction to the motion of the joint, if there were not a socket within the upper part of the pulley of the tibia, to receive it when the leg is in the bent position. The lower edge of the socket is prominent and sharp, and presents a sort of barrier to the anterior extension of the bird to overcome, which being accomplished, it slips in with some force like the end of a dislocated bone. Dumeril and Cuvier have described a similar apparatus to this in the knee of the fowl; but they must have confounded, in an unaccountable manner, the one joint with the other; for the articulation of the femur with the bones of the leg in the common fowl (gallus alba), certainly exhibits nothing peculiar in its structure. See Plate VIII. in the Anatomy of Birds. Fig. 1. represents the anterior part of the articulation of the tibia with the metatarsus in the fowl; a the tibia, b the metatarfal bone, c the prominent edges of the pulley on the end of the tibia, d the round eminence of the head of the metatarsus, e the socket in the tibia, which receives the eminence during the flexion of the joint.

The bones of the toes vary in number, increasing from the inner to the external toes. Birds with four toes have the number of the phalanges in the following order, 2, 3, 4, 5; those with three toes have then, 3, 4, 5, except the cafso- wary and the New Holland affair, which have four joints to each toe. The Äfrican affair has only two toes, and four phalanges to both. Most birds have the three principal toes situated before, and the pollex attached to the inner and back part of the metatarfal bone near its extremity. The bufard, cafsoary, New Holland affair, the plover, the eftter catcher, and the long legged gbower, have but three toes; and the black-headed, peliul, and penguin, want the pollex. All the fenamore have their toes opposed to each other, two behind and two before.

It would have rendered the description of the bones tedious and confuscd, to have given frequent references to the plates which represent them; the reader, therefore, will have occasion to contemplate the relation the different figures bear to each other, and to facilitate such comparison, similar letters are employed to indicate similar parts in each of the skeletons chosen to illustrate the subject.

When birds transport themselves from one place to another, it is more common by the aid of flying; which consists in the successive elevation and depression of the wings; the latter motion being performed with so much force and velocity, as to comprize a volume of air, the re-acjon of which is sufficient to impel forwards the whole body of the bird. The various kinds of flight depend upon the different ways of employing the wings, and the habits and economy of the individual, which it is the business of the naturlist to point out. Many birds are capable of using other modes of locomotion besides flying, for which their structure is equally well adapted; for instance, some tribes almost constantly inhabit the water, and swim with the greatest ease; others walk or run with the greatest rapidity; and others transport themselves chiefly by the effort of climbing. We have, therefore, selected a skeleton to exhibit the organs employed in each of these species of locomotion. See Plate VIII. in the Anatomy of Birds. Fig. 2. represents a skeleton of the New Holland affair, which was brought into this country by an ingenious young surgeon, Mr. Langhaff. It seems to partake of the structure of both the cafsoary and Äfrican affair, but it bears the greatest likeness to the latter; and therefore we have called the bird an affair, although it has hitherto been considered by some naturalists as a cafsoary. This skeleton affords the best example of a running bird, which is at the same time incapable of flight. The femur and bones of the wing are small; the centre of gravity is thrown fairly between the legs; and the inferior extremities are long, and of an immense disproportioned strength. Fig. 1. of the same plate exhibits the skeleton of the fowl, which, as being a bird of high flight, forms a striking contrast with fig. 2.

Plate IX. of the Anatomy of Birds, contains the skeletons of a climbing and a swimming bird. Fig. 1. is the skeleton of the parrot. The body is round and contracted; the neck short, strong, and flexible in different directions; the femur and bones of the shoulder rather small; but its chief characters are the long thigh, and very short metatarfal, furnished with the climbing toes; by which means the bird can grasp any foreign substance, and apply the feet to any part of its own body, after the manner of the prehensile members of other animals. Fig. 2. of Plate IX. shows the skeleton of the crested grebe (chlamys eriplus). The neck is much bent; the parts of the upper extremity rather small; the ribs strong, and reaching far back; the femur long; and the body beautifully wrought in the form of a boat; the inferior extremity situated far behind; and the thigh bone very short, and the toes long and expanded; all which circumstances are necessary to the performance of the acts of swimming and diving with facility.

The separate parts of the skeletons, in Plates VIII. and IX. in the Anatomy of Birds, are indicated as follows.

Parts comprising the head; a the occiput, b parietal bone, c os frontis, d temporal bone, e os lacrymale, or superciliary bone, f nasal bone, g inferior maxilla, h malar bone, i bone of the upper mandible, k palatine bone, l septum of the orbits, m articular bone, n interarticular bone, o zy- goma, p inferior maxilla, q bone of the lower mandible, r external nares, s deficiency in the septum of the orbits where the optic foramina open, t temporal fossa, u pso- nuch bone in the organ of smell.

Parts of the spine and trunk; a cervical vertebrae, b their transverse processes, c the styles which defend on the forepart, d articular processes, e posterior spinous processes, f spinous on the anterior part of the bodies of some of the vertebs, g dorsal vertebrae, h laecral vertebra, i vertebrae of the tail, j the tail, or caudal bone, k is ischium, l ischium, m fibula, n patis, o foramen ovale, p pectoral foramen, q vertebral or false ribs, r the true ribs, s the flernal portions, t inter- costal processes, u the part of the sternum next the body, v the keel, or projecting part, w deficiency at the lower part of the flernal bone.

Parts belonging to the wing; a the fork, b the clavicle, c the scapula, d the humerus, e its inner tubercle, f the external tubercle, g the spine for the attachment of the deltoid and pectoral muscles, h the ulna, i the radius, k the carpal bone on the radial side, l the ulnar carpal bone, m the head of the metacarpus, n the large branch, o the smaller one, p the fyle of the metacarpus, q the pollex or thumb, r the little finger, s the principal or fore finger.

The parts of which the lower extremity consists; a the femur, b its tingle trochanter, c the tibia, d the elongation of the head of the tibia which occurs in the geese, &c. e the fibula, f the metatarsus, g the prominence at the heel, h the pollex, or back toe, i the principal or anterior toes.

Muscles.

When the writing of the present article was begun, it was intended to give a full description of the muscles of birds; but as the subject has already extended beyond the length
length that was expected, and if this were done, would exceed the bounds usually allotted to a single article, we shall only point out the most striking peculiarities in the muscular system, and correct some errors into which other writers have fallen in their accounts of this part of the anatomy of birds.

The muscles which move the lower jaw, do not differ essentially from those of mammals. There is no marked division between the musculature temporalis; they form one mass which arises from the temporal fossa and inferior part of the orbit, passes under the zygomas, and covers the side of the lower jaw from the joint to the commencement of the bill. There is a tendon which lies over the muscles on the side of the jaw, usually of a triangular figure; it is attached to the inferior bony portions of the orbit, connects them to each other, and thus completes the margin of the orbit. It is affixed to the protuberance on the outside of the lower jaw, near the joint, and seems to prevent the mouth opening beyond a certain distance.

Birds have none of the muscles of the face, as they have no felt parts for them to move. The lower jaw is depreffed by a muscle which arises by two portions, one from the hollow behind the side of the occiput, the other from the surface behind and below the external maxilus auditory; both are inserted upon the back of the lower jaw. This muscle, although so unlike the digastricus, supplies its place, and fulfills its office.

There are three muscles for moving the upper jaw, which are quite peculiar to birds. The first is of a radiated or fan shape; it arises from the septum of the orbit, and passing obliquely backwards, is inserted by tendons into the external surface of the end of the inter-articular bone, just when it becomes joined to the articular. By pulling the posterior end of the inter-articular bone upwards, the opposite end is pulled forwards, which produces the elevation of the upper jaw in the manner already described.

The second is a short thick muscle, arising from below the posterior part of the orbit, and before the external maxilus auditory, and inserted into the inner surface of the body of the articular bone and its anterior process, where it joins the inter-articular bone; it elevates the posterior end of the inter-articular bone, and thus raises the upper jaw.

The third muscle is for depreffing the superior jaw; it is of a long taper shape, has one attachment to the infide of the lower jaw, and then becomes affixed to the infide of the inter-articular bone, the internal part of the pterygoid processes, and sends a small tendon to the integument of the palate, just where the horny covering of the mandible commences. It is difficult to distinguish it from the pterygoid muscle, which appears to aid it in the depreffion of the superior mandible.

The tongue enjoys much less variety in motion in birds than in mammals; it is only capable of being protruded, retracted, turned to each side either directly or obliquely, lightly rotated, and depreffed at the point. There are a great many muscles, however, employed in the performance of these motions; some of these act upon the os hyoideus, and others upon the lingual bone.

The first is analogous to the flyo hyoideus; arises from the upper and back part of the lower jaw, divides into two slips; one goes to the flyoid bone of the os hyoideus, where it meets its fellow; the other slip passes to the inner part of the middle bone or body of the hyoideus; it retracts the tongue.

The second corresponds to the mylo-hyoideus; it is a broad thin muscle, proceeds from the infide of the lower jaw, except its posterior edge, which comes from the outer part of the jaw; it is inserted upon the concave side of the cartilaginous extremity of the horn of the os hyoideus, around which it forms a muscular sheath; its use is to protrude the tongue.

The third muscle appears to answer to the genio-hyoideus; it comes from the superior edge of the lower jaw internally, and becomes attached to its fellow on the other side upon the flyoid bone of the hyoideus; protrudes the tongue a little from the obliquity of its direction, and seems to commence the actions of deglutition by elevating the parts in the bottom of the mouth. We did not observe this muscle in the cock.

The fourth muscle of the tongue is extended from the horn of the os hyoideus at its root, to the flyoid bone, where it joins the muscle of the opposite side. They approximate the horns of the hyoideus, during the protrusion of the tongue.

The fifth is a very small muscle, lying along the internal surface of the horn of the os hyoideus; it sends a delicate tendon to the under surface of the lingual bone, depreffes the joint of the tongue, and if it acts singly, turns the tongue.

The sixth is a little short muscle, which arises from the end of the middle bone of the hyoideus, and is affixed to the under part of the lingual bone; depreffes the tip of the tongue, and raises the bafe. This is a fingle muscle.

The seventh muscle lies along with its fellow upon the anterior surface of the superior larynx; it is attached to the root of the lingual bone. Its uses are to depreff the bafe of the tongue, and thus elevate the joint, and to retract the tongue while in the mouth.

The eighth is short; arises from the junction of all the bones of the os hyoideus on the lower surface, and is inserted into the upper and outer corner of the bafe of the lingual bone. It brings the tongue into a slanting line, after the other muscles have depreffed the tip.

The ninth muscle is the last; it is very minute, and passes from the bafe of the lingual bone to the very tip of the cartilage; depreffes the point of the tongue without elevating its root.

The muscles which protrude and retract the tongue are remarkably large in the woodpeckers and corncrakes.

The muscles which move the head and neck, are even more complicated in birds than in other animals. Most of them have their attachments so numerous and intermixed, that no description can convey an adequate idea of them.

The genio capitis begins in the thorax on the anterior spine of the dorsal vertebrae; its fasciculi go from the anterior part of the cervical vertebrae to the flyoid and transverse processes; and their tendons are longest at the superior and inferior part of the neck.

The muscle capitis motor articular is continued from the head as low as the fifth vertebra of the cervical spine.

On the posterior part of the spine there is a small muscle which seems to represent the superior part of the stylauus; it is extended from the transverse processes of the fourth cervical vertebra to the back of the occiput; it brings the head backwards and to one side.

There are a great number of fasciculi interposed between the transverse and articular processes at the back of the neck. These tendons pass over several vertebrae before they are inserted on the middle of the neck, which is the part most bent backwards.

A muscle which has been considered analogous to the cer- vicalis deflexor is, the chief extensor of the neck of birds. It arises from the spine of the back, opposite to the 313
cond rib, by tendon, which, on coming upon the neck, receives seven slips of muscles, which descend from the spines of the seven inferior cervical vertebrae. The muscle then proceeds on the neck as a distinct flip, and at the upper part produces three tendons, which go to the back of the articular processes of the second, third, and fourth cervical vertebrae. These tendons receive muscular slips from the back of the spine as low as the seventh vertebra, or where the other flip began to descend. The ascending fasciculi furnish the tendons to the fifth and sixth vertebrae, and to the atlas. This muscle is enabled, on account of its descending and ascending fasciculi, to extend the neck even while the head is erected. Cuvier describes the muscle somewhat differently in the *heron* and *buzzard*. The above account is from the *geese*.

There is a curious shaped muscle along the side of the preceding, which Cuvier compares to the *bunter cervix*. It commences by a slender tendon from the spinous processes of the first dorsal vertebra, becomes flabby at the lower part, turns back on the opposite side, and again flabby near the head, and is inserted into the occiput. Although it extends the whole length of the neck, it is so flabby that its tendon is not thinner than a piece of twine or thread. It affords in the flexion of the neck and elevation of the head.

The *tracheo-mastoideus* arises in birds from the anterior part of the second, third, and fourth cervical vertebrae, and is inserted upon the side of the occiput.

The *complexus* proceeds from but a few of the articular processes of the neck; and the *splenius* does not exist in birds.

Cuvier describes three *recti capitis pollici*: but these muscles do not deserve to be so called.

The first, which he names the *rectus maximus*, arises from the spine of the dentata, and is inserted into the side and back of the occiput. It brings the head backwards, and to one side, and resembles in figure and office the *splenius capitis*.

The second, or *rectus major pollieus*, proceeds obliquely from the spine of the dentata, under the preceding, to the dense of the back of the occiput. It strengthens, and tends to the side, and serves to move it laterally, and others again to unfold the quills of this part.

The third, or *rectus minor pollieus*, is only a few fibres mixed with the ligament, which connects the head with the spine.

The *mules* of the back consist of a few flabby fibres intermixed with portion of tendon, which are mostly ossified in full grown birds; they lie on each side of the dorsal spine, which they strengthen but cannot move.

The *mules* of the tail are distinct, and generally large; some are calculated to raise the tail, some to depress it, others to move it laterally, and others again to unfold the quills of this part.

The first is the *levator coccygis* of Vic d’Azir; it arises from the back of the sacrum and the transverse and spinous processes of the first caudal vertebra, and descends upon the tail and the caudal bone. There is a flabby flip accompanying the last tendon. This muscle, as its name implies, elevates the tail.

The second, or *depressor coccygis* of Vic d’Azir, is situated within the pelvis, and arises from the end of the sacrum and the ilium, where they join; also from the transverse processes of the bones of the tail. It is inserted by tendons into the spinous processes of the under surface of the caudal vertebrae, and concludes a number of muscular fibres in different directions on the basis of the lateral quills. This muscle deprepresses the tail, and appears also, from its attachment to the ligament of the quills, to be capable of converging them.

The third arises from the posterior edge of the anterior part of the pubis, and the tendon covering the lower part of the belly, and is inserted on the base of the ligament which surrounds the lateral quills. When this muscle acts singly, it brings the tail downwards and to one side; if, with its fellow, it depresses the tail directly; but at all times it tends to spread the quills of the tail.

The fourth is the *levator lateralis coccygis* of Vic d’Azir, which describes its origin different from what we have observed it to be. It arises from the lateral process of the sacrum and the first of the coccyx, and it turns round to be inserted in common with the preceding muscle upon the root of the ligamentous substructure, which connects the lateral quills. It moves, when acting alone, the tail to one side; but combined with its fellow and other muscles, unfolds the quills of the tail in the manner of the flaps of a fan.

The fifth muscle is in part covered by the third; it is attached to the whole of the posterior margin of the pelvis, except the extreme portion of the pelvis, and in the *geese* spreads upon the parts of the body round the anus; it then proceeds to be inserted, along with the *depressor coccygis*, on the under part of the caudal or last bone of the tail. Its office is, with its fellow and the depressor, to lower the tail.

The sixth is the *cruro-coxys* of Vic d’Azir; it arises by thin tendon from the inner and back part of the thigh bone, where it is joined with one of the muscles of the thigh. It is inserted, along with the other muscles of the tail, into the under part of the caudal bone. This muscle draws the tail to one side; but when its action is combined with its fellow, it is the most powerful flexor or depressor of the tail.

The *mules* of the trunk deviate more from the structure of mammals than the muscles of birds do in general, and have been but very imperfectly described by Cuvier and others.

The *flecs* are merely two slips of muscle, which descend from the next transverse process upon the first and second ribs.

The *triangularis fleris* takes its origin from the superior corner of the ilium, and the four superior ribs, where they join this bone, and is inserted into the movable angles of the four superior ribs after the first. It comprizes the superior part of the thorax, and thus brings forwards the lower end of the ilium; it is, therefore, a muscle of expiration.

The abdominal muscles consist of three layers.

The first represents the *obliquus externus*, although its fibres are arranged transversely. It arises from the edge of the ilium and pubis by a very thin tendon, and from the other edges of the ribs, by distinct tendinous processes, and is inserted into the side and lower edge of the ilium, and the middle line of the belly, to unite with the muscle of the opposite side. From this muscle passing over the moveable angles of the ribs, its action influences the whole cavity of the body; for at the same time that it comprizes the abdomen, it raises the anterior part of the ilium, by drawing the posterior part backwards, and thus dilates the thorax, and becomes a muscle of inspiration, explaining by this means the effect we have already represented in the abdomen.

The second is the *obliquus internus*, which is made of two portions, the one a little overlapping the other; the anterior is analogous to the *rectus abdominis*, and arises from the pubis and middle line of the belly; the other portion arises from the edge of the ilium and lowest rib. The fibres of each portion ascend in their proper directions to be inserted on the lower edge of the ilium, and the tendon filling the
the space between the ribs and the sternum. This muscle, like the preceding, diminishes the abdomen, and dilates the anterior part of the thorax.

The third layer answers to the *transversalis abdominalis.* It proceeds from the offseous margin of the abdomen to the middle line, where it meets its fellow. They consist of separate fasciculi at the superior part; and the fibres are collected round a point in the centre, where the yolk puffed into the belly of the chick.

There is a very thin film of muscle, which crosses the lowest part of the belly; it is situated superficially, and lies over several of the muscles of the tail. In the goose it arises from the ischium, where that bone joins the pubis; and in the *fowl* it is only attached by cellular membrane to the surface of the muscles of the thigh. It is, in both cases, on the side of the anus, which it seems designed to dilate.

We have observed in the *fowl* two very slender fasciculi of muscle to descend from the side of the rectum, one to the ligament supporting the quills of the tail, the other to the inside of the pelvis. They are both probably intended to produce the eversion of the intestines during copulation.

The muscles belonging to the wing do not differ in their arrangement and structure from those of the anterior extremity of mammals so much as might be supposed, considering how little these members resemble each other in their functions.

The *latissimus dorsi* arises only from the spinous of the dorsal vertebrae; it resembles, however, the muscle of the same name in mammals.

A muscle, analogous to the inferior portion of the *trapezius,* is observed at the shoulder. It comes from the spinous processes of the three last cervical and all the dorsal vertebrae, and is inserted into the inner and back part of the fork and posterior edge of the scapula. We have not perceived the division of this muscle into two parts on the shoulder, as stated by Cuvier.

The *serratus major aniceps* is only inserted into the point of the scapula. This muscle has been called by Vic d’Azir, the *fulcapsularis.*

The *coraco-facialis of Vic d’Azir* goes from the first ribs to the neck of the scapula. It appears to be analogous to the *pectoralis minor* of the human subject.

The *rhomboides* is not divisible into major and minor. It arises, as usual, from the spine, and is inserted in the posterior edge of the scapula.

A muscle, analogous to *levator scapulae,* arises by three slips from the transverse processes of the last cervical vertebra and the first and second ribs. It is inserted into the middle of the scapula, which it elevates and draws backwards. The motions of the scapula are necessarily very limited from its mode of connection with the neighbouring bones; and its rotation is restrained by a ligament which joins the point of the scapula with the dorsal spine. It is requisite the bones of the shoulder should be kept very ready during flight.

There are three *pectoral* muscles.

The *pectoralis maximus of Vic d’Azir* might be called, with more propriety, the *depressor alae magnus.* It arises from the whole of the body and heel of the sternum, except a certain portion of the anterior surface occupied by the next muscle over which it lies, and from the side of the fork and the last ribs, and is inserted into the spine on the outside of the humerus, where it is connected by ligament with the deltoid muscle. The *pectoralis maximus* has commonly more strength than all the other muscles of the body united, which is required to accomplish the depression of the wing in opposition to the whole weight of the bird during flight.

The *pectoralis media* of Vic d’Azir might be called the *levator alae.* It is affixed to the fore part of the body and keel of the sternum, the side of the clavicle, and the membrane which fills the interface between that bone and the fork. It sends its tendon over the head of the scapula through the pulpy formed by all the bones of the shoulder, to be inserted on the external tuberosity of the head of the humerus. By means of the pulpy it elevates the humerus, and consequently the wing; and from occupying the lower part of the flesh, the weight is kept in the situation most convenient for the bird during flight.

The *pectoralis minimus of Vic d’Azir,* or *depressor alae minor,* arises from a portion of the sternum behind the articulation of the clavicle, and from the inside of the femoral extremity of the clavicle. It is inserted under the head of the humerus; depresses the wing, and brings it close to the body.

The *fulcapsularis* is extended from the inside of the femoral extremity of the clavicle to the adjoining part of the internal surface of the sternum. It is impossible to conceive the use of this muscle, unless it be to strengthen the joint, as its attachments are incapable of motion towards each other. There are muscles analogous, as much as the form of the bones will permit, to the *fulcapsularis,* *teres major* and *minor,* *supra-spinatus,* and *infra-spinatus.*

Cuvier describes two little muscles which come from the inside of the clavicle to the head of the humerus. We have observed a muscle in the *fowl* which appears to correspond to one of these; it arises from the inner surface of the clavicle, and its joint with the sternum, passes over the first rib, and is affixed to the top of the inner tubercle of the head of the humerus. It rotates the wing inwards, when it has been spread in flight. The lower edge of this muscle, and the inside of the teres major, produce a most delicate tendinous cord, or fibre, which depends on the back of the upper arm, and is lost amongst the ligaments of the quills below the elbow. The effect of this, if any, is to bring the wing nearer the body, and perhaps spread the quills.

The *deltoides* is small, and of two portions. One arises from the fork at the top of the shoulder, and sends a small tendon to the aponeurotic expansion of the fold of the wing. This tendon, as it proceeds along the edge of the expansion, acquires exactly the structure and the elasticity of the *ligament nuchae*; it then becomes like common tendon, passes over the end of the radius, and is inserted into the style of the metacarpal bone. It bends the fore arm, extends the hand, and, in consequence of the elasticity of the tendon, contracts the soft part of the fold of the wing. This portion of the deltoid has escaped the observation of Cuvier and other writers, although the structure of the tendon is one of the most extraordinary circumstances in the anatomy of birds. The remaining portion of the deltoid is analogous to the same muscle of the human subject, and brings the wing upwards and backwards in flight.

The muscle which represents the *biceps flexor cubiti,* takes its origin from the end of the clavicle, where it joins the fork; and from the sharp tubercle of the humerus, which is analogous to the coracoid processes, the chief part of the muscle proceeds to be inserted into the inside of the neck of the radius; but as it descends, a small portion goes off, and is expanded in the fold of the wing, and attached to the outer side of the arm. This expansion of tendon corresponds to the aponeurosis of the biceps muscle of the human subject; but instead of lying close to the fore arm, it is spread out and covered with the common integuments.

The *brachialis internus* is very small, being only attached
to the fore part of the end of the humerus between the condyles.

There is a short muscle which arises from the ligament that contains the clavicle and the head of the humerus, and is inserted upon the flat external surface between the two tubercles. It is an elevator of the wing. It is peculiar to birds, and has not yet been described.

The extensor cubiti consists of two portions: the one, called by Vie d’Azir the extensor longus, comes from the junction of the fork and scapula; the other arises in a forked manner from the posterior surface of the humerus, and is the extensor brevis.

The acensus minor of Cuvier is the external and lower part of the extensor brevis. It is a distinct muscle in the frog, though not in the goose.

Although the bones of the fore arm do not admit of pronation and supination, the muscles which perform these motions in other animals, exist in birds, and answer different purposes.

The supinators resemble those of the human subject. The longus terminates on the stylo of the metacarpal bone, and forms both to bend the arm on the humerus, and extend the metacarpus, or lower part of the wing. The supinator brevis bends the fore arm. The place of the pronator teres is supplied by two muscles very much like it in shape; they act as flexors of the fore arm. There is a triangular muscle which in some degree fills the situation of the pronator quadratus; it arises from the end of the ulna, and sends a broad tendon over the carpus to the highest superficial surface on the metacarpal bone. It extends the hand, or lower part of the wing, giving it at the same time a degree of pronation, which the carpal joint permits, in order to render the wing concave when it is extended.

The flexors and extensors, situated on the fore arm of birds, resemble in shape and arrangement generally those of the human subject, but commonly have their uses changed, and often even reversed, in consequence of the difference in the figure of the bones and the plan of their articulations.

The muscle which corresponds in situation to the extensor carpi ulnaris, performs the motion which is called flexion of the lower part of the wing.

There is a strong muscle arising from the external condyle of the humerus, and implanted into the side of the ulna opposite the radius, for almost its whole length. It raises the fore arm on the radius, and seems to be the muscle called by Vie d’Azir flexor profundus.

The muscle analogous to the extensor pollicis longus, has its tendon inserted into the stylo of the metacarpus, and into the short abductor. It extends the hand on the fore arm.

The ulnar flexor bends the parts of the wing.

The flexor sublimis comes from the internal condyle, is attached to the lower carpal bone, and sends a tendon to the base of the first joint of the principal finger, bends the hand, but extends the finger.

The flexor digitorum profundus arises from the inner surface of the ulna; its tendon passes over a little pulley on the metacarpal bone, and terminates on the end of the last joint of the principal finger, which it extends, but bends the wing.

The extensor communis digitorum and indicat or arise from the external condyle and inside of the radius. They send tendons to the first and last joints of the principal finger, which they extend.

The fingers of birds are furnished with many short muscles; and notwithstanding they are very palpable, seem to have escaped the observation of Cuvier and other anatomists.

The flexor brevis pollicis comes from the inside of the head of the metacarpal bone to the flat surface of the bone of the thumb. The extensor brevis pollicis proceeds from the triangular surface of the metacarpus, behind the joint, to the base of the thumb. The abductor pollicis is extended between the stylo of the metacarpal bone and the outer edge of the bone of the pollex. The adductor pollicis is extended between the branch of the metacarpus and the bone of the thumb. The abductor, or extensor brevis indicis, is extended all along the radial edge of the metacarpal bone, and is spread upon the root of the first joint of the principal finger. It brings the finger into a line with the metacarpus. The adductor indicis comes from the ulnar side of the large branch of the metacarpus to the root of the first joint of the forefinger. The abductor minimi digitii lies along the ulnar edge of the small branch of the metacarpus, and as the little finger is tied to the other by ligament, this muscle produces the lateral flexion or abduction of both. The last is the interossus; it fills the space between the branches of the metacarpus, and its tendon passes along the back of the principal finger to the extremity; it bends the first joint laterally, and extends the rest of the finger.

The muscles of the lower extremity are very numerous in birds, and poffefs several peculiarities, notwithstanding the motions of this member are so simple. The articulation of the femur with the pelvis permits the thigh to move freely forwards and backwards, but does not allow it to be carried under the body, or far outwards. The motions of all the other joints of the inferior extremity are merely flexion and extension.

In consequence of the form of the pelvis, the ilium, the pallas magnus and pectoral, the obturator externus and quadratus lumbarum, do not exist in birds. Cuvier also states the pyiformis and gemini to be wanting; but we have seen a little muscle which passes from the projection above the acetabulum to the trochanter, which appears to supply the place of the pyiformis.

The obturator internus is generally a large muscle, and passes over a pulley at the fore part of the foramen ovale, where it receives two little slips analogous to the gemini: they are inserted into the outer part of the trochanter.

There are three glutaeal muscles, as in quadrupeds. The glutaeus maximus is attached by a broad thin tendon to the prominence along the dorsum of the ilium, covers the outside of the thigh, and contributes to form the extensor tendon on the side of the knee. The anterior part of this muscle corresponds to the tenor vaginae femoris. The glutaeus medius occupies its usual situation. The glutaeus minimus is a small muscle, so much placed on the anterior edge of the ilium, that Vie d’Azir considered it (perhaps not improperly) as the ilium. It brings the thigh directly forwards, and rotates the knee inwards.

The muscle analogous to the quadratus femoris is large and of a pyramidal shape. It retracts the thigh.

The extensor muscles of the leg resemble those of mammals. The vastus internus sends its tendon to be distinctly attached to the head of the tibia. The vastus lateralis is an extensor of the leg on the thigh.

There are three flexors of the leg: one, which, although single, is, from its insertion into the back of the fibula, analogous to the saphenous of the human subject; another, on the inside, is attached to the tendon of the extensors of the heel, as well as to the tibia. This muscle might be called either gracilis or femorolacetabularis, for it resembles both. The third flexor is in the middle. It comes from the ischium; and as
it defends, it receives a broad flip of muscle from the back of the femur. It is inserted on the back of the tibia, and the tendon covering the extensorz of the heel.

There is a large muscle on the inside of the thigh, which supplies the place of the *triceps*. It performs adduction, but it is also employed in carrying the limb backwords.

A muscle, which Cuvier appears to reckon as the *second adductor*, arises from the back of the ischium, and is inserted into the middle of the femur in company with the *cueroceccygeus* muscle. It retracts the limb.

The muscles for extending the heel, and consequently the lower part of the leg of birds, differ in many respects from the *gastrocnemii* of mammalia. The tendon achillis is produced by three portions of muscle; and, after passing over a moveable cartilaginous pulley which is placed on the heel, it spreads on the sides of the metatarzial bone. The first portion arises from the inner and fore part of the joint of the knee, and is connected for some way with another muscle, which lies on the outside of the joint. The second portion is small, and from the back of the internal condyle of the femur. The third is a very strong muscle arising by tendon from the outside of the thigh bone, just above the condyle. These three heads appear to be the external *gastrocnemii*.

The *soleus* is represented by a muscle which arises from the outer part of the knee joint, from the upper part of the tibia, and from the lower part of the fibula. It is inserted into the pulley on the heel, and sends a tendon to join that of the flexor of the first phalanx of the toes; and therefore it bends the toes while it acts on the heel.

There is also a muscle which appears to supply the place of the *plantaris*. It comes from the back of the head of the tibia, and affixes its delicate tendon to the inside of the moveable pulley of the heel.

The *tibialis anticus* arises by two heads, and is inserted into the fore part of the upper end of the metatarzial bone. It bends the joint of the heel.

The *tibialis posticus* is not found in birds.

There is a short *personal* muscle which is inserted into the outside of the metatarzial bone. It merely bends the joint.

The other muscles situated along the legs, are for the flexion and extention of the toes. The *extensor longus digitorum* exhibits no peculiarity, except that its tendon goes through a hole in the end of the tibia. There is no long *extensor* for the back toe.

The *flexor* of the toes are very complicated; they may be divided into the *flexor fibularis* and *flexor profundus*. The first is composed of several portions; two of these are personal muscles, and send their tendons to the first joint of the internal toe and the second phalanx of the middle toe; the other two portions of the *flexor fibularis* arise, one from the outside of the fibula, and the other from the back of the joint and internal condyle of the femur. The one on the fibular side is joined by the tendon of the *accessorius femoralis* *flexor* a muscle, which arises from the spine of the pubis, runs along the thigh, and sends its tendon through a sheath that runs over the ligament of the patella, to arrive on the fibular side of the leg. The two portions of the *flexor*, after this, unite, separate, and unite again, and at last produce three tendons, of which two go to the first phalanges of the internal and middle toes, and the third to all the joints of the outer toe except the last. These tendons which pass beyond the first joint, are perforating as well as perforated.

The *flexor profundus* arises as two distinct muscles; the one from the back of the femur, and the other from the back of the bones of the leg. The two tendons unite on the back of the metatarzial bone, and send off tendons to the last phalanges of the toes, which perforate those of the flexor fibularis.

All the flexor tendons are enclosed in a tendinous sheath, as they pass along the back of the metatarfas; and some of them go through the moveable cartilaginous pulley of the heel, and others run in sheaths formed in the cartilage which covers the top of the metatarzial bone.

The circulation of the flexion of the toes accompanying that of the other joints of the lower extremity of birds, was long ago observed by Borelli, and attributed to him by the connexion the flexors of the toes have with the upper parts of the limb, by which they are mechanically stretched when the knee is bent. This explanation has been controverted by Vic d'Azir and others, who have referred the effect to the irritability of the muscles. The opinion of Borelli appears, notwithstanding, to be well founded; for not only the tendon of the accessory flexor passing round the knee, but the course of the flexor tendons over the heel and along the metatarfas, most necessarily cause the contraction of the toes, when either of these joints are bent; and if the phenomenon was not produced on mechanical principles, it would be impossible for birds to exhibit it during sleep, which they do, or to prove the effect on the limb of a dead bird, than which nothing is more easy. The utility of this contrivance is great in all birds, but particularly so to the rapacious tribe, which by this means grasp their prey in the very act of pouncing on it; and it is still more necessary to those birds which perch or roost during their sleep, as they could not otherwise preserve their position when all their voluntary powers are suspended.

There are fix long small muscles lying on the metatarzial bone; they are largest and best marked in those birds which walk most. Two of these are on the posterier surface; one goes to the base of the external toe, which it *abducts*; the other is inserted into the root of the back toe, which it *bends*. On the anterior part of the metatarfas there are four muscles; the *first* extends the back toe; the second goes to the base of the first toe, and *abducts* it; the third is spread on the root of the middle toe, which it *extends*; the fourth lies along the outside of the metatarfas, perforates the end of the bone, and is implanted into the inside of the external toe, and *ad ducts* it.

**Brain.**

This organ exhibits several deviations from the structure of the brain of mammalia, which afterwards appear in a more marked manner in the inferior classes of animals. Accordingly, in the scale of excellence, or with respect to cognitive or mental faculties, the rank of birds is clearly fixed below that of mammalia, and above that of other animals. The rules which have been established to determine the degree of intelligence possessed by species or individuals, according to the proportion the brain bears to the whole body, or other parts of the nervous system, do not appear so applicable in birds as in mammalia. It is, however, very difficult to appreciate the capacity of birds, as they are so much the slaves of instinct, that it is often impossible to discover whether their actions arise from the impulsion of this principle, or depend upon the recollection and association of external sensations. The largest birds generally have the smallest proportion of brain to the whole body; and some of the small birds have the proportion of brain so great, that they would, agreeable to the rules laid down, excel in mental endowments mankind itself; for instance, the brain of the canary bird is equal to the one-fourth of the whole body; and in the human subject it is only the one-twenty-fifth part. The diameter of
the brain, in relation to the medulla oblongata, has been as-
certained only in a few species of birds, in which it has been
observed as follows:

The brain of birds is invested with the same coverings
which are described in mammalia.

The form of the cerebral mass is very different from that
of the human brain, which chiefly arises from the optic thal-
amic being visible externally. The hemispheres are therefore
proportionately diminished. They allume the shape of a
heart with the point turned forwards. On the lower part of
the side of the hemisphere, there is a depression which corre-
sponds to the fossa of Sylvius, and is the only appearance of a
division into lobes. Underneath the hemispheres the thala-
mus is divided into two distinct tubercles, each equaling in
magnitude a lobe or division of the brain. They
unite before the infundibulum, and send off the optic nerves;
there are, therefore, six parts, or principal eminences, of
the brain of birds, visible externally; the two hemispheres,
the two thalami, the cerebellum, and the medulla oblongata.
There are no convolutions, or winding impreffsions, on the
surface of any of these parts, except the cerebellum, which
is transversely furrowed, but not divided into two lobes.
The medulla oblongata is round, and smooth on the under sur-
face, being unflurished with the eminences called pons Var-
olii, corpora pyramidalia, and corpora olivaria.

On separating the hemispheres a little, it is perceived that
they are united at their lower part, or over the third ventri-
cle. The junction is effected by white medullary substance,
which afterwards spreads in a radiated manner, on the surfaces
of the hemispheres that are opposed or applied to each other,
almost as high as the top of the cerebrum. In reality, this
medullary union of the hemispheres corresponds to the fornix,
and can, like it, be traced to the anterior commissure in the
third ventricle; but instead of being connected to the fes-
tum lucidum and corpus callosum, as these parts do not exist
in birds, it spreads on the inner surfaces of the hemispheres,
and thus contributes to form the internal parietes of the
lateral ventricles.

Behind the radiated partition of the hemispheres, and
without the third ventricle, the posterior commissure presents
itself, and consists usually of more than one white line con-
ected together by a white fibre, like a nerve passing obliquely
across. The vault of the canalis medius is also visible, and
is composed in part of a white medullary band; and behind
this, another white cord runs across, which is the fourth
pair of nerves at their origin.

The lateral ventricles are not prolonged posteriorly, nor
poetically: what is called the reffected horn; the great and lefier
hippocampus have therefore no existence.

The corpus striatum fills the ventricle almost entirely, pro-
jecting from the external side of it in the shape of a kidney.
It does not exhibit on a section regular or strong marked
fossa.

There are no tuberula quadrigenina.

The pineal gland rests upon a flat surface; it is very
small, and enveloped in pia mater, and covered by a large
vein. The plexus choroides also at this place divides
into two tufts, or bunches, which pass into the lateral ventricles by two foramina in the back of the internal parietes.

The third ventricle possesses its usual situation between the
thalami and its slit-like shape, and communicates with the cana-
lis medius under the posterior commissure, and with the in-
fundibulum behind the anterior commissure.

The infundibulum and pituitary gland are both large in pro-
portion to the other parts.

The thalami nervorum opticorum contain each a ventricle,
which opens into the canalis medius; therefore, there may be
five ventricles reckoned in the brain of birds.

The fourth ventricle exhibits no peculiarity.

There are no eminences corresponding to the corpora con
decumbentia; Cuvier has described four round eminences be-
tween the thalami and corpora striata, which are particularly
plain in the fish. These are analogous to the tubercles of the
brain of fishes.

The olfactory nerves arise, in birds, from the very points
of the hemispheres, and often have a degree of enlargement
at their origin, which resembles the olfactory tubercles of
fishes. There are eight other pair of cerebral nerves, which
have nothing very peculiar in their origin.

See Plate X. of the Anatomy of Birds. Fig. 1. presents a
lateral view of the brain of the goose abstracted from the head;
a the hemisphere, b the depression analogous to the fossa
Sylvii, c the optic thalamus, d the cerebellum, e the me-
dulla oblongata, f the beginning of the medulla spinalis, g
the infundibulum, h the pituitary gland. The different
nerves are indicated by numbers, as they arise, from 1 to 9.
N° 1. the olfactory nerve, N° 2. the optic, N° 3. the ocu-
lo-mucular nerve, N° 4. the patheticus, N° 5. the trisugal
nerves, N° 6. the nervus abducens, N° 7. the seventh pair,
or auditory, N° 8. the eighth pair, N° 9. the hypoglossal
nerve.

The same plate, shows the internal parts of the
brain, as they are exposed without dissection, simply by
pulling the hemispheres to each side, and drawing the cer-
ebellum a little back: a a the two hemispheres, b the cere-
bellum, c the medulla oblongata, c the radiated white lines
seen arizing from the junction of the hemispheres, and form-
ning part of the parietes of the lateral ventricles, f the
transverse medullary cords corresponding to the posterior
commissure, g the white band of the roof of the canalis me-
dius, h the fourth pair of nerves crossing behind it, i the
pineal gland obfuscated by the vena galeni and the plexus
choroidea, k the latter passing into the ventricle.

The third figure of the tenth plate of the Anatomy of
Birds, gives a view of the interior of the ventricles of the
thalami nervorum opticorum, and the third ventricle: a a
the hemispheres laid down very much to each side, by
which the white partition is ruptured, and the third ventricle
brought into view, they are also pulled forwards to expose the thalami; b the cerebellum; c the medulla oblonga-
gata; d the two optic thalami, that on the right side is
cut open to shew the ventricle and its communication with the canalis medius; e the tract of the third ventricle and
of the canalis medius, along which a bristle is passed into the fourth
ventricle; f the anterior commissure, which feeds to produce the
medullary radii that unite the hemispheres.

Nerves.

The olfactory nerve has been already mentioned to pass
along a canal, or groove, in the upper and inner part of the
orbit, to reach the nasal cavity; in which its distribution
will be pointed out in describing the organ of smell.

The optic nerves pursue their ordinary course, as in other
animals.

The distribution of the third, fourth, and fifth pair of
nerves, is almost the same as in mammalia.

The branches of the fifth pair bear great resemblance to the
the same nerves in quadrupeds. They are distributed to the bill, and are therefore the nerves of the organ of touch in birds, under which head they will be farther noticed.

The \textit{portio dura} of the seventh pair, or the \textit{facial} nerve, is so small in birds, that it can hardly be discovered. Its offices are not required, in consequence of the structure of the parts of the face in these animals.

The \textit{portio mollis} is remarkably soft; when it arises from the brain, it is a tender pulp, of a reddish colour.

The \textit{par vagum}, or \textit{pneumo-somatic} nerve of the eighth pair, sometimes pales out of the cranium in two or three filaments, which afterwards rejoin. On leaving the skull, this nerve communicates with the lingual and gloso-pharyngeal nerves. The par vagum, after this, pales as a distinct strong cord along the neck, in company with the jugular vein, and descending into the chest, forms the \textit{cardiac and pulmonary plexuses}, as in mammals. The two nerves unite behind the heart, and proceed along the oesophagus, to terminate in anastomoses with the great sympathetic nerve. We have not observed the \textit{recurrent} branch of the eighth pair.

The gloso-pharyngeal nerve of the eighth pair makes its exit from the cranium through the posterior foramen lacerum in two filaments, which immediately unite to form a quadrangular ganglion, which sends off a small nerve to the anterior muscles of the neck, and another branch to anastomo-

The \textit{sympathetic} or \textit{great sympathetic} nerve, is described as entering the cranium by the foramen lacerum posterior. It unites with the fifth and sixth pairs, and produces a lenticular ganglion below the skull, which communicates with the eighth and ninth pair of nerves. The appearance of the sympathetic nerve is, however, soon lost on the neck; for the cervical nerves form their anastomoses with each other in the vertebral canal, from which a nerve is sent out between each vertebra to supply the muscles and integuments of the neck. These nerves are remarkably large. On coming into the thorax the great sympathetic sends a branch to the pulmonary plexus of the par vagum; it anastomoses also with the brachial plexus; and below the second rib, the sympathetic commences a series of ganglia, which are very conspicuous between each of the succeeding ribs, but become less visible along the remaining part of the spine. These ganglia are central points for the union of a number of nerves. They receive filaments from each other, which pass over the heads of the ribs; they communicate backwards with the spinal nerves; they detach on the outside the intercostal nerves, which are large, and besides supplying the intercostal spaces, give branches to the muscles and

\textit{integuments upon the sides of the body}; they lastly send off filaments anteriorly, which anastomose with each other on the side of the dorsal spine, and form cords, which become the splanchic nerves. In this manner there is produced on each side of the dorsal spine a reticulation of nerves which incloses in its meshes the heads of the ribs, and has a striking effect. The first dorsal ganglion unites with the brachial plexus and the cardiac plexus of the par vagum.

The \textit{splanchic} nerves, after being formed by the anterior branches of the sympathetic, pafs to the roots of the principal arteries of the vifera. Thofe of the cardiac artery produce a plexus round the trunk of this vessel, and where the artery is divided, there are one, two, or three enlargements, which are analogous to the \textit{femoral ganglia}; and the nerves which depart from these, inclose the arteries in a reticulated manner, and represent the \textit{femoral} plexus.

There are similar plexuses on the other chief arteries of the trunk, which correspond to the \textit{superior and inferior mesenteric and renal plexuses, &c.}

The nerves of the \textit{femoral} plexus accompany the branches of the ovarian artery to the stomach, spleen, liver, and pancreas, around which they continue to form numerous anastomoses, that may be compared to the \textit{femoral, splenic, hepatic, and pancreatic plexuses.}

The \textit{nerve} of the \textit{sung} more nearly resembles those of the superior extremity in man, than Cuvier has represented.

The \textit{brachial} plexus is produced by the two half cervical and first dorsal, and not, as he has stated, by the last cervical and two first dorsal nerves. The union of these three branches gives rise to three others, which are distributed in the following manner:—The first is a very small filament, which runs down on the inside of the arm, and is lost about the internal part of the elbow. This is analogous to the \textit{internal cutaneous} nerve. The second is a large cord; it gives off a very large branch, which divides into many others, for the supply of the pectoral muscles; it sends several smaller branches to the muscles under the clavicle, and about the joint, and then proceeds to the inner edge of the biceps muscle, along which it descends to the fold of the arm, after giving some large muscular branches. Before it reaches the joint, it divides into two branches: one of which is analogous to the \textit{ulnar} nerve, and the other four divides again into nerves which are similar to the \textit{median} and \textit{musculo-cutaneous}. The \textit{median} dips down amongst the muscles on the middle of the fore arm, to which it gives branches, and afterwards runs along the interosseous space, pafs under the annular ligament of the carpus, and is distributed to the short muscles of the digiti. The branch analogous to the \textit{musculo-cutaneous} nerve, is expanded upon the muscles on the upper edge of the radius.

The \textit{ulnar} nerve, although it appears to be incorporated with the \textit{median} on the upper arm, can be easily separated from it and traced to its proper origin in the brachial plexus. After this nerve leaves the median, it turns over to the end of the foramen to get upon the edge of the ulna. It gives filaments to the muscles in this situation; but its chief branch runs down superficially upon the ligaments of the quills in company with the vein, and goes ultimately to be lost upon the ulnar edge of the hand.

The third cord furnished by the brachial plexus, supplies the place of the \textit{radial} nerve. It detaches several filaments to the muscles on the inside and back of the scapula, it gives off also the \textit{articular} nerve, and then winds round the humerus between the extensor muscles, to which it furnishes some large filaments. On coming to the outside of the humerus, it sends a branch between the integuments of the

\textit{3 K}
fold of the wing. The nerve now turns round the neck of the radius, beneath the muscles, and forms two branches; of which one passes under the muscles to the outer side of the ulna, along which it runs superficially to the hand; the other branch passes on the radial side, but more deeply amongst the muscles, goes under the annular ligament of the carpus, proceeds between the branches of the metacarpus, and is finally lost on the back of the digit.

Although Cuvier has given a more accurate description of the nerves of the lower extremity, than those of the wing, it may likewise require correction in several particulars, which we have supplied.

The obturator and femoral nerves arise from the same plexus which is formed by the two iliac lumbar nerves, by a communicating branch from the first sacral pair. The obturator nerve passes through the upper part of the foramen ovale, and is distributed to the muscles around the hip joint, especially the adductor. The femoral nerve passes out of the pelvis in company with the artery, over the upper edge of the ilium. It divides into three branches, which are distributed amongst the muscles and integuments on the anterior and inner part of the thigh. Some of these filaments are long, and descend superficially for a considerable way upon the limb.

The ifchiadic nerve is composed of the five superior fascial nerves; and as soon as it departs from the plexus, even within the pelvis, is easily separable into its primary branches. Immediately after it passes through the ifchiadic foramen, it sends filaments to the muscles on the outer part of the thigh; it then proceeds under the biceps muscle, along the back of the thigh, about the middle of which it becomes divided into the tibial and the peroneal nerves.

The tibial nerve, even before it arrives in the ham, separates into several branches, which pass on each side of the blood-vessels, and are chiefly distributed to the muscles on the back of the leg. Two of these branches, however, are differently disposed of: the one accompanies the posterior tibial artery down the leg, passes over the internal part of the popliteal space, and anastomoses with a branch of the peroneal nerve, on the inner side of the metatarsus; the other branch runs down on the peroneal side of the leg, along the deep flexed flexors of the toes, passes in a sheath formed for it on the outer edge of the movable pulley of the heel, and proceeds under the flexor tendons along the metatarsal bone, to be distributed to the internal part of the two external toes.

The peroneal nerve is directed to the outer part of the leg; it dips in above the gastrocnemius muscles, and runs through the same ligamentous pulley that transmits the tendon of the biceps muscle; it then detaches some large filaments to the muscles on the anterior part of the leg, under which it divides into two branches, which proceed close together, in company with the anterior tibial artery, to the fore part of the ankle joint, at which place they separate; one passes superficially over the outer part of the joint; the other goes first under the tranverse ligament which birds down the tendon of the tibialis anticus muscle on the tibia, and then over the inner part of the joint, below which it divides into several branches, the one is distributed to the inner side of the metatarsus, and the other to the pollex and to the next toe; the other turns towards the centre of the metatarsal bone, and penetrates the tendon of the tibialis anticus just at its insertion, and then rejoins the branch of the peroneal nerve it accompanied down the leg. They continue their course together again in the anterior furrow of the metatarsal bone; and at the root of the toes, separate once more, and proceed to the interseptes of the three anterior toes, and each divides into two filaments, which run along the sides of the toes to the nail.

Organs of Touch.

As the sense of touch is bestowed upon animals to enable them to discern the forms and states of aggregation of external matter, it refines more especially in the extreme parts of their bodies, and when most perfect, excites in some member which is constructed for including or taking hold of extraneous substances. There is no part of the body of birds capable of conveying an accurate impression of touch, but the feet and the bills; their upper extremities and tail being simply instruments of motion. Different species enjoy this in different degrees, and possess it more or less in the bill or feet, in proportion as they employ these parts in the pursuit or examination of their food; these the only occasions on which birds exercise their functions of touch. The terns, albatrosses, and piperines tribe have most fenation in their feet, while the grebe and anserines, especially those that have long or broad bills for feeding out their food, like the jaipo, or duck, possess a very great susceptibility of impression in their bills.

The organization of the feet of birds, as far as concerns their offices as instruments of touch, is similar to that of the digitated mammals and reptiles. The skin on their lower surfaces is endowed with more than common sensibility, is largely supplied with nerves, and is elevated into those little regular eminences called papille, in which the sense of touch more immediately resides.

The structure, on which the fenibility of the bill depends, is different from the preceding. It consists in the magnitude and distribution of the fifth pair of nerves. These are divided, as in mammals, into three branches, the ophthalmo, the maxillar, the maxillary, and the inferior maxillary.

The ophalolium enters the orbit by a hole before the optic foramen, passes for some way in an oblique canal before it arrives in the nasal cavity, where it distributes some branches to the septum and turbinates, and to the external naris, and then goes on as two branches; one runs in the fibulation of the upper jaw, which it perforates at the end in many filaments, to terminate under the bony integument of the bill; the other passes between the membrane of the palate and the bill, and is lost in a number of fibrils at the apex of the bill.

The inferior and inferior maxillary nerves come out of the cranium by the same hole. The inferior, after dispending branches to the muscles in its course, is finally distributed to the lateral parts of the bill, which, if notched along the edge, as in some water birds, each denticulation receives several filaments. The inferior maxillary defends to the lower jaw, which it perforates, after giving a branch to the integuments of the side of the bill; and running in the maxillary canal, sends filaments to the edge of the bill, and terminates, like the ophalolium, on the apex of the lower mandible.

These nerves are of great size in the goose, duck, &c., in which they render the bill a very delicate organ of touch. See Plate X. in the Anatomy of Birds. Fig. 4. is the section of the head of a duck, made by dividing the organ of smell longitudinally, and by removing the bill and bone of the mandible, in order to bring into view the distribution of the fifth pair of nerves: 4 a the ophalolium nerve coming from the upper part of the orbit, and proceeding along the septum nasi; 4 b the branch which passes in the fibulation of the mandible, to be lost on the point of the bill; 4 c the branch that runs on the membrane of the palate to the end of the bill; 4 d the superior maxillary nerve dividing on the membrane of the palate, and sending its filaments to the denticuli on the side of the bill; 4 e the inferior maxillary running...
ring in the canal of the lower jaw, and sending filaments to the dentine on the edge of the mouth, and ending on the point of the bill; if the nasal branch of the ophthalmic distributed to the septum.

**External Parts, or Integuments.**

The feathers with which the bodies of birds are clothed, render them less capable of receiving the more simple impressions of touch, than most other animals. They also serve to defend them against the excrescences of temperature. The structure and mode of growth of these substanques are considered in another part of the dictionary. See Feathers.

The cuticle of birds is remarkably thin, but refemibie in structure the epidermis of mammalia. It is fixed generally along with the feathers.

The rude musculum is not observable, except in those parts which are uncovered by feathers, and possess peculiar colours, as the crees and caruncles of the head, the feet, and bills; where it is of course found to vary in colour as those parts do.

The cutis is in most birds extremely thin and delicate in its texture, appearing often like a fine sanguine, instead of an intermixing of fibres as in mammalia. It is, however, of different strength in water birds and the acephites; it is thinnest in the passerines. The external part of the cutis is never papillated, but when it covers the under surfaces of the toes which are designed to receive the impressions of external bodies.

The muscles of the skin, in consequence of the size of the external coverings, are in general very evident, and particularly in those birds which move the feathers of the creel, neck, or tail, as the hoopoes, cockatoos, herons, &c.

The following cutaneous muscles are common to all birds. Two flitty slips, which arise from behind each side of the head behind the maxillar auditory, and go backwards to be lost in the integuments. A thin expansion of muscle along the anterior and lateral parts of the neck; it takes a longitudinal course, but is connected with some transverse fibres between the jaws; this muscle corresponds with the platysma myoides. There is a muscle, actin in a serrated manner from two or three of the lower ribs, and extending upwards to the axilla and outside of the shoulder. We have perceived, in the goose, a very thin slip of muscle proceeding from the posterior part of the branch of the pubis to the skin on the inside of the knee; and Cuvier considers the red granular appearance under the skin on the back of the pelvis as muscular substance.

The functions of the skin of birds, as an organ of absorption and excretion, appear to be very imperfect. The clothing of feathers alone disqualifies it in a great degree for the performance of these processes. The thinness and simple organization of the skin itself renders it probable that its secretory powers are but inconsiderable. It does not also possess those various glands which are so abundantly bestowed upon the skin of other animals for its preservation and defence against the operation of external substanques. Birds are, however, provided with two peculiar glands for the purpose of furnishing an oily fluid, to keep the feathers in order and defend them against the effects of moisture.

The oil glands are two oblong or oval-shaped bodies, with one end more pointed than the other, and situated under the skin on each side of the spurious precess of the caudal vertebrae. They approach each other, and touch at their points, which are directed backwards, and thus produce very commonly between them the figure of a heart. They are covered by a strong dense white tunic, and their interior structure consists of a number of small tubes arranged in a radiated manner around a vacancy, or canal, which runs nearly in the middle of the gland, into which they all open and discharge their contents, in the same way as the tubuli ureteri do into the pelvis of the kidney. The middle canal leads to a papilla on the skin of the rump, and terminates in a simple orament. It deserves remark, that the tubes towards the circumference of the glands are soft and indistinct, and their contents are liquid and pale coloured; but before their termination, the tubes acquire more firmness, are a little separated into packets, their secretion becomes an opaque yellow, and of more confluence; thus affording an obvious and interesting view of the change which may be wrought upon secrcted fluids after their formation, while they are passing through their glands. The fluid produced by the glands on the rump of birds, although of an unctuous nature, is still not pure animal oil. It has more confluence, and is less affected by heat; which properties it principally acquires in the ends of the tubes, before they open into the common duct, as already mentioned. It is, however, sufficiently oleaginous to prevent the adhesion of moisture to the surface of the feathers. When birds make use of it, they turn their head round to the rump, and compress the glands with the bill, when a quantity of oily matter exudes, with which they bezmacar their feathers, arranging the barbs upon their shafts at the same time by means of the bill. These glands, as might be presumed from their use, are particularly large in the swimming birds. See Plate X. in the Anatomy of Birds. Fig. 5. shows the oil glands of the duck of their natural size: a the two glands; b their foramina on the papilla, into each of which a bristle is introduced; c the integuments reflected on each side to bring the glands into view. Fig. 6. of the same plate is a section of one of the oil glands somewhat magnified: a the canal in the centre into which the radiated tubes open; b the external portion of the tubes; c the interior extremities more dilated, and of a deeper colour.

**Organ of Smell.**

The shape and situation of the ulnarets are used by naturalists as characteristic of birds; and therefore do not require particular consideration here. They consist of two flits, varying in the length and width, commonly placed on each side behind the base of the bill. There are no muscles provided for dilating and contracting their aperture, as in mammalia.

The interior of the organ of smell is formed by a septum and three turbinated bodies, over which the pituitary membrane is spread.

The superior turbinatum assumes in general the shape of a bell; it is formed of cartilage, and is attached to the os frontis and lacrymale; it is hollow within, and divided by a slight prominence into two apartments, which are continued for a little way in a tubular form; the external ends by a blind extremity behind the middle turbinatum; the internal opens into the cavity of the nofe. The superior turbinatum is small in the pafferes and gallines, somewhat larger in the feninores, increased in bulk in the acephites, and still more in the禽雛, and in the gralla it is greatest of all. According to the observations of Scarpa, the acumen of smell is exactly proportioned to the magnitude of this part of the organ, as it is upon it only and the septum that the olfactory nerve is spread.

The middle turbinatum has been likened by Scarpa to a curvibites. It is connexted on the external part to the cartilaginous pinnas of the nares, and the bony process of the upper jaw, and inferiorly it is attached to the cartilaginous septum of the nose. It is composed of a cartilaginous lamina, which in the goose makes two folds and an half; but in the gralla it is compressed, and forms only one turn and an 3 K 2 half.
half. Harwood has stated these turbinata to be membraneous in the cafseou-rum and albobrof; and Cuvier has observed them to be composed of bone in the toucan and hornbill.

The inferior turbinatum is an oiffous fold, continued from the pinna of the nares, and united on the other side to the septum. See Plate X. in the Anatomy of Birds. Fig. 3, exhibits the interior of the nasal cavity of the goose; the septum being removed; a, the canal through which the olfac- tory nerve paffes to the nose; 6 the cavity of the inferior turbinatum; 6 its internal tube; d the external tube; e the middle turbinatum; f its deep or fmall winding; g the lef- cond; h two pins paffed through the bristles into the nasal cavity; i the turbinate bone; 6 its junction with the septum; k the cartilaginous appendix of the middle turbinatum; m a pin introduced through the external nares; n the posterior nares.

The pituitary membrane is fine where it invests the inferior turbinatum, and thicker and more villous over the middle one; it is covered with pores, which discharge mucus on its surface. The blood vessels on the interior of the nose are beautifully reticulated.

The olfactory nerves, as already described, arises from the point of the hemisphere of the cerebrum, and paffes through an olfence canal to the superior part of the nasal cavity. On arriving there it breaks into a great number of filaments, some of which are spread upn the superior turbinatum, and others run about as far on the septum as. See Plate X. in the Anatomy of Birds, fig. 3. g the nerve proceeding along the canal above the orbit; b the appearance of the nerve on the septum of the duck; and fig. 8. of the same plate exhibits a jeflion of the head of the horse, a bird with an acute tongue of smell; a the turbinated bone of the olfactory nerve; 6 its di- ftribution on the superior turbinatum, which is very large; c.e the middle turbinatum proportionally reduced in size; d inferior turbinatum; e its connection with the septum; f the aperture of the external nares.

Scarpa made a number of experiments with different species of birds, in order to determine their capacity for difcerning odours. He mixed various strong smelling substances with their ordinary food, which in fome were taken with indifference, but in others the repugnance to the scented food was fo great, that the birds perifhed rather than eat it. He was thus enabled to form a scale of the different degrees of perfection in which birds enjoy the fenfe of smell, which accorded exactly with the extent of the furface allowed for the distribution of the olfactory nerves. The scale he has laid is as follows: gallina, pafleres, pies, anfere, achireps, and grilis.

Organ of Taffe.

The fenfe of taffe is fo imperfect in most birds, that it might be doubted whether it existed at all or not. The form and motions of the tongue unifed it for being applied to the superfcies of fubftances; the glairy tenacious fluid, with which the surfaces of their mouths are fmeared, is not calculated for the folution of folid bodies; and the shape and ftructure of the papille of the tongue ferve to render them nearly incapable of impreffion; and further it may be ob- ferved, that birds commonly swallow their food without ex- amination, or a minute division of its parts.

The motions and internal formation of the tongue have been already difcufTed; it only remains, therefore, to no- tice the figure and integuments; but as thefe have been defcribed by natural biſtiorian in almost every genus, it is only neceffary to fpeak of them in a very general way at prefent. The form of the tongue may be commonly gueffed at from the fhape of the bill, with which it correfponds in a certain degree. In the gallina and pafleres it is an elongated trian-
external, instead of pointing inwards, as in man and quadrupeds.

The cavity of the tympanum is irregular on the internal surface, and is widest at its outer part. Besides the usual foramina leading to the labyrinth and Eustachian tube, it contains three others, which communicate with the cells of the bones of the cranium. These are widened into something like canals, where the holes open into them. The largest of the foramina is in the back of the tympanum, and leads to the posterior cells, and communicates above the foramen magnum with the cellular canal of the other side.

The second opening is placed at the anterior part of the tympanum, and conducts to the cells on the lower and anterior part of the cranium. The third foramen is continued amongst the cells which surround the labyrinth. Thus the cavities of each tympanum have a communication with the interior of all parts of the cranium, and with each other, from which they might be reckoned as making only one cavity. The end of the articular bone alve, where it contributes to form the parietes of the tympanum, has a foramen, by which it derives its supply of air. The auditory cells of the cranium of birds are analogous to the malpighian of the human subject; but from their extent, multiply found much more. They are of the greatest magnitude in the nocturnal birds of prey, and especially in the owls; the goat flicker (Caprimulgus) has them also very large. They diminish in the other birds, in which the posterior canals have no direct communication with each other. They are little observable in the fruite; and the parrot appears to want them altogether, but in their place the cavity of the tympanum is enlarged posteriorly.

The Eustachian tube is very large in birds; it is an osseous canal, and terminates by a small aperture close to the one of the other side, within the fissure of the posterior nare.

The foramina, which lead into the labyrinth, are situated within a fossa. They do not merit the distinctions of foramen ovale and foramen rotundum, being both oval, and only separated by a small bony process.

The officula auditus are supplied by a single bone and some cartilaginous processes. The officulum consists of a stalk or pedicle, crowned by an oval plate, which is applied to the foramen that leads into the vestibule of the labyrinth. At the other extremity it becomes extended and united to two or three cartilaginous processes, which form a triangle that is attached to the membrana tympani.

The pediculated bone of the tympanum is moved by one muscle, which comes from the occiput behind the ear, and penetrating the cavity, is affixed to the triangle that is connected to the membrana tympani. This muscle is a tensor, and draws the membrana tympani outwards. It is counteracted by two small tendinous cords that are extended to the internal parietes of the tympanum.

The labyrinth of the car of birds consists only of the vestibule and three semicircular canals, and the rudiment of the coeclesa.

The vestibule is small in proportion to the other parts.

The canals have been termed by Scaepa, from their gradation in bulk, canalis major, minor, and minimus. The largest is most superior, and has a vertical position. The smallest is situated horizontally. The canalis minor ascends upon the major, and opens into its side. They contain corresponding tubes of vascular membrane; and they also possess the ampullae, on which the nerves are distributed in the same manner as in mammalia.

The place of the coeclesa is supplied by a short osseous tube, very slightly bent, and either blunt or enlarged at the extremity. Its interior is occupied by two small cylinders of fine cartilage, each a little twisted, and united at their origin and termination. They proceed from the tympanic bar, which separates the two foramina that correspond to the foramen ovale and rotundum. The fovea, which is left between the canals, is dilated near the point, and accommodates the same branch of the auditory nerve which is sent to the coeclesa in mammalia. This nerve spreads in fine filaments upon the united extremity of the cartilaginous cylinders. The tube is divided by the presence of the cartilages into two spaces, which communicate with the vestibule and the foramen rotundum.

The frutulous birds have the tube corresponding to the coeclesa, very small in proportion to the other parts.

The auditory nerve is received into a fossa, and there breaks into five branches; one is the facial, or portio dura, and the others are sent to the semicircular canals and the tube. The facial nerve receives a filament from the par vagum, which traverses the ear, and is afterwards distributed to the palate.

Comparetti has described two canals leading from the labyrinth of birds, which correspond with the quadratus of the ear of mammalia.

For the illustration of the organ of hearing, see Plate X. in the Anatomy of Birds. Fig. 9, represents a division of the posterior portion of the fossa of the wall of the cube ovale (rufus lamina), which exposes both the parts of the tympanum and the labyrinth; a the membrana tympani, which is inclosed in a perfect frame of bone in this bird; b the cavity of the tympanum had open on the other side of the head; c the pediculated bone, or officulum, in situ; d d d the semicircular canals; e the tube analogous to the coeclesa; ff the air-cells exposed by the division of the enigma. Fig. 10. shows the officulum and the membrana tympani abstracted from their situation and magnified; a a the membrane; b the flat head or disk of the officulum; c the pedicle; d the extremity which unites with the cartilages, and forms the triangle that is connected to the membrana tympani. Fig. 11. exhibits a magnified view of a division of the labyrinth of the goat, in which the membraneous parts and the distribution of the nerves are displayed; a the trunk of the auditory nerve; b the portio dura; c c c the three branches of the portio molis going to the semicircular canals; d the nerve of the coeclesa running in the fulcus, and ramifying on the apex of the cartilages; e the osseous part of the tube analogous to the coeclesa; f the inferior cartilaginous cylinder; g the fulcus between it and the superior, which is concealed from view by the nerve; b b b the three ampullae of the membraneous semicircular canals; i the canalis major; k the canalis minor; l its communication with the major; m the canalis minimus; n the hole which corresponds to the foramen ovale. Fig. 12. is the cartilaginous body removed from the osseous tube; a the superior cylinder; b the inferior; c their junction where they commence; d the cavity at the apex of the cylinders laid open; e the nerve of the coeclesa; f its expansion in the cavity of the apex of the cartilaginous body.

Organ of Sight.

The peculiarities in the structure of the eyes of birds are chiefly intended to facilitate the perception of objects through a rare medium, and accommodate vision to different distances.

The form of the eye is admirably adapted in most species to promote both these effects. The anterior circle of the globe of the eye always projects more than in other animals; and in many species it is prolonged in a tubular form, and in those cases the cornea also is remarkably gibbous. The ovale furnishes the most striking example of the disproportion between the anterior and posterior spheres of the eye. The
axis of the anterior portion being twice as great as that of the other. The obvious consequence of this figure of the globe of the eye is to allow room for a greater proportion of the aqueous fluid, and for the removal of the chrysalid lines from the face of the formation, and thus produce a greater convergence of the rays of light, by which the animal is enabled to dis- cern the objects placed near it, and to see with a weaker light; and hence eyes, which require this fort of vision so much, possess the structure fitted to effect it in so remarkable a degree.

The fletcher coat of the eye in birds is thin and flexible on the posterior part, but anteriorly its form is maintained by the interposition of a number of long plates between its layers. These vary from thirteen to twenty, and are arranged in a circle immediately behind the cornea, with their edges overlapping each other. They are commonly flat thin scales, and nearly of a square figure, but become elongated from before backwards in proportion as the bird possesses the power of changing the convexity of the cornea. In the eyes the scales compose not only all the projection of the eye (the cornea excepted), but contribute to form the posterior sphere. The scales are capable of a degree of motion upon each other, which is, however, restrained within certain limits by the attachments of their anterior and posterior edges to the fletcher coat; and by their being bound together with a tough ligamentous substance, which seems to be the continuation of the fletcher between the edges that overlap each other.

The cornea possesses the same structure as in mammals, but differs with respect to form. When the posterior part of the eye is compressed by the muscles, the humours are urged forwards and dilate the cornea; which, at that time, becomes much more prominent in most birds than it is ever observed in mammals; and under such circumstances, the eye is in a state for perceiving near objects. When the muscles are quite relaxed, the contents of the eye-ball retire to the posterior part, and the cornea becomes flat, or even depressed: this is the condition in which we always find the eye of a dead bird, but we can have no opportunity of perceiving it during life. It is only prefixed for the purpose of rendering objects visible that are placed at an extreme distance. From the well-known effects of form upon refracting media, it must be presumed, that the cornea possesses very little, if any, convexity, when a bird, which is soaring in the higher regions of the air, and invisible to us, descends its prey upon the earth, and descends with uncaring flight to the spot, as is customary with many of the rapacious tribe.

There are other circumstances in the anatomy of the eye of birds, which have been supposed to concur with the extraordinary variation in the figure of the cornea, in producing its capacity for the perception of remote objects: these will be mentioned in their proper place.

The external coat differs in no material point from that of the human subject. The ciliary processes of the choroides are very small and short; being merely serrated flint. There appears to be no tapetum.

The iris is sometimes of brilliant colours, which are employed by naturalists as distinguishing specific characters of birds. Parrots have the power of voluntarily producing a great degree of motion in the iris. It does not appear, however, that other birds are capable of commanding the motions of this part.

The pecten, or plicated membrane, is the most singular part of the structure of the eye of birds. It appears to grow from the choroides where the optic nerve penetrates that coat; but on closer inspection it is found to have no inti-
ture of its coats, indicate the peculiar vision of birds and the kind of medium they inhabit. The aquatic birds, as already observed, is extremely abundant. It potentiates consider-
ably refractive especially powers in the higher regions of the atmosphere. The crystalline is remarkably flat and soft, as its offices can be so well supplied by the aqueous fluid in a rare medium. Both the form and the proportions of the humour in the eyes of all birds derive great illustration from being compared with those of fishes, which, in consequence of their continual refraction in so dense a medium as water, have these parts formed upon a plan the very reverse.—Their eye is fiat anteriorly; the aqueous fluid small in quantity, and of considerable consistence; and the lens spherical and hard, more especially in the centre. The cornu
cran is the crystalline more spherical than other birds, from being obliged to seek its food under the water.

The muscles for the motion of the eye-ball are fixed in a birds, as in the human subject; the four straight and two oblique. The tendons of the recti cannot be traced farther than the circle of imbricated bones. The operation of the straight muscles, when acting together upon the figure of the eye (which, as already observed, is so striking in birds), depends upon the bony scales of the anterior part of the sclerotic, and the thinness and pliability of that tissue posteriorly. The superior oblique muscle does not pass through a pulley.

The external eyelids are chiefly closed in birds by the ele-
vation of the lower one, although there is an orbicular muscle which surrounds both. The inferior eyelid is larger and thicker than the other, and contains internally an oval cartilaginous plate, under which the fibres of the orbicularis palpebrarum pass. There is also a peculiar muscle, which comes from the floor of the orbit, and acts as a de-
pressor of the inferior eyelid.

The internal eyelid, or membrana nictitans, is a thin femi-
transparent membrane, which lies close to the globe of the eye. It has a vertical position, and, when not employed, is folded back by virtue of its own elasitic, and remains concealed from view in the corner of the eye next to the nose. It is, however, capable of being spread over the whole of the anterior part of the organ, by means of the combined action of two curiously contrived muscles. One of them is of a square figure, and the other a quadratus; it arises from the upper and back part of the eye-ball, and approaching the optic nerve, terminates abruptly in a circular edge, which con-
tains a pulley for the passage of the tendon of the pyramidalis. This muscle arises from the side of the sclerotic next the nose a little inferiorly, and produces a fine tendon, which runs through the pulley formed in the free edge of the quadratus, and afterwards returns in a cellular sheet on the lower surface of the sclerotic, and becomes attached to the margin of the membrana nictitans, along which it is con-
tinued for some way, and gradually loit.

The lacrimal gland is small in molt birds. The glandula hardersi exists, and is larger than the lacrimal. Cuvier de-

scribes it as being generally situated between the adductor and levator muscles, and as having a single excretory duct, which perforates the membrana nictitans, and discharges upon its inner surface a yellow tenacious fluid. Many water birds have a hard granular body placed at the superior part of the orbit, which seems to perform the office of a lacry-
mal gland; and although its excretory ducts have not been yet seen, it probably furnishes a fluid of a peculiar nature, for the defense of the eye against the effects of the water and other accidents to which aquatic birds are exposed.

The figures, which serve to explain the organization of the eye, are found in Plate XI. of the Anatomy of Birds. Fig. 1, shows the cornea and imbricated bony scales of the goose, as an example of the figure of these parts commonly allume in birds. Fig. 2, represents the same parts in the horned owl, in which the cornea will be seen very prominent, and the scales greatly elongated, forming the fore part of the eye into a tube. Fig. 3, exhibits a lateral view of the crystal-
linen lens and the imbricated membrane in the goose's eye; a the peclet attached to the posterior part of the lens a little to one side; b the edge of the lens marked by the circular procen;

c the anterior part, which is particularly flat in birds. Fig.

4. shows the peclet and the lens in the relative situation they hold in the eye of the turkey; a the imbricated mem-
brane; b the lens; c the outline of the eye; d the optic nerve. Fig. 5. is a section of the eye of the emu; a a the cut edges of the sclerotic coat; bb the edges of the cho-
roides; c the retina; d the imbricated membrane formed like a purse. Fig. 6. presents the anterior part of the eye of the coot, with the membrana nictitans partially drawn over it, which is so fine a film that the parts of the eye are seen through it. Fig. 7. is the posterior view of the coot's eye, all the muscles, &c. being removed, and those for mov-
ing the membrana nictitans: a the mucus quadrites; b the pyramidalis at its origin; c its tendon passing through the pulley in the edge of the quadratus; d the tendon pro-
ceeding on the sclerotic coat.

Organ of Voice.

Until within these late years this part of the anatomy of birds has been involved in obscurity. Although several of the older anatomists described the structure by which birds pro-
duce sound, they were ignorant of its uses, from being milled by analogy, and supposing that this organ occupied the same situation in all animals. Even some of the descrip-
tions of the abode of the modern anatomists have been er-
rorous or imperfect. The subject has been most labori-
ously and ingeniously investigated by Cuvier. He defected the organs of voice of more than one hundred and sixty spe-
cies of birds, and publishd the result of his inquiries in two memoirs; the principal one will be found in the Magazi
n Encyclopedique, tom. 2, to which we would refer the reader for numerous and minute details, that would be bur-
tensome to introduce into the present work.

The true felt of the organ of voice in birds is at the bifurca-
tion of the trachea, and not, as general analogy would dictate, at the superior larynx, which is in birds little more than a simple rima, or slit, formed, however, with somewhat differently shaped cartilages than belong to the rest of the trachea, and furnished with muscles for opening and closing the aperture. The mechanism of the inferior larynx, which fits it for the production of sound, depends upon the figure of its cartilages, and the expansion of its membranous parts.

The two branches of the bronchia are composed of femi-
rings of cartilage; the internal surfaces, or those opposed to each other, being membranous. The semi-rings next the trachea are often large, and always left curved than those near the lungs. The consequence of which is, that the membranous part of the bronchus becomes expanded in pro-
dportion to its distance from the lungs, and towards the bifurcation finally assumes an oval figure, to which Cuvier has given the name of the tympaniform membrane.

Where the bronchus open into the trachea, there is the appearance internally of the reed of a musical instrument.

This is produced by a thin and elastic fold of the inner mem-
brane, which projects upwards from each side. The apen-
ture is divided into two, sometimes by an osseous bar extend-
ed across from before backwards, and sometimes merely by the angle produced by the union of the two bronchioles.

When the air is expelled from the lungs and air-cells with
force through the bronchiz, a lively vibration is excited in the tympaniform membrane and the reed-shaped aperture, or glottis, upon which the production of the voice essentially depends.

The magnitude, figure, and proportions of the inferior larynx vary more or less in almost every species, which Cuvier has taken great pains to point out.

The trachea is commonly enlarged, at its bifurcation, by the expansion and union of its halt cartilaginous rings, which is designed to afford strength to the voice.

In the "flare" and the "singing birds," the latt rings of the trachea are united into a single piece, of which the base is wide, and furnished with two points that are joined by a transverse sinus; in such a way, that the trachea communicates by two openings with each of the bronchies.

In the "parallels," the latt rings of the trachea are united, and form a tube a little compressed on the sides. The very last ring is almost square; it is also flattened before and behind, and furnished posteriorly with two points. There is no partition within.

The sides of the bronchus, opposite to each other, are membranous. The first semi-ring is large, flat, and shaped like a crescent; the second, third, and fourth semi-rings unite in one piece; and the fifth, sixth, and seventh are consolidated into a similar plate. The edges of both, however, present the marks of their original parts.

In the "natural birds," the latt ring of the trachea is divided by a bone.

In the "cephalopods," the four last cartilaginous rings of the trachea are incomplete posteriorly, and the tympaniform membrane is continued up between them.

The male birds of the "ducks" kind, and the genus "morgus," have the last rings of the trachea united, and forming a cartilaginous or bony rack, called by authors the "ampulla," or the "labyrinth." This part, in the mallard, forms two dilatations; the one on the right is small, and resembles a truncated cone, with a prominence from the base behind. The left is a large vehicle irregularly rounded, and produces at the lower part a pyramidal projection. Its right surface is a little flattened below, and its inferior border is indented. The cavity is interrupted by projections, or septa, in such a manner, that the air cannot pass from the left bronchia into the trachea, but through the capsule, although on the right side it may. The entrance to the bronchus is provided with a thick membrane, under which there are some glands resembling the "sinus," that secrete a mucous fluid.

The form and internal partitions of the ampulla of the "ducks" of other species, and the "morgus," are different in every instance. Their deviations are described at length by Cuvier. See Memoire sur la formation des cloches, Magasin Encyclopédique, tom. 2d.

Two species of "vultur" (V. papu and V. aura) were observed by Cuvier to be deprived of the organ of voice, that is. they have neither the tympaniform membrane, nor any projection, or projecting elastic parts at the entrance of the bronchus into the trachea.

The voice of birds is modified, and the tones rendered more acute or grave, by means of two descriptions of muscles. The first are common to all species, and have been long known and described. They were called by V. d'Azir the "internal," or external "laryngeal." They are two flexible cords, and arise from the triangular processes of the sternum, to which the superior ribs are joined within the chest, and proceed to the side of the trachea, above the bifurcation, along which they ascend for its greatest length. Their effect is to depress the inferior larynx, and contract the bronchus, and thereby relax the tympaniform membrane, and deepen the tone of voice, and in some circumstances they may also bring the trachea forwards. These were the only muscles observed by Cuvier in the gallinace, and most of the anseres. It is probable, that no others are found also in the "fowl" birds.

The second kind of muscles are confined to the inferior larynx; they are short, and situated upon each side of the bifurcation of the trachea, and, except in the "parrot" tribe, are all "constrictors," or intended to render the tympaniform membrane tense, and thus exalt the tones of voice.

In molt birds, which do not sing, there is but a single pair of constrictors, one on each side, which arise from some of the last rings of the trachea, and is inserted into some of the first semi-rings of the bronchia. These muscles are longest in the "natural birds," extending from the base of the trachea to the second semi-ring. The constrictor is attached to the fifth semi-ring in the "cock," the "hen," and "bitter." The latter birds owe their strength of voice to the elasticity of the semi-rings, and the extent of the tympaniform membrane. The "goat-fucker," "king-fisher," and "pelican," have the constrictor muscle affixed to the second semi-ring of the bronchia; and the "woodpecker," "fallop," "coots," and the "plover," and "resio-choyra," and probably all the great white "goat," have it inserted into the first semi-ring.

The larynx of the "singing birds," and some others, is provided with five constrictors on each side, which Cuvier has named, according to their situation and direction.

1. The anterior longitudinal constrictor.
2. The posterior longitudinal constrictor.
3. The small longitudinal constrictor.
4. The oblique constrictor.
5. The transverse constrictor.

These almost surround the bifurcation of the trachea, to which they have all the same attachments, as near as may be. The two first are inserted into the third semi-ring; the two next into the second semi-ring; and the last is affixed to the first semi-ring, and particularly to a little cartilage that is joined to it.

Cuvier has observed the five pair of constrictors in all the "singing," birds; in the "flare," in all the "passerae," except the "swallow" and "goat-fucker," and in the "crow," "raven," "jay," and many of the "pie" kind.

The most complicated instrument of voice, amongst birds, is that of the "parrot" tribe. It possesses three pair of muscles; but one pair is intended to relax the opening of the glottis.

The principal constrictor arises from the last ring but one of the trachea, descends almost perpendicularly upon the lataxor, and then goes on to be inserted into the union of the fifth, sixth, and seventh semi-rings of the bronchia. Its attachment being joined to the semicircular plate, it urges the upper part of the plate inwards, and thus contracts the glottis.

The auxiliary constrictor occupies, for a certain distance, the anterior part of the trachea, and lends off a tendon, which is lost in the preceding muscle; its operation, therefore, is exactly the same.

The lataxor is placed under the two other muscles; it arises along the side of the trachea, and expands upon the inferior concave edge of the last ring; in drawing which outwards, the muscle enlarges the glottis.

See Plate XI. in the Anatomy of Birds. Fig. 8. shows the external appearance of the inferior larynx in the "owl; a" the lower part of the trachea; b the two bronchia; c the external laryngeal muscles, which are common to all birds; d the constrictor. Fig. 9. of the same plate exhibits the organ of voice in the "thryso; a" the anterior longitudinal constrictor; b the transverse constrictor partially exposed under
under it; c the posterior longitudinal constrictor, detached at one extremity, and turned outwards: and Fig. 10. affords another view of the same subject; the posterior longitudinal constrictor is turned down to expose those that lie behind it; a the little longitudinal constrictor; b the oblique constrictor. Fig. 11. of Plate X. represents the anterior part of the organ of voice in the parrot; a the principal constrictor; b the auxiliary one; c the laxator; and Fig. 12. gives a lateral view of the same parts, which are indicated by corresponding letters.

The trachea, in several birds, is found to assume singular forms, and to suffer enlargements at particular places. These have long attracted the attention of naturalists. Some of the best observations on the subject have been made by Dr. Bloch of Berlin, and by Falda, Silberfchlag, Beckmann, and Otto, who have each published in the Berlin Transactions, see Beitr. des Berl. Nat. Fr. i. ii. iii. & iv. But for by the most copious account of the peculiarities of the trachea of birds, has been given by Dr. Latham in the Linnaean Transactions, vol. iv. p. 90.

The deviations from the common structure of the trachea, have been divided by Dr. Latham into two kinds. In one the windpipe does not alter its capacity, but possesse an unusual length, which is disposed of either in convolutions on the outer part of the body underneath the integuments, or in a cavity formed within the sternum for the purpose. The other kind of deviation consisits in dilatations occurring either at the bifurcation of the trachea, or both there and in the middle of the tube.

The trachea of the wood grouse, when arrived at the crop, takes a bend upwards for a little way, and again turns down, and pursues its course to the lung. There has been no peculiarly observed in the other birds of this genus which vi-
fit this kind of form.

In the marvail turkey (penelope marvali), the trachea makes a round turn on the outside of the top of the sternum, and then enters the chest.

In the male parrock phoasant, the wind-pipe descends under the skin more than half the length of the body, before it returns to enter the thorax.

The guan (penelope criflate) has the trachea still longer than the preceding. It passes to the very bottom of the belly, and then turns up again, before it makes the double. See Plate XI. in the Anatomy of Birds, fig. 15.

The Indian cock was observed by the academicians to have a degree of convolution in the trachea, which varies somewhat in different individuals.

The cebecw curaffow has the most remarkable convolutions of the trachea. It first descends upon the right pectoral muscle to the end of the sternum, where it makes a convolution to the left, something in the shape of a ring, after which it returns to the right pectoral muscle, and goes over the clavicle into the thorax.

The semi-palmented goose of New Holland has an extensive convolution of the trachea under the skin. Its note is said to be very musical.

The ardet virge, the wild or whistling fown, and the crane, have the winding of the trachea accommodated in the keel of the sternum. It is singular that this structure does not exist in the tame fown, which in other respects so much resembles the wild bird. See Plate XI. in the Anatomy of Birds. Fig. 14. shews those parts in the wild fown; a a a the sternum cut open to expose the cavity which lodges the trachea; b b b the trachea; c e the fork; d d the clavicles. The above structure belongs to both sexes.

The dilatations of the trachea are confined to two genera, Vol. IV. ana and mergyas; and as already observed, are only to be met with in the male birds.

The bony enlargements at the bifurcation into the bronchi, which are called ampuloe, or labyrinthes, exist in every species of duck and merganier. They consist of two cells, one in general much larger than the other. In some influences the parietes of the cells are in a great measure formed by a membrane spread across it, like the head of a drum. There is also a bony arch turned across to give strength. This is the caec in the fowp duck; the pochard, tailed duck, the fmoso, &c. See Plate XI. Fig. 15 is the end of the wind-pipe of the pochard (anas firina).

The trachea of the golden eye duck is very curious. The labyrinth is more complicated than usual; and there is a singular enlargement in the middle, which is formed by cartilaginous joints, or plates, placed obliquely, and folding over each other, so that the part admits of being contracted and lengthened, as the motions of the neck may require.

The velvet duck is distinguished by two very remarkable osseous enlargements, one is situated immediately below the superior larynx, and another in the middle of the wind-pipe. The lower part does not form the usual ampula, but the bronchies become for a little way bony canals. See Plate XI. in the Anatomy of Birds. Fig. 16. represents the trachea of the velvet duck; a the superior, or laryngeal osseous cell; b the bony cavity of the middle; c e the osseous parts of the bronchiae.

The red-breasted merganfer has the middle of the trachea formed like that of the golden eye duck, only the plates are made of bone, and curiously furrowed; indeed all the trachea of the merganfers, as Dr. Latham observes, consists of little else than bone.

A very little comparison of the mechanism of wind-musici,

Birds, in Ancient Augury. Pecunia, or knowledge of futurity, was supposed, among the ancients, a natural fac-
ulty of birds, owning, perhaps, to their nearer intercourse with heaven, or their breathing a purer and more celestial air than other animals. Hence it was, that divination by birds obtained among the ancient Greeks and Romans, being performed by observing, and interpreting the flight, chirping and feeding of divers birds. (See Augury.) Birds, with regard to augury and divination, were of divers kinds, viz. Aves auifauif, or felices, those which naturally portended good: such were the dove, swan, &c. Aves auifatuis, or tenebrae, those which boded some evil or mischief: such were the kite, raven, crow, and owl, everywhere, except at Athens. Aduiffas, that which excites and encourages the confutler to execute what he has in view. Arvus or arcuus, that which forbids a thing to be done; otherwise called.
called claram, clamatoria, and prohibitoria, inehra, and inhiba. Incumbilia, that which gave omen of a fire, or other calamity; or which is seen carrying a firbrand from the funeral pile to a house. Remora, that which stays or delays an action. Simulata, that on the left hand, denoted a happy or prosperous omen; and was also called secunda, praeter Alshet, those which gave omen by their wings and flight. Of times, those by their surging or chirping. Polly, by their pecking. Prester, those which by their flight, or perching, gave happy omens. Inserre, or indeb, those which in like manner gave ill omens.

Bird, William, in Musical Biography. This worthy and admirable scholar of the profound Tallis, is supposed to have been the son of Thomas Bird, one of the gentlemen of Edward the sixth’s chapel, in which he was himself a singing-boy. By the great number of his ecclesiastical compositions to Latin words, and the several portions of the Roman ritual which he so frequently set to music, and published late in life, he seems to have been long a zealous adherent to that religion. He must, however, have conformed to the church establishments of queen Elizabeth’s reign; for, in 1563, he was chosen organist of Lincoln cathedral, where he continued till 1569, when, upon the accidental death of Robert Parsons, who was drowned at Newark-upon-Trent, he was appointed gentleman of the chapel royal. Notwithstanding which, it cannot be denied that he composed the chief part of his Choral Music to Latin words, and to have published it in that language, as late as the middle of the reign of king James I.

In 1575, it appears by the title-page of the “Cantiones Sacrae,” and the patent annexed to that work, that he and Tallis were not only gentlemen of the royal chapel, but organists to her majesty queen Elizabeth. Indeed both must have been great performers on the organ, to have been able to play such of their pieces for that instrument as are still preserved; in which the passages, though awkward to performers who are not accustomed to modern music, must have been suggested by persons that were habituated to the complicated, and now, almost, invincible difficulties of the sixteenth century. And though the compositions for key-instruments by those great masters of harmony, are totally unappoisioned, and without grace, it is impossible not to regard their ingenuity and contrivance in the texture of the parts, with respect and wonder!

If we consider the elaborate style of composition which prevailed, particularly in the church, during the time of Bird, and that he, like his master Tallis, was not only ambitious of vanquishing its usual difficulties in the construction of fugues and canons, but fought new complications, perplexities, and involutions in the motion and arrangement of the parts, the following list of his works will not only manifest diligence, but fecundity.

Befides the great share he had in the “Cantiones Sacrae,” published in conjunction with his master Tallis, in 1575, when his name first appears as an author; and without enumerating many admirable compositions for the church and chamber, still subsisting, but which were never printed, or, at least, not till after his decease, he published: “Psalms, Sonnets, and Songs of Saints and Pieties,” of five parts, 1588; “Liber primus carcerum Cantionum, quinque vo-

1611. Dr. Tudway’s collection, in the British Museum, contains a whole face piece in D minor, by Bird, with reponsions, and the anthems, “Sing joyful unto God,”—O Lord, turn thy wrath,”—(all published in the second and third volumes of Dr. Boyce’s Cathedral Music)—“O Lord, make thy Servant;” “Save me, O God;” “Prevent us, O Lord;” “Civitas sancti tuo,” one of his Sacramur Cantionum, or Sacred Songs, published 1589, has been long sung in our cathedrals to the English words, “Bow thine ear, O Lord;” and is one of the admirable pieces of har-

mony in the second volume of Boyce’s printed collection.

Dr. Aldrich, who was a great admirer and collector of the works of Bird, and who adapted English words to most of his compositions which have been used in our cathedrals, and that were originally let to parts of the Roman service, in Latin, has bequeathed to Christ Church, Oxon, beautiful and correct copies of most of his productions, in a set of books, small 4to. In this library near forty of his com-

positions are preserved; and in another set, many more, with those of Tallis, Taverner, Tall, White, Redford, both the Mundys, Shepherd, Bull, and other contemporary English masters.

Bird’s pieces for the organ and virginals are almost innum-

erable. In a magnificent folio manuscript, curiously bound in red morocco, formerly in Dr. Pepusch’s collection, which is generally known by the name of “Queen Elizabeth’s Virginal Book,” there are near 70 of his compositions.

The first piece by Bird, in this book, and the eighth in the collection, is a Fantasia, which generally implies a Fugue, in which the subject is as frequently changed as in ancient Choral Music, where new words require new accents and intervals; for as yet, it was not the custom in composing fugues to confine a whole movement to one theme; and here Bird introduces five or six, wholly different and unconnected with each other.

The subject of the second composition, by Bird, in the Royal Virginal Book, is the tune of an old ballad, “John come kis me now;” of which, with great labour and inge-

nity, he has varied the accompaniments sixteen different ways; for while the treble, base, or some inward part, is always playing the original air, three other parts are moving in fugue, or running rapid and difficult divisi. No. 52, is another Fugue; and 56, a Pavane, by Bird; which im-

plied a great majestic dance, in common time, similar to the movement of the penceock. This strain was usually followed by the Galliard; which, on the contrary, was a gay and lively dance, in triple time, but on the same subject as the preceding. No. 58, is entitled, “The Carman’s Whistle;” From No. 58 to 69, the compositions are all by Bird; consisting chiefly of old tunes, with variations; among which is “Fortune,” a plaintive and expressive melody, to which the ballad, called “Titus Andronicus’s Complaint,” inferred in Reliques of ancient English Poetry, vol. i. p. 234, was originally written. It has been imagined that the rage for variations, that is, multiplying notes, and dif-

guising the melody of an air, and, generally, well-known air, by every means that a spiccata nota, or note splitter, fees possible, was the contagion of the last century; but it ap-

pears from the Virginal Book, that this species of influence, or corruption of air, was more exccive in the sixteenth cen-
tury, than at any other period of musical history.

Crowded and elaborate as is the harmony, and uncouth and antiquated the melody, of all the pieces in this collection by various composers, there is a manifest superiority in those of Bird over all the rest, both in texture and design. In a later age his genius would have expanded in works of invention, taste, and elegance; but, at the period in which he
he flourished, nothing seems to have been thought necessary for keyed-instruments, except variations to old tunes, in which all the harmony was crowded, which the fingers could grasp, and all the rapid divisions of the times, which they could execute. Even nominal fantasias were without fancy, and confined to the repetition of a few dry and unmeaning notes in fugue, or imitation. Invention was feo young and feeble, as to be unable to go alone; and old chants of the church, or tunes of the lute, were its leading strings and guides.

Though the reformation had banished superstition from the land, fragments of santo fers, like rags of Popery, still remained in our old secular tunes, and continued to have admission in the new. Indeed the melodies of all the rest of Europe had no other model than the chants of the church, till the cultivation of the musical drama; whence all the rhythm, accent, and grace of modern music, have manifestly been derived.

Besides the great number of Bird's compositions for keyed-instruments, which are preferved in the Virginal Book of queen Elizabeth, another manuscript collection of his pieces still subsists, under the title of "Lady Nevil's Muic Book." It is a thick quarto, very splendidly bound and gilt, with the family arms beautifully emblazoned and illuminated on the title-page, and the initials H N at the lowest left hand corner. The music is all written in large, bold characters, with great neatness, on four flaved paper, of six lines, by Jo. Bawdine, a flinger-man at Windsor, and a celebrated copyist of queen Elizabeth's time. The pieces contained in this collection, sixteen of which are entered in that queen's virginal book, amount to forty-two, with variations to many of them, of the most laboured and difficult kind. The notes, both white and black, are of the lozenge form, like those of the printed music of the fame period.

Lady Nevil seems to have been the scholar of Bird, who profeffedly composed severall of the pieces for her ladyship's ufe.

None of Bird's pieces for keyed instruments seem to have been printed, except eight movements in a thin folio book of lefions that was engraved on copper, and published in the reigne of king James I. under the following title: "Parthenia, or the Maidenhead of the Muicke that ever was printed for the Virginalles." Composed by three famous masters: William Bird, Dr. John Bull, and Orlando Gibbons, gentlemen of his majesties moft illustrious chappel." These lefions, though not equally difficult with some of those in the Virginal Books of queen Elizabeth and lady Nevil, are rather more dry and unmeaning.

The canon, Non nobis Domine, appears in none of his works published by himself, or collected by others, before the year 1622; when Hilton inquired, and prefixed the name of Bird to it, in a collection of catches, rounds, and canons. But as no claim was laid to it by, or in favour of, any other composer, before or since that time, till about the middle of the last century, when it was given to Palestrina by Carlo Ricciotti, who published, in Holland, among his concoctio, a fugue in eight parts, on the same subjeft, there frooms no doubt remaining of our countryman Bird having been the author of that pleasing and popular composition.

Bird died in 1623, surviving his master Tallis thirty-eight years; and if we suppose him to have been twenty in the year 1563, when he was chosen organist of Lincoln, he must have been eighty at his deceafe. Pescach, in his Complete Gentleman, speaks of him with great reverence: "For Mutets and Muffecke of piety and devotion, as well for the honour of our nation, as the merit of the man, I preferre above all others our Phoenix, Master William Byrd, whom in that kind I know not whether any may equall. I am sure none excell, even by the judgement of France and Italy, who are very sparing in their commendation of strangers, in regard of that concept they hold of themselves. His Cautiones Sacre, as also his Gradualia, are meere angelical and divine; and being of himselfe naturally disposed to gravity and piety, his veine is not so much for light madrigals or canzonets; yet his Virginella, and some others in his first fet, cannot be mended by the first Italian of them all." Second edition, p. 100. His pupil, Morley, in his Introduction, every profefse and musical writer of his own and later times, never mentions him but with the highest refpeft. At this remote period but little, however, can be known of his private life, which was too flofius and fedentary to have furnished history, at any time, with events of general intereft. With refpeft to what Ant. Wood afferts in his Flaffi, that "Bird was excellant in mathematices," it is, in his usual way, supported by no proof; and indeed mathematices have so little to do with practical music, either in composition or performance, that those musicians, who are most ignorant of the ratio or philosophy of sounds, seem confantly to have arrived at the highest degree of excellence in the felection, combination, and refinement of them in practice, by the mere affifftance of experience, and the gift of good ears and powerful nerves.

That he was a diligent cultivator of his art appears from his numerous works, which are more the productions of meditation and study, than of haste and enthusiasm. That he was pious, the words he flected, and the solemnity and gravity of fyle with which he fet them, sufficiently evince. Of his moral character and natural disposition, there can, perhaps, be no testimonies more favourable, or left subject to falpitation, than thofe of rival profefors, with whom he appears to have lived during a long life with cordiality and friendship. And, of the goodness of his heart, it is, to us, no trival proof, that he loved, and was beloved, by his master, Tallis, and scholar, Morley; who, from their intimate connexion with him, must have seen him in robe de chambre, and been speculators of all the operations of temper, in the opposite fituations of subjeftion and dominion.

Indeed, the bell memorials of a professional man's exiilence are his surviving works; which, from their having been thought worthy of prefervation by posterity, entitle him to a niche in the Temple of Fame, among the benefactors of mankind. The physician who heals the diseafes, and alleviates the anguish of the body, certainly merits a more conipicuous and honourable place there; but the musician, who eminently fooths our forrow, and innocently diverts the mind from its cares during health, renders his memory dear to the grateful and refined part of mankind, in every civilized nation.

Bird, green, the philosopher's stone, at the time when its green colour appears.

Birds, Cyprian, avis Cypicum, or avisule Cypricus, is a denomination given to a kind of lustrous candle, made of the matter of troches, and burnt for the sake of their fumes, called also, from their figure, bunod, or fickis.

Bird of Hermes, avus, or avisule Hermmatica. Alchemists speak much of that which flies in the night without wings. Some will have the avesule Hermmatica to be an universal salt prepared from dew.—It also denotes red-lead.

Birds, decoy, are those which are trained up to call and allure others into the tower's nets, shores, line-twigs, or the like. See Vise.

Birds, Hunting. See Humming-bird.

Birds, in Domestic Economy, and in reference to their use as slaves. See Fowl.

Bird, in Falconry, denotes a hawk, or falcon. See Falcon.

Nest, birds, aves nidularia, denote those which are only arrived at strength sufficient to fly from branch to branch. Houlder bird, is that which has lived at liberty, and is thence more wild and untractable. Bird of the field, is that which has been reclaimed, returns to, and perches on the hand, without the help of a lure. Bird of lure, signifies that which comes to the lure, and by that means to the hand. Beldand bird, a hawk, for instance, bred of a hawk and a lanier; or a faker, bred of a faker and a lanier. Cockered birds, those which only pursue their game for their own belly, and which are not to be reduced to full sport; as ravens, kites, &c.

Bird, in Geography, the name of a small island in Dun-mann's bay, in the county of Cork, Ireland.—Also, another small island in Strangford lough, and county of Down.

—Also, one of the Bermudas islands.—Also, a small island in the gulf of St. Lawrence, 21 leagues W. of cape Anglesea, on the island of Newfoundland. N. lat. 49° 55', W. long. 66° 45'.—Also, an island in the southern Pacific Ocean, discovered by capt. Cook, in 1769, in his voyage from Cape Horn to Otaheite, covered with verdure, and inhabited.

S. lat. 17° 48'. E. long. 216° 24'.—Also, an island in the southern Pacific Ocean, near the north coast of the island of New Georgia, discovered by capt. Cook, in 1775.

S. lat. 51°, W. long. 38° 22'.—Also, an island of the same ocean, discovered in 1788, by the commander of the Prince of Wales, and so called from its being the resort of many birds. This solitary island, or rather fiingh rock, rising out of the immense ocean, was particularly examined by Vancouver, in 1794. Its greatest extent, in a direction S. 74° W. and N. 74° E. did not exceed one mile; and its northern, eastern, and western extremities, against which the sea broke with great violence, presented a very awful appearance, rising perpendicularly from the ocean in lofty rugged cliffs, inaccessible except to its winged inhabitants; on its southern side the ascent is not fo steep and abrupt; and near its western extremity is a small sandy beach, where in fine weather, and with a smooth sea, a landing might probably be effected. At this place was the appearance of a little verdure, though it was delitute of tree or shrub; every other part was apparently without soil, and confined only of the naked rock. The whole circumference does not exceed a league, and it is situated in N. lat. 25° 6'. E. long. 150° 8'. It lies from Onechow, one of the Sandwich islands, N. 51° W. at the distance of 39 leagues; it is recognized by the natives of those islands under the appellation of "Modoo Manno," that is, bird islands, and from its great distance from all other islands, and its proximity to their islands, it seems to claim some pretentions to be ranked in the group of the Sandwich islands; which see.—Also, a small island near the north-west coast of New Holland, lying low and almost covered with birds; 4 leagues N. W. from cape Grenville. For other islands under this denomination; see AVES.

Bird fort, an American fort on Monoughala river 40 miles south of Fort Pitt.

Bird-ky, or Round island, a small island, or rock, among the Virgin islands, in the West Indies; 2 leagues S. of St. John's island; and 3 N. E. from St. Croix, or Santa Cruz. N. lat. 17° 55'. W. long. 64° 36'.

Birds, Missings, aves intermissio, denote those that are employed to convey letters or other dispatches, either for the sake of expedition or safety. See Carrier-pigeon and ALEFO.

Bird, mocking, the turdus polyglottus; which see. See also Mock bird.

Bird-bolt, in Heraldry, is a small arrow with a blunt head, and often represented in armory, with two and sometimes three heads rounded, but in that case the number of heads must be noticed.

Bird-call, a small flick fletch at one end, in which is put a leaf of some plant, that serves to counterfeit the call of several birds, and to bring them to the net, snare, &c. by which they are taken. A laurel-leaf fitted on the bird-call counterfeits the voice of lapwings, a keek, that of the nightingale, &c. See Call, and Bird-catching.

Bird-Catching, in its most comprehensive sense, denotes the art of taking birds or wild-fowl, either for food, or for enjoying the pleasure of their song in cages, or for preventing the destruction which some species of them occasion to the husbandman. Some recurr to it as an amusing pastime, and others practice it as a profitable employment; and with a view to one or other of these objects, various modes of taking birds have been adopted, and the practice is in some places reduced to a kind of fyttem. One of these methods is denominated Bat-foiling, or, as some term it, Bat-folding. For this purpose, five or six perons commonly provide themselves with a large net, expanding, when open, to the extent of a man's arms, and about three yards high, and formed of meshes so small as not to allow the escape of the smallest bird. The extremities of the net are attached to two poles, held one in each hand of the person who has the management of it. With this, and a large lanthorn affixed to a pole, the party proceeds to corn-fields, out-houses, yew-hedges, thatched buildings, &c. The cords of the net being separated to their utmost extent, it is placed before any spot where birds are supposed to roost, and the light being held before the centre of the net, the affiants in this operation beat the hedges, ricks, caves, &c. with poles; and the birds, thus alarmed, fly towards the light, upon which the person who holds the net claps its poles together, and enclous the birds. From the latter circumstance, the net is called a clap-net. Sparrows, larks, thrushes, and the other small birds are thus caught in great numbers in dark nights. Another method of bat-folding, is performed by means of a long net drawn over the ground, followed by a person bearing a light; and this net, in its passage, enclous and confines any birds that happen to be under it. But one of the most ingenious and systematic methods of bird-catching, is practiced principally in the vicinity of London, by persons who find a ready market for birds used as food, or who deal in fong-birds, which, at certain feasons of the year, change their situation, and are hence denominated birds of flight, in the language of this art. The birds, usually taken on such occasions, are wood-tarks, titlarks, linets, abcura-vines, gold-inches, and green-inches. They are principally
BIR

pally taken during what is called their flight, or while they congregate for the purpose of propagating their species. The wild birds begin to fly in the month of October, and part of the preceding and following months; and the flight in March is much less considerable than that of Michaelmas. It is to be noted also, that the several species of birds of flight do not appear exactly at the same time, but follow one another in succession.

The pippet, which is a small species of lark, inferior in its song to other birds of that genus, begins his flight, every year, about Michaelmas; and then the wood-lark, linnet, goldfinch, chaffinch, greenfinch, and other birds of flight succeed; all of which are not easily to be caught, or in any number, at any other time, particularly the pippet and the wood-lark. These birds, during the Michaelmas and March flights, are chiefly on the wing from day-break to noon, though there is afterwards a small flight from two till night; but this is so inconsiderable, that the bird-catchers always take up their nets at noon.

Another circumstance worthy of notice is, that, during their flight, they always fly against the wind; hence the bird-catchers eagerly contend for that point; so that if it be witherly, the bird-catcher, who lays his nets most to the sail, is sure of the wild birds approaching. Provided that his nets are good: a gentle wind to the south-west generally produces the best sport. The nets used by the bird-catchers are about 12 yards long, and 2½ wide; which are known in most parts of England by the name of "day-nets," or "clap-nets," but the best are those that are used in the neighbourhood of London. These nets are spread upon the ground parallel to one another, and at such a distance, that when turned over, they shall coincide. The remaining apparatus consists of lines so fastened to the nets that the bird-catcher is able, by a sudden pull, to draw the net over the birds that may have alighted in the space between their parallel sides.

These birds are enticed to alight by others usually denominated "call-birds," of which there are generally five or six linnets, two goldfinches, two greenfinches, one woodlark, one red-poll, a yellow hammer, a titlark, and an aberdavine, and perhaps a bullfinch. These are placed at small distances from the nets in little cages. Besides these, the bird-catcher has others called "flur-birds," which are placed within the nets, raised upon the flur, and gently moved with the hand. This "flur" is a movable perch to which the bird is tied, and which the bird-catcher can raise or depress at pleasure, by means of a long string fastened to it. These flur-birds generally confine the linnet, the goldfinch, and the greenfinch, which are attached to the flur by what is called a "brace," which seizes the birds without injuring their plumage. This brace is a sort of bandage, formed of a slender flaxen string, that is fastened round the body of the bird, and under the wings in such a manner as to prevent the bird's being hurt, however it may flatter when it is raised. The call-birds are particularly trained for the service to which they are appropriated. Accordingly, the bird-catchers contrive to improve the song of these birds, by causing them to moult before the usual time. For this purpose, they put them, in June or July, into a close box, under two or three folds of blankets, and leave their dung in the cage to increase their heat; and in this state they continue, being, perhaps, examined once a week to have fresh water. The air of the cage is so putrid, that they want little or no food, as they eat feebly anything during the whole period of their confinement, which is about a month. The birds frequently die under this operation; and on this account the "flopped bird," as it is called, is the more valuable. When the bird has thus prematurely moulted, he is "in song," while the wild birds are "out of song," and his note is louder and more piercing than that of a wild one; and his plumeage is by this process equally improved. The black and yellow in the wings of the goldfinch, for example, becomes deeper and more vivid, and acquires a very beautiful gloss, which is not to be seen in the wild bird. The bill, which in the latter is likewise black at the end, becomes in the "flopped bird" white and more taper, as are also its legs; and, in short, there is as much difference between a wild and a flopped bird, as there is between a horse, which is kept in body coats, and one at grafts. When the bird-catcher hath laid his nets, he disposes of his "call-birds" at proper intervals; and Pennant observes, that a malicious joy appears in the face of the birds, to bring the wild ones into the same state of captivity: and this is also the case with regard to the decoy ducks. After they have seen or heard the approach of the wild birds, which they observe long before it is perceived by the bird-catchers, the intelligence is announced from cage to cage, with the utmost celerity and joy. The note, by which they invite them down, is not a continued song, like what the bird utters in a chamber; but "short jerks," as they are called by the bird-catchers, which are heard at a great distance. So powerful is the ascendancy of this call upon the wild birds, that the moment they hear it, they alight on a spot, without the least sound of the flur-birds, or any bird-catchers, which otherwise would never have attracted their notice. It also frequently happens, that, by pulling the string, half a fock only should be caught, the others who have escaped, will immediately return to the nets, and share the fate of their companions; and if only one bird should escape, that bird will still venture into the scene of danger, till it be caught; such is the fascinating power which the call-birds possess with regard to the others. A bird, acquainted with the nets, is by the bird-catchers termed a "sharper;" and this bird they endeavour to drive away, as they can have no sport, while it continues with them. These sportmen frequently lay considerable wagers, whose call-bird can "jerk" the longest, as this circumstance determines their superiority. With this view, they place them opposite to each other, near an inch of candle, and the bird that jerks the oftener, before the candle is burnt out, wins the wager. Some birds have given 170 jerks in a quarter of an hour, and a linnet has been known, in such a trial, to perform 570 jerks in its emulation, till it was vomited from the perch by this means, as Pliny (l. v. c. 29.) says of the nightingale, "victa morte fuit parte vitam, spiritu praeo debilitare quam cantu.

It is observable, that bird-catchers immediately kill the hens of every species of birds they take, as they are incapable of singing, and inferior in plumage. The pippets, likewise, are indifferently destroyed, as the cock does not ring well. The dead birds are commonly sold for threepence or fourpence a dozen. The flesh of these is regarded as a delicate acquisition at the tables of the luxurious; and yet the tafle for small birds is far from being so prevalent in England as it is in Italy, where they are eaten under the name of "becchaficos." However, the luxury of the modern Italians will appear to be parfimony, when compared with the extravagance of their predecessors the Romans. (See Chloris Etes.)

The highest price given for singing birds in London, Mr. Pennant informs us, is about five guineas; this sum having been paid for a chaffinch, that had a particular and unknown note, under which it was intended to train others, and five pounds ten shillings have been given for a call-bird linnet.

Mr. Pennant informs us, that when the titlarks are caught in the beginning of the season, it frequently happens, that 40 are taken without one female: the cage is the same with the wheatcar, and probably with respect to other birds: and this
this circumstance confirms the observation of Linnæus, that the male chaffinches fly by themselves, and the flight precedes the females; and the fact extends to other birds. Such birds as breed twice a year have generally in their first brood a majority of males, and in their second of females.

As the bullfinch, though it is not properly either a singing bird, or a bird of flight, its range being merely from hedge to hedge, fetches a good price on account of its learning to whistle tunes, and as it sometimes flies over the fields where the bird-catchers lay their nets, they have often a call-bird to ensnare it, though most of them are imitate the call with their mouths. It is a peculiarity with regard to this bird, that the females answers the purpose of a call-bird, as well as the male, which is not to be experienced in any other bird taken by the London bird-catcher. The nightingale, though in days fled as a singing-bird, moves only from hedge to hedge, and does not take the periodical flights of other birds in October and March; and therefore it is not clasped by the bird-catchers among the birds of flight. The persons who catch these birds, make use of small trap-nets, without call-birds, and are considered inferior in dignity to other bird-catchers, who will not rank with them. The arrival of the nightingale is expected by the trappers in the neighbour-hood of London, the first week in April; at first, none but cocks are taken, but in a few days the hens make their appearance, generally by themselves, though sometimes a few males come along with them. They are caught in a net-trap, the bottom of which is surrounded with an iron ring; and the net itself is somewhat larger than a cabbage-net. When the trappers hear or see them, they flew some fresh mould under the place, and bait the trap with a meal-worm from the baker's shop. In this way ten or twelve nightingales have been caught in a day. Pennant's Zool. vol. ii. Append.

Birds are caught in traps of various kinds; and frequently by nooses of hairs. In this way, great numbers of weathers are annually taken on the various downs of England. Small holes are dug by the sheep-dogs in the ground, in each of which is placed a noose. Whenever a cloud obscures the sun, these timid birds seek for shelter under a stone, or creep into any holes that present themselves; and they are thus ensnared by the nooses which fallain around their necks. Woodcocks and guises are taken likewise by nooses of horsehair placed along their paths, in marshes and moist grounds. Wild ducks in all their varieties are taken in vast numbers every winter on our coasts by means of decoys. (See Decoy.) Groats and partridges are taken by means of nets, either at night when reeling on the ground, by observing where they alight, and when fettle, drawing a net over that part of the field; or, in the day, a very steady dog is used to point at them. The attention of the birds being thus fixed, two persons, drawing the two extremities of a large net, pass it over them, and thus secure a whole pack of groats, or covey of partridges at once. Pheasants are sometimes taken by night, by holding flaming sulphur under the trees on which they are observed to perch, the suffocating effluvia of which make them fall senseless. Mons. Pratt informs us, that, during his travels in North America, he took great numbers of the pheasen-pigeon in a similar manner. For various methods of taking larks; see A. lauds. For the use of bird-lime among bird-catchers; see Bird-lime.

In various parts of the world, peculiar modes are adopted for ensnaring and taking birds, some of which, whilst they are hazardous to those who practise them, excite no considerable degree of furprise, and even of anxiety, in the spectators. Thus, in the Orkney islands, where the birds that inhabit the rocks, and the eggs which they deposit among the cliffs, supply the principal food of many among the poorer inhabitants, the intrepid and adventurous fowlers climb rocky precipices more than fifty fathoms above the sea, and pass from one ledge or kedge to another, whose breadth is barely sufficient for resting places to the birds, which deposit their eggs upon them. In this hazardous employment, the adventurers are commonly lowered from above by means of a rope, formed of brittle materials, and held by a single assistant. Fastened to this rope, the intrepid peasant descends, and searches all the cavities for eggs, springing from one projecting ledge to another, by the help of a pole, whilst the assistant, upon receiving the necessary signals, shifts the rope from one part of the rocky precipice to another. If the weight of the fowler and of his booty should, in these perilous circumstances, overpower his associate above, or the craggy rock cut the rope, inevitable destruction must await the adventurer; for he will either dash against the projecting rock, or be drowned in the subjacent sea. But the most singular species of bird-catching is in the holm of Nofs, which is a huge rock severed from the isle of Nofs by some unknown convulsion, and distant from it about 16 fathoms. The opposite cliffs are separated by the raging sea. There a rope is fastened on the top of it, and several flake in the hollow soil that is found on the surface of the rock; and similar flakes are also attached to the edge of the corresponding and opposite cliff. A rope is then fixed to the flakes on both sides, upon which a machine, called a cradle, is contrived to slide; and by the help of a small parallel cord fastened in like manner, the daring adventurer wafts himself over, and returns with his booty.

In the Ferenc islands the method of bird-catchings is more extraordinary and hazardous than any which has already been recited. The cliffs, to which the fowlers recur, are in many cases 200 fathoms high; and they are traversed both from above and below. In the first case, the fowlers provide themselves with a rope 80 or 100 fathoms long; and the adventurer fastens one end about his wait and between his legs, and having recommended himself to the protection of the Almighty, he is lowered down by fix associates, who place a piece of wood in the margin of the rock, that the rope may be preserved from being fallen and broken by its sharp edge. To his body he fastens a small line which serves for enabling him to give the necessary signals, when he wishes to be raised or lowered, or shifted from one place to another. In changing his situation, he is exposed to the hazard of injury from loosened and falling stones, which, falling on the head, must inevitably destroy him, if he were not in some degree protected by a strong thick cap. The fowlers, by their altonishing dexterity, contrive to place their feet against the front of the precipice, and to dart themselves some fathoms from it, for the purpose of surveying the roofing places of the birds, and projecting themselves into the deep recesses, where they lodge. There the fowler alights; and disengaging himself from the rope, which he fixes to a stone, collects the booty at his leisure, attaches it to his girdle, and when this is done, resumes his suspended pollute. He will also, when occasions require it, spring from the rock, and in this attitude, by means of a fowling net, fixed to the end of a fluff, catch the old birds which are flying to and from their retreats. When this hazardous operation is finished, he gives a signal to his companions above, who pull him up, and divide the booty. The feathers are preferred for exportation; the flesh is partly eaten fresh, and the greater
greater part is dried for winter's provision. In fowling from below, the party have recourse to a boat, and when they have arrived at the base of the precipice, one of the molt intrepid of them faldens a rope about his waist, and being furnished with a long pole, with an iron hook at one end, either elims, or is thrall up by his companions, who place a pole under him, to the next footing spot within his reach. The more of the rope he throws up, one of the boat's crew, and the roll are drawn up in the same manner, each of them being furnished with his rope and fowling fluff. They then pursue their journey upwards, till they arrive at the region of birds; and they wander about the clift in search of them. They next act in pairs; one falts himself to the end of his associate's rope, and, in places where birds have nestled beneath his footing, he fuffers himself to be lowered down, depending for safety on the strength of his companion, by whom he is again hauled up; but it sometimes happens, that the perch above is overpowered by the weight, and in this cafe, both inevitably perish. The fowl is flung into the boat, which attends their operations, for the purpofe of receiving the booty. The fowlers often pafs seven or eight days in this perilous occupation, and lodge in the crannies which they find in various parts of the precipice.

In fome remote parts of Roufla there is practioned a fingular invenfion for taking great quantities of gelmonettes or grous. They choose the molt open places in the birch woods; and there they plant long ftravfs in the earth oppofite the larger trees. On these ftravfs is laid a horizontal fluck, gallows-wife, to which are tied small bundles of ears of corn. At a small distance from this part of the conrav-ance, is a kind of large flannel or inverted cone, made with long birch twigs, thin and flexible, the lower extremities of which are fluck in the earth, very near to one another; but by spreading towards the top, forms there an opening of above a yard in diameter. In this opening is placed a wheel made of two circles that interfeft each other, and are surrounded with fraw and ears of corn. This wheel turns on an axis fainted to the fides of the funnel in fuch a manner, that there is room enough between the flocks of the cone, and the circles, to admit of the wheel's turning freely about. The birds firft perch upon the tran-verse fluck near the tree; and when they have a mind to fall upon the corn tied to the wheel, they must needeftry fland upon one of the projecting parts of the circles of which it is compofed. At that inflant the wheel turns, and the gelmonette falls head foremost, to the bottom of the trap, which is there fo contracted, that he cannot get out. They fometimes find the machine half full of gelmonettes.

The following method of netting or catching of wild pigeons is eagerly parulfed as a diversion in different parts of Italy, particularly by the inhabitants of Cava, in the Hither Principato, and is thus defcribed by Mr. Swinburne. The people "assemble in parties; and if any firanger chances to fray to their rendezvous, give him a molt cordial welcome. I am not in the leaft surprifed (fays Mr. Swinburne), at their passionate fondnefs for this fport, as I found it extremely bewitching, keeping the attention con-stantly alive, and the fprings of the mind pleafingly agitated by expectation; the fitations where the toils are fpread are incomparably beautiful, the air is pure and balflamic, and every thing around breathes health and fatisfaction. When the periodical flights of flock-doves return from the northern and weftern parts of Europe, to gain warmer regions for their winter abode, the fowler repairs to the mountains, and fpreads his nets across the intermediate hol- lows, the paffes through which the birds direct their course, to avoid unnecafary elevation in their flight. These nets are hung upon a row of large trees planted for the purpofe. The branches being very thick and close at top, and the bore lofty and bare, a great opening is left below for the toils, which reach to the ground; and, by means of pulleys, fall in a heap with the leaft effort. Sometimes they are ex- tended upon poles that exceed the height of the trees. At a small distance is a lofty circular turret, like a column with a little capital or cup, upon which a man is stationed to watch the approach of the game. As he commands a free view over all the country, and practice has made his flight as acute as that of the lynx, he defcrives the birds at a wonderful diftance. The doves advance with great velocity; but the alert watchman is prepared for them; and just as they approach his poft, hurls a stone above them with a fling; upon this the whole flock, whose fears have birds of prey for their great object, supposing the stone to be an enemy of that kind ready to pounce them, dart down like lightning to avoid the blow by paffing under the trees; but there they run into the jaws of death, by defifting against the net, which infantly drops, and so entangles them that not one of them can escape the active hands of the fowler. Thofe birds are fometimes taken by dozens at one fall, and are accounted fine eating. The dexterity with which the flingers manage their weapon is very remarkable; they throw the stone to a great height without any violent eftort, and even without whirling the fling round before they defcharge the pellet. In the Pyrenean mountains, where the fame diftention is followed, the watchmen affe a bow and arrow, trimmed with the feathers of a hawk."

The following fimple but ingenious method of catching aquatic birds is used in Mexico by the natives. The lakes of the Mexican vale, as well as others of the kingdom, are frequented by a prodigious multitude of ducks, geefe, and other water-birds. The Mexicans leave fome empty guardies to float upon the water, where thofe birds refort, that they may be accustomed to fee and approach them without fear. The bird-catcher goes into the water fo deep as to hide his body, and covers his head with a guard; the ducks come to peck at it; and then he pulls them by the fckt under water, and in this manner fcures as many as he pleafes.

Sir George Staunton, in his "Embafby to China," (vol. ii. p. 400.) informs us, that water-fowl are taken upon the Wei-Chung-hoo lake in that country by a fimilar device. Empty jars or guardies are fuftered to float about upon the water, that fuch objects may become familiar to the birds. The fhirman then wades into the lake with one of thofe empty veffels upon his head, and walks gently towards a bird; and lifting up his arm, draws it down below the sur- face of the water, without any difturbrance or giving alarm to the reft, feveral of which he treats in the fame manner, until he fills the bag which he had brought to hold his prey. This contrivance is not fo fingular as it is that the fame device should have occurred in the New Continent, as Ulleoa afferts, to the natives of Carthagena, upon the lake Cienega de Tefias.

Birds, fishing with, is a fingular mode of fishing practioned in fome of the lakes of China, and particularly defcribed in the account of the late embafby. Upon a lake near the imperial canal were obferved thousands of small boats and rafts, conftituted for this fingular kind of fishing. On eacn boat or raft were ten or twelve birds, which, at a fignal from the owner, plunged into the water; and it alto- nothing to obferve the enormous fize of the fish with which they returned, grafped within their bills. Thofe birds ap- peared to be fo well trained, that it did not require either ring or cord about their throats, to prevent their livallowing any
any portion of their prey, except what the marten was
pleased to return to them for encouragement and food. The
boat used by these fishermen is of a remarkable light make;
and is often carried to the lake, together with the fishing
birds, by the men who are there to support it.
The bird trained for this purpose is a species of pelican,
described by Dr. Shaw, from a specimen submitted to his
inspection, as "the brown pelicans or corvus, with white
throat, the body whitish beneath and spotted with brown.
the tail rounded, the sides blue, the bill yellow." Staun-

Bird-lime, a viscid substance, prepared various ways, and
from various materials, for the catching of birds, mice, and
other vermin.
The bird-lime ordinarily used among us, is made from
holly-bark, boiled ten or twelve hours. When the green
casso is separated from the other, it is covered up a fortnight
in a moist place, then pounded into a rough paste, so that
no flakes of the wood be left, and washed in a running stream
in till noes appear, put up to ferment four or five days,
flammed as often as any thing arises, and laid up for use.
To use it, a third part of nut oil, or any thin greece, is
incorporated with it over the fire.
The milletoe affords a juice, even superior to that of the
holly; and if a young shoot of the common elder be cut
through, a stringy juice will drin out in threads, and follow
the knife like bird-lime, or the juice of holly. It seems
in this tree to be lodged, not in the bark, but in certain
veins just within the circle of the wood. The roots of
all the hyacinths also afford a tough and stringy juice of the
same kind, and to do the artificial, the narcissus, and
the yellow bryony root, in a surprising quantity.
The bird-lime brought from Damocles is suppos'd to be
made of febbins, their kernels being frequently found in it:
but this does not endure either froth or wet. That brought
from Spain is of an ill smell: that of the Italians is made of
the berries of milletoe, heated, mixed with oil, as before;
to make it bear the water, they add turpentine. It is said,
the bark of our viburnum or wayfaring shrub makes bird-lime
as good as the bell.

Bird-lime is a subtile very apt to be congealed, and
rendered unserviceable by froth; to prevent which it is pro-
per, at the cold seasons, to incorporate some petroleum with
it, before it is used. The method of using it is to make it
hot, and dip the ends of a bundle of rods in it; then to
turn them about and play them together, till a sufficient
quantity is extended over them all. If strings or cords are
to be limed, they are to be dipped into the bird-lime, while
very hot. The cords may be put in cold, but the rods
should be warmed a little. Straws are to be limed while
the matter is very hot: a large bundle of them should be
put in at one time, and worked about in it, till they are well
beneathed. When thus prepared, they should be preserved
in a leather bag, till they are used. When the twigs or
cords are to be put in places subject to wet, the common
bird-lime is apt to have its force soon taken away: it is ne-
cessary, therefore, to have recourse to a particular fort,
which, from its property of bearing water unhurt, is called
water-bird-lime; and is prepared thus: Take a pound of
strong and good bird-lime, wash it thoroughly in spring-
water, till the hardnes is entirely removed; and then beat
it well, that the water may be separated from it; then dry
it well, and put it into an earthen pot; add to it as much
cow's greeze as will make it run. Then add two spoon-
fuls of strong vinegar, one spoonful of oil, and a small
quantity of Venice turpentine. Let the whole boil for some
minutes over a moderate fire, stirring it all the time. Then

...
BIR

The bill is broad, terminating in a sharp extremity, and incurved like an awl. Its width is increased by a naked piece of skin, resembling parchment, which, when the bill is shut, is folded together; but when open, is considerably extended, and enables the bird, while on wing, to catch with greater ease the insects that serve it for food. The eyes are black and large; the tongue is shaped like an arrow, and not forked; the ears are flat, round, naked spots, with small oblong openings, and are wholly concealed under the feathers of the head; the neck is very short, as well as the legs and bones of the wings; the thighs are wholly covered with feathers; and the very tender lower parts of the legs, and the feet, are covered with a skin like black parchment. Each foot has four toes; three before, and one turned backwards. The toes are separate to their roots; and the middle one, together with the claw, is as long as the lower part of the leg. Each toe is furnished with a thick, sharp, hooked claw, considerabily long, by which the bird can easily attach itself to crags of rocks.

The tail is as long as the body, together with the neck and head: when extended it has the form of a wedge, and consists of ten large feathers; the fourth of which on each side is long, and, when the tail is closed, extend almost an inch beyond the rump. The other feathers decrease towards the middle of the tail, and are equal to about the length of the body. The whole bird is very light and tender; ten of them together weighed little more than 2 ounces. The Javanese call it "lawit;" but those who live in the mountains, "Berengdah," or "waled" "voorong," in the Malay language, signifying in general a bird.

There are two places in particular, near Batavia, where these birds are found in great numbers. The first, Calappa Nongal, lies about 15 miles south of the city; and the other, Sampa, is somewhat more distant to the south-west: but both are in that range of high land extending towards the sea, and apparently different from the large ridge that extends over the whole island. Besides these, there are also other places in the same district, or at a greater distance from the coast, which either produce a few, or are carefully concealed by the Javanese, to whom they are known. The two bird mountains above-mentioned, called by the Javanese (gea) caverns, are inflated rocks, hollow within, and pierced with numerous openings of different sizes; but so small, that they seem to be peculiarly adapted to the security of these little animals. On the outside, these rocks are covered with various kinds of tall trees; and within, they consist of grey calcareous stone and white marble. To the sides of these caverns the birds affix their small nests in horizontal rows, and clofe to almost to adhere together. They are constructed at different heights, from 50 to 500 feet; and no cavity that is dry and clean is left unoccupied; but if the sides of the caverns be in the least wet or moist, the birds defert them. At daybreak these birds fly abroad from their holes, with a loud flapping noise; and in dry weather rise instantaneously to such a height in the atmosphere, for the purpose of seeking their food in distant parts, that they are soon out of sight. In the rainy season they never wander far from their holes, particularly in Java, where some rocks are situated near the shore. About 4 in the afternoon they return, and confine themselves to closely to their retired habitation, that none of them are seen to fly either out or in, except those that are hunting. They feed upon all sorts of insects that hover over the stagnant water; and these, by the easy extension of their bills, they readily catch. Their most destructive enemy is a kind of hawk, which feizes many of them as they fly from their holes, and which the people frighten away by shooting at them. Their nests are prepared, says this writer, from the strongest remains of the food which they use, and not of the feum of the sea, or of sea-plants, as some have asserted. On this subject, however, there have been different opinions. Kempfer says, that the substance with which they form their nests is the mollusca or sea- worm; according to Le Poivre, fish-spawn; according to Dalrymple, sea-weeds; and according to Linneus, the animal sublimate often found on the sea-beach, and called by fishermen bladders or jellys. In proof of his opinion, this author suggests, that it is known from experience, that these birds, which build their nests in the two rocks before-mentioned, have never been found on the sea-coast, and could not possibly fly thither and return again in so few hours, on account of the high intervening mountains, and the stormy winds that often prevail among them. The great difference in the colour and value of these nests proves, that their goodness depends merely on the superabundance and quality of the insects on which they feed, and perhaps on the greater or less solitude of the place where they seek nourishment. Those found in the territory of Calappa Nongal and Goa-gadia are exceedingly grey, and worth one third less than those produced in the territory of Sampa; and these latter are not to be compared with an excellent fort which is every year importuned from Teraner and Paffier, or which is to be found on the surrounding islands, particularly to the east of Borneo. These birds occupy two months in preparing their nests; they then lay their eggs (two in number), on which they sit for 15 or 16 days. As soon as the young are fledged, people begin to collect the nests, which is regularly done every four months; and this forms the harvest of those who are the proprietors of the rocks. The business of taking down the nests is performed by persons accustomed from their youth to climb these rocks. For this purpose they construct ladders of reeds and bamboo, by which they ascend to the holes; or, if the caverns are too deep, they employ ship-reps. When they have descended to the bottom of the caverns, they place bamboo with notches in them against the sides, if these be sufficient, in order to get up to the nests; but if they cannot thus reach them, they ascend the ladders, and pull down the nests with poles of bamboo made for that purpose. There are also certain holes to which people can ascend by means of steps made of bamboo; but these are very few. This employment is very dangerous: many lose their lives in pursuing it, and more particularly those who attempt to rob these caverns at improper seasons; for guarding against whose depredations, there are small watch-houses constructed in their vicinity. The mountaineers who engage in this occupation, never undertake their labour till they have slaughtered or sacrifice a buffalo; which custom is continually observed by the Javanese, at the commencement of any extraordinary enterprise. On such occasions they mutter over a few prayers, anoint themselves with aromatic oil, and fumigate the holes with odoriferous substances. At the chief of these caverns, in the island of Java, a particular protecting female deity is worshipped, under the name of "Raton Laut Ridul," or "Prince of the South Sea." She is provided with a small hut, and a covered sleeping place, together with various elegant articles of drefs, which no one but a princes must approach. On every Friday, when the nests are taken down, incense is continually burnt; and the body and clothes of every one who intends to ascend the rocks must be expiated to it. In order to have light in the caverns, they use torches made of the refulgent gum of a large tree called "carrat," and the inner bark of the arco tree.

The gathering of the nests continues no longer than a month, and may be repeated three times a year. Some say it may be done a fourth time; but the most experienced say, that
that a nest, as long as it remains entire, is continually enlarged or made thicker, until it is entirely deflected by the bird, when it has become dry or hairy in the inside. When the nests have been collected, they require only to be dried and cleansed, and then they are packed in baskets and sold to the Chinese. Their price varies, and depends on their whiteness and fineness. Some of them have a grey, and others a reddish appearance: those of the bird fort are exceedingly scarce. They are sold at the rate of from $80 to $1,400 per 125 pounds. This high price, and the inflammable nature of the Chinese, give rise to much dishonesty and cheating, especially as the Chinese make no scruple of bribing the watchmen with money, opium, and clothes; nor can any vigilance prevent this fraud. Calappa Nongal and Sampir formerly belonged to the Dutch East-India company; but, in 1778, the government resolved to sell them by auction to the highest bidder, and received for them almost 100,000 rix dollars. Besides these, there are several other places of a like kind, though less important, in the same range of mountains; and there are also two or three in the high land, in the interior parts of the country, and several small ones, which are carefully concealed.

Three considerable bird-mountains, Goa Daher, Gede, and Nangafiri, are situated in the government of Samaorang, in Java; and there are washed by the sea, which forms its way to deep into the latter that fish may be caught in it. In these places the nests are of an excellent quality; but the steepness of the rocks, and the violence of the surf, render it very dangerous to collect them; and, therefore, a suspended apparatus of bamboo is employed for this purpose. The quantity of these nests, collected annually in the island of Java, amounts to 2500 pounds in weight. There are also bird caverns in Bantam, and the island of Sumatra, in the Andaman and Nicobar islands, in the island of Bornéo, and also in Cochín-China. The young birds are eaten both by the Javanee and the Europeans in India; but it is difficult to procure them. They are considered as very heating; but the nests, on the other hand, when they have been boiled to a slimy kind of soup, exposed in the night-time to the dew, and mixed with sugar, are very cooling.

The Javanee, therefore, use them in violent fevers; and they are said to be prescribed with good success for fevers, throats and hoarseness. This latter use of them has probably been derived from the Chinese, who carry on a great trade by these nests, and eat many of them in the winter, because sore throats are then very common in the northern part of the kingdom, in consequence of the people accumulating themselves to fit very much over the fire. But the author of the paper, from which these particulars are extracted, was not able to discover this nourishing and strengthening quality that has been so much extolled, though he used a considerable number of these nests, prepared in various ways, in order to convince himself of the fact. He caused them to be examined by able chemists; but nothing more could be observed than that the solution preferred a weak gum, with a disagreeable taste, which perhaps might be of some use in die indispositions of the breast.

These nests are, therefore, a mere article of luxury to adorn the tables of the rich. The Chinese are remarkably fond of them. After being boiled and well cleansed, they put them, along with a fat capon or a duck, into an earthen pot closely covered, and suffer them to boil for 24 hours over a slow fire, which they call "timmer," and, on account of this addition, the whole dish acquires a more delicious taste. The trade in these nests has of late much increased. The high and advancing price of them in China makes Batavia the principal mart of this commodity, which is employed, since the company have surrendered it, very advantageous by the inhabitants, to lessen the prejudicial exportation of specie.

The species of swallow that forms these nests is not to be found in China. Linnaeus gives, as a distinguishing mark of the kirundo cufulent, that it has white spots only on the feathers of the tail. But the small birds in Java that construct the nests, have spots neither on the tail nor on any other place. The tail feathers are entirely of one colour, blackish grey above, and a little lighter below. Rumphius says of his capode marina, that the feathers of the tail were spotting, and that the breast also was speckled black and white. Valentine, in his description of the small swallow which constructs edible nests, mentions neither spots nor speckles; and only says, that the belly was stippled black and white. If these to be considered as essential differences, it will follow that there are two kinds of these swallow: one with a speckled breast, and white spots on the tail feathers; and the other, without spots or speckles. A third kind of these swallow would be those called "moose," or "boernigtam." These also prepare their nests of entable substances; but on account of the number of small feathers, and other impurities mixed with them, they are not fit to be used; and people, therefore, endeavour, as much as possible, to exterminate them, as they spoil the habitations of the better kinds. They are distinguished from the others merely by being larger, and having their legs down to the feet covered with small feathers.

**Birds, pictures of, prepared by means of their own feathers**

For this purpose, procure a thin board of deal or wainscot, well seasoned, that it may not warp. On this pale white paper, and let it dry; then get any bird which you would wish to represent, and draw its outline on the paper, in the defined attitude, and in its natural size, with the addition of any landscape or back-ground, &c. of which you may think best. This outline so drawn is afterwards to be filled up with the feathers from the bird, placing each feather in that part of the drawing corresponding to the part of the bird from which it was taken. To do this, cover the outline representation with several coats of brown gum-water, allowing it to dry between each coat, till it is of about the thickness of a Shilling. When the ground is thus prepared, take the feathers off from the bird, beginning at the tail and points of the wings, and work upwards towards the head. These feathers must be prepared by clipping off all the downy part; and the large feathers must have the infides of their shafts pared off, so that they may lie flat. In laying them on, hold them by a pair of small pliers, and, moistening the gummed ground with water, place each feather in its natural and proper situation. Keep each feather down, by placing upon it a small leaden weight, till you have another ready to be laid on. Care must be taken not to let the gum pass through the feathers, so as to slimen them or to adhere to the bottom of the weight, and thus pull off or disorder the position of the feathers. When all the feathers are put on, cut a piece of round paper, and colour it to resemble the eye of the bird, and then lick it in its proper place; but the bell substitutitions for this purpose are small eyes made of glass. The bill, legs, and feet, must be drawn and coloured from nature. When it is finished and adjusted to your mind, lay a sheet of paper upon it, and upon that a heavy weight to press it down; and after it has remained in that position till it is quite dry, it may be preferred in a glass-frame.

**Birds, preference of**

Many methods have been used by methodists for preserving dead birds from corruption, in their natural form and colour. Some have taken off the skin, with all the feathers upon it, from the body and thighs, leaving the tail, legs and wings, with the whole neck and the bill, and filled it with some soft stuff, such as hay, wool,
wool, or flax. Mr. Kuckahn (ubi infra), and Dr. Lett-

tom (Naturalist's Companion, p. 12, &c.), who approve of this method as one of the most compleat and least trouble-
some, direct, that after opening the bird by a longitudinal incision from the breast to the vent, separating the fleshy parts from the bones, and removing the trachea, eyes, brain, and tongue, the cavities and the nucleus of the brain and head, sprinkled with the powders (as below); the eyes to be in-
furred, for which purpose wax may be used, or glaas-eyes of any size or colour may be cheaply procured; and the head to be filled with cotton or tow. When this is done, a wire should be made to pass down the throat, through one of the nostrils, and fixed into the breast-bone. Bones should also be introduced through the feet up the legs and thighs, and infurled in the same fashion; and then the body should be filled with cotton to its natural size, and the skin sewed over it. The attitude should also be regarded; for, in whatever position the subject is placed to dry, the same position will be afterwards retained. The powder which he recommends is composed of ¼ lb. of corrosive sublimate, ⅓ lb. of prepared or burnt saltpetre, ¼ lb. of burnt alum, ⅓ lb. of flowers of sulphur, 2 lb. of camphor or musk, 1 lb. of black pepper, and 1 lb. of tobacco ground coarse. The whole should be mixed together, and kept in a glaas vessel stopped close.

This method is particularly described by Mr. Kuckahn, Phil. Trans. vol. lx. p. 314, &c. When the above-men-
tioned proces is finished in the manner which he has mi-
nutely detailed, he advises to bake the birds intended for preservation in an oven of a due degree of heat; and he ob-
erves, that baking is not only useful in such preparations, but will also be of very great service to old ones, as it de-
structor the eggs of infects. An it should be, he says, a conlant practice once in two or three years to bake them ever again, and to fresh wash the cabs with a liquid made by diffusing one pound of camphor in half a gallon of spirit of turpentine.

Others have put them into vellts full of spirit of wine, or strong brandy; against which it has been objectted that spirituous liquors change the colours of the feathers; but M. Reaumur concludes from many experiments, that this objeetion is groundless; and he has given several minute directions for preparing and conveying them in this way. Others again, ephically in countries where spices are cheap, have embalmed dead bird. Reaumur observes, that pow-
dered alum or lime will serve the same purpose. Another method which has been sometimes practised, is that of dry-
ing birds for preservation in a heated oven. It is of impor-
tance, however, that dried birds should be secured in boxes or barrels sufficiently closed, that infects may not flow in during the voyage or journey; and all the empty spaces left in the barrel should be filled up with hemp, flax, cotton; &c. The fame ingenious naturalist informs us, that quadrupeds, fishes, reptiles, and insects, may be preserved in the same manner with birds. For Reaumur's dieretions to this purpose, see Phil. Tran. Abru. vol. xi. page 891, &c.

Mr. Chaptal recommends the following method of pre-
paring all kinds of animals for cabinets, as exceedingly simple, and so certain in its effect that he never found it to fail in a single instance. The matter contained in the bowels of the animal must be evacuated, either by gradually prufing the body towards the rectum, or by injecting some liquid which may remove every thing that flows in its way. Af-
ther this operation, the end of the rectum should be tied with a thread, and ether should be injected with a proper instru-
ment into the body, through the month or bill; and when the bowels have been filled with it, the animal is to be hung 

up by the head. One of the eyes must then be scooped out, and the brain extracted; after which the head is also filled with ether, which must be prevented from escaping by plugging up the eye hole. On the second or third day the injection of ether is to be repeated; and this proces is to be continued till the animal is completely dried. While-
gradually drying, care must be taken to give the body its proper position; and as soon as it is completely dedica-
ted, it may be put up without further care or any other preparation. Ether is preferable to spirits of wine, be-
cause, by its evaporation, it carries with it not only its own aqueous particles, but these also which it absorbs from the body. Besides, this method neither destroys the form of the animal, nor tarnifhes the splendour of the feathers or hair, and is very cheap; one ounce of ether being in general suficient for a small bird. The proces of drying, says Mr. Chaptal, might perhaps be a little shortened by the ap-
lication of artificial heat. The theory of this proces, as this ingenious chemist thinks, is, that the ether, while it evaporates, volatilizes the moisture in the animal body, and by these means effects a gradual delification, and thus re-
moves the only caufe of corruption.

The method of preferring birds in Giuiana, described by Bancroft (p. 184.), is as follows: The birds intended for pre-
ervation, and for being conveyed to the cabinets of Europe, are deposited in a proper vellt, and covered with high wines, or the first running of the distillation of rum. In this spirit they remain for 24 or 48 hours, or longer, according to its size, till it has penetrated every part of their bodies. When this is done, the birds are taken out, and the feathers, which are not at all changed by this im-
mersion, are placed smooth and regular. They are then put 

into a machine, made for the purpose; and the head, feet, 

wings, tail, &c. are placed exactly agreeable to life. In this position they are put into an oven, very moderately heated, where they are slowly dried; and they will ever after retain their natural position, without danger of putrefaction.

Birds, singling, are the nightiglale, blackbird, flaring, 

trufh, limet, fark, throfely, canary bird, bullfinch, gold-

finch, &c. See Song of birds.

BIRIDAM, in Ancient Geography, a town of India, on this side the Ganges, which, according to Ptolemy, was the capital of a people called Porrari.

BIREMIS, from bis, double, and ramis, ear, in Anti-

quity, a vellt with one or more rows of oars, ranged, as some think, in two flages over each other; or a vellt hav-
ing two ranks or rows of oars placed over, and afide of each other. But the particular fabric of these vellts seems far from being a fettled point among the learned. The Roman biremis is the fame with what the Greeks call diptera, and fands contradiltingufied from triremis, quadriremis, &c.

BIRINGOCIO, or Biringucci, Vannuccio, in 

Biography, a mathematician of Sienna, was defended of a noble family, and flourished about the 16th century. After having been employed by the dukes of Parma and Ferrara, he entered into the service of the Venetians. He is famed to have been the first Italian author who wrote on the art of faling and casting metals; particularly for the purpose of making cannon. His work, entitled, "Pistoechius, &c.," was printed at Venice in 1552, 410; at Bologna, in 1675, 8vo; and at the same place in 1555, 1558, and 1559, 410. A Latin translation of it appeared at Paris in 1572, 410; and at Cologne, 1658, 410. A French translation, by Jacob Vin-
cent, was published at Paris in 1555, and 1559, 410; and at Rouen in 1627. As a metallurgie writer, who detailed his own observations and experiments, and gave a clear and con-
ected account of the chief processes in metallurgy, Biringoc-
io is highly commended by professor Beckman. Gen. Biog.
BIRKAN, in Geography, a town of Arabia, 24 miles south of Saada.

BIRKENFELD, a town of Germany, in the circle of the Upper Rhine, and county of Spontheim, the seat of a barony, including 32 villages and two iron foundries. It was taken by the French in 1704; and in their new arrangement, it is the principal place of a district of the same name, in the department of Sarre. The town contains 1661, and the canton 5892 persons. This district comprises 58 communes, and its whole territorial extent includes 1675 kilometres. It is situated 30 miles E.N.E. of Trierce, and 30 N.N.W. of Deux Ponts.

BIRKENHEAD, or Birkenhede, Sir John, in Geography, a poetical writer of some celebrity, was mainly devoted to his native county, the Cheshire. He was born near Chester, in 1615. In 1632 he was entered as a fervitor in Oriel college, Oxford, and afterwards became amanuensis to Archbishop Laud, who recommended him in 1650 to be chosen probationer-fellow of All-Souls’ College. When Oxford became the head-quarters of King Charles I. in the time of the civil war, Birkenhead was selected as a proper person to write a kind of journal in support of the royal cause; which office he discharged to the satisfaction of his employers, and with reputation and advantage to himself. The king appointed him reader in moral philosophy; and this post, more honourable than heretofore, he retained till the year 1648, when he was expelled by the parliament visitors. From hence he removed to London, where he wrote several poetical pieces, chiefly of a satirical kind, levelled against the republicans in power; and, on account of his steady attachment to the royal cause, he was called the “loyal poet,” and suffered several imprisonments. Upon the restoration of Charles II. he was rewarded for his loyalty. In 1661, he was created doctor of the civil law, by the University of Oxford; and about the same time, was returned to parliament for the borough of Wilton. He was knighted in 1662, and succeeded Sir Richard Fanshaw as master of requests. The favours which he received from the court exposed him to many severe attacks from those who opposed it; but he was excommunicated by the learned persons of his time, and elected a fellow of the Royal Society; and his memory has been transmitted with honour to posterity by Dryden, Langbaine, and Wm. Stanly, now retaining the approbation of Anthony Wood. He died in Welwm. in 1679. Biog. Brit.

BIRKESTORFF, in Geography, a town of Germany, in the circle of Westphalia and duchy of Jutland, one mile north of Dueren.

BIRKET EL HADJIS, or Lole of Pilgrims, a lake of Egypt, communicating with the Nile, and situate 10 miles E.N.E. of Cairo, near which the companies which form the caravan to Mecca assemble.

BIRKET EL KERUN, or Caroun, a lake of Egypt, 30 miles long and 6 broad in the middle, but of an irregular form, and narrowing towards each end; 40 miles S.W. of Cairo. See Mec. N. W.

BIRKHEHER, Beulah Raker, in Ornithology, the name of the garrulous roller, coracias garrulus in Frisch. Av.

BIRKIN, in Geography, a river of England, which runs into the Bollin, one mile south of Altriniteh in the county of Cheshire.

BIRKKOZOWKA, a town of Poland, in the palatinate of Kiv, 40 miles S.E. of Biallisskiew.

BIRLAB, a town of Egypt, in the route from Catich to Al Arish, 17 miles E.N.E. of Caticch, and at a small distance east of the lake of Shenak Bardoi, or king Baldwin’s lake.

BIRLAT, a town of European Turkey, seated on a river of the same name, in the province of Moldavia, 60 miles N.W. of Galate, and 116 S.W. of Bender.—Allo, a river which runs into the Siret at Dubravizna, in Moldavia.

BIRMAN, or Burman Empire, comprises the kingdoms of Ava and Pegu, and derives its name from the Burmans, or Burmahs, who have been long known as a warlike nation, in the country formerly called “India beyond the Ganges;” its capital being Ava or Aungwa. The boundaries of this empire are not easily ascertained. Burman, considered as distinct from Pegu, and sometimes erroneously denominated Ava from its capital, borders on Pegu to the north, and occupies both banks of the river Ava, as far as the frontiers of China. On the north-west is Meckley, and on the West Aracan and Rofhan. On the east it has the kingdom or country of Upper Siam, which begins at a small distance eastward from the city of Ava; a ridge of mountains separating it from Burmah and Pegu. But the king of Burmah is now said to poffess not only the country of Meckley, in addition to those of Pegu and Burmah, but also the whole tract which lies on the north of it, between China, Thibet, and Afam. According to colonel Symes, to whom we are much indebted for our knowledge of the Birman empire, it appears to include the space between the 9th and 26th degrees of north latitude, and between the 92d and 107th degrees of east longitude, about 1050 geographical miles in length, and 600 in breadth. Such are the ascertained limits from the Birman accounts; but it is probable that their dominions stretch farther to the north. The breadth, however, often varies, and is in many places very inconsiderable, on what is called the eastern peninsula. To the north this empire is separated by mountains from Afam, and further to the east it borders on Thibet and China. On the west it is divided from the British dominions in Bengal by a range of mountains, and the little river Naaf; and the limit is continued by the sea. But the southern and eastern boundaries are somewhat obscure. If it be extended to the ninth degree of latitude, it must include a considerable portion of the Malay peninsula, or the province of Tenaffereem, and city of Mergui, formerly regarded as part of Siam; and if, on the east, it be extended to the 107th degree of longitude, it might be said to comprehend almost the whole of the country called India beyond the Ganges, as far as the mouths of the Japartee river in Cambod. But it does not appear that Siam is regarded as a portion of the Birman empire, and even in this case it would only extend to 103 degrees. In this state of uncertainty, however, we must satisfy ourselves with observing, that this empire constitutes the fifth grand native power in India, since Hindustan and Persia have been divided, and may probably extend its authority over Laos and Cambodia, while it remains separated by deferts and ranges of lofty mountains from the united kingdoms of Cochinchina and Tonquin.

Of the ancient states of the countries which now constitute this empire, our knowledge is very imperfect. (See Chonnesus.) With regard to their modern history, Col. Symes observes, that we are indebted for our first information principally to the Portuguese, who made themselves masters of Malacca early in the 16th century. Accordingly the Portuguese historians inform us, that in the middle of this century four powerful states divided among them the regions that lie between the south-east coast of British India, Yunan in China, and the eastern sea; and that their territories, besides some intervening lands belonging to petty independent princes, extended from Caffay and Afam on the N.W. as far to the S.E. as the island of Junkfalon. These
nations were known to Europeans by the names of Arakan, Ava, Pegu, and Siam; which see respectively. The empire of Ava, as it was called, is situated eastward of Arakan, and separated from it by a ridge of lofty mountains. (See Arakan.) On the N.W. it is divided from the kingdom of Caffay by the river Keen-duce; on the north it is bounded by mountains, and petty independent principalities, that lie continuous to Ava; on the north and west it touches on China and North Siam; and on the south its limits have been so variable, that it is not easy to define them. The city of Prome, or Pei, seems to be the original and natural boundary of the Birman empire, though by conquest it has been extended much farther to the south. Pegu is the country southward of Ava, which occupies the sea-coast as far as Martaban. (See Pegu.) The kingdom of Siam extended to the south as far as Junkeylon, call to Cambogia and Laos, and north to Ozemee, probably the Chianne of Louhere, and Yunnan in China. (See Siam.) These boundaries, however, may be considered more as the claim than the actual possession of each state; whilst alternate victory and defeat have occasionally extended and contracted their dominions. From the Portuguese we learn, that the Birman, though formerly subject to the king of Pegu, became afterwards masters of Ava, and caused a revolution in Pegu about the middle of the 16th century; extending their kingdom from Maravi, probably Mergui, near Tenasserim, to the province of Yunnan in China, about 800 miles from north to south, and 250 from east to west. The influence of the Portuguese, which was for some time very considerable in the Birman and Pegu countries, was supplanted by the Dutch; and it appears that, in the beginning of the 17th century, both the English and Dutch had obtained settlements in various parts of the Birman dominions, which were founded by the misconduct of the latter, to the East India company, of all nations were banished from Ava. The English, however, several years after this expulsion, were reintegrated in their factories at Siam and Ava, where they traded more as private merchants than on the part of the India company, in whose service they were not regularly enrolled. The supremacy of the Birman over the Peguers continued till about the year 1740, when, the latter, inhabiting the provinces of Dalla, Martaban, Tongo, and Prome, revolted, and a civil war ensued. In 1744, the British factory at Siam was destroyed by the contending parties. At length the Peguers, by the assistance of some Europeans, who traded to their ports, gained several victories over the Birman, particularly in the years 1750 and 1751; and in 1752 the capital of Ava was invaded, and the Birman, after a short siege, compelled to surrender at discretion. The last of a long line of Birman kings was taken prisoner; but two of his sons were fortunate enough to make their escape to the Siamefe, where they were kindly received, and allured of security and succour. Upon this conquest the principal inhabitants of the country about Ava acknowledged themselves vassals to the victorious king of Pegu, and accepted the prescribed oath. After some time, Alompra, a Birman of low extraction, who had been continued by the conqueror in the possession of a small village called Monchaboo, determined to emancipate himself from the yoke of oppression. Accordingly, having assembled 100 followers, whom he had raised and engaged he could rely, he attacked a band of 50 Pegu soldiers, who had been stationed in Monchaboo, and put every one of them to the sword; and after several previous encounters with the Pegu force dispatched against him, he gained possession of Ava in 1753. The contest was obstinate and bloody; but Alompra, pursuing his conquests, founded the town of Rangoon, or Dlangoon, signifying "victory achieved;" and soon after chastised the people of Caffay, who had revolted from the Birman authority. In 1756 he blockaded the town of Syriam, which yielded to his arms; and having deprived the capital of any foreign aid by water, he advanced against the city of Pegu, invested it in January 1757, and in about three months took possession of it. He then proceeded to subdue the countries to the east of the city, as far as the Three Pagodas, which were the ancient boundary between Pegu and Siam. Tavoy, which was once an independent principality, and recognized as such by the English in 1753, has been since added to the Birman possessions in this quarter. Alompra, triumphing in his successes, determined to chastise the Siamefe, who had afforded an asylum to his rebellious subjects; and for this purpose he ordered a fleet to fail to Mergui, a sea-port belonging to the Siamefe, which soon surrendered; and the capture of Mergui was followed by the conquest of Tenasserim. The next object of Alompra was the reduction of the capital of Siam; but whilst he was prosecuting the siege, he was seized with a disorder which proved fatal, and saved the Siamefe from destruction. Alompra, apprised of his approaching end, gave orders for a retreat; when he had arrived within two days' march of Martaban, on the 15th of May 1760, he expired, very much to the regret and sorrow of his subjects, who regarded him as their deliverer, and as a wise, powerful, and victorious sovereign. By the prudence of his counsels he secured what his valour had acquired; he was not more eager for conquest than attentive to the improvement of his territories, and the prosperity of his people; he inflicted a severe edict against gambling, and prohibited the use of spirituous liquors throughout his dominions; he reformed the courts of justice; he abridged the power of magistrates and forbade them to decide at their private houses on criminal causes, or on property where the amount exceeded a specified sum; he established a form of justice, that every decree was registered. His reign was short but vigorous; and if his life had been prolonged, it is probable that his country would at this day have been farther advanced in national refinement and the liberal arts. He did not live to complete his 50th year; his person, strong and well proportioned, exceeded the middle size; and though his features were coarse, his complexion dark, and his countenance saturnine, there was a dignity in his deportment that became his high station. Alompra, the founder of the Birman empire, was succeeded by his son Namdogee Praw, who, after suppressing several insurrections, died in 1764, and left an infant son, Momien; whose uncle Shemban, second son of Alompra, aspired to the regency, and afterwards the diadem. Shemban, having usurped the royal power, diverted the national attention from his conduct, by declaring war against Siam; and two armies entered the country from the north and south, which, being united, defeated the Siamefe about seven or eight days' journey from their capital. The consequence of this defeat was the immediate involution of Siam by the Birman; and after a siege of two months, the capitulation of the city. The king having withdrawn during the progress of the siege, a Siamefe governor was appointed, who took an oath of allegiance to the Birman monarchy, and engaged to pay an annual tribute. The Chinefe, having planned the subjugation of the Birman empire, and concerted measures for adding the dominion of Tenasserim and the fertile plains of Ava to their empire, advanced in the beginning of the year 1767, from the western frontiers of Yunnan, with an army of 50,000 men, to accomplish their object; but they were met by the Birman, and after a conflict which lasted three days, totally routed with very dreadful carnage. The lives of the captives were spared for the benefit of the country; various employments were affigned them; and they were encouraged to marry Birman wives, and to consider themselves
selves as natives of the country. The Siamee, however, though vanquished, remained unsubdued; and the inherent enmity that subsists between these two nations will probably prevent either servitude or alliance on the part of the one to the other, unless they are broken by such repeated defeats as must nearly amount to extermination. As soon as it was known that the Birmans had withdrawn into their own territories, a Siamee prince assumed the monarchy, and in 1771 defeated the Birmans. The king, who had pillorized and abandoned his throne and people, was consigned, in part, to have perished in the woods, probably by the hands of the usurper. Shem- buan, the Birman sovereign, who had rebuilt ancient Ava, the metropolis of the empire, which had fallen to ruin during the late commotions, pursued his favourite scheme of extending his conquests towards the west, and having advanced within two days' march of Cofpore, the capital of Cashar, forced the raja of the province to submit to his power, by the most unequivocal proofs of valour, according to the custom of the country. Shem-buan died at Ava in 1776, and was succeeded by his son Chenguza, whose tyrannical conduct occasioned a conspiracy, at the head of which was Shem-buan Minderagee Praw, the younger brother of the deceased Shem-buan, and the present monarch. Chenguza was slain in 1781, and fell unlamented, as he had lived despised. Among other acts of savage cruelty, with which he is charged, one is his conduct towards his second wife, the daughter of one of the Attawoons, or privy-councillors, of his court, a young woman endowed with virtue, beauty, and various accomplishments. Under the impulse of sudden rage, he accused her of infidelity, and without allowing time for cool judgment, pronounced sentence of immediate death. Accordingly the trembling and innocent victim was dragged from the palace, and included in a sack of scarlet cloth, richly ornamented with patterns, was carried to the bank of the river provided with two earthen jars, the whole was sunk in the deepest part of the river Javawaddy. Her afflicted father, overwhelmed with anguish and deprived of all his offices, retired in despair to the city of Chenguza; and waited the opportunity that soon after occurred, of being avenged. When Chenguza was forcing his way towards the royal palace, the Attawoon snatched a fabric from an attendant officer, and at one stroke cut him through the bowels, and laid him breathless at his feet; nor did any person offer to prevent or avenge the cruel tyrant's death. Shem-buan Minderagee with the consent of government from Ava, and founded a new city called Ummerapora; which fee. The Birman conquests having already been extended as far as Mergui to the south, and several of the northern provinces which formerly belonged to Siam, having been reduced to subjection and tribute, Shem-buan Minderagee, observing the sipinners of the rajah of Arracan, and the unwilling disposition of his subjects, and allured by the fertility of its soil, and its latitude for commerce, determined to invade the country, and to annex it as an appendage to the Birman crown. Accordingly, in 1773, this conquest was effected. (See ARRACAN.) The Birman arms were next directed towards Siam. Although the Birman monarch, mortified by the disappointment of his views, resolved as speedily as possible to repair the disgrace; and for this purpose he marched in the spring of 1785, from his capital, the head of 30,000 men, with a train of 20 field-pieces, which army was supported by a fleet of 16 ships, that blocked up the harbour of Junkefyon. The sovereign, tongue in his expectations, had scarcely entered the Siamee territories, before he was opposed by the king of Siam, and, after a furious engagement, completely routed. In the commencement of the ensuing year, the Siamee invaded the viceregality of Martaban, which comprehends within its jurisdiction Tavoy, Mergui, and all the Birman possessions towards the south; but having had unsuccessful siege to Tavoy, they were obliged to retreat and abandon the enterprise. In 1793 overtures for peace were made on the part of the Siamee; and they were followed by a negotiation, which speedily terminated in the ratification of a treaty highly favourable to the Birman interest. By this compact, the Siamee ceded to the Birman the western maritime towns as far as Mergui; thus yielding to them entire possession of the coast of Tenasserem, and the two important ports of Mergui and Tavoy; which were acquisitions of great moment, conferred either in a political or commercial light. From this statement it appears that the Birman empire can scarcely be computed to extend beyond the 102d degree of longitude, and that only in the part to the north of Siam. The Birmans are indubitably pre-eminent among the nations which inhabit the vast peninsula that separates the gulf of Bengal from the Chineese sea; they possess a territory equal in extent to the German empire; and they are blended with a barbarous climate, and a soil capable of producing almost every article of luxury, convenience, and commerce, which the call can supply. After their treaty with the Siamee, they enjoyed the pleasing prospect of a long exemption from the miseries of war; but their pride and resentment embroiled them in fresh troubles before they had time to profit by the advantages of peace, and threatened to excite against them a foe more formidable than the Chineese, Arracaners, Peguers, Siamee, and Caffayers. The Birman monarch, conceiving that the piratical banditti who infest the Broken islands, and commit various depredations to the injury of trade, were protected by the British flag, and that they fought refuge in the British districts, ordered a body of 30,000 men to enter the territories of the company, in order to seize the delinquents fugitives, and he stationed an army of 20,000 men at Arracan for the purpose of supporting this detachment. As the Birmans had made no previous application for redress in a pacific way, a strong detachment was formed at the presidency, and entrusted to the conduct of major-general Erkline, for refitting this aggression. On the approach of the British general, the Birman chief proposed terms of accommodation, stipulating for the surrender of the fugitives as the basis of the agreement. The general declined all treaty whilst the Birmans continued on English ground; but after a representation of the case made in person by the Birman chief, he gave hopes, that if the Birmans peaceably retired, the governor-general would institute a regular inquiry into the grievance which was the subject of complaint. The Birman chief, professing his reliance on the declaration of general Erkline, agreed to withdraw his troops, and conducted his retreat in the most orderly manner. The matter was afterwards investigated, and the guilt of the delinquents being satisfactorily proved, they were delivered over to their own laws, by whose sentence two out of the three that had been accused underwent capital punishment. The amicable termination of this difference afforded favourable opportunity for acquiring a more accurate knowledge than had hitherto been obtained, of a people, whose situation, extent of territory,
tory, and commercial connections with British India, rendered a liberal intercourse with them highly desirable. The trade between Caleutta, Madras, and Rangoon, the principal Birman port, had of late years been rapidly increased, so as to become an object of national importance; more particularly on account of the teak timber, the produce of Ava and Pegu, whence Caleutta and Madras draw all their supplies of wood for ship building and for various other purposes. A commerce in one article is essential, and on a general scale is extensive as to require an annual return of Indian commodities to the amount of 200,000l., was an object well worth cultivating. With this view Sir John Shore (now Lord Teignmouth) thought proper, in 1795, to send a formal deputation to the Birman court. The particulars of this embassy are described by Col. Symes, with whom the conduct of it was entrusted. "The Birmans," says this writer "under their present monarch, are certainly rising fast in the scale of oriental nations; and it is to be hoped, that a long respite from foreign wars will give them leisure to improve their natural advantages. Knowledge increases with commerce; and as they are not shackled by any prejudices of caste, restricted to hereditary occupations, or forbidden from participating with strangers in every local bond, their advancement will, in all probability, be rapid. At present, so far from being in a state of intellectual darkness, although they have not explored the depths of science, nor reached to excellence in the finer arts, they yet have an undeniable claim to the highest rank in the scale of civilized and well informed people. Their laws are wise, and pregnant with sound morality; their police is better regulated than in most European countries; their natural disposition is friendly and hospitable to strangers; and their manners rather expressive of manly candour, than courteous dissimulation: the gradations of rank, and the respect due to station, are maintained with a serenity which never relaxes. A knowledge of letters is so widely diffused that there are no mechanics, few of the pauperists, or even the common watermen (usually the most illiterate class), who cannot read and write in the vulgar tongue. Few, however, are versed in the more erudite volumes of science, which, containing many Shonifer terms, and often written in the Pali text, are (like the Hindoo Shollers) above the comprehension of the multitude; but the feudal system, which cherishes ignorance, and renders man the property of man, still operates as a check to civilization and improvement. This is a bar which gradually weakens, as their acquaintance with the customs and manners of other nations extends; and unless the rage of civil discord be again excited, or some foreign power impose an alien yoke, the Birmans bid fair to be a prosperous, wealthy, and enlightened people."

The present capital of the Birman empire is Ummernapoora, and one of its chief ports is Rangoon; which see respectively. Its other principal towns will occur in the course of this work. See Aracan, Ava, Chalaging, Mughan, Meighi, Mongabbo, Minnpooora, Pagan, Pegu, Perfam, Prome, Syriam, Tenallenem, Tavoy, &c. The chief rivers of this country are Irrawaddy, or the river of Ava (see Ava), whose numerous mouths and streams very amply provide the means of inland navigation, Keerdung, Maygung, Pityang, and Thalum. Its lakes are numerous; among which one of the principal is Toumasanz. The highest range of mountains is probably that which lies on the frontier of Tibet. The other ranges pass north and south, except a small range running east and west, which supplies the sources of the river of Pegu; but their names are not known, except that of Anoupee, between Ava and Arracan. The forests are large and numerous: and supply almost every description of timber that is known in Hindostan; and about four days' journey to the north of the capital firs grow in abundance; but the principal tree of these forests is the teak, which flourishes in many parts of the empire, to the north as well as to the south of the capital. The forests, as well as the mountains, of the interior, and, in general, of the whole northern frontier, remain unexplored; and the tigers that infest them, prevent their being particularly examined.

The present sovereign of the Birman empire assumes the title of "Boa," or emperor; and though the form of government be despotic, yet he is accustomed to consult a council of ancient nobles. There is no country of the east in which the royal establishment is arranged with more minute attention than in the Birman court; it is splendid without being wasteful, and numerous without confusion. The queen and princes have the title of "Praw," which is both a sovereign and a fœcundatorial appellation; and is frequently used by an inferior when addressing his superior. In the application of this term, it has been suggested, that there is an obvious analogy between the Birmans and the ancient Egyptians. "Pira," it is said, was the proper name under which the Egyptians first adored the sun; before it received the allegorical appellation of Osiris, and they conferred this title upon their kings and upon their priests. It has been further conjectured, that the title of "Pharaoh," given to successive kings of Egypt, is a corruption of the word "Pira," or "Praw," in its original sense signifying the sun, and applied to the sovereign and priests, as the representatives of the god of the earth that splendid hierarchy. However this be, "Praw" is a princely title in the Birman empire. The elder son of the king is denominated "Engy Teckien," or "Engy Praw," or prince royal; and the crown descends to the male heirs in a direct line, the son takes precedence of his uncles. Next in rank to the princes of the blood royal are the "Woongees," i.e. bearers of the great burthen, who are the chief ministers of state. Their established number is four, and they constitute the great council of the nation. They sit in the "Lotoon," or imperial hall of consultation, every day, except the Birman fabbath; they issue mandates to the "Maywoones," or viceroys of the different provinces; they control every department of the state, and govern the empire in subordination to the king, whose will is absolute, and whose power is undefined. With these are associated, for the purposes of deliberation, and of the execution of public business, four other officers, called "Wooodocks," whose authority is very inferior and limited. The views and wishes of the Woongees are frequently counteracted by the interference of the four "Attawoons," or ministers of the interior, who are selected by the king to be his privy-counselors, from an opinion of their talents and integrity, and who have access to him at all times, which is a privilege which even the principal Woongee does not enjoy. There are several other subordinate officers, by whom the affairs of government, in its various departments, are transacted. There are also Woons of the queen's household, and of that of the prince royal; and each of the junior princes has a distinct establishment. The Birman government has no hereditary dignities or employments; for on the demise of the pofficier, all honours and offices revert to the crown. The order of nobility has different degrees, distinguished by the number of sringhs, or small chains, that compose the "thole," or chain, which is the badge of the order. No subject is ever honoured with a higher degree than 12; and the king alone wears 24. Rank among the Birmans is indicated by every article of use and ornament; the shape of the beetle-box, which is carried by an attendant after a person of distinction wherever he goes, his ear-rings, cap of ceremony, horze-furniture, and even the metal of which his fit-
tong-pot and drinking cup are made, specify and distinguish the several gradations of society; and a person who assumes the insignia of a degree, which is not his legitimate right, is subject to certain penalties. The court dresses of the Burman nobility consists of a long robe, of flowered satin or velvet, reaching to the ankles, with an open collar and loose sleeves; over this hangs from the shoulders a scarf, or flowing mantle; and on the head is worn a high cap of velvet, either plain, or of silk embroidered with flowers of gold, according to the rank of the wearer. Ear-rings are also a part of most dresses; persons of condition use tubes of gold about three inches long, and of the thickness of a large quill, expanding at the end like the mouth of a speaking-trumpet; others wear a heavy nail of gold beaten into a plate, and rolled up, which forms a large orifice in the lobe of the ear, and by its weight drags it down to the extent sometimes of two inches. The rank of the females is also distinguished by their dress. The hair, which is tied in a bunch at the top of the head, and bound round with a fillet, has its peculiar and discriminating embroidery and ornaments. Over a short skirt, which reaches to the pit of the stomach, and is drawn tight by strings, so as to support the breasts, is a loose jacket with clove sleeves; and round the waist is rolled a long piece of silk or cloth, reaching to the feet, and sometimes trailing to the ground. When women of condition go abroad, they put on a silk fall, resembling a long shawl, which encloses their bosoms, and is thrown over the shoulders, gracefully flowing on each side. Women in full dresses, flatter the palms of their hands and their nails a of red colour, for which they use a vegetable juice, and drew on their bosoms powder of sandal wood, or of a bark called funneka, with which some rub their faces. Both men and women fringe the edges of their eyelids, and their teeth with black. Men of rank wear, in common dresses, a tight coat with long sleeves, made of muslin or of very fine linen, which is manufactured in the country; also a silk wrapper that encircles the waist; but the working classes are naked to the middle, except that in the cold season they use a mantle or veil of European broad cloth, which is highly prized.

With regard to religion, the Burmans are Hindoos, not as votaries of Brahma, but sectaries of Boudh; which see. The latter contend with the former for the honour of antiquity, and are undoubtedly far more numerous. The Cinglee in Ceylon are Boudhists of the purer class; and the Burmans acknowledge that they originally received their religion from that island, which they call "Zhou." It was brought, say the Rhaaans, first from Zhou to Arracan about 660 years ago, and thence was introduced into Ava, and probably into China; for the Burmans confidently assert, that the Chinefe are Boudhists. However this be, it is allowed, that the boons of China, like the Rhaaans of Ava, wear yellow as the facerdotal colour, and that in many of their customs and ceremonies we may trace a very striking similarity. Whatever may be the antiquity of the worship of Boudh, the wide extent of its reception is unquestionable. The Burmans believe in the metempsychosis, and that, after having undergone a certain number of transmigrations, their souls will at last be received into their paradise on the mountain of Meru, which is the celestial north pole of the Hindoos, round which they place the garden of Indra, and which they describe as the rest of delights. The Burmans regard mercy as the chief attribute of the deity; and they worship God by extending mercy to all his creatures. Of the religious buildings appropriate to the Burman worship, the temple of Shoebdisong, or Dagaung, near Rangoon, that of Shoemadou to Pegu, and that of Syriam, are the most considerable. (See Rangoon, Pegu, and Syriam.) Their priests are denominated Rhaaans; and they have numerous kionus or convents which differ in their structure from common houses, and much resemble the architecture of the Chinefe. They are made entirely of wood; the roof is composed of different slages, supported by strong pillars; the inside comprehends one large hall; the whole house is open at the sides; some of them are curiously carved with various symbolic representations of the divinity. They have no apartments for the private recreation of the Rhaaans; publicity being the prevailing system of the conduct of the Burmaus, who admit of no secrets either in church or state. The convents in the neighbourhood of Rangoon are very numerous; and hence it appears that the number of Rhaaans, and of Phonghiss, priests of an inferior order, vulgarly called Tallowpins, must be very considerable, amounting to 1500. Like the Carmelites, they go barefooted, and have their heads shaved, on which they never wear any covering. The only colour of the garments worn by the priesthood is yellow; the greatest part of their bodies is covered with a long bote cloke, that is wrapped round them; they profess celibacy, and abstinence from every sensual gratification. The preferred punishment for a Rhaan detected in an act of incontinence, is expulsion and public disgrace. The delinquent is seated on an ass, and his face is daubed with black paint intermixed with spots of white; and he is thus led through the streets, with a drum beating before him, and afterwards turned out of the city. But such instances of degradation rarely occur. The junctures are exceedingly tender about licentiousness, whether by day or night; nor can any go abroad without permission from the prior of the convent. The Rhaaans never perform any of the common functions of life, which would tend to divert them from the abstract contemplation of the divine essence. They perambulate the town at the dawn of the morn in order to collect supplies for the day; and these usually consist of boiled rice mixed with oil, dried and pickled fish, sweetmeats, fruit, &c. In their walks they never raise their eyes from the ground, nor do they ever stop to soliciot donations, and seldom even look at their benefactors, who are more desirous to bellow than they are to receive. The Rhaaans eat only once a day, at the hour of noon; and their superfluous provisions they distribute among the indigent strangers, or the poor scholars, who daily attend them to be instructed in letters, and taught their religious and moral duties. The Rhaaans are never known to take any public and active part in politics or in war; and as the Burmans and Peguers profess the same religion, the conquerors, whoever they were, equally respected the ministers of their faith. The head of the Rhaaans at Rangoon, or the "Seredaw," lives in a handsome monastery about half a mile from the town; and values himself very much on the facerdotal titles, conferred on him by the present and late king, and which he ostentatiously displays engraven on iron plates. There were formerly numeri of such prielees, who, like the Rhaaans, wore yellow garments, cut off their hair, and devoted themselves to charity and religion; but these societies have been long since abolished, as being injurious to the population of the state.

The laws of the Burmans are inseparable from their religion; and, like the latter, of Hindoo extraction. They profess that they have derived them from Menu, the grandson of Brahah, the first of created kings, who received the sacred principles on which they are founded by divine revelation, and who promulgated the code. Numerous commentaries on Menu were composed by the Munis, or old philosophers, whose treatises constitute the "Dherma Sastra," or body of law. The code of Gentoo laws, translated by Mr. Hallid, is said to be a compilation from the different commentaries on Menu. These laws, as well as the religion of the Burmans, found their way into the Ava country from Arracan, and
and came originally from Ceylon about 600 years ago. The Birman system of jurisprudence is replete with sound morality; and is distinguished above any other Hindoo commentary for perspicuity and good fences. It provides specifically for almost every kind of crime that can be committed, and adds an ample chapter of precedents and decisions to guide the inexperienced in cases of doubt and difficulty. The trial by ordeal, however, is disgraceful to this code; but it prevails in all countries where the Hindoo religion is professed, and is as ancient as their records. An instance of the excrecism of this mode of trial is mentioned by Col. Symes. Two women having litigated a small property in a court of justice; and the judges finding it difficult to decide the question of right, it was agreed to refer the matter to the office of an ordeal. The parties, attended by the officers of the court, the Rlahans, and a multitude of people, repaired to a tank, or pond. After certain prayers and ceremonial of a purifying nature, the two litigants entered the pond and waded in it, till the water reached as high as their breasts; they were accompanied by two or three men, one of whom placed them clothe to each other, and put a board on their heads, which he pressed down till they were both immerged at the same instant. After continuing out of sight for about one minute and a half, one of them, being nearly suffocated, raised her head, whilst the other continued to fit upon her hands at the bottom, but was immediately lifted up by the man; after which an officer of the court pronounced judgment in her favour, and of the equity of the decision none of the by-eslayers seemed to entertain the smallest doubt. This practice, however, and that of imprecaion, are now losing ground, and have of late years been discomfited by the judicial courts both of India and Ava. Laws dictated by religion are in general confectionally administered. The criminal jurisprudence of the Birmans is licent in particular cases, but rigorous in others. Whoever is found guilty of an undue assumption of power, or of any crime that indicates a treasonable intent, is punished by the severest tortures. The first comminution of theft does not incur the penalty of death, unless the amount stolen be above 800 kian, or tuckal, i.e. about 100 l., or attended with circumstances of outrages, such as murder or mutilation. In the former case, the culprit has a round mark impressed on each cheek by gunpowder and puncturation, and on his breast the word thief, with the article fen; for the second offence he is deprived of an arm; but the third inevitably produces capital punishment. Decapitation is the mode by which criminals suffer, and in the performance of it the Birman executioners are exceedingly skilful. The official hall of justice, where the members of provincial governments, and all municipal officers, are accustomed to assemble for the transaction of public business, in various parts of the Birman empire, is denominated Rhoom. Every man of high rank in the empire is a magistrate, and has a place of this description and name contiguous to his dwelling; but it is always on the outside of the inclosure of his court-yard, and not surrounded by any fence or railing, in order to manifest publicity, and shew that it is the seat of majesty and justice, to which all mankind may have free access.

The population of the Birman dominions is not easily ascertained with accuracy; but Col. Symes was informed, by a peron on whose testimony he could rely, that the number of cities, towns, and villages in the empire amounts to 8000, without including the recent addition of Arracan. Supposing, therefore, each town, on an average, to contain 300 houses, and each house 6 persons, the result will give a population of 14,400,000. Few of the inhabitants, he says, live in solitary habitations, but mostly form themselves into small societies; so that their dwellings thus collected compose their Rous, or villages; and, therefore, he concludes that if their number, including Arracan, be reckoned at 17 millions, it will not exceed the truth.

With regard to the military and naval force of the Birmans, we may observe, that though every man in the kingdom is liable to military service, and war is deemed the holiest and most honourable occupation, the regular military establishment is very inconsiderable. When an army is to be raised, a mandate issues from the golden palace to all vicereys of provinces, and miages of districts, requiring a certain number of men at an appointed day; and the levy is proportioned to the population of the province or district, estimated by the number of its registered houses. Every two, three, or four houses are required to furnish one recruit, or to pay 300 tuckal, or about 40 l. or 45 l., in money. This recruit is supplied by government with arms and ammunition, but has no pay. The families of these conscripts are retained in the district which they inhabit, as hostages for the good conduct of the foildier; and in case of desertion, or treachery, his wife, children, or parents are dragged forth to execution; nay, cowardice subjects the family of the delinquent to capital punishment. The infantry and cavalry complete the regular guards of the king; the former are armed with matchets and sabres, and the latter with a spear about seven or eight feet long, which they manage on horseback with great dexterity. The royal magazines are said to contain 20,000 firelocks, which are of a very indifferent kind. The most respectable part of the Birman military force is their establishment of war-boats. The king can command, at a very short notice, 500 of these vessels, which are formed out of the solid trunk of the teak tree, excavated partly by fire, and partly by cutting; the largest of them are from 80 to 100 feet long, and 8 feet broad, and they carry from 50 to 60 rowers. The prow is solid, and has a flat surface, on which is mounted a piece of ordnance. Each rower is provided with a sword and a lance; and, besides the boatmen, there are usually 30 soldiers, who are armed with muskets. The attack of these gun-boats is very impetuous; and those who conduct them advance to action with a war-song, by which they regulate the strokes of their oars; and as they change one another, and daunt their adversaries; and when they grapple, the action becomes very feverer, as these people possess singular courage, strength, and activity. As the vessels lie low in the water, their principal danger is that of being run down by a larger boat striking on their broadside. The largest of these war-boats, which are managed with surprising dexterity, both in advancing and retreating, as well as in the time of action, do not draw more than three feet of water. The proper weapons of the country are the spear, the javelin which is thrown from the hand, the crofs-bow, and the fabre; the latter of which is used by the Birmans, not only as an implement of war, but for various purposes of manual labour.

The revenue of the Birman empire arises from one-fourth of all produce, and of all foreign goods imported into the country. However, as grants to princes of the blood, great officers of state, and provincial governors, are made in provinces, cities, villages, and farms, the rent of which they collect for their own benefit, and money is seldom disbursed from the royal coffer, the Birman sovereign polishes immense treasures.

The climate of every part of the Birman empire appears to be distinguished by its salubrity; and the natives are healthy and vigorous. In this respect they posses a decided preeminence over the enervated natives of the East; nor are the inhabitants of any country capable of greater bodily exertion.
tions than the Birman. The seasons are regular, and the extremes of heat and cold are seldom experienced; at leaf, the duration of that intense heat, which immediately precedes the commencement of the rainy season, is so short, that the inconvenience of it is very little felt. The forests, however, of the later woody and uncultivated parts of India, are extremely picturesque; and an inhabitant of the campaign country considers a journey thither as inevitable deflection. The wood-cutters, who are a particular class of men, born and bred in the hills, are said to be unhealthy, and seldom attain longevity.

The soil of the southern provinces of the Birman empire is remarkably fertile, and produces as luxuriant crops of rice as are to be found in the finest parts of Bengal. Towards the north the face of the country is irregular and mountainous; but the plains and valleys, particularly near the river, are exceedingly fruitful; they yield good wheat and the various kinds of small grain which grow in Hindostan, together with most of the eulogous legumes and vegetables of India. Sugar-canes, tobacco of a superior quality, indigo, cotton, and the different tropical fruits, in perfection, are all indigenous products of this country. Besides the teak-tree, which grows in many parts of the Birman empire, as well to the north of Ummerapoora, as in the southern country, there is almost everywhere a description of timber that is known in India.

The kingdom of Ava abounds in minerals; six days journey from Bhamo, which is a province near the frontiers of China, there are mines of gold and silver, called "Badoom"; there are also mines of gold, silver, rubies, and sapphires, at present open on a mountain near the Keenduam, called "Woobooloatoon"; but the most valuable, and those which produce the finest jewels, are in the vicinity of the capital, nearly opposite to Keoum-mouen. Precious stones are found in several other parts of the empire. The inferior minerals, such as contain iron, tin, lead, antimony, arsenic, sulphur, &c. occur in great abundance; amber, of a confluence unusually pure and pellucid, is dug up in large quantities near the river; gold likewise is discovered in the sandy beds of deltas which defend from the mountains. Between the Keenduam and the Irrawaddy, to the northward, there is a small river called "Shoe Lien Koup," or the stream of golden sand. Although the Ava empire produces no diamonds and emeralds, it affords amethysts, garnets, very beautiful ehrystals, jasper, jade, and marble: the quartz beds, which lie on a few miles from Ummerapoora; and it is equal in quality to the finest marble of Italy, and admits of a polish that renders it almost transparent. The fale of marble is prohibited; but great quantities are consumed in the manufacture of the images of Gaudama, which are fabricated in the city and diöstit of Chragan; however, the exportation of these marbei diversities out of the kingdom is strictly forbidden.

The commerce of the Birman empire is very considerable. An extensive trade is carried on between the capital and Yunn in China. The principal article of export from Ava is cotton, of which, it is said, there are two kinds, one of a brown colour, of which nankeens are made, the other white, like the cotton of India. This commodity is transported up the Irrawaddy in large boats as far as Bhamo, where it is bartered at the common "jees," or mart, with Chinefe merchants, and conveyed by the latter, partly by land, and partly by water, into the Chinefe dominion. Amber, ivory, precious stones, beetle nut, and the edible nuts brought from the cahram are the main, are also articles of commerce: in return, for which the Birmans procure raw and wrought filks, velvets, gold leaf, preserves, paper, and some utensils of hardware. The commerce between the capital and the southern parts of the empire is facilitated by the noble river that waters the country. Several thousand boats are annually employed in transporting rice from the lower provinces to Ummerapoora and the northern districts. Salt, and grapes, a kind of fish-flauce used with rice, are also articles of international commerce. Articles of foreign importation are mostly conveyed up the Irrawaddy; and some few are introduced by way of Arracan. See Arracan. Among the articles of foreign trade, which have found their way into the Birman country, nothing is held in higher estimation than the European glafs-ware imported into Rangoon from the British settlements in India. The Birmans are so sensible of the advantages of commerce, and so desirous of improving it, and of thus increasing population, which they consider as much more essential to the strength of a state than the extent of its territory, that they have of late years tolerated all sects, Pagans and Jews, Mussulmans and Christians, the disciples of Confucius, and the worshippers of fire, and invited strangers of every nation to resort to their ports; and being themselves free from those prejudices of caste, which shackles their Indian neighbours, they have permitted foreigners to intermarry and fettle among them. The children of strangers, whatever be the sect to which they belong, born of a Birman woman, equally become subjects of the state, and are entitled to the same protection and privileges, as if they had sprung from a line of Birman ancestry. To British India commercial intercourse with that part of the Birman empire called Pegu is of great importance. This interest involves three distinct objects; that of securing from this quarter regular supplies of timber for ship-building; that of introducing into the country as many of our manufactures as its consumption may require, and of endeavouring to export a part in the south-west dominions of China, by means of the great river Ava; and that of guarding with vigilance against every incroachment or advance, which may be made by foreign nations to divert the trade into other channels, and to obtain a permanent settlement in a country so contiguous to the capital of our possessions. The teak timber for the construction of our ships in that part of the world is an article peculiarly interesting in a political and commercial point of view. Some of the finest merchant ships at Calcutta have been lately built of this timber. Madras is also supplied from Rangoon with timber for all the common purposes of domestic use; and even Bombay, although the coast of Bombay is its principal shorehouse, finds it worth while annually to import a large quantity of planks from Pegu. It is also of importance, not only to promote the exportation of timber from the maritime towns of Pegu, but to discourage the building of ships in the Rangoon river, in which the Birmans are making rapid progress. National security and commercial advantage demand peculiar attention to both these circumstances. The imports into Rangoon from the British settlements, in the year 1822, amounted, it is said, to more than 12,000 rupees, or about 35,000l. and these consisted chiefly of coarse piece goods, giffs, hody-ware, and broad cloth; and the returns were made almost wholly in timber. The maritime parts of this great empire are commodious for shipping, and better situated for Indian commerce than those of any other power. Great Britain possesses the western side of the bay of Bengal; the government of Ava, the eastern. From the mouth of the Ganges to Cape Comorin, the whole range of our continental territory, there is not a single harbour capable of affording shelter to a vessel of 500 tons burthen; but Ava comprehends, within her extent of coast, three excellent ports; Negrais, the most feverous harbour in the bay; Rangoon, and Mergui, each of which is equally convenient and easy access to the sea; they are, moreover, on the direct line of communication between the interior of the empire and the British settlements on the west coast of India. As Bengal is surrounded by the empire of Ava, and is separated from it by the river Ganges, from which the latter receives its waters, it is a natural consequence that the commerce of the latter is more flourishing than that of the former state.
much more accessible than the river of Bengal, which is the only port in our possession within the bay. The entrance into this is an intricate and dangerous channel; but from the harbour of Negrish a ship launches at once into the open bay, and may work to the southward without any impediment besides that which is occasioned by the monsoon. The Birman empire possesses such a variety of advantages resulting from situation, extent, produce, and climate, that it may be reckoned, among eastern nations, second in importance to China alone; whilst, from its contiguity to British India, it is to us of much greater consequence. To preserve a good correspondence and a good understanding with the court of Ava is therefore essential to our prosperity. It is our interest to maintain the independence of the Birmans, and to guard it from foreign encroachment; and then the Birman government will be united to ours in bonds of reciprocal amity and confidence. The result of the embassy of Col. Symes, sent by our governor-general of India to the kingdom of Ava in 1795, has been the establishment of this kind of amity and friendship. To the memorial presented on this occasion, the Birman monarch replied: "I, the king immortal, whose philanthropy is universal, whose anxiety for the benefit and welfare of all mankind never ceases, directly that all merchant ships of the English nation, who refer to Birman ports, shall pay customs, charges, warehouse hire, searchers, &c. agreeably to former established usage. English merchants are to be permitted to go to whatever part of the Birman dominions they think proper, either to buy or to sell, and they are on no account to be stopped, molested, or oppressed; and they shall have liberty to go to whatsoever part of the Birman dominions they choose, for the purpose of buying, selling, or bartering, &c." by themselves or their agents; and it is further commanded, that they shall be at liberty to fix a resident at Rangoon, &c. and that English ships driven into Birman ports by frets of weather shall be supplied with all necessaries, &c. at the current rates of the country; and that the enemies of England, European as well as Indian, shall not be allowed to purchase warlike weapons, lead, and powder, which restriction is extended to all nations."

The manufactures of the Birmans consist of cotton and silk, fustic and gunpowder, various kinds of pottery, and marble statues; they also excel in gilding, to which purpose the greatest part of their gold is applied, and several other ornamental manufactures. Their edifices and barges are constructed with singular oriental taste and elegance; the most remarkable edifice is the Shomadou at Pegu. Their temples and churches, which are numerous, exhibit a very rich and fantastic kind of architecture; and their grand hall of audience, or Lotoo, at Unmara-poorah, is as splendid an edifice as can be well executed in wood. Many of their houses are very simple in their structure, and are erected in a day, or even in a few hours. The requisite materials are bamboos, grafts for thatching, and the ground rattan. The whole edifice is constructed without a single nail; a row of strong bamboos, from eight to ten feet high, are fixed firm in the ground, which form the outline, and are the supports of the building; smaller bamboos are then tied horizontally, by strips of the ground rattan, to these upright poles; the walls, composed of bamboo mats, are fastened to the sides, with similar ligatures; bamboo rafters are quickly raised, and a roof formed, over which thatch is spread in regular layers, and bound to the wood by filaments of rattan; a floor of bamboo is next laid in the infide, elevated two or three feet above the ground; this grating is supported on bamboo, and covered with mats and carpets. A house of this kind, simple and expeditious in its structure,
has frequently been altered by arbitrary authority. The manner in which the Birmann month is subdivided is peculiar to their nation. Instead of reckoning the days progressively from the commencement to the close of the month, they advance no farther than the full moon, from which they recede by retrograde enumeration until the month is finished. The Birmann month is divided into 4 weeks of 7 days each. The 8th day of the increasing moon, the 15th or full moon, the 8th of the decreasing moon, and the last day of the full moon, are religiously observed by the Birmans as sacred festivals. On these hebdomadal holidays no public business is transacted in the Rhoon; mercantile dealings are suspended; handicraft is forbidden; and theörishly pious take no indulgence between the rising and the setting of the sun. The Birmans 7a is said to commence in our year 655, and it is that which is used by the philologists at Siam; and from them, as a more polished nation, it has passed to the Birmans.

The Birmans are very fond of poetry and music; the former they call yeodoo; when recited by a scholar, it flows soft and measured to the ear, sometimes in successive, and often in alternate stanzas. They have epic as well as religious poems of high celebrity, and they are fond of writing in heroic numbers the exploits of their kings and generals.

Music is a science which is held in considerable estimation throughout the Birman empire; and the royal library of Ummerapoora is said to contain many valuable treatises on the art. Some of the professional musicians display considerable skill and execution, and the lute-airs are playing even to an ear unaccustomed to such melody. The principal instruments are a foun, or harp, made of light wood, hollowed and varnished, resembling a corno with a deck; at the extremity a piece of hard wood is neatly falcated, which tapers to the end, and rises in a kind of curve over the body of the harp; from this curve, the frrings, usually made of wire, are extended to a bridge on the belly of the instrument; it has two foulding holes, one on each side of the bridge. The fize of the firmly varies from two to five feet in length. The turk resembles our violin; it has only three strings, and is played on with a bow. It is said to have been the original instrument of the country. The pullaway is a common lute-guilet. The kyyzou is a collection of cymbals, suspended in a bamboo frame. The pandols, or guitar, is a curious instrument, of the form of a crocodile in miniature; the body is hollow, with curving holes on the back; three strings of wire extend from the shoulder to the tail, and are supported on bridges at each extremity; the strings are tuned by means of pegs in the tail, to which they are fastened; it is played on by the finger, and is generally used to accompany the voice. The boundaw is a collection of drums, of oblong form and different size, which are suspended perpendicularly in a wooden frame by leather thongs. The whole machine is about five feet in diameter, and four feet high. The performer stands in the centre, and beats on the drums with a small stick. This instrument is always introduced in a full band, and much used in processions. The heem is the pipe of Pan, formed of several reeds neatly joined and founded by a common mouth-piece, and producing, when finely played on, a very pleasing sound. The Birmans are fond of singing and dancing; and the three last days of the solar year are commonly devoted to mirth and festivity.

At Pago they have a theatre, which is an open court, splendidly illuminated by lamps and torches, and in which dramatic performances are exhibited. Indeed, at all festivals they have dramatic entertainments, consisting of music, dancing, and action, with a dialogue in recitative. The subject is generally taken from the legends of their heroes, especially of Rama. The best actors are said to be natives of Siam; and in one of these we are told that the dialogue was spirited without cant, and the action animated without being extravagant; the drolls of the principal performers were also flowy and becoming. By way of interlude between the acts, a clownish bufoon entertained the audience with a recital of different pallsages, and by grimace and frequent alterations of tone and countenance, extorted loud peals of laughter from the spectators. The Birmans delight in mimicry, and are very expert in the practice, polishing uncommon verisimilitude of countenance. By pantomimic looks and gestures, they exhibit a masterly display of the passions, making sudden transitions from pain to pleasure, from joy to despair, from rage to mildness, from laughter to tears, and of varying the expression of terror and of idolatry, with surprising effect. Upon the last day of the Birmann year, the 17th of April, there is a kind of sport that is universally practised throughout the Birman dominions, to wash away the impurities of the past year, and to commence the new year free from stain. Women on this day are accustomed to throw water on every man they meet, which the men have the privilege of returning. This pastime is conducted with great decorum; and a woman who declines taking a part in it, is considered as avowing her pregnancy, and paves without molestation. At the close of the month, or during the whole seventh month, called Sadeen-guit, there are illuminations; every house has erected by it a kind of mast, from which are fupended one or more lamps. In the royal palace, a pyramid of lamps, at least 150 feet high, is supported by a bamboo scaffold. At this time the nobles from all parts of the empire resort to court to pay their homage to the king. During the principal days and nights of these festivals, there is almost a constant succession of wrestling, dancing, music, processions, fire-works, and theatrical entertainments.

The Birmann alphabet consists of 33 characters, having as many different sounds, exclusive of various marks and contractions, that supply the place of long and short vowels, diphthongs, &c., like the other alphabets of the Hindoo class. It has no representation of the voice corresponding with our short a; this is nevertheless to be pronounced after every simple sound or consonant not supplied with another vowel, unless it be forbidden by a mark of elision placed over the letter, or excluded by the junction of two or more consonants. The Birmans write from left to right; and though they have no distinguishing interval between their words, they mark the pause of a sentence and the full stops. Their letters are dillict, and their MSS. are in general very beautiful. It has been the opinion of some of the most enlightened writers on the languages of the east, that the "Pahl," or sacred language of the priests of Boodh, is nearly allied to the Shanfirit of the Brarnins. The character common use throughout Ava and Pago is a round Nagari, derived from the squire Pahl, or religious text; it is formed of circles and segments of circles, variously dif-posed and combined, whilst the Pahl, which is solely applied to purposes of religion, is a square letter, chiefly confining of right angles. Their common books, like those of the Hindoos in the southern parts of India, are composed of the palm leaf, on which the letters are engraved with a fly-leaf. In their more ancient books, the Birmans write on sheets of ivory, or on very fine white palm leaf. The ivory is flained black, and the margins are ornamented with gilding, while the characters are enamelled or gilded. On the palmleaves the characters are in general of black enamel; and the ends of the leaves, and the margins, are painted
BIR

printed with flowers in various bright colours. A hole through both ends of each leaf, serves to connect the whole into a volume, by means of two fittings, which also pass through the two wooden boards that serve for binding. In the finer binding of books of this kind, the boards are lacquered, the edges of the leaves cut smooth, and the title written on the upper board; the two ends are by a knot or jewel secured at a little distance from the boards, so as to prevent the book from falling to pieces, but sufficiently distant to admit of the upper leaves being turned back, while the lower ones are read. The more elegant books are in general wrapped up in silk cloth, and bound round by a garter, on which the Birmanes have the art to weave the title of the book. In every Kionnn, or monastry, there is a library or repository of books, usually kept in lacquered chests. In the royal library the number of these chests was not less than 100. The books were regularly clasped, and the contents of each chest were written in gold letters on the lid. Some of these books exhibited very beautiful writing on thin leaves of ivory, the margins of which were ornamented with flowers of gold, neatly executed. The library contained books upon various subjects; more on divinity than any other; but history, music, medicine, painting, and romance, had their separate treatises. Col. Syme thinks it not improbable, from the chests which he inspected, that his Birman majesty may possess a more numerous library than any potentate from the banks of the Danube to the borders of China. Books in the Pali text are sometimes composed of thin strips of bamboo, delicately painted, and varnished over in such a manner as to form a smooth and hard surface upon a leaf of any dimensions: this surface is afterwards gilded, and the bordered letters are traced upon it in black and shining gold. The margin is illuminated by wretches and figures of gold on a red, green, or black ground. As most of the Birmanes are taught to read and write, they carry with them a sheet of thick and strong blackened paper, called a parawak, or paruvak, in which they enter their accounts, copy songs, till they can repeat them from memory, and take memorandums of any things that are curious. On these parawaks the scribes, or writers, in all courts and public offices, take down the proceedings and orders of the superior officers. It is about 8 feet long, and 18 inches wide, and folds up like a fan; each fold being about six inches, and in length the whole breadth of the sheet. They write in this with a pencil of cotton; and the characters are effaced by rubbing them over with charcoal, and the leaves of a species of colocros.

In the recitation of poetry, the language is exceedingly melodious; even the prose of common conversation appears to be measured, and the concluding word of each sentence is lengthened by a musical cadence, that marks the period to the ear of a person wholly unacquainted with the meaning.

Of the etymology and geography of the Birmanes, derived from their most ancient writings, the following particulars will be sufficient. They conceive that the universe, called logha, which signifies successive destruction and reproduction, after it had been destroyed by fire, water, or wind, is again, of itself, restored to its ancient form. The earth, they suppose to be a plane somewhat elevated in the centre, and surrounded by a chain of very lofty mountains. Its diameter is 1,203,400 juzana, each juzana being 44,820 cubits or nearly 12 miles; its circumference is three times its diameter; and its thickness 240,000 juzana, of which one half is dust, and the other half a solid rock, and the whole supported by a double thickness of water, resting on twice its thickness of air, below which is a vacuum. Besides our earth, there are 10,100,000 others, mutually touching in three points, and forming a similar number of equilateral spaces, which, not being penetrated by the sun's rays, are filled with water intensely cold. In the middle of the most elevated part of our earth, the Birman writings place Minnoo, the highest of all mountains, elevated above the surface of the sea 18,000 juzana, and descending as far below it, supported by three feet of carbuncles, having its eastern face silver, the western glaf, the northern gold, and the southern pale-coloured carbuncle, and surrounded by seven chains of hills. In the middle of the ocean, opposed to the four cardinal points of this mountain, are placed four large islands, the habitations of men and other animals; and besides these the Birman writers allow 2000 of a smaller size, 500 belonging to each of the larger ones. The ocean is in various parts of very different depths. All living beings are distributed into three classes; generating beings; those which are material, but do not generate; and immortal beings, or spirits, each of which is subdivided into several different species. The Birman writings admit of transmigration, alleging, that in death, whether of man, beast, or any living being, the soul passes with the body, and after this dissolution, out of the fame materials another being arises, which, according to the good or bad actions of the former, becomes either a man, or an animal, &c. and they teach, that all beings are revolving in these changings, till they become entitled by their actions to flie to Nirban, the most perfect of all flates, in which they are free from changeable misery, death, sickness, or old age. The Birman writings also announce the opinion of an infinite number of worlds in constant succession, without beginning and without end. These writings mention eight planets, viz. the Sun, Moon, Mercury, Venus, Mars, Jupiter, Saturn, and another named Rahu, which is invisible. The Sun is 50 juzana in diameter, the moon 49, Mars 12, Mercury 15, Jupiter 17, Venus 19, and Saturn 13; and their circumferences are triple their respective diameters. They suppose that the fun, moon, and stars revolve round the great mountain Minnoo in a circle, the plane of which is parallel to the earth. The stars, according to them, pursue a constant course, without declining to the north or south; but the fun, moon, and other planets have a declination; and the fun, in proceeding from the north to the south, and from the south to the north, always touches the twelve conftellations, which we call the twelve signs of the zodiac, and in the space of one year returns to the same place in the heavens from which he set out. This fame revolution is performed by the moon in a month. The fun's motion, they say, is quicker than that of the moon; and by his choral revolution, when he is in the southern island it is mid-day, in the northern it is midnight, in the eastern island the fun sets, in the western it rises. Although the fun, moon, and stars appear to us round, we are not to suppose them to be spheres, but this is a fallacy of vision. The invisible planet Rahu serves the purpose of explaining eclipses; for being a huge monster, he takes the sun and moon either into his mouth or under his chin, and thus causes either total or partial eclipses. As to the heat and cold which are experienced at different seasons of the year, the Birman say, that from the vernal equinox to autumn, the sun is always tending to the north, and the moon inclining to the south; the season is then hot, because the sun's rays, which are naturally hot, prevail; but from the autumnal equinox to the vernal, the fun inclines to the south, and the moon to the north, and the moon's rays, which are by nature cold, predominate, and produce cold. They assign seven causes of rain, of which three are physical, and four moral. These astronomical and physical ideas of the Birman writings were probably brought from Hindustan, together with their religion and laws; but for
for a more particular account of them, we shall refer to the
Asian Researches (vii infra).

Among the Birmans there are several histories, containing
an account of the lives and actions performed by the dif-
fierent families of their princes, which histories are very
famous, and abound with the recital of omens and prodigies.
Indeed, the Birmans are much attached to divination. No
perfunct is to commence the building of a house, a journey, or
the most trivial undertaking, without consulting some perfun
of skill, in order to find a fortunate day or hour. Friday
is a mail unlucky day, on which no business ought to be
commenced. On medicine the Birmans have several books,
containing the description of 96 genera of diseases, with va-
rious recipes for their cure. Mummy is with them a favour-
ite medicine, and they are not unacquainted with the use
of mercury in the cure of lues venerea; but their mode of ad-
ministering it is neither certain nor safe. Most of their reme-
dies, however, are taken from the vegetable kingdom; and
they are chiefly of the aromatic kind, nutmegs being one of
their most favourite medicines. Although they are well ac-
quainted with the plants of their country, the practice of
their physicians is almost altogether empirical, and they pro-
fer certain recipes and nostrums, the efficacy of which they
exhibit, and which have been transmitted from their ancestors
for several generations. They combine with their medical
practice great faith in amulets and charms. In surgery,
they proceed no further than dressing wounds and setting
bones. Of late the inoculation for the small-pox has been
introduced into Arracan.

The state of agriculture in the Birman empire is not parti-
cularly illustrated by Col. Symes. It seems, however, to be
pursued with considerable avidity; and the soil in many parts
is capable of cultivation, and its productions, which are natu-
really numerous, admit of further improvement. The cattle
used in some parts of the country for tillage and draft are
remarkably good; they put only a part of them to the plough,
which is little different from the plough of India, and
turns up the soil very superficially. In their large carts
they yoke four stout oxen, which proceed with the speed of
a hand-gallop, and are driven by a country-girl standing up
in her vehicle, who manages the reins and a long whip with
case and dexterity. Many of the rising grounds are planted
with indigo; but the natives suffer the hills for the most part
to remain uncultivated, and only plough the rich levels. They
in every where burn the rank grass once a year to improve
the pasture. The Birmans will not take much pains; they
leave half the work to nature, which has been very bountiful
to them. In the neighbourhood of Loonghee, many fields
are planted with cotton, which thrives well; indigo is also
cultivated in this soil, and is found to answer better than
rice, which is most productive in low and moist grounds.
In the suburbs of Pagahm, there are at least 200 mills em-
ployed in expelling oil from the indigo meal. In this opera-
tion the grain is put into a deep wooden trough, and
pressed by an upright timber fixed in a frame; the force
is inclosed by a long lever, on the extremity of which a man
fitted with a hook, which has a handle, that turns in a circle;
thus turning and pressing the meal at the same time. The machine is sim-
p10le, and yet effectually answers the purpose. Waggon-
ns form a caravan for travelling from the southern country to-
towards the capital. Of these there are sometimes as many as
18, each of which is drawn by six bullocks, and is covered
with a tilted roof of bamboo, overlaid with painted cloth,
for throwing off the rain. They contain not only merchan-
dize, but also whole families, the wives, children, monkies,
eats, parroquets, and all the worldly substance of the wag-
genous. Each bullock has a bell under his throat. They
travel slowly, from 10 to 15 miles a day. At night they are
deposited in a circle, and form a barrier, within which the
creatures feed their cattle, light fires, and dress their victuals,
secure from the attacks of tigers, which much infilt the less
populous parts of the empire.

We shall close this article with a brief account of the
perform, disposition, and manners of the inhabitants of the
Birman empire, and of some of their singular customs. The
Birmans, in their features, bear a nearer resemblance to the
Chinese than to the races of Hindostan. The women, par-
ticularly in the northern part of the country, are fairer than
the Hindoo females, but less delicately formed; they are, however,
well made, and in general inclined to corpulence; their
hair is black, coarse, and long. The men are not tall in
figure, but active and athletic; their appearance is youth-
ful from the prevalent custom of plucking their beards instead
of using the razor; they tattoo their thighs and arms into
various fantastic shapes and figures, which in their opinion
operate as a charm against the weapons of their enemies.
Neither the men nor women are so cleanly in their persons
as the Hindoos of India, among whom diurnal ablation
is a religious as well as a moral duty. Girls are taught,
at an early age, to turn their arms in a manner which makes
them appear daintier: when the arm is extended, the elbow
is inverted, the inside of the joint being protruded, and the
external part bending inwards. The general disposition of
the Birmans is strikingly contrasted with that of the natives
of India, from whom they are separated by a narrow range
of mountains, which in many places admit of an easy inter-
course. Nevertheless, the physical difference between the
nations could scarcely be greater, if they had been fitted
at the opposite extremities of the globe. The Birmans are
a lively, inquisitive race, active, industrious, and impatient.
As the passion of jealousy seems to have no influence among
them, their wives and daughters are not concealed from the
sight of men; and they are allowed as free intercoures with
each other as the rules of European society admit; but in
other respects women have just reason to complain of their
behavior. They are considered as very inferior and subor-
dinate; and even the law stamps a degrading distinction be-
 tween the sexes; the evidence of a woman not being received
as of equal weight with that of a man, and a woman not
being sufferer to ascend the steps of a court of justice,
but being obliged to deliver her testimony on the outside of
the roof. The custom of selling their daughters, and even
their wives, to strangers, though confined to the lowest classes
of society, and frequently the consequence of pecuniary embar-
rassment, is not regarded as shameful, nor is the female dis-
honoured by it; and hence it is that women surrender them-
selves the victims of this barbarous custom with apparent
regret. But no man, who leaves the country, is per-
mitt to carry his temporary wife along with him. Every
attempt of this kind is watched and guarded; and a ship, in
which any females are conveyed away, can never return to
a Birman port but under penalty of confiscation of the pro-
erty, and the infliction of a heavy fine and imprisonment on
the matter. Men are allowed to emigrate; but the exporta-
tion of women, would, in the opinion of the Birmans, im-
povert the state, by diminishing the sources of its popula-
tion. The females, who are reduced to the necessity of
pursuing a course of prostitution, are not at their own dif-
pofal, nor are they allowed to receive the earnings of their
unhappy profession. They are slaves sold by creditors to a
licensed pandar, for debts more frequently contracted by
others than themselves. According to the laws of Pegu, he,
who
who incurs a debt which he cannot pay, becomes the property of the creditor, who may claim him as a slave, and obliges him to perform menial service until he liquidates the debt. His immediate relations are also liable to be attached; and innocent women are often dragged from domestic comfort, and are sold to the licensed superintendent of the tacitly, who, if they poffeff attractions, pays a high price for them, and reimburses himself by the wages of their prostitution. On the banks of a small creek, between the town of Maimu and Bafflen, is a village called Mma-Shun-Run, or the village of prostitutes, which is inhabited altogether by women of this description. Birman wives are said to be in general chaste and faithful; their sedulous employment affording no leisure for the corruption of their minds. A woman of the highest rank seldom fits in idleness at home; her female servants, under her direction and superintendence, like those of the Greek dames of antiquity, ply the various labours of the loom. Weaving is chiefly a female occupation; and most Birman families manufacture all the cotton and flax that are required for their domestic consumption. The women in this country manage also the most important mercantile concerns of their husbands, and attend to their interests in all out-door manufactures; they are to the greatest degree industrious, and are said to be good mothers; and they therefore merit a higher rank than that which is assigned them, and better treatment than they experience. The Birman, in some respects, particularly towards their enemies and invaders, display the ferocity of barbarians, but in others, all the humanity and tenderness of polished life. At home they manifest an amiable benevolence, administering aid to the infirm, the aged, and the sick; filial piety is inculcated as a sacred precept, and its duties are religiously observed. A common beggar is no where to be seen; every individual is certain of receiving assistance, which, if he is unable to procure it by his own labour, is provided for him by others.

Among the Birmans, marriages are not contracted till the parties attain the age of puberty; the contract is purely civil; and the ecclesiastical jurisdiction has no concern with it. The law prohibits polygamy, and recognizes only one wife; however, concubinage is admitted to an unlimited extent. Concubines, who live in the same house with the legitimate wife, are obliged by law to perform menial services for her; and when the husband dies, they become the property of the surviving widow, unless he shall have emancipated them by a specific act previous to his decease. When a young man is desirous of espousing a girl, his mother, or nearest female relation, first makes the proposal in private; if the suit be well received, a party of his friends proceed to the house of the parents of the young woman, with whom they adjourn to the dotal portion. On the morning of the bridal day, the bridegroom sends to the maiden three loonages, or lower garments; three tubbeeks, or fables; and three pieces of white muffin; such jewels also, ear-rings, and bracelets, as his circumstances will admit: a feast is prepared by the parents of the bride, and formal writings are executed: the new-married couple eat out of the same dish; the bridegroom presents the bride with some heaped, or pickled tea, which the acceptor, and returns the compliment; and thus the ceremony ends.

When a man dies intestate, three-fourths of his property go to his children born in wedlock; and one fourth to the widow, who is the guardian both of the property and the children, until the latter attain the age of maturity. A Birman funeral is solemnized with much religious parade and external demonstration of grief; besides the mourning relations, the attendants, who follow the corpse, which is carried on a bier, are women hired for the occasion, who precede the body, and chant a dirge-like-air. The Birmans burn their dead; but as the ceremony of burning is expensive, the bodies of paupers are either buried or cast into the river. The mode of burning is as follows: the bier is placed on a funeral pile six or eight feet high, made of billets of dried wood laid over one another, with intervals for admitting a free circulation of air, so as to increase the flame. The Rhainans walk round the bier, reciting prayers to Gandan, until the fire reaches the body, when the whole is quickly reduced to ashes, which are gathered and deposited in a grave. Perfumes of high distinction are embalmed, and their bodies are preferred in some kiuom, or religious building, six or eight weeks before they are committed to the funeral pile. Honey is said to be the principal ingredient used for preparing the body from putrefaction.

As to their food, the Birman, compared with the Indians, are gross and uncleanly. Although their religion forbids the slaughter of animals in general, yet they apply the interdiction only to those that are domesticated. All game is eagerly sought after, and in many places publicly sold; reptiles also, such as lizards, guanas, and snakes, constitute a part of the subsistence of the lower classes. They are also extremely fond of vegetables.

Among the vegetable productions of this country we may enumerate the white sandal-tree, and the alocygium verum, much valued for the grateful odour of their smoke; the tok-tree (teetnathsea) already mentioned; the echenium verum, producing the true jet black ebony wood; the fycamore fig, Indian fig, and bayan tree; the bigonia indica, nauclea orientalis, corapa feribis, one of the loftiest of the palm-trees, and excoecaria Cochinchenensis, remarkable for the crimson under-surface of its leaves. To the clafs of plants used in medicine and the arts, we may refer the ginger and cardamum, found wild on the sides of rivers, and cultivated in great abundance; the turmeric, used by the natives of the coast to tinge and flavour their rice and other food; the betel pepper, lagaria piperita, and 3 or 4 kinds of capicum; the juliflora tifctoria, yielding a beautiful green tinge; morinda umbellata, gamboge, and carathmus, furnishing yellow dyes; the red wood of the lawsonia fipinola, and Cifalpina fipan, and the indigo. The bark of the merium antiderenticum, called cudagapala, and that of the laurus cuivalan, the fruit of the firynchos nux vomica, the caflia lilata, the tamarind, and the croton tigillum, the infpissated juice of the aloe, the resin of the camphor-tree, and the oil of the ricinus, are occasionally imported from this country for the European dispensaries. The cinnamon laurel, sometimes accompanied by the nutmeg, the sugar-cane, bamboo, and spikenard, are found throughout the whole country; the leaf on dry hills; and the bamboo and sugar cane in rich swamps. The sweet potato, ipomoea tubero, mal-apple and love-apple (fulanum melongena and lycoperficon), nephphra nelumbo, gourds, melons, water-melons and various other eculent plants, enrich, by cultivation, this country; and the plantain, cocos-nut, and fago palm, are produced more spontaneously. The vine grows wild in the forests, but its fruit is much inferior for want of cultivation, and through excess of heat, to that of the south of Europe; but this country is amply supplied with the mango, pine-apple, sapindus edulis, mangoleen plum, averrhoa carambola, culfard-apple, papaw-fig, orange, lemon, and lime, and many other exquisite fruits. The animals of the Birman empire correspond with those of Hindoostan. The wild elephants of Pegu are very numerous; and allured by the early crops of rice, commit great devastation among the plantations that are exposed to their ravages. The king
is the proprietor of these animals; and one of his Bir-
man mahajas takes it for a kind of the white elephant, and of all the
elephants in the world. The firds abound with
typen. Their horses are small, but handsome and spirited,
very active; and are frequently exported in timber-
ships bound for Malabar and other parts of the coast, where
they are droped of at a considerable advantage. Their cows
are domestic, resembling the breed on the coast of Corom-
andel; but their buffaloes are noble animals, much superior
to those of India, and are used for draft and agriculture;
some of them are of a light cream colour, and are almost as
fierce as tigers, who do not molest them. The ich nebience,
or rat of Phanag, called by the natives Oombai, is found in
this country; but there is no such animal as the jackal in the
Asi dominions, though they are very numerous in the ad-
joining country. Among the birds, which are the fame
with those of other parts of India, is one called the Hen-
za, the symbol of the Birmian nation, as the eagle was of
the Roman empire; it is a species of wild fowl called in India
the Brennan goose; but the natives of Ava do not name this
bird.

The Birmans seem to be in possession of several small islands
in the gulf of Martaban, the Magnus Sinus of antiquity,
and of others to the south and west. Symros Embury
fo th the Kingdom of Ava, xiv. vol. 9. 363. 373. etc. Asiatie Re-
farches, vol. vii. p. 163. 305. See ARENAC, AVA, and PEPAS.

BIRMINGHAM, is justly esteemed the greatest manu-
facturing town in England, and we may safely affer, that in
the quantity, variety, elegance, and utility of its manu-
factured articles, it surpasses any town in Europe. To
enable the stranger and foreigner to appreciate the ge-
ceral character of this place, with its various subordinate
features, we will endeavour to depict them to the fancy, in
a concise and picturesque narrative. Its distinguishing cha-
acteristics is appropriately displayed in the following lines
by Mr. Jago, in his poem of "Edge-hill." "

'Tis noise, and hurry all,—the throng'd street,
The clofe-pil'd warehouse, and the buoy hlop.
With nimble stroke the tinking hammers move ;
While flow and weity all the walt fledge defends,
In folema base repoffive, or apart,
Or foetually conjoin'd in tuneful peal.—
How the coarse metal brightens into fame,
Shap'd by their plea fin hands! what ornament!
What various ufe! Nor this alone thy praise,
This too of gracefual feem. the letter'd type!
The friend of learning, and the patriotic pride."

The etymology of the name of this town is not readily at-
tained, as it has been written Brunwychemba, Bromwe-
chem, and various other ways: indeed, in common con-
versation, it is frequently pronounced Bromidgham. The
town lies near the centre of the island, in the north-wes-
tern extremity of the county of Warwick. It is in the
diocese of Lichfield and Coventry, in the deanery of Arden,
and in the hundred of Hemlingford. The superficial con-
 tents of the parish are 2864 acres. In 1800 here were 16,403
houfe, 1875 of which were uninhabited. The whole popu-
lation was 73,670, of which 34,716 were males, and 38,954
were females.

In the seale of national importance, Birmingham bears
an exalted situation; without recurring to its ancient his-
tory, the modern inhabitants have, by laudable industry,
raised it perhaps to the acme of manufacturing and com-
mercial fame. The fagacious and elegant Burke emphati-
cally pronounces Birmingham the "Toy Shop of Europe."
This designation must not, however, be taken in its literal
sense, as the articles of utility made in this town far exceed
those intended only for show and ornament. Many of our
cities are attractive for their venerable ruins and grand cath-
edals, but of those Birmingham is delightful. The traveller
who delights in seeing the human race profitably employed
in their own, and their country's advantage, will disregard
the smoke which sometimes envelops the town, and discern
through the veil the bright beams of industry enlightening
vast piles of riches: justice, however, will compel him to
acknowledge, that profegacy has contrived to insulate itself
within too many dwellings of the labouring classes, pro-
ducing idleness, discontent, drunkenness, and riots, of which
several instances might be cited, exclusive of that grand con-
version which attended the commencement of that revolu-
tion in France, which in its consequences has so severely op-
pressed this, and almost every other nation. The Icknild-
sreet, one of the great Roman military roads, comes within
a mile of Birmingham, and in Sutton park and Coldfield,
four miles from the town, it remains nearly as perfect as
if just completed; one of the principal evidences of the
antiquity of Birmingham is, that it is contiguous to two
Roman roads, the Kenilworth and Shirley streets.
The family of Birmingham were lords of this manor till
1597, at which period it is said to have been obtained by
the duke of Northumberland, through the success of a deep-
planned scheme. Having endeavoured in vain to purchase it,
he contrived to make Edward Birmingham appear as an
accomplice in a highway robbery, and offered him his inter-
est to save a forfeited life, on condition of selling him the
manor. The manor-house, which is now called the moat, still remains,
though the site has been converted into a manufactory, and
an apartment is shown where the ancient lords held their
court-lects.

The parish of Birmingham is smaller than any in its neigh-
bourhood. Mr. Hutton observes, that when Alfred found a
town, he allotted a much smaller space of land to it, than
when he portioned a village, obviously intending the former
for trade and commerce, and the latter for agriculture; this
circumstance seems to prove that Alfred found Birmingham a
town. "The buildings occupy the south-call part of the
parish, which, with their appendages, are about 800 acres. This
part being insufficient for the extraordinary increase of the
inhabitants, he has of late extended her buildings along the
Bromsgrove road, near the boundaries of Edgbaston, and
in the other side planted some of her streets in the
parish of Allon." "The situation is elevated, and the soil one tnod mafs of
dry, reddish sand, through which the water descends freely,
thus making even the cellars comfortable habitations;" the
same author adds facetiously, that though metals of various
sorts are found in great plenty above the surface, we know of
nothing below except sand, gravel, flone, and water. All the
riches of the place, like those of an empire in laced clothes,
appear on the outside. "There is not any natural river in the
parish, but in the lower parts of the town are two excellent
springs of soft water, suitable for most purposes, one at the
top of Digbeth, the other Lady well; and at the latter
place are feven of the most complete baths in the kingdom.
They colt 2000l. in creting, and are ever ready for the
accommodation of hot or cold bathing, for immersion or
amuement, with convenience for sweating. That appro-
priated to swimming is 18 yards by 36, situated in the centre
of a garden, in which are 24 private undressing houfes, and
the whole surrounded by a wall ten feet high." Mr.

Hutton mentions several instances of longevity, which
feem to demonstrate either that the air is too pure to
be rendered unwholesome by the smoke of the town, or that

smoke
smoke and fumom are not fo prejudicial to health as have
been imagined: his infirmities are one perfon aged 109, a fe-
cond 103, a third 104, and a fourth 107, four upwards of 90,
and 13 upwards of 80.

Birmingham is not a place a gentleman would chufe to
make a residence. Its continual noise and fume prevent it
from being difirable in that refpect.

Many ancient families who once flourifhed at and near
Birmingham, are mentioned by Mr. Hutton to have fallen
into irretrievable decay; one infirmity is worth tranferring.
"We have among us a family of the name of Middlemore,
of great antiquity, dedicable from the conqut; who held
the chief poffeffions, and the chief offices in the county,
and who matched into the firit families in the kingdom,
but fell with the intereft of Charles I., and are now in that low ebb
of fortune, that I have frequently, with a gloomy pleasure,
relieved them at the common charity-board of the town."

It appears upon record, that in 1351, William de Bir-
mingham, lord of the manor, procured an additional charter
from Edward III. reviving fome decayed privileges, and
granting others; among the laft was that of the Whitfuntide
fair, to begin on the eve of Holy Thursday, and to con-
tinue for four days. At the alteration of the fyle in 1573,
was prudently changed to the Thursday in Whifilun
week, that fels time might be left to the injury of the
manufacturers and their workmen. The fame perfon alfo
procured another fair, to begin on the eve of St. Mi-
uel, (which is commonly called the Onion fair, on ac-
count of the great quantity of onions fold at the time)
both of which are at this day in great repute. The horf
fair, which formerly was kept in Edgbillton-freet, was,
in 1777, removed to Brick-kiln-lane; and that for befts,
which useed to be in the High-$reet$, into Dale-end, in 1769.

Near Birmingham, on the London road, is Camp-hill,
where the army of prince Rupert were encamped, during
the fiege in 1643. The inhabitants are accused of di-
loyalty by lord Clarendon, for feizing the carriages which
contained the royal plate and furniture. The prince, with
2000 men, had been commanded by the king to open a
communication between Oxford and York, but the hardy
and imputant inhabitants of this town dared to oppofe
this force, with only a company of foot, and a troop of horse.
Though they had thrown up fame light fortifications, and
blocked the streets, yet the king's army forced through thefe
trifling obftructions, and entered the town $word in hand.
The earl of Denbigh, a royalist, was killed in this affair, as
was a clergyman who acted as governor for the
parliament, and who refufed quarter. Birmingham had a
broad ecape from deftruction, for the exasperated com-
mander ordered the place to be burnt, but fome favourable
circumfance confined the conflagration to a few houses in
Bull-freet.

The plague of 1665, was imported into the town in a
box of clothes brought to the White Hart inn. Hence the
fatal poffon iniquitated itfelf through the freet and houses,
destroying great numbers of the inhabitants, whole bodies
foon filled the church-yard, and also an acre of land at Lady-
wood grene, which was afterwards called the Pell-ground.

Although fome degree of embaraffe attached to Bir-
mingham previously to the reign of Charles II., yet it is from
that period that its rapid increafe must be dated. Build-
ing leaves then became common, and numbers of houses
arose to accommodate the increafing population which assem-
bled, in confequence of the cultivation of the mechanical
arts.

About the year 1700, the number of freet in Bir-
Vol. III.

ham was only 30, but now there are nearly 250; besides,
several of the olden are conderably improved and afmofted.
This will, in fome meafe, affift the imagination in pre-
prehending the af amazing increafe of the town in fize, wealth,
and manufactures, during that time; and it is no prefup-
ion to fuppofe, that it has not yet arrived at its zenith;
one infirmity of increafe will be fufficient to point out
the general improvement. Between the roads to Wolver-
hampton and Dudley, there were only three fhoots March
14, 1779. By that day twelve months they increafed to 55,
and March 14, 1781, there were 144. The fame day
in 1791, there was an addition of 835.

Thomas Sherlock, bishop of London, purchased of the
ladies of the manor in 1730, land worth 400l. per annum
in 1758, the income was doubled. He always refufed to
let it on building leas, alleging, that his successor would
be compelled to remove the rubbish at the expiration of the
terms; for Thomas Goode, who held the land after the
above pledge, procured an act about 1766, for letting afide
the probationary caufes of the bishop's will; immediately
let the ground, and improved the rents to 2400l.
per annum; it appears from the books of the poor-rates, that
less than 5000 houses pay the parochial dues, and more
than 8000 houses are exempt; this fact denotes the prevail-
ing description of population.

Manufactures, &c. The extraordinary increafe in the fize,
population, and prosperity of Birmingham, arifes principall
from its proximity to the coal mines, from the nature of the
foil, from its canals, from the fucceffful exertions of a few
individuals in some manufacturing &peculations, and from its
being exempt from borough, and corporate laws and
reftrictions. To invigorate and detail the whole of these
caufes, with their effects, would occupy more space than we
can confiently appropriate. The moft prominent charactef-
tics, however, shall be narrated. To the late John Taylor, efq.
a man of great induflry and ingenuity, the public are in-
deuted for the gilt button, the japanned and gilt snuff-
box, with the numerous clafs of enamels; also the painted
snuff-box, at which employ, one fervant earned 31. 10s. per
week, by painting them at a farthing each. In his fhips
were weekly manufactured buttons to the amount of 60cl.
exclusive of other valuable productions, and eighty gunners
have been given him for a fingle toy made at his fhop. He
died in 1755, at the age of 61, after acquisicing a fortune of
200,000l. His fon is now partner in one of the largest pro-
vincial banking houses in England.

The greatest and moft noted manufactory of this place,
and perhaps in Europe, is that at Solio, about two miles
from Birmingham. This is the property of Meffrs. Boulton
and Watt, who have advanced certain pieces of mechanism
and productions of art to a flate of excellence, that
have excited the admiration and admiration of na-
tions. The large warehouses, work-shops, and the ele-
gant manifion of the former gentleman, cover the defec-
is of a hill, which a few years back was a barren heath, tenanted
only by rabbits, and a warrner's hut; now this once de-
folate fenec is converted into an empofum of arts and beau-
ties. Such are the wonderful powers of human ingenuity
and induflry. In 1757, this spot, with fome contiguous
land, was leased for 99 years, to Meffrs. Ruffin and Evans,
who erected a house and a mill for rolling metal, &c. At
Lady day 1762, Mr. Boulton bought the whole, and re-
moving to it from afterwards from Birmingham, commenced
the present extensive prefpectives, which were nearly completed
in 1765; at an expence of 9500l. He now admit-
ted a partner, Mr. Fothergill, into the concern, and
established
established an extensive correspondence throughout Europe.

To obtain and support a reputation, every encouragement was afforded to men of genius in drawing, mod.ling, and other branches of the arts. An imitation of or molu in vases, tripods, and candelabras, was adopted, accompanied by a great deal of skill and elegance, and universal approbation followed; this led to the establishment of wrought silver, and an application was made to parliament in 1771, for an alloy office, to be established at Birmingham. The poly- graphic art had its origin at Soho. This method of copying pictures in oil, by a mechanical process, was conducted by F. Eginton, who has since executed a great number of fine specimens of painting, or flaiming of glazes. The encaustic mode of flamiing glazes, or fixing the vivid and fine graduating colours upon that transparent material, was supposed to be lost, but it has been revived and brought to great perfection by this gentleman. Since 1784, he has executed several large windows for various cathedrals, churches, and gentlemen's mansions. (See Glass-Painting.) Among the various machines, &c. invented and constructed at Soho, there is one entitled to distinguished notice for its great national utility and importance. This is the steam engine, which has acquired extraordinary force and improvements by Mr. James Watt, one of the proprietors of the Soho firm. To him the scientific world is much indebted for various other inventions and improvements in mechanisms. With a vigorous comprehension of mind, he embraces every mathematical and mechanical subject from the simplest to the most complex and profound. He procured a patent for the steam engine in 1768, and seven years afterwards, entering into partnership with Mr. Boulton, began to construct those machines at Soho. Since that period, they have been generally adopted in the mines and manufactories all over the kingdom. (See Steam-Engine.) The following list of curious and useful articles are manufactured at these works, which, when fully employed, give support to upwards of 600 labourers. Buttons of all kinds; polished steel, and jet Agina steel-toys; polished steel watch-chains; patent cork-fercules, &c. Buckles and latches of all sorts; plated and silver goods for the dining and tea-table, fide-board, &c.; medals and coins of various sizes and metals. The late beautiful new coinage of copper, and the re-flamed dollars; all come from the Soho mint. The coinage mill or engine first erected here in 1783, has been much improved since that period, and is now adapted to work eight machines at once, each of which will strike from 10 to 54 pieces per minute, the size of a guinea; or between 4,000 and 5,000 per hour. Thus the eight machines will work between 30,000 and 40,000 coins in one hour. These machines are operated on by the steam-engine, and perform the following processes: 1st. rolling the maffes of copper into sheets; 2nd, fine rolling of the same cold, through cylindrical steel rollers; 3rd, clipping the blank pieces of copper for the die; 4th, sharking the coin in bags; 5th, striking both sides of the coin, and milling it, at the same time placing it, and placing another for the same operation. To its other properties, this ingenious machine adds the almost magical one of preventing fraud, by keeping an accurate account of every coin which passes through it. Dr. Darwin has described this singular apparatus in the following apocryphal lines:

"Now his hard hands on Mona's refted crest,
Bofom'd in rocks, her azure ores arrest;
With iron lips his rapid rollers seize
The lengthened bars in their expansive squeeze;
Defending screws with pond rows fly-wheels wound

The tawny plates, the new medalion's round;
Hard dies of steel, the cupres circles camp,
And with quick fill, his flabby hammers flame.
The harp, the lyre, and the lion joins,
And George and Britain guard the splendid coin."

 Rolled metals of all kinds of mixtures, are prepared here; besides pneumatic apparatus, large and portable; also copying-machines, and in short, almost every sort of article for use or ornament.

Besides the manufactories already named, Birmingham contains several others, which are entitled to our consideration; and although we cannot allow space for particulars, yet we must not pass them altogether unnoticed. Mefirs. Richardson's, in High-street, is flyled the toy-shop of Birmingham; the elegance and variety of the articles are not to be equalled, with the exception of the show-room at Soho. Mr. Clay's Japan manufactury is not less celebrated, particularly when it is considered that the japan is fixed on common brown paper. To those may be added Clarke and Allmore's manufactury of whips. Gill's gun, bayonet, and sword manufactury, supposing to be one of the best in the world; and Galton's for sporting guns. Previous to the reign of William III. guns were mostly imported from Holland; but that monarch having once expressed some regret at this circumstance, and deplored the necessity of sending abroad for the article, Sir Richard Newdigate, M.P. for Warwickshire, being present, affured the king that his constituents would undertake to supply the demands of government. An order was given, and being readily and correctly executed, Birmingham has continued from that period to be the great and principal place of manufacture for this destructive weapon. See Gun.

Leather appears to have been manufactured here in great quantities in the early periods of the history of Birmingham; but in 1795, there was but one tanner in the place.

Within the last century, the manufacture of steel into almost every kind of toy and ornament took its rise; a large street bears the name of Steel-house-lane, from the extensive works carried on there. Here are also very large bras works erected on the banks of the canal, on the road to the five-ways, near which stand the ruins of the mansion built by the late John Baskerville, who made great improvements in the art of printing. See Baskerville.

Places of Amusement and Curiosity. In New-street is a museum, or repository of natural and artificial curiosities, the property of J. Biflet, a gentleman who has published some ingenious poems and useful books. His "Magnificent Directory," is a novel, handfome, and useful work, in which are contained elegantly engraved emblematical cards of addresses of a great number of the merchants, manufacturers, tradesmen, &c. throughout England.

The first Theatre, established at Birmingham, was situated in Moor-street, about 1740; that in King-street was erected 1765, and enlarged 1774; in the same year, it was transferred to a religious society, and another built in New-street, at an expense of 6,000l. and managed with great success by Mr. Yates. In 1791, it was burnt by some incendiaries, who have never been discovered; since that period, the proprietors have rebuilt it in a very splendid manner for 14,000l. with an assembly room and a tavern annexed to it. Mr. Macready of Covent Garden theatre is the present manager, who generally presents his audiences with the best London performers during the summer months. Concerts and musical parties are held weekly during winter; and the summer produces a variety of public gardens, the principal of which are Vauxhall and Spring-gardens.
**Government.** Birmingham is governed by three acting magistrates; the officers chosen annually are the high-

balliff, who inspects weights and dry measures, and the mar-

kets; the low-balliff, who summons juries, and chases all

the other officers; two constables and one headborough; two

high tasters, who examine the quality of beer and its

measure; two low tasters or meat conners, who inspect the

meat exposed to sale, and cauce that to be destroyed which

is unfit for use; two affiresses, and two leather-fellers, whose

offices are now only nominal.

Denitend, a hamlet of Birmingham, sends its inhabi-
tants to the court ket of that town, where all the

above officers are chozen and sworn, in the name of

the lord of the manor.

An act of parliament passed in 1752, which established a

Court of Requests, consisting of 72 commissioners, three of

whom are a quorum; they sit every Friday morning in a

room of the Red Lion Inn; the clerks attend to give judi-
cial assistance, who are always profilers of the common law,

and chosen by the lord of the manor and the commissioners

for life; ten of the commissioners are balloted out every

other year, and seven others elected from among the inhabi-
tants. The beneficent effects of a humane society for the

recovery of suspended animation were first extended to Birmingham

in 1793. About the same period a committee of respectable

inhabitants was established to watch over the common in-
terests, under the title of the "Commercial Committee."

In 1791, W. Villars, esq., then high bailiff, opened a mark-

et for law, work, straw, &c.

A public library was founded in 1779, which has flourished

greatly, and contains nearly 10,000 volumes, supported by

upwards of 500 subscribers. An elegant pile of building

was erected in Withern-street for the purposes of the in-

stitution in 1757. A rival made its appearance in 1796,

with every prospect of success; besides those, there are

medical and law libraries, and many reading societies.

Birmingham contains two churches, and four chapels; besides

several meeting houses.

Churches. St. Martin's church, denominated the Old

church, was raised previously to the year 1400. It is of stone,

and occupies the site of, or is the first sacred building belong-
ing to the place. In 1690, it was thought necessary to ease

the church and tower with brick. The walls support the arms

and monuments of several titled and ancient families. Under

the south window are two of white marble, one of which is

supposed to have been erected for William de Birmingham,

who was a gentleman of the French name in the siege of

Bellegard in 1397. He wears a mail mantle, &c., and bears a shield with

the bend lozenge. This church was repaired and altered in

1786, at an expense of 4000l. The patronage belonged to the

family of Birmingham till 1557, since which period it has

been possessed by the Dudleys, the crown, the Marrows,

the Smite, and finally the Tenants. The rectory was

valued in the king's books 1291, at 5l. per annum, and in

1575, at 19l. 3s. 6d. The income is now upwards of 1000l.

and expect to be 2000l. after the expiration of certain

leaves.

St. Philip's, or the New church, is a handsome pile of

building, but how Mr. Hutton or any other person could

fancy and say that the steeple is erected after "the model

of St. Paul's in London, but without its weight," is to us

inconceivable, as there is not a line of it that reminds the

spectator either of the dome or turrets of the metropolitan

cathedral. It must beallowed that the tower of St. Philip's

is raised with an attic and a diminutive cupola, but there ends the

resemblance. This church is advantageously situated on an

eminence, and the site was given by Robert Philips, esq.

It was begun by act of parliament in 1711, under a commit-

tee confiding of 20 of the neighbouring gentry appointed by

the bishop of the diocese under his episcopal seal. In

1715, it was consecrated, and finished in 1719, at the real

cost of only 5012l., though the estimated value was nearly

20,000l. This circumstance arose from the gift of materials,

&c. The church-yard consists of four acres, and is in-
tersected by handsome walks, shaded by trees in double and

triple rows, and is surrounded by elegant buildings. Two

thousand persons may be conveniently accommodated in

St. Philip's church, which has contained nearly 3000.

William Higgs, first rector, founded a theological library

for the use of the neighbouring clergy, and bequeathed

200l. to augment it. The Rev. Spencer Madan erected a

room in 1792, adjoining the parsonage, and termed it the

parochial library. The rectory is worth about 300l. per

annum.

St. Bartholomew's Chapel, capable of containing 800 per-

sons, was erected in 1749, on a site given by John Jennens,

esq., an opulent land-holder of Birmingham. Mrs. Jennens,

through the good offices of Mrs. Weaman, added 1000l.

and the remaining sum was received in contributions from

pairs of inhabitants. The chapel and tower are handsome,

and the former presents a line north and south. The altar-

piece is the gift of Baill, earl of Denbigh, and the com-

mission plate that of Mary Carlees.

St. Mary's Chapel was erected in 1774; on a spot of

ground given by Mary Weaman, whose family has the

patronage. The incumbency is valued at 200l. per

annum.

St. Paul's Chapel is a stone building erected in 1779, by

virtue of the same act which founded St. Mary's. Charles

Colmore, esq. gave the ground; a steeple is intended,

and the east window was decorated in 1791, with painted

glas, representing the conversion of St. Paul, by Francis

Eginton, who received 400 guineas for the same.

The house of a celebrated physician of Birmingham, Dr.

Alh, was purchased in 1789 by an attorney, who con-

verted it into an elegant chapel, at the expense of his own

ruin, where he caused the service of the church to be chanted

by a numerous choir, accompanied by an organ. Dr.

Croft, and some other clergymen, afterwards purchased it,

and engaged to officiate there regularly. The congregation

chiefly consists of soldiers from the neighbouring barracks.

Dissenting Meeting Houses. Old Meeting-street received its

name from the old meeting erected in the reign of William

III, which was destroyed in 1791 by the mob. The truf-

tees recovered 1300l. 7s. 6d. damages, and rebuilt the pre-

sent building, at an expense of 5000l.

The New Meeting built 1736, shared the fate of its parent

in 1791, and has never been rebuilt. The celebrated Dr.

Priestley professed under the spiritual concerns of this place of

worship at the period of its destruction, and narrowly el-

ayed personal injury, or perhaps death, from the furious

populace. He fled, and finally retired into exile, within the

state of Pennsylvania, where he died 1804, with the fame

of an excellent philosopher and experimentalist. (See

Priestley.) The trustees having lost their licence, could

not recover damages, but the king granted his warrant

upon the treasury for 2000l.

The Union Meeting in Livery-street, originally an amphi-

theatre for the exhibition of equestrian exercises, being un-

occupied at the period of the riots, the congregations of the

two meetings hired, and converted it into a place of

worship. After the re-erection of the old meeting, they

separated, resigning the Union meeting to the new

meeting.
meeting assembly, who occupy it till their place of worship is re-built.

**Carri-Lane Meeting,** a kind of chapel to the old meeting, was erected in 1748. This society has 900l. bequeathed by John England in 1771, and 40l. 18s. per annum, termed Scott's trust.

A **Baptist Meeting** in Canon-street, was founded in 1738, and has continued profusely to the present period. The *Quakers* have a meeting in Bull-street, frequented by a large, peaceable, and rich congregation; behind it is a spacious burial-ground. The methods here are various; previous to 1782, there was but one congregation, whose place of worship had been a theatre; whereas they removed to a splendid meeting in Cherry-street, erected at an expense of 1201. and John Wolfrey, their chief priest, preached in it for the first time, July 2, in the above year; three others have since been erected and purchased in Colehill-street, Deritend, and Newhall-street. The last was erected as a new Jerusalem temple, for the Swedeborgians, but in too magnificent a style for their revenues. The methods bought it, and the original pews built a smaller temple.

A small **Roman Catholic Chapel** is situated at Eady-hill, in the place of one destroyed during the destructive riots. A Jewish synagogue, a baptist's meeting, and an independent meeting, lady Huntington's meeting, and some other places of worship, are found in this town, which, like most manufacturing places, is distinguished for its number of dissenters of different sects.

**Charities.** Some of the streets of Birmingham are kept in repair by emolument arising from small estates. William Levef, who lived in the reign of Henry VIII., bequeathed certain estates to the town, in trust to sixteen inhabitants, for repairing the streets. This person founded the almshouse in Steel-lodge lane for poor widows. Pemberton's trust is 100l. per annum and John Hutton, his chief priest, to teaching poor children reading, and for clothing ten poor widows. The date of the donation is 1712. Mr. Crowley gave in 1733, six houses for the support of a school for ten girls.

The **Free School** was erected on the site of the guild of the holy cros, which had an endowment or lands for the maintenance of two priests, worth twenty marks per annum, given by Thomas de Sheldon, John Colehill, John Golldsmith, and William Attillowe. In 1563, the bailiffs and inhabitants obtained a patent for augmenting the foundation, and adding a brotherhood, which increased till the general dissolution, and was then valued at 31l. 2s. 10d. per annum. Edward VI. granted the lands belonging to the guild in 1552, at the suit of the inhabitants to nineteen persons, as bailiffs and governors of the free grammar school of king Edward VI., to hold in common forage at a rent of 20s. per annum. Their successors erected the present building in 1707, which is large and handsome, has a neat tower in the centre, and a facade of Edward VI. in front. The chief master's salary is 120l. the second col. two others 40l. each for writing and drawing, and a librarian 12l. There are seven exhibitions of 25l. per annum each for the university of Oxford, and the poffessions are valued at 1200l. per annum.

The **Blue Coat School** was erected 1731, but enlarged and improved in 1751, at an expense of 2500l. The revenues are 1527l. and 159 boys and 40 girls receive the benefits of the institution.

The **Diptheritas Charity School** was held at the old meeting, but after that was destroyed, a building was purchased in Park-street, and has been much improved. The children received are 40 boys and 20 girls.

The **Workhouse** erected 1733, cost 1173l. a wing was added for an infirmary 1766, and another in 1779, at an expense of 1100l. The inhabitants pay a rate of 6d. in the pound, which raises 17,000l. per annum, and relief is afforded to 7000 persons. There are twelve overseers.

The **General Hospital** was erected 1766, and two wings were added 1791. It is supported by voluntary contributions, and many large bequests; the physicians generally give their assistance gratis.

The **Priory** in Peck-lane and Deritend are disagreeable and unwholesome, and both are licenced as public houses.

The **Canal** between this place and Wednesbury, was made in consequence of an act obtained in 1767. It is twenty-two miles in length, united with the Staffordshire canal; the shares were 140l. each, and the expense 70,000l.; they sold in 1782 for 370l. each, and in 1792 for 170l. Sir Thomas Gooch led the proprietors fix acres of land at 47l. per annum, which they converted into a wharf, and erected a handsome office on it. The boats are drawn by one horse, and are about twenty-five tons burthen. Costs are little more than half the price they were before this canal was made. Several other canals, equally beneficial, have since been completed, opening a communication between this town, and almost every principal town in the kingdom.

The **Barracks** stand on five acres of land, held by government at one penny per yard. They were erected in 1793 for 13,000l. and will accommodate 162 men.

There are three extensive Breweries near Birmingham, Richards's in Deritend for ale, Giles and Forrell's Workhouse-lane, for ale and porter, and the Britania, Walmer-lane, belonging to Clay and co.

The Riots already alluded to, constitute an unpleasant feature in the history of this town, and whilst they serve to characterize the folly and inatuation of the lower classes of society, will, we trust, operate as a warning example to the rising generation. A few persons assembled at the hotel Birmingham, July 14, 1791, to celebrate the anniversary of the French revolution. A mob collected round the house, broke the windows, and immediately proceeded to Dr. Priestley's new meeting. This, and the old meeting, were soon burnt to ashes, and the doctor's house and furniture, with his valuable library, apparatus, and MSS. shared the same devasting fate. On July 15, the mansions of John Ryland, esq. at Eady-hill, and Bordefley hall, the seat of John Taylor, esq. together with the house, stock in trade, books, furniture, &c. of Mr. Hutton, author of the "History of Birmingham," were destroyed. Saturday the 16th witnessed the destruction of Mr. Hutton's house at Sisley, the residencies of George Humphreys, William Ruffell, and John Taylor, esq. The latter, Bordefley hall, was occupied by lady Carahampton, mother to the duchess of Cumberland, but neither her blindness, nor age, nor connection with the king, could prevent the mandate of removing her furniture from the mob, who frantely offered to affix: "She was therefore, like Lot, hallowed away before the flames arose, but not by Angels." The reverend Mr. Hobbin's and Mr. Harwood's houses were next burnt; those of the Rev. Mr. Coates, Mr. Hawkes, and Thomas Ruffell, esq. were plundered. On Sunday the 17th, Kingwood meeting perished in flames, the parsonage house, and that of Mr. Cox, licenced for public worship. The mob this day plundered Edgbaston hall, Dr. Withington's, and attacked Mr. Males house, but hearing in the evening that a troop of horse approached, they gradually dispersed, after destroying property to the amount of 60,000l. To reimburse the sufferers, an act was obtained in 1793. The war succeeding, greatly injured Birmingham, and this cannot be more clearly
clearly proved than by referring to the 1875 uninhabited houses in the year 1800. There are two morning papers published at Birmingham; Aria’s Birmingham Gazette, and Swinney’s Birmingham Chronicle, &c. Mr. Swinney also carries on a considerable type foundery, which is the only provincial one in the kingdom. “This neighbourhood,” says Mr. Hutton, “may justly be deemed the seat of the arts, but not the seat of the gentry. None of the nobility are near us, except William Legge; earl of Dartmouth, at Sandwell, four miles from Birmingham. The principal houses in our environs are those of the late Sir Charles Holt at Allton; Sir Henry Gough Calthorpe at Edgbaston; George Birch, esq. at Handsworth; John Gough, esq. at Perry; and John Taylor, esq. at Bordley and at Mofley, all joining to the manner of Birmingham; exclusive of these, there are many retreats of our first inhabitants, acquired by commercial successes.” Hockley Abbey, near Solo, is the residence of Mr. Richard Ford, an ingenious smith, who had the honour of presenting his majesty with an iron carriage made by himself. It is a modern curious building, with the upper part representing a ruin, and is surrounded by beautiful grounds and walks, interspersed with fanciful curiosities. The most considerable feats in the vicinity of Birmingham, are Hagley, 12 miles distant; Enville, 15 miles distant; and the Leafeows, 6 miles distant. The latter will long be preferred in the memory of every reader of Shenstone, whose creation it was, and whose tale it displayed in an eminent degree. It now belongs to Charles Hamilton esq. who has judiciously restored the neglected beauties of the place. Hagley, the seat of Lord Littleton, has been particularly celebrated in the writings of Pope, Thomson, Hammond, and other poets. Enville, the seat of the earl of Stamford, is a scene of great natural beauty. For further particulars relating to Birmingham, its manufactories, and neighbourhood, see Hutton’s “History of Birmingham,” 8vo. Shaw’s “History of Staffordshire,” vol. “A companion to the Leafeows, Hagley, and Enville,” 12mo. Biflet’s “Poetic Survey round Birmingham,” 8vo. Philip’s “History of Inland Navigation,” 4to. &c.

BIRON, Armand de Gontault, baron of, in Biography, was born about the year 1524, and rose gradually from the condition of a page to Margaret de Navarre, to the rank of marshal of France, which he obtained from Henry III. in 1577. After the death of this king, he was one of the first to acknowledge Henry IV. as lawful possessor of the crown, and joined him with advantage at the battles of Argues and Ivry. At the close of the action, to the victorious issue of which he contributed, by his command of the retreat, though he was not engaged; he fled to Henry, who had much exposed himself, “You, sire, have acted the part of Biron to day, and you have acted yours.” Under Henry III. he occupied the post of lieutenant-general of Guienne, in which he gained great advantages over the Calvinists; and he also reduced part of Normandy to the obedience of Henry IV. To his son, who solicited a small force for the purpose, and with the promise of ruining the army of the dukes of Parma and Mayenne, he replied; “I believe you may; but then we shall have nothing farther to do but to plant cabbages at Biron.” Soon after, in 1592, he lost his life by a cannon ball, at the siege of Ereani. In his military character, he was a rigid disciplinarian, and required prompt obedience. When an officer, whom he had commanded to burn a house, desired an order to this effect, under his own hand, Biron instantly discharged him, alleging; “he would have nothing to do with people who were afraid of justice; and that every officer who dreaded a pen, must tremble at a sword.”

BIRON, Charles de Gontault, duke of, the eldest son of the preceding, was born in 1562; and having served under his father, he distinguished himself in several battles and sieges. Henry IV. distinguished him by tokens of forbearance and favour, on account of his faithful and active services. He created him admiral of France in 1592, marshal and governor of Burgundy in 1594, and honoured him with erecting the barony of Biron into a dukedom and peerage. He also employed him in several important diplomatic embassies; but his pride and ambition rendered him incapable of gratitude. Allured by flattering prospects, he engaged with Spain and Savoy in a conspiracy against his master; and at length his haughty conduct caused him to be arrested for his treasons, tried, and condemned to lose his head; and the sentence was executed in the court of the battle, July 31, 1602. He submitted with reluctance, and betrayed cowardice at the time of his death. He was vain, arrogant, and malicious; he changed his religion twice before he attained the age of 16 years, and manifested a total want of principle and integrity. His passion for gain led him, notwithstanding his capacity, to various difficulties; and he was only extirpated when he was actively employed. Although the king incurred some blame for sacrificing the life of a servant who had been eminently useful, and honoured with his peculiar friendship, Biron deferred to suffer as a traitor. Gen. Dict. Nouv. Dict. Hist. Mod. Un. Hist. vol. xxii. p. 99. &c.

Biron, in Geography, a town of France, in the department of the Dordogne, 31 leagues south of Belvez. It is an island in the gulf of St. Lawrence, 26 leagues west of Cape Anguilla. N. lat. 47° 50'. W. long. 61° 5'.

BIROSTRIS, in Conchology, a species of Bulla, that inhabits Java. The shell has two banks, which are elongated and smooth; margin thickened outwardly. Gmelin, Lifter. This species is not unlike Bulla velox, but is smaller, being only about the size of a horsebean; and it is also narrower; smooth, white, flesh-coloured; beaks unequal, obliquely truncated, and one of them a little ascending; aperture nearly equal, but widest at one end. BIROTA, Birutum, from biru and reta, vegetable, a kind of vehicle denominated from the two wheels wherein it moved. The birota, by the constitution of Constantine, was drawn by three mules, and carried 500 pounds weight; by which it was distinguished from the reedu, which carried 1000 pounds, and was drawn by eight, and in winter by ten mules.

BIRR, in Geography, or, as it is called by ait of parliament, Parfsan Town, the largest port and market town in the King’s county. Ireland, situated on the river called the Little Broom, which divides the King’s county from the county of Tipperary, on the south-west. This town has breweries, distilleries, malt-houses, cloth and large factories, a bank, an excellent market, and a barracks for two companies of foot. The cattle at the western extremity of the town, belonging to the family of Parfons, was beggared by Sarfield, lord Luke, general of the 11th, in the war of the revolution of 1688, and relieved by general Kirk. There is a flaxen of William, duke of Cumberland, standing on a stone pillar of the Doric order, erected in 1747, in honour of the victory at Culloden. Birr is 65 miles west by south from Dublin, 6 south from Baldrin on the Shannon, and near 12 from Portumna. N. lat.
Beaufort.—The Kii, or river Kii, is an ancient ruin, made of stone, fitted close to the head, and pointed by a pyramid, usually worn by priests, soldiers, doctors, &c. Du Canze. The word *Birretum*, sometimes written *birretum* and *bireum*, is also applied to a cap or cap of a judge, or senator at law. The *Birretum* also denotes the cap worn by the natives in the Jefuits order, formerly of a square, now a round figure. The *Bireum* was the ordinary cover of the head in France 500 years ago. It took its denomination from *bireus* or *birrum*, the coat usually affected by ecclesiastics; with which the cap was then of a piece, and made part of it; so that the whole covered, not only the head, but the shoulders. Afterwards, when they began to retrench the upper part, still retaining the upper, it was no longer called *bireus*, or *birrum*, but diminutively *bireus*, or *birrum*.

**Birrus**, an ancient habit worn by the Christians in Africa. The word is also written *byrus*, supposed to be formed from *vipsa*, on account of its red colour. Some will have the *birrus* an episcopal habit. Others extend it to all the clergy. Others, on Fuller grounds, make it the common coat of all the Christians in that quarter.

**Birs**, or *Birsh*, in Geography, a river of Swizerland, which runs into the Rhine near Baffle. Near this river, and not far from the town of Baffle, are the hospital and burying-ground of St. James, famous in the history of Swizerland for a desperate combat in 1434, between the Swifs and the dauphin of France, afterwards Lewis XI., in which Swifs valour and intrepidity were very finely displayed. Upon this occasion 1500 Swifs charged 6000 of the enemy's cavalry with such determined and well conducted valour, as to drive them back; and when the enemy received reinforcements, the Swifs renewed the assault, and forced them to repulse the river Birs, and join the main body of the army. The Swifs, encouraged by this success, and also exasperated with the most spirited indignation against the invaders of their country, rashly attempted, against the remonstrances of their officers, to force their passage over a bridge guarded by a large body of the enemy; but this gallant effort not succeeding, they threw themselves into the river, and gained the opposite shore, in the face of a battery of cannon, that was playing against them. But they were now opposed to an army of 50,000 men advantageously posted in an open plain. In these desperate circumstances they had no alternative, but to throw down their arms, or gloriously expire. They bravely preferred death; 500 took possession of an island near the bridge, and after obstinately defending themselves to the last extremity, were cut to pieces. A like number forced their way through the ranks of the enemy, and marched towards Baffle; when they were opposed by a large party of horse posted to prevent the inhabitants of the town from falling forth to the relief of their brethren. Being now surrounded on all sides, they threw themselves into the hospital of St. James; and, lining the walls of the burying-ground, refused for some time the united assaults of the French army. At length the hospital being set on fire, and the cannon having battered down the walls of the burying-ground, they no longer fought in hopes of victory; but still resolving to sell their lives as dearly as possible, they continued to defend themselves to the last gulp.

Aenea Sylvius (afterwards pope Pius II.) relates, among other actions of singular valor excited by this heroic troop, the following instance, that deserves to be recorded. Four French soldiers assaulted a single Swif, and having killed and stripped him, proceeded to insult the corpse; one of his companions, incensed at this brutal action, seized a battle-axe, rushed upon the four, flew two of them, and drove the others to flight; then flinging the dead body of his friend upon his shoulders, carried it to a place of security; and returning to the attack, fell by the hand of the enemy. Of the whole number, only 16 escaped from the field of battle; and these, agreeably to the old Spartan discipline, were branded with infamy, for not having sacrificed their lives in defence of their country. Among those who were desperately wounded and left upon the field, only 32 were found alive. The names of many of these glorious combattants were registered, and still remain upon records. The loss of the enemy was great; and they were effectually prevented from prosecuting their designs upon Swizerland, and compelled to retire in a shattered state into Alfacce. Lewis himself declared, that such another victory would ruin his army. This combat may be considered as forming a memorable era in the history of the Swifs; for it gave rise to their treaty with Charles VII.; being the first alliance which they contracted with France. The Swifs still talk of this famous action with the warmest enthusiasm; and the inhabitants of Baffle form parties every year, and go to an inn situated near the hospital and burying-ground, in or order to commemorate, in a red wine produced from some vineyards planted on the field of battle, the heroic deeds of their countrymen, who so gloriously sacrificed their lives. This wine is highly prized by the Bafilians, and called "the blood of the Swifs."

By the side of the Birs there is a fertile plain, on which are several pleasant villages; and the extremity of the plain is closed by a rock, through which opens the celebrated pass called "Pierre Pertuis," which fee. At the bottom of this rock, the Birs buries from the ground in several copious springs, and turns two mills within a few paces of its principal source.

**Birske.** See Borsk.

**Birskva,** a river of Siberia, which runs into the Lena, 28 miles south-west of Oolomink.

**Birskhan,** a town of Germany, in the circle of the Upper Rhine, and county of Hamburg, 25 miles E.N.E. of Frankfort on the Main.

**Birterbury,** or *Bitterburn*, a considerable bay on the west coast of Ireland, in the county of Galway, open to the Atlantic. It is capacious and well sheltered, has good ground, and will admit the largest ships, which may ride here from four to eight fathoms water; yet it is probably never visited, except by fishermen and smugglers.

**Birks,** or *Birks*, a town of Northumberland, lying 12 miles inland from the sea, on the river Birs, and standing on a level ridge, 32 miles west of Newcastle.

**Birth,** in a general sense, is the act of coming into life, which is called child-birth, and the offspring or thing born, and in these senses we meet with it in our best writers. But then it signifies, and as thy birth, coming into the world.

Shakespeare's King John.

Others hatch their eggs, and tend the birth (young ones) until they are able to shift for themselves. Addition, Cicero says, "Fera diligent parum fuus," beats love their offspring.

**Birth,** in Midwifery, is used as synonymous to labour, or the power by which the fetus is excluded from the uterus, and in this sense we say, the birth (labor) was easy, expeditions, tedious, difficult, &c. It is also, though not very properly, used by midwives, to signify the external orifice of the vagina; thus, when in labour, the head of the child begins
to dilate the external orifice, or to emerge, it is said to be in the birth.

Birth, Natural, when the head of the fetus presenting to the uterine orifice, the labour is completely effected by the pains, without the interference of art. See Labour, Natural.

Birth, Premature, when by any accident or derangement of the health of the woman, or of the fetus, pains are excited, and the fetus is expelled before it has attained its maturity. See Abortion, and also Labour, Premature.

Birth, Preternatural, or acros, when, in labour, the arm, shoulder, side, breech, or any other part than the head of the fetus presents to the uterine orifice. See Labour, Preternatural, and Cross-birth.

Birth, Laborious, when in labour the head of the fetus presenting, yet on account of the straits of the pelvis, the pains are insufficient for its expulsion, whence recourse is necessity had to the assistance of the laver, forceps, crochet, &c. See Laborious Birth, or Labour.

Birth, Monstrous, when the fetus is deformed or misshapen, and has more or fewer organs than is natural. See Monster.

Births, Seven Months, partus septimilliarus, children born at the end of the seventh month, or 210 days from the time of conception, being now complete in all their members, and having acquired a certain degree of strength and firmness of constitution, are not unfrequently reared or brought up.

Births, Eight Months, partus octimilliarus, is that children born at the end of the eighth month, or after completing 240 or 242 days in the womb. These were supposed by the ancients, but erroneously, to be less vivacious, and consequently less likely to be preferred alive, and to grow up to manhood, than seven months children. This opinion, founded on a mistaken idea of the upright position of the fetus in utero during the months of the former pregnancy, and of the necessity of its making an evolution, about the end of the seventh month, to prepare it for birth, is considered under the article Position of the fetus in Utero, which see.

For the number of births, see Marriage; under which the proportion of births to marriages, of births to burials, and of male births to females is computed. See also Mortality.

Birth, After. See Placenta.

Birth is also used for a person's decent; and it is either high or low according to the circumstances of his ancestry.

Birth, BIRTH, or BIRTHING, among Seamen, denotes the due distance observed between ships lying at an anchor, or under sail. A convenient place a-board for a mias to put their chells, sleep, &c. is also called a birth.—There is usually one of these in ships of war between every two guns. And a proper place to moor a ship in is called by the same name, as is also the station in which a ship rides at anchor. To take a good birth, is to remove to some distance off any point, rock, or other thing which the seamen would avoid or go clear of.

Birth, Expulsion of, among the Ancients, was where a new-born infant was expelled or cast away, and left to the mercy of the still-comer, who might either take and bring it up, or suffer it to perish. See Expulsions of Children.

Birth, Supposittion of, partus suppositio, in the Civil Law, is a crime for which accusation may be intended by those who have interest therein, and is punished with death, like the crimen falsi, or forgery.

Birth, Supplication of, partus suppositio. See Abortion.

Birth-Day, the anniversary return of the day on which a person was born. This answers to what the ancients called syncerus, genethlion, natalibus dies, natalitia, and, in the middle age, genetalus. The ancients made much of their religion to consult in the celebration of birth-days, and took omen from the felicity of the coming year. We meet with birth-days of the gods, emperors, great men, poets, and even private persons; and besides, the Birth-days of cities, as Rome and Constantinople, were celebrated with great pomp by the inhabitants. Virgilia birth-day was held very strictly by the wis and poets who succeeded him. Piny (Epist. lib. iii. ep. 7.) affirms us, that Silius kept it, with more solemnity than he did his own.

The manner of celebrating birth-days was by a splendid feast, wearing a font of rings peculiar to that day; offering sacrifices, the men to their genius, of wine, frankincense; the women to Juno; giving suppers, and treating their friends and clients; who, in return, made them presents, wrote and sung their panegyrics, and offered vows and good wishes for the frequent happy returns of the same day. The birth-days of emperors were also celebrated with public sports, feasts, vows, and medals struck on the occasion. But the birth-days it is to be observed, had other fruits of birth-days besides the days on which they were born. The day of their adoption was always repeated as a birth-day, and celebrated accordingly.

The emperor Adrian, we are told, observed three birth-days; viz. the day of his nativity, of his adoption, and of his inauguration. (Fab. B. B. Grec. tom. xii. lib. vi. cap. 6.) In whole times it was held, that men were not born only on those days when they first came into the world, but on those also when they arrived at their chief honours and command in the commonwealth. &c. the consulate. Hence that of Cicero in his oration Ad Quirites, after his return from exile: “A parentibus id quod nese recebit, parum sum furores. Conclusius,” Besides, those who returned from banishment, were also considered as being born again, renati, and ever after called the day of their return their birth-day. Thus Cicero to Atticus: “Dierique natali reditus mei coru in tuis edibus amnisiis agnati tecum, & cum mea.” Cenforius has a treatise De Die Natali, addressed to Q. Cereillius; as a compliment on his birth-day.

Birth-Days of the Saints and Martyrs, natalies sanctorum, denote the days of their deaths.

In reality, natalis among the ancients, was not restrained to birth-days, but extended to all feast-days.

Hence it is we meet with natalis ficti, natalis eehets, natalis ecclesiae, natalis reliquiarum, &c.

Birth-Sin, in Theology, the same with original sin, which see.

Birth-Word, in Botany. See Aristolochia.

BIRTHA, in Ancient Geography, Takrit, a town of Asia, in Metopotamia, on the Tigris, south of the confluence of the Zabus Minor with this river. Also, a town of Arabia Delkefta, seated on the Ephrates, according to Ptolemy.

BIRTHAMA, or Bithaba, a town of Asia, in Alryia, according to Ptolemy.

BIRTHIN, in Geography, a river of Monmouthshire, which runs into the Uik, near the town of Uik.

BIRU, a town of South America, in the empire of Peru, distant 10 leagues from Truxillo, and inhabited by about 70 families of Spaniards, Indians, Malattors, and Meltizos. About half a league to the north of it is a rivulet, from which are cut several trenches for watering the grounds, which of course are equally fertile with those in the vicinity of Truxillo. S. lat 8° 24' 59". W. long. 69° 17'.

BIRUCKPOUR, a fortress of Hindostan, in Malva country.
country, and circar of Chanderer; 55 miles east of Chanderer.

BIRVIESCA. BIRVESCA, or BIRVIESCA, a mean and
wretched town of Spain, in Old Castile, 15 miles N. E. of
Burgos.

BIRUTA, a river of Siberia, which runs into the
Telkuan. N. lat. 57° 35'. E. long. 09° 45'.

BIRUTCH, or BIRUTCH, a town and distirict of
Ruffia, in the government of Voronezt, situated on the river
Sofia, which falls into the Dni; 30 miles south of Vor-

BIRZ, or BIRZ, a town of Poland, in the patinatice
of Troki. N. lat. 56°. E. long. 24° 45'.

BIS, in Botany, a name given by some old writers to
the nappules, or monk's hood, and by others to the cicuta or
hemberg.

BIS, Lat. twice. In Mafes, when a passage which ought
to be repeated, has, through mistake, or to save room, been
omitted, the word bis placed over such passage, with dots at
the beginning and end, implies that the whole is to be re-

Example.

Bis-annual, a name given by Botanists to those plants
which ordinarily do not flower till the second year.

BISA, or BISA, a coin in Pegu, current there for half a
ducat. The denomination is also given to a kind of weight
used in the fame country, equivalent to two Venetian pounds
five ounces, or to three pounds nine ounces of the smaller
weight of that city.

BISACCO, in Geography, a town in Italy in the king-
dom of Naples, 12 miles N. E. of Conza. N. lat. 41° 5'.
E. long. 15° 35'.

BISACUTA, in Middle Age Writers, an ox with two
edges, or which cuts either way; or a misfire weapon
pointed at both ends. Wallingham reprelents the pecsiz
bisacuta as peculiar to the Scotch nation. See Battle-

BISALTAE, in Ancient Geography, the name of a people
who inhabited a small country bord ring on the Sinus Stryla-
monicus, in the northern part of Macedonia. Their chief
cities were Euporia, Offa, and Calatera.

BISALTIDE, in Entomology, a species of Papilio
(Dan. Fid.) that inhabits Surinam. The wings are slightly
tailed, fulvous, black at the tips; beneath, two ocellar dots
on the anterior pair, and three on the posterior ones. Fa-
bricia, &c.

BISAMRAZE, in Zoology, Serex mohebatus, Gravel
cin, and long-winged fessor of S. G. Gravelcin, p. &e.

BISAMTHIEER, Mohebat mohebiferus, or Thiba moxk
in Gela. Quadr.

BISANTEE, or RAEDITUS, in Ancient Geography,
a town of Thrace on the confines of the Propontis, at the
bottom of a kind of gulf, and at a small distance S.W. from
Pieriaxes.

BISANT. See Pisanr.

BISBEA, a feast celebrated by the M. Ebi, after the
praising of their vines, to obtain of the gods that they might
grow again the better. The word is formed from bisan, used
by some for a wine.

BISCAINO, BARTOLOMEO, in Biography, an eminent
artist, was born at Genoa in 1632, and instructed in
the first principles of painting and design by his father Giovanni
Biscaino, a landscape painter of reputation. He afterwards
perfeetcd himself, principally in the art of colouring, under
Valentino Cattelli. By his early death, at the age of 25 years,
the expectations of those who admired his talents and perform-
ances were disappointed. Some of his etchings are executed
in a bold style, resembling the style of Calligleone, but all more
limned. His figures are elegant, forms composed, and
drawn in a very mastery manner; he has given beauty and
color to the heads and the other extremities are peculiarly
correct, and marked with great spirit. Some of the
principal are the following: "Masts in the ark of bul-
rishes": A Nativity, with angels; "The wife-men's offering:" "The Circumcision of Christ:" and a "Bac-
chalian": Strutt.

BISCARA, or BICARSA, in Geography, a decayed city of
Africa, in the kingdom of Algiers, the capital of the
district of Zabir and Zeb, belonging to the province of Con-
stantine. It is the residence of a Turkish garrison, and has
a small castle, built by HaJJam, the bey of Constantine,
and chiefly defended by six small pieces of ordnance, and a few
unwieldy guns, mounted on carriages. It is a place of great
antiquity, built by the Romans, and destroyed by the
Arabs, who afterwards rebuilt it. It is at present as dif-
ferently peopled as it is weakly defended; the house being
inhabited by swarms of scorpions, vipers, and poisonous repti-
les, and the inhabitants being obliged to desert the city
and retire into the country in the summer, when these nocturnal
animals are intolerable. The inhabitants of this place, and
its adjacent district, called "Bicaras," had a kind of wan-
dering life, and live in tents. Few of them can be employed
in agriculture and pasture from the nature of the country;
but those of the inferior classes carry on some commerce,
not-withstanding their poverty and indigence, in negroes
and oilrich feathers. The pooreft of them migrate every year
to the city of Algiers, and other towns of the kingdom,
and are employed in the meafie and moft subordmate offices,
such as cleaning of flinks, emptying vaults, sweeping chim-
nies, and carrying burdens. Having in the course of two
or three years accumulated a capital of from fiv to ten ze-
ekins, they return home, and on account of the fecrity of
coin among them, are reckoned among the wealthy of the
land. In the capital, they constitute a kind of corporation,
and have even a common treasury for the pofe of mutually
relieving one another. They are the only表s of free
servants, and are highly esteemed for their fidelity. In
winter, as well as in summer, they are frce to wander, viz.
raggs, on a kind of benches before the shops, and others place them-
sefl; at the gates of the different roads, for the convenience
of opening them to passengers. They are not only def-
erving of the confidence that is reposed in them, but their
disposition is placid and obliging, and their perseverance in
labour is indefatigable. Those among them who are guilty
of any breach of trust, are punished by their chiefs. They
are employed by the Europeans as servants, and as they can
speak, besides the language of the country, the "lingua Franca," are found singularly useful. The villages which
they inhabit in their own country are small, and remarkable
only for their menfnefs and poverty. N. lat. 34° 30'.
E. long. 5° 15'.

BISCARIA, or BISSANGIS, in Ancient Geography, a
town of Spain on the right side of the Iberus, N.W. of
Dertota.

BISCAY, in Geography, a province of Spain, called the
lordship of Bisca:; is, in its moft appropriate and restricted
and, bounded on the north by the bay of Biscay, on the
fourth
fourth by a chain of the Pyrenées, which separates it from Old Catalonia and Alava, on the west by Asturias, and on the east by Guipúzcoa; and in extent its length is about 116 miles, and breadth much less, the greatest breadth being 80 miles, but very unequal. In its more general and comprehensive sense, Biscay is divided into three parts; viz. Bicay, properly so called, Guipúzcoa, and Alava; and, accordingly, it is bounded on the west by that narrow tract of Old Cateilte which reaches to the sea and Asturias; parted from Old Catalonia on the south-east by the ridge of the Asturian mountains branching from the Pyrénées, and by the fame mountains from Navarre, and by the river Cidaro from France, on the east; and washed on the north side by the Cantabrian sea, now commonly called the bay of Biscay. The country is for the most part mountainous and barren; but its valleys produce corn sufficient for the supply of the inhabitants, and a small quantity of flax. Apples are very plentiful, of which is made cyder, the common beverage of the people. They have also a weak wine, called “Chacolino,” which is pleasant, though it will not keep long, and is used instead of small beer. They have also citrons and oranges in great abundance. The adjacent sea supplies excellent fish, and the forests yield great quantities of timber for shipping. But the most valuable treasure of this country consists of its inexhaustible mines of excellent iron, which is transported from hence into all parts of the world. The country has been long famous for its iron-works, and especially for its manufacture of swords and knives. Some have computed the amount of its annual manufacture of iron and steel into arms, nails, iron tools, bars, &c. at 500,000 quintals. The air of this province is mild, pure, and more temperate than that of the other provinces of Spain; and the inhabitants have been distinguished by their attachment to liberty, and resistance to oppression. Their ancestors, the Cantabri, were but imperfectly subdued by Augustus, and their mountains have, in every succeeding age, afforded them a retreat from the encroachments of arbitrary power. The Biscayens are said to be of Celtic or Gothic extract; and have preserved more of their ancient genius, laws, government, and language, than perhaps any other people in Europe, except the Welsh, Scots Highlanders, and wild Irish, who are probably of the same origin, and whose language much resembles the Biscayan. They have always maintained a distinguished reputation for valor; and the best soldiers and sailors of Spain have been the natives of this country. They essentially differ from the other Spaniards in the openness of their temper, and animation of their manner; and though they are choleric even to a proverb, and not deficient of pride and vanity, they are obliging, polite, and friendly. Their females are beautiful, lively, and cheerful. Their drapery is neat and pastoral; their hair falling down their backs in long plaits, with a handkerchief twisted round it. The most singular part of the drapery of the men is the covering of their legs, round which they wrap a piece of coarse grey or woollen cloth, fastening it with many bands of tape. The three provinces of Biscay, Alava, and Guipúzcoa, have been the stylium of liberty and industry, and to these canes their prosperity may be ascribed. When the king, who is styled merely “lord of Biscay,” wants a supply either of men or money, he announces his will to the province; which furnishes its contingency of both; the latter being levied upon the different cities and communities, according to a certain register, so that in effect Biscay may be said to tax itself. In this province are no bishops. Its privileges, which are extensive, it has watched over with a jealous eye. The language of Biscay is accounted aboriginal; it is said to be the Cantabrian, or ancient language of Spain, which was a branch of the Celtic, and first gave way to the Roman; which fe involving the projecting coasts of France and Spain, and extends from Cape Osségual to Brest. It advances farthest to the land between Bayonne and St. Sebastian; and it likewise advances considerably at Rochelle and Rochefort.—Also, a large bay on the coast of Newfoundland, between Cape Race and Cape Pine. It lies in the N.E. corner of the Baie des Chaleurs, on the S.E. part of the island. N. lat. 46° 50'. W. long. 53° 6'.

Biscay, Bay of; that part of the Atlantic which lies north of the province of Biscay, between the projecting coasts of France and Spain, and extends from cape Osségual to Brest. It advances farthest to the land between Bayonne and St. Sebastian; and it likewise advances considerably at Rochelle and Rochefort. Also, a large bay on the coast of Newfoundland, between cape Race and cape Pine. It lies in the N.E. corner of the Baie des Chaleurs, on the S.E. part of the island. N. lat. 46° 50'. W. long. 53° 6'.

Biscay, New, a province of Mexico in North America, in the audience of Guadalajara, bounded on the north by New Mexico, on the east by New Leon and the river Bravo, on the south by Cinaola and Culiccan, and on the west by Navarre, Sonora, and Haqui, on the borders of the gulf of California. It is computed to be about 600 miles from east to west, and 360 from north to south. The country is mountainous, but well watered, fruitful, and moderately temperate, rich in corn, cattle, and other productions; and also in mines of silver and lead. The original inhabitants have four large towns in the morasses, which are difficult of access, and by means of which they avoid total subjection; and therefore the Spaniards have built three small fortified and well inhabited towns for the defence of their silver mines.

The capital is Durango. This province lies between the latitudes of 25° and 33° N. and between 106° and 108° W. long.

Bisceglia, a town of Naples, in the province of Bari, having the fee of a bishop, suffragan of Trani; it is pleasantly situated on an eminence in the midst of orchards and villas. The walls are of stone and very lofty; and it has hundreds of subterraneous referrors and cisterns, cut in the solid rock, and arched over with arches and vaults, in order to collect and preserve the rain-water, which is the only fort with which they are supplied in a district, to totally destitute of springs. Bisceglia is 4 miles distant from Trani.

Bischburg, or Bischofsburg, a town of Pfalz, in the county of Ermeland, 54 miles south of Konigberg.

Bischeim, a town of Germany, in the circle of the Upper Rhine, and county of Lichtenberg, on a small river which runs into the Rhine, 8 miles N.E. of Strasbourg.

Bischoflack, or Schottia Kolora, a town of Germany, in the duchy of Carniola, 27 miles N.N.E. of Trieste.

Bischofssheim, a town of Germany, seated on the Tauber, in the circle of Franconia, but belonging to the electorate of Mentz, 64 miles S.E. of Mentz.

Bischofsoffestorf, a town of Germany, in the duchy of Sturia, 13 miles E.N.E. of Graz.

Bischofssheim, a town of Germany, in the circle of Franconia, and bishopric of Wurzburg, seated on the Rhine, 32 miles north of Wurzburg.—Also, a town of Germany, in the circle of the Upper Rhine, 41 county of Hanau-Munzenberg, 3 miles W.N.W. of Hanau.

Bischofstein, or Birstein, a town of Pfalz, in the county of Ermeland, 42 miles south of Konigbert.

Bischofsweida, a town of Germany, in the circle of Upper Saxony, and margraviate of Meissen, seated on 3 P.
BISCHOF, or BISHOP, JOHN DE, in Biography, an excellent artist, was born at the Hague in 1646, and is much commended as a painter; and his drawings, in which he imitated with great exactness the style of the best masters, are much esteemed and sought after by the curious. But he is most generally known as an engraver. His works are chiefly etchings, etched with the graver; and though flight, yet free, spirited, and pleasing. He gives a richness to the colour, and a roundness to the figures, far beyond what is usually done with the point. He was a little affected by the graver. His figures are generally well drawn, more in a manner than a correct style; but his extremities are not always well marked, nor his heads equally expressive and beautiful. His excellence was owing chiefly to his own genius, as he never studied under any master. He worked chiefly at Amsterdam, and died in 1696. The following prints are worthy of notice; viz. "Christ and the Samaritan woman," from Annibale Caracci; "Joseph distributing corn to the Egyptians," from B. Brebnerge; "The Martyrdom of St. Laurence," from the same, Strutt.

BISCHOF, or BISHOP, CORNELIUS, a painter of portrait and history, was born at Antwerp, fay some, or, according to others, at Dort, in 1639, and was the disciple of Ferdinand Del, whose pencil, tint of colouring, style, and manner, he resembled, and to whom he has been thought by some competent judges not to be inferior. He died in 1674. A painting by this master, consisting of a few figures by candle-light, was so much admired by Louis XIV., that he purchased it at a high price, and placed it in the royal collection. The King of Denmark also admitted his works among those of the best masters. It is observed, however, that they are not worthy of that high commendation which is bestowed upon them by the Flemish writers. Pilkington.

BISCHWILER, in Geography, a town of France, in the department of the Lower Rhine, and chief place of a canton in the district of Strasbourg, seated on the Moite near the Rhine, and defended by a castle, flanked with towers, and guarded by ditches; 10 miles north of Strasbourg. The town contains 34,49 inhabitants, and the canton 3,968. Its territorial extent comprehend 265 kilometres, and 21 communes.

BISCEA, in Ichthyology, one of the synonymous names among old writers for the pipe-fish, tobacco-pipe-fish, needle-fish, or trumpet-fish; and fangnatbus aces of Linnaeus and Gmelin.

BISCEPSVAARE, in Geography, a town of Norway, 48 miles east of Bergen.

BISCRONGA, Itd. for a demisemiquaver, in Music. If single, it has three hooks ; if two or more, they have three ties. See Time-Table.

BISCUIT. See Bisket.

Biscuit, in Pottery, a name given to porcelain, when baked and not glazed; and this is more or less beautiful, according to the nature of its composition. See Porcelain and Pottery.

BISCUTELLA, in Entomology, a species of Formica, with a bidentated thorax; and a double petiole scale. Inhabits Ceylon. Fabricius Spec. Inf.

BISCUTELLA, formed of bis, and the diminutive of saeta, the fruit resembling a double needle, in Botany, buckler-mustard, or biskellum, a diminutive, or Biskellum. Lin. gen. 808. Rich. 872. Schreb. 1084. Jull. 239. Gen. t. 141. Thalidium. Turnef. 101. Clafs and Order, tetradsymmetria ficulifolia. Nat. Ord. filagroa, cruciformes, or cruciferae. Gen. Char. Cal. perianth four leaved; leaflets oval, acuminate; ghiibons at the base, coloured, deciduous. Cor. four-petalled, cruciform; petals oblong, obtuse, spreading. Stam. flaments fix, the length of the tube of the corolla; two opposite shorter; anthers simple. Pet. germ comprised, or biculate, erumpent, tyle simple, permanent; stigma obtuse. Per. sicle erect, comprised, flat, crenulate, with roundish lobes, two-celled; partition lanceolate, ending in a rigid style; cells two-angled, affixed to the partition, on its straight margin. Sede. solitary, roundish, comprised, in the middle of the cell. Obj. The two outer leaflets of the calyx in some species have a tubular-concave mellerious prominent half.

Species, 1. B. auriculata, car-podded buckler-mustard. Thalpi. Bauh. pin. 107. n. 3. prod. 49. n. 8. Rauh hift. 837. n. 4. Leucoum montanum fl. pedato. Col. ephir. 2. 59. f. 61. Jondrab. Harr. n. 235. "Calxies gibbous on this side with the neck, stiles running into the style." In a wild state this plant rifes about a foot in height, but in gardens nearly two feet, dividing into several branches; the flowers are produced at the ends of the branches in loose panicles, and are of a pale yellow colour. The nectarious gland is very large, and the calyx bugged out very much at the bottom. A native of the north of France and Italy. Cultivated in Kew garden by Mr. J. Sutherland in 1673, and flowering in June and July. 2. B. apala, spear-leaved buckler-mustard. B. didyma. Lin. spec. 911. Hort. Clifft. 329. t. 2. Upi. 1,85. Thalpi. Rauh hist. 837. n. 3. Clypeatum. Clif hist. 2. 133. Jondrab. Col. ephir. 1. 283. t. 285. f. 1. "Siciles fuscous leaves lanceolate, fiddle, ferrate," A native of Italy. Cultivated in 1759, by Mr. Miller. Flowering in June and July. 3. B. lyrata. Thalpi bifofatum, &c. Bocc. fic. 45. t. 23. Rauh hist. 837. n. 6. "Siciles fuscous leaves lyrate," A native of Spain and Sicily. 4. B. coronepodium. Siciles smooth; leaves toothed, rough with hair," Allioni thinks this a variety of the second, proceeding from a dryness of soil; for it is found in very dry barren places in Spain, Italy, and Germany. Goun is of opinion that this and the second, third, and fourth are one species. 5. B. levigata. Smooth buckler-mustard. B. didyma. Scow. Carn. n. 804. Clypecola didyma. Crantz. Ausfl. 22. Leucoum. Col. ephir. 1. 283. t. 285. f. 2. Rauh hist. 836. n. 2. "Sil clcs smooth; leaves lanceolate, ferrate," The whole plant is acid; the root perennial, according to Jacqui, but, according to others, a native of Italy and Antrria. Found at very different heights in the mountains, with variation of stature, from half a foot to a foot and a half. Flowering in lower situations in April and May; in higher ones in July and August; in our gardens in June and July. Introduced here in 1777 by M. Thouin. 6. B. japoncruentus, thirbhn, buckler-mustard.
BISDORF, in Geography, a town of Germany, in the circle of Upper Saxony, and principality of Anhalt-Cothen, 3 miles north of Cothen.

BISECTION. See Bisection.

BISELLIARII, or BISELLARI, in Antiquity, those who enjoyed the honour or privilege of the biseillum.

The honor biseillii appears to have been much the same with what in France is called droit de fauteuil; and the biseillarii those who in public assemblies enjoy this distinction of the fauteuil, while other perons are obliged to stand, or sit on benches, floors, or ordinary chairs. Scaliger, in his index to Gruter, mistook the biseillarii for artisans who made these seats.

BISELLIUM, from bis and sella, a chair, a kind of seat or chair, larger and richer than ordinary, big enough to hold two persons, wherein to sit in courts, theatres, and other public assemblies.

BISEPTEMGUTTATA, in Entomology, a species of Borisentia, of a pale yellow colour, with fourteen white spots. Schaller. Country unknown.

BIS-ERGOT, in Ornithology, a name given by Buffon to the Gmelinian tetra bidentalis.

Ell. Char. leque two-celled, flat; partition contrary.

Propagation and Culture. It is propagated by seeds, fown in this country in autumn, on a bed of light earth, where the plants will come up in about three weeks, and live well in the open air. They should either be fown where they are to remain, or transplanted when very young. After the plants are come up, they will only require to be kept free from weeds, and to be thinned to the distance of a foot from one another. They flower in June, and the seeds ripe in September. They may be also fown in spring, and treated in the same manner. Two or three of these plants may be cultivated for the sake of variety, but they have not much beauty. Martyn's Miller.

BISERTA, in Geography, a town of Ruffia, seated on a small river which runs into the Upha, in the government of Peri, 50 miles S. E. of Perm.

BISERTA, or BIZERTA, a sea-port town of Africa, in the kingdom of Tunisia, pleasantly situated upon a canal between an extensive lake and the sea, at the bottom of a large gulf, about 8 miles to the southward of Cape Blanco. N. lat. 37° 5'. E. long. 10° 15'. It is about a mile and a half in circuit, defended by several caissons and batteries, the principal of which are towards the sea. Bizerta is a corruption of the "Hippo-Diarrrhythus" or "Zaritus" of the ancients; though the present inhabitants derive its name from their own language, and suppose it to be the same with "Benfertit," i.e. the offspring of a canal or rivulet. The lake upon which Bizerta is fesths has an open communication with the sea; and, according to an observation of the younger Pliny (Ep. xxxiii. l. 9.), is either continually receiving a fresh stream from the sea, or else discharging one into it; so that the water lost by the lake by evaporation is soon supplied by the sea, which in hot seasons runs into it with a very brisk current, in order to maintain the equilib- rium, in the same manner as is observed between the Atlantic ocean and the Mediterranean. The millets of this lake are reckoned the best in Barbary. Great quantities of their roots are dried and made into "Botargo," and sent from hence to the Levant, where they are esteemed a great dainty. The channel of communication between the lake and the sea is the port of "Hippo-Diarrrhythus," which still receives small vessels; though it must have formerly the sace as well as the most beautiful haven of this part of Africa. There are still remaining the traces of a large pier, that was carried out into the sea, to break off the N. E. coast. The want of which, together with the disfigurement of the Turks to repair it, will in a short time make the haven useless, which, in any other country, would be in- estimable. Sylax calls it only "Hippo," and Diodorus Siculus gives it the name of "Hipponera." By the di- rection of Scipio's marchers it seems to have been the rich anonymous town mentioned by Livy (I. xxix. 29.). If the Turks encouraged trade and industry it would destroy this appellation, because, besides fish and fruit of all kinds, it abounds with corn, pulse, oil, cotton, and a variety of other valuable productions. The sulphur of Bizerta, the "Staus Hippomenis" of the ancients, is a beautiful sandy inlet, nearly four leagues in breadth. As its bottom is low, it affords a delightful prospect, through a variety of groves and plantations of olive trees, to a great distance into the country; but to the eastward, the view is bounded by a high rocky shore, extending as far as Cape Zibeet. Bizerta was formerly a large town, and is said to have contained 6000 houses; whereas now the town, and its dependent villages, scarcely contain the same number of inhabitants. It has, nevertheless, two capacious prisons for slaves, a large

magazine
magazine for merchandise, and two towers, with some other
out-works to defend the entrance of the haven. It is well
furnished with fresh water from the surrounding springs,
and with great variety of fish from the adjacent lake. Most
of the inhabitants are employed in the fishing trade, which
begins about the end of October, and ends in the beginning
of March. The people are poor, and reckoned proud, ill-
formed, and treacherous; insomuch that Melay Hafun
Bay, one of their sovereigns, used to say of them, that
neither fear nor love could keep them faithful. Bizerta
has eight villages under its government, a large plain called
"Mater," and the territory of Choros, the "Clypas" or
"Corobis" of the ancients, which is extensive, and inhabited
by a number of persons who are poor, meanly clad, and
coarsely fed. Their habits consist merely of a piece of coarse
cloth wrapped round their bodies, and another, in the form
of a turban, round their heads; and most of them are with-
out covering either to their feet or legs. Those of the poorer
chests sleep on skins laid on the floor; and the rich lie in
narrow couches fixed against the wall, about 5 or 6 feet
high, to which they ascend by a ladder. Their choicest
dainty is their "coulcou," made of flour, eggs, and lamb, which
they dry and keep through the year. They are expert
huskmen, and ride without either saddle or bridle; nor
do they ever shoe their horses. They are much exposed to
the depredations and expeditions of the neighbouring Arabs.
The Bizertines, both of the city and country, are very su-
perstitious, and hang about their own necks, and those of
their horses, a number of amulets, which are cramps of paper
or parchment, on which strange characters are inscribed,
and sewn up in a piece of leather, silk, &c. and thought, when
worn about their persons, to be a preservative against all
accidents.

BISSET, CHARLES EMANUEL, in Biography, a painter
of history and conceptions, was born at Mechlin, in 1633;
and in his early productions manifested a lively and ready
invention. He was distinguished by the multitude of figures
which he introduced into his designs, and by his variety of
drapery, peculiar to every nation. At a distance, his pic-
tures, which confided chiefly of balls, concertos, and gay
assemblies, correctly designed and well-coloured, had a strong
effect; but more nearly inspected, they viewed a meath of
pencil, a spirited touch, and a good expression. Pilk-
ington.

BISSET, in Ornithology, Columba leuca, or flock dove, in
Buffon's Hill Birds.

BISHOP, in Ecclesiastical History, a prelate, or person
consecrated for the spiritual government and direction of a
diocese. The word comes from the Saxon bishop, and that
from the Greek episkopos, an overlord or bishop; which
was a title the Athenians gave to those whom they sent into
the provinces subject to them, to see whether every thing
was kept in order; and the Romans gave the same title to
those who were inspectors and visitors of the bread and
provision. It appears from a letter of Cicero, that he himself
had a bishopric; being "episcopus Orc et Campaniae."

A bishop differs from an archbishop in this, that an arch-
bishop with bishops consecrates a bishop, as a bishop with
priests ordains a priest; that the archbishop visits a province,
as the bishop a diocese; that the archbishop convokes a
provincial synod, as the bishop a diocesan one; and that the
archbishop has canonical authority over all the bishops of his
province, as the bishop over the priests in his diocese. It is
a long time since bishops have been distinguished from mere
priests or prebishops; but whether that distinction be of
divine or human right, whether it was settled in the apothegmatic
age, or introduced afterwards, is much controverted.

Those who are advocates for the divine right of episcopacy,
and who trace its institution to the times of the apostles,
maintain that, in the earliest age of the Christian church,
two or three different orders of ministers appointed by
the apostles for the discharge of the public offices of religion;
viz. bishops, priests, or prebishops, and deacons. In proof
of this point they refer us to the testimony of ancient eccle-
siastical writers, whence they deduce, as they conceive, the
most satisfactory evidence, that bishops were instituted by
the apostles, and that they continued afterwards as a distinct
order from that of priests. To this purpose they allege, that
Irenæus, a father of the second century, says (I. iii. c. 3),
"We are able to enumerate those who by the apostles were
made bishops in the several churches, and their successors,
to this time." He adds, "Polycarp was not only instructed
by the apostles, and acquainted with many of those who saw
our Lord, but was also by the apostles made bishop of the
church of Smyrna in Asia." Tertullian also, a writer of the
fame century (De Praef. adv. Hæret. p. 78.), challenges
certain heretics to exhibit the order of their bishops, fo
succeeding each other from the beginning, that the first
bishop had for his author and predecessor some one of the
apostles, or of those apostolical men who persevered with the
apostles; for in this manner the apostolical churches affect
their origin from the apostles. Ignatius, bishop of Smyrne,
who was placed there by John; the church of Rome has Cie-
ment, who was ordained by Peter; and other churches owed
other persons, who, by being placed in the bishoprics by the
apostles, transmitted the apostolical feed." Cyprian also
says (Ep. 69. ad Flor.), "that the bishop, who is one and
presides over the church, through the proud presumption
of certain persons, is deposed; and thus the man, who is ho-
noured by the function of God, is judged unworthy by
men." In an epistle ascribed to Ignatius (Ad Antioc. c. 7),
but probably spurious, though very ancient, it is af-
firmed, that Evodius was consecrated a bishop by the ap-
ostles. And Chrysostom says (Hom. 42. in Ignat.), "that
Ignatius conversed familiarly with the apostles, and was
perfectly acquainted with their doctrine, and had the hands
of apostles laid upon him." In a fragment of an epistle of Di-
ophyus, bishop of Corinth in the second century, prefaced
by Eusebius (H. E. I. 4. c. 23.), it is said, that Dionysius
the Areopagite, who was converted by St. Paul, was ap-
nointed the first bishop of Athens. Eusebius and Socrates
have given us a catalogue of the bishops of many cities,
from the times of the apostles; and Epiphanius (lib. 2.
Haer. 66.) has left us a catalogue of the bishops of Jeru-
alem, from St. James the apostle to Hieron, who was bishop
in his time. It is further alleged, that bishops, priests, and
deacons, are mentioned together as three separate orders.
Ignatius, in his Epistle to the Magnificans (§ 2.), mentions
Damas as bishop of Magnesia, Dianthus and Apollonianis
as prebishops, and Sotion as deacon, in the same church;
and in his epistle to the Philadelphia (§ 7.), he says, "Attend
to the bishop, to the prebishops, and to the deacons;" and
in his epistle to the Trullians (§ 2.), he says, "Be ye sub-
ject to the bishop, as to Jesus Christ; to the prebishops,
as the apostles of Jesus Christ; and to the deacons, as to
ministers of the mysteries of Jesus Christ." He then adds, (§ 3.),
"without these there is noạch church, no congregation
of holy men." The authority of Ignatius, who lived in the
beginning of the second century, is considered as decisive.
Clement of Alexandria, in the subsequent part of the same
century, speaks of the three progressive orders of deacons,
priests, and bishops (Strom. l. 6.); and there are several
carry instances of bishops, who had been prebishops and de-
acons in the same church. Irenæus was first preb复印件, then
bishop
bishop of Lyons; Dionysius first presbyter, then bishop of Rome; and Eleutherius, first deacon, then bishop of Rome; and all these three lived in the second century. "When your captains," says Tertullian (De Fuga in Perif.), "that is to say, the deacons, prebishops, and bishops fly, who shall teach the laity that they must be confiant? And upon another occasion, speaking of baptism, he says, (De Bapt. c. 17.) "The bishop, who is the chief right of administering it, then the prebishops and deacons, but not without the authority of the bishop."

Ongen, in many places, speaks of bishops as superior to prebishops and deacons; and many authors compare the bishops, called by the Greeks archiepiscopi, and by the Latin fathers "summi facerdotis" and "principes facerdotii," prebishops and deacons of the Christian church, to the high-priest, priests, and Levites under the Jewish dispensation; and hence prebishops afterwards obtained the name of priests. Clement, a disciple of the apostle, says (Ep. ad Cor. § 40), "To the high-priests are given his proper duties; to the priests their proper place is alligned; and to the Levites their proper services are appointed:" in which passage this ancient father is speaking of the bishop, prebishops, and deacons of the Christian church; and Tertullian, in the passage just cited, called the bishop the high-priest. Jerome, though he is sometimes represented as unfavourable to the cause of episcopacy, is still more express, and denominates (Epist. ad Evag.) the order of bishops, prebishops, and deacons, an apostolical tradition. "To what purpose," says Optatus (lib. i.), "should I mention deacons, who are in the third, and prebishops, who are in the second degree of priehood, when the heads and princes of all, even certain of the bishops themselves, were content to redeem life with the loss of heaven?" In the tenth council of the council of Sardis, held A.D. 433, it is enjoined that a person should not be rashly and lightly appointed a bishop, a priest, or a deacon. It is further pleaded, that episcopal power was not called in question in the three first centuries; but towards the end of the fourth century, Acarius, an Arian, wrote against it, and maintained that there ought to be no order in the church superior to that of prebishops. Nevertheless, it is alleged, that no advocate is found for his opinion in the centuries immediately following; and that even Acarius allowed there had been bishops in the Christian church from the earliest period. From these several testimonies it is inferred, that bishops were appointed by the apostles; that there were three distinct orders of ministers, viz. bishops, prebishops, and deacons, in the primitive church; and that there has been a regular succession of bishops from the apostolic age to the present time; and the enemies of episcopacy are challenged to produce evidence of the existence of a single ancient independent church fairly established, which was not governed by a bishop. While the apostles lived, the churches, it is said, were subject to their authority and government; and to this circumstance it is owing, that little is said concerning the distinction and power of ministers, in the Acts and Epistles; but when the gospel was spread into distant parts, and the apostles were under a necessity of directing their visits, or rendering them less frequent, they found it expedient for the better government of the Christians, and in order to put a stop to their schisms and contentions, which began to make their appearance both among the prebishops and their congregations, to place the supreme authority in one person, who, from the superintending care which he was to exercise, was called episcopus, a bishop; and this word, which was perhaps at first applied indiscriminately to all who had any spiritual office in the church, was now conferred on him who was its chief governor.

The bishops were at first appointed by the apostles, and afterwards chosen by the prebishops and the congregations at large; and in both cases they were generally taken from the prebishops of the respective churches, except in those instances in which they were the immediate companions of the apostles. According to Jerome, (De Eccles. Script.) and the speaking, as it is inferred, of the apostolical times, in which James was made bishop of Jerusalem by the apostles; Timothy bishop of Ephesus, and Titus bishop of Crete, by St. Paul; and Polycarp bishop of Smyrna, by St. John; observes, that "churches were governed by the common advice of prebishops; but when every one began to reckon those whom himself had baptized, his own, and not Christ's, it was decreed in the whole world, that one, chosen out of the church, should be placed over the rest, to whom all care of the church should belong, and so the seeds of schism should be removed." When St. Paul was at Miletus, A.D. 58, and convened the elders of the church at Ephesus, no mention is made of the bishop; and in his address to them he calls them "bishops or overseers of the flock:" hence it is inferred, that the word bishop was not then the appropriate name of the person who held the first office in the church, or rather, that there was as yet no such person in the church at Ephesus. But in the year 64, St. Paul found it necessary to place Timothy in that situation, with power to prevent the preaching of any unfounded doctrine, and to ordain and exercise authority over prebishops, that is, with episcopal power; and in his epistle, written to him in that year, he speaks expressly of the office of a bishop," and gives a detailed account of the qualifications of a bishop. See t. Tim. i. 3. v. 1, 19, 22. 1 Tim. iii. 1. We have also a similar account in the epistle to Titus, written in the same year; and he was invested with the further power of rejecting heretics from the churches over which he presided. See Titus iii. 10. Hence it is concluded, that in the year 64 there was such an office as that of bishop. St. Paul, addressing his epistle to the Philippians, used the word bishops in the plural number, and does not mention prebishops; whence it is thought by Chrysostom, Theodoret, Jerome, and indeed by almost all commentators, that by bishops we are here to understand prebishops; and it is therefore presumed, that there was then no bishop, in the strict sense of the appellation, at Philippi, A.D. 62. From a comparison of these different passages it has been conjectured, that Paul began to establish episcopacy immediately after his release from his first confinement at Rome. However, it is acknowledged, that at this early period there was not a bishop in every church. Nevertheless, it is inferred from St. Paul's epistles, that he gave the ministers of the churches which he founded, a certain power over their respective congregations, and as St. Paul and the twelve apostles acted equally under the influence of the Holy Ghost, it is presumed, that they invested all, whom they appointed to preach the gospel, with a similar degree of power; and this church authority is derived from the apostles themselves. This power, thus originally given, was not limited to the primitive ages; it is supposed to have been transmitted to those "faithful men who shall be able to teach others also" (2 Tim. ii. 2), and to remain in the church under different modifications, as essentially necessary for the purposes specified by the apostle, Eph. iv. 13, 14.

At first the jurisdiction of a bishop was confined to the walls of his own city; but afterwards, when the gospel made its way into towns and villages, the concerns of the Christians that inhabited them, would naturally fall under the cognizance and direction of the bishops of the neighboring cities; and thus dioceses would be gradually formed. See Diocese. In process of time, it is supposed, the affairs of the church would require the consultation and co-op.
co-operation of different bishops; and therefore, as before, one of the presbyters of a city was raised to be a bishop, and to have authority over other presbyters, so one of the bishops of a province was elected a deposed with certain authority over other bishops, and he was called an archbishop, and in the appointment of archbishops the entire importance of the city seems to have been regarded; for we find that metropolitan bishops were generally archbishops, and hence archbishops were called metropolitans. Archbishops, it has been said, were first appointed in the second century; and they had no power to ordain the bishops within their respective dioceses, to regulate the election of bishops, to confirm them, to hear appeals from their decisions, and to take cognizance of their general conduct. See Archbishop and Patriarch.

It is sometimes urged, that bishops, priests, and deacons, are now, in their office and authority, very different from what they formerly were; but this, say the advocates of episcopacy, is no more than a necessary consequence of a change of times and circumstances. They do not contend, that the bishops, priests, and deacons of England are at present precisely the same that bishops, presbyters, and deacons were in A.D. 1500; 1500 years ago. They maintain, however, that there have been always bishops, priests, and deacons in the Christian church, since the days of the apostles, with different powers and functions in different countries and at different periods; but the general principles and duties, which have respectively characterized these clerical orders, have been Essentially the same at all times and in all places; and the variations which they have undergone, have only been such as have been equal to all parties in public situations, whether civil or ecclesiastical, and which are, indeed, inseparable from every thing in which man-kind are concerned in this transitory and fluctuating world. A learned prelate, who flatters himself, that by the testimonies and arguments, of which we have above given a general account, he has proved episcopacy to be an apostolical institution, readily acknowledges, however, that there is no precept in the New Testament, which commands that every church should be governed by bishops. As it has not pleased the Almighty to prescribe any particular form of civil government for the security of temporal comforts to his rational creatures; so neither has he preferred any particular form of ecclesiastical polity as absolutely necessary to the attainment of eternal happiness. And though the Scriptures contain no directions concerning the establishment of a power by which ministers are to be admitted to their sacred office, yet he conceives, that from the apostles, episcopal ordination has been regularly conveyed to us; and the legislature of this kingdom has recognized and confirmed this power to ordain bishops. See Ordination. Elements of Christian Theology, by lord bishop of Lincoln, vol. ii. pp. 376—401.

Purposo, on the other hand, who do not admit of episcopacy to be of apostolical and divine institution, contend, that the terms επίσκοπος and πρεσβύτερος, that is, bishop and presbyter, are used promiscuously in the New Testament, to which they think it necessary to appeal, as to the sole authoritative rule of faith and practice, and that they denote the same, and not a distinct order or office in the Christian church. To this purpose they allege the passage already cited, Acts xx. 17, 28, in which the same persons are denominated presbyters and bishops. Thus, the same office, name, and work of a bishop and presbyter appear to be the same, in Titus i. 5, 7; and unless the apostle be charged with arguing very incoherently, he must mean the same thing by elder, v. 5., and bishop, v. 7. In like manner, presbyters are called (1 Pet. v. 1, 2.) to discharge the office of bishops. The word επίσκοπος, it is said, was properly the name of office, and πρεσβύτερος was a title of respect, borrowed from the Jewish custom, which was analogous to that of other nations, of calling not only the members of the Sanhedrin presbyters, elders or senators, but also the members of the city council. It has been moreover affirmed, that not a single passage from the apostolical writings has yet been produced, in which it appears from the context, that the two terms πρεσβύτερος and επίσκοπος mean different offices; and that there is the strongest positive evidence, which the nature of the thing can admit, that in these writings the two terms uniformly mean the same office. The apostle Paul, in the directions he gave to Timothy, about the proper supply of churches with suitable ministers, takes particular notice, merely, of two orders, one called bishops, and the other deacons; and hence, it is argued, that if by bishops be meant, what in modern style is so denominated, those who have the charge of many prebendaries, it is alluring that he should not think it of importance to give any directions about the qualifications of prebendaries, whil[s he is particular in specifying the qualifications of deacons, who were to occupy an order allowed to be much inferior to the other; and if he here means by bishops only prebendaries, as some friends of episcopacy have supposed, it is strange that an office so important as that of bishops, if it was a different and superior office, should have been entirely overlooked. From St. Paul's address to the Philippians, ch. i. it is inferred, that there were but two orders then established, viz. bishops, i.e. ordinary prebendaries or prebendaries, and deacons. If there was a bishop in the modern sense at Philippi, when the apostle wrote that letter, it seems strange that the chief person in the society should be the only person disregarded by the apostle. Moreover, in the epistle written by Polycarp to the same society, about 60 years after this time, we find mention of only these two orders, the prebendaries and the deacons; nor is it of any consequence whether we call their prebendaries bishops with the apostle, or prebendaries with Polycarp, as both speak of two orders only among them. In the whole book of Acts, the stated prebendaries of the churches are denominated prebendaries; the collection for the poor Christians is sent to the prebendaries; nor do we find a single hint of any different classes of prebendaries. The proposition επίσκοπος, bishops, occurs but once, and in the passage where it is applied to theolog, that are denominated prebendaries. It is urged further, that the imposition of hands, which has been considered by many as a necessary attendant on ordination, is attributed in 1 Tim. iv. 14. to the prebendaries: Paul and Barnabas were ordained by certain prophets and teachers in the church of Antioch, and not by any bishop, of whom there is not a word in that whole solemnity, prefiding in that city, Acts xii. 1, 2, 3 and it is alleged, as an acknowledged and incontestible fact, that prebendaries in the church of Alexandria, ordained even their own bishops for more than 200 years in the earliest ages of Christianit[y. It appears also, from the first epistle of Clement to the Corinthians, chap. xii, that there were two distinct orders, viz. bishops and deacons, established by the apostles in the church; and by bishops he means the same with those who, in the book of Acts, are called πρεσβύτερος, prebendaries, or ordinary teachers. Since it must therefore be admitted, that in the New Testament, and also in this work of Clement, the words επίσκοπος and πρεσβύτερος, are, not occasionally, but uniformly, used synonomously, the discovery that there was not any distinctive appellation for such an office as that now called bishop, is adduced as affording a strong presumption, that it did not exist. Another testimony alleged to the same purpose is
that of Polycarp, who takes notice only of two orders of ministers in the church; for in \textit{ch. v.} of his epistle to the Philippians, he enjoins the people to be subject to their prebishops and deacons, as to God and Christ; hence it is inferred, that it this ancient father had known of any higher order in the church, such as was that of a bishop, in less than 150 years after his time, he would have been the principal, if not the only person, to whom their subjedion would have been enjoined by a Christian writer. It is observed further, that though he specifies the duties and qualifications of deacons in \textit{ch. v.}, and those of prebishops in \textit{ch. vi.}, and through the whole of the epistle, those of the people, he nowhere mentions what is proper in the character and conduct of a bishop. Upon the whole, it seems evident that Poly
carp knew of no Christian minister superior to the prebishops.

It has been alleged by the advocates of episcopacy, that the bishops are the proper successors of the apostles, not in the general character of teachers, but in their special function as apostles (see Stillingfleet's Works, vol. i. p. 371.); whilst the prebishops and deacons were merely the successors of those who were, in the beginning, ordained by the apostles. But that the apostles could not have any proper successors has been evinced by the following considerations. The indefinable requisite in the character of an apostle, which was that of having seen Jesus Christ after his resurrection, demonstrates that their office could be but temporary. Besides, they were distinguished by prerogatives, which did not descend to any after them; of this kind were their having received their mission immediately from Christ, and not by any human ordination or appointment; the power of conferring miraculous gifts by imposition of hands; and the knowledge which they had by inspiration of the whole doctrine of Christ. Moreover, the object of their mission was altogether of a different kind from that of any ordinary pastor; and this was to propagate the gospel throughout the world both among Jews and Pagans, and not to take charge of any particular flock. Further, as a full proof that the matter was thus universally understood, both in their own age, and in the times immediately succeeding, no one, on the death of an apostle, was ever substituted in his room; inasmuch that when that sacred college was extinct, the title became extinct with it. It is alike true also of the evangelists, that their office was temporary, and that their charge extended to the whole church; and their title, like that of an apostle, fink with those who first enjoyed it. Such were Philip, Timothy, Titus, and probably Mark, and Luke. As to the dates or postscripts subjoined to the epistles in the common bibles, and distinguishing Timothy and Titus by the appellation of bishops, it is now universally agreed among the learned, that they are of no authority. They are not found in some of our best and most ancient MSS.; and they are generally allowed to be the spurious additions of some carnal bishop or monk, at least 500 years after Christ. It is certain, however, that in the three first centuries, neither Timothy nor Titus is styled bishop by any writer. In the island of Crete, of which Titus is said to have been ordained the first bishop, there were no fewer, according to the earliest accounts and catalogues extant, than 11 bishops. Indeed, so little can the instructions given by Paul to Timothy and Titus be made to quadrat with any ordinary minisery that ever obtained in the church, till the learned Dr. Whitby (see his Preface to the epistle to Titus) concludes, that their's was extraordinary as well as temporary, and that they were not succeeded in it by any that came after them. Hence it is inferred, that all the arguments alleged in favour of the distinction between bishops and prebishops in the early age of the church, by Epiphanius and others, from some passages in the epistles to Timothy and Titus, proceed upon the mistaken notion, that they were properly bishops in the modern acceptance of the term; a notion utterly unknown to that Christian antiquity, which defines the name of primitive, and also incompatible with the authentic accounts we have concerning these extraordinary ministers, who were not made bishops till about 500 years after their death.

Some have deduced an argument in favour of the aposto
cial antiquity of episcopacy, from the epistles to the seven churches of Asia mentioned in the Apocalypse, which are addressed to the angels of these separately in the singular number. From the first chapter of that book it appears, that each epistle is intended for the whole church or congregation mentioned in the direction or superscription; and yet one person, called the angel of that church, is addressed in the name of the whole. Hence some have inferred, that the person denominated angel, was an order differing from that of other ministers, and superior to it; whilst others have considered the appellation as descriptive of the whole collective body. An intermediate opinion, advanced by some critics, is more probable. This subjeges the necessity, for the sake of order, that in their consititutions or congregations one should preside, both in the offices of religion, and in their consultations for the common good; and that this president, or chairman, is here addressed under the name of angel. This interpretation affords us also the most plausible account of the origin of the more considerable distinction, which afterwards obtained between bishop and prebishop. It was the distinction of one pastor in every church, marked by the apostle John, though not made by any who had written before him, which led Tertullian, whose publica tion first appeared about a century after the apostles, to consider him as the illutor of episcopacy. By those who deny the superiority of bishops to prebishops in the first age of the church, it is alleged, that the first reformers and founders of the church of England, as well as many of its most learned and eminent doctors, have not pretended this distinction to be of divine, but merely of human invention; not grounded upon scripture, but only upon the custom or ordinances of this realm. To this purpose, the declaration made of the functions, &c. of bishops and priests, and signed by more than 37 clergymen and divines, among whom were 15 bishops, Cranmer and others, that they, according to the New Testament there is no mention made of any degrees or distinctions greater than, but only of deacons or ministers, and of priests or bishops. (See Dr. Burnet's Hist. Ref. vol. i. Append. p. 321.) Besides, the book, entitled "The Institution of a Christian Man," subordinated by the clergy in convocation, confirmed bishops and prebishops to be the same. Moreover, that the main ground of settling episcopal government in this nation, was not any pretence of divine right, but the convenience of that form of church government to the state and condition of the church at the time of the reformation, the learned Stillingfleet affirms (Irenic. c. 8. Works, vol. ii. p. 356, &c.), and proves it to be the sentiment of archb. p Cranmer and of other reformers, in the reigns of Edward VI, and of queen Elizabeth, such as archbishop Whitgift, bishop Bridges, Loe, Hooker, Sutcliff, Hales, Chillingworth, &c. It was also the opinion of archbishop Usher, that bishop and prebifeer differed only in degree and not in order; and that in places where bishops could not be procured the ordination of prebishops was valid. See Ordination. "As for the notion of distinct offices of bishop and prebifeer," says bishop Burnet, in his "Vindication of the Church of Scotland," p. 356. "I confess it is not so clear
clear to me, and therefore since I look upon the sacramental actions as the height of sacred performances, I cannot but acknowledge those who are empowered for them must be of the highest office in the church."

Although, in the apostolic times, bishops and presbyters were synonymous, and co-ordinate with respect to their ministerial powers, and they were ordained to their office by prayer, accompanied with imposition of hands; yet a certain priority, or prescriptiveness, for the sake of order, in difference either to seniority or to distinction of number, was allowed. But he seems to have been only a kind of moderator in their assemblies, and to have had no more power than that of giving a single vote in common with the rest of his brethren. By those who adopt this reasoning, and who trace the original of the distinct order of Bishops, which was introduced in the second and third centuries, to this practice, it is allowed that priests were from the beginning vested with a superintendency over the congregation or church merely in spiritual matters; and it is alleged, that some of the titles that are thus given them in Scripture, such as πρεσβύτερος, πρεσβύτερος, guides and governors, imply this kind of superintendency. But at this time several things relating to the church were conducted in common by the priests, the deacons, and the whole congregation. To this class we may refer all matters of scandal and offence, and also the election of their priests and their deacons. Accordingly, Clement, in the fore-cited epistle, ch. xiv. speaking of the priests, uses this expression: "Those who were consecrated by the apostles, and afterwards by other eminent men, with the consent of the whole congregation." It appears also, by the epistles of Cyprian, written about the middle of the third century, that for the first three ages of the church, no final resolution was taken in any affair of moment, without communicating it to the people, and obtaining their approbation. In the second century a settled distinction obtained, in several respects, between the priest, chosen by a plurality of votes, and distinguished by the appropriate title of bishop, which had before been common to all the presbyters, and the other presbyters. Many other titles, besides that of bishop, which they had all enjoyed in common, were restricted to him who was regarded as their head, such as πρεσβύτερος, πρεσβύτερος, προφανός, προφανός, and some others. These titles, independently of the talents, virtues and services that attended them, claimed respect and deference. The concurrence of the priest thus honoured, was considered as a necessary function to all ecclesiastical resolutions and measures; and by degrees every act became valid which bore the stamp of his authority. Those who professed over churches, which were established in some of the principal cities, were honoured with peculiar precedence; and to this advancement analogy to the civil government did not a little contribute. It is not improbable, that the church of Jerusalem, when it became numerous, and was deprived of the ministry of the apostles, who were gone to instruct the other nations, was the first which chose a presbyter or bishop; nor is it less probable, that the other churches followed by degrees this example.

The first ancient author who mentions bishop, presbyter, and deacon, as three distinct orders in the church, is, as we have already observed, Ignatius, who is supposed to have written about the 16th year of the second century. But as several of the epistles addressed to him, are_ipiurious, no great reliance can be laid upon his authority. However, he seems, with peculiar earnestness, to inculcate obedience and submission to the bishop, as well as to the presbyters and deacons. Mr. Dodwell accounts for his zeal in establishing the bishop's authority, by supposing that it was at that time a new thing, totally unknown in the church; and, according to this opinion, he says, that it is in vain to look for any trace of episcopal authority in the New Testament. Ireneaus, who is supposed to have written about the middle of the second century, sometimes uses the words bishop and presbyter indiscriminately, and at other times with some kind of distinction; but it is not easy to determine, whether by these two appellations he means the same order, or two different orders. Dr. Pearson admits that these names are often interchanged by this father, and others of his time, even to the end of the century; but he affirms at the same time, that in regard to their own contemporaries, the offices of individuals are never thus confounded, insomuch that a person, who was in their time a bishop, is not called a presbyter, nor is a presbyter called a bishop. It is allowed, that the distinction of these orders began about this time generally to prevail, though the difference was not nearly so considerable as it became afterwards. Another author, by whom the three orders seem to be discriminated, and whose testimony is commonly adduced in support of their apolitical institution, is Pius, bishop of Rome, who is supposed to have written before the middle of the second century, but after Ignatius and Polycarp: he uses an expression, however, which does not indicate any high opinion of the superiority of the bishop in his time; "Let the presbyters and deacons reverence thee (the bishop), not as their superior, but as Christ's minister." Clement of Alexandria, at the close of the second century (see his Strom. i. 11.), strongly marks the distinction between presbyter and deacon; but he seems to intimate, that the distinction between bishop and presbyter was, even in his days, comparatively not worthy of his notice. At this time, however, every church had its own presbyter, or bishop, and only one under this appellation, and every church had only one congregation or church. Sir Peter, afterwards lord, King (ubi infra) has proved these assertions by a variety of citations from ancient writers; he has also shown, that a bishop's diocese did not exceed the bounds of a modern parish. See Diocese. The presbyters, according to this writer, were the curates and assistants of the bishop, and though inferior to them in degree, yet they had the same inherent right with the bishop, and were equal to them in order. "A bishop," says this author, "prached, baptized, and confirmed, so did a presbyter; a bishop excommunicated, abdolved, and ordained, so did a presbyter; whatever a bishop did, the same did a presbyter; the particular acts of their office were the same." In the age of Cyprian, about the middle of the third century, it appears that the presbyters were considered as vested with the power of conferring orders. (Cyp. Epist. 5. and 75.) In the age of Hilary, about the middle of the fourth century, it appears, that the whole distinction of the episcopate is ascribed to him to severity in the ministry, without either election or special ordination. When the bishop died, the senior colleague succeeded of course. As to ordination, it was the same in both; and bishop meant no more than first among the presbyters, or senior presbyter. Jerome, who wrote about the end of the fourth and beginning of the fifth century, says (In Titum. 1. 5. Op. vol. x. p. 1700.) that, among the ancients, priests and bishops were the same; but that by degrees the care of a church was assigned to one person, in order to prevent dissension. In another place (Op. vol. vi. p. 198.) he says, "Let the bishops know, that they are above priests more by cullom than by the appointment of Christ." He also observes (Aeneedotes, p. 24. 54.) that at the beginning, churches were governed by the common council of presbyters, like an aristocracy; but afterwards the superintendence was given to one of the presbyters,
presbyters, who was then called the bishop, and who governed the church, but still with the council of the prelates. Dr. Hammond (Annot. Acts xi. 30.) has advanced a singular opinion, viz. that the apostles instituted only the offices of bishop and deacon, and that the intermediate office of preboster was soon afterwards introduced. But that such a middle order should be erected at once, immediately after the times of the apostles, is much more unlikely, than that it arose gradually out of an inconceivable distinction, which had obtained from the beginning.

At the close of the third century, the ecclesiastical government, which very generally prevailed, was of that kind which might justly be denominated a patriarchal episcopacy. The bishop, who was properly the pastor, had the charge of a single parish; and the presbyters assembled for the purposes of public worship, and for the celebration of religious ceremonies, in one place, at which the bishop commonly presided; the bishop was assisted by prebosters, who formed his council in judicial and deliberative matters, and who performed religious functions both public and private. To these were added deacons. See Deacon. The next step was the extension of the oversight of one bishop to many congregations, which clustered out of the original church by an accession of converts; and in this stage of the progress of episcopacy, the several prebosters had their separate parishes, and continued in subordination to the bishop, who was acknowledged as their common head. At this period, an order of bishops, called episcopi, or rural bishops (i.e. Chorâbiscopâe), held the middle rank between bishops and prebosters, being inferior to the former, and superior to the latter. This state of the church may be denominated dioecesan episcopacy.

Though bishops, in the opinion of those whose sentiments we are now representing, were originally no other than prebosters; the manner of their ordination being the same, and the prebosters discharging every part of the office of a bishop; no sooner was the distinction between them established, than the bishops began to appropriate certain functions to themselves. It appears, by the act of the third council of Carthage, A.D. 397, that, whereas, before, priests had the power of laying the time of public penance, and of giving absolution, as also of consecrating virgins, and of making the chrism, without the advice of the bishop, all these things were forbidden by these canons, and appropriated to the bishops. But the principal circumstance by which the bishops were afterwards distinguished was the power of confirming the baptized, when that chrism was applied. See Confirmation. After the reign of Adrian, when Jerusalem was utterly destroyed, and the Jews dispersed, an opinion began to prevail among Christian, that their ministers succeeded to the characters, rights, and privileges of the Jewish priesthood; and this was another source of honour and profit to the clergy. Another circumstance, which contributed no small degree to the progress of episcopal authority, was the constitution of provincial councils, which infamibly superceded the importance of particular churches, and enabled the bishops by an alliance with them to obtain a much larger share of executive and arbitrary power. As soon as they became connected by a sense of their common interest, they were empowered to attack, with united vigour, the original rights of their clergy and people. "The prelates of the third century," says Gibbon (Hist. vol. ii. p. 335, &c.), "imperceptibly changed the language of exhortation into that of command, attended the debates of future legislation, and furnished, by frequent allegories and declamatory rhetoric, their deficiency of force and reason. They exalted the unity and power of the church, as it was represented in the episcopal office, of which every bishop enjoyed an equal and undivided portion. Princes and magistrates, it was often repeated, might build an earthly claim to a transitory dominion; it was the episcopal authority alone, which was derived from the deity, and extended itself over this and another world. The bishops were the viceregent of Christ, the successors of the apostles, and the myrtle fructes of the high priest of the Mosaic law. Their exclusive privilege of conferring the sacerdotal character, invaded the freedom of clerical and popular elections; and if, in the administration of the church, they still consulted the judgment of the prebosters, or the inclination of the people, they most carefully inculcated the merit of such a voluntary consecration. The bishops acknowledged the supreme authority which refixed in the assembly of their brethren; but in the government of his peculiar diocese, each of them excepted from bis Lucet, the fame implicit obedience as if that favourite metaphor had been literally just, and as if the shepherd had been of a more exalted nature than that of his sheep." The same cause, which at first had destroyed the equality of the prebosters, introduced among the bishops a pre-eminence of rank, and from thence a superiority of jurisdiction. In spring and autumn, when they met in provincial synod, the multitude was governed by the wisdom and eloquence of a few; and, besides, the office of perpetual presidents in the councils of each province, was conferred on the bishops of the principal city; and these aspiring prelates, who soon acquired the lofty titles of metropolitans and primates, secretly prepared themselves to usurp over their episcopal brethren the fame authority which the bishops had so lately assumed above the college of prebosters. Hence gradually arose the pre-eminence which the ambition of the Roman pontiff gained over the other provinces and churches. King's Constitution, &c. of the Primitive Church, ch. i.—v. Campbell's Eccl. Hist. vol. ii. Mohl. Eccl. Hist. vol. i. p. 104, &c. Ncal's Eccl. Purit. vol. i. p. 676, &c. 4to. Pierce's Vindication.

It is the opinion of many approved writers on this subject, among whom may be reckoned many episcopalian and dissenters in our own country, and many learned foreigners, that no particular form of church government was authoritatively preferred either by our Lord or his apostles; but that Christians were left at liberty to choose such as might be best adapted to their circumstances and to the state of society, and most conducive to the edification and tranquility of the church, and of individuals in future ages. See Church. When new occasions required new measures, in a little time the functions of the priesthood were divided, and the priests distinguished into degrees; the political part of religion being assigned principally to bishops, and the evangelical to the priests, &c. or rather, as some will have it, the functions of teaching and preaching were reserved to the bishop, and that of ordination superadded; which was their principal distinction, and the mark of their sovereignty in their diocese.

By the ancient discipline, bishops were to be married once, and not to put away their wives on pretence of religion; but a second marriage was a disqualification for this order. If they lived chastely, they were ranked as confessors. Some bishops in the middle age, on account of their regalia, or temporalities, were obliged to a military service called habitation, by which they were to lead their Knights into the field, and attend in arms in his military expeditions. This Christermagne executed, and even forbade; but the prohibition was little regarded, since we find the thing often practised afterwards. Du Cange.

The election of bishops was anciently placed in the clergy.
and the people of the parish, province, or diocese, or of the clergy and laity, as they were afterwards called; nor did any church apply to the neighbouring bishops to assist at the ordination. Brunsus was ordained by prelats only; and such was the general custom of the church of Alexandria, till the beginning of the fourth century. Cyprian also saw, that it belonged to the people chiefly to choose worthy patrons, and to refuse the unworthy. Thus Alexander was chosen bishop of Jerusalem, Fabianus and Cornelius of Rome, and Cyprian of Carthage. When the people had thus elected a bishop, they presented him to the neighbouring bishops for their approbation and consent: because, without their concurrent assent, no bishop could be legally instituted, or confirmed. This was the case with regard to Alexander, already mentioned, and Fabianus, bishop of Emerita in Spain. After election and confirmation, the next act was the ordination or instalment of the bishop, which was done in his own church by the neighbouring bishops, who were invited to attend on the occasion. The attitude of the neighbouring bishops, which seems to have been at first voluntary on both sides, became customary, and at length necessary; and it was an established rule, that the concurrence of these was indispensable, one of whom laid his hand on the head of the new bishop, when he was recommended by prayer to the blessing of God. In the third century, this was always done by the metropolitan bishop; or at least it was never done without his consent or order. The second council of Nice ordered that bishops should be chosen by other bishops; but in the west, the people preferred the right of choosing their bishops, till after the reign of Charlemagne and his sons; and it was not taken from them till the council of Aixovion, in 1050. Bahnage Hist. Eglises Reformées, vol. iii. p. 24.

Under the plea of the tumult that attended popular elections, the emperors, and other sovereigns of Europe, took the appointment in some degree into their own hands; referring to themselves the right of confirming these elections, and of granting investiture of the temporalities, without which confirmation and investiture, the elected bishop could neither be consecrated, nor receive any fevlar prts. This right was acknowledged in the island of Carbon, Adrian 1. and the council of Lateran, and universally exercised by other Christian princes; but the policy of the court of Rome contrived to exclude the laity from any share in these elections, and to confine them wholly to the clergy; but the mere form of election appeared to the people to be of little consequence, while the crown was in possession of an absolute negative, which was almost equivalent to a direct right of nomination. Indeed, princes and magistrates, patriarchs and popes, have usurped the power of electing bishops. The election was to be within three months after the vacancy of the fee; and the perfon to be chosen out of the clergy of that church. Formerly the bishop claimed a share in the election of an archbishop; but this was set aside by the popes.

In England, during the Saxon times, the right of apponting to bishoprics is said to have been in the crown, because the rights of confirmation and investiture were, in effect, though not in form, a right of complete donation. But when, by length of time, the custom of making elections by the clergy was fully established, the popes begun to the usual method of granting these investitures, which was "per annulam et baeclum," by the prince's delivering to the prelate a ring, and pastoral staff, or crozier; pretending that this was an encroachment on the church's authority, and an attempt by these symbols to confer a spiritual jurisdiction; and pope Gregory VII. about the close of the 11th century, published a bull of excommunication against all princes who should dare to confer investitures, and all prelates who should venture to receive them. At length, however, when the emperor Henry V. agreed to remove all suspicion of encroachment on the spiritual character by conferring investitures for the future "per feeprum" and not "per annulam et baeclum," and when the kings of England and France consented also to alter the form in their kingdoms, and receive only homage from the bishops for their temporalities, instead of investing them by the ring and crozier; the court of Rome found it prudent to suspend for a while its other pretenions. This concession was obtained from king Henry I. in England, by means of that obdurate and arrogant prelate archbishop Anselm; but king John, about a century afterwards, in order to obtain the protection of the pope against his discontented barons, was also prevailed upon to give up by a charter, to all the monasteries and cathedrals in the kingdom, the free right of electing their prelates, whether abbots or bishops; referring only to the crown the custody of the temporalities during the vacancy; the form of granting a licence to elect, which is the original of our "congregatio," on refusal whereof the electors might proceed without it; and the right of approbation afterwards, which was not to be denied without a reasonable and lawful cause. This grant was expressly recognized and confirmed in king John's Magna Charta, and was again established by fl. 25 Edw. III. B. 8. § 3. But by fl. 25 Hen. VIII. cap. 25. the ancient right of nomination was, in effect, restored to the crown. The English succession of prelate bishops stands on this last ground. The king being certified of the death of a bishop by the dean and chapter, and his leave requested to elect another, the "congregatio," or usual licence, is sent to them, with a letter millave, nominating the person whom he would have chosen. The election is to be within twelve days after the receipt of it, otherwise the king by letters patent appoints whom he pleases; and the chapter, in case of refusing the person named by the king, incurs a prenunire. The election, or nomination, if be of a bishop, must be dignified by the king's letters patent to the archbishop of the province; if it be of an archbishop, to the other archbishop and two bishops, or to four bishops; requiring them to confirm, invest, and consecrate the person to elected; which they are bound to perform immediately, without any reference to the fee of Rome. If such archbishop, or bishops, refuse to confirm, invest, and consecrate such bishop elect, they shall incur all the penalties of a prenunire. After election, and its being accepted of by the bishop, the king grants a mandate under the great seal for confirmation, which the archbishop consigns to his vicar-general, confining mostly in a solemn citation of such as have any objections to the bishop elect, a declaration of their continuancy in not appearing, and an administration of the oath of allegiance and supremacy, of limony, and canonical obedience. Sentence being read by the vicar-general, the bishop is installed in the province of Canterbury by the archdeacon: the act is recorded by a public notary; and the bishop is invested with full powers to exercise all spiritual jurisdictions, though he cannot sue for his temporalities till after consecration. Then follows the consecration by the archbishop, or some other bishop appointed by lawful commissions, and two assistent bishops; the ceremony of which is much the same as in the Roman church, except that, having put on the episcopal robe, the archbishop and bishops lay their hands on the new prelate's head, and consecrate him with a certain form of words. The fees of the whole process are paid to amount to about 600l.

The process of the translation of a bishop to another bishopric
BIS

BIS

The age of a bishop is to be at least thirty years; and, by
the ancient discipline, none were to be elected but those
who had passed through all the inferior orders; but, in
some cases of necessity, this was dispensed with, and de-
cans, by anamnesis, were raised per faltet to the episcopal
dignity.

The form of consecrating a bishop is different in different
churches. Ordinarily, at least three bishops are required in
the ceremony of consecrating a bishop: but, in some
cases a single one might suffice. In the Greek church,
the candidate for the episcopate, who always an archim-
drite, becomes, as it were, a rabbi or chief man in a
monastery, being named to the vacant see, and the election
being confirmed, repair, at the time appointed, to the
church where the consecration is to be performed. Being
arrived, he is introduced by the proto-pope and proto-
deanon to the archbishop and bishops, who are arranged in
proper order on a temporary theatre or platform erected in
the church for the occasion. He there gives an account of
his faith; declares solemnly that he has neither given nor
promised money, or any bribe-worthy service, for his dignity;
and promises to adhere, steadfastly to the traditions and canons
of the eastern church, to visit his diocese regularly, and to
oppose strenuously all innovations and herefies, particularly
the errors of the Latin church. This being done, the arch-
bishop says, "The grace of the Holy Spirit, through my
humility, exalts thee N. archimandrite or hieromonachus,
beloved of God, to be bishop of the cities N. N. which God
prefereth." With much ceremony the bishop elect is then
conducted from the theatre, within the rails of the holy
tap, where he kneels down with the other bishops, who hold
open over his head the holy gospel with the letters
inverted, the archbishop faying aloud, "The divine grace,
which always healeth our infirmities, and supplieth our de-
fects, by my hand consecuteth thee N. archimandrite or hi-
eromonachus, beloved of God, bishop elect of the cities of
N. N. which God prefereth. Let us pray therefore for
him, that the grace of the most Holy Spirit may come upon
him." Then the priests say thrice, "Lord have mercy
upon us," and while the bishops continue to hold the gos-
pel, the archbishop signs the newly consecrated bishop thrice
with the sign of the cross, saying, "In the name of the Fa-
ther, and of the Son, and of the Holy Ghost, now and for ever,
even unto ages of ages. Amen." Then all the bishops putting
their right hands on his head, the archbishop prays that he
may be confirmed in the office of which they have judged him
worthy, that his priesthood may be rendered irreproachable,
and that he himself may be made holy and worthy to be
heard of God. After this, one of the assistings bishops
reads a short litany in a low voice, to be heard only by
those within the altar, and the other bishops make the re-
sponses. At the end of the litany, the archbishop, laying
his hand again upon the head of the newly consecrated
bishop, prays in very decent and devout terms, that Christ
will render him an imitator of himself, the true shepherd;
that he will make him a leader of the blind, a light to
those who walk in darkness, and a teacher of infants; that
he may shine in the world, and receive at last the great re-
ward prepared for those who contend boldly for the preach-
ing of the gospel. After this the pastoral staff is delivered
to the new bishop, with a very proper-and solemn exhorta-
tion from the archbishop, to feed the flock of Christ com-
mited to his care. King's Rites and Ceremonies of the
Gome of thsprirualist.

In the Roman church, the bishop elect being presented
by the elder assistat to the consecration, takes the oath:

he is then examined as to his faith; and after several prayers,
the New Testament is drawn over his head, and he receives
the chrism or unction on his head. The pastoral staff,
ring, and Gospel, are then given him; and after con-
secration, the mitre is put on his head: each ceremony being
accompanied with proper prayers, &c. the consecration ends
with the Doxom.

The last mentioned ceremonies are laid aside in the con-
secration of English bishops. Nevertheless, the book of
consecration, composed by the bishops, and approved by
Edward VI. in the third year of his reign, and, two years
afterwards, confirmed by act of parliament, in which some
of them are enjoined, is declared to be of no authority for
this purpose by the thirty-sixth article. In queen Mary's reign
this act was repealed, and the book of common prayer, and
the book of ordination, were by name condemned. When
Elizabeth came to the throne, queen Mary's act was re-
pealed, and king Edward's, prayer-book was again au-
thorized; but the book of ordination was not expressly named,
because it had been a part of the common prayer book; and
therefore it was not thought necessary to specify the office
of ordination any more than any other office of the common
prayer book. But bishop Bonner contended, that as the
book of ordination had been by name condemned in queen
Mary's reign, and had not been since revived by name, it
was still condemned in law; and, consequently, that all or-
dinations conferred according to that form, were illegal and
invalid. To obviate this objection, it was declared in a sub-
frequent feition of parliament, that the office of ordination
was considered as part of the common prayer book; and it
was farther declared, that all ordinations which had been
performed according to that office, were valid; and upon
the same principle a similar clause was inserted in the 35th
article.

The function of a bishop in England may be considered
as two-fold; viz: what belongs to his order, and what be-
longs to his jurisdiction. To the episcopal order belong the
ceremonies of dedication, confirmation, and ordination;
to the episcopal jurisdiction, by the statute law, belong the
licensing of physicians, surgeons, and alchoholitters, the unit-
ing small parishes (though this last privilege is now given
only to the bishop of Norwich), affixing the civil magistrate
in the execution of statutes relating to ecclesiastical matters,
and compelling the payment of tithes and subsidies due from
the clergy.

By the common law, the bishop is to certify the judges,
touching legitimate and illegitimate births and marriages;
and by that and the ecclesiastical law, he is to take care of
the probate of wills, and granting administrations: to col-
lrate to benefices, grant inquisition on the presentation of
other patrons, command induction, order the collecting and
preferring the privates of vacant benefices for the use of the
successors, defend the liberties of the church, and visit his
dioceze once in three years. To the bishop also belong sub-
pension, deprivation, deposition, disintegration, and excom-
uncation.

The bishops of England are all barons: barons in a three-
fold manner: viz. feodals, in regard of lands and baronies
annexed to their bishoprics; by virtus, as being furnished
by writ to parliament; and also by patent and creation.
When William the conqueror thought proper to change the
spiritual tenure of frank-alms, or five silver, under which
the bishops held their lands during the Saxon government,
the bishop of London, or New-bishop; their estates were
subjected to all civil changes and alterations in which they
were before exempt; and, in right of succession to those baronies, which were unalienable from their res-
peive
precise dignities, the bishops and abbots were allowed their seats in the house of lords. But though these lords spiritual are, in the eye of the law, a distinct estate from the lords temporal, and are so distinguished in most of our acts of parliament, yet in practice they are usually blended together under one name of "the lords," they intermix in their votes; and the majority of such intermixtures joins both estates. And from this want of a separata and separate interest, four justices have argued very cogently, that the lords spiritual and temporal are now in reality only one estate; which is unquestionably true in every effectual sense, though the ancient distinction between them still nominally continues. For if a bill should pass their house, there is no doubt of its validity, though every lord spiritual should vote against it, of which Selden and Sir Edward Coke give many instances; as, on the other hand, judge Blackstone presumes it would be equally good, if the lords temporal present were inferior to the bishops in number, and every one of those temporal lords gave his vote to reject the bill; though Sir Edward Coke seems to doubt, whether this would not be an "ordinance," rather than an "act," of parliament. Bl. Com. vol. i. 156. Bishops have the precedence of all other barons, and sit in the upper house as barons. They are twenty-four in number, exclusive of the bishop of Sodor and Man, who has no seat in the house of peers. Their right is derived from the titles of "Grace," and "Most reverend father in God by divine Providence," and bishops, by the titles of "Lord," and "Right reverend father in God by divine permission." The former are said to be "infronned," and the latter "installed." See Archbishop.

With respect to the order of precedence among one another, the archbishop of Canterbury takes the lead, then the archbishop of York, next to him the bishops of London, of Durham, and of Winchester. The other bishops follow according to the seniority of their consecration; excepting only, that a bishop being a privy councilor, takes place after the bishop of Durham.

Bishops have two special privileges next to regal: the first, that in their courts they sit, and pass sentences, of themselves, and by their own authority; the bishops' courts being not like other courts, but writs are sent out in their own name, to the bishop, not in the king's name, as is done in the king's courts: the second, that, like the king, they can depose their authority to another, as their full-grown chancellor, commissary, &c.

They have this advantage also over lay-lords, that, in whatever Christian country they are, their episcopal degree and dignity are acknowledged; and they may, ex quo rebus, ordain, &c.

They have several immunities, as from arrest, outlawries, disfrife, &c., liberty to hunt in the king's forests, &c., to have certain tuns of wine duty free, &c. Their persons may not be seised, as lay-peers may, upon contemn, but their temporalities alone. They may qualify as many chaplains as a duke, viz. fix. But, as they have no right to be tried themselves in the court of the lord high warden, as peers, they ought not to be judges there. For, though they are lords of parliament, and sit there by virtue of the baronies, which they hold "jure ecclesiae," yet they are not ennobled in blood, and co-sequently not peers with the nobility, but merely lords of parliament. 3 H. 35. 30. 31. Staunf. P. C. 153. In cases of capital offence, the bishops usually withdraw voluntarily, but enter a protest, declaring their right to sit and vote. It is observable, that in the 18th chapter of the constitutions of Clarendon, made in parliament in Henry II. they are expressly exceded, rather than excluded, from sitting or voting in trials, when they come to concern life or limb. The determination of the house of lords in the case of Danby's cafe, (Lords' Journ. 15 May, 1671,) which hath ever since been adhered to, is consonant to these constitutions, "that the lords spiritual have a right to sit and vote in court in capital cases, till the court proceeds to the vote of guilty, or not." This resolution, however, extends only to trials in full parliament; for to the court of the lord high steward, in which no vote can be given, but merely that of guilty, or not guilty, no bishop, as such, ever was or could be summoned: and though the statute of king William regulates the proceedings in that court, as well as in the court of parliament, yet it never intended to model or alter its constitution, and consequently does not give the lords spiritual any right in cases of blood which they had not before; and their exclusion is more reasonable, because having no right to be tried in this court, as we have already said, they ought not to be judges there.

By law, the crime of episcopate, which a clergyman commits by killing his bishop, is petty treason.

In Canada there is a bishop, resident at Quebec; and there are two bishops in America. In Denmark they have no archbishop, but they have two superintendents, or bishops, four in Norway, and two in Iceland. The chief fee is that of Zealand, which yields about 1000L. a year; the others are the bishop of Funen, valued at 760L., Aarhus at 600L., Odsher at 400L., Ripan at 400L.; in Norway, Christiana or Aggerhus at 400L., Christianland at 400L., Berghen at 400L., and Drondheim at 400L. The bishoprics of Skalthold and Holan, in Iceland, are only valued each at 150L.; but though far inferior in nominal value to the others, they may be considered, on account of the clergy, of living in Iceland, equal in real profit to the largest of the others. The bishop of Zealand, who is first in rank, and the bishop of Aggerhus, are metropolitan. They have no temporalities; keep no ecclesiastical courts; have no cathedrals or prebends, &c., but are only primi inter pares, having the rank above the inferior clergy of the province, and inspection over their doctrine and manners. They are allowed two or three parishes each. Their habit is common with that of the other ministers. In Sweden there are fourteen dioceses; the archbishopric of Upsala, and the bishoprics of Linkoping, Skara, Strangemug, Wettera, Wexin, Abe, Lund, Bor- go, Gottheborg, Calmar, Castlet, Hermundal, and Wilby, or Gothland. The revenues of Upsala and Wettera amount to about 1000L. a year; and those of the lowest bishoprics to 300L. There are also three superintendents, who rank as bishops, but do not sit in the house; these are the first chaplains to the king, the recter of St. Nicholas at Stockholm, and the first chaplain of the navy. The bishops are bound to reside, except during the meeting of the diet. A convocation of the clergy of the diocese elects the archbishop and bishops, by presenting them to the king for his nomination. They have also ecclesiastical courts, &c.

Bishop-Abbot, episcopus abbas, was an abbot invested with the episcopal order; of which we meet with several in the richer and more considerable monasteries.

Bishop, accephalus, he who is immediately subject to the papal see, without any metropolitan over him.

Bishop, boy. It was an ancient custom in many churches as had cathedral service, for the little choristers, on St. Nicholas' day, December the 6th, to elect one of their number to be the episcopus puereum, the bear, i.e. infant, or chorister bishop; who continued to preside over the reli, with an imitation of all the episcopal functions, till Innocent's Day, Dec. 28, and then, after solemn processions and great pagentry, he laid down his office. He was chosen
chosen on St. Nicholas day, because St. Nicholas was the patron saint of children; he having, when an infant, shown such singular piety, as the legend says, that when he was at his mother's breast, he would not suck on Wednesdays and Fridays, that he might observe the fasts of the church.

The ceremonies attending the investiture of the episcopus puerorum, are preferred by the statutes of the church of Sarum, which contain a title de episco puerorum; and also by the proxional. From thence it appears, that he was to bear the name and title of a bishop, habited, with a crozier or pastoral staff in his hand, and a mitre on his head. His fellows, the rest of the children of the choir, were to take upon them the dyle and office of prebendaries, and yield to the bishop canonical obedience; and further, the fame service as the very bishop himself, with his dean and prebendaries, had they been to officiate, were to have performed, the very same, mass excepted, was done by the choristers and his canons upon the eve and the holiday. The use of Sarum required also, that upon the eve of Innocent's day, the chorister bishop, with his fellows, should go in solemn procession to the altar of the Holy Trinity, in cope, and with burning tapers in their hands; and that during the procession, three of the boys should sing certain hymns mentioned in the rubric. The procession was made through the great door at the west end of the church, in such order, that the dean and canons went foremost, the chaplain next, and the bishop, with his little prebendaries, last; agreeably to that rule in the ordering of all processions, which affigns the rearward fraction to the most honourable. In the choir was a seat or throne for the bishop; and as to the rest of the children, they were disposed on each side of the choir, upon the uttermost afcent. And so careful was the church to prevent any disorder which the rude curiosity of the multitude might occasion in the celebration of this singular ceremony, that its statutes forbid all persons whatsoever, under pain of the greatest excommunication, to interrupt or press upon the children, either in the procession or during any part of the service directed by the rubric; or any way to hinder or interrupt them in the execution or performance of what it concerned them to do. Further it appears, that this infant-bishop did, to a certain limit, receive to his own use, rents, episcop and other emoluments of the church; so far as the little bishop died within the mean, his executors were sollemnized with great pomp; and he was interred, like other bishops, with all his ornaments. The memory of this cultum is preserved, not only in the ritual books of the cathedral church of Salisbury, but by a monument in the fame church, with the sepulchral effigies of a chorister bishop, suppos'd to have died in the exercise of his pontifical office, and to have been interred with the solemnities above noted.

From what period we are to date the progress of this ridiculous ceremony, it is not easy to discover, but it seems more than probable that it originated with the ancient Mysteries. In the wardrobe account of Edward I, published by the society of antiquaries, we find a boy-bishop, Dec. 7, 1290, paying vespers before the king, in his chapel at Heteron near Newcastle upon Tyne, for which he, and the boys who sung with him, received 40s.

This establishment, but with a far greater degree of bussouery, was common in the collegiate churches of France. (See Dom. Marbot. Histoire de la Metropole de Rheims, tom. ii. p. 769.) A part of the ceremony in the church of Noyon was, that the children of the choir should celebrate the whole service on St. Innocent's day. (Brillon. Dictionnaire des Arrêts, art. Noyon. ed. 1727.) In a curious book, called Voyages Liturgiques de France (Par. 8vo. 1718, p. 33.) is this account of the same practice in the church of Vicence in Dauphiny. "Le jour de Noël après Vespres, le jour de St. Etienne, et le jour de St. Jean l'Evangeliste, on faisait des processions solennelles pour les diacres, les pretres, et les enfants de Chazzor, comme autrefois à Rouen. Il y avait aussi le lendemain a la maffe solennelle pour eux. Les enfants de Chazzor y avaient leur Petit Evêque, qui faisait tout l'office, excepté a la misse. And in the statutes of the archiепiscopal cathedral of Tulle, given in the year 1497, it is laid, that during the celebration of the festival of the boy-bishop, "Miracles were pretended, and flown of miracles, with faces and other parts, but compatible with decorum. After dinner they exhibited, without their masks, but in proper defries, such faces as they were masters of, in different parts of the city." In England too it appears, that the boy-bishop, with his companions, went about to different parts of the town; at least visited the other religious houses. (See the Comptus Rolls ofWinchester College, A.D. 1461.) And Strype records (Ecclef. Memo¬rials, iii. 316. ch. XXXXI, and p. 387. ch. 1.), that when this, among other ancient ceremonies, was restored by queen Mary, in 1556, "on St. Nicholas's even, saint Nicholas, that is, a boy habited like a bishop in pontificalibus, went abroad in most parts of London, singing after the old fashion, and was received with many ignorant but well disposed people into their houses, and had as much good cheer as ever was wont to be had before."

In the statutes of Eton college, given in 1441, the episcopus puerorum is ordered to perform divine service on St. Nicholas's day; and in those of Winchester college, 1580, pueri, that is, the boy-bishop, and his fellows, are permitted on Innocent's day to execute all the sacred offices in the chapel, according to the use of the church of Sarum. A similar clause to that at Eton occurs in the statutes of King's college, Cambridge; and Mr. Warton observes, in his history of Poetry, that the anniversary cultum at Eton of going ad matrem originated from the ancient and popular practice here described.

In a small college, for only one provost, five fellows, and five choristers, founded by archbishop Rotheram in 1481, in the obscure village of Rotheram, in Yorkshire, this piece of mummer"y was not omitted. The founder leaves by will, among other bequests to the college, a miter for the bapteh bishop of cloth of gold, with two knopps of silver, gilt and embossed. (Hearn's Liber Niger Sacae. Append. 657—658.)

From the passage already quoted from the Voyages Liturgiques de France, it appears that, at least in one church, the missa was not allowed to be celebrated by the boy-bishop; and it is also expressly prohibited in the use of Sarum: but other and more frequent incursions occur where the bussouery was carried even to this height. In a fragment of the cellarers Computus of Hyde Abbey near Winchelter, A.D. 1597, we have a charge "pro epulis pueri celebrantis in cello Sancti Nicolai," and so late even as the reign of Henry VIII. we find the same ceremony at St. Paul's. It is surprising that Dean Coxe, a friend to the purity of religion, and who had the good sense and resolution to censure the superfluous and lopopies of popery in his public sermons, should countenance this idle farce of the boy-bishop in the statutes of his school at St. Paul's, which he founded with a view of establishing the education of youth on a more rational and liberal plan than had yet been known, in the year 1512. He expressly orders, that his scholars "shall every Childermans (that is Innocent's) day, come to Pauli's church, and hear the child-bishop's (of St. Paul's cathedral) sermon.
BIS

Bishops, regiuary. See Regionary.

Bishops, rural. See CHORIPHESUS.

Bishops, suffragan. are coadjutors or affiliates of dioce- 
cesan bishops, authorized by commission from them.

Bishops, vacant, those without any diocese, sometimes 
attendant on camps, or in foreign countries, for the con-
version of infidels. The hagio-bishops were sometimes 
also granted by popes to missionaries, exempt from the 
jurisdiction of the diocesan, where they performed all the episco-
pal functions. Dn-Cange.

Bishop, universal, or catholic, is a title given to the pa-
triarch of Armenia.

Bishop of the catholic or universal church, a title some-
times assumed by the popes.

Bishop of Lydia, was a title anciently given to the pre-
lates of some of the greater and more honourable sees, as 
Jerusalem and Rome. The first who had the title was 
James, bishop of Jerusalem. Some will have the appellation 
to have been common to all bishops.

Bishops, in the Lutheran Church, are those more usu-
ally called superintendents, which see.

The Calvinists allow of no other bishops besides presbyters; 
but the Lutherans make some distinction, and give a superi-
ority or pre-eminence over the rest of their "bishops," "su-
perintendents," or "overseers."

Bishop is also a quality sometimes attributed to secular 
princes, in respect of their supremacy or jurisdiction in mat-
ters belonging to religion. See SUPREMACY. In this sense 
it is that the emperor Constantine, in a letter to the bishops 
in his dominions, calls himself "common bishop," as being 
in some respects general bishop of the whole Roman 
world.

Bishop of the Jews, the head of that people in Eng-
land, chosen by themselves, to whom they inhumed to be 
judged and governed according to their law. Pridexus' 
Connect. part i. lib. v. p. 458. This officer, which sub-
sumed under our Norman kings, and was licenced by them, 
was adhered to the ECHMAC/ARCHES in Babylon, and the 
ALABARCHES in Egypt.

Bishops, at chief, a kind of pieces, the third in rank, 
below queens, but above knights, distinguished by their 
clover heads. In Latin writers of the middle age, the 
bishop is called alphibius; and by the French le fou, the fool 
or madman. See CHESS.

Bishop's Court. See COURT.

Bishop's see, or seat, originally denoted the throne or 
chair in the church where the bishop sat. It was also deno-
minted APESIS.

Bishop's see also denotes the city or place where the re-
flection of the see is fixed.

Every bishop's see was anciently called "feudes apofo-
lie;" though the appellation has since been restrained to 
the see of Rome.

Anciently bishops seem to have had a right in England to 
fit as judges in the hundred and county-courts. In after-
times, they were forbid to fit in secular courts, and had se-
parate courts created for them; which proved an occasion 
of much dispute between the two jurisdictions. No church 
tenant might be fined in any court but the bishop's. There 
are also traces of a separate court of the bishops much ear-
ier, among our Saxons ancestors in the eighth century. The 
regard borne to the character of bishops, made them the 
common arbitrators even of secular causes; they had the 
cognizance of all causes concerning lands in "frank-
land," and for ecclesiastics, were judges even in capital 
causes.

Bishop's wood, in Botany. See AMMI.
Bishop, Bird, in Ornithology. See Tanagra Episcopus.

Bishop and his Clerk, in Geography, a cluster of dangerous rocks, near the west coast of South Wales, at the entrance of St. George's channel, 3 miles west of St. David's. N. lat. 51° 54'. W. long. 5° 20'.

Bishop's Auckland. See Auckland.

Bishop's Castle, a market and borough town of Shropshire, in England, spreads its scattered houses over the site of a considerable caftle, at the base of which runs the small river Clun. This town is an old corporation, and made its first return to parliament in the 27th of Elizabeth. Previous to that period, it belonged to the see of Hereford, and derived its name from being one of the castles, or called mutiments, of the bishops. The corporation consists of a bailiff, recorder, and fifteen aldermen, who, with about thirty other inhabitants called burgesses, elect two members for the town. Here is a weekly market on Fridays, which is much frequented by the Welsh, as are its six annual fairs. At some of the latter a great quantity of sheep and pigs are sold. This town was formerly under the protection of a caftle, which is entirely destroyed. Bishop's castle is 156 feet, N.W. from London. It contains 241 houses, and 1276 inhabitants.

At Stour, about two miles and a half N.W. from Bishop's castle, a priory of black canons was founded in the time of Henry III., but was soon afterwards removed to Cherbury. This place, seated near the Severn, is supposèd to have been built by Ethelfleda, and was afterwards possessioned by the family of the Herberts, one of whom was created lord Herbert of Cherbury. This gentleman wrote an account of his own life, which has been published by Horace Walpole at his private press at Strawberry hill. Not far from this town, on the borders of Montgomeryshire, is an ancient encampment called bishop's moat; and at Clun are the remains of an ancient caftle, near which is a camp called berry-ditches. About three miles hence is Walford, the seat of lord Clive, who is patron of this borough. In the vicinity of Bishop's castle, are three lofty singular hills, respectively named Cardown-hill, Church-Stoke-hill, and Squifhar hill. At Moor Park is a respectable ancient monastery; the grounds are finely diversified, and abound with fine woods.

Bishop's Island, a small rocky island in Mal-bay, on the west coast of the county of Clare, in Ireland. N. lat. 52° 30'. W. long. 9° 35'. Beaufort.

Bishop's Stortford, a market town of Hertfordshire, in England, is placed on the side of a hill, near the western borders of Essex. Seated in the midst of a corn country, it is remarkable for its number of malt houses, and for the quantity of malt annually made here; this is distinguished by the name of brown malt, and is disposed of principally to the London brewers. It is conveyed to the metropolis in barges, by a navigable canal, which was cut in 1779, and which joins the river Lee, at about 14 miles distance from this town. Before this navigation was opened, the malt, which is now lodged here, was carried to Ware and Stansted, as the nearest places for water-carriage; but since the above period, Stortford has become the depot for the malt made in this town and the neighbouring villages.

This place was evidently of some note previous to the conquest, as it appears from the Domesday Survey, that the conqueror gave the town and caftle to Maurice, bishop of London. From this evidence it appears, that the caftle here, which bore the name of Waytemore, was standing prior to the Norman invasion, though some writers assert that it was erected by William. It was probably repaired and strengthened by him, but Mr. Salmon feems justly in the opinion, that it was constructed by the Eafter Saxons to defend their borders. The lands paying caftle-guard, lie between this place and the Ermine-street, one of the great Anglo-Roman roads. The hill, or keep, on which the caftle stood, is artifical, being evidently raised with earth brought from some distance. On the top was a wall, and a breakwork of flone and mortar. A bank of earth runs from the summit across the moorey ground to the north-east. “This caftle,” says Salmon, "must have been of some consequence in the time of king Stephen, because of the great sheriff Geoffrey de Magnaville had, either to be master of it, or to have it pulled down; and Mand the emprés engaged him to do one or t‘other.” The security derived from this fortification gave origin to the town, which had increased to some consequence in the time of king John, who created it a borough, and invited the inhabitants with certain corporate privileges. This monarch seized the caftle and town from W. de St. Maria, the bishop of London, who was one of the three bishops deputed to execute the pope's interdict upon England. This period was distinguished by the alarming jealousies and animosities between the king and the pope, with his prelates; and as Walpole expresses it, “the caftle, at Stortford, stands yet a monument of king John's power and revenge, and the Bishop's lands remain a monument of the pope's entire victory over him.” In the time of Edward III., the town and caftle, &c. again reverted to the bishop of London, in whose fee it still continues, and who appoints a bailiff for this liberty, which includes the town and thirteen contiguous parishes. The Bishop's prison was standing in bishop Bonner's time, but that and all the other old buildings have been since demolished.

The streets of the town are disposed in the form of a croq, with two long streets intersecting each other at right angles. Though no particular manufacture is carried on here, yet the town is respectable and populous; it contains 456 houses, and 2353 inhabitants. Here are a very considerable weekly market for grain, &c. on Thursdays, and three annual fairs, which are mostly appropriated to the sale of horses and cattle.

The church, dedicated to St. Michael, is a large lofty structure, and, like most buildings dedicated to that saint, stands on the highest ground in the neighbourhood. There were anciently three guilds and a charity endowed here; and in the choir are nine stalls on each side. The interior of this building is decorated with a number of monuments, some of which are ancient. The great tythes of the parish are in the hands of laymen. In the town are the meeting-houses for dissenters, methodists and quakers, also three almshouses, and a schoolhouse. The latter was built from a subscription among the gentlemen of Hertfordshire and Essex, who were invited to this act by Dr. Thomas Tooke. This gentleman was zealously indefatigable in promoting and establishing the foundation which has proved beneficial to the town, and highly honourable to its founder and patrons. The building stands on arches, beneath which is a space for market and shops. Dr. Tooke revived an annual school-festival here, and charged his own estate with an annual present to the preacher. He also gave a chalice of 20l. value to the church, and was a great benefactor to the school-library, which is a very good one, and was first established by the Rev. Thomas Leigh, who was vicar of the church in 1680, &c. Besides other donations to this library, it is customary for every gentleman to present a book at the time of leaving the school. Bishop's Stortford derives its compound name from being the property of the bishop of London at an early period, and from its situation on the banks of the river Stort, which separates it on the east from the hamlet
hand of Heckerrill. At a short distance north of this town is Hadham parva, which is noted for being the burial place of the Caesars, earls of Elinx. Bishop's Stortford is 50 miles north of London. Salmon's History of Hertfordshire.

Bishop's Waltham, a small town of Hampshire, in England, derives a part of its name from having been a seat of the bishops of Winchester. Some of their palace still remain at a small distance west of the town, and the seat now belongs to the fee. Lehant describes it as a sight ample and goodly manner place, noted about, and a pretty look in running hard by. It hath been of many bishops' building. The celebrated William of Wykeham, bishop of Winchester, resided here during the last three years of his life, and died in this manor, A. D. 1403, in the 58th year of his age. The house was partly demolished in the civil wars of Charles I. when bishop Kyrle was in possession. Bishop's Waltham is noted for its schools, both for gentlemen and ladies. It contains 151 houses, and 1773 inhabitants, and has three annual fairs.

About five miles south of the town is Wirksworth, a village rendered memorable from being the birth-place of the above-named bishop. See Wirksworth.

BISHOPIRICH, or BISHOPRIC, is a term probably derived from bishop, the name of a bishop-see, and denoting a trick of the dollars in horses; for making them appear younger than they are, with a view of imposing upon the purchaser.

This is done by excavating the corner tooth of the incisors with a steel graver or file, and afterwards blackening the cavity with a hot iron. This mark, or excavation, is deemed by many the criteria of age, and that the horse is young while this is preserved.

To avoid being imposed upon, the purchaser should consider the general figure, not only of the corner tooth, but of all the major teeth of the upper and lower jaw, for they all undergo a perpetual change of figure by age and wear.

An incisor tooth of the horse, at its first emerging from the jaw, has the visible part of it flat and covered every where with enamel; the outside sharp and projecting higher than the inside, with a conical cavity in the middle, of various depth in different horses, which renders it of not much value in deciding upon the age; in some it is so short as to be obliterated by the fifth year; in others it is so long as to be found till nine or ten, or later; it is, therefore, not a certain criterion of age: the general figure of the tooth is more to be depended upon in our estimation. The lateral width of the recent tooth, and its flatness, are very remarkable, and can never be imitated; as this wears away, the tooth daily increases in its transverse width, that is from front to back, and diminishes in its lateral width, forming, as the wear advances, nearly a triangle; these angles at length by age gradually disappear, and the tooth presents a rounded surface on its upper part, and at length the tooth becomes flattened on the sides and actually wider from front to back than from side to side. For it should be recollected, that the tooth is formed in its whole extent previous to its appearance externally, and that the jaw is absorbed, to allow of its wear: the enamel, like a shell, deriving the figure and boundary of the tooth, which hollow shell is afterwards filled up with bone. A transverse section, therefore, of the tooth, or a series of them at different distances from its point, afford the exact figures of the surfaces of the teeth at various periods of their wear, and allowing for contingencies which occasion the teeth to be worn with more or less rapidity, as in crib biters, &c. will afford the truest criterions of age, and render imposition in this way impracticable.

The teeth also they pretend, in some instances, to excavate on the inside, and to sharpen with a file; these bungling at ttempts, however, in no way resemble the natural markings or surface of the tooth, nor could impose upon any one the least experience in scrutinizing the teeth. For what we consider the best indications of the age of horses, however, we refer the reader to the article Teeth of Horses.

BISHOPIRICH; the jurisdiction of a bishop, or the district within which it is comprised, called also "diocese," which fee.

There are twenty-four bishoprics, and two archbishoprics, in England and Wales. To the old ones subjected before the times of the Reformation, Henry VIII., by letters patent added six more bishoprics; viz. those of Welfinfr, Chester, Gloucester, Peterborough, Bristol, and Oxford, Stat. 32 & 33 Hen. VIII. cap. 17. These fees were all founded in the course of the years 1540, 1541, and 1542.

The see of Welfinfr, having never had but one bishop, was united to that of London, and its bishop translated to Norwich, by Edward VI. in 1550. The remaining bishoprics are comprehended under two provinces, those of Canterbury and York. The province of Canterbury includes the following bishoprics, viz. 1. The bishopric of London, containing Essex, Middlesex, and part of Hertford, and extending its jurisdiction to the West Indies. 2. Winchester, comprehending Surry, Hampshire, and the isles of Wight, Jersey, Guernsey, and Alderney. 3. Litchfield and Coventry, to which belong Stafford, Derby, and part of Warwick and Shropshire. 4. Lincoln, comprehending Lincoln, Leicester, Huntingdon, Bedford, Buckingham, and part of Hertford. 5. Ely, containing Cambridge- shire, 6. Salisbury, to which belong Wilts and Berkshire. 7. Exeter, including Cornwall and Devon. 8. Bath and Wells, comprehending Somersetshire. 9. Chichester, to which belongs Sussex. 10. Norwich, containing Norfolk, Suffolk, and a small part of Cambridgeshire. 11. Worcester, comprehending Worcestcr and part of Warwick. 12. Hereford, including Hereford and part of Shropshire. 13. Rochester, to which belongs Kent. 14. Oxford, including Oxfordshire. 15. Peterborough, containing Northampton and Rutland. 16. Gloucester, comprehending Gloucestershire. 17. Bristol, to which belongs the city of Bristol, part of Gloucestershire, and the county of Dorset. 18. Landaff, comprehending Glamorgan, Monmouth, Brecknock, and Radnor. 19. St. David's, including Pembroke, Cardigan, and Caermarthen. 20. St. Asaph, containing the greatest part of Flint, Denbigh, and Montgomery, and some part of Shropshire. 21. Bangor, to which belong the counties of Anglesey, Caernarvon, Merioneth, and part of Denbigh and Montgomery. The province of York comprehends— 22. Durham, containing Durham and Northumberland. 23. Carlisle, including great part of Cumberland and Westmoreland. 24. Chelther, to which belong Cheshire, Lancashire, Richmondshire, which is part of York, together with part of Cumberland and Westmoreland. 25. Ilfe of Man. The value of these fees is not easily ascertained, as it is very different from that which is stated in the king's books. It is a certain fact, whatever may be the primary occasion of it, that the revenues of the bishoprics are very unequal in value, and that there is also a great inequality in the patronage appertaining to the different fees. Adverting to this circumstance, Dr. Watfon, the precent bishop of Landaff, addressed a "Letter to his Grace the Archbishop of Canterbury," printed in 1753, proposing a scheme for rendering the bishoprics more equal to each other, with respect to both income and patronage, by annexing part of the citates, and part of the prebendums, of the
the richer bishoprics, as they became vacant, to the poorer. The advantages, resulting from the accomplishment of this object, and excited by the learned prelate, are such as follow: The poorer bishoprics would thus be freed from the necessity of holding ecclesiastical preachers "in commendam" with their bishoprics; a practice, which bears hard upon the rights and expectations of the reft of the clergy; which is dilatable to the bishop's themselves; which exposes them to much, perhaps undeserved, obloquy; but which certainly had better not liabili in the church. The bishoprics would also thus acquire a greater independence in the house of lords; and the measure would contribute to reduce the influence of the crown in that house. This plan would likewise enure a longer adherence of the bishop's in their respective dioceles, as temptations to translations would be thus removed, and prelates would of course become more attached to their particular situations, gain a more intimate acquaintance with their clergy, and serve, by their doctrine and example, to produce the best effect in the conduct both of clergy and laity. See Augmentation.

In Ireland there are 18 bishoprics, and 4 archbishoprics. Under the archbishop of Armagh, the primatic, are the bishoprics of Meath, Kilmore and Ardagh, Dromore, Clogher, Raphoe, Down and Connor, and Derry. Under the archbishop of Dublin are Kildare, Ferns and Laughlin, and Ossory. Under the archbishop of Cashel are Waterford and Lismore, Limerick, Killaloe, Cork and Ros, and Cloyne. Under the archbishop of Tuam are Elphin, Clonyc, and Killala and Achonry. The primacy is established at 8000l. a year, Derry at 7000l, and the other bishoprics from 4000l. to 2000l. The catholics have a hierarchy nearly similar; but the metropolitans and bishops are considered by the pontiffs as merely titular.

The ancient ecclesiastical establishment of Scotland comprised two archbishoprics, those of St. Andrews and Glasgow, and eleven bishoprics (that of Edinburgh having been only establihed by Charles I.), which, in the order of antiquity, may be thus enumerated; Galloway (St. Andrews), Dunkeld, Moray; five founded by David I., Brechin, Dunblane, Aberdeen, Roys (Glasgow); that of Argyle, or Lismore, was founded about the year 1200, before the bishopric of Dunkeld did not break the Irish tongue; the bishops of Orkney and of the Western islands date from an earlier period, while their fees were not subject to the Scotch crown. But since the revolution in 1688, the ecclesiastical government of Scotland is of the Prelbyteral form; and of course they have no bishoprics.

Bishoprics, as well as archbishoprics, may become void by death, deprivation, and resignation; but a bishop must resign to his metropolitan. See Archbishops.

**BISI, Bonaventura, in Biography, an eminent painter and engraver, and a monk, as some say, of the order of St. Francis, was born at Bologna, and became a disciple of Lucio Maffari. His chief excellence consisted in copying in miniature the pictures of Correggio, Guido, Titian, and other masters, which he finished with surpassing beauty and elegance. Many of his works, which are highly valued, are in the duke's gallery at Modena. He also amnified himself by etching some few plates from Parmegiano, Guido, &c. One, probably from his own design, was a "Holy Family," with Elizabeth and St. John, dated 1631. He died in 1662; but his age is not known. Strait and Pilkington.**

**BISIGNANO, in Geography, an incomparable town of Naples, in the province of Campania, situated on a hill near the river Crati, surrounded by lofty mountains, and defended by a strong fortres. It gives the title of prince to the last remaining branch of the ancient house of St. Se-**

The text continues with historical information, including the number of miles, amounts of monies, and other details about specific locations and events. The narrative is rich in historical and geographical details, providing a comprehensive overview of the bishoprics and archbishoprics of the time, including their establishments, the hierarchy, and their significance in the religious and political landscape. The text also delves into the historical context of Scotland, detailing the establishment of bishoprics and archbishoprics, and the influence of the papacy. The final section introduces a historical figure, Bonaventura Bisi, known for his painting and engraving skills, and his connection to the Franciscan order. The text concludes with a geographical entry on Bisiignano, a notable town in Naples, featuring its geographical setting, defense, and historical significance. The narrative is rich in detail, providing a comprehensive understanding of the described locations and historical contexts. The text is marked by its scholarly approach, providing a wealth of information that would be invaluable for historical and geographical research. The narrative is clear and concise, allowing for a deep understanding of the historical and geographical contexts presented. The text is a valuable resource for anyone interested in the history and geography of the regions described.
BIS

man fits upon the end of the machine, and literally rides up and down throughout its whole circular direction, till the dough is equally indented; and this is repeated till it is sufficiently kneaded; at which time by the different positions of the lines, large or small circles are described, according as they are near or distant from the wall, till you have fairly the idea of an immense pentograph. The dough in this state is handed over to a second workman, who slices it with a prodigious knife; and it is then in a proper state for the use of those bakers who attend the oven. These are five in number; and their different departments are as well calculated for expedition and correctness, as the making of pins, or the working or printing of types. On each side of a large table, where the dough is laid, stands a workman; at a small table near the oven stands another; a fourth stands by the side of the oven, to receive the bread; and a fifth, to supply the meal. By this arrangement the oven is as regularly filled, and the whole exercise performed in as exact time as a military evolution. The man on the further side of the large table moulds the dough, having previously formed it into small pieces, till it has the appearance of muffins, although rather thinner, and which he does two together, in his hand, and as fast as he accomplishes this task, he delivers his work over to the man on the other side of the table, who flamps them with a docker on both sides with a mark, on which are cut the broad A, the letters PLY, and the number of the oven in which the biscuits are to be baked. As he rides himself of this work, he throws the biscuits on the smaller table next the oven, where stands the third workman, whose business is merely to separate the different pieces into two, and place them immediately under the hand of him who supplies the oven, whose work of throwing, or rather chucking, the bread upon the peel, must be so exact, that if he looked round for a single moment, it is impossible he should perform it correctly. The fifth receives the billet on the peel, and arranges it in the oven; in which duty he is so very expert, that though the different pieces are thrown at the rate of seventy in a minute, the peel is always disengaged in time to receive them separately. As the oven stands open during the whole time of filling it, the biscuits first thrown in would be first baked, were there not some counteraction to such an inconvenience. The remedy lies in the ingenuity of the man who forms the pieces of dough, and who, by imperceptible degrees, proportionally diminishes their size, till the loss of that time, which is taken up during the filling of the oven, has no more effect to the disadvantage of one of the biscuits than to another.

So much critical exactness and neat activity occur in the exercise of this labour, that it is difficult to decide whether the palm of excellence is due to the moulder, the maker, the splitter, the chucker, or the docker; all of them, like the wheels of a machine, seeming to be actuated by the same principle. The biscuits are to deposit in the oven seventy billets in a minute; and this is accomplished with the regularity of a clock; the clack of the peal, during its motion in the oven, operating like the pendulum.

The biscuits thus baked are kept in repositories, which receive warmth from being placed in drying lofts over the ovens, till they are sufficiently dry to be packed into bags, without danger of getting mouldy; and when in such a state, they are then packed into bags of a hundred weight each, and removed into locomotives for immediate sale.

The number of bake-houses, belonging to the Victualling Office at Plymouth, are two; each of which contains four ovens, which are heated twenty times a day; and in the course of that time bake a sufficient quantity of bread for 16,000 men. The granaries are large, and well contrived; when the wheat is ground, the flour is conveyed into the upper stories of the bake-houses, whence it descends through a trunk in each immediately into the hands of the workmen.

The bake-houses, belonging to the Victualling Office at Deptford, consists of two divisions, and has twelve ovens; each of which bakes twenty loaves daily (Sundays excepted); the quantity of flour used for each loaf is two bushels, or 112 pounds, which baked produce 102 pounds of bread. Ten pounds are regularly allowed on each loaf for shrinkage, &c.

The allowance of billet in the hay is one pound each man per day, so that one of the ovens at Deptford furnishes bread daily for 2040 men.

BISLAN, in Geography, a town of Egypt on the Nile, 3 miles south of Damietta.

BISLEY, anciently called Bisley, is a small market town, and a very extensive and populous parish of Gloucestershire, in England. The parish includes an area of 6600 acres, the surface of which is diversified with steep hills and narrow valleys. On the sides of the former are some inclosed arable lands, intersected with copse; and the latter are mostly kept for meadow pasture. Bisley, Chalford, and some neighbouring hamlets, are chiefly inhabited by persons engaged in the woollen manufactures; and many fulling and dressing mills are erected on the river which runs through this parish. A small weekly market is held here on Thursdays, and here are two considerable fair yearly. The church is a large handsome building, and, being seated on a high hill, is conspicuous for many miles. Here is a small free school, and an establishment for clothing five widows yearly. The canal, which unites the Thames and Severn, passes through this parish; and near the verge of it, at Sapperton, enters a subterraneous tunnel, which is cut through the earth to an extent of two miles and five furlongs. This tunnel is lined with masonry, and arched over at top, with an inverted arch at the bottom, except at those places where the solid rock rendered it unnecessary. The expense of cutting it was about eight guineas per cubic yard; but the plan of unifying the waters of the two great British rivers induced the proprietors to encounter extraordinary expense and trouble. The connection of the rivers Thames and Severn, by means of this canal, and also with the internal parts of the kingdom, by the Oxford and Coventry canals, which lead to Birmingham, and also to the counties of Stafford, York, Chester, and even to Wiltshire, forms a line of communication with the capital of the greatest importance, and which has proved of great utility to the manufacturing towns through which it passes.

On the 20th of April 1769, the acting engineer, Mr. Clowes, passed through the tunnel for the first time, in a vessel of thirty tons burden; and the junction was completed, and a vessel passed from the Severn into the Thames, for the first time, on the 19th of November in the same year, in the presence of a large congregation of people, who came to witness and rejoice at the event. In 1788, their majesties went from Cheltenham, on purpose to view this tunnel, which excited their surprise and admiration, more particularly when they learnt it had been conducted and completed by a private gentleman. The canal is 30 miles and 7 chains in length; in which course the water is raised 241 feet 6 inches, and made to fall 110 feet 6 inches. The parish is 522 houses, and 437 inhabitants. Judge's History of the County of Gloucester. Phillips' History of Inland Navigation.

BISLINGUA, double-tongue, in Botany, a name used by many authors for the narrow-leaved rufures, or Butcher's
BIS

Bismarck, in Geography, a town of Germany, in the circle of Upper Saxony, and Old Mark of Brandenburg; 12 miles west of Stockholm.

Bismarck, or Bismark, a town of Africa, in the kingdom of Algiers; 25 miles west of Algiers.

Bismarck, in Mahomedan Cufman, a solemn form, viz. in the name of the most merciful God, completely placed at the beginning of their books and writings in general, as a peculiar mark or distinguishing characteristic of their religion; it being counted an impurity to omit it.

The Jews, for the same purpose, make use of the form, "in the name of the Lord, or, "in the name of the great God." Sale.

Bismarck is also used among the Arabs, as a word of invitation to eat. An Arab prince will frequently sit down to eat in the street before his own door, and call all that pass, even beggars, by this word, who do not fail to come and sit down to eat with him; for the Arabs are great lechers, and set every body on a footing with themselves. Pocock's Egypt, &c. p. 482.

Bismuth, Wifsmanum, Walkerius; Wfsmithr, or Bismuth, Germ.; Bismuth, Fr.; Plumbam cinereum, Anthimium ferrum, cin-figus, of the older chemists.

Bismuth is a brittle metal, of a reddish white colour, and foliated fracture, is fusible at nearly the same temperature with lead, soluble with ease in nitric acid, and precipitable from it in the form of a white oxyd by the addition of pure water.

§ 1. Ores of Bismuth.

The colour of this mineral is silver-white, with a slight tinge of red, frequently exhibiting an iridescent appearance on its surface. It occurs very rarely in mass, being generally disseminated, or investing; it is also met with feather-shaped, or reticular, or in lamelle of a rectangular or triangular shape, either solitary, or heaped upon each other. It exhibits a metallic lustre of considerable brilliancy. Its fracture is perfectly foliated, or broad-irradiated. It is semi-dieute, and breaks with some difficulty into irregular, somewhat blunted-edged fragments. Sp. grav. according to Kirwan, = 9.57.

Native Bismuth is fusible at a very moderate temperature, often by the heat of a common candle; when exposed to the action of the blowpipe on charcoal, it volatilizes in the form of a white vapour, not unfrequently accompanied with an arsensical smell. It dissolves very easily, and with effervescence, in cold nitric acid; and is precipitable in the form of a white powder, on the addition of pure water.

The only two substances, with which native bismuth is liable to be confounded, are the fulpeture of bismuth and diametrical bismuth; the former of these, however, is not fusible with effervescence in cold nitric acid; and the latter may be distinguished by its colour and ductility.

Bismuth is one of the most partially disulphated metals hitherto known; and it is chiefly found native, accompanied with kupfernickel, white and grey cobalt, black blende, native silver, and rarely galena. Its gangue is quartz, calcareous spar, or barofolinite; and it has hitherto been found only in veins in primitive mountains.

It is found at Joachimthhal, in Bohemia; at Freyberg, Annaberg, &c. in Saxony; in Sweden, Transylvania, and Brittany.

The colour of this substance is between lead-grey and tin-white; but on the surface it is usually yellowish or irredef- cent. It is found either lamellar and in masses, or disseminated, or in small acicular crystals. Its primitive figure, according to Haug, is that of a quadrangular prism. Its internal lustre is metallic and very brilliant; its fracture is broad or narrow fracted, or foliated like galena. Sp. gr. according to Kirwan, = 6.131. It stains the fingers in a slight degree; and when reduced to powder, is of a glittering black.

When exposed to the blowpipe, it melts easily, giving out a fulphureous odour and a blue flame, and is almost entirely volatilized before it can be brought to the metallic state. There has been no very accurate analysis made of this ore; but from the experiments of Sages and La Peyrouse it appears to contain about 60 per cent. of bismuth, 36 of sulphur, and a little iron. There is some external resemblance between the lamellar variety of this mineral and galena; but the superior fusibility of the former is an easy and infallible characteristic.

Sulphuret of bismuth is very rare; and, where it occurs, is always accompanying native bismuth. It is found at Joachimthhal, in Bohemia; Altenberg and Johann-Georgenthal, in Saxony; and at Baltasar, near Ridderhytta, in Sweden.

This mineral is of a greenish yellow colour, passing into aub-heay, or flour colour. It is sometimes found in mass, but more commonly disseminated or investing. It is opaque, and possesses a slight degree of internal luster. Its fracture is fine-grained, uneven, or earthy. Sp. grav. considerable, but has not yet been accurately ascertained. It is either friable, or of the consistence of chalk, but occasionally gives fire with fuel, on account of the particles of quartz with which it is mixed.

When exposed to the action of the blowpipe on charcoal, it is very easily reducible to the metallic state. It is soluble in nitric acid without effervescence, and precipitable for the most part by the addition of water.

Oxyd of bismuth is an extremely rare mineral. It has hitherto only been found at Schneeberg, in Saxony, accompanying native bismuth; in the Black Forest mines, in Swabia; and at Joachimthhal, in Bohemia. It is often confounded with the green earthy iron ore; but may be at once distinguished by its easy reduction before the blowpipe. Emmerling, vol. ii. p. 434. &c. Wiedemann, p. 887. Brochant, v. 2. p. 343. Haug, v. 4. p. 184. Kirwan, vol. ii. p. 263.

§ 2. Affiny and Analysis of Bismuth Ores.

Sulphur and iron are the only sublimes that have been as yet detected in combination with this metal, as far as can be inferred from very imperfect analyses of the preceding ores. But Rappoth, in his examination of the bismuthic silver ore from Schlapach (Analit. Eff. vol. i. p. 556.), found it to be a combination of lead, silver, iron, copper, and sulphur, with bismuth; and from the experiments of this able chemist it is deduced the following general method of analyzing the ores of bismuth.

Having reduced the ore to a tolerably fine powder, pour it upon it, in a capacious flask, five times its weight of nitric acid previously diluted with one third of water. The acid will begin to act immediately, without the assistance of heat; nitrous gas will be diffused in great quantity; and the solution will assume a greenish yellow colour. When the acid has taken up as much it can, or nearly so, pour it off, and digest the undiffused residue in a moderate heat, with equal parts of nitric acid and water, renewing the

3 R = 
menipurus
BIS

menstruum from time to time, till all the soluble parts of
the ore are taken up. Add together the solutions, and
reduce them by gentle evaporation to about half their
bulk (if any crystals are deposited, add a little pure warm water
just sufficient to take them up again); then pour the whole
into a large quantity of rain water, at least twenty times
the bulk of the solution. The liquor will immediately af-
fume a milky appearance, and, by standing a short time,
will deposit a white heavy precipitate (a), which, when
carefully lixiviated, is pure exsul of bismuth. Add all the li-
quors together, and concentrate them by evaporation to one
half of their bulk; then drop in a strong solution of muri-
atic acid ammonium, as long as any precipitate takes place;
deep in the supernatant fluid as accurately as possible, and,
without washing the precipitate, digested it for some time with
moderately strong nitric acid; the undissolved part of the
precipitate being separated, washed, and dried, is pure muri-
lat of silver (b). The nitrous solution is now to be diluted
with a large quantity of cold water, and a precipitate of
oxyd of bismuth (c) will be thrown down. The diluted ni-
trous solution being mixed with the other liquor, the whole
must be evaporated, till a considerable number of crystals are
deposited; at this time, the addition of sulphuric acid will
occasion a white deposit of sulphat of lead (d). The re-
mainder of the solution is now to be superheated with cauli-
acle liquid ammonia, by which the iron will be deposited
in the flake of brown oxyd (e), and the copper will form
with the ammonia a blue solution; this being saturated
lightly to excess with sulphuric acid, will deposit the cop-
per (f) upon a piece of clean iron. The residue of the ore
that was undissolved by nitric acid, being weighed, and ex-
plored to a low red heat, will give out its sulphur (g), the
quantity of which may be estimated with considerable ac-
curacy by the loss of weight. It is now finally to be digested
with ten times its weight of boiling muriatic acid, by which
some oxyd of lead will be taken up; and this, by evapora-
tion and the addition of sulphuric acid, may be procured in
the flake of sulphat lead (b). The residue being washed
and dried is the flaky gangue of the ore (i).

Hence the ore will be decomposed into

Oxid of bismuth (a) and (e),
Muriated silver (b),
Sulphated lead (a) and (b),
Oxid of iron (c),
Metallic copper (f),
Sulphur (g),
Stony matrix (i).

§ 3. Reduction of Bismuth ore.

The separation of this metal from the substances with-
which it is found united in the mine, and the reduction of
it to a marketable state, is perhaps the chiefest of all the met-
tallurgical processes, on account of the ready fusibility of
bismuth, and its being found for the most part in the me-
talliferous veins. The following were the methods practiced
in the time of Agricola (De Re Metallica, p. 319.) A round
pan, two or three feet wide, was lined with well rammed
clay and charcoal, and covered with billet wood, upon
which were laid alternate flrata of ore and wood. When
the pile was thus built to a sufficient height, fire was applied
to the top, and the bismuth, as the heat penetrated through
the mafs, became melted, and trickled down into the hole
beneath, where it collected in an irregular mafs; being then
withdrawn, and broken into pieces, it was remelted in iron
or carthen pots, separated from the impurities that floated
on its surface, and finally cast into flat cakes, or loaves, for
sale. Another method was to divide a large pine tree lon-
gitudinally, and cut out the central part of the wood, thus
forming it into a gutter; this being placed somewhat in-
clined, the ore was laid in the upper end, on a bed of chips
and small wood, sufficient, when set on fire, to liquify the
bismuth, which, flowing down, was collected in a hole or
vessel placed at the end of the trough.

The decadence of wood has, however, put an end to these
rudish and extravagant methods; and the ores of bismuth are
now reduced in a common reverberatory furnace, the bed of
which is lined with charcoal, whence the melted metal is re-
moved in iron ladles, and cast into masses weighing twenty
or thirty pounds, in which state it is brought to market.

Bismuth is a white metal with a reddish yellow tinge; is
considerably hard, but brittle, exhibiting a broad foliated
fracture; has a bright, almost specular metallic luster; and
is somewhat sonorous, when struck. Though brittle, it
may be compressed very considerably by judicious hammer-
ing, and therefore varies greatly in its specific gravity.
According to Mufchenbroock, its fp. gr. when fresh melted, is
= 8.716; but when laminated, is = 9.638. Bergman
fixes its gravity at 9.67; and other authors make it as high
as 9.8, or even 10. The lamina, of which this metal is
composed, have but little adhesion to each other; hence the
primitive form of its crystals, which is that of a regular octa-
hezoron, may very easily be ascertained by deformity. It is
 fusible at 460° Fahr., and may be poured into a paper cone
without burning it. If, after it has begun to solidify, the
fluid part is poured off, a group of crystals is obtained in
cubes, or rectangular plates. When exposed in clove fel-
ts to a violent heat, it sublimes and attaches itself to the
cooler part of the apparatus in the form of brilliant
plates.

§ 5. Oxids of Bismuth.

The combined action of air and moisture upon bismuth,
at the usual temperature, is very slight; it becomes covered
with a reddish grey superficial tarmish, and afterwards ap-
pears to undergo no further change. At a melting heat, it
shortly becomes covered with an iridescent film, and by ex-
poping fresh substantances to the air, is wholly converted into
a yellow bismuth oxide, weighing about \( \frac{1}{3} \) more than the
original metal. This oxide melts into a yellow glafs at a
moderate red heat, and soon penetrates through the most
compact earthen crucibles, though not quite so easily as
glafs of lead does. When bismuth is exposed to a strong
heat, with free access of air, it burns with a faint blue
flame, and throws up at the same time a copious white
oxide, which was formerly called flowers of bismuth; towards
the end of the process the oxide acquires somewhat of a
yellowish tinge, probably on account of a small portion of
phosphor, or other impurities. The glafs, or vitreous oxide
of bismuth, is a very active flux for earths and the more
difficultly fusible oxides; on account, however, of the superior
cheapness and efficacy of lead, it is seldom used for this
purpose.

1. Concentrated sulphuric acid has no action on bismuth,
except when boiling hot; in this state, it is rapidly decom-
poured, giving out sulphurous acid gas, and reducing the
metal to a white pulverulent oxide; by a low red heat the
decomposition is so complete, that a quantity of actual sul-
phur is volatilized. The white mafs being washed with a
little warm water, parts with nearly the whole of its acid,
holding a small portion of bismuth in solution: this fluid,
by careful evaporation, deposits minute soot cryftalline
needles of sulphant of bismuth, from which, by the mere
affination of water, the metal may be separated in the form of
white oxide. The sulphated oxide, produced in the first
part of the process, is remarkably more difficult of reduction than any of the pure oxyds of $\text{S}_5$.

2. Sulphureous acid is incapable of attacking metallic bismuth, but readily combines with its oxyd, forming a white insoluble fulminate of a sulphureous flavour, reducible into metallic globules before the blowpipe, decomposable with effervescence by sulphuric acid, and when distilled, giving out its acid, a mass of pure white oxyd remaining behind.

3. Nitric acid acts upon bismuth in a remarkably violent manner. If the metal is in powder, and the acid somewhat concentrated, at the instant of their mixture, even without the assistance of heat, a rapid decomposition of the acid takes place, accompanied with the production of nitrous gas, azot, and sometimes of ammonia; and the bismuth is converted into a white oxyd. If the acid is previously diluted with an equal weight of water, and the bismuth is added gradually in small pieces, the decomposition goes on more quietly, the metal is diffused in proportion as it oxydates, and the acid may be made to take up nearly half its weight of bismuth. By cautiously adding to this solution an equal bulk of distilled water (each portion being well mixed with the whole mafs by stirring, before the addition of a succeding portion), a black precipulent precipitate takes place, which has not yet been analysed, but has been taken for fulphur or charcoal. If the acid made use of is still more dilute, confining, for example, of four parts of water, and one of nitric acid, the black matter is not diffused. Nitrat of bismuth, when thus purified, is clear and colourless, and by gentle evaporation crystallizes in the form of flattened rhomboids, or compreced tetrahedral prisms terminated by three sided pyramids. This salt, when exposed to a dry air, is considerably efflufcent; but in a humid air, becomes covered with a white, somewhat moist coating of oxyd. When thrown on hot coals, it detonates feebly, giving out faint red sparks, and leaves behind a greenish yellow oxyd of difficult reduction. If a crystall of nitrat of bismuth is thrown into some pure water, it immediately becomes covered with a white opaque oxyd, but the decomposition of this salt is more trifling, if a solution of it is made use of. For this purpose, let a jar be nearly filled with clear rain water, and drop into it nitrat of bismuth as long as any precipitation takes place, then mix the whole by agitation, and let it stand for an hour to settle. The bottom of the vessel will now be covered with a fine heavy powder of a dazzling white, which, when repeatedly wafted and dried, is pure oxyd of bismuth, formerly called magilery of bismuth, and well known as a cement under the name of blanc de fard. This preparation, if made with pure nitric acid, and well wafted, is of a dead white; but if a little muriatic acid is mixed with the nitric, and the precipitate is wafted with a small portion of cold water, it will be in the form of minute glittering scales with a beautiful pearly lustre, and is then called by the French blanc de pertes. In both plates it is extensively employed, particularly by the French ladies for whitening the skin, but is subject to turn grey, brown, and even black, by any hydrogenous and sulphurous vapours. This oxyd of bismuth does not appear to retain any nitric acid; and its component parts are fixed by Bergman at 77 of metal, and 23 of oxygen; but, by the more accurate experiments of Klaproth, its contents are ascertained to be 81 of metal to 19 of oxygen. Nitrat of bismuth is not, however, totally decomposable by water; for the clear fluid, that is separated by filtration from the oxyd, may still be made to yield a precipitate by a carbonated alkali, muriatic acid, or muriated ammonium. Klaproth found (Analyst. Eff. vol. i. p. 557.), that 100 grains of bismuth, dissolved in nitric acid, yielded with water 88 grains of oxyd, and 35 more were obtained from the diluted solution, by the action of muriatic acid added in drops as long as any precipitate ensued. This oxyd is very easily reduced by fusion in a covered crucible, with a little nitre and tartar.

4. Bismuth in the metallic state is acted upon with difficulty by muriatic acid, even when it is concentrated and affihed by heat. During the digestion, a small quantity of acid hydrogen gas is given out; and, by slow evaporation, small deliquescient needle-shaped crystals are deposited of muriat of bismuth. This salt, however, may be obtained in much greater quantity, and more easily, by substituting the oxyd of bismuth for the pure metal. If the bismuth mafs, which remains behind after evaporation to dryness, is distilled in a glass retort, nearly the whole of it comes over at a moderate heat, and concretes into a soft white mafs, called formerly buter of bismuth. Bunter of bismuth, like butter of antimony, is intensely caufic to the taste, deliquesces in a moist air, and when dropped into water, is decomposed, a fine white oxyd being precipitated.

5. Liquid oxy-muriatic acid acts upon metallic bismuth with considerably more energy than muriatic acid does: the metal is oxydized without the difengagement of hydrogen, and the result is muriat of bismuth. It is probable, that by substituting the oxyd of bismuth for the pure metal, oxy-muriat of bismuth might be produced: this, however, is not as yet confirmed by experiment. If bismuth, previously reduced to fine powder, is poured into oxy-acidum muriaticum gas, the metal is instantly ignited and oxydized, and falls in a flower of fire to the bottom of the vessel.

6. Tincture of gall, or gallic acid, precipitates bismuth of a greenish colour from its solution, as pruftrat potash does a yellow oxyd.

7. There is scarcely any thing known concerning the other bismuthic salts. They are formed by digesting the yellow oxyd in the various acids that have not been already mentioned, and are for the most part but little soluble in water. The proportions of their ingredients have not been ascertained with any accuracy, nor are they applied to any use.

The fixed alcalies have no effect on metallic bismuth, but unite both in the humif and dry way with its oxyd. Ammonia is said to acquire a greenish yellow colour by digestion with the metal when pulverized, and certainly dilutes its oxyd in considerable proportion. The action of the earths upon bismuth is unknown, except that flex and oxyd of bismuth combine by fusion into a clear greenish yellow glass.

§ 8. Action of the Neutral Salts on Bismuth.

None of the neutral salts in solution appear to exert any affinity on bismuth or its oxyds; but, in a dry heat, many of them are decomposed by it.

Nitre, being mixed with pulverized bismuth, and projected into a red hot crucible, is decomposed with a flight denation; the bismuth becomes oxydized, and then unites in part with the alkaline base of the nitre.

Muriat of soda, according to Pott, is in some degree decomposable by metallic bismuth. This fact, however, is not confirmed by later chemists; and it is probable, that the salt, which Pott made use of, was not free from muriated magnesia, and that the bismuth was partly oxydized.

Muriated ammonium is totally decomposable by oxyd of bismuth. On the first impression of the fire, very pure ammoniacal gas is difengaged; and by a low red heat, the muriated bismuth rifes in the form of a thick white vapour, which concretes, in the receiver and neck of the retort, into buter of bismuth; if the oxyd of bismuth is in very small proportion
BIS

proportion to the muriat of ammonia, the greater part of this salt rises entire, but mixed with a little muriat of bismuth, forming the bismuthic flowers of sal-ammoniac of the old chemists. When these flowers are thrown into water, the bismuth is deposited in the form of a white oxide.

Oxymuriat of potash mingled with powdered bismuth, and projected into a hot crucible, is decomposed with great violence, and the metal is completely oxidized. A mixture of three parts of this salt, and one of bismuth, produces a flash and a loud detonation, if laid on an anvil and struck smartly with a hammer.

§ 9. Bismuth with combustible Bodies.

If one part of sulphur, and four of bismuth, are triturated together, and afterwards exposed to a full red heat in a covered crucible, a brilliant flaried metallic mass of sulphur of bismuth is obtained, similar in its properties to the native sulphuret mentioned in § 1. It may be made to crystallize, by allowing it to cool very gradually, and pouring off the fluid part as soon as the surface is crofted over. The cavity thus formed will be found to be lined with long tetrahedral prisms corroding each other, and occasionally of a deep indescribable blue and red colour, forming groups of exquisite beauty. The sulphur of bismuth is much less fusible than the pure metal; it parts with nearly the whole of its sulphur by long roasting, and is decomposable by nitric acid, which dissolves the bismuth without touching the sulphur.

Sulphuretted hydrogen converts the white oxide of bismuth into a black mass, of which neither the properties nor proportions have been ascertained.

Phosphorus has very little affinity for this metal. Pelliot tried in vain by several methods to prepare phosphuret of bismuth. In some of his experiments, the metallic globules, when red hot, gave out a faint lambent flame, but exhibited no other proof of combination with phosphorus. Fat oils, by the assistance of heat, difsolve the oxide of bismuth, and form with it a thick tenacious phialer.

§ 10. Alloys of Bismuth.

Bismuth appears to increase remarkably the fusibility of all the metallic compounds into which it enters; but it is to be lamented, that we are greatly in want of accurate experiments on this interesting branch of inquiry.

1. Bismuth and gold. See Gold.
4. Bismuth and copper. See Copper.
5. Bismuth and lead. Equal parts of these two metals unite easily by simple fusion, forming an alloy of a brilliant white colour, considerably harder than lead, and, though not ductile, more malleable than pure bismuth. By diminishing the proportion of bismuth, the malleability of the mass is increased, without so far impairing its fusibility, hardness, and luster.
6. Bismuth and tin. A small quantity of bismuth increases the hardness and brilliancy of tin, without rendering it less ductile; hence the bell foils for glass mirrors are made of this alloy, as also are some kinds of pewter.

Bismuth with lead and tin. Fusible metal. Plumbers' solder. The fusibility of the alloys of bismuth is in no instance to be reckoned as in that discovered by Newton, and hence commonly called Newton's fusible metal. It is made by melting together eight parts of bismuth, five of lead, and three of tin. The mass is very brittle, and when broken exhibits a porcelainous appearance, with little or no luster; it is so fusible as to become liquid when held on a piece of flint paper over a candle, without scorching the paper; and becomes as fluid as quicksilver in boiling water. If the bismuth is reduced to one part, the proportions of lead and tin remaining the same, the alloy is plumbers'folder; and it differs from the preceding in being somewhat less fusible and considerably malleable.

§ 11. Medical Use of Bismuth.

BISNAGUR, in Geography, an ancient kingdom of Hindoostan, called Narfinga, from the name of one of its rajahs, or sovereigns, was formerly the most extensive, powerful, and rich monarchy in the Indies, and comprehended almost all the countries in the peninsula south of the 16th parallel, or the whole of the Carnatic and some other kingdoms. Some have distinguished between the kingdoms of Bisnagur and Narfinga, but it is not easy to determine, whether they were two separate, or two co-existing kingdoms. It appears, probable, however, that in the 16th century Bisnagur included the greatest part of the peninsula. The inhabitants of this ancient empire, which is said to have continued 800 years, were Pagan, and denominated Badagars; and spoke the Tahmil, or Dimal, language, which is the same with the Malabaric; but the radagun was used at court. According to the Portuguese writers, the kingdom of Charantaka had no sovereign prince till the year 1200, and the first it was Boka, a shepheard, who styled himself rau or rajah, that is emperor; which title has descended to his successors. Boka, it is said, in memory of a victory which he obtained over the king of Delhi, built the famous city of Bisnagur, corruptly called Bifnungur. The crown continued in his line till it was usurped by Narfinga, from whom this kingdom took its name, as it did that of Bisnagur from the city. The king of Bisbungur was a powerful prince about the year 1520; and about the year 1565 the capital was restored to by merchants from all parts, as being the greatest, if not the only mart for diamonds in the east; and its riches were equal to its extent. At this time it was invaded by the king of Viipapur, and other northern princes of the Deccan; and in 1567 the rajah, or king, retired, with his court, first to Penuconda, and at a subsequent period, or about 1597, its existing sovereign removed to Kanedgeri, or Chandegheri, an inland city, strong by nature and fortified by art, so as to be deemed impregnable. About the middle of the 17th century, this large monarchy was again invaded and utterly destroyed, by Adel Shah, king of Viipapur, who formed a league with the king of Golconda for this purpose. The unfortunate rajah fled into the mountains, where he remained till 1667. About 20 years after, the kingdom of Bisnagur fell under the power of the Moguls, by the conquest which Aurungzebe made of the kingdoms of Viipapur and Golconda.

BISNAGUR, rather BISNAGUR, sometimes written BEIJANUGUR, the capital of the kingdom, is situated on the 4th bank of the Toomubudra river, and according to M. Buffey's map, distant about 50 miles S. E. or S. S. E. from Bencapur. From it, Fazlaha, a says, that it was founded by Beldrando, king of the Carnatic in 1452, and was thus placed in order to guard the northern frontier of his empire. See the preceding article. This city was visited by Caesar Frederick in 1565, and was then a very large city; its circuit, as he says, being 24 miles, and containing within it a number of hills and pagodas. He reckons it 8 days' journey,
journey, or about 140 geographical miles, from Goa. Its ruins are extensive, several rugged hills and rocks being covered with temples that still appear beautiful; the circumference seems to be about 8 miles. N lit. 15° 15'. E. 35° 34'. Bejaangur lies directly opposite to Annambo, about 1 mile north from the bank of the river Trombudda, which is at present the principal town of a small district of the same name; one being the Jaghair, or citadel, the other the place of residence of the descendant of the ancient kings of Bejaangur, who, about 2 centuries ago, ruled the greatest part, if not the whole, of the peninsula, under the title of the empire, or kingdom of Cachara. Lieutenant Emmett, an English officer, who examined the ruins of Bejaangur, traced between immense piles of rocks, crowned with pagodas, several streets from 30 to 45 yards wide, some of which now produce fine rice. One street extends about N. E. and S. W. half a mile, and is about 35 yards broad, having colonnades of stone on each side, and a very large pagoda at the S. W. end, in perfect repair. On the west side of this street is a large mango grove, which is bounded by the Trombudda. Many streams flow through the woods, which have been formerly employed to fill a great number of canals. Composer fort is distant about half a mile, and surrounded with hills through which the road winds in ascents and descents, paved with large flences.

BISNEE, a town of Asia, in the country of Beuton, 116 miles S. E. of Taffaldoton, and 188 N. E. of Mohordabad.

BISNOW, or Bisunoo, a feast among the Indian baboons, or call of merchants. The banana feast consists of two buffalo; that of bisnow, and that of samaraab. The followers of the former hold one God, whom they call ram-rose, and allow of no lieutenants, or deputy-gods, as is done by those of the feast samaraab; but they allow their god a wife, and have idols, which they dress up with gold chains, and collars of pearl and precious stones, and pay them worship, by singing hymns in their temples, and dancing before them to the sound of flageolts and kettle-drums.

In this feast, the wives do not burn themselves after their husbands' death, as is practised by those of the samaraab feast; but content themselves with a perpetual widowhood.

BISOMUM, Bisomum, compounded of bis, twice, and the Greek epos, body, of a body, in Antiquity, a tomb for two bodies, or the abode of two. The ancients frequently buried two, three, or four bodies in the same sepulchre, disposed side by side of each other; for it was held an impurity to lay one on top of another. Hence the sepulchres of the primitive Christians had the words bisom, trisom, quadrisom, &c. inscribed on them, to indicate the number of bodies deposited in them. Du-Cange.

BISON, in Entomology, a species of Scaravus, with the anterior part of the thorax pointed; and two banded horns on the head. Inhabits Spain, and the southern parts of France. Colour black. The female has on the anterior margin of the thorax an elevated or carinate edge.

Bison, in Zoology. See Bos Ferau, or Wild Ox.

BISPINOSA, in Entomology, a species of Mantis, with a roundish thorax, bidentated in front; wing-cases very short, and bordered with yellow. Fabrichius.

BISPINOSA, a species of Cicada (Mamifera, Tettigonia). It is of a large size, and inhabits the island of Sinamara. The colour is brown, with a single spine on each side of the thorax; wings dusky, with a streak of black spots. Fabrichius Mantili.

BISPINOSUS, a species of Cerambix (Stenocerus) that inhabits South America. Thorax unarmed, and slightly bidentated; wing-cases bidentated; joints of the abdomen armed with two spines; and the body tesselate. Fabrichius.

BISPINOSUS, a species of Carabus that inhabits Europe. This is of a black colour; posterior part of the thorax truncated; anterior spines with two spines. Liam. Leck. Mut.

BISPINOSUS, a species of Tarabus. found about Goethingen, and described by Fabrichius. The colour is brown; abdomen ferruginous, and black at the base, with two spines on the front of.
French and Portuguese have established themselves. The
crests of the married women consist of a cotton girdle, and
bracelets of glass, coral, and copper; but the virgins are
altogether naked; and those of high quality mark their bod-
ies with hideous figures of snakes and other reptiles. The
princes of the island is only distinguished from other females
by the elegance of these paintings, and the richness of her
bracelets. The dress of the men of all ranks is merely a skin
fixed before and behind to their girdle. One singular orna-
ment is a large iron ring, upon which they ring changes
with a piece of iron, so as to cover it with their cailtans as
if they used the most polished language. This
artificial language is used only by persons of rank and
fashion. All the Billaans are idolaters, but their system of
religion is very crude and untidiness. Besides their
chief idol, called "China," every one creates a divinity
according to his own fancy; trees are held sacred by them,
and, if they do not adore them as gods, they worship them
as the refidence of some divinity. Their government
is despotic, the will of the emperor being the law to his
people; at his death all his women and slaves are sacrificed
and buried near their master, in order to attend him in the
other world. Although they are at almost perpetual war
with some of their neighbours, they have among themselves
no civil discord. Before the emperor resolves to invade
any adjacent territories, he orders the "bonbalon" to be
formed, which is the general signal to arms, on which all
persons in the pay of government assemble at a fixed place,
and embark on board their canoes, each of which carries
about 30 men, and the whole fleet consists of about 30
canoes. Before the fleet sets out, they offer sacrifices in great
number to their gods, which are made of wood, and the favourable
answer of the priests, when they confute these
dainties, ensures their success. When they attack any towns
or villages, they carry off the inhabitants, and every article
of value, and divide the booty between the emperor and
those that have been engaged. The canoes are sold to the
Europeans, except such as are of quality or fortune, who are
reftored to their friends on condition of their sending
a number of slaves in their room. The emperor is paid to al-
low free commercial intercourse with all strangers. The
Portuguese demolished their fort on the island in 1703. See
Balontis, Bisagos, and Bulam.

**Bissection**, in Geometry, the division of any quantity
into two equal parts, otherwise called bipartition, which fe.
See also Division, &c.

**Bisendorf**, in Geography, a town of Germany, in
the circle of Welfphalia, and bishopric of Osnabruck, 5
miles S. E. of Osnabruck.

**Bissenporr**, a small district of Bengal in the East
Indies, which is governed by a Bramin family of the tribe
of Rajpoots, and which has uniformly preserved its inde-
pendence. In this district, it is said, the purity and equity
of the political system of the inhabitants is in a very great
degree uncorrupted. By the singular position of this country, its inhabitants have
been enabled to maintain their primitive happiness, and the
gentleness of their character; and they have been fecured
from the danger of being conquered, or of impairing their
happiness in the band of their fellow-creatures. Nature has
surrounded them with water, and they only need to open the
channels of their rivers in order to inundate the whole country.
The armies that have been sent to subdue them have been so
frequently drownd, that the plan of enflaving them has been
laid aside; and the projectors have thought proper to con-
tent themselves with an appearance of submilion. In Bif-
Senpourt, liberty and property are sacred; robbery is un-
known; and every stranger, who enters this territory, is
under the protection of the laws, which provide for his se-
curity. The guides, to whose conduct he is committed,
become responsible for his person and effects; whilst he re-
 mains, he is maintained and conveyed with his merchandise
at the expense of the flate, unless he expresses his desire to
stay longer than three days in the same place; and should
this be the case, he is obliged to live at his own charge.
In this flate, it is said, probity and honesty are so prevalent,
that if any one finds a purse, or any other article of value,
he hangs it upon the flrst tree he finds, and informs the
necare guard, who gives notice of it to the public by beat of
drum. Out of about 320,000 I. annually received at an
average by the government, without injury to agriculture or
trade, what is not wanted to defray the unavoidable ex-
penes of the flate, is laid out in improvements. The rajah
is enabled to engage in these liberal employments, as he pays
the Moguls only such tribute, and at such times, as he thinks
proper. Raynall's Hist. Sett. East and West Ind. vol. i.
p. 425.

**Bissenpraag**, a town of Asia in the country of
Siranuga, situated near the base of a mountain, on which
stands the famous temple of Buddenanat. It is a place of
some importance, as being the residence of the pendants
and principal Hindoos of Buddenanat. Here they hold their
durbars, exercise their laws, and the duties of their religion,
in the greatest flate of security from foreign intruders, and
can at any time exclude themselves from the rest of the
world, by a removal of the "johalas," or rope bridges,
which form the communication across the Aluknundra.
This river receives at Bissenpraag another river, proceeding
from the called as large as itself, called "Dood Ganga,"
or the Milk river, and also "Dhoulee." Near its junction
with the Aluknundra, it runs between two villages, called
"Gonna" and "Nitty." The town consists of about
800 houses, and is a place of some trade; the inhabitants

**Bisset, Charles**, in Biography, studied medicine
several years at Edinburgh, as he informs us in his Essay
on the medical conftitution of Great Britain, published in
1762, and was then promoted to be second surgeon to the
hospital in Jamaica, where he continued from 1740 to 1745,
when he returned to England, and purchasing a commifion
in the army, he served as lieutenant and engineer in Flanders
until the peace in 1748. He now resumed the practice of
surgery, and settled at Skelton in Cleveland, Yorkshire, and
soon after published "A Treatife on the fecury," "1755, 8vo.
He had before, viz. in 1751, published "An Essay on the
theory and construction of fortifications." In 1765 he ob-
tained a diploma from the university of St. Andrews, con-
fifiting him doctor in medicine. He died at Knayton near
Thirsk, in May 1791, in the 75th year of his age. New

**Dissectialis**, or **Dissectialis olla**, an ancient
measure or vessel, containing twelve ounces, or two Sex-
taries.

**Dissectile**, or **Leap-year**, in Chronology, a year
containing of 366 days, happening once each four years,
by reason of the addition of a day in the month of Fe-
bruary, to recover the six hours which the sun spends in
his course each year, beyond the 365 days ordinarily al-
lowed for it.

The day thus added, is also called biscistle; Cesar hav-
ing appointed it to be introduced by reckoning the 24th of
February twice; and as this day, in the old account, was
the same as the sixth of the calends of March, which had
been long celebrated among the Romans on account of the
expulsion of Tarquin, it was called "his sextas calendas
Martii;"
pointed, round pointed, or with a probe point, &c. Sometimes it is made to slit within a handle; at other times the blade is fixed and immovable. For particular purposes, the blade is concealed, so as to project only at the moment when the instrument is used by the surgeon; on which account it is called by the French bistouri caché.

On some occasions, it is found convenient to employ a director, or a cushion, at the same time we introduce the bistouri: for example, when it is intended to prise the cutting instrument along a narrow fissure, or under the prepuce, up to a certain point before we make any incision, (see the articles Prepuce, and Sinus); but wherever there is room for the introduction of a forefinger, that mode is preferred by modern surgeons as a guide to the bistouri, being much more convenient and secure than any artificial director. The precise form of a bistouri must be regulated according to the nature of the operation required, and the end to be obtained. See the article Scalpel, and consult the engravings of chirurgical instruments attached to this Cyclopaedia.

BISTRAIA, in Geography, a town of Bohemia, in the circle of Chrudim, 6 miles S. E. of Politzka.

BISTRAIA, a town of Russian Tartary, on the west side of the Dnetz, 70 miles N. E. of Azof.—Alfo, a river of Russian Tartary, which runs into the Donetz, 64 miles N. E. of Azof.

BISTRE, among Painters, a composition made of the most glossy and highest burnt foot, pulverized, and passed through a fine sieve, then baked in a little gum-water, and made into cakes: or it is the burnt oil, extracted from the foot of wood. It is a brown transparent colour, and has much the same effect in water-color painting, where it is used, as brown ink in oil.

The bill is prepared from the foot of dry beech wood, by gridding it with urine or water, in a smooth pale, and then diluting it with more water; after the grofer substance has subsided, the liquor is poured off into another vessel, and left to settle three or four days; the fine matter that remains is bile.

That the bile of our colour shops has been prepared by a process of this kind, and not, as some have supposed, by evaporating the infusion of foot to an extract, may be presumed, says Dr. Lewis (Com. Epist. Phil. Techn. p. 540), both from its appearance and its qualities. He observes, that different parcels of bile differ considerably in their colour, on account, probably, of the different qualities of the feet from which they were made.

In the Handmaid to the Arts, vol. i. p. 126. we have the following recipe for preparing it. Put the foot of dry wood (of beech when it can be procured) into water, in the proportion of 2 pounds to a gallon, and boil them half an hour. Then, after the fluid has stood some time to settle, but while yet hot, pour off the clearer part from the earthly sediment at the bottom: and if on standing longer it form another earthly sediment, repeat the same method; but this should be done only while the fluid remains hot. Evaporate the fluid to dryness; and what remains will be good bile, if the foot was of the proper kind. That which is good is transparent, when moistened with water, and of a warm, deep brown colour.

Instead of this, some use the hatchets of a pea, with a little Indian ink, others red chalk, others black lead, &c. See Washing.

BISTRIANKA, in Geography, a town of Russian Tartary, on the south side of the Don, 140 miles E. N. E. of Azof.

BISTRIATA, in Entomology, a species of Cicada (Dr. Scop.)
BIT

fierc) that inhabits France. This is yellow, with two transverse bands of brown. Geoffroy.

BISTRICZ, or BISTRITZ, in Geography, a town of Transylvania, and capital of a county, to which it gives name, situate on the river Bistrice, which runs into the Samos, 4 miles S.W. of Kezovar. The town is 42 miles N. E. of Claustrub, and 256 E. of Vienna. N. lat. 45° 33′. E. long. 25° 3′.

BISTRIGALIS, in Entomology, a species of PHALANA (Tryall), with cincinnati wings, with two serrigenous streaks, and a black dot. Inhabits Europe. Limnæus.

BISTRIGARIA, a species of PHALANA (Geometrica), with cincinnati wings, undulated, with two linear streaks. A native of Europe. Linn. &c.

BISTRIGATA, a species of PHALANA (Geometrica). It is griseous, with two whist hreaks. Inhabits Europe.

BISTRITZA, in Geography, a town of European Turkey, in Mălăvii, on a river of the same name, which runs into the Siret, 6 miles S. E. of Bucov. The town is 20 miles S. W. of Jaffy.—Also, a town of Walachia, 16 miles W. S. W. of Kinnik.

BISTRIZ, a town of Moravia, in the circle of Brunn, 6 miles W. S. W. of Els.

BISTROFF, a town of France, in the department of the Meuse, and chief place of a canton in the district of Morhang, 4 miles N. E. of Morhang.

BISTRY, a town of Bohemia, in the circle of Konigin-gratz, 10 miles from Gitschin.

BISUGA, a river of Russian Tartary, which runs into the sea of Azof, 48 miles S. W. of Eifkoi.

BISULCATUS, in Entomology, a species of Curculio that inhabits Italy. This is black, with a cincinnati border all round, and two furrows on the back. Fabricius.

BISULCUS, a species of Ionnum, of a black colour, with two impressed lines before; legs rufous; ring short. Linn. Muf. Lekh.

BITS, or BITTS for Horses, in the Mange, are pieces of iron of various figure and construction, which, being placed in the horse's mouth, serve, by the affistance of the reins, to restrain or guide his motions.

The term bits, or bits, is considered by some as originating from the horse's biting or chewing them between the teeth when placed in his mouth; in the French language is used a term allo of familiar signification, les mords, which would seem to corroborate the above etymology of it:—another however, equally natural, presents itself in the common word bit, or bitt, that is piece of iron; this apparatus being always made of one or more pieces of this metal.

The art of biting horses may be said to consist in furnishing the mouth with the most proper mouth-pieces, &c. for obtaining from them an obedience to the will of the rider, and exacting a due performance of all the movements and restraints which may be defined, or at least which are dependent upon the operation of the reins. Rightly understood, and well administered, this art affords the power of communicating to the horse support and confidence, with greater ease and security to the rider. The misapplication of its rules, on the contrary, or an inattention to them, where the mouth is not totally inoffensive, will produce painful sensations to the horse, with disgust and rebellion, and to the rider uneasiness and perhaps danger.

It is to be lamented that the preceptuous opinions of the uninformed have been too much the guide of the public in their estimation and choice of the proper bits for horses, as also in too many other things respecting these useful animals, tending often to accumulate unnecessary suffering and injury upon them. The writers on this subject are few and unsatisfactory; we shall, however, except Mr. Berenger, whose work is a noble effort to emancipate this branch of science from barbarity and ignorance; and from him we shall take occasion to make some extracts in the sequel of this article. Here it will be proper to observe, that this author, by the term bit, has designated the curbed bit only; but we have ventured, for the sake of purifying a more connected view of the subject, to include in this term any piece or pieces of metal placed in the horse's mouth, for the purposes of guidance or restraint.

In our account of the different kinds of bits, and their effects, we shall begin, for the sake of order, with the description of a bit of the most easy and simple construction possible, and then proceed to the most complicated.

A short iron rod, made rather wider than the mouth of the horse, and provided with a hook or ring at each extremity for fastening the reins to, affords us an instance perhaps of the greatest possible simplicity in the construction of a bit; and such a one only slightly curved forwards, to allow more liberty for the tongue, is at present in general use for the heavier kind of draft horses, the bearing rein being usually attached to it, passing over the hames of the collar.

A similar rod to the former, broken in two pieces, and connected by a joint in the middle, is the next in point of simplicity, and is in common use for horses of light draft, as in those employed for the curricule, coach, &c. and is attached by the bearing rein to the hook of the faddle, and this kind of bit is mostly termed with us a bridon.

The next in point of farther complication of parts, and which fiercely can be said to differ from the former, is the common snaffle. This is provided with two crofs pieces, which rest against the lips or sides of the mouth; for as the snaffle is intended for the faddle horse, and the reins go to the hands, so the crofs pieces are useful in preventing the bits from being drawn through the mouth, which precaution is not so necessary where the bits are affixed to the bearing rein. The bridon, we may observe, is also made in general smaller than the snaffle, as well as without crofs pieces.

The distinction, however, between a bridon and snaffle is insignificant and of little consequence; for on all occasions crofs pieces are the most convenient; and it will be easily seen that the bridon is merely an imperfect snaffle, possessing no peculiar character which can form a real distinction.

The term, also, when confined to this object is misapplied; for the French, from whom we have borrowed it, by le bridon understand the snaffle and its rein, in opposition to le bride, by which they denote the curbed bit and reins.

In war, and on other occasions, the bridons was used as a leaffer buide, or bride of reserve, in case of the failure of the former from any accident; and hence the origin of its name.

The number of parts of which the mouth-piece of the snaffle is composed, may be increased to any extent, as it may be made with one, two, or several joints; but as it is evident these additions will not essentially alter its properties or effects, it would be useless to purvue a distinct consideration of them.

But the condition of the snaffle admits of being so altered and changed by the variation of its figure, its substance, and its surface, as to acquire new properties and effects which will require particular attention; its gentleness or rigour will depend almost wholly on these conditions. A mouth-piece made of two entirely straight pieces will be more severe than when these are somewhat curved, as the curved bit is more apt to embrace and include the lips between it and the bars than the
the straight one. A thin and slender bit or snaffle, it will be easily perceived, will roll with more severity and sharpness upon the thick, thick and obtuse one; the former, therefore, or the sharp bit, is employed more particularly for restraining such horses as are hard mouthed, and too eager, while the latter is used for such as have a proper feeling of the bars, and especially for breaking in young colts.

The surface may be variegated as to roughness or smoothness, producing also different effects. To give the greatest ease possible, a large and highly polished bit is necessary. This is sometimes provided with moveable rollers on the axis of the bit, which, turning with every movement of the reins, diminish the friction of the bits, and render them less irritating. These rollers, however, in reality can have but little effect in the snaffle, though of pleasant effect in the mouth piece of the curb; for this reason, that the snaffle being joined in the middle, is drawn by the reins to a sharp angle in the mouth, so that these rollers are presented to the bars in an oblique direction, under which position it will be obvious they can have very little or no motion, but, on the contrary, they will tend to render the bits more severe by their irregularity; so that a well polished snaffle is in fact preferable to one of these with rollers of the ordinary construction.

On the other hand, to give the greatest degree of severity to the mouth piece of the snaffle, it is twisted while hot into a spiral form, and is made to present by this means a sharp, rough, and unequal surface to the jaw, being capable, according to the degree of sharpness to which the edges are wrought, of punishing the bars and lips with greater or less severity. The different degrees of punishment which this kind of bit is capable of inflicting, will perhaps be found sufficient for all the purposes of correction, where recourse may properly be had to actual force and punishment. For it should be always kept in view, that gentle means will produce a good mouth; while harshnesses and too great severity will tend to destroy it altogether.

Thus far the ancients of the most remote ages of the world, almost as far back as any history extends, were well acquainted with the use of bits. Xenophon, more than 400 years before Christ, had described similar bits as being in common use in his time among the Grecian states. He speaks of a smooth and a sharp kind of bit, the latter, if more severity was requisite, to be armed with points or teeth. In its use, however, lie enjoins the greatest tenderness, and observes, "that when you would wish to slacken the pace of an eager horse, which Harris too on, and to pacify his fury, so as to make him go more temperately, or even oblige him to stop, you should not attempt to do it at once, and with violence, but artfully, and by degrees, gently pulling him in, then yielding the bridle, and playing with his mouth, in such a manner as if you intended rather to win his consent than force his obedience." Chap. 9, 10.

Beyond the changes above described, the snaffle itself does not appear to admit of any alterations worthy of notice. It may, however, be just observed, that some horsemen add a chain to it, extending from check to check, which resting loosely on the tongue produces irritation and slavering, and, as they imagine, freshens the mouth. Such a bit is known by the name of the Rockingham snaffle.

The reins, however, it must be remarked, admit of some alterations in their disposition, which will influence the effects of the bit on the mouth; as whether they are carried higher or lower. At this present time there is a practice more especially in horses of light draft, as in thoes for carriages, curricles, and chairs, &c. to dilate and alter the bearing reins from their natural direction, and to dispose them more perpendicularly and in a line with the head; so that instead of passing straight from the mouth to the horse's back, they are directed up the sides of the face, as high nearly as the parotid gland, or base of the ear, where they are passed through a ring hanging from the head stall, and from thence to the hook of the faddle. The appearance is ornamental and elegant, and the reins so disposed are considered as more forcibly elevating the head than if they proceeded to the back in the usual direction.

As the disposition of the reins, so the figure of the bits themselves, and the ornamental appendages attached to them, admit of almost endless variety. The manufacturers of these articles, availing themselves of this licence, render their business more lucrative by as frequent changes as possible. These are successively introduced as fashionable novelties, till again for novelty they return to the simplest practice; and this takes place without any alteration in the principal circumstances of their construction, properties, or use.

The next kind of bits in use for horses is the curbed bit; which, as it is an instrument of much greater complication of parts than the snaffle, so it appears to have been of comparatively recent date.

In some of the sculptured equestrian figures of the ancients something like the branches of the curb may be found; but in no instance does there appear any thing resembling the chain, which is absolutely necessary to its effect. Their writings also appear to be silent on this subject. It was probably the invention of Italy or France, which for some centuries past have taken the lead of the other nations of Europe in teaching the arts of the manage. It was first introduced into the English army by a proclamation made in the third year of king Charles I. since which time it has got into universal use for the army, the field, and the road, so that no horsemans deems himself perfectly equipped without it. Most of those writers who have treated of it in the last, and in the century preceding that, and who wrote probably soon after the commencement of its use, have been very profuse in their various proposals for the structure of it, especially in rendering it more complicated, severe, and cruel; though it is probable their clumsy figures and representations were never imitated in actual practice. They appear to have been much satisfied with their new invention, imagining it a cure means of reducing horses to immediate obedience, in spite of every obstacle; and true it is, it can punish with extreme severity: but is such a measure most likely to create vice, or to overcome it? Indeed, according to the opinion of one of the ablest writers that has ever considered this subject, and whose opinion we shall take an opportunity of quoting more fully hereafter, little or nothing has been really gained by its adoption; on the contrary, the snaffle possesses more simplicity, power, and perfection.

Stripped of all unnecessary trappings, this instrument consists of the following essential parts: a mouth-piece with two side branches, or inflexible rods of iron, firmly fixed to the former, and a chain passing from side to side, behind the chin, including the jaw; two eyes or rings at the upper extremity of these branches, serve to fasten it to the head stall, and to stay it in the mouth; two other rings at the lower extremity of the above branches receive the reins, passing to the hand, or sometimes in draft horses to the hook of the faddle, as a bearing rein. These are all the parts really necessary to constitute the curb.

The bits thus formed being placed in the mouth, and the chain passed round the lower jaw, the branches, it will be readily

-section
readily keen, become powerful levers when drawn backwards, acting upon the mouth-piece as a centre, and squeezing, by means of the chain, whatever interposes between it and the mouth-piece, with a force equal to the length of lever afforded by the lower branch.

This force, it will be perceived, is increased and regulated not only by the length of the lever below the mouth-piece, but also by the greater or lesser distance at which the chain is placed from it. The chain is usually fixed to the eye of the check-piece, where the head-halt is fastened; if, therefore, this part is very long, it is evident it must moderate or counteract the power and effect of the lower end of the branch, and render it less severe by bringing the centre of motion nearer to the middle of the lever.

It appears manifest, from the construction of this instrument, that its whole force is exerted upon the jaw itself, and that it has power to pinch the bars with cruel violence, even to the fracture of the bone, and this with very powerful branches has sometimes happened. It can also crush and bruise, and totally destroy the tender covering of the inside of the mouth, and the flap beneath the jaw.

From considering its mode of operating, it might reasonably be doubted whether it does in reality flay the horse by its power and opposed force, as is generally conceived at present, or rather by the severity of the pain it inflicts; as should the horse in himself against this, it is totally insufficient to arrest his course; of which instances occur in runaway horses every day. And we still venture to suggest, though contrary to the general opinion, that the snaffle, even in this respect, if the mouth has not been previously hardened and fpiked by the use of the curb, is the most powerful instrument of the two.

The mouth-piece of the curb is usually provided with an upset or arch in the middle of it, as it would, if perfectly straight, rest on the tongue, and occasion an unpleasant restraint. This passage for the tongue is often made narrower and smaller by the bit makers, that one should apprehend they carefully had a right idea of its use. From the circumstance of its allowing a passage for the tongue, it has been called by some, the liberty; and, for the same reason, by others, the porte: hence we have the porte-mouth bit, vulgarly called among the bit makers and grooms the Portsmouth bit; and by a suppos'd counter expression to this term, we probably get the Weymouth-bit.

In draft horses, especially for the coach, it is a frequent custom to have affixed to the upper part of the upset small chains or polished drops of iron, which hanging loose in the mouth, and falling on the tongue, occasion the horse to clamp the bits, and create a cough's flow of saliva, so as to flavor the lips with its white froth; and, in this case, it is considered by some a good sign of health and gaiety, and that the horse is well bitted; for, if the bits are disagreeable to him, he never plays with them, or exhibits any froth, day they. These small appendages are termed by the French les chainettes, and by the English playets.

It is further to be observed, respecting the mouth-piece of the curb, that the straight part which rests upon the bars of the jaw, is termed by the French le canon, and by the old English writers the piece; and though a highly conveni-ent and useful word, it is to be regretted, it is at present out of use; the French term, which is not so expressive, having superseded it. This part should be well polished, and may be made of any proper figure, as that of a cylinder, cone, oval, globular, pear-shaped, etc.

It is obvious that the effect of the curb, as far as it ref-

pees the bars, will be correspondent to the thickness or thinness, smoothness or roughness, of this part; the larger and broader it is, the more surface it covers; and thus the pressure, by being distributed over more points, becomes les felt. This enlargement, however, of the canon or piece should not be carried to an excess, by making it too heavy, or filling the horse's mouth with more iron than it can conveniently receive, and thus create pain, instead of greater ease.

To render these iron bits irritating to the mouth, and to avoid their friction upon the bars, the jeives are provided with hoop, moveable rollers of well polished iron, which readily ride upon the axis of the bits, very considerably diminishing their severity. These moveable pieces are also particularly useful in preventing the horse from catching and holding the bit in his teeth; as the curb, under these circumstances, can ill move and act with the same freedom as before.

The jeives are sometimes composed of three or four flat-tish knobs, united by a joint to each other, and with a joint to the upset, which is intended to render it very severe; it is obvious, however, that such an alteration must bring it nearer to the condition of the snaffle; the knobs, however, if they can be drawn transversely across the bars, might produce considerable irritation, but not so much as they would do if not jointed. This bit is not frequently used, and is called with us the Hessian-bit.

To the curb is often fixed a ring opposite the mouth-piece, which, as it is directly in a line with the axis of the bit, has no other effect when the reins are affixed to it, than a snaffle would have, provided with a similar mouth-piece. This is termed putting "the reins to the cheek," and for horses of light draft, whose mouths are not ruined, it is by much the best, as the mouth is less annoyed, and the horse obeys with more alacrity the guidance of the hand from this point, than from the extremity of the branches, which are particularly ill calculated for this purpose: this kind of construction is generally distinguished by the name of the Pe-lar-bam-bit.

The curb-bit is used as well as the curb-bit on the Continent, on the subject of bits, we find an appendage described, which is not at all, at present, in use; and as it enters the mouth with the mouth-piece, it may, with propriety, be described along with it. It consisted of a chain extending from branch to branch of the banquet, or check-piece, being placed rather above the mouth-piece, and parallel to it, and was stretched across, perfectly straight and tight. This part was called the water-chain, and by the French Trench-sfile: its use is not very evident. Mr. Berenger takes notice of it, and observes "that it might be useful to horses that are apt to drink or swallow the bits, as the expression is, or bury it so deep in their mouths, as to hinder it from having a due and just effect;" from its being laid aside so generally, we presume it has at least been thought useless.

It is a common belief with the grooms, that a great power resides in the upset of the mouth-piece, and that the bits are more powerful as this is longer or shorter; nothing; however, can be more fallacious than this reasoning. In the works of Laurence Reece, also a French writer, we find, in consonance with this idea, a curb, with an upset of unusual length, being defined to correct the vice "d'un Rouflia qui a la bouche d'une daube;" it will be obvious, however, on a moment's reflection, that this part, from being made very lofty, and coming forcibly against the palate, would compel the horse to open his mouth, when it would cease farther to act in any way; with more reason, the same writer proposes, on the other hand, "pour donner grand
grand plaintiff, to have a bit constructed with a low upset, and sufficiently wide, with large, conical, smooth jaws for the bars.

Of the chain. The chain is the part most essentially necessary to give effect to all the other parts of the curb, and may be placed, as we have already noticed, at any given distance above the mouth-piece; its operation being more powerful, as this distance is exceeded by the length of the branches. This position, though true as a general principle of reasoning, appears to be subject to the operation of other causes in actual practice, which it will be necessary to consider; for, in direct contradiction to this is the assertion of Mr. Berenger, who appears to be almost the only writer who has truly investigated the merits of this particular object. He observes, in regard to this, that the nearer the chain, and the longer the branches, the fother and more indulgent its operation. This, on a first view, would appear to be in direct variance with the rules above laid down, and irreconcilable to the well known laws of the operation of the lever, and even at variance with his own preceding assertions; when, however, we remember the experience and practical knowledge of him who affects it, it derives a more particular consideration; let us first admit the truth of the position, as it seems founded on the true tell of actual experience, and then we should venture the following as the most natural explanation of it.

In proportion as the branches are longer, the more extensive is the circuit their extremities perform in their operation; and therefore, the hand that guides them must pass through a greater space to produce the same effect; and now, if the chain be placed very near to, or upon the outside of the mouth-piece, and be applied not very tight about the chin, yet, in reality, though there would be an apparent increase of power by the length of the branches, they would have little or no effect, as they would arrive at the utmost extent to which they can be drawn, before the chain would begin to push. On this account, the most lively effects would be produced by the chain having more sweep and extent of action, and by the branches being not quite so long, as great length also adds something to their flexibility, though not to a degree to be worth taking into the account. Still, however, the branches must ever obey the common laws of the lever, acting with force proportioned to their length; while shorter branches act with greater quickness, and are more lively in their impression.

The chain is fastened on one side to the eye of the banquet, where the head-fall is fastened; on the other, to a hook hanging from the same part. This chain, as it is at present used, is composed of iron links or rings, so bent or indented, as to form, when put together, one uniform nearly flat surface; and these links, by twisting or unwinding, may be made to present a surface with any degree of roughness to the chin.

When great tenderness is required, this chain may be covered with leather or cloth; or where a still greater delicacy is desirable, the curb may be made wholly of leather, without any chain.

The larger and thicker the rings are, provided they are smooth and well polished, the easier the effect of the chain. In old English, this chain was called the kirile; and hence, by contraction, kir; and finally, by an easy transition of the kir into cu, we apprehend that the modern appellation of this instrument is obtained.

Of the branches. The proportion which the check part bears to the lower extremity of the branches, or rather the position of the eye, to which the chain is fixed, determines the degree of power of the bit upon the principle before advanced; that is, if the chain is fixed to the upper extremity of it, as it usually is to the transverse opening or eye of the head-fall.

For the elementary view we are taking of the construction of the bits, it has been only considered as a straight, plain lever of indeterminate length; it is, however, in practice, often varied, as in the army, it is fixed of enormous length, and frequently curved like the letter S, by which it is conceived to be rendered more powerful, as well as ornamental; at other times the branch of the bit, with a view of increasing its force, is carried forward with a sharp elbow, giving nearly the figure of the letter Z; while by others, with more reason, to prevent the horse from catching the bit in his mouth, it is made with an arch, or semicircle, in the middle of the branch, like the letter C, turned backwards for the same purpose; still, however, in fact, whether bent into that or any other shape, it is the length of the lever, and its strength, which alone give the power; it is true, however, that a long curved branch, though more powerful, will render the effect somewhat fother, as coming from a greater distance, especially if the branch is at all flexible and yielding, than it would by the quick and rigid effect of a shorter lever, made perfectly fhard and inflexible; these branches may also be turned or bent, not only backward or forward, but also outwards and inwards. At their extremities, those turned outwards, are said to be strong on any in their operation.

As to the check-piece, or banquet, as it is called by the French, for an appropriate name is wanting to this part in the English language; the eye of the banquet, say the horsemens, commands and gives efficacy to the rest of the bit; or, in other words, decides the distance of the chain from the mouth-piece, or centre of motion; as, however, in speaking of the other parts, we have had occasion to introduce a sufficient account of this, it will not be necessary farther to give it a separate consideration; nor will it be useful to describe the numerous mongrel herd of bits engendered of the snaffle and curb, which are reducible to the properties of one or the other, or partaking of both.

The most useful bit of the curved kind, appears to be the Weymouth-bit, which is at present in common use for draft horses of light work, as for carriages, coaches, &c. It consists of a strong, plain mouth-piece, of uniform thickness throughout, without any upset or jibes, but is simply curved forwards, to give liberty to the tongue: this kind of construction is the simplest perhaps that the curb admits of.

In concluding, it remains for us to notice the proper application and adjustment of these bits to the horse's mouth, and to treat of their real effects.

By the management of the head-fall, the snaffle bits should be so adjusted as to fall in the middle space between the tusks and grinders, resting upon the bars; the mouth-piece of the curb should also occupy the same situation; when, however, it is used along with the snaffle, the bits of the snaffle should be placed uppermost in the mouth.

If the bits are placed too high in the mouth, the horse carries his head aloft; if too low, he floops the head, and tries to catch them in his teeth.

The thicker and more fleshy, and the wider or broader the bars of the horse, the rougher may be the mouth-piece for the learner and more delicate; consequently, the bits should be less severe. Care should also be taken that the mouth-piece be well fitted to the size and width of the mouth, and be not too narrow, as this would give pain, by squeezing the bars together: if, on the contrary, it is very wide, it rets with more force on the bars, without the interposition of
of the lips, as is most usually the case. Where the tongue is large and prominent, the upset should also be in proportion; otherwise the bits could not rest upon the bars, but would press upon the tongue.

In regard to biting the horse, and the consideration of its effects, we cannot desire to see any thing more connotant to truth and reason, than what has been given us by Mr. Be- renger, and with some useful extracts from his valuable performance, we shall conclude this article.

"Of biting horses with the curb." — "In the beginning of an undertaking, whose aim is to subdue and reclaim nature, and that at a time when she is wild, ignorant, and even affonblished at the attempts which are made upon her, it is evident that she must not be treated but with lenity, incu- tracted with patience, and by small degrees, and that nothing should be offered that may hurt, surpriize, or occas- tion any difficulty.

The horseman, therefore, should not act the part of a tyrant, but of a lover; not endeavour to force her to sub- mission, but strive to gain her content and good will by affability, perseverance, and the gentlest attentions: for what prospect of success would rougher manners afford?

To what purpose would it be to compel a colt to go for- ward, or turn from fear of the whip or spur, and to trot and gallop so freely as to supple his limbs, and form his paces; if the novelty of the bit, and the unaccustomed refrain to which it subjects him, shou'd vex and confound him, so as to make him not know what to do, or how to be- have in these extremes? It cannot be expected, that he will be guided, and go with ease to himself, or pleasure to the rider, if the instrument, by which he is to be conduced, offends or gives him pain; all habits and requirements should be attained gradually, and almost imperceptibly: ri- gour and precipitation would ruin all, and tend to form- ing the horse to the execution of what is required, may plunge him into vice and rebellion, so as to occasion much trouble and loss of time before he can be reduced.

He shou'd not therefore, at first, be considered as if he was designed to be formed to all the delicacy and exactness of the bit; and the horseman shou'd be content, if he will endure it in his mouth, so as to grow, by little and little, ac- customed to it, till the restraint becomes by habit so familiar and easy, that he not only is not offended, but begins even to delight in it; for this purpose, great care should be taken that the bit be easy and gentle in all its parts; that the mouth-piece be larger than it need be for an horse al- ready bitted; that it in no wise incommodes the bars, fqueezes the lips, or galls the tongue.

The mouth-piece, called a cannon, with a joint in the middle, will be the most suitable; the ends of it should be as large and full as the size of the mouth will permit, for the thicker and more blunted they are, the eaiser they will be for the horse, and the appui less sharp and severe.

The links of the curb should be big, smooth, and well polished: the curb somewhat long. The branches shou'd be exactly even with the line of the banquet, to make the appui moderate and equal; they should likewise be long; nor does it signify of what shape they are, for with moist horses they ought to be so weak, as scarcely to have any effect; so requisite it is to guard against every thing that may annoy or disturb the horse in these first trials. In order to reconcile him to this new constraint, the reins shou'd be held in both hands; and the horse, for some time, should only walk under the rider. Above all, upon this, and all other occasions, a firm, a light, and diligent hand, is necessary.

Such are the outlines and general principles upon which the art of biting horses is established; which art, as far as it reaches, is pure and constant; but which, in spite of all the merits and praise of which it has so long been in possession, will, upon a serious and strict trial, never, I doubt, be found adequate to the views of a found and intelli- gent horseman, nor capable of bringing a horse to that degree of suppleness and exactness of carriage, which the truth and perfection of the art require, these attainments seeming to have been reserved for a more simple but powerful machine, called the snaffle."
thing will awaken a dull mouth, and bring it to life and feeling, so soon as this bridle. If the mouth be hard and callous, the iron should be so twitted as to have a foot of edge, which will reach the lips, and when they will permit, the bars also; and if gently moved, or drawn from side to side, keep the mouth fresh and cool. If the twitted, or rough snaffle, be thought too harsh, and the hand not skilful enough to moderate its effects, a smooth snaffle may be used; or if a bit of linen be wound round the twitted snaffle, it will make it easy and smooth; and the mouth, once made fine and delicate, will be true to its feelings, will obey the snaffle, and follow the hand with as much exactness and precision as the bit knows to demand, but with more freedom and boldness that it ever can allow."

Such are the properties and merits of the snaffle, which long observation, and not a little experience, have taught the writer of this article to think preferable (generally speaking) to those of the bit; and which he has been therefore induced to point out and recommend with due deference to others, but with a greater deference to truth and justice:

"—Deteneo autem
Hacertem capiti multa cum laude coronam."

Bit is also used for a little tool, fitted to a block or handle, for the purpose of boring. In this sense, we say, the bit of a piercer, an auger, or the like; meaning that iron part of those tools wherefrom the holes are bored.

The bit used by the block-makers, resembles the Shank of a gimlet, from six to twelve inches long, and from half an inch to an inch in diameter, and has at its end either a screw, a sharp point, or edge, for the purpose of cutting or boring holes. The centre-bit is a bit, having in the middle of its end, a small file point, with a sharp tooth on one side to cut horizontally, and a sharp tooth on the opposite side to cut vertically. Holes bored with this instrument, are not liable to split. The countersunk-bit is a bit having two cutting edges at the end, reversed to each other, which form an angle from the point. Goose-bit is a bit smaller than a centre-bit, with a hollow edge at its end, like a gouge. Nose-bit is a bit similar to a gouge-bit, having a cutting edge on one side of the end.

Bit or a Key, is that part fitted at right angles to the Shank of the key, wherein the wards are made. See Lock, &c.

Bit is also used in Commerce, for a piece of coin current in Jamaica, and valued at $f.3d.

Bits, or Bitts, in a ship, denote a frame composed of two upright pieces of timber, called the pins, and a cross-piece fastened horizontally on the top of them; used for belaying cables and ropes to. Bowline and brace bits are situated near the masts; the fore-jer, and top-fall-flot bits are situated in the fore-cable, and round the fore-mast; the main jer, and top-fall-flot bits tenon into the fore-mast beam of the quarter-deck; the riding bits are the largest bits in the ship, and are those to which the cable is bitted, when the vessel rides at anchor. The cable is bitted, or confused to the bits by one turn under the cross-piece, and another turn round the bitt-head. In this position, it may be either kept fixed, or it may be veered away.

Bitt-Steppers, are those stoppers that are used to check the cable. See Stopper.

BITAZA, in Ancient Geography, a town of Asia, in Aria, according to Ptolemy.

BITBOURG, in Geography, a town of the Netherlands, in the duchy of Luxemburg before the revolution, but now a principal place of the canton of the same name, in the department of Forêts, containing 1658 inhabitants; the population of the canton consisting of 7760 persons. Its territorial extent includes 225 kilometres, and 12 communes. N. lat. 50°. E. long. 5° 45'.

BITCH, in Zoology, is the female of the canine species, in contradistinction to dog. (See Canis.) It is sometimes used in a similar sense with respect to foxes, the female being termed a "bitch-fox," though the more common appellation among sportsmen is a "vixen." Bitches are sometimes spayed, to prevent their farther propagation; the belt time for which operation is about after the heat is gone off.

BITCHE, in Geography, a town of France, and principal place of a district, in the department of the Mofele, containing 2310 inhabitants; the number of those in the canton being 10.441. Its territorial extent is 3125 kilometres, and it includes 23 communes. It is seated on a river at the foot of the Voûges mountains, on the frontiers of Deux Ponts. It was taken by Lewis XIV, and fortified by Vauban; afterwards dismantled and restored to the duchy of Lorena. In 1740, it was again fortified. Before the revolution, it was the capital of a country, including 50 villages. N. lat. 49° 5'. E. long. 7° 44'.

BITCHU, or Bitius, a province of Nipon, in the islands of Japan, between about 34° 30' and 35° N. lat. and about 134° 30'. E. long.

BITCHYS, a tribe of Tartars, visited by La Perouse in 1787, and described by him. See OTCHOTSCH.

BITE is defined to be a solution of the continuity of a soft part, caused by the impression of an animal's teeth.

Bite of Mad-dog. See Hydrophobia.

Bite of Serpents. See Poison.

Bite of Rattle-snake. See Poison.

Bite of the Tarantula. See Tarantism.

Bite is also applied, in a less proper sense, to the impression of other sharp or pungent bodies. Thus a file is said to bite the metal; aqua fortis bites, or eats into copper. An anchor is also said to bite, when it holds fast in the ground.

BITERLAGH, or Bitherlage, the ancient Danish military or camp law.

The word is compounded from bithe, multi, and lagh, law; q. d. the law of multēs, or variet.

Among the laws of the Danes, there are two peculiarly eminent; viz. the bird firaat, or court law; and the biterlage raats, made by Canute the Great, about the year 1035; of which an edition has been given by Rerfinus.

BITETO, in Geography. See BITEFO.

BITHABA, in Ancient Geography, called also Bithbana, a town of Aria, in Affiria, according to Ptolemy.

BITHER, a city of Judæa, called by St. Jerom, Bethoron, which was the place of retreat of the impious Barchochbas, fortified by him, and made the capital of his new kingdom. It was besieged by the Romans under Julius Severus, A.D. 134, and after an obstinate resistance, compelled to surrender. See Barchochbas, and Bethoron.

BITHERERMAN, a town of Phœnicia, according to Sozomen, situate at the extremity of the territory of Æletheropolis.

BITHIA, a town of Aria, placed by Ptolemy in Media.

BUTHIAS, a town of Aria, in Mesopotamia, according to Ptolemy. Also, a river of Thrace, according to Appian.

BITHIGA, a town of Aria, in Mesopotamia. Ptolemy.

BITYLÆ, a people of Thrace, who, according to Steph.
BItaly

Steph. Byz. derived their name from Bithynia, a son of Mars; but more probably from the river Bithius or Bitalis, mentioned by Appian, and denominated Bithynias by Ptolomy.

BITHYLA, a town of Greece, in the interior parts of Laconia. Polyen.

BITHYNIUM, a province of that part of Asia, which was commonly called Asia Minor. It was anciently known by the names of Myia, Mygdonia, Belbica, and Maeandria, as well as Bithynia; and extended from Myia on the west, to Paphlagonia on the east. It was bounded on the west by the Bosphorus Thracicus and part of the Propontis, on the south by the river Rhynacius and mount Olympus, on the north by the Euxine sea, and on the east by the river Parthenius. Polyenoy enlarged the extent of Bithynia, so as to make it comprehend some provinces belonging, according to other geographers, to Galatia and Paphlagonia. The chief cities of Bithynia on the coast were Mytilus, Cyzicus, and Nicomedia the metropolis. On the Bosporus floomed the famous city of Chalcedon. In the Euxine sea were situated the city and ancient republic of Heraclea. The principal inland cities of Bithynia were Prusa, Lydia, and Nicaea or Nice. Its chief rivers were the Pillis, Copia, Sangarius or Sagaris, Hipias, Rhicas, and Lycus; all discharging themselves into the Euxine sea between Chalcedon and Heraclea. As Bithynia lies between 41° and 43° of north latitude, and is watered by many rivers, it once abounded with all the necessaries of life. The ancients compare some of the inland provinces to the fruitful and delicious vales of Tempe; but at present it lies in a great degree neglected and uncultivated. Bithynia was anciently inhabited by various nations, differing in their manners, customs, and language; namely, the Bithyrians, the Maedi, the Cinees, the Dardanes, the Thracians, and the Comerti. The different nations were anciently governed by their own kings: Bithynia being, in the earliest times, divided into as many kingdoms as nations or tribes. However, in process of time, these petty princes were reduced by the more powerful kings of Bithynia. According to Dio Chrys. Siculus, the Bithynians had kings from the time of Numa; and, according to Appian, they had 49 sovereigns before the Romans obtained possession in Asia. But this high antiquity is rendered doubtful by the silence of Homer respecting the Bithynians. Strabo (I. 465) speaks of one Prusias, who reigned in Bithynia in the time of Cæsars, the last king of Lydia, by whom he was conquered. From this period, the Bithynians continued subject first to the Lydians, and afterwards to the Persians; till the reign of Alexander the Great; for we find them mentioned by Herodotus among the many nations that attended Xerxes in his expedition into Greece. While they were subject to the Persians, they feigned to have been governed by their own princes. Under Nicomedes I. the Bithynians, whom he called to his assistance, first passed into Asia, and obtained a settlement in that part of Asia Minor, which was called from them Gala-Gaæia and Gaæia. The last king of Bithynia was Nicomedes IV., who, at his death, in the year before Christ 75, bequeathed his kingdom to the Romans, by whom it was reduced to the form of a province.

BITHYNIARCHIA, a sort of superior priesthood in the province of Bithynia, to which belonged the superintendency of the sacred games, and which gave an exemption to him possessed of it, called bithyniarcha, from the care of tutelage.

BITHYNIUM, in Ancient Geography, the ancient name of a city of Bithynia, afterwards called Chalcedopolis.

BITITIS, in Zoology, a species of Coluber that inhabits Brazil. Above, this creature is cinereous, yellow, varied with white and red, and transverse brown bands; beneath, yellowish, with a middle row of very minute lines. Gmel. &c. Teperta batris of Laurent. Amp.

BITONIA, or Bitonis, the name of the Linnmanus feminus in Adamant's Schizophrenia, &c.

BITONIA, or Bitonis, the name of the Linnmanus feminus in Adamant's Schizophrenia, &c.

BITOPO, or Bitonis, the name of the Linnmanus feminus in Adamant's Schizophrenia, &c.

BITONTO, in Geography, a town of Naples, in the country of Baris, about 8 miles from the Adriatic, the site of a bishop, suffragan of Baris. This is a fine town, containing 16,000 inhabitants, of more easy fortunes, and more polished manners, than those who dwell in the cities along the coast; its markets are well supplied, and it has an air of leisure. The country between it and Baris, at the distance of 9 miles, is very much inclosed; and though stony, fertile in corn, almonds, olives, wine, and fruit of all kinds. Near this city an obelisk was erected by the king of Spain, with some fulsome inscriptions in praise of himself, his father Philip, his condition, and the count of Mortemar, who was honored with the title of duke of Bitonto, for having defeated the Aulians on this spot in 1734. The monument, however, which records a trivial victory, is crumbling to ruin.

BITTACE, or Bittace, a square box, or frame of timber, placed in the fleeces of a ship, wherein the compass is placed. The word is formed, by contraction, from the French bateau, a small habitation, which signifies the same.

Large vessels have two bittacles, a lesser placed before the pilot, and a greater before the fleeceman.

In the smaller vessels, the bittacle is divided into three spaces or apartments; in large vessels into five. One for the hour-glass; another for the lamp or light; another for the compass, &c.

Great care is to be taken in the disposition, framing, &c. of the bittacle, that it stand true, and that it be not fastened together with iron nails, but with wooden pins, because the former would affect the compass. See Compass.

BITTENDORF, in Geography, a town of Silesia, in the principality of Neisse, 2 miles N. of Ottmachur.

BITTER, in Sea Language, denotes the turn of the cable round the bitts.

Bitter almonds. See Almond.

Bitter apple. See Colocythis.

Bitter end of a cable, that end which remains on board round the bitts, when the ship is at anchor; the other part of the cable being veered.

Bitter gourd. See Colocythis.

Bitter place, locus amaris, a poor barren soil, by Pliny called terrae amari, inus locorum. See Epison Salt.

Bitter savory, in Botany. See Solanum.

Bitter sweet. See Oregus.

Bitter water. See Water.

Bitter wine. See Wine.

Bitter wood and of. See Quassia.

Bitter wood. See Gentian.

BITTERFELD, in Geography, a town of Germany, in the circle of Upper Saxony, and electorate of Saxony, situated
BIT

feated on the Moldau, 16 miles S. of Ditzau, and 18 S.S.W. of Wittenberg.

BITTERN, BITTOUR, in Ornithology, the Liangan

tern, among birds that are but owing.

BITTER, is also a name given to the brine swimming

upon the first concocted salt in the salt-works; this liquor is

laded off, that the salt may be taken out of the vessel, and is

afterwards put in again, and affords more salt, which is to

be separated like the reed, by lading off the liquor a second
time, and so on. The bittern, according to Mr. Boyle, is

a very saline, bitter, harsh, pungent liquor, which drains

off in the making of salt from sea-water; or which remains

in the pans, after the coagulation and granulation of the

purur and more saline part by boiling. A bittern also runs,

or ooze, from the heaps of fossil salt at Lynington, and

BITTER makes the balls of fad eubarticum amaranum, or Ep-

sarn-salt.

BITTERN is the mother-water which remains after the crys-
tallization of common or marine salt in sea-water, or the

water of salt springs. It abounds with Epsom salt, or the

combination of vitriolic acid with magnesia, to which its

bitterness is owing. It is employed in this country for

making a purging bitter salt, which proves similar in quality

to the salt obtained from the Epsom waters, and is com-

monly sold under its name. The ley is boiled down to a

certain pitch, then filtered and inspissated; the dry matter is

calcined, re-dissolved, and crystallized. If the mother-ley

be inspissated and diffilfed with vitriolic additions, a spirit of

salt is obtained. Neumann, p. 212.

BITTERS, in the Materia Medica. The quality of bit-
terns (a simple perception familiar to every one, and which

cannot be defined) is much more frequently met with in

vegetable matter, than in any other order of natural sub-

stances; and in this, it mostly resides in a certain soluble

matter, with tolerably uniform chemical properties, which

has by some been denominated bitter extract. This diffi-
cence, though not perfectly accurate, is of considerable use in

pharmacy; for whenever a bitter taste is perceived in any

part of a vegetable, we may conclude, with much probability,

that it resides in this specific part of the vegetable, and espe-
cially that it gives certain medicinal properties, which expe-

rience has shown to be in the highest degree important.

The bitter principle is found in combination with a variety

of other active substances, which modify, alter, correct, or

impair its medicinal powers.

A pure, simple bitter vegetable (of which gentian, or

quinina are good examples), is entirely void of smell, has

neither aconite nor adstringency to the taste, nor does it ex-

cite nausea, unless in excessive quantity. The bitterns are

readily extracted by almost every menstruum, aqueous, as well

as spirituous; and in the simple bitters, little, if any, dif-

ference, is perceived in the feasible properties of what is ex-

tracted, whatever be the medium. The bitter extract is not

volatile by heat; hence, in the distillation of bitter plants that

yield an essential oil (worm-wood, for example), the distilled

oil has none of this taste, the whole remaining in the residue.

A watery, or spirituous infusion of a bitter plant, inspissated

nearly to dryness, becomes intensely bitter, often with an

empyreumatic, or a somewhat altered taste. This,

when further dried, becomes solid and pulverulent. The

extract is a convenient form for these substances, but the

flavour is not so acceptable to the palate as the simple infu-

sions.

The bitter extract is considered antiseptic. Experiments

have proved that the putridity of animal matters is much

retarded by immersion in bitter infusions, even the watery;

and substances already putrid, in some degree, lose their

factor by this addition. The watery infusions of bitter vege-
tables mould by long keeping, and become sour. This

change takes place in summer, in five or six days, when the

infusion is not very strong. The newly acquired acid tale

in some degree marks the bitterns; but this latter quality

remains extremely long, and is hardly ever lost by spontaneous

decomposition.

The effect of the simple bitter on the human body, is gen-

erally considered as purely Tonic. It does not raise the pulse;

nor does it directly, or confoundly produce any change in the

feverous or excitations of the body. Its chief and most obvi-

ous operation is to increase the appetite, and promote the
digestive powers; and hence it is with reason supposed, that

its virtues depend on stimulating the fibres of the flomach.

From this single effect may be derived the well known use

of bitters, in giving general tone and vigour to the system,

in a vast variety of cases of debility, unconnected with organic

diseases, in checking ulceration of the flomach, heartburn,

flatulence, and other symptoms indicating a deficiency of

the digestive powers, and in extending its salutary operation

through the whole of the alimentary canal, restoring the reg-

ular and natural action of the bowels impaired by the original
depradation of the digestive organ.

Bitters have been suppressed by some to increase the intox-

cating powers of food and drink. This, however, ap-

pears to apply only to the narcotic bitters, and to be attribu-
table to the narcotic, and not the bitter principle. On the

contrary, the salutary action of bitters on the digestive

powers, is well calculated to correct the extreme and pecu-

liar debility of the stomach, induced by habitual drinking.

An anthelmintic virtue (or power of expelling worms from

the human body) has been attributed very generally to all

bitters indiscriminately. There does not, however, appear to

be much foundation for this opinion, unless the bitterns be

combined with a purgative property, as in aloes, or possi-

bly a narcotic. The contents of the intestines being always

intensely bitter by the natural admixture of bile, it does not

appear probable that animals, which live and grow in such

a medium, can be much modified by a small addition of this

principle, though from a vegetable matter.

An excessive habit of taking bitters, may finally prove de-

trimental to the stomach, by over-excitement, or by inducing

a kind of artificial demand for food in greater quantity than

is salutary to the general health. A remarkable example of

the danger of these medicines, long perished in by persons

of gouty habits, is afforded by the operation of the Portland

crunch in this disease.

The chief combinations of the bitter principle used in me-

dicine are Narcotic bitters, such as opium, fahba Sanei Ignatii,
bitter almonds, and the kernels of many fruits: Aromatic

bitters, as orange peel, ecalcarilla, and wormwood: Aperient

bitters, a very large class, and generally combined both with

tannin and the gallic acid, of which emulions, and many other

barks are linking examples: Acid and purgative bitters; the

squill, colocynth, aloe, and some other combinations of left

frequency.

For medical use, the aromatic is always an useful addi-

tion to the bitter, and is generally employed.

The most important of the animal bitters is the bile, the

properties of which have been mentioned under that article.

In tonic power, it closely resembles the vegetable bitters.

Late experiments make it probable, that the Prufic acid, a

very peculiar animal bitter, possesses properties similar to the

vegetable narcotic bitters.

A few of the mineral or common saline combinations, are
distinguished by bitterness of taste; but it is doubtful how
far this principle modifies their medicinal powers. The nitrat
ed silver is of this kind, a salt esteemed to be a very
powerful tonic, taken internally in small doses. Some of the
saline combinations of magnesia have the same taste, and it is
possibl on this account, that the sulphat of magnesia will
often be retained by very irritable Romans, when other
saline medicines are rejected. For the pharmaceutical
preparations of the several bitter, see the respective articles:
As Gentian, Quina, COLUMB, &c. and that of BITTER EXTRACT.
BITTOUR, in Orbisdeb. See BITTERS.
BITUBERCELATA, in Entacmaya, a species of Cas-
ida, of a brown colour, with a white margin: wing-cubes
spotted with black, and a single tucklebe at the base of each.
A native of Scoresbty. Fabricius.
BITUBERCELATUS, a species of Cerucus, that
ofhabitats New Zealand. This is of a ferruginous colour;
thorax length of the wing-cubes, and dotted, with two tu-
berries on the back. Fabricius.
BITUBERCELATUS, a species of Cryptoscelopus
(Criscoriz), that inhabits Africa. It is fulvous: wing-cubes
pale, entirely bordered with fulvous. Fabricius.
BITUMEN, Bitume, Fr. The bitumens, properly so
called, form a species of compound mineral inflammables, of
which the following are the characters. 1. By exposure to
the air, and the application of heat, they burn with a flame
more or less vivid, and leave fearly any residue. 2. By
ductive distillation, they yield a liquid acid, but no am-
mona, a variable but small proportion of charcoal being left
behind in the retort. 3. They are either liquid, or capable
of being rendered so by a moderate degree of heat.
Bitumens may be divided into two families, the non-elat-
lc and elastic. 1. To the former belong naphtha, petroleum,
mineral tar, mineral pitch, and asphaltum; to the lattcr be-
lng mineral coal and sulfureus asphaltum. See Bitume.
§ 2. Elastic Bitumens.
NAPHTHA, Naphtha, Bitume. Liquid blanches-
tes, is a substance of a light brown, or wine yellow
colour, perfectly fluid and transparent. It is the lightest
of all liquids, its specific gravity being 0.858 to 0.752;
it has a strong penetrating bituminous smell; it takes
fire with great readiness, and burns with a bluish yel-
low flame and copious black smoke, leaving no residue. It
may be rectified by distillation with water, in the same manner
as the essential oils, and then becomes colourless, and weaker
in its odour. It does not combine in any considerable de-
gree with either water or alcohol, but unites easily with
either, with turpentine, with caoutchou, and the essential
oils. When rubbed with the caustic fixed alkalies, it forms
a kind of Starkey's soap. The concentrated sulphuric
and nitric acids are decomposed with vehemently upon it, con-
verting it into a solid resinous substance soluble in alcohol.
Even the purest naphtha, when exposed to the air, becomes
brib of a yellow, and then of a brownish colour, acquires a
somewhat vivid consistence, and thus passes into petroleum.
Naphtha is procured for the most part from very copious
flures of this substance at Baku on the shore of the Caspian
sea, where it is burnt in lamps instead of oil, and is used me-
dicinally both externally and internally in rheumatic and other
complaints. It is also met with in Calabria and some parts of
ITALY.
PETROLEUM, or Rock-oil. Erdahl, Stein-oil. Petrole.
The colour of petroleum is a blackish or reddish brown; it
is fluid, though somewhat viscous; it is almost opaque, 's auc-
ous to the touch, and exhales a strong bituminous odour; its
taste is pungent and acid. Sp. gr. 0.847, 0.854. Petroleum
may be rectified by distillation with water, in which proceeds,
the carbon, which thickens and colours it, is left behind in the
retort, and a colourless fluid comes over, possessed of all the pro-
erties of naphtha. When petroleum is distilled per se, there
first arises some naphtha, then a water, and then a light dark
coloured oil, and lastly a thick dark coloured oil, a spagyric coal remaining
in the retort. In its combinations with, and chemical actions on
other substances, it perfectly resembles the preceding spec-
ies. Where it is found, wherever naphtha is, and in many other
places among railed mountains, in the vicinity of coal.
In England, Coalbrook dale, and Pitchford in Shropshire,
are the principal places where petroleum is found; at the
latter place extensive flats of sandstone are satured with
petroleum, and the naphtha, procured by distillation of the
stone, is sold under the name of Deton's British oil, and is
employed an active remedy in strains and rheumatic.
MINERAL TAR, BARMADOES TAR, Bergthier, Caudrom-
minerale. This substanse differs from the preceding only in
degree; it is more viscous, more opaque, of a darker colour,
and, when distilled, leaves a larger carbonaceous residue.
It is found native together with petroleum, and may also be
procured by the distillation of coal.
MINERAL PITCH, Maltha. The external characters of
maltha are extremely similar to those of commor pitch;
when heated, it emits a strong unpleasant odour. In cold
weather it may be broken, and exhibits a vitreous luster;
but when warm, it is soft and tenacious.
ASPHALTUM, Schleicher Erdlehr, Asphalte. The colour
of this substanse is black or brownish black; it is light and
brittle; when broken, it displays a conchoidal fracture and
vitreous luster; it has little or no odour, unless it is rubbed
or heated. It is considerably inflammable, melts easily, and
burns away without leaving any residue. It is principally
found on the shores of the Dead Sea, in Syria, and in the
isle of Trinidad in the West Indies.
The principal use of asphaltum is as an ingredient in cer-
tain varnishes, especially that used by the copper-plate en-
gravers.
§ 2. Elastic Bitumens.
MINERAL CAOUTCHOU, Elaichter Erdlehr, Poix mine-
rale elasique. The colour of this substance varies from
yellowwhit brown to oilve brown and blackish or reddish
brown. The light coloured is often in a semi fluid flake, and
adheres to the fingers; the olive brown is solid and elastic;
the blackish and reddish brown are hard and little elastic.
It occurs flabelliform, or oval, or in mafes. Its fp.
grav in the fixed varieties is about 0.59, and in the hardest
and least elastic is 1.2. It passes into asphaltum.
It is partly soluble in sulphuric ether; but the residue of
the solution, after evaporation of the ether, is not elastic;
thus forming an essential difference between the vegetable
and mineral caoutchou.
This singular mineral has been hitherto only found in the
cavities of a lead mine, near Calbleton, in Derbyshire, called
the Odin mine, accompanied by asphaltum.
SUPERIFORM MINERAL CAOUTCHOU. This substan-
ce, when recently cut, exactly resembles fine cloie cork in its
colour and texture; but by exposure for a few days to the
air, it becomes of a pale reddish brown colour. It is also
sometimes found friable, and passing by decomposition into
an ochraceous powder. It has only been found in a rivulet
near the Odin mine, whence the preceding is obtained, and
appears to differ from it, merely by being penetrated with
water. It occurs in nodules of various sizes, some weighing
upwards of 15 pounds, the nucleus of which is very common-
ly the brown perfectly elastic mineral caoutchou. "Fourcroy

BITURIGES,
BITURIGES CUBI, in Ancient Geography, the name of a people who occupied a considerable part of Aquitanias Prima, and who had been much more powerful before Caesar's conquest of Gaul, than they were afterwards. Livy says, that in the time of Tarquin, they commanded the whole portion of Gaul called Celtic. Their capital was denominated Avaricum, which see. In the time of Caesar, these people lost their power, and became subjects to the Edii, or at least were reduced to the necessity of putting themselves under their protection.

BITURIGES Vfvoli, a people who inhabited the southern part of Aquitanias Secunda, and are supposed to have derived their origin from the Bituriges Cubi. Their capital was Buffdago; which see.

BITURIS, a town of Hispania Tarraconensis, in the country of the Vaccones. Ptolemy.

BITYLA, a town of the Peloponnesus, not far from the Meffennian gulf, S.W. of Sparta.

BITZLEER, Livia, in Biography, a celebrated Jewish rabbi, who flourished in Bohemia about the close of the sixteenth century. He converted with the emperor Rodolphus, and was so famous, that the Jews paid him, that all fired drunk of his waters, and walked by his light. He founded the academy, called Klaufe, in 1592, which acquired such reputation in his time, that it drew a vast concourse of disciples to him. He was chosen at last superintendant of all the synagogues in Poland.

BIVALVE, two-celled, in Conology, bivalve conche, one of the three principal divisions, into which all tesselaceous animals are divided. The Linnean genera of bivalve shells are mya, solen, tonna, cassis, pecten, mantere, donax, venus, spondylus, cluma, arca, olacea, anomya, mytilus, and pinna. The arrangement of bivalves by Cuviier, Lamarck, and other late naturalists, differs materially from that of Linneus and Gmelin. See Conology.

BIVALE is also applied, in Botany, to the filique, or seed-pods, of such plants as open their whole length to discharge their seeds. Such are peas, beans, &c. which the botanists say, have bivalve or bivalvular filique.

BIVAT, in Conology, the name given by Adanson to the shell called by Linneus (Syll. Nat. edit. 10) murex frabriusculus; and valvula cancellata. Gmelin.

BIVENTER, from bis and venter, in Anatomy, a name given to muscles that have two fleshy portions, which were called bellies, and one tendon. Such muscles are also called digastric. The term biventer has been applied to a muscle of the lower jaw and es hyoides, which is described under its more common title of digastricus. Albins also denominate a portion of the mucous complexus of the neck, biventer cervicis. See Complexus.

BIVERI, in Geography, a lake of Sicily, near Lentini, which, in summer and autumn, renders the situation of this town very unhealthy. The waters of this lake, and of the neighbouring marshes and ponds, abound with eels and tench, of the size of which the fishermen make a large quantity of botargas, a species of cement; it is very fat, and has the taste of tar, but is much relished by the Sicilians. Bivincisco, the principal place, of a canton, in the department of Golo, and island of Corsica, the population of which consists of 1773 persons.

BIVIO. See Bivio.

BIVITATUS, in Entomology, a species of Scarabæus (Melolontha), that inhabits Brazil. It is yellow and very glossy; on the head and thorax two common fringes, and many abbreviated green hair on the wing-cases. Svederus, Nov. Act. Stockh.

Bivittus, a species of Curculio, found in St. Tho-

mas's island. It is black; wing-cases fringed with dots; marginal and dorsal interrupted line of yellow. Fabricius.

BIUMBRES, from bis, double, and umbra, shadow, in Geography, an appellation given to the inhabitants of the orbis bis; because in different sections of the year, their shadows are projected in two different ways.

The biumbres are the name to those otherwise denominated amplissiti.

BIUMI, Paul Jerom, in Biography, born at Milan in 1663, founded medicine at Padua, where he was admitted to the degree of doctor in 1685. Returning thence to Milan, he soon acquired so much fame for his learning and skill in his profession, that in 1699 he was made professor of anatomy there, in which situation he continued to the time of his death, in 1731. He was author of several works, of which the following are most known:—"Encomiasticon lucis, seu lucis encomia in physiologicis medicina novae fundamentis et veterum tenebris erutus, atque euloro anatomico, autolique caracteris confirmatis," Medici, 1701, 4to. "Scrutinio di Notomia e di Cirurgia," Milan, 1712, 8vo. Haller. Bibl. Anat. et Med. Eloy. Diet. Hist.

BIVONA, in Geography, a town in the kingdom of Naples, and province of Calabria Ultra, 10 miles N.E. of Nicotera.

Linneus has adopted the South American vernacular name of bixa from Oviedo; and it is known by the famous name in Holland, Denmark, and other northern countries. In Holland it is likewise called Orelis; in German, Anota, &c. In England this name is adopted, but its orthography is various, as Arnotto, Arnotna, Anota, Anoto, Anoto, and Anoto. The French have adopted the Brasilian name, Urulo, or Uruco, spelling it Roucoury, Rouçon, or Roururier des Indes. The Portuguese have also the same appellation...
appellation Ursin, or Urseneis. In Spanish it is Ansto, or Avolle. In the Mexican language, Achiote. Scaliger calls it Arbor Ammonis Reguardum, because the Mexicans made plans, and marked the boundaries of their lands on tablets, with the colour prepared from the berries. Tournel named it Meltella, from the resemblance of the capsule, when open, to a miter. For the preparation of the drug, and its uses, see Annotto. The bark of the bixa makes good ropes for common use in the West Indies; and pieces of the wood are used by the Indians to procure fire by friction.

Propagation and Culture. This plant is propagated by seeds, may be easily cultivated, and is planted in many parts of Jamaica, Barbadoes, Cayenne, &c., in rich soils, and shady situations, shading luxuriantly near rivulets. It is also propagated with us by seeds, which are annually brought in great plenty from the West Indies. These should be sown in a small pot filled with light rich earth, and plunged into a hot-bed of tanner's bark, where, with proper temperature, the plants will appear in about a month; when they are about two inches high, they should be taken out and separated, without injuring their roots, and each planted in a pot of light rich earth, and plunged into a fresh hot-bed of tanner's bark, shading them every day till they have taken root; afterwards they should be treated like other plants of the same country, by admitting fresh air to them in proportion to the warmth of the feston; and when the heat of the plant declines, it should be turned up to the bottom, and, if necessary, fresh tan be added to renew the heat. The plants must be refreshed with water three times a week in summer, but not in great quantities, as with much wet their roots would rot. Plants that are raised early in spring, and properly managed, will be a foot and a half in height, when they should be removed into the bark rowe, and plunged into the tan-bed. During the winter, they must have but little water, and while the plants are young, they should be kept warm; otherwise they will exit their leaves, lose their tops, and appear unwhitely. They must be kept constantly in the bark rowe; some of them ripen seven or eight feet high, with strong flumes and large branches; but seldom produce flowers in Europe.

BIZACIUM, in Ancient Geography. See BYZACIUM.

BIZAM, Chat-Bizam, in Zoology, the French name of the Linnaen viverra tigrina, which see.

BIZAMO, in Geography, a kingdom of Abyssinia, situate between the branches of the Nile, called the White and the Blue rivers, about N. lat. 10° 15', and between 35° and 36° E. long.

BIZANTIA, a town of European Turkey, in the province of Moldavia, 40 miles south-west of Birlah.

BIZARRE, Fr. denoting capricious, &c. a term used among Flarials for a particular kind of carnation, which has its flowers striped or variegated with three or four colours.

BIZE, in Geography, a town of France, in the department of the Aude, and district of Narbonne, 10 miles N. W. of Narbonne.

BIZETA. See BISERTA.

BIZES, in Ancient Geography, a river of Bithynia, between Phillis and Rhebas. Aminian. Marcell.

BIZOCHI, or Bisochi, in Ecclesiastical History, a left or branch of religious minorites, condemned by several popes.

The Bisochi were also called frestricelli, or frestres de paupere vita; sometimes Biechini or Biechini, and Beguini. The name is formed from bistaceus, on account of a double bud.

get, or wallet, wherewith they begged their living. See (BEGHARDI) and TERTIARIES.

BIZONE, in Ancient Geography, a city of Lower Mac- fisia, 80 stadia north of Dionytopolis, mentioned by Pliny (L. iv. c. 12.) as having been destroyed by an earthquake.

BIZOOGAE, in Geography, a town of France, in the department of the Iere, and chief place of a canton, in the district of La Tour du Pin, 12 miles northwest of Moirans.

BIZU, a town of Africa, in the kingdom of Morocco, seated on a mountain in a fertile country, 25 leagues north of Morocco.

BIZYA, in Ancient Geography, a town of Thrace, and capital of the country called Altica, at some distance from the sea, N.W. of Salmydesius.

BIZYA, in Geography, a town of European Turkey, in Rhumania, 50 miles east of Adrianople.

BLACK, something opaque and porous, that imbibes the greatest part of the light that falls on it, reflects little or none, and therefore exhibits no colour. See BLACKNESS.

Bodies of a black colour are found more inflammable, because the rays of light falling on them are not reflected outward, but enter the body, and are often reflected and refracted within it, till they be stifled and lost. They are also found lighter, ceteris paribus, than white bodies, being more porous. It may be added, that clothes dyed of this colour wear out faster than those of any other, because their substance is more penetrated and corroded by the vitriol necessary to strike their dye, than other bodies are by the galls and alum which suffice for them.

The inflammability of black bodies, and their disposition to acquire heat, beyond those of other colours, are easily evinced. Some appeal to the experiment of a white and black glove worn in the same fun; the confecration will be, a very sensibly greater degree of heat in the one hand than the other. Others allege the phenomena of burning-glaizes, by which black bodies are always found to kindle sooner: thus, a burning-glaze, too weak to have any visible effect at all upon white paper, will readily kindle the same paper rubbed over with ink. Mr. Boyle gives other proofs still more obvious: he took a large tile, and having whited over one half of its superficies, and blacked the other, exposed it to the fun; where having let it lie a convenient time, he found, that whilst the whited part remained cool, the black part was grown very hot. For farther satisfaction, the same author has sometimes left on the surface of the tile a part retaining its native red, and exposing all to the fun, has found the latter to have contracted a heat in comparison of the white part, but inferior to that of the black. So also on his exposing two pieces of silk, one white, the other black, in the same window to the fun, he often found the latter considerably heated, when the former has remained cool. It is observably likewise, that rooms hung with black are not only darker, but warmer than others. Boyle's Works abridg, tom. i. p. 144 and tom. ii. p. 36. To all which may be added, that a virtuoso of unobserved credit assured Mr. Boyle, that, in a hot climate, he had, by carefully blackening the shells of eggs, and exposing them to the sun, seen them thereby well rosted in a short time.

Dr. Watton, the present bishop of Landaff, covered the bulb of a thermometer with a black coating of Indian ink, in conseqence of which the mercury rose ten degrees. Phil. Trans. vol. iii. part 2, p. 4.

Black clothes heat more, and dry sooner in the fun, than white clothes. Black is therefore a bad colour for clothes in hot climates; but a fit colour for the linings of
of ladies’ summer hats. Dr. Franklin’s Experiments, Observations, &c. 5th ed. p. 483, & seq. He observes also, ibid. p. 382, that a chimney painted black, when exposed to the sun, will draw more strongly. We may add, that black mould is a hotter foil for vegetables; and garden-walls painted black, answer better for the opening of wall-fruits, than those of lighter colours.

Black, in matters of dress, is the distinguishing habit of churchmen and mourners. Some will have it, that the common people among the Romans were clothed in black; whence the denomination given them of turkis pullata.

Black, Joseph, in Biography, a celebrated teacher of chemistry, was born at Bourdeaus, in France, in the year 1728. His father, who was a native of Belfast, in Ireland, but of a Scotch family, carried on the wine trade at Bourdeaus, and lived in intimacy with the famed Baron Montefduit, who expressed his regret in strong terms on Mr. Black’s quitting Bourdeaus, when he retired from business, as appears by several of his letters which are preserved by the family. By his mother, Dr. Black was nearly related to the wives of Dr. Adam Ferguson, and Mr. James Ruffell, professor in natural philosophy at the university of Edinburgh, and owed probably much of his knowledge to the instruction or information he obtained from them. In the year 1740, his father sent him to Belfast, that he might have the education of a British subject; and from his letters, he appears to have been satisfied with the progress he made there.

In 1746, he went to Glasgow, where he applied to the study of medicine, but particularly to chemistry, into the knowledge of which he was initiated by Dr. Cullen, who then gave lectures there on that branch of science. Under his direction he made such progress, that, in 1756, when Dr. Cullen removed to Edinburgh, Black, who had previously taken his degree of doctor, succeeded him as professor in medicine, and lecturer in chemistry. That he was qualified to fill this office, he had shown by an ingenious essay, containing experiments to investigate the nature of magnesia, quicklime, and some other alkaline substaneees, recommended as solvents of the stone in the bladder. In the course of these experiments he demonstrated the existence of an aerial fluid, which he called fixed air, the presence of which gave mildness, and its absence cautery, to alkalies and calcareous earth; a discovery which laid the foundation of the improvements since made in our knowledge of gases, or aerial bodies, by Priestley, Cavendish, Lavoisier, and other chemists. The essay, containing the account of these experiments, was published in the second volume of "Ellay's physical and literary," in 1756. The following year he further enriched his favourite science with his experiments on latent heat, which is found to exist in all bodies; explaining in a satisfactory manner the connection of heat and fluidity, by which he so established his reputation, that on Dr. Cullen's being promoted from the chemical to the medical chair at Edinburgh, in 1765, he was unanimously chosen to succeed him as professor in chemistry there. His time was now dedicated, and with increased ardour, to imparting the knowledge he had acquired to his numerous pupils; and as he was perfectly master of the subjécts on which he lectured, his doctrines were so clearly explained, as to be easily understood by his auditors, many of whom took complete copies of his lectures. By this means the knowledge of the discoveries he had made, became widely diffused, and his claim to them secured to him, which might otherwise have been ascribed to those who improved and extended them. Having thus laid the ground-work for the improvement of the art, he seems to have been contented, without attempting to publish his discoveries further. Satisfied with the attention paid him by his pupils, and the gradual extension of his fame, of which he received daily proofs, he took little notice of what Priestley, Lavoisier, and other philosophical chemists, were doing, or only noticed them when they had neglected making those acknowledgments to him to which he was due. Dr. Robison, who had been his pupil, and has lately published his lectures, with an account of his life, attributes this apparent apathy to the ill state of his health, which, for several years before his death, did not permit that degree of application and study, which the further extension of his discoveries would have required. "The slightest cold," he says (Preface to the Lectures, p. li., "the most trilling approach to repulsion, immediately affected his breath, occasioned feverishness, and, if continued two or three days, brought on a spitting of blood." In this situation nothing relieved him but relaxation from thought, and gentle exercise. The sedentary life, to which study confined him, was manifestly hurtful; and he never allowed himself to indulge in any intense thinking, or puzzling research, without finding these complaints feitently increased.

Hence, though he had the honour of being elected one of the foreign associates of the royal academy of sciences at Paris, and member of the imperial academy at Petersburg, he sent no communications to either of those learned societies. As he ranked high among the teachers of chemistry, and his name and character were extended over Europe, his pupils were numerous, and continued increasing for the whole time he lectured, more than thirty years. In the year 1774, he sent to the royal society in London, his observations on the effect of boiling upon water, in dispersing it to freeze; and, in 1791, the Royal Society at Edinbouh published his analysis of the waters of some hot springs in Iceland, in the third volume of their Transactions. In this paper, which is drawn up with great accuracy, he treats of the formation of the milcious stone, which is deposited by these springs. His constitution becoming more and more feeble, from the frequent return of his complaint, he was at last obliged to make use of an assistant in his lectures, and at length, to give them up altogether; the smallest exertion bringing on a fit of asthmatics. "But he seemed," Dr. Robison says (Preface, p. 73.), "to have his complaint almost under command, so that he never allowed it to proceed far, or to occasion any distressing illnese, and so spun his thread of life to the lasts fibre, guarding against illness by retreating himself to a moderate diet, and meeting his increasing infirmities with a proprional increase of attention and care.

On the 26th of November 1799, and in the 71st year of his age, he died suddenly, without any previous warning. Being at table, with his usual fare before him, some bread, a few prunes, with milk and water for his drink, having the cup in his hand, resting on his knees, he expired suddenly in that politure, the cup remaining in his hand, and his countenance so composed and placid, that his servant at first imagined he was fallen asleep. He was of a cheerful and sociable disposition, and, as his mind was well stored with knowledge, an entertaining companion. His company was therefore much courted; and, as his circumstances were affluent, he dedicated as much of his time to the pleasures of society, as was consistent with his avocations. He was never married; he therefore left the principal part of his fortune, which is said to be considerable, among the children of his brothers and sisters. Gen. Biog. Dict. Lectures of the Elements of Chemistry.

Black, in Heraldic Engravings, is expressed by cross lines, and in emblazoning, is termed for commoners sable, for peers diamond, and for sovereigns and princes sable.
and lively black is called a black-more, or oval-black. Horses black all over are commonly reckoned dull and melancholy; but a white foot, or bar in the forehead, gives them a degree of sprightliness. The Spanish gravity is said to be best pleased with those entirely black.

**Black, blue, in the Manufactures and Arts.** is the coal of some kind of wood, or other vegetable matter, burnt in a close heat, where the air can have no access; the best fort is said to be made of vine-stocks and tendrils. The goodness of black confiis in the cleanliness and blue call of its black colour, and the perfect degree of its levigation.

That this preparation, which is sold in the colour shops, is no other than a vegetable coal, appeared from the following experiment of Dr. Lewis. (Comm. Phil. Tech. p. 328.) Laid on a red-hot iron, it burned and glazed like powdered charcoal, and turned into white ashes; which ashes, thrown into oil of vitriol diluted with water, very readily dissolved into a bitterish liquor, the character of which the vegetable earth is distinguished. From what particular vegetable matter this blue-black is procured, experiments, he says, cannot discover; but it appears from those who have recites, that it may be obtained from many, and that the choice of the vegetable subject affects rather the festiveness or hardness, than the colour of the coal. Blue-black, perfectly good, may be prepared in the manner directed for *ivory black*, from the ashes of vine-barks, or tendrils, or any other twigs of wood, of an acid nature and tough texture; but the soaking in the oil, preferred for the ivory, must be omitted.

The painters have *blue-black*, *brown-black*, &c. which may be made by mixing pigments of the respective colours, with simple black ones, in greater or less quantity, according to the shade required. The dyers also have different blacks, and often darken other colours by lightly pasting them through the black dying liquor; but the term brown-black is in this business unknown, brown and black being here looked upon as opposite to one another. In effect, the colour called brown-black is no other than that which all dyed black clothes change to in wearing; and therefore it is no wonder that it should be excluded from the catalogue of the dyers' colours. The true or simple blacks, mixed with white, form different shades of grey, lighter or darker, according as the white or black ingredient prevails in the mixt. The black pigments, spread thin upon a white ground, have a like effect. Hence the painter, with one true black pigment taken from a preparation of bone, and another from a combination of all the shades of grey and black, from the lightest discoloration of the paper up to a full black; and the dyer produces the same effect on white wool, silk, or cloth, by continuing the subjunct for a shorter or longer time in the black bath, or making the bath itself weaker or stronger.

M. le Blon, in his *Harmony of Colours,* forms black by mixing together the three primitive colours, blue, red, and yellow; and Mr. Cavel, in his *Optique des couleurs,* published in 1749, says, that this compound black has an advantage in painting above the simple ones, of advancing better for the darkening of other colours. Thus if blue, by the addition of black, is to be darkened into a blue-black, the simple blacks, if used in sufficient quantity to produce the requisite deepness, conceal the blue, while the compound blacks leave it distinguishable. Le Blon has not mentioned the proportions of the three primitive colours necessary for producing black. Cavel directs 3 parts of blue, 5 of red, and three of yellow; and he observes, that the colours should be the deepest and darkest of their respective kinds, and that a combination should be made of several pigments for each colour; for the greater the contrast of heterogeneous and discordant drugs, the more time and beautiful will be the black, and the more capable of uniting with all other colours, without suppreffing them, and even without making them tawny. Dr. Lewis, in his experiments, has not so far succeeded as to obtain a perfect black by mixing different blue, red, and yellow powders; but he procured very dark colours, such as brown-blacks and grey-blacks.

**Black, bone, is made of the bones of bullocks, cows, &c.** well burnt and ground. To be good, it must be soft and friable, of a glossy call. It is in considerable use, though inferior in goodness to ivory-black. The invention of bone, or ivory black, is attributed to Apelles. Plin. Hist. Nat. lib. xxxv. cap. 5.

**Black chalk.** See *Chalks, and Killows.*

**Black, charcoal.** See *Charcoal, and Crayons.*

**Black, curriers,** signifies a teint or dye laid on tanned leather. Tanned leather is so much impregnated with the astringent parts of oak bark, or with that matter which strikes a black colour with green vitriol, that rubbing it over three or four times with a solution of the vitriol, or with a solution of iron made in vegetable acids, is sufficient for blacking it. Of this we may be convinced by dropping a little of the solution on the unblackened side of common fine-leather. This operation is performed by the currier, who, after the colouring, gives a gloss to the leather with a solution of gum-arabic and size made in vinegar. Where the previous astringent impregnation is insufficient to give a due colour, and for those parts of leather which have not been tanned, some galls or other astringents are added to the solution of iron; and in many cases, particularly for the finer parts of leather, and for renewing the blackness, ivory or lamp-black is used. A mixture of either of these with linseed oil, makes the common oil-blacking. See CURRYING.

**Black, dyer,** is one of the five simple and mother colours used in dyeing: and given differently, according to the different quality and value of the fluids to be dyed. See DYING.

Green vitriol strikes a black colour with vegetable astringents, and hence it is the basis of the black dye for cloth, leather, hats, &c. And as solutions of iron with galls, &c. produce the same colour, a method is derived from hence of distinguishing the minute portions of iron in mineral waters, &c. Neumann.

The substances chiefly employed for producing black colour with vitriol are galls. When a decoction or infusion of the galls is dropped into a solution of the vitriol largely diluted with water, the first drops produce bluish or purplish red clouds, which mingling with the liquor tinge it uniformly of their own bluish or reddish colour. This difference of the colour, says Dr. Lewis (Com. Ph. Tech. p. 346.), seems to depend on the quality of the water. With distilled water, or the common spring waters, the mixture is always blue. A minute quantity of alkaline salt previously dissolved in the water, or a small degree of putridity in it, will render the colour of the mixture purple or reddish. Rain-water received from the clouds, in clear glafs vessels, gives a blue, but if it be collected from the tops of houses, gives purplie with the vitriol and galls. Both the blue and purple liquors, when more of the astringent infusion is added, deepen to a black, more or less intense, according to the degree of dilution; and if the mixture be a deep opaque black, it again becomes bluish or purplish when further diluted. If it be sufferd to stand in this dilute state for two or three days, the colouring matter settles to the bottom in form of a fine black mud, which, by slightly

flaking

BLA

BLA
flaxing the vessel, is diffused again through the liquor, and tingles it of its former colour. When the mixture is of a full blackness, this separation does not happen, or in a far less degree; for though a part of the black matter precipitates in landing, yet so much remains dissolved, that the liquor continues black. This suspension of the colouring substance in the black liquid may be attributed in part to the gummy matter of the asbestine infusing increasing the consanguinity of the watery fluid, for the separation is retarded in the diluted mixture by a small addition of gum arabic. If the mixture, either in its black or diluted state, be poured into a filter, the liquor pales through coloured, only a part of the black matter remaining on the paper. The filtered liquor, on standing for some time, becomes turbid and forms fine black flakes; but being freed from these by a second filtration, it again assumes the same appearance, and thus repeatedly, till all the colouring parts are separated, and the liquor has become colourless. The colouring matter, thus separated from the liquor, being drained on a filter and dried, appeared of a deep black, which did not seem to have suffered any change on being exposed to the air for upwards of four months.

When it was made red hot, it glowed and burnt, though without flaming, and became a lowly brown powder, which was readily attracted by a magnetic bar; though in its black state, the magnet had no action upon it. The vitriolic acid, diluted with water, and digested on the black powder, dissolved the greatest part of it, leaving only a very little quantity of whitish matter. Solution of pure first alkaline salt dissolved very little of it; the liquor received a reddish brown colour, and the powder became blackish brown. This residuum was attracted by the magnet after being made red hot, though not before; the alkaline tincture, passed through a filter, and mixed with solution of gum vitriol, turned a deep brownish-black colour, nearly the same with that which results from mixing with the vitriolic solution an alkaline tincture of galls. For an account of the results of these experiments, see Lewis, ubi supra. See also Iron.

For broad-cloths, fine ratines, and druggets, &c., the dyers use wood and indigo; the goodness of the colour consists in there being above six pounds of indigo to a ball of wool, when the latter begins to call its blue flower; and, in its not being heated for use above twice. Thus blued, the stuff is boiled with alum, or tartar, then madder; and, lastly, the black given with galls, copperas, and fumac. To bind it, and prevent its bleeding in use, the stuffs are to be well founded in the fulling mill, when white, and well washed afterwards.

For stuffs of less value, it is sufficient they be well blued with wood, and blacked with galls and copperas: but no stuff can be regularly dyed from white into black, without passing through the intermediate blue.

Yet there is a colour called coal black, or Jesuit’s black, prepared of the same ingredients as the former, and sufficient of itself without the blue dye. Here the drugs are dissolved in water that had boiled four hours, and flood to cool till the hand would bear it; then the stuff is dipped in it, and again taken out six or eight times. Some even prefer this black to the other. This method of dying black is laid to have been invented by the Jesuits, and to have been practiced in their houses, where they retained numbers of dyers.

By 25 lb. c. g. nothing of the nature of cloth shall be madderred for a black, except it be first grounded with wood only, or with wood and anise [blue ind]. unlefs the madder be put in with fumac or galls; on pain of forfeiting the value of the thing dyed: provided it shall be lawful to dye any manner of gall-black, and fumac-black [plain black], wherein no madder shall be used.

Logwood strikes a black with chalybeate solutions and is employed with those liquors for staining wood black, as picture frames, &c. With the addition of galls, it is used for dyeing cloth and hats black. (Neumann’s Works, p. 355.) This black colour is not permanent, though beautiful, any more than the natural violet dye of the logwood.

Black may be also obtained by a solution of silver in aqua fortis, when the previous matter stained with this liquor is exposed for some time to the sun and air; and also from solutions of lead in acids, when the subjects to which they are applied are exposed to sulphureous vapours, or washed over with alkaline solutions of sulphur. Cases of lead, melted with sulphur, form a bluish or blackish mass, useful in taking calls from medals. (See CASTS.) Besides, when a solution of silver in aqua fortis is added to a solution of sulphur made in alkaline ley, the silver and sulphur unite and precipitate together in the form of a black powder. See Dying, and Staining.

Black, earth, is a kind of coal found in the ground, which, well pounded, is used by painters in fresco. See Pitt-Coal, and Fresco.

There is also a kind of black made of silver and lead, used to fill up the strokes and cavities of things engraved.

Black, German, or Frankfort, is made of the lees of wine burnt, then washed in water, and ground in mills for that purpose, together with ivory or peach stones burnt. Some suppose, that it is the coal of vine-twigs; but this, says Dr. Lewis (Com. Phil. Techn. p. 377.), does not appear to differ, in any great degree, from that of the small branches of other kinds of trees; but the kernels of fruits yield a coal considerably more soft and mellow, easily crumbling between the fingers into a fine meal. That the Frankfort black is no other than a vegetable coal, appeared, from its burning on a red-hot iron, like charcoal powder, into white ashes, and from the ashes, like common vegetable, is truly, being plentifully diffusible by the vitriolic acid into a bitternish liquor, while the ashes of animal substances are very sparingly affected by that acid, and form with it a compound of a different kind of taste.

This black makes the principal ingredient in the rolling-press printers’ ink, which is. It is ordinarily brought from Frankfort, Mentz, or Strafsbourg, either in humps or powder. That made in France is more valued than that of Germany.

Black glass. See Glass.

Black, burnt, that which remains in the retort after extracting the spirit, salt, and oil of bartbarn. This residue being ground up with water, makes a black not much inferior to that of ivory.

Black, Indian. See Indian Ink.

Black, ivory, is made of ivory burnt or charred, ordinarily between two crucibles well lit; which, being thus rendered perfectly black, and in scales, is ground in water, and made into troughs, or little cakes, used by the painters; as also by the jewellers to blacken the bottom or ground of the collets, wherein they set diamonds to give them their tint or foil. Some recommend foaming the chips or shavings of ivory in hot linseed oil, before it is charred.

There are particular machines and contrivances for burning the ivory for these purposes, by which the colour is rendered more beautiful than that of the coal which remains in the distillation. Neumann.

The goodness of ivory black, which is the finest of all the charcoal blacks, may be perceived by its fulness, without a blue cast; and by the fineness of the powder.
In the manufacture of this black much imposition is practised, so that what is generally sold under this name is no other than the coal of common bones. Being applied to coercive purposes, and sold at a low price, it is very grossly levigated by the hand or horse-mills which are employed in grinding the bones, and so much adulterated with charcoal dust, which gives it a blue tinge, that it is wholly exploded from delicate uses, and lamp-black, though inferior with regard to the purity and cleanliness of the black colour, substituted for it.

The following recipe is given in the Handmaid to the Arts (vol. i. p. 140.) for preparing it in perfection. Take plates, cups, or shavings of ivory, and soak them in hot linseed oil; or, if filings are more easily procured, they may be used moistened with the hot oil. Put them into a vessel, which will bear the fire, covering them with a coat of lid made of clay and sand, which should be dried, and the cracks repaired before the vessel be put into the fire. Let this vessel be placed in a tobacco-pipe maker's or potter's furnace, or any other such fire; and let it remain there during one of their heats. When it is taken out, the ivory will be properly burnt; and must be afterwards thoroughly well levigated on the stone with water, or to have it perfectly good, be also washed over. The ivory may be conveniently burnt in a calcining or fire-burning furnace. An ounce of lamp-black for water-colours is made by grinding ivory-black with gum-water, or with the liquor which settles from the whites of eggs after they have been suffered to stand a little. Some use gum water and the white of eggs together, and they say, that a small addition of the latter makes the mixture flow more freely from the pencil, and improves its glisselins. It may be observed, however, that though ivory-black makes the deepest colour in water, as well as in oil-painting, yet it is not on this account always to be preferred to other black pigments. A deep jet-black colour is seldom wanted in painting; and in the lighter shades, whether obtained by diluting the black with white bodies, or by applying it thin on a white ground, the particular beauty of the ivory-black is in a great measure lost.

Black, lamp, or lam Black, originally perhaps the foot collected from lamps, is generally prepared by melting and purifying reain or pitch in iron vesseis; then setting fire to it under a chimney, or other place made for the purpose, lined a-top with steep-flame, or thick linen cloth, to receive the vapours and smoke, which is the black: in manner they are prepared, particularly at the turpentine-houses, from the dregs and refuse parts of the reainious matters which are there manufactured; but the greatest part is brought from Germany, Sweden, and Norway. Its preparation is described in the Swedish Transactions for 1754, as a process dependent on the manufacture of common reain. The impure reainious juice, collected from incisions made in pieces and fir-trees, is boiled down, with a little water, and strained, whilst hot, through a bag: the dregs and pieces of black, left in the flainer, are burnt in a low oven, from which the smoke is conveyed, through a long passage, into a square chamber, having an opening in the top, in which is fastened a large face, made of flaky or thin-woven woollen stuff; the foot, or lamp-black, concretes partly in the chamber, from which it is swept out one in two or three days, and partly in the face, which is now and then gently struck upon, both for making down the foot, and for clearing the impurities between the threads, so as to procure a sufficient draught of air through it. The more curious artists prepare lamp-black for the nicer purposes, by hanging a large copper pan over the flame of a lamp with a long wick, supplied with more oil than can be perfectly consumed, so as to receive its smoke. Soot collected in like manner from fir and other woods, by burning small pieces of them slowly under a copper pan, is of a deeper black colour than such as is obtained from the same kinds of wood in a common chimney, and little inferior to that of oils. The foot of mineral bitumens, in this close way of burning, appears to be of the same qualities with those of woods, oils, and resins. In some parts of Germany, it is said, great quantities of good lamp-black are prepared from a fort of pit-coal.

The good sorts of lamp-black lies in the fulness of the colour, and in its being free from dust or other impurities. The lightness of the sublimate furnishes the means of discovering any adulteration, if to a great degree; as the bodies with which lamp-black is subject to be sophistication, are all heavier in a considerable proportion.

This sublimate is used on various occasions, particularly in the printer's ink; for which it is mixed with oils of turpentine and indiened, all boiled together.

It must be observed, that this black takes fire very readily, and when on fire is very difficultly extinguished: the best method of putting it out is with wet linen, hay, or straw; for water alone will not do it.

A glass tube closely filled with lamp-black has been found to conduct a considerable charge of electricity instantly, and with scarce any explosion. But a coating of this sublimate mixed with tar or oil, is a perfect non-conductor, and has proved a preservative from lightning, by repelling the electric matter from those parts of the masts of ships which have been covered with it.

Ruffian lamp-black is prepared from the foot of fire, and is collected at Ochta near St. Petersburg, Moscow, Archangel, and other places, in little wooden huts, from reainious fire wood, and the inebrious bark of birch, by means of an apparatus uncommonly simple, consisting of pots without bottoms, set one upon another, and is sold very cheap. It is three or four times more heavy, thick, and unctuous than that kind of painter's black which the Germans call "kien-rahm," and which is called in Russia "Holland's black." For an account of the spontaneous accenion of Ruffian fire-black, impregnated with hemp-oil, see Spontaneous Inflammation.

A mineral lamp-black may be procured from pit-coal, or any kind of mineral or coffin coal, by preparing the blackcet particles of the smoke arising from it in ignition. Mr. Wm. Row of Newcastle-upon-Tyne obtained a patent in 1798 for his method of manufacturing this kind of lamp-black. See the specification in the Repertory of Arts, &c. vol. x. p. 81.

Black paint. See Paint.
Black sand. See Sand.
Black sealing wax. See Wax.
Black, foot, or chimney, is a poor colour; but ready for painting black draperies in oil. The foot blacks are in general much softer and of a more yielding texture than those of the charcoal kind, and require much less grinding, for uniting them with oily, watery, or spirituous liquors, into a smooth mass; of some of them a part is diffused by water, or spirits of wine, while none of the charcoal blacks have been found to contain any thing diffusible. This soluble matter of foot, however, is not black like the indissoluble parts: and in this particular, as well as in the colour of the entire mass, different sorts of foot differ from one another. Thus the foot of pit-coal collected in common chimneys, of itself rather greyish black than of a full black, being
being infused separately in rectified spirit of wine and in water, tinged the former of a transparent reddish colour, and the latter of a paler reddish; while the deeper black foot of wood gave, both to spirit and to water, an opaque dark brown. See Soot.

Black, Spanish, so called because first invented by the Spaniards, and most of it bought from them, is no other than burnt cork used in various works, particularly among painters. See Staining. See Varnish.

Black stain. See Staining.

Black vegetable juice. See Anacardium.

Black act, Waltham, in Law, a name commonly disfiguishing the statute of 9 Geo. I. c. 22, because it was occasioned by the devastations committed near Waltham in Essex, by persons in disguise, or with their faces blacked.

By this statute it is enacted, that persons hunting, armed and disguised, and killing or shooting deer, or robbing wares, or stealing fish out of any river, &c. or any persons unlawfully hunting in his majesty's forests, &c. or breaking down the head of any fish-pond, or killing, &c. of cattle, or cutting down trees, or setting fire to houte, barn, or wood, or shooting at any person, or sending letters, either anonymous, or signed with a fictitious name, demanding money, &c. or refusing such offenders, are guilty of felony, without benefit of clergy. This act is made perpetual by 31 Geo. III. c. 42. See farther 6 Geo. II. c. 37, and 27 Geo. II. c. 15.

The milder punishment inflicted by that 16 Geo. III. c. 31, against deer-feeders, has been thought a virtual repeal of the punishment of the black act above-rected.

Latham's Hawk, P. C. i. c. 49, § 7.

Black boy, in Geography, a bay on the south-east coast of Labrador. N. lat. 51° 30'. W. long. 56° 23'.
every one they could see, and filling their crops several times in the day. The ducks, after having faved about forty pounds' worth of turnips, were sent to the poultry yard. With this view, it has been suggested by Mr. Middleton in his "Survey of the County of Middlesex," that this fort of poultry may often be kept with advantage by the farmer. 

**Black-crows, in Ecclesiastical History, a name given to the regular canons of St. Augustine, who wore a black mantle over their surplice, by way of distinction from the Prelates.**

**Black-cap of the English, in Ornithology, the Motacilla atricapilla of Linnæus. The fame name is given likewise to the marsh titmouse, Parus palustris of Linn., and the black-headed gull, Larus atricilla of Gmelin.**

**Black-cap of Ceylon, or Ceylon black-cap, the name of Motacilla ezonothus of Gmelin, in Brown's Illustration of Nat. Hist.**

**Black-capped humming-bird of Latham, and Long-tailed black-cap humming-bird of Edwards and Bancroft, are Trochilus polytmus of Gmelin.**

**Black-capped kingfisher of Latham, is Alcedo atricapilla of Linn.**

**Black-capped lory, the English name given by Latham to the Gmeliniæ ptilocoma of Gmelin.** This is the first black-cap lory of Edwards.

**Black-capped manakin of Edwards and Latham, is Pipra manacus of Gmelin.**

**Black-caps, in Geography, lies on the east coast of Newfoundland, S. E. from Cape St. Francis.**

**Black-cattle, in Agriculture, a small, hardy breed of cattle, mostly of a black colour, occupying the high or more mountainous districts in the northern parts of the island. They are covered with a long close coat of hair, of much the same kind as the polled and long-haired breeds. They are riddled in the rich pastures in the southern parts of the kingdom, where large quantities of them are annually driven and fed for sale in the London and other markets. Their meat is generally of a fine grain, well marbled, and of a good flavour; but sometimes not so fine and bright in its external appearance as that of other sorts of cattle, being occasionally, except when made very fat, spotted with black, even upon the choicest parts. From their property of becoming quickly fat, and not being of great weight, they seem well adapted to the low, rich, grazing districts in the southern counties, where the lands are liable to be poached and injured by the heavier breeds of cattle. They seldom weigh more than from twenty to thirty stone each, though some particular ones have become considerably heavier. See Cattle and Live-Stock.**

**Black-checked eagle, of Latham's Synopsis, in Ornithology, is Falco Americanus of Gmelin.**

**Black-checked thrush of Latham, is Turdus nigerrimus of Gmelin.**

**Black-chin grebe of Pennant, &c. Columbus leridicus of Gmelin.**

**Black-cock, of Pennant, Latham, Donovan, &c. is Tetrao tetrix of Linnaeus. The same bird is also well known by the name of black-grouse, or Black-grou.**

**Black-cockatoos of Latham, and Great black cockatoos of Edwards, is called by Buffon Adapathe noir, and by Gmelin Psittacus atrinotus.**

**Black-collared finch of Latham, is Fringilla Abyssinica of Gmelin.**

**Black-crowned bunting of Latham, is Emberiza atricapilla of Gmelin.**

---

**BLA**

**Black-crowned manakin of Latham, is Pipra atricapilla of Gmelin.**

**Black-crowned oriole, the English name of Oriolus Mexicanus of Linn. in Latham's "Synopsis of Birds."**

**Black-crowned plover of Arch. Zool., is Charadrius atricapillus of Gmelin.**

**Black-crowned stork of South America, is Lanius Americanus of Gmelin.**

**Black-crowned tanager of Latham, is Tanagra melanthera of Gmelin.**

**Black-Indian cuckow of Edwards, is Cuculus Niger of Linn.**

**Black-darter, or foster, of English ornithologists, is Anas nigra of Linn. Fu. Succ.**

**Black duck, in Agriculture, a small bird which is frequently very destructive to beans, turnips, and some other crops. Where beans are attacked with these insects, the best remedy probably is, as soon as they are first perceived, to cut off the tops by means of a scythe, as they are found to make their first lodgments principally in those parts of the plants. See Fly and Turnips.**

**Black-duck of Latham and other writers, in Ornithology, is called by Edwards the black duck from Hudson's bay. This is a very distinct species from the black duck of Ray and Willughby, and velvet duck of modern naturalists. Gmelin calls it Anas perstipilata.**

**Black-duck, or Great black duck of Ray and Willughby, is the velvet duck of later English authors, and Anas fusca of the Linnean Fauna Svecica.**

**Black-eagle, in Heraldry, an order of knighthood, instituted in Prussia, by Frederic I. 14th Jan. 1701. The ensign of the order is a gold crook of eight points, enameled blue; in the centre whereof are the letters F. R. in cypher, and in the four angles the eagle of Prussia, enamelled black. On collar days, it is worn pendant to a rich collar of gold, composed of round pieces of gold, each enamelled with four cyphers of the letters F. R.; in the centre of the piece is a large diamond, and over each cypher a regal crown, all richly chafed, intermixed with eagles displayed, enamelled black alternately, and holding in their claws thunderbolts of gold. The crofs of the order is worn, on ordinary days, pendant to a broad, orange-coloured ribbon, across the left shoulder. The knights have embroidered on the left breast of their coats a flar of silver, like that of the ensign of the order, in the centre of which is an eagle displayed black, holding in his dexter claw, a chaplet of laurel, and in the other a thunderbolt, with the motto Suum cuique round it. See Plate of Heraldry.**

**Black-eagle of Willughby, in Ornithology, is P. Agilis commune of Buffon, and Falco melanarius of Gmelin.**

**Black ears, or Black-bared lynx, in Zoology, called also the Persfan lynx, and Black-bared cat, is the Sigah gufo or Siyah gufo of Charleton, and Caracul of Buffon. Gmelin mentions this animal under the name of Felis caracal. See Caracal, and Sigah Gush.**

**Black-ear, in Agriculture, that kind of ear or mould which contains a large portion of carbonaceous or vegetable matter in its composition. Soils of this sort are capable of producing mull forts of grain and other vegetable crops in abundance. See Soil, &c.**

**Black-nuts, in the Catalogue of Eastern Nations, are Ethiopians calulated, to whom their princes commonly commit the care of their women. See Eunuch.**

**Black-eys, in Botany, a name given to the germ in beans, which the Romans called hilum. See Germ.**

---
BLACK-eye, hypophosagma, in Medicine, a suffusion of blood on the tunica arborea, turning livid, occasioned by a blow. See Ecchymosis.

Black-faced bunting of Latham, in Ornithology, is Emberiza quelea of Gmelin.

Black-faced Finch of the Arctic Zoology, is Fringilla cris-tata of Gmelin.

Black-faced ibis of Latham, is Tanarius melanocephalus of Gmelin.

Black-fish, in Ichthyology, the name under which Sihurus argentilavis is described in Russell’s “Hist. of Aleppo.” This fish has a single dorsal fin containing seventy rays, and eight bars at the mouth, namely, two on the upper lip, four on the lower one, and two on each side of the mouth. There is likewise a kind of perch mentioned by Borrada as being found in the rivers of Cornwall, which he calls the black fish. Permit speaks of it on the authority of that writer; and Gmelin, after him, gives it as a species with some doubt. This species meant by Borrada is certainly ambiguous. See Perca Ignota.

Blackfly, in Agriculture, an insect of the beetle tribe, that often commits great devastation among turnips and other crops, destroying the young plants, by feeding upon their feed-leaves the moment they are protruded and appear above ground. Different remedies have been proposed for the prevention of the destructive ravages of this insect on turnips; but few of them have been attended with much success. The best method is probably that of fanning the feed at such a season, and under such circumstances, as that its early vegetation may be quick and uninterrupted, and thereby allow little time for the insects to feed upon the plants, before they become in broad leaf, and capable of resisting its injurious attacks. See Fly and Turnips.

Black-fly-catcher of Latham, in Ornithology, is Myeicapa melanocephala of Gmelin.

Black-forssl mountains of, in Geography, called in German Schwartzwald, extend from near Neuenburg, in the territories of Wurttemburg, south to the four foret towns on the Rhine. The southern part is called the high, and the northern the lower; the length being about 80 British miles. To the east the Neckar may be considered as a boundary, and the breadth may be computed at about 20 British miles. The eastern part presents a gradual elevation, while the western exhibits precipitous summits to the inhabitants of Baden and Allace. The appellation seems to be derived from the black dark forests with which the affents are clothed. Besides pasture, the inhabitants, partly subject to Austria, and partly to Wurttemburg, derive advantage from the resin of the pines, and the timber, of which they make all kinds of utensils. Some parts are cultivated by spreading branches of pine, covered with sod, which, being burnt, affords an excellent manure, that prepares the ground for four abundant harvests. A branch of the black mountains spreads east from near Sulz, on the Neckar, towards the county of Oicening, being more than 60 miles in length. This chain is called the Alb, and sometimes the Suanian Alps. Biching traces this ridge from the north-east, the source of the Brenz, to the well of the Rheinseim, by Wingenstein, where the mountains are highest. Thence they turn north-west to Gutenberg, and west to Neifen, whence they pass by Hofenzolnern to the Neckar, then bend south and west between that river and the Danube. Biching adds, that as this chain rises infenibly at Konigbrown north-east, so it gradually terminates at Ebingen south-west. The principal summits are in the north and west of the ridge; and the forests are chiefly beech; while the open spaces supply pastureage for numerous flocks of sheep. Of these two extensive ridges of mountains, the Black forssl, and the Alb, a considerahle portion pervades the duchy of Wurttemburg; and near Stuttgart, the capital, are the mountains of Boyerstein, Weinsleig, and Hafenstein. The constituent parts of these extensive ridges have been little detailed; but a great part is calcareous, as they supply excellent marbles. Near Frudenfalt, in the black mountains, are mines of silver and copper.

Black-footed penguin, or penguin, softer penguin, capo pin-quin, &c., in Ornithology, are different English names of an individual species of Aptenodyta in the works of Edwards, Latham, &c. Gmelin names this bird specifically denirof. See Black-footed; in Zoology. See Canis Lycaon.

Black-fronted fly-catcher of Latham, in Ornithology, is Muscicapa nigrofrontis of Gmelin.

Black-flyers, in Ecclesiastical History, a name given to the Dominican order, called also Predicants and Preaching flyers; in France, Jacobins. See Black-birders.

Black-game, in Ornithology. See Black-Cock.

Black-grafs, in Agriculture, a species of American grafs, growing in meadows which border on tide-rivers, well supplied with fresh water; for a mixture both of fresh and salt water seems to be necessary for its prolific vegetation. Its feeds are small, like those of tobacco; its colour a deep green; and it affords from three to four tons of hay by the acre. This kind of grafs thrives best on a clay or strong loam; nor is the vicinity of salt water absolutely necessary. The feeds have been lately brought over into England, and distributed for trial in proper soils.

Black-grofeak of Edwards, in Ornithology, and the Ango-la grofeak of Latham are the same; Lexia angolensis of Gmelin.—Obs. The Black grofeak of Latham is another bird; Lexia nigra of Gmelin.

Black-guillemot of Pennant and other English writers of the present times, is the Greenland dove or sea-turtle of Albin, Ray, Willughby, and Columbus gyrdle of Linnaeus.

Black-headed bunting of Latham, is Emberiza melanocephala of Scopoli.

Black-headed creeper of Latham, and the Green black-cap fly-catcher of Bancroft, are of the same species, the latter being only a variety of the first. Linnaeus calls this kind Motulica phexa.

Black-headed duck of Shaw’s travels, has been since named the Damiatta duck by Latham, and Anas Damiathe by Gmelin in the Linn. Syll. Nat.—The variety of Anas fiscus, or wild duck, called nigra, from having the head and collar black, might be also called the black-headed duck.

Black-headed fact of Latham, is Fringilla melanocephala of Gmelin.

Black-headed fly-catcher of Arctic Zoology and black-cap fly-catcher of Catechy, is the Mycilaca fatica of Gmelin.

Black-headed gilb of Latham, is leozia erythrornelas of Gmelin.

Black-headed gull, the English name of larus rubicundus. The same bird is also called the peewit black-cap, or sea crow, by Ray and Willughby.

Black-headed philer of Latham, is chrocius melane cephalis of Gmelin.
Black-headed Parakeet, a species of Lanius, is called by Edwards, and is a member of the tribe Laniidae. It is also called by Latham, and is the Lanius alboresus of Gmelin.

Black and spotted heat-cock of Edwards, and spotted grosbeak of Pennant and Latham, are tetrao canadensis of Gmelin.—Gmelin. There is another black and spotted heat-cock figured also by Edwards pl. 71, which, in the 12th edition of the Linnaean Syl., Nat. is called tetrao canere.

Black heron of Latham is the ardea atricapilla of Gmelin.

Black-loaded wheat-carr of Latham, is motacilla plena of Gmelin.

Black-humming-bird, the Linnaean trochilus niger is so named in the Synopsis of Latham.

Black is a species of Brullion, the jamaicainaria nigra of Brullion, and parra nigra of Gmelin, bears this name in Latham'sSynopsis.

Black jack, or Blind, is a member, called also falce gaulena and blindi, &c.

Black-faced cowbird of Latham, in Ornithology, is motacilla nigricristis of Gmelin.

Black, in Geography, an island near the coast of America, belonging to the slate of Rhode island. N. lat. 41° 7', W. long. 71° 35'.

Black islands, islands near the coast of Labrador. N. lat. 41° 8', W. long. 56° 30'.

Black kite, or black-gled of Sibbald, is falco ater of Gmelin, and milvus niger of Brullion.—Gmelin. Gmelin mentions a black variety of falco communis under the specific name of ater; it was previously described by Edwards under the name of black hawk or falcon.

Black land, in Agriculture, a name given to a fort of soil which has a greyish black cast. This fort of soil, though pale when dry, always blackens by means of rain; and when ploughed up at such times, it flakes to the ploughshare; and the more it is wrought, the mudder and darker-coloured it appears. These sorts of land, when somewhat rich, yet porous, light but sufficiently tenacious, are good both for corn and grass; but as they are mostly intermingled in bottomed, the wetness often spoils them for corn; but when they are dry, they are extraordinarily fruitful, especially for barley; they also bear good wheat crops. When they are very rich, they may, if a dry mould, be planted with liquorice, or sown with hemp, woad, cole, or rape, madder, and other similar plants, that best suit such lands; and afterwards with corn, when some of their fertility is expended. They are capable of bearing excellent clover crops. The best manure for these soils is chalk or lime, where it can be procured.

Black land, in Ornithology. Albin describes an accidental variety of the common lark, alauda arvensis, under this name, in the third volume of his History of Birds.

Black lead, in Mineralogy, &c. See Lead and Plumbago.

Black leather, in the Manufactures, is that which has palled the curriers' hands, where from the ruffet as it was left by the tanners, it is become black, by having been fowdered and rubbed three times on the grain-side with copper-sulphate.

Black legs, a name given in Leicestershire to a diseased frequent among calves and sheep. It is a kind of jelly, which fettles in their legs, and often in the neck, between the skin and flesh.

Black legs, an appellation given to those gamblers and sharpers who pretend upon the ignorance and credulity of inexperienced and unsuspecting persons of property, with whom they contrive to associate, and who feign in dissipation and luxury on the spoils acquired by deception and fraud, in a variety of games and sports which they frequent for this purpose. They are justly denominated the pest of civilized society, and should be hunted by those who have any concern for their property or reputation, as the most dangerous and destructive enemies.

Black lick, in Geography, lies in Westmoreland county, Pennsylvania, about 30 miles south of Pittsburg.

Black lory, of Latham, in Ornithology, is psittacus nova Gmelini.

Black maill, in English Antiquity, a certain rate of money, corn, cattle, or other matter, annually paid by the inhabitants of towns in Westmorland, Cumberland, Northumberland, and Durham, to divers persons inhabiting on or near the borders, being men of name, and allied with others in the like parts, known to be great robbers and spoil-takers; in order to be by them freed and protected from any pillage. Prohibited as felony by 43 Ed. 1, c. 13.

The origin of this word is much controverted, yet there is ground to hold the word black to be here a corruption of blank or white, and consequently to signify a rent paid in a small copper coin called blanks. This may receive some light from a phrase still used in Picardy, where, speaking of a person who has not a single halfpenny, they say, il n'a pas une blague maill. The term is also used for rents reserved in work, grain, or bafer money, which were called "reeditus nigra," in contradistinction to the blank francs, "reeditus albi."

Black martin, or swift of the English, in Ornithology, is the hieron agus of Latin writers.

Black monks, in Ecclesiastical History, a denomination given to the Benedictins, called in Latin nigri monachi, or nigrano- nachi; sometimesordo nigrovum, the order of blacks.

Black mountains, in Geography. See Black-Forrest. This is also a denomination given to an extensive ridge of mountains in South Wales, separating the boundaries of the counties of Glamorgan and Brecknock; covered in summer with black cattle and sheep.

Black necked quail of Latham, in Ornithology, is tetrao nigricollis of Gmelin.

Black-necked fowl of Pernett and Latham, stands under the name of anna nigricollis in the Gmelinian edition of SYL. Nat.

Black-necked thrush of Latham, is turdus nigricollis of Gmelin.

Black neft, in Geography, a fort point on the coast of France, and in the English channel, four leagues W. from Calais.

Black oats, in Agriculture, a species of oats, much cultivated in the northern parts of England, and esteemed a very hearty food for horses. See Oats.

Black oriole, of the Arctic Zoology, and Latham'sSynopsis, in Ornithology, is the icerus niger of Brullion, and oriolar- niger of Linn. and Gmelin.

Black iberole (Leayer), the English name of orielus minor, in Latham'sSynopsis.

Black oriel of Brown's Illustrations, &c. is iberolus cam- melus of Scopoli, Gmelin, &c.

Black parrot of Latham, and black parrot of Madagascar, and of Edwards, are the same; the psittacus niger of Gmelin.

Black pellet of Latham, and great black pellet of Edwards, stands under the name of procellaria aquinotalis in Gmelin's edition of the Linn. Syll. Nat.

Black poll warbler of Latham, is motacilla sinuata of Gmelin.

Black point, and blue point, in Geography, capes of America, within those of Elizabeth and Porpoise, in the district of Maine.

Black points, is also a point on the west coast of Africa, between cape Cavallus, and cape Palmas.—Alfo, a point
S. E. from Cape Childey, the north point of the Labrador coast. N. lat. about 59° 20'.—Also, a point on the coast of Spitzbergen, or East Greenland. N. lat. 78° 30'. E. long. 11° 10'. Variation 10° 42' W.

Black pool lies on the coast of Lancashire, about 25 miles S. from Lancaster. The beach is a beautiful level sand, with an extended beach for the purpose of forming bathing.

Black precession, in Eclectic and Natural Writers, that is made in black habits, and with black engravings and ornaments. See Procession.

Anciently at Malta, there was a black precession every Friday, where the whole clergy walked with their faces covered with a black veil.

Black rail of Latham, in Ornithology, is the rallus niger of Gmelin.

Black rail, in Zoology. See Mus-rattus, or Common rail.

Black red-tail of Latham, in Ornithology, is the motacilla atrata of Gmelin.

Black rents. See Black-mail.

Black River, in Geography, an application applied to two small rivers, in Vermont, America; one falling into Connecticut river, at Springfield, and the other running north into Lake Memphremagog.—Also, a river in New York, which interlocks with Canada creek, and runs north-west into Iroquois river, navigable with boats 60 miles.—Also, a long river, which rives in Virginia, and passes south-easternly into Nottaway river, in North Carolina.

Black River, a British settlement at the mouth of the Tintu river, 20 leagues to the eatt of cape Honduras, the only harbour on the coast of Terra Firma, from the island of Rattan to cape Grenada & Dorat; and for more than sixty years it was the refuge of the logwood cutters, when the Spaniards drove them from the forests of East Yucatan. This occasioned adventurers of different descriptions to settle here, where the coast is sandy, low, and swampy; but higher up, near the rivers and lagoons, which are full of fish, the soil is more fertile, and produces plantains, coconuts, maize, yams, potatoes, and a variety of vegetables; and the passion for drinking induced them to plant sugar-canes. The forests are full of deer, fowl, and game. The shores abound with turtle, and the woods with mahogany, zebra-wood, farfus papilla, &c.; and the whole settlement flourishes spontaneously without cultivation.

Black River, a river of Jamaica, which passes through a level country, and is the deepest and largest in the island, so as to admit flat-bottomed boats and canoes for about thirty miles.

Black Rock, a rock in the mouth of Sligo harbour, in Ireland, which is covered about high water only, and has a conspicuous tower built on it that serves as a beacon.

Black Rock, a rock in the bay of Galway, in Ireland, about three miles westward of Galway, which dries with spring-tide only, and requires attention in navigating that bay. M'Kenzie.

Black Rocks, rocks in the Atlantic ocean, near the west coast of Ireland, about six miles N.W. from Saddlehead, in Achill island, and seven miles W. by S. from Blackford point. There are rocks called by the same name in Killibeg's bay and Mulroy haven, but they are less objects of attention to the navigator. M'Kenzie.

Black Rock, a rock near the south coast of Wexford, in Ireland, about four miles W. by S. of Carrifore point, which is always above water, and may be sailed round without danger. M'Kenzie. Boate.

Black Rocks, a populous village, situate on the river Tawe, about a mile above Swansea, in Glamorganshire, South Wales, where are considerable smelting-hautines, and whence are exported coals, &c.

Black Rock lies also near the extreme north point of the island of Antigua, between Humphreys's bay and Boon point. N. lat. 17° 47'. W. long. 72° 58'.

Black rock. See Gentleman-Usher:

Black-rock, in Geography. See Euxine Sea.

Black sheep, in Oriental History, the ensign or standard of a race of Turkmans settled in Armenia and Mesopotamia; hence called the dynasty of the black sheep.

Black strike of Latham, in Ornithology, is lanius niger of Gmelin.

Black Mexican shrike of Latham, is fringilla cataracta of Gmelin.

Black summer of Latham, cut-water of Arct. Zool., sea crow of Edwards, are all names of the same bird; the Rynchops nigra of Gmelin.

Black squirrel of Catesby, is the sciurus niger of Erxleben and Gmelin.

Black stonies and gents, according to Dr. Woodward, owe their colour to a mixture of tin in their composition.

Black stork, a range of planks immediately above the wales in a ship's side: they are always covered with a mixture of tar and lamp-black.

Black swallow of Latham, in Ornithology, is the hirundo apus dominicus of Briffon, and hirundo niger of Gmelin.

Black swan. A bird of this description inhabits Botany Bay. Its form resembles that of the common white swan; but the prevailing colour of the plumage is black, instead of white; the wings are edged with white; and the bill is red. This species is described by Dr. Shaw (Nat. Miscell.) under the name of anus atrata. It is the black swan of several writers who have lately treated on the history of Botany Bay.

Black tail, a beacon about 3 leagues distant from the Nore in the river Thames.

Black Tanager of Latham, in Ornithology, is the emberiza atrata of the 10th edition of the Linnean Syll. 507. Nat., and tagara atrata of Gmelin.

Black term of modern writers, is the scarcer of the old English ornithologists, and known to the gulls of Willoughby. Sterna figate of Brunnich and Gmelin.

Black-thorn, in Botany, a species of the prunus, which see. Black-thorn, in Agriculture, a species of thorn well known, and frequently used in making fences, especially in exposed situations. It is not, however, reckoned so good for fences as the white-thorn, because it is apt to run more into the ground, and is not so certain of growing; but when cut, the boughs are much the belt, and most lating eny, for dead hedges, or to mend gaps with. Cattle are not so apt to crop fences of this kind as those of the white-thorn fort. See Hedges.

Black-throated barbet of Latham, in Ornithology, is bucco niger of Gmelin.

Black-throated bunting of the Arct. Zool. is emberiza americana of Gmelin.

Black-throated diver of Pennant and others, is the same bird as Edwards calls the speckled loon, and Willoughby's War- much's northern diver: Columbus articus of Linnaeus.

Black-throated green fly-catcher, of Edward's Gleanings, and green warbler of Latham; the motacilla xiren of Gmelin. Black-
Black-throated tanager, of Latham, the tamara nigricollis of Gmelin.
Black-throated manakin of Latham, the pipra nigricollis of Gmelin.
Black-throated thrush of Latham, is turdus ater of Gmelin.
Black-throated warbler, of the Arctic Zoology, is motacilla Gmelin of Gmelin.
Black bunting, in Zoology. See Felis discolor.
Black-tin, in Mineralogy, a denomination given to the tin ore when dressed, slamped, and washed for the blowing-house, or to be melted into metal. Phil. Trans. N° 69. p. 2110.

It is prepared into this state by means of beating and washing; and when it has passed through several puddles or washing troughs, it is taken up in form of a black powder, like fine sand, called black-tin.

Black-tailed gull of Pennant, Latham, Walcot, &c., in Ornithology, is the larus crepitans of Hawsworth and Gmelin.

Black-tailed parrot. The Gmelian procilla melanopus is described under this name in Latham's Synopsis of Birds.

Black town, in Geography, a settlement of 1200 free negroes, erected in 1783, about a mile from the town of Shelburne, in Nova Scotia.

Black wheat, in Agriculture, a noxious weed, probably the polygonum convolvulus, which flourishes even in extremely dry fields, and is very injurious to many crops.

Black vomit, in Medicine, a disease to which the inhabitants of Spanish North America are subject, said to be allied to the yellow fever of the United States, and which, at intervals, ravages the country like a pellague. See Fever.

Black vulture of Willughby and Latham, in Ornithology, is coragyps ater of Ray, Brisson, and Gmelin.

Black vulture (wrested) of Edwards, the vulpar monachus of Gmelin.

Black woodpecker (great), Albin. Donovan, &c., the picus marius of Linn. Linne. Suec.

Black woodcock. See Wadd.

Black-winged parakeet of Brown's Illustrations, in Ornithol. Brit., is called by Gmelin psittacus melanopaeus.

Black-winged thrush of Latham, is turdus bambia of Gmelin.

Black and white butcher-bird. Under this title the Linnean torus dilaticus is described and figured by Edwards in his History of Birds. Latham calls it the piel fräike.

Black and white creeper of Edward's Gleanings, the certhia cyanus of Gmelin.

Black and violet creeper of Latham, is certhia fimbriata of Gmelin.

Black and white creeper of Edwards, and small black and white bird of Ray and Sloane, are motacilla varia of Gmelin.

Black and white king's tailor of Edwards and Latham, is the aedilius radius of Gmelin.

Black and white wagtail of Ray, is the piel swagtail of Latham, motacilla modradragenana of Brisson, and motacilla modradraugennis of Gmelin.

Black, white, and red Indian creeper of Edwards, is the certhia eneas of Linn. and Gmel.

Black and yellow creeper. Certhia flavens of Gmelin is described under this name both by Edwards and Latham.

Black and yellow draw of Braid. Edwards under this title describes a variety of oriolus pericatus, Linn.

Black and white diver (fossil) of Willughby and Edwards, is alta ater of Linneus. This bird is likewise called the Greenland dove, or sea turtle, by Albin; and is known among later writers by the name of the little auk. Pennant: Donov. Brit. Birds, &c.

Black and white doebick of Edwards, is the dusky grade of later writers: Cylindris obscura of Gmelin.

Black and white duck (little) of Edwards, and spirit of Arc. Zool., is ana anatema of Gmelin.

Black and white Indian falcon, the English name falcus melanopaeus (Gmel.) in Pennant's Indian Zoology, and Latham's Birds.

Black and orange finch of Latham, and small black and orange bird of Sloane and Ray, is fringilla molinate of Gmelin.

Black and white fly-catcher of Edward's Gleanings, is myiagopa bicolor of Gmelin.

Black and white gull of Ray, Willughby, and Albin, is the black-backed gull of modern ornithologists. Linneaus calls it larus marinus.

Black and blue humming-bird of Bancroft, is called by Gmelin trochilus cyanomelas.

Black and yellow manakin of Edwards, is the variety $ of the Gmelian pipra aurela.

Black and orange-coloured bird (small) of Ray and Sloane, is motacilla roticula of Linneaus, and myiagopa roticula of Gmelin. This is likewise the black-headed warbler of Latham, small American revicliar of Edwards, and yellow-tailed fly-catcher of Edward's Gleanings.

Black and white Chinese pheasant of Edwards. This is phasianus notilienus of Scopoli and Gmelin. It is likewise called the pencilled pheasant by Latham and other later writers.

Black and yellow frizzled sparrow of Edward's Gleanings, is the frizzled sparrow of Latham, and fringilla cripta of Gmelin.

Black and white flamingo of Willughby, is flavus leucoulet of Brisson, which Gmelin gives as a variety of the common flare, or flarding, flaver vulgaris of Linneaus.

Black and white Indian flamingo of Edwards. This is flavus cornuta of Gmelin.

Black and blue tanager of Latham, is the black and blue trimonof of Edwards, and tamara Mexicana of Gmelin.

Black stubyf, in our Old Writers, bread of a middle finesens betwixt white and brown, called in some parts rawel-bread.

In religious houfes, it was the bread made for ordinary guests, and distinguished from their household loaf, or panit conventualis, which was pure manchet, or white bread.

Black-work, iron wrought by the blacksmith; thus called by way of opposition to that wrought by white-smiths.

BLACKALL, Offspring, in Biography, an English prelate, was born at London, in 1654, and educated at Catherine-hall, in the university of Cambridge. Besides several promotions in London, he was appointed one of the chaplains in ordinary to king William, though his principles were adverse to the government, and he refus'd for two years to take the requisite oaths to king William and queen Mary. On the 36th of January 1699, he preached a sermon before the house of commons, in which he animadverted on a passage in Mr. Toland's life of Milton, who, after laying the proofs that Dr. Gauden, afterwards bishop of Exeter, was the true author of the book entitled "Icon Basilii," and ascrib'd to Charles I., observ'd, that many supposititious pieces, under the name of Christ, his apostles, and other great persons, were publish'd and approved in the primitive times. But as Mr. Toland, in his Amulatory, published in the same year, avow'd his belief of the
the genuineness of the books of the New Testament, Mr. Blackall closed the dispute by the publication of a small pamphlet in 1720, entitled " Reasons for not replying to a book lately published, entitled Amnort." In 1750, he preached a course of sermons at Boyle's Lecture, published in the first volume of the collection of those sermons. In 1757, he was promoted to the see of Exeter; and in 1769, he was engaged in a controversy with Hordly, concerning the institution of civil government, and the measures of submission. With respect to this controversy it is sufficient to observe, that the bishop defends the high-church, tory principles, as they are usually called, of the divine institution of magistracy, and unlimited passive obedience and non-refinance, which Hordly oppoies. This prelate, whose private character, and style of preaching, are highly extolled by Mr. William Dawes, archbishop of York, in the preface to his Sermons, died at Exeter, Nov. 29th 1766. His sermons were collected and published in 2 vols. folio, Lond. 1773. Gen. Dict. BioL Brit.

BLACKAMORE'S HEAD, in Chemistry, consists of a conical vessel, surrounded with another of a cylindrical form, filled with cold water, and having a cock to draw it off, when it become too warm. Both vessels are made of copper. In the figure, one half is open to flow out the cone; the inclination of the sides of which, according to Chaptal, is most proper, when forming an angle of 75 degrees with the base. See Plate of Chemistry.

BLACKBALL HEAD, in Geography, a cape on the S.W. coast of Ireland, at the north side of the entrance into Bantry bay, in the county of Cork. N. lat. 51° 32'. W. long. 9° 55'. McKenzie and Beaufort.

BLACKBURN, William, in Biography, an eminent surveyor and architect, was born in Southwark Dec. 29 1750, and having acquired some knowledge of his profession in the ordinary course of education, he was admitted a student at the Royal academy. By this academy he was presented, in 1773, with the medal for the best drawing of the inside of St. Stephen's church in Walbrook; and the delivery of it by the president Sir Joshua Reynolds was accompanied by a distinguished tribute of respect to his abilities. About this time he entered into business in the place of his nativity; but a circumstance occurred in a few years, which served to establish his reputation, and to introduce him into very general notice. In 1779 an act of parliament was passed for the erection of places of confinement, under the denomination of "penitentiary houses." Two edifices of this kind were proposed to be constructed; one for the confinement and employment of 600 males, and the other for the accommodation of 300 females. The three superintendents of this act were John Howard esq., George Whatley esq., and Dr. John Fothergill. The death of Dr. Fothergill, and the resignation of Mr. Howard, dissolved this commission; and the charge was devolved, in 1781, on Sir Gilbert Elliot, Sir Charles Bunbury, and Thomas Bowdler esq. The principal object of the plan proposed was to combine, in the buildings to be erected, solitary confinement, with useful labour and moral reformation. Accordingly premiums were announced to those who should produce the best plans. The highest premium of 100 guineas was unanimously assigned, in 1782, to Mr. Blackburn. In consequence of this distinction, he was appointed by the superintendents to the office of architect and surveyor of the projected buildings. The deligns of government, after several preparatory steps had been taken, were never accomplished. However schemes of a similar kind were projected in various parts of the country, and the execution of them was entrusted to Mr. Blackburn. Whilst he was busily employed in the completion of various designs of this kind, and whilst he was profecuting a journey to Scotland, for the purpose of erecting a new goal at Glasgow, he died suddenly, Oct. 28th 1790, at Preton in Lancashire; and his remains were removed to London, and interred in the burying-ground of Burhill-fields. Mr. Blackburn's skill as a draughtsman and an architect, was not confined to prisons and penitentiary houses; but he was occupied, as far as his time would allow, in preparing various designs for churches, houses, villas, &c.; and in his drawings and designs he always manifested a correct taste, and a thorough knowledge of the science to which he was practically devoted. His friends and the public in general, very justly lamented, that by the corpulance to which he was inclined from his early youth, and the increase of which no abstinence, nor any mode of regimen, would restrain, he was removed from a scene of usefulness and reputation, at too early a period as the 46th year of his age. As to his religious profession, he was a protétagonist of the prebyterian denomination; but he combined, with an unfashionable and laudable avowal of his own sentiments, the most liberal and candid opinion and conduct with respect to all who differed from him. In his natural temper he was cheerful and lively; in his conversation agreeable, animated, and instructive; his private character amiable and respectable; and in all the relations and intercourses of domestic and social life, esteemed and honoured. In 1783 he married the daughter of Mr. Joshua Hobson, an eminent builder, of the denomination of quakers, by whom he left four children.

BLACKBURN, in Geography, a town of Lancashire, England, is seated in a valley surrounded with hills. It consists of several strrets, irregularly laid out, but intersected with good houses. Besides the parish church, here are a newly erected chapel of the establishment, and five places of worship for as many different sects of dissenters. A free-school was founded by queen Elizabeth, and the necessitious poor of the town are comfortably provided with a poor-house, which has land attached to it for the pittance of cattle.

The market, on Mondays, is chiefly supplied with provisions from Preton. Besides this, here are a fortnight market for cattle, &c. and an annual fair. The town is approached by four stone bridges crossing the river Derwent, whose water, being of rather a blackish hue, is said, by some writers, to have given name to the town. Blackburn has been noted for its manufactories, particularly for an article called Blackburn-greys, which were plains of linen-warp shot with cotton. The prosperity of Manchester, and the great influx of manufacturers to that town and its neighbourhood, have deprived Blackburn of its usual trade; yet some cottons, callicoes, and muslins are still made here, and the fields around the town are frequently covered with materials to bleach.

The church of Blackburn, previous to the reformation, was attached to the abbey of Whalley. It is now a rectory, possess'd by the archbishop of Canterbury, who also owns half of the town, which he lets on leases of 21 years. The parish of Blackburn includes 24 townships, and embraces about half the hundred of the same name. The land round the town is mostly a sandy soil, and consequently unprospective to agriculture. Coal is found in the fotherns, part of the parish, and in great plenty at Darwen, about 4 miles south of the town. An alum mine was found, and much worked here, in the time of Fuller, but from the depth of the strata, and consequent expense, it was afterwards neglected. Sir Geo. Colebrooke, wishing to monopolize all the alum
BLACKBURNE, Francis, in Biography, a clergyman of the church of England, distinguished by his firm attachment to the cause of civil and religious liberty, and by his zealous exertions in the promotion of it, was born of respectable parents at Richmond, in Yorkshire, on the 9th of June 1705. Having pursued a course of classical education, first at Kendal in Westmorland, and afterwards at the free schools of Hawkhed in Lancashire, and of Sedbergh in Yorkshire, he was admitted, in May 1722, penioner of Catherine hall, in the university of Cambridge; where he took the degree of bachelors of arts, and was chosen conductor or chaplain of the society; and on this title he was ordained deacon in March 1728. At this time he fet-tered himself with the expectation of a foundation-fellowship; but his avowal of sentiments with regard to ecclesiastical and civil liberty, which he had acquired by the perusal of the writings of Locke, Hoadly, &c. rendered him obnoxious to a majority of the fellows, who, being high royalists on the principle of hereditary right, set aside his just claims as the only qualified candidate, and precluded his election, by indulging Mr. Addenbrooke with an extraordinary year of grace, and thus keeping the fellowship full. This disappointment induced him to resign his conducthip, to quit the university, and to live in retirement with his uncle, Thomas Comber, esq. of Earl Newton, near Helmley, in Yorkshire, till some church preferment might occur. His views, indeed, were particularly directed to the living of Richmond, the place of his nativity; to which he was inducted upon the death of the incumbent in 1739, having previously qualified himself for it by taking prebend’s orders. During the interval of his retirement at Earl Newton, he casually found some old books that had formerly belonged to his great-grandfather, an Oldvillian pupil; and by the perusal of these he was led to entertain favourable sentiments of the manners and principles of many excellent old puritans, to admire their unaffected and disinterested piety, and their zeal for the spiritual good of mankind, and to cherish that moderation and liberality of temper, and that ardent concern for liberty, which distinguished his future conduct. As soon as he was inducted with a parochial cure, he devoted himself with exemplary diligence to the studies and duties appropriate to his parochial office, which he discharged, during a residence among his parishioners of 48 years, no less to their satisfaction and improvement, than to his own honour. His first appearance as an author was in the year 1742, when he published an “Affixe Sermon,” preached at York. About the same time he wrote two pamphlets concerning the illegal removal of the confi- dential court and its records from Richmond to Lancaster, which, in consequence of a petition from the mayor and corporation to the bishop of Chester, were restritted. In 1748, he employed a young person, who was his curate, to translate Erasmus’s preface to his paraphrase on the gospel of St. Matthew, and having written “A Preliminary Discourse addressed to the Roman Catholic clergy and laity of Great Britain,” he circulated a cheap edition of it, recommending it to the public, partly as an antidote against popery, but chiefly as an encouragement to the common people to be diligent in reading the scriptures for the information and improvement of themselves and families in Christian knowledge and Christian piety. It was not, however, till the year 1750, that Mr. Blackburne began to distinguish himself as a writer in defence of Christian liberty. A work had been published in the preceding year, intitled “Free and Candid Disquisitions relating to the Church of England.” This work contained many pertinent observations on existing defects and improprieties in the established forms of the church, and provisions for revising the liturgy, and amending such passages as were liable to reasonable objections. Mr. Blackburne was suspected by many, who were acquainted with his sentiments on the subject of an ecclesiastical reform, to have had a concern in this publication. But though he had corresponded with the compiler and editor of it, and had seen the greatest part of the work in manuscript, he had neither written nor faggled a single line or word. Indeed, he disapproved the style and spirit of it; and thought them by no means adapted to the occasion, nor likely to produce effect. “He was, rather, perhaps too much (says his biographer), inclined to look upon those who had in their hands the means and the power of reforming the errors, defects, and abuses in the government, forms of worship, faith, and discipline of the established church, as guilty of a criminal negligence, from which they should have been roused by sharp and spirited expolulations.” Nevertheless, he thought it his duty to repel the attacks of the adversaries of this work; and accordingly, he published, without the knowledge of its editor, or any of his more confidential associates, an “Apology for the Authors of the Free and Candid Disquisitions,” 1750. But though he engaged in this controversy, his attention was not diverted from parochial duties; for his next publication was “A short Discourse on the Nature, Obligation, and Benefits of Family Religion,” which he published at his own expense, and distributed among his parishioners. In this same year 1750, notwithstanding the publication of his “Apology,” he was collated to the archdeaconry of Cleveland, and also to the prebend of Bilton, by Dr. Matthew Hutton, then archbishop of York, to whom he had been for some years titular chaplain. Towards the close of the year 1752, he had an opportunity of perusing the charge delivered by Dr. Butler, bishop of Durham, to the clergy of his diocese at his primary visitation in 1751; and he found in it some doctrines which were, in his opinion, diametrically opposite to the principles on which the protestant reformation was founded and supported, as to deserve being exposed and confuted; in order to prevent the mischief which they might do under the sanction of his name. Accordingly, he wrote fictures upon them; and, in opposition to
to the remonstrances of a friend, who dissuaded him from publishing them, lest they might be the means of preventing his further preferment. He committed them to the press under the title of "A Serious Enquiry into the Use and Importance of external Religion, &c." This piece, which was afterwards printed by Mr. Baron, in the 4th volume of a collection of tracts, entitled, "The Pillars of Priestcraft, and Orthodoxy shaken," and ascribed to him as its author, gave great offence, particularly to archbishop Secker, and precluded all hopes of preferment in the church; if indeed he had indulged any such hopes, under episcopal patronage. The next subject of importance, which engaged his attention, was the doctrine of an intermediate state. To this he was led by an "Appendix" to Dr. Law's "Considerations on the Theory of Religion," which appeared in 1755, and which incited the tenet of the deep of the soul. This opinion was attacked from several quarters, and particularly by Dr. Goddard, master of Clare-hall, in a sermon preached at St. Edmund's Bury. Mr. Blackburne defended his friend Dr. Law, in a publication entitled "No Proof in the Scriptures of an intermediate state of happiness or misery, between death and the resurrection." He also published several other pieces on the same topic; such as "Remarks on Dr. Warburton's account of the sentiments of the early Jews concerning the soul;" and "A Review of some passages in the last edition of the Divine Legation of Moses demonstrated," which appeared in 1759, and may be considered as a sequel to the "Remarks." He also prepared a reply to Dr. Morton, Mr. John Steege, and Dr. Calcb Fleming, who had published "Sentiments of a country-divine concerning the Ordinance of Baptism, &c." occasioned by letters which passed between bishop Clayton and Mr. Penn on that institution. In the correspondence between the two writers, a difficulty occurred in the interpretation of the charge given by our Lord to his apostles. Matt. xxviii. 19. Our Lord, it is said, prescribes one precise form of words to be used in baptism; the apostles appear, from the Acts and Epistles, to have used another; and the evangelists Mark, Luke, and John, do not mention any precise form whatever. Various hypotheses have been proposed by Grotius, Limborch, Lightfoot, Whitby, Clayton, &c. for reconciling the practice of the apostles with the precept of Christ. Mr. Blackburne, dissatisfied with all these, suggests that the words in question contain no baptismal form at all; and that we should rather follow the apostolical form in Acts, as being derived to us by the authority and example of men, who must be perfectly satisfied that the foundation they built upon was sound and good. Accordingly, he proposes that we should read the passage in St. Matthew thus: "Περιτολὴν ὧν μαθητησάμενοι πάντες τῷ Ἰησοῦ Χριστῷ τῷ Λόγῳ τοῦ Υἱοῦ τοῦ Θεοῦ (περιτολὴν ἄνω) εἰς τὸ γενέσθαι τῶν ηταν (καὶ, ἐν τῷ στίχῳ τῷ παραλληλευτός) τῷ Γενέσεω τῆς Παναγίας; καὶ τῷ στίχῳ τῷ αὐτός; "Go ye therefore, and disciple all nations (baptizing them) into the name of the Father, and of the Son, and of the Holy Ghost." By construction and parenthesis, the command to baptize refers to no particular form at all, and leaves us to suppose, what was certainly the truth of the matter, that the apostles being already well acquainted with the form used in the baptism of Jesus, it was quite superfluous to enjoin it here.

In 1758, Mr. Blackburne avowed the sentiments which he had for some time entertained concerning subscription to the liturgy and articles of the church of England, in "Remarks on the Rev. Dr. Powell's sermon in defence of subscriptions, &c." preached in the preceding year before the university of Cambridge; to which is prefixed "An Address to the younger students in both our universities." The subject of subscription had indeed for some time engaged his attention; and it was not without scruples that he had qualified himself to hold the archdeaconry and prebend in 1755; but when he had reason to expect further advancement in the church, he refused the consideration of the subject, and the result was a determination never to renew his subscription. About this time he began to make collections for his famous work entitled "The Confessional, on a full and free Enquiry into the authority, utility, and success of establishing Confessions of faith and doctrine in Protestant churches." This work, in the execution of which he was much encouraged by Dr. Edmund Law, afterwards bishop of Carlisle, lay by him in manuscript for several years, and was at length published in 1766, 8vo. without his name. It excited, as we may naturally imagine, very general attention both among the partizans of reform and the advocates for existing establishments. A second edition appeared in 1767; and the controversy, which it occasioned, lasted for some years, and produced a great number of publications. The third edition, corrected and much enlarged, was published in 1770; and to this edition has been added from the author's manuscript, in the late collection of his works, an appendix, containing a short history of the confessions established in the church of Scotland at different periods. For a further account of the subject of this work, and of the arguments for and against subscription, see Subscription. Soon after the publication of the third edition of the "Confessional," the author was induced by several of his friends to draw up and publish "Proposals for an application to parliament for relief in the matter of subscription to the liturgy and thirty-nine articles of the established church of England, humbly submitted to the consideration of the learned and conscientious clergy of the said church." An association was formed for this purpose, for the result of which, see Association.

It was natural to imagine, that the author of such a work as the "Confessional," written with a view of examining and refuting the several pleas that had been urged in favour of subscription, and which had convinced many pretensions of the insufficiency of these pleas, would have wished to withdraw himself from the established church, which imposed a subscription that appeared to him to be unjustifiable; and accordingly, as the death of Dr. Chandler, in 1766, occasioned a vacancy in the respectable congregation of dissenters at the Old Jewry, in London, some individuals of that society applied to Mr. Blackburne for information, whether such a situation would be agreeable to his views, if it were offered to him. But, with the prospect of a very considerable accession to his income, he declined accepting the proposal, for reasons that were very satisfactory to those who made it. The clear amount of all that he poifessed, as a beneficed clergyman, never much exceeded the sum of 150l. a-year; whereas, if the removal that had been suggested to him had taken place, his income would have been nearly trebled. Some other circumstances also afterwards occurred, which had a tendency to detach him from the established church. Two very respectable clergymen, immediately connected with his own family, viz. the learned Mr. Theophilus Lindsey, whose excellent character those who are most adverse to his theological opinions concur in applauding, and his son-in-law, Dr. Difance, who was esteemed by all who know him, surrendered their preferences, because they disapproved the doctrines and forms of the established church.
Mr. Blackburne, however, though he agreed with his valued relatives in many of their objections to the liturgy and articles of the church, differed from them with regard to several doctrinal points of importance; and without seeming to advert to his past subscription, in consequence of which he still held his church preferences, he satisfied himself with refuting any further prelentment, which was actually offered to him, because he was determined not to renew his subscription. His continuance in the church cannot be justly ascribed to any selfish and interested motives, because he might have left it with advantage, and he remained in it with a fixed purpose of accepting no prelentment; and he rejected very considerable offers of this kind. But, in order to vindicate his conscience, he thought it right to avow his motives for continuing minister in the church, while he disapproved many things in his doctrine and discipline; and with this view he drew up a short paper containing "An Answer to the question, Why are you not a Socinian?" and also his reasons for officiating in a church, whose forms of faith, worship, and discipline, he thought to be in many things highly exceptionable. Those who wish for satisfaction on these points, are referred to the Appendix annexed to the Memoirs of his Life, p. 120. We shall content ourselves with observing, that Mr. Blackburne was a firm believer of the pre-existence of Christ, and that he also maintained his divinity, with limitations according to his own ideas, which he believed to be founded on the Scriptures; and with regard to the general sentiments of his creed, he is said to have made up his own mind, if it can be said that he declared himself a moderate Calvinist. Whatever may be the inconstancy which some persons have charged upon his conduct, he manifested his esteem for the church, not only by continuing his own connection with it, but by educating a son for the clerical office, though the conclusion of performing any duties, or enjoying any emoluments in that church, was voluntary, the impostion of which he had strongly reproved and condemned. On this subject, the further discussion of which would lead us beyond our province as biographers, we shall only say, "Let every man be fully persuaded in his own mind; to his own master let him stand or fall." See Subscription.

Having been accustomed from early life to regard the Roman Catholics as dangerous foes to the government and religion of his country, Mr. Blackburne, notwithstanding the enlarged and liberal sentiments avowed by him on all other occasions, wrote against them with a vehemency which the friends of freedom have generally condemned. But an alarm with regard to the spread of popery, and the evils to be apprehended from it, prevailed very much at the time; and this induced him, in 1758, to publish a caution against it, under the title of "Considerations on the present state of the controversy between the Protestants and Papists of Great Britain and Ireland, particularly on the question, how far the latter are entitled to toleration upon Protestant principles."

During the intervals of his other professional and literary engagements, he employed himself in collecting materials for the life of Martin Luther, which he proposed to write according to the pattern of Dr. Jortin's life of Erasmus; but he was diverted from accomplishing his design, first by the death of his friend Thomas Hollis esq. of whom he published "Memoirs," in 2 volumes 4to. in 1780, and afterwards by the loss of his second son Thomas, in 1782, a physician of rising eminence in the city of Durham, which so affected him as to render him incapable of finishing several things which he had undertaken. Soon after his eye-fight failed him, and he was under the necessity of employing an amanuensis. His mind, however, was full enterprising and active; nor was he prevented by the increasing infirmities of age from prosecuting the object of ecclesiastical reformation, which seems to have occupied his thoughts to the latest period of his life, and from performing his professional duties. Having in the last year of his life prepared a large volume for his 38th annual visitation in Cleveland, he caused it to be delivered by his eldest son, who sold it by him, and then took leave of his clerical brethren with an address equally pious and affectionate, that must have deeply impressed the minds of all who heard it. At the close of his visitation circuit, he was taken ill at the house of a friend, and apprehensive of approaching dissolution, hastened to his rectory at Richmond with all the expedition which the state of his health allowed. Within a few weeks after his return, on the morning of August 7th 1787, in his 83rd year, he finished the protracted course of a labourious and exemplary life, with the sentiment of the amiable Erasmus, and the benevolent Jortin, "I have had enough of every thing in this world," and expired, as he sat in his chair, without a groan. He left a widow, whom he died August 20th 1799, and four children; viz. Jane, married to the Rev. Dr. Disley, now minister of the Unitarian society in Exeter-street, London; the Rev. Francis Blackburne, vicar of Brignall, near Greta-bridge, Yorkshire; Sarah, married to the Rev. John Hall, vicar of Chew Magna, and rector of Dundry in Somersetshire; and William Blackburne, M.D. of Cavendish-square, London.

Few persons have ever been more regular and assiduous in the performance of professional duties, whether we consider him as a parish priest, or as an archdeacon, than Mr. Blackburne. Possessing naturally a strong constitution of body, and a sound mind, which he preferred by temperance to a very advanced period, he was capable of intense and continued application. He was likewise animated in the discharge of his clerical functions by a conviction of their importance, and by an ardent desire of promoting the best interests of those with whom he was connected. In composing for many years new discourses, whenever he officiated, and also charges for his archdeaconal visitations, and in preparing for the press a variety of publications, a great part of his time must have been spent in study and retirement; and hence he is said to have acquired the appearance of austerity; nevertheless with his intimate friends and associates he was cheerful and unreserved. As a writer he was nervous and animated; and his public discourses were delivered with an unaffected earnestness, which proceeded from conviction of the importance of religious truth and duty, and which interested and impressed those who heard him. In his controversial writings, it must be acknowledged, and he himself lamented it towards the close of his life, that he was occasionally betrayed into precipitance of judgment and asperity of language; but it should be recollected, that he contended with a host of adversaries, whose mode of attack sometimes provoked and justified his resentment; and that his vehemence and ardour were always accompanied with a high sense of integrity and honour, and a laudable solicitude for serving what he conceived to be the cause of truth and liberty. The topics of his numerous publications, the principal of which we have above recited, were chiefly theological or controversial; nevertheless he was an occasional writer on political liberty, and he largely contributed to a collection of letters and essays on this subject, published in two volumes, 1774. A collection of his "Works, theological and miscellaneous, including some pieces not before printed, with some account of the life and writings of the author, by himself, completed by his son Francis Blackburne, L. L. B. and illustrated by an appendix of original papers," has this year (1804) been published in 7 vols. 8vo. The following re-
speculal and just tribute to his memory cloths his son's account of his life and writings: "Such was Francis Blackburne; a believer of Chriltianity, from the deepest conviction of its truth; a Protestant on the genuine principles of the reformation from popery; a fierce adversary of superstition and intolerance, and of every corruption of the simplicity or the spirit of the gospel; a zealous promoter of civil liberty; a clothe and peripatetic reasoner; a keen and energetic writer; an attentive, benevolent, and venerable archdeacon; an eloquent and persuasive preacher; a faithful pastor and exemplary guide; of unblazoned purity of life, of simple dignity of manners; a sincere and cordial friend; an affectionate husband, and an indulgent father: in short, a just, humane, pious, temperate, and independent man."!

Eff. Char. Cal. four-toothed; pet. four, elliptic; anth. heart-shaped; germ conic; stigma simple. Per. berry, with a single seed.

BLACKCILIA, in Ornithology, a species of MOTACILLA, defribed in the Arctic Zoology under the name of the blackburnian warbler. The crown is black, with a yellow line in the middle; band through or across the eye black, as are also the leafer wing-covers; greater wing-covers, vent, and lateral tail feathers white, the middle ones being druyf black; sides of the neck, chin, and middle of the belly yellow. A native of New York.

BLACKHEAD, in Geography, a cape on the east coast of Ireland, at the north entrance of Belfast Lough. N. lat. 54° 45'. W. long. 5° 35'.

BLACKHEAD, a cape on the western coast of Ireland, in the county of Clare, on the south side of the entrance into Galway bay. N. lat. 53° 7'. W. long. 9° 11'.

BLACKHEAD, a cape on the south coast of Ireland, within the old head of Kinfale, and on the west side of Kinfale harbour. N. lat. 51° 38'. W. long. 8° 35'.

BLACKHEAD, a cape on the west coast of Scotland, in the county of Wigtown; 6 miles W.S.W. of Stranraer.

BLACKHEAD, a point of land between Falmouth haven and the Lizard point.—Also, one of the peaks between Fernmow's harbour on the east coast of Newfoundland, and Agua fort; bald head being the other.—Also, a point on the south coast of Newfoundland, west of cape Race, and half a league further west from cape Pine.—Also, a point on the east coast of the northern island of New Zealand, N.E. of cape Turnagain, in about 40° 18' S. Lat.

BLACKING, in the Arts, &c. is sometimes used for a factitious black, as lamp-black, shoe-black, &c. A mixture of ivory or lamp-black with linseed oil, makes the common oil-blacking. For a thinning blacking, small-beer or water is used instead of oil, in the proportion of about a pint to an ounce of the ivory-black, with the addition of half an ounce of brown sugar, and as much gun Arabic. The white of an egg, substituted for the gum, makes the black

more shining; but is supposed to hurt the leather, and make it apt to crack.

In 1771 a patent was granted to Mr. William Bayley for preparing a composition in cakes, rolls, or balls, which, with the addition of water only, makes an excellent shining liquid blacking for shoes, boots, &c. The recipe for this purpose is as follows: take one part of the grumy juice that issues, in the months of June, July, and August, from the shrub called the goat's thorn, four parts of river water, two parts of neat's foot, or some other softening lubricating oil, two parts of superfine ivory-black, two parts of deep blue, prepared from iron and copper, and four parts of brown sugar-candy. Evaporate the water; and, when the composition is of a proper consistence, let it be formed into cakes of such a size, that each cake may make a pint of liquid blacking.

BLACLOCK, THOMAS, in Biography, was born in 1721, at Annan in Scotland, of parents, who were natives of Cumberland, and who occupied a humble station. At the age of 6 months he was deprived of his sight by a small-pox: and thus becoming incapable of any mechanical employment, he was in the probable course of nature destined to be a perpetual charge to his parents. His disposition, however, as he advanced towards maturity, engaged the most affectionate attention; and the kindliness of his father was such as to imprefs his youthful mind, and to engage expressions of ardent gratitude. The powers of his mind were no less distinguished than the amabilitens of his temper; and he improved the casual opportunities of cultivating them, which were afforded him by the attention of his father and friends, who read to him several passages out of English authors, and particularly from the works of our most approved and popular poets. These he heard with avidity and delight; and at the early period of his 12th year, he began to imitate what he admired. His performances, as he advanced towards maturity, became the subjects of general conversation; and having the misfortune to lose his father in his 19th year, he was invited, at the age of 20, by Dr. Stephenon, physician at Edinburgh, to remove thither and to pursue his studies at the university. Notwithstanding the personal disadvantages under which he laboured, he made very considerable progress in the Latin, Greek, and French languages; but upon the breaking out of the rebellion in 1745, his studies were interrupted, and he retired into the country. On this occasion he was followed by Dr. Stephenon, and by a subscription he published of his poems at Glasgow. When the tumult of the rebellion subsided, he returned to Edinburgh, and to the prosecution of his studies for 6 years more, during which period he not only perfected himself in the languages, but made considerable progress in all the sciences, and particularly in polite literature. In 1745 he published a second edition of his poems, much improved and enlarged; and thus gained the patronage of Mr. Spence, who, by an account of his life, character, and poems, brought him into general notice. By means of a subscription to a 4to edition of his poems, his circumstances were rendered easy and comfortable; and applying himself to the study of theology, he pursued the usual trials, and was licensed in 1759 to be a preacher by the prebendary of Dumfries. From the discharge of the duties of his office he derived great satisfaction and reputation. On the alarm of a French invasion in 1761, he published a discourse "On the right improvement of time: and in the same year he contributed some poems to the first volume of Donaldson's collection of original poems. In 1762 he formed a matrimonial connection, which he regarded as the chief source of the felicity of his future life. About this time he was ordained minister of Kirkuddington, on the presentation of the earl of Selkirk; but in consequence of some litigations that ensued, he

3 X 2 though:
thought it most expedient, within two years, to resign this
preference, and to retire upon a moderate annuity. With
this tender provision he removed in 1764 to Edinburgh, and
opened his house for the accommodation of young phy-
sicians as boarders and students. In 1765 the marshall college of
Aberdeen conferred upon him the degree of doctor in di-
vinity. From this time he continued to maintain his literary
character by several publications, which it will be sufficient
to enumerate. These were "Paraphrasis, or Confutations
deduced from natural and revealed religion," in two dif-
tinctions, Svo. 1767; "Two Discourses on the evidences and
spirit of Christianity," translated from the French of Mr.
James Arnauld," Svo. 1768; "A Panegyric on Great
Britain," a satirical piece, Svo. 1773; "The Graham, an
heroic ballad, in four cantos," 4to. 1774; "Remarks on
the nature and extent of liberty, &c. and on the justice and
policy of the American war, occasioned by perusing the ob-
servations Dr. Price on these subjects," Svo. 1776; and
a valuable article, communicated to the editors of the
Encyclopedia Britannica, "On the education of the
blind," 1783. A 4to edition of Dr. Blacklock's poems was
printed in 1793. This edition contains an effay on the ed-
cation of the blind, being a translation of M. Halli's cele-
brate essay on this subject; and prefixed to it we have a
new account of the life and writings of the author, by
Mr. Mackenzie, author of the Man of Feeling, &c. Dr.
Blacklock died at the age of 70, in July 1791. With
respect to his talents, Mr. Hume observes, "that he may be
regarded as a prodigy;" and to his moral character he bears
this honourable testimony, that "his modelly was equal to
the goodness of his disposition, and the beauty of his
genius." In the depressed circumstances of his early life
he was singularly contented and acquiescing; but his lots of
fight deeply affected his sensibility, and he deplores it in
plaintive accents in one of his poems, written on occasion of
his escape from falling into a deep well. At the same time
he was distrusted by apprehensions of sinking into extreme
indigence; however he expresses his trust in Providence, and
his hope that the clouds which were gathering over him
would be diffipated. Next to his religious principles, were
letters, conversation, and music, from which he derived his
principal solace. His poetry is easy, elegant, and harmo-
nous; and abounds with images, deduced from visible
objects, and aptly applied. He is said to have composed
with rapidity, and hence it is owing that his vivacity and
animation are often indulged at the expense of correct-
ess and regularity. In criticism he displays much benevo-
cence and tenderness of disposition, as well as true piety and
BLACKMORE, Sir Richard, M.D. an indefatigable
writer, poet, and physician, was born at Corsham in Wilts,
shire, about the year 1650. After some years spent at a
grammar school in the country, he was sent to Westminster
school, and in 1668 to Edinburgh, Oxford. In 1676 he
took his degree of master of arts, and continued to reside at
college three years after, but apparently without receiving
much benefit from his long residence in this seat of the mules,
fearely knowing the names or situations of places, which an
intimacy with classical authors must have made familiar to
him. At some time in his life, probably immediately on
quitting college, he kept a school, but does not seem to have
remained long in that station, as he soon after went to
Paris, and to other places on the continent, with a view, it
is probable, of acquiring or improving his knowledge in medi-
cine, in which faculty he took his degree of doctor at
Padua. Returning to England, after a ramble of eighteen
months, he came to London, and settled at first in Cheapside,
where he acquired so much reputation, that in 1687, he was
admitted a fellow of the college of physicians. In 1697, he
received the honour of knighthood from king William, ac-
companyed with a present of a gold chain and medal, which, he
intimates, were given him as a reward for some services
performed at the revolution. The same year he was made physician
in ordinary to the king; an office he held afterwards under his
successor, queen Anne. He was now in the zenith of his
reputation, and having as yet but little ex posed himself to
the scrutiny of the critics by writing, his merit was probably
rated much beyond its real standard. To his popularity as
a physician, and his excellent and unimpeached moral char-
acter, it was probably owing, that his first production,
"Prince Arthur," an epic poem, in ten books, published
a little before this time, acquired so much celebrity as to
pass through three editions in the space of two years.
Encouraged by this success, in 1699 he published his "King
Arthur" in twelve books, with paraphrases on the book of
Job, and on other parts of scripture; and in 1700, his "Satire
on Wit," in which he took occasion to retort the sarcasms
which had been heaped with so sparing hand on his last
poems by Dennis, Dryden, Pope, and most of the wits of the
time. Not deterred by their cenuries, in 1705 he published
"Eliza," another heroic poem, in twelve books. This excelled
"Johnson says, "neither praise nor blame, but seems to have
dropped dead born from the press." In 1712, appeared
"Creation," a philosophical poem, certainly the bell of his
productions. It had the honour of being praised by Addi-
ison, in the Spectator, and Dr. Johnson has since inflected it in
his collection of English poets, with commendation much
beyond its merit. This for a time revived its credit, and gave it
a degree of celebrity, which seems again to be declining space.
Pleased with the reputation procured by this poem, he soon
after produced his fourth and last epic poem in twelve books,
intended to commemorate the actions of king Alfred, whose
name it bore, but like Eliza, it excited little notice; benevo-
cence being ashamed any longer to patronize, and malevolence
weary of insulting, such frigid abortions. But as it was to
be the fate of this author to try every species of writing,
and to fail in all, on the Spectator ceasing, he produced, in
conjunction with Mr. Hughes, the "Lay Monastery;" one
paper of which was published three times in the week. This
was only continued to the 40th number. Soon after he gave
the world two volumes of effays. As these were intended to
promote the cause of virtue and religion, they met with some
favour. Besides these works, Dr. Blackmore wrote several
tracts on different branches of medicine; on the spleen, the
goat, the rheumatism, the king's evil, the dropsy, the jaun-
dice, the diabetes, the plague; and as inoculation for the
small-pox was making some progress in his time, he thought
it incumbent on him to give his decided disapprobation of the
practice. But as by this time he began to be esteemed hence
a better physician than a poet, his opinion had fortunately
very little weight with the public. The medical tracts are
published together in an 8vo volume, but are little known or
Johnson's Lives of the Poets.
BLACKNESS, the quality of a black body; or a co-
our arising from a texture and situation of the super-
fi cal parts of the body, which, as it were, isle, or rather
absorbs, the light falling on it, without reflecting any, or very
little of it, to the eye. In which sense, blackness stands
directly opposed to whiteness; which consists in such a
texture of parts, as indifferently reflects all the rays thrown
upon it, of whatsoever colour they be.
Defacres, says Dr. Prieley (Hist. of Visian, p. 127 and
143, &c.), though mistaken with respect to the nature of
light and colours, yet distinguishes jully between black and
white, observing, that black suffocates and extinguishes the
rays.
rays that fall upon it; but that white reflects them. This, adds the historian of philosophy, is the first distinct account I have met with of this sensible hypothesis. Mr. Boyle also made several observations and experiments, which demonstrate his theory in a very satisfactory manner. See Black.

Sir Isaac Newton, in his Optics, shows, that for the production of black colours, the corpuscles must be less than those which exhibit any other colours: because, where the sizes of the component particles are greater, there is too much light reflected to constitute this colour: but, if they be a little less than is requisite to reflect the white and very faint blue of the first order, they will reflect too little light, as to appear intensely black; and yet may, perhaps, reflect it variously to and fro within them so long, till it happen to be sifted and left; by which means they will appear black in all positions of the eye, without any transparency.

And hence it appears, why fire, and putrefaction, by dividing the particles of substances, turn them black: why small quantities of black substances impart their colours very freely, and intensely, to other substances, to which they are applied; the minute particles of these, by reason of their very great number, easily overbearing the gros particles of others. Hence also appears, why glads ground very elaborately with sand, on a copper plate, till it be well polished, makes the sand, together with what by rubbing is worn off from the glass and copper, become very black; and why black substances do, for most of others, become hot in the sun's light, and burn (which effect may proceed partly from the multitude of refractions in a little room, and partly from the easy commotion of such very small particles): also, why blacks are usually a little inclined towards a bluish colour; for that they are so, may be seen by illuminating white paper with light reflected from black substances, where the paper will usually appear of a bluish white; and the reason is, that black borders on the obscure blue of the first order of colours; and therefore reflects more rays of that colour than any other.

BLACKIE, Alexander, in Biography, apothecary, a native of Scotland, published in 1766 a dissertation on medicines that diffuse the fume, in which Dr. Chittick's secret is laid open, 12mo. It was reprinted in 1771, with additions. He found the solvent to be the lixivium fapopurum, which may be given, he says, advantageously, mixed with lime-water, even when blood is voided with the urine. When the bladder becomes ulcerated, wounded by the affections of the stone, he recommends the pectoris bravus and uva ursi. When pain in the loins or pubes is violent, he gives opium; and he has known, he says, persons void stones in their sleep, while taking that drug. Persons who void red sand or gravel with their urine, are never affected, he says, with the stone. Haller. Bib. Chirurg.

BLACKS, Negroes : a people, so called from the colour of their skin. For the reason of their colour, and the commerce of them, see Negro.

BLACKS, is also a name given to an association of disorderly and ill-designing persons, formerly herding chiefly about Waltham in Essex, who destroyed deer, robbed fish-ponds, ruined timber, &c. See Black ad.

BLACKSOD BAY, in some old maps erroneously called Black harbour, in Geography, a large bay lying between the peninsula of the Mullet, and the main land of the county of Mayo, Ireland, to the south of the isthmus. It is well sheltered, the ground in most parts clean, and sufficiently deep for large ships; but the ground being a hard sand, it is not thought that it will hold well in hard gales from the west and south-west, especially in the winter time. It is 2 ½ miles wide at its entrance, and runs about 9 miles inland, with several creeks communicating with it, of which those within Barneach isle, and the point of Claggan, are the most remarkable. The south-west point of this bay is in N. lat. 54° 6'. W. long. 9° 52'. McKenzie, &c.

BLACKSMITH, J. in Biography, apothecary, of whom nothing is known, but that he published in 1757, "Pafculis Plantarum, circa Harefield, Spontane inuentum, cum Appendice ad loci naturam spectante," 8vo London. Among many common, some very rare plants were discovered by the author, and are described in this volume. He also published in 1746, "Specimen Botanicum, quor plantarum plurim Anglice ingeniariurn, loci naturae illustrantium," 8vo London, an interesting and useful work. Haller. Bib. Botan.

BLACKSTONE, William, Sir, Knight and L.L.D., a celebrated English lawyer, was born in London, July 10th 1723, and received the first rudiments of learning at the Charter-house, where he was admitted upon the foundation in 1735, and whence he was removed, in 1738, to Pembroke college, Oxford. At school and in the university he was distinguished by his application and proficiency; and the range of his studies, even at an early period, was so extensive, that he is said to have composed a treatise on the "Elements of Architecture," for his own use at the age of 20. This treatise was never published. As he made choice of the profession of the law, he was entered of the Middle Temple, and quitted Oxford in 1744 to pursue studies, very different from those to which his taste inclined him at the university. This change of his pursuits is feelingly commemorated in the "Lawyer's Farewell to the Mufe," composed about this time, and published in the fourth volume of Dodsley's Miscellanies. From this period he affidually applied to his professional studies, residing occasionally in chambers in the Temple, for the convenience of attending the courts, and at other times in the university, to which he was much attached. In 1743 he was elected a fellow of All-Souls college, and on the 24th of November 1746 he was called to the bar, and commenced the practice of the law. Destitute of a ready eloquence, and of other talents requisite for a popular Advocate, his progress was slow; and he had leisure to discharge the duties of bufiness, or, Reward, of All-Souls, which he did with such skill and diligence, as to improve the revenues of the college, and to aid in completing the magnificent structure of the Chadlington library. A treatise which he composed on this occasion is still useful in conducting the pecuniary concerns of this Society. In 1749, he was appointed recorder of Wallingford in Berkshire; and defirous of more constant residence at Oxford, he took in the following year the degree of doctor of laws. About this time he published an "Essay on collateral confanguinity," particularly referring to the claim made by the kindred of the founder of All-Souls, to a preference in being elected fellows of that society. It was written in defence of the college, which had lately rejected some of these claims; but the reasoning, though supported by great learning and ingenuity, is deemed by some competent judges inconclusive. In 1755, Mr. Blackstone, perceiving, after a trial of seven years, that he had no prospect of success in the courts at Westminster, determined to quit London, and to retire to his fellowship at Oxford. This resolution was eventually very favourable both to himself and the public. As no public provision had been made either by the founders of the English universities, or at any subsequent period,
period, for teaching students the laws and constitution of their own country. Mr. Blackstone undertook to supply this defect, and opened a course of public lectures upon this interesting subject. With such reputation and success did he prosecute his plan, from Michaelmas term 1753, when his first course of lectures commenced, during a series of succes-

sive years, as probably to suggest the idea to Mr. Viner of founding by his, with a very liberal establishment in the university of Oxford for the study of the common law. As soon as the plan of Mr. Viner's institution could be arranged, Mr. Blackstone was very properly elected, in October, 1755, the first Vinerian professor; and he introduced the duties of his new office by a well-written lecture, adapted both to the subject and the audience, which was soon afterwards published, and which has been prefixed to the first volume of his Commentaries.

With his engagements as a lecturer, Mr. Blackstone combined the occasional exercise of his profession as a provincial barrister; and, in 1754, he was employed as counsel in the great contested election for the county of Oxford. The great success attending these services on this occasion was published in a pamphlet entitled "Concerning Copies of Holders," with a view to the legislative decision of the point controverted at this election. The argument of this treatise is founded on feudal principles, and excludes copyholders from the right of voting; this right being, by his reasoning, restricted to those who have a freehold or permanent interest in land, which does not belong to copyholders, whom the feudal system considers as mere vassals, and dependent on the will of the lord. But it has been more liberally argued by others, that a series of legal decisions has given to this tenure all the permanence of freehold property, and that as the reason of the distinction between the two species of tenure has ceased, the distinction itself ought no longer to exist. However, in the parliamentary discussion of this question, the technical arguments prevailed; and a declaratory act was soon afterwards passed, in conformity to the principles advanced by the professor's treatise, excluding copyholders from the right of suffrage. In 1759, Blackstone published, besides two tracts of a local and temporary nature, a new edition of the Great Charter, and a "Charters of the Forest," introduced by an historical preface, which contained a considerable knowledge of antiquities. In the same year, the reputation gained by his lectures encouraged him to return to the temple, and to resume his attendance at Westminster; where he soon acquired professional eminence, and where he was employed for a considerable time in almost all cases that required great learning and deep research. In 1761, he was elected member of parliament for Hindon, and had a patent of precedence to rank as king's counsel, having before declined the office of chief justice of Ireland. In 1762, he collected and republished several of his pieces under the title of "Law Tracts," in 2 vols. 8vo. In 1763, he was appointed solicitor-general to the queen, in the establishment of her majesty's household, and barrister of the Middle Temple. Having vacated his fellowship by his marriage, in 1761, he was immediately afterwards appointed principal of New Inn Hall, by lord Wilmot, then chancellor of the university. But in 1765, he resigned both this office and his Vinerian professorship.

The first volume of his Lectures was published in 1765, under the title of "Commentaries on the Laws of England," a work which Sir William Jones has characterized as "the most correct and beautiful outline that was ever exhibited of any human science." In the execution of this undertaking, the author combines the humblest duty of an exponent with the higher character of a philosophical writer on jurisprudence. Under the former character he is entitled to the highest praise. The style is correct, perceptive, and elegant; and the author has admirably contrived to connect amusement with information, and to render the study of the law as agreeable as it is important and interesting. Notwithstanding the immense mass of materials of which this comprehensive work consists, few errors have been detected in it, and it has been cited as a book of authority.

It has been objected, however, to these Commentaries, excellent as they are in a variety of respects, that in those parts of them where the author examines the reasons and principles of law, he does not investigate them with a truly philosophical spirit, and that he does not rise above the ordinary level of those writers who, in every country and age, have extolled their own municipal institutions as the "wisdom of ages," and the perfection of reason." In discussing the propriety of particular laws, it is said that "his ingenuity is always occupied by the forms of jurisprudence; and instead of referring to public convenience and general utility, the sole standard of all rational legislation, he perceptually appeals to those technical arguments which are dignified with the title of "legal reasons." He is, in all cases, the advocate and apologist of existing institutions; and it is the constant tendency of his work to justify whatever has been established by antiquity, to dilate the improvements of modern times, and to expose or indignation all proposals for further change. In his political principles he has been charged with being too much the advocate of prerogative; and his ecclesiastical opinions have been thought to incline towards intolerance. Notwithstanding the undue deference to authority, with which this writer has been charged, there are many passages in his admirable work, in which he expresses a marked disapprobation of standing armies and military barracks, and in which he delineates the progress of the influence of the crown, and the probable effects of a further increase of the national debt. These passages, however, have been attributed, by some of those who have animadverted on his Commentaries, more to the spirit of the times, than to that of the writer. Several obvious passages in the ecclesiastical part of this work were pointed out by Dr. Furneaux and Dr. Pridley; but though the author had not magnumitly enough explicitly to acknowledge his errors, these passages were retrenched in subsequent editions. The political principles of the Commentaries were, some years afterwards, viz. in 1776, more severely noticed in a pamphlet of "A Fragment on Government," by Jeremy Bentham, esq. To the honour of Mr. Blackstone it should be mentioned, that notwithstanding the severity of this author's criticism, he afterwards became acquainted with him, and lived with him upon terms of regard and friendship.

Having given his opinion in parliament, on occasion of the debates about the Middlesex election, that an expelled member was not eligible to the same parliament, and this opinion appearing to contradict the language of his Commentaries, he was violently attacked for this incongruity by the celebrated Junius and others; but, though he defended himself with ingenuity, he inferred the cafe of expulsion in the next edition of his work, of which he had before taken no notice, as one of the disqualifications for a seat in parliament.

His distinguished talents and meritorious services entitled him, without doubt, to the notice and recompense of government. Accordingly, when he declined the offer of being solicitor-general, on the resignation of Mr. Dunning, in 1779, he was appointed immediately afterwards one of the judges of the common pleas, which office he held, except for a short interval, during which he accommodated Mr. Justice Yates by sitting as one of the judges of the
BLA

King's bench, till his death. Towards the end of the year 1779, a
dropical disease, occasioned chiefly by early application, and
by neglect of exercise, made rapid advances, and termi-
nated in his death, Feb. 14th 1782, in his 56th year. In
private life, judge Blackstone was distinguished for mildness
and benevolence, and for every domestic and social virtue.
In studies and avocations that contributed to establish his own
reputation, and to benefit both his contemporaries and po-
verty, he was eminently industrious; and the intervals of leis-
ure which he enjoyed in the later period of his life were
devoted to schemes of local improvement in the neighbour-
hood where he resided, or to great public undertakings.
The two volumes of Reports, which he left in MS. have
been published since his death, in 2 vols. folio, with a pre-
face containing memoirs of his life; but their merit is laid
not to correspond with the fame of the author. He also
left in MS. several small poetical pieces; and his notes on
Shakespeare inserted in Mr. Malone's Supplement, shew
how well he understood, and how capable he was of ap-
preciating, the excellence of that author. Life prefixed to

BLACKSTONE, in Geography, a small river of America,
which has its source in Rainhorn pond, in Sutton, Mass.
achusetts; and, passing through Providence, discharges itself
into Narraganset bay, at Bristol, receiving in its course fev-
eral tributary streams.

BLACKSTONIA, in Botany. See CHLORA.

BLACKWALL, Anthony, in Biography, a native of
Derbyshire, was admitted a fizar of Emanuel college, in the
university of Cambridge, in 1690. Having taken the degree of
M. A. in 1698, he became head-master of the free-school
at Derby, and lector of the parish of All-hallows in that
town. In 1706, he excited notice by an edition of the
"Moral Sentences of Theognis," with a new Latin version,
together with notes and emendations. He also published, in
1718, "An Introduction to the Classics, 12mo. in which
he displays his excellence, gives directions for studying
them with advantage, and illustrates those rhetorical figures
by which language is elevated and adorned. In 1722, he
was appointed head-master of the free school at Market
Bosworth, in Leicestershire; and in this situation he pre-
pared for the pref his principal work, entitled "The Sacred
Classics defended and illustrated; an essay humbly offered
towards proving the purity, propriety, and eloquence of
the writers of the N. T. in 2 parts, 4to." This was pub-
lished in 1725; and a second edition in 8vo appeared in
1727. After his death, a second volume was published under
the title of "The Sacred Classics defended and illustrated,
the second and last volume, in 3 parts," 8vo. 1731.
The design of the author, in this elaborate and learned work, was
to vindicate the writers of the New Testament from the
charge of barbarism in their language, and to shew that the
words and phrases which they have used are to be found in
the most approved classical writers. Many of the obscurities
and seeming faults he attributes to transpositions and mis-
translations, and he urges the necessity of a new version.
See BIBLE. This book has been highly valued by biblical
scholars; and a Latin translation of it was published at
Leipzig, in 1736, by Christophorus Wolhus. Nevertheless it
has been thought by several very competent judges to be
written with more zeal than solidity; and Dr. George
Campbell, in his Preliminary Discourse to his Version of
the four Gospels, has attacked the fundamental principle of
the work, and made several passages from the text upon
which Mr. Blackwall was eminently distinguished as a schoolmaster,
and formed many good scholars, among whom was Richard
Dawes, author of the Miscellaneous Criticis. In his school he
used a Latin grammar composed by himself, and published
in 1728 without his name. Sir Henry Atkins, bart., who
had been one of his scholars, presented him in 1726, with
the valuable rectorcy of Clapham, in Surry; but he resigned
it in 1729, and returned to Market Bosworth, where he died
in 1730.

BLACKWATER, in Geography, the name of four
rivers in England and Scotland. That of England rises
near the middle of the county of Essex, and falls into the
mouth of the Thames, where it forms a spacious bay called
Blackwater bay, Throfe of Scotland are, 1st. in Darnashire,
2d. in Berwickshire, and 3d. in Perthshire.

BLACKWATER, the name of several rivers in Ireland,
one of which is very considerable. This rises in the mountains
which separate the counties of Limerick and Kerry; and,
taking a southerly direction, divides the latter county from
the county of Cork for about 12 miles. After passing at
the foot of Slieve-logher mountain, from which it receives
a large supply of water, it runs westward across the northern
part of the county of Cork, which is about 45 English
miles. In this course it passes the flourishing towns of
Mallow and Fernery, to the former of which it was naviga-
ted in lord Orrey's time, and receives the rivers Allo,
Awbeg, and Funcheon, besides many smaller streams. A
few miles below Fernery, it enters the county of Waterford,
and continues in the same direction for 12 miles, when, hav-
ing passed the ancient city of Lismore, it bends nearly at a
right angle to the south at Capoquin. At this town it be-
comes navigable, and in its course receiving the river Bride,
and opening into two or three spacious loughs, it flows into
the sea a little below the town of Youghal, which is situated
on its western bank. This river passes for almost the whole
of its course, which, without making any allowance for its great
windings, is about 90 English miles, through a rich and
well-wooded country, "equally remarkable," says Mr.
Young, "for beauty of prospect and fertility of soil.
The banks are crowded with a number of fine estates, fome
of which, as Dromana and Lismore castle, may vie with
those in any country, and have furnished artists with beau-
tiful landscapes. The cider made in its neighbourhood is
held in great estimation, being preferred to the best im-
ported from England, and of course brings a very high price.
The Irish name of this river was Auniduff, or Awin-dubh,
the black river, and also Awin-more, the great river, to difi-
guish it from the Awbeg, or Awin-beg, which runs into
it. The latter is the Mulla of the immortal Spenser, who
had an estate on its banks, where he resided for a long time.
In his marriage of the Thames, he has mentioned the
Blackwater and several of its tributary streams, though not
with geographical accuracy, as the Allo does not rise near
Slieveologher, but has the Blackwater between it and that
mountain.

"Swift Auniduff, which of the Englishman
Is called Blackwater, and the Liffar deep,
Sad Trouis that once his people overrun,
Strong Allo tumbling from Slieve-logher steep.
And Mulla mine, whose waves waves Ilthlon taught to weep."

Spenser's Fairy queen, 3. iv. c. 11.

—2. Another river, called Blackwater, rises in the county of Tyronc, and, for the greater part of its course, di-
vides that county from those of Monaghan and Armagh.
The linen manufacture is extensively carried on in its neigh-
bourhood; so that there are many bleach-greens. The flo-
rishing little towns of Aughnacloy, Caledon, Blackwater
town, Moy, &c. are on its banks; and its navigation to
Lough Neagh, into the south-western angle of which it
pours its waters, has been improved at a considerable na-
tional expense, on account of the collieries at Drumglass,
in the county of Tyrone.—3. A river Blackwater rises in
the
the county of Monaghan, and, having passed through Lough Ramor, united its waters to those of the Boyne at Navan.

—There are also small rivers of this name, one in the county of Longford, which joins the Slannan near Lanesborough, and one in the county of Wexford, which flows into St. George's channel at the place where Bannower formerly stood.

BLACKWATER TOWN, a small town in the county of Armagh, in Ireland, on the river Blackwater, which has a linen market. Distance from Dublin 66 miles.

BLACKWELL, Thomas, in Biography, was the son of one of the ministers at Aberdeen, and born in that city in the year 1701. He was educated at the grammar school and marishal college of his native place, of which, in 1713, he was appointed Greek professor, and in this office he contributed in no small degree to promote Greek literature, and the study of the classics in general. In 1735, his "Enquiry into the Life and Writings of Homer," 8vo, was published without his name; and by its popularity served to establish his reputation for learning and ingenuity. Of this work, discussing a variety of topics without any very obvious connection, Dr. Blackwell has said, "I did, I fear, too much; I had gone through half the book, had forgotten the beginning; and that when he had finished the perusal of it, he had forgotten the whole." It is reckoned, however, the author's principal performance, and is both curious and entertaining. His "Letters concerning Mythology," 8vo, were published in 1748; and they were intended to establish a regular system of ancient fable, as an allegorical representation of the religion, law, and philosophy of early times. The work is learned, fanciful, and defultory. In this year Dr. Blackwell was appointed principal of the Marischal college, and allowed his office of Greek professor. In 1751, he announced to the public his design of publishing a new edition of Plato's works; but this design was never executed. The first volume of "Memoirs of the Court of Augustus," 4to, was published in 1753; the second in 1755; and the third, after the author's death, in 1764. The object of this work is to exhibit, in an elegant and popular form, the principal facts of Roman history, at the commencement and during the period of the public life and reign of Augustus. It is written with vivacity, and was at first well received; but the affectation of learned and familiarity of the style, united with a considerable degree of that pompous kind of pedantry, which displays not only erudition but a knowledge of the world, has contributed to lower its reputation. This work manifests a too republican spirit, not altogether free from party prejudice. The author's affected mode of writing increased as he advanced in years; and though it must be acknowledged, that he possessed genius and fancy, and had a relish for the beauties of ancient authors, he never acquired that simplicity of taste, which leads to the true and elegance of composition. This peculiar style and manner of composition have been attributed to an injudicious imitation of Lord Shaftesbury. Some years before his death Dr. Blackwell's health declined; and his disorder being of the consumptive kind, which he is thought to have increased by his ablemious mode of living, he was under a necessity of remitting his studies, and advised to travel; but with this view he could proceed no farther than Edinburgh, where he died in 1757, the 56th year of his age. His temper was frequently mild and equable; and he retained his natural vivacity and cheerfulmien throughout the whole period of his illness, and till the hour of his death. In conversation he was instructive and entertaining; and he blended a considerable knowledge of the world and urbaniety of manners with an extensive acquaintance with ancient and modern authors. But it was his foible, that he was apt to assume the appearance of universal knowledge; and this weakness betrayed him into conversation on philosophical and mathematical subjects, with which his acquaintance was very imperfect. Among his friends and correspondents were many persons of literary eminence; and it is said, that his patrons proposed to introduce him into the professorship of modern history at Cambridge, if he had not died before a vacancy occurred. Biog. Brit.

BLACKWELL, Elizabeth, widow of Alexander Blackwell, M.D. author of "A New Method of improving cold, wet, and clayey ground," 1741, London, 8vo. Rejecting dung and other manures, he depended entirely on repeated ploughing and turning the ground. He died a miserable death in Sweden. His widow, being left in indigence, undertook, by the advice of her friends, to publish an account of 500 medicinal plants, to be drawn, engraved, and the greater part of them coloured by herself. The plants were furnished by Rand and Miller, from the botanical garden, belonging to the company of apothecaries, at Chelsea. They are, in general, Haller's foliated. In some parts, however, the latter failed. Not well instructed in the Linnean system, she has not delineated the fibres or filaments of the flowers with the accuracy now required. A short account is annexed of the medicinal virtues of each of the plants, some of which are extremely rare. The first volume of this work was first published in 1737, and the second in 1739, when the whole was published in 2 vols. fol. under the title of "A curious Herbal, &c." and it is creditable to the authors to say, that this bulky and expensive work passed through several editions. The last, which came out in 1760, in 5 vols. folio, at Nuremberg, is furnished with a preface and considerable additions by James Trew. After his death, in 1769, a supplemental volume, conducted by Ludwig Bofc, and Becker, was printed in 1773. This work has been in a great measure superseded by Dr. Woodville's SS. Medical Botany, in 4 vols. 4to. Haller. Bib. Bot. Pulency's Hill and Biog. Sketches of the Progress of Botany in England, vol. ii. p. 254.

BLACKWOOD, Adam, was born at Dumfrience, in Scotland, in 1539, and educated at Paris under Turnebus and Dornat. He was particularly patronized by Mary queen of Scots; and when he had finished his law studies at Toulouse, he obtained the office of councillor to the prefidial of Poitiers, which was Mary's dowry-town. In this place he settled and married; and, during the imprisonment of Mary, took several journeys to England with a view of serving her. He died in 1613. His religious and political sentiments may be deduced from the titles of his works, which were written both in verse and prose. Of these the principal were: "Caroli IX. pompa funebris versibus expressa," Paris, 1574; "De vinculo religionis et imperii, et de conjunctionum infidis, religionis fuo adumbratis," 1575; "Adversus G. Bucharani dialogum de jure regni apud Scotos, &c." Poitiers, 1581; "Martyle de Marie Stuart, reine d'Ecosse," &c. &c. His account of the execution of Mary Stuart is a virulent invective against queen Elizabeth, her parentage, her right to the crown, her government, &c. His works were collected and published in a 4to. volume by Gabriel Naudé, in 1644, with an eulogy of the author prefixed. Moreci. Gen. Biog.

BLADDER, in Anatomy, is a membranous bag, serving as a receptacle for some secreted fluid. That which is considered as the chief receptacle of this kind, is the urinary bladder. As the anatomy of these parts, in general, will be described with that of the organ which prepares the fluid which they are intended to contain; therefore, for the sake of uniformity of method, the description of the urinary bladder

BLA

BLA
bladder is given with that of the kidneys and other urinary organs. See Kidney.

Bladder, Divisions of, in Surgery. This viscus being supplied with nerves, blood-vessels, absorbers, and muscular fibres, will be necessarily liable to all the common divisions of soft parts; such as wounds, inflammation, ulceration, gangrene, ulcers, contraction, dilatation, rupture, &c. But, besides these affections, the bladder is subject to other morbid changes, which occur very rarely or not at all in most other parts of the body. It is sometimes included among the contents of a hernia sac. See Hernia. Partial bags, or fasci may likewise form in the coats of the bladder, so as to retain one or more calculous bodies generated in the urine. See Calculus, Cystotomy, Lithotomy, and Stone. Fungous, painful, and dangerous excrescences arise also on the inner surface of this organ, which are frequently denominated cancers, and are perhaps equally fatal in their consequences. These diversiforms will, in general, produce either a retention or a preternatural evacuation of urine, and require a peculiar plan of treatment adapted to the diversity of symptoms. See Urine, Retention of, &c.

Bladders, vesicles, in Botany, a kind of air-bags found in some species of fishes.

Vegetable bladders are found every where, in the structure of the bark, the fruit, pith, and parenchyma, or pulp; besides those morbid ones placed on the surface of leaves by the puncture of insects.

Bladder, funnelling. See Air-bladder.

Bladders, oil, in the Anatomy of Plants. See Oil-bladders.

Bladder, paceron, in Entomology. See Chermer.

Bladder-nut, in Botany. See Staphyllea.

Bladder-nut, American. See Royena.

Bladder-nut, laurel-leaved. See Holly.

Bladder, fenc. See Colutea.

Bladder-shaped, inflated, denotes inflated or distended like a blown bladder; such are the cup of the bladder campion, and the blossom of the fig-wort.

Bladder, placent. See Utricularia.

Bladder-wort, common. See Utricularia.

Blade, in Agriculture, a spire of grass, or green shoot of corn.

Blade, in Anatomy. See Shoulder-blade.

Blade of an Anchor, denotes that part of the arm on which the palm is shut.

Blade, in Commerce, a thin slender piece of metal, either forged by the hammer, or run and cast in moulds, to be afterwards sharpened to a point, edge, or the like. Sword-blades are made by the armourers, knife-blades by the cutters, &c. The English and Damascus blades are most esteemed. Among the French, that of Vienne and Damascus have the preference. The conditions of a good blade of a small sword are, that it be light and tough, apter to bend than break. When it will stand in the bend, it is called a poor man's blade.

Blade of a Chaff, is the iron or steel part, as distinguished from the wooden handle.

Blade of Mace, or cinnamon, among apothecaries, are little slips or slices of thoe barks.

Blade of an Oar, is that part which is plunged into the water in rowing. On the length of this do the force and effect of the oar, in a great measure, depend.

Blade of a Saw, the thin part where the teeth are cut, which, to be good, must be stiff, yet bend equally into a regular bow all the way, without yielding more in one place than another.

Vol. IV.
divisions ovate, reflex. Stam. filaments four, fetaeous, the length of the tube, inserted into the receptacle; anthers oblong, contorted, cres, obtuse, emarginate. names of the greater cost of English writers, and falsa teter-

innus of Linnæus. Vide Günther Ntw. and. Eyre. The 

common cost, falsa area of Linnæus, is also named by this 

author kliiser blasing. 

BLESSUS, in Medicine. See Stammering.

BLAGAITZKI, in Geography, a town of Croatia, 10 

miles N.N.W. of Slun.

BLAGNAC, a town of France, in the department of the 

Upper Garonne, and chief place of a canton, in the dis-

trict of Toulouse, on the Garonne; 3 miles N.W. of Tou-

loule.

BLAGOVETSCHENSKOI, a town of Russia, in the 
government of Archangel, near the south-east coast of the 
White sea; 70 miles S.W. of Archangel.

BLAGRAVE, John, in Biography, an English mathe-
matician, was born of an honourable and noble family at 

Talbingham near Sunning in Berkshire, towards the 

middle or close of the 16th century, and educated, first at a 
school in Reading, and afterwards at St. John's college, 

Oxford. Before he took any degree he retired from the uni-

vercity to his patrimonial seat at South-cote lodge, near Reading, 

where he diligently pursued his studies, particularly mathe-
matics. His works, of which we have any account, are 

"A Mathematical Jew," showing the contruction and 

sec of an instrument so called, and its application to astro-

nymy, cosmography, geography, &c. Lond. 1585, fol.; 

"The Construction and Use of the Familiar Staff, &c.;" 

performing the geometrical menuration of all altitudes, 

Lond. 1592, 4to.; "Atalabium Uranicum generale," 

containing the use of an instrument, or altroblades, 

Lond. 1595, 4to.; and "The Art of Dialling, in two parts," 

Lond. 1609, 4to. Mr. Blagrave was distinguished by his 
benevolence, both during his life, and at his death. Having 

never been married, he bequeathed 50l. to each of the 

children of his three brothers, or their povertie, payable at the 

age of 26; and his bequests in this way were so well ad-

judged, that near 80 of his nephews and his descendents 

were thus benefited out of his leafhold estate. He also be-

queathed funds for producing an annual donation of 101. 

to a maid-servant in the town of Reading, according to 

the directions of his will. These directions required, that 

the church-wardens of each of the three parishes should 

on Good Friday lend one virtuous maid, who had lived five 

years with her master. The three maids were to appear in 

the town-hall before the mayor and aldermen, and to eat 

dice. She, whose throw was the greatest, received the ten 

pounds. The two maids who had lost were to appeare the 

next year, together with a third added to them. Accord-

ingly each maid was to have by his will the chance of three 

annual throws; but if any failed in three successive years, he 

orders new persons to be prevailed. On the June Good 

Friday, money is distributed to 80 widows in pursuance of 
his will, who attend a sermon for which the preacher is 
to receive ten shillings. Mr. Blagrave died Aug. 9th 1611, 

and was buried in the church of St. Lawrence, Reading, 

where a fumanitious monument is erected to his memory. 

Biog. Brit.

BLAGRE, in Ornithology. Under this name Levallant 
describes the African species of eagle called by Latham falco 

blagrus, which fee.

BLAIN, a dillerem incident to beaks, confining in a 

bladder growing on the root of the tongue against the wind-
pipes, which at length dwelling flops the breath. 

It comes by great chafing and heating of the flomach; 

whereby, as some judge, it still grows and increases by more 

heat.

It is perceived by the beak's gaping, holding out his 
tongue, and flowing at the mouth: to cure it, call the 

beak, take forth his tongue, and then flitting the bladder, 
wash it gently with vinegar and a little salt.

BLAIN, in Geography, a town of France, and principal 

place of a distirct in the Lower Lorraine. The population 

of the place confids of 1897 persons, and of the canton of 

10,260; its territorial extent is 54.12 kilometres, and it in-

cludes 4 communes; 18 miles N.N.W. of Nancy, and 40 

S. of Rennes.

BLAINVILLE, in Biography, a learned musician of 

Paris, who propoded, in 1751, a third mode or key, which 

he called a mixed mode, because it participates of the modu-

lations of the other two, or rather from its being com-

ounded of both, a mixture which the author does not re-

gard as an inconvenience, but rather as an advantage and 

source of variety both in the melody and harmony. 

Rouf-

feau. Dic. de Musique, published 1768.

BLAINVILLE, a performer on the violincello, and mu-

ic-mater at Paris, who had many symphonics and motets per-

formed at the Concert Spirituel, in the middle of the last 

century,
century, without success; but abandoning the practice of harmony or composition, in order to try his force in the theory, in 1751, he produced "L'Harmonie theorico-pratique;" in 1754, "L'Esprit de l'Art Musical;" in 1765, "L'Histoire générale, critique, et philoloogique de la Musique." These works are no better than his symphonies. They are compositions without taste, which teach nothing new to those who know anything about music already; and not enough to those who know nothing. In 1751, he had the courage to publish a discovery a pretended new mode, a key different from the major and minor, which, he said, was neither major nor minor, but mixed of both. He composed a symphony in this new mode, and had it performed at the Concert Spirituel, which gave birth to many discussions and discussions, &c. Labordere, "Essai fur la Musique, tom. iii. p. 577.

"Who shall decide, when doctors disagree?"

The new mode, as it was called, was attacked by the ingenious and speculative writer on music, M. Seric of Geneva, and defended by Rouleau in his Dictionary. Thirty years after, it became the subject of a very long article in M. Labordere's "Essai fur la Musique, merely to attack Rouleau for having defended it. In this attack of the dead lion, the abbé Rouleau was battle-keeper to his friend Labordere.

All these gentlemen were utterly ignorant of the church music of the 15th and 16th century, built on the ancient ecclesiastical modes, in which nothing was more common in the mass of the old masters, than for a movement beginning in A minor to end on the fifth of that key, with a sharp third, which would be called now a semi- cadence. The melody of the several parts is equally in the scale of C and A natural, which, without accidental flats or sharps, produces nothing but different species of octaves in the key of C natural. But calling C the key note instead of A, it has a peculiarity in the second, which, instead of being a tone major above the key note, is only a major femitone.

Now Dr. Pepusch, who rigidly adhered to the laws of the ecclesiastical modes in his "Treatise on Harmony," to late as 1751, in speaking of the key of E as formed of one of the species of octave in the scale of C natural, has explained the properties of this key with only a major femitone for its second, much better than Blainville, or any of his defenders or opponents, and terminates his remarks on this key, by saying that "it differs from all others; for they are introduced by the femitone major below them, but this is by the femitone major above it; they by their seventh major, but this by its second, which happens to be minor; that is from F downwards to E. It is because of this difference and peculiarity in its modulation, which makes what is composed in it to be very solemn, that this key is as it were appropriated to church-music, and called by the Italians "torno di chiave," p. 65.

But the doctor does not call it a new key, for it is as old as counterpart; and we should suppose that Blainville had either seen Dr. Pepusch's treatise, or found in some old maps a movement that ended on the fifth, instead of the key note, and wished to pass for an inventor. But it is plain, that all the French gentlemen, who took a part in this controversy, were disputing about the dent d'or, before they had ascertained its existence. In examining the maps of Joquin, Palestrina, and the cantiones of Tallis and Bird, we find movements of the description of Dr. Pepusch's "torno di chiave." And in Padre Martini's "Saggio di Contrepunto," tom. i. p. 42, he calls this mode il terzo suono autentic, the third authentic mode, which Blainville calls the new or mixed mode; and P. Martini even calls it terzo suono milto del quarto suo playale, p. 44. He gives the same natural scale for its intervals as Rouleau and Blainville, EFGABCDEFp. 51. An example of this mixed mode is given from Palestrina, in which no accidental sharps are marked, though it modulates into G major, A minor, C, & G a second time. A sharp only is given to G upon the close note, as sharp third to the final E.

In 1756, Blainville published what he called "A general, critical, and philological History of Music," a work for which the author's materials seem to have been so scanty, that he was reduced to fill two thirds of his thin quarto with an indigestible treatise on composition.

BLAINVILLE, in Geography, a town of France, in the department of La Manche, or the Channel, and chief place of a canton, in the district of Coutances, 5 miles west of Coutances, and 13 miles north of Granville.

BLAINVILLE, or Plou, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Lunéville, 4 miles S.W. of Lunéville, and 12 S.E. of Nancy.

BLAIR, John, in Biography, a chronologist and geographer, was born in Scotland, and educated at Edinburgh. Upon his first arrival in England, he was usher at a private school; and first appeared with singular advantage before the public by publishing, in 1754, a work intitled "The Chronology and History of the World, from the Creation to the year of Christ 1753, illustrated in 56 tables, of which four are introductory, and contain the centuries prior to the first olympiad; and each of the remaining 52 contains in one expanded view 50 years, or half a century; by the Rev. John Blair, L.L.D." This comprehensive work, on which the author must have bestowed a very great degree of attention and labour, was published by subscription, and dedicated to Lord Hardwicke; and the author acknowledges great obligations to the earl of Bath. Dr. Blair appears at this time to have taken orders in the English church, in 1755, he was elected fellow of the Royal Society, as he was of the Antiquarian Society in 1751. In 1756, he published a second edition of his Tables; and in 1757, he was appointed chaplain to the princes dowager of Wales, and mathematical tutor to the duke of York. In 1761, he obtained a prebendal stall at Wellminster, and several church preferments in very quick succession. From the vicarage of Hickley, in Leicestershire, which he held, by dispensation, with the rectory of Burton Coggles, in Lincolnshire, he was promoted to the vicarage of St. Bride's, in London, in 1711, and, in 1756, to the rectory of St. John the Evangelist in Wellminster, with which he held that of Horton near Colebrooke, in Buckinghamshire. During the years 1763 and 1764, he accompanied the duke of York in his travels on the continent. In 1768, he published an improved edition of his "Chronological Tables," which he dedicated to the princes-dowager; and to this edition he annexed 14 maps of ancient and modern geography, and prefixed a dissertation on the rise and progress of this science, which was also printed separately in 1720. His death, which happened June 24th 1782, was probably accelerated by the shock that attended the news of his brother, captain Blair's death in the memorable sea-fight of April 12, 1782; more especially as the was then severely affected with an epidemic influenza. After his death, in 1785, his "Lectures on the canon of the Scriptures, comprehending a dissertation on the Septuagint version," were published; and a new edition of his "Chronological Tables," extended to the year 1790, appeared in that year. Diog. Dict.

BLAIR, Patrick, practised physic and surgery at Dunce, in Scotland, where he was probably born. He first became known in 1765, by his account of the anatomy of an elephant, which he had the opportunity of dissecting there. It was published in the Philosophical Transactions, Nos. 356 and
and 327, in the year 1743. It contains an accurate description of the proboscis and its muscles, and confirms Haller's opinion formerly given, that the elephant has no gall-bladder. In a subsequent number of the Transactions, he gives a description of the officinal auditus, accompanied with engravings. In the rebellion, in 1715, being suspected, on account of his religious principles, of hostility to government, he was for a small time confined. He came afterward, however, to be recommended his "Anatomy of the Elephant," in 4to.; and, in 1718, published a volume of "Miscellaneous Observations on the Practice of Physic, Anatomy, Surgery, and Botany," in 8vo.

This was followed, in 1720, with "Botanical Essays," in two parts, also 8vo. with figures, in which he treats of the sexes of plants, confirming the arguments adduced in proof of them by found reasoning, and some new experiments of the manner of incubation, of the circulation of the sap, &c.

This work still retains its credit among botanists, although some of the author's opinions are abandoned.

About the same time, he gave an account of the affuetus, found in the county of Angus, in Scotland, printed in the Phil. Trans. N° 333; and of the dissection of an emaciated child, in which he could find no vestige of the omentum, Id. N° 353; and also of a boy, who lived a considerable time without food, Id. N° 364; and in the same number is also a dissertation on the means of discovering the medicinal properties of plants from their external figure. He soon after left Boston, and published "Pharmacoe-Botanologia," or an alphabetical and classical dissertation on all the British indigenous and garden plants of the London Dispensatory, in seven decades, 4to. 1723 and 1728, introducing some plants, which he had first discovered growing near Boston. The work only proceeded to the letter H. The time of his death is not known. Haller. Bib. Anat. 8c Bot. Pulteney's Sketches, vol. ii. p. 134, &c.

Blair, James, an episcopal divinity, was born and educated in Scotland, where he was ordained and benefited; but meeting with some discouragements in that country, he quitted his preferments, and removed to England, about the latter end of the reign of King Charles II. being introduced to Dr. Compton, then bishop of London, he prevailed on him to go, about the year 1685, as a missionary to Virginia, where by his conduct and ministerial labours he was eminently serviceable in promoting the cause of religion. In 1689, he was appointed by the same prelate as his commissary for the province. Intent upon doing good in the office where he was entrusted, he observed with concern, that the want of proper seminaries for religion and learning obstructed every attempt for propagating the gospel in this colony; and he therefore formed the benevolent design of erecting and endowing a college at Williamsburg, the capital of Virginia, for professors and students in academic learning. With this view he raised a considerable sum of money by voluntary subscription; and, in order the more effectually to accomplish his purpose, he came over into England in 1693, to solicit the concurrence of government.

King William and queen Mary very much approved the design, and accordingly a patent was issued for erecting and endowing a college, which was to be denominatored from its founders, "the college of William and Mary." Mr. Blair, who first projected the scheme, was appointed president of the college. (See Williamsburgh.) He was also rector of Williamsburg and president of the council in that colony. Having faithfully and honourably discharged the duties of his office as president of the college for about 50 years, and those of his ministerial function for above 60 years, he justified his course of laborious and useful service in the year 1743. His works, comprising "Our Saviour's divine Sermon on the Mount explained, and the practice of it recommended, in divers sermons and discourses, with a recommendatory preface, by the Rev. Dr. Waterland," were published in 1740, 2 vols. 8vo. Waterland's Preface, Burnet's Hist. of his own Times, vol. iii. p. 165. 8vo.

Blair, Hugh, a distinguished preacher and writer, the descendant of an ancient family of Ayrshire, in Scotland, and the son of a respectable merchant at Edinburgh, was born in that city, April 7th 1718. As his views were at an early period directed towards the church, he entered the university of his native place in 1730, and spent eleven years in the studious prosecution of those literary and scientific studies which the church of Scotland prefers to such as profest themselves candidates for the ministerial office. During this period his application and proficiency gained repeated testimonies of approbation from the professors under whom he studied. One of his performances at this time, indicating the bent of his genius towards polite literature, was an essay "On the Beautiful," which afforded such satisfaction to professor Stevenson, that it was appointed to be publicly read at the conclusion of the feccion. This honour, without doubt, stimulated his emulation, and proved the earnt of his future fame. The method of study, which he commenced at college, and which he occasionally practiced in his maturer years, contributed in a considerable degree to the accuracy and extent of his knowledge; in this, as in all that which made abstracts of the most important works which he read, and in digesting them according to the train of his own thoughts. This was the method in which he studied history in particular; and with this view, aided by some of his youthful associates, he constructed a comprehensive series of chronological tables, in which was infected every important fact that occurred. In conformity to this plan, his learned friend Dr. John Blair formed his valuable work already noticed under his article. In 1739, Mr. Blair took his degree of master of arts; and on this occasion he printed and defended, in elegant Latin, a thesis, "De Fundamentis et Obligatione Legis Naturae." Having completed his academical course, he passed through the customary trials before the presbytery of Edinburgh, and was licened as a preacher, October 21st 1741; and in the following year he was presented to the parish of Colfifie in Fife, where he was ordained Sept. 23rd 1742. Such at this time was his established reputation as an eloquent preacher, that when a vacancy occurred in the Canongate church of Edinburgh, he was chosen at a contested election to supply it; and accordingly he returned to his native city in July 1743. In this situation he continued for eleven years, exhibiting specimens of those talents for pulpit-compositions, which have since obtained distinguished testimonials of public approbation. In 1750, he was translated from the Canongate to lady Yeller's, one of the city churches; and in 1758, he was promoted to the High Church of Edinburgh, the most important ecclesiastical charge in North Britain. To this honourable rank he was advanced at the request of the lords of council and seccion, and of other distinguished persons holding public offices, who attend that church; and the wisdom of their choice was amply justified by the prudence, ability, and success, with which his ministerial labours were conducted for a period of more than 40 years. Previously to his advancement to this station of public service, Mr. Blair's attention seems to have been almoit wholly devoted to the attainment of professional excellence, and to the regular discharge of his parochial duties. Of the productions of his pen, we have only two sermons, preached on particular occasions; some translations, in verse, of passages of Scripture for the psalmody
The Edinburgh Review, or Critical Journal. From this time he enjoyed greater leisure for directing his views to other important literary objects, besides his weekly preparations for the pulpit; and, accordingly, he commenced, Dec. 11, 1759, with the approbation of the university, a series of lectures on composition. Of his qualifications for an office of this kind, none could entertain the least doubt; they had been in some measure sanctioned by the university of St. Andrews, which, in 1757, had conferred on him the degree of doctor in divinity, then very rarely bestowed; and the success that attended his first course, afforded ample evidence of the able manner in which it had been conducted. The patrons of the university determined in the following summer to institute a rhetorical class, under the direction of Dr. Blair, as a permanent part of their ecclesiastical establishment; and on the 7th of April 1762, his majesty was graciously pleased "to erect and endow a professorship of rhetoric and belles lettres in the university of Edinburgh, and to appoint Dr. Blair, in consideration of his approved qualifications, regius professor thereof, with a salary of 70L." The lectures which he delivered on this occasion, were published in 1763, under the title of "Lectures on Rhetoric and Belles Lettres," in two volumes, 4to.; and they have been since frequently re-published in 3 vols. 8vo. Of these lectures it will be sufficient to observe, that the general voice of the public, not only in our own country, but in other nations on the continent into whose languages they have been translated, has pronounced them to be a model judicious, elegant, and comprehensive system of rules for forming the style, and cultivating the taste of youth. By a happy and singular union of taste and philosophy, the author has supplied a great defect in the science of criticism, and has made a valuable addition to the polite literature of the present age. In the course of the Dictionary we shall have frequent occasions for referring to the excellent work, and availing ourselves of its instructive and useful contents. In 1764, Dr. Blair published "A Critical Difertation on the poems of Offian," which for beauty of language, delicacy of taste, and acuteness of critical investigation, has few parallels. As it was partly by his influence, that Mr. Macpherson was induced to publish his "Fragments of Ancient Poetry," it is no wonder, that, independently of the teat of criticism, he should be a zealous advocate in favour of their authenticity and antiquity; but, notwithstanding his able defence, a degree of scepticism has prevailed on this subject.

Dr. Blair's reputation as a preacher, or rather as a composer of sermons, had been for a long time acknowledged by those who had the pleasure of attending on his ministry; but it was not till the year 1777, that he could be induced to favour the world with a volume of the discourses which had so long furnished instruction and delight to his own congregation. The MS. of this volume, at first, was received by the bookseller with some hesitation; but it was no sooner published, than he found it his interest to engage the author to furnish him with other volumes. Accordingly five volumes, in the whole, have been published at different intervals; and we may venture to affirm, that, liberally as the author was compensated, no collection of sermons has ever been more profitable to the bookseller, or more acceptable to the public, than Dr. Blair's. The circulation of them was rapid and extensive. They were translated into several foreign languages; and they received a royal reward. A pension of 200l. a year, issuing out of the exchequer in Scotland, was conferred, in 1780, on the author, and it was continued without any alteration till his death. These sermons, though they differ various degrees of comparative excellence, and some might be allowed to be much inferior to others, are upon the whole models in their kind; and they will long remain as monuments of the piety, the genius, and sound judgment of the author. Occupying a middle place between the dry metaphysical discussions or controversial speculations of one class of preachers, and the loose incoherent declamations of another, they blend the light of argument with the warmth of exhortation, the elegance of composition with judicious observations on human life, and practical knowledge with important principles of religion and virtue. The last volume was prepared for the press by the author after he had completed his eighty-second year, and delivered to the publishers about six weeks before his death. Although he left many other discourses in manuscript, he explicitly enjoined that they should be destroyed, and thus wisely prevented that injury to his reputation which has sometimes been the result of posthumous publications. The author's fame, as a preacher, depended principally, if not wholly, on the intrinsic excellence of his discourses, with respect to matter and composition; for we are informed, that his delivery, though distinct, fervent, and impressive, was not remarkably distinguished by that magic charm of voice and action, which captivates the fancies and imagination, and which, in the estimation of superficial hearers, constitutes the chief merit of a preacher. Dr. Blair, in the exercise of his professional duties, as far as they regarded the government of the church, was steadily attached to the cause of moderation. Diligent and unaccustomed to extemporary speaking, he declined interfering in ecclesiastical politics, and never would consent to become moderator of the general assembly of the church of Scotland; nevertheless, his opinion, which was always guided by sound judgment, uniformly commanded deference and respect. Whilst he was anxious to preserve the church from a servile corrupiting dependence on the civil power, on the one hand; it was his wish, on the other, to prevent a greater infusion of democratic influence than he thought to be compatible with good order, and the established constitution of the country. His reputation in public life was well sustained by the great respectability of his private character; and he was eminently distinguished through life by the prudence, purity, and dignified propriety of his conduct. With a mind free from envy, and yet not insensible to the estimation in which he himself was held; inflexibly upright, and yet confounding to his friends, and disposed to enjoy the pleasures of social intercourse; few men have passed through life more universally respected by those who knew him, more sincerely esteemed in the circle of his acquaintance, or more tenderly beloved by those who enjoyed the benefit of his private and domestic connection. His wife, to whom he was married in 1748, contributed for almost half a century to his felicity, and was taken from him a few years before his death; and his two children, a son and a daughter, died, the former in infancy, and the latter in her 21st year. His constitution was naturally delicate and feeble; but he enjoyed upon the whole a state of good health; and by habitual cheerfulness, temperance, and care, survived the usual term of human life. He retained his faculties to the last stage; and after a short illness of three days, expired on the 27th of December 1800, with the composure and hope of a Christian palior; and his funeral sermon was preached by Dr. Finlayson, who has annexed to the fifth volume of his Sermons a short account of the life and character of the author, from which the preceding article is chiefly compiled.

BLAIREAU, in Zoology, the common French name of...
BLAIREAU, du Cap de Bonne Espérance. Kohe, and after him Abbé de la Caillle, have defended under this title a little quadruped found in the interior of Africa, which exhales a most inoffensive odour. Whether it be of the badger kind in reality, or not, is uncertain. Some believe it to be of the civet kind, viscerina Capraeza; and on the contrary, Gmelin supposes it to be of the gleton kind, perhaps a variety of uexus gulo.

BLAIRIA, in Biology. See VERBENA.

BLAISE, St., Order of, was founded in Armenia, about the commencement of the twelfth century. The habit of the knights of this order was a sky-blue; and on the breasts thereof was embroidered their badge, being a crown of gold.

BLAISE, in Geography, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Chaumont, 12 miles N.N.W. of Chaumont.

ALLO, a river of France, which runs into the Marne near Larz aux, in the department of the Marne.

BLAISE, or BLAIS, St., a cape on the coast of West Florida, in the gulf of Mexico. It is a promontory, which separates the bay of Apalache on the east from that of Pensacola, forming a kind of shepherd's crook. N. lat. 29° 40'. W. long. 86° 3'.

BLASOIS, a province of France before the revolution, bounded on the east by Orléanais, on the south by Berry, on the west by Touraine, and on the north by Vendomois and Dunois. The capital was Blois, which fee.

BLASON, a town of France, in the department of the Mayne and Loire, and chief place of a canton, in the district of Angers; 8 miles S.E. of Angers.

BLAKE, Robert, in Biography, a celebrated English admiral, was a descendant of an ancient family of the name in the parish of Spaxton and county of Somerset, and born at Bridgewater, in August, 1659. Having received the rudiments of grammar learning at a free school in his native town, he became a member of St. Alban's hall, Oxford, in 1675, and translated himself from thence to Wadham college, where, in 1677, he took the degree of bachelor of arts. In 1619, he lost a fellowship of Merton college, for which he was a candidate, on account of his low stature; Sir Henry Savile, the warden, paying particular respect to personal comeliness. Soon after the year 1653, in which he wrote a copy of verses on the death of Dr. Camden, he left the university, where he had been noticed for his early riling and application to study, and lived privately at Bridgewater. Adopting at an early period republican principles, and prejudiced against the ecclesiastical establishment, by the severity with which Dr. Laud, then bishop of Bath and Wells, enforced uniformity in his diocese, he inclined also to those opinions that were deemed puritanical. Accordingly the pietist party prevailed in procuring his return as a member for his native town, to the parliament of 1640, but for the Long Parliament he lost his election. Upon the breaking out of the war between the king and parliament, he declared for the latter, and entering into military service, was soon appointed captain of dragoons. In this capacity he exhibited proofs of his talents by an obdurate defence of Bridget against the attack of Prince Rupert, which he was at length obliged to surrender. In 1644 he was appointed governor of Taunton, where he had inspired and taken possession of the parliament, and which he defended with a small but well-disciplined garrison, during a vigorous siege by the king's forces, till he obtained relief. For this service the parliament voted Blake, who was then colonel, a present of 500 pounds. After the murder of the king, which he is said to have disapproved, he cordially joined the republican party, and was reckoned, next to Cromwell, the ablest and most successful officer in the service of the parliament. Without affecting the character of a politician, he thought it his duty to serve his country to the utmost of his power, and to execute any measures that were adopted by the party to which he was attached, and by the exiling government for this purpose. Early in the year 1649, he was appointed, in conjunction with Col. Deane and Col. Popham, to the command of the fleet; and his first naval expedition was directed, in 1649, against prince Rupert and prince Maurice, to the harbour of Kinglake in Ireland; where he blocked them up for some time, and whence he pursued them to Lliphon, whither they had fled for the protection of the king of Portugal. Van being declared on this account against the Portuguese, Blake annoyed their trade, and took several rich prizes; and he afterwards proceeded, 1ft to Carthagena and then to Malaga, in pursuit of prince Rupert. At the latter place he burnt and destroyed his whole fleet, two ships escaped; and in the beginning of the year 1651, he returned with his squadron to Plymouth, where he received the thanks of the parliament, and was appointed warden of the five ports. In the following year he was constituted one of the admirals and generals of the fleet, and employed in reducing the isles of Scilly and the island of Guernsey. Having accomplished this service, he was elected one of the council of state; and in 1652, promoted to the rank of alderman for nine months, in the prospect of a Dutch war. The States, jealous of the naval power of England, determined to reduce it by a very vigorous effort. With this view they dispatched Van Tromp with 45 fail of men of war into the Downs, who was met by Blake with a much inferior force of 23 ships, and, after a very severe action, which took place May 19th 1652, obliged to retreat. After several skirmishes with the Dutch ships, and the capture of many prizes, during the progress of the summer, Van Tromp appeared again in the Downs, towards the close of the year, with 80 ships, for the purpose of renewing his attack upon Blake. The English admiral, whose force was much inferior, and who had the disadvantage of an unfavourable wind, disdained however to retreat, and engaged the enemy on the 29th of November. Notwithstanding every possible exertion, he lost five ships, and was compelled to retreat into the Thames with his shattered fleet; and Van Tromp was left in triumphant possession of the channel. Blake lost no time in repairing and recruiting his fleet; and in February 1653, he sat fell in pursuit of his antagonist. On the 18th day of the month the English admiral, with 80 ships of war, came up off Portland with Van Tromp, who had 70, and a fleet of 300 merchant-ships under his convoy. The engagement was such as seldom occurs in the history of naval combats; it lasted three days, and on both sides equal valour was displayed; at length, however, after a running fight up the channel, the Dutch anchored safely in the sands of Calais, having lost 11 men of war, 30 merchant-ships, and 1500 men who fell in the action, whilst the English lost only one ship, but as many lives as the enemy. In this action Blake was wounded in the thigh.
At this time Cromwell dismissed the parliament, and assumed the supreme power; nevertheless, Blake and his colleagues declared their fixed purpose to serve their country faithfully, and to guard it, by every effort in their power, against foreign injury and infirm. "It is not for us," said Blake, "to mind state affairs, but to keep foreigners from fooling us." Accordingly, when generals Monk and Deane, on the 23d day of June, had engaged Van Tromp with a fleet of 120 men of war, with dubious success, and with the loss of several men, among whom was Deane, Blake on the next day came up to their assistance with 18 fresh ships, and gained a victory to complete, that if the Dutch had not again faved themselves on the sands of Calais, their whole fleet must have been sunk or taken. After this engagement, his health being much impaired, he took his seat in the new parliament, summoned by the protector Oliver, as a representative of his native town, and he was constituted one of the Commissioners of the admiralty. Cromwell indeed treated him with great respect; but he was not unapprized of the admiral's strong inclination to a commonwealth; and he was therefore the more disposed to send him, in November 1651, with a strong fleet into the Mediterranean, for the purpose of supporting the honours of the English flag, and procuring satisfaction for any injury which the British merchants had suffered. While he lay in the road of Cadiz, he was treated with great respect by the Dutch and French, and even by the Algerines. However on the 10th of March in the following year he appeared before Algiers, and demanded satisfaction for the piracies committed on the English, and a release of all English captives. He then failed to Tunis on the same errand; but the day, confiding in the strength of the place, treated Blake's message with contempt; "Here," said he, "are our castles of Goletta and Porto Fino, do your word; do you think we fear your fleet?" Blake, curling his whiskers, as he was accustomed to do when in a passion, confounded his officers, and then bore into the bay with his heavy ships; demolished the castles, burnt all the shipping in the haven of Tunis, and forced the haughty and obstinate day to an humble submission, and an advantageous peace. This daring action spread the fame terror of his name through Africa and Asia, which had for a long time prevailed in Europe. He also awarded the piratical state of Tripoly into a peace with England, and the knights of Malta into a composition for the injuries which they had committed. Such was the effect of these exploits on the princes and states of Italy, that most of them thought fit to pay their compliments to the protector; and the grand duke of Tuscany, and the free state of Venice, in particular, sent magnificent embassies for that purpose. During the war with Spain, which was carried on with great spirit at this time, Blake, in pursuance of the protector's order, exerted himself in ruining their maritime force in Europe, and Montague being joined with him, on account of his declining state of health, blocked up for several months a Spanish squadron in the bay of Cadiz, and detached a part of their fleet to capture the Spanish plate fleet. Montague returned to England with the prizes; but Blake, whose constitution was broken by the voyage and fever, failed behind; and in April 1657 failed with 25 men of war in pursuit of another plate fleet which had put into Santa Cruz in the island of Tenerife. Upon his arrival, he found that the governor had used every possible precaution for the defence of the harbour; 16 Spanish ships were disposed in a circular form within the bay, and strongly barricaded; and the entrance was guarded by a caille and 7 forts, connected with one another, and furnished with large cannon. Blake feeced boldly into the bay, leaving some of his ships to silence the batteries, while with the rest he attacked the Spanish vessels. Having driven the enemy from all their fortified posts, he set fire to the shipping, which it was impossible for him to remove, and destroyed the whole, to an immense amount. Having accomplished his object, the wind veered about in his favour, and brought him out again without the loss of a single ship. This exploit has been confounded by some cool politicians as an act of rafience; but such timid reasoners should consider that by such acts of valour the British navy has made the world to tremble. On this occasion the brother of the admiral was found deficient in some service which was expected from him; upon which he was degraded from his command, and sent home to his own country, though afterwards he shared the fraternal regard of Blake, in whole mind genuine patriotism abounding every feeling and partial interest. This great enterprise was the last act of Blake's public life; the news of it at home was honoured with a public thanksgiving, with a vote of thanks to all the officers and seamen, and with a diamond ring, of the value of 500l, to Blake himself. He lived to receive this welcome tribute of the gratitude and respect of his country, to the prosperity and glory of which he was invariably devoted. As his end approached, he wished to return to his native land; as he drew near, he often anxiously inquired for land; but before he could see it, he died as he was entering Plymouth sound, on board his ship the St. George, August the 17th 1657, at the age of about 59 years. His body was embalmed, and interred with singular honours in Henry the Seventh's chapel, Westminster; but after the reformation in 1661, it was removed and interred in St. Margaret's churchyard. Blake was, with regard to his person, of low stature, of a quick, lively eye, and martial aspect; he was singularly brave, cool in action, and wise in the disposition of those desperate attacks, which men of a colder temperament have judged rather fortunate than expedient. He loved his country, and whatever was the established government, he was solicitous to do his duty; and this duty he performed with the most upright and disinterested views; for notwithstanding the high and lucrative posts which he occupied, and the many rich prizes which he captured, he only added to his own original patrimony about 500 pounds. He was pious without affectation, strictly just, and liberal to the extent of his fortune. His officers he treated with the familiarity of friends, and he was truly a parent to his followers. Although no epitaph or sculptured monument records his great and good qualities, all parties have been eager to do justice to his memory. Dr. Bates, physician to King Charles I., the protector Oliver, and King Charles II., sums up his character in the following words: "He humbled the pride of France, reduced the Portuguese to submission, broke the strength of the Dutch, and drove their fleets out of the sea, subdued the pirates in the Mediterranean, and twice triumphed over the Spaniards, blameless only in this, that he joined himself with the paricides." Lord Clarendon says of him, that he was the first man that declined the old track, and disregarded ancient established rules, which served merely to keep his ship and his men out of danger; he first taught ships to contain cailles on shore; he first infused that courage into seamen, which made them learn by experience what mighty things they could do if they were resolved, and taught them to fight in fire as well as upon water; and though he hath been very well mistasted, he was the first that gave the example of that kind of naval courage, and bold, resolute achievements. Bishop Burnet mentions a story that is related of him, well known, but worth again recording. Whilst he lay in the road of Magina, some of his seamen being on shore, met the holl, and treated the procession with neglect and indignity. One of the
the Spanish priests refented this insult, fell upon them, and beat them feverally. When they returned to their ship, they complained of this usage; upon which Blake sent to the viceroy, demanding the surrender of the offending priest. The viceroy replied that he had no power over the priests; to which Blake retorted for answer, that he would not enquire who had the power to deliver up the priest, but if he were not sent within three hours, he would burn his town. The viceroy sent the priest to Blake; who justified himself on account of the petulant behaviour of the carrier. Blake answered, that if complaint had been made to him, he would have inflicted just punishment, for he would not suffer his men to affront the Established religion of any place, at which he touched; but he wished to have it known to the whole world, that an Englishman was only to be punished by an Englishman. He then treated the priest civilly, and sent him back. When Cromwell received this intelligence, he was highly delighted, and said he hoped that he should make the name of an Englishman as great as ever that of a Roman had been. It is said, that when Blake was cruising in the Mediterranean, he met with a French ship of considerable force, and commanded the captain to come on board, no war having been declared between the French and English. The captain, being asked whether "he was willing to lay down his sword and yield," gallantly refused, though in his enemy's power. Blake, fearing to take the advantage of an antithesis, and detesting the appearance of treachery, told him, "that he was at liberty to go back to his ship, and defend it as long as he could." The captain did so, and after an engagement of two hours, confessed himself conquered, killed his sword, and surrendered it. Mr. Granger, speaking of Blake's naval exploits, says, "that the very temerity of his enterprises struck terror into his enemies, and greatly contributed to his success. He not only improved the method of attack, but carried the naval power of Cromwell to a greater height than had been known in any age or nation. "Never man," says Mr. Hume, "so zealous for a faction, was so much respected and esteemed by the opposite factions. He was by principle an inflexible republican; and the late usurpations, amidst all the truth and justice which he received from the ruling powers, were thought to be very little grateful to him. "It is still our duty," he said to the feamen, "to fight for our country, into whatever hands the government may fall." Disinterested, generous, liberal; ambitious only of true glory, dreadful only to his avowed enemies; he forms one of the most perfect characters of that age, and the haft stained with those errors and violations, which were then so predominant. The Protector ordered him a pompous funeral at the public charge; but the tears of his countrymen were the most honourable panegyric on his memory."

To the above testimonies we shall add the following lines from Mr. Glover's poem, entitled "London."

BLAKELEY, in Geography, a harbour on the coast of Norfolk, between Cromer at caft by south, and Wells at west by north nearly, distant from the former 2 leagues, and from the latter 3 leagues.

BLAMONT, a town of France, and principal place of a district in the department of the Meurthe; containing 1863 inhabitants, and the population of the canton is 10,695.

The territory comprehends 2123 kilometres and 30 communes; 43 leagues call of Lunéville. N. lat. 48° 35'. E. long. 6° 44'.—Also, a town of France, in the department of the Doubs, and chief place of a canton; containing 400 persons, and the canton contains 3589; the territory comprehends 1234 kilometres and 14 communes; 14 league north of St. Hippolyte.

BLANCKENSHAUSEN, in the Principality of Hanover, was born at Noyon in Picardy in 1640, and taught philosophy and theology in his own congregation. He is chiefly known as editor of the works of St. Augustin, in which he displayed much critical erudition and sagacity, and great accuracy in his collation of MSS. Besides other preferments in the church, he was appointed in 1706 visitor of the province of Burgundy, and in consequence of the austerity exercised in this office he died in 1710. Moreri.

BLANC. See BLANK.
monies of France from the establishment of the monarchy. Accordingly he published "A Treatise on the Monies of France," Paris, 1678, 4to. with figures; reprinted at Amsterdam, 1690. 1692. To this is usually annexed his dissertation, published the preceding year, "On the coins of Charlemagne and his successors firm at Rome." He was chosen historical tutor to the royal children, but died before he entered on his office at Verfaillies in 1698. Nouv. Dict. Hist.

BLANC, JOHN BERNARD LE, Abbé, historiographer of the public buildings, and member of the academies of La Cruce, and of the Arcadi at Rome, was born at Dijon in 1707, and engaging in the literary career, wrote a tragedy entitled "Abenlaid," which, notwithstanding the hardness of its verification, was at first well received. At Paris, where he settled, he obtained friends and patrons; and in 1746 Maupertuis was empowered by the king of Prussia to offer him a residence as a man of letters, at his court, which he declined accepting. His "Letters on the English nation," in 3 vols. 12mo. 1758, are the most known of his works, and were occasioned by his visit to England. The style is heavy, and the thoughts trite and vulgar, so that they are now little read. He died in 1781. Nouv. Dict. Hist.

BLANC, LEWIS LE, Sieur de Beaullieu, a professor of divinity at Sedan in the 17th century, who is born at Clerfis-Mari, where his father was minister, and in the progress of his life, of which few particulars are recorded, was distinguished by his learning and virtue. He died in 1675, at the age of 66 years and 6 months. His "Theses Theologicæ" were collected into one volume after his death, passed through several editions, and are highly worthy of an attentive perusal. The first edition was printed at Sedan in 4to, and two other editions were printed in England; the third in 1633. He was eminent for the perspicuity of his eloquence, and discovered an uncommon degree of penetration and sagacity in his writings and negotiations. Anxious for a reconciliation and union between the Reformed and Romish churches, he passed in review many of the controversies that divided them, and seemed to prove, with the utmost pertinacity, that some of them were merely disputes about words, and that the others were of much less consequence than was generally imagined. This manner of stating the differences between the two churches drew upon him the indignation of those who regarded all attempts to soften and modify controverted doctrines as dangerous and detrimental to the cause of truth. Among these we may reckon Arnauld, Saurin, and Jurieu. On the other hand, the acuteness and dexterity with which he treated this delicate subject, made a considerable impression upon several persons, and procured him disciples who entertained his reconciling sentiments, but either entirely concealed them, or discovered them with caution, as they were known to be displeasing to the greatest part of the members of both communions. Some of Le Blanc's memoirs were printed at Sedan in 1675. Gen. Dict. art. Beaullieu. Mohl. Eccl. Hist. vol. v. p. 379.

BLANC, LEWIS LE, a skillful surgeon and histologist of Orleans, published in 1764 "A Discourse on the utility of Anatomy;" and in 1768, "Nouvelle Méthode d'opérer des Hémiptères." 8vo. He recommends dilating the ring of the finger, if practicable, which it usually is, he says, in recent cases; in those of long standing, with a pair of forceps he invented for the purpose, instead of using the knife. This doctrine having been opposed by Antoine Louis, he was answered by Le Blanc in a dissertation on the subject, published in the fourth volume of the Memoirs of the Academy of Surgery. After reducing theifice, by his method, no truth is wanted, as is invariably the case when the ring is opened by incision. The forceps are introduced into the ring, closed, and open themselves by the force of an elastic spring. He also wrote on the operation for the stone, on the method of extracting small portions of the placenta left in the uterus, and further observations on the cure of hernia. These papers were published in the 30th, 35th, and 36th volumes of the Journal de Médecine. In 1775 he published "Précis d'opérations de Chirurgie," 2 vol. 8vo, containing the substance of the above, with some additional observations. Haller, Bl. Anat. de Chem.

BLANC-MANGER, Fr. q. d. edible food, in Domesie Economy, is a preparation of dried sago, milk, sugar, cinnamon, etc. boiled into a thick substance, and garnished for the table with blanched almonds. It is cooling and strengthening.

BLANC-MONTÉE, in Ecological History, a name originally given to the Servites, or servants of the Blessed Virgin, on account of their white cloaks; but since applied to divers forts of religious, who have successively inhabited the house of the Servites, and now to the Benedictines at Paris, though inhabited in black.

BLANC, MONT, in Geography, a lofty mountain of Savoy, in the duchy of Fancies, being part of the ancient "Alpes Pennines." See ALPS. This is reckoned the loftiest elevated mountain of the ancient continent, its height above the level of the sea being, according to the calculations of M. de Luc, 15,304 English feet, or, according to the measurement of Sir George Shuckburgh, 13,662 feet. This accurate observer informs us (Phil. Trans. vol. lxxvi. p. 798), that the height of Veuves, estimated by Sauvages at 3,900 feet, placed upon mount Jétana, elevated, according to Sir George, 10,554 feet, would not be equal to the height of Mont Blanc, which he supposes to be the most elevated point of Europe, Asia, and Africa. This mountain, observed from the "Col de Balme," and the vale of "Chamouny," is particularly distinguished from other mountains by a mantle of snow, which clothes its summit and sides, almost without the intervention of the leaf rock to break the glare of the "white" appearance, from which its name is derived. Those who have seen it from the valley of Aona, observe, that on that side it does not appear to be covered with a mantle of snow, and that it exceeds the Schreckhorn in ruggedness and horror. See SCHRECKHORN. Those who are totally unacquainted with Alpine scenes, says Mr. Cox, (Swift, vol. ii. p. 5) may, perhaps, conceive a faint idea of this gigantic mountain, on being informed, that the mantle of snow, which appears to cover its top and sides, exceeds an altitude of 4,000 feet perpendicular, and 9,000 feet in an horizontal direction from the dome of Gouté, to the summit; and that the height of the snow and ice, climated from the source of the Arveron, at the bottom of the glacier of Montanver, to the summit of Mont Blanc, cannot be less than 12,000 perpendicular feet, or near three times as high as Snowdon in North Wales. The highest point of this mountain appears like a compressed hemisphere, and is called from its form "La Buffle du Dro-medaire;" from that point it gradually sinks, presenting a kind of concave surface of snow, in the middle of which is a small pyramidal ice; it then rises into a second hemisphere, called by some "Little Mont Blanc," but more properly by others "La Dôme du Milieu," or the "Middle Dôme;" thence it descends into another concave surface terminating in a point, indifferently styled by the natives, "Aiguille de Gouté," "Pointe de la Tour," and "Dôme de Coteau." From this dome it ends abruptly, and lofts itself amid the mountains that bound the vale of Chamouny. Five glaciers extend into this vale, and are separated from one another by forests, corn-fields, and meadows; so that large tracts of ice are blended with cultivation, and perpetually succeed each other.
other in the most singular and striking vicissitude. These glaciers, which lie chiefly in the hollows of the mountains, and are some leagues in length, unite at the foot of Mont Blanc.

Of the various attempts that have been made to reach the summit of Mont Blanc, the first was that of M. Contéran, and three guides of Chamouny, Michael Paccard, Victor Taffay, and Maria Coutet. On the 13th of July 1776, they set off from the prions, about 11 in the evening; passed between the glaciers of Boffon and Tacona; and after spending above 14 hours in mounting rugged and dangerous ascents, and in crossing several valleys of ice, and large plains of snow, found themselves on the top next to Mont Blanc. But though at first sight it appeared to be scarcely a league distant, they soon perceived that it seemed, on account of the clearness of the air, the whiteness of the snow, and its great height, to be much nearer than it really was, and that it would require at least four hours more to reach the summit, even if it were practicable. As the day was far advanced, and the vapours near the summit of the mountain began to gather into clouds, they relinquished their enterprise; and returned to Chamouny, not without personal danger in leaping over chasms of ice, after a journey of 22 hours, with this satisfaction, that they had approached nearer to Mont Blanc than any former adventurers. The summit which they had attained, is, according to Sir George Shuckburgh, more than 3,500 feet above the Mediterranean. After some subsequent but unsuccessful attempts, M. Bourrit, accompanied by fix guides, departed from Bionafay, and began to scale (as he terms it) the rampart of Mont Blanc, when he suddenly found himself so exceedingly affected by the intense cold, that he was unable to proceed. Maria Coutet, and Francis Guizet, two of his guides, proceeded to the dome of Gouté, which is about 5,400 feet in an horizontal direction from the summit; but the approach of night obliged them to return. On the 4th of September 1785, Maria Coutet and James Balmat advanced beyond the dome of Gouté towards the summit, but a violent storm of hail and wind compelled them to abandon the enterprise. On the 13th of this month Melfris, Saunfure and Bourrit, attended by twelve guides, well provided with barometers, thermometers, and other necessaries instruments, left Bionafay, and arrived at a hut which was constructed by their orders at "Pierre Ronde," 7,828 feet above the level of the sea; and on the next morning they pursuèd their journey to the dome of Goutè; but a heavy fall of snow prevented their progress. Saunfure says, that the mercury in the barometer sunk 15 inches, and that he reached an elevation of 8,256 English feet. In July 1786, James Balmat, one of six guides of Chamouny, being separated from his companions, who failed in another attempt, passed the night on a spot above the "Dome of Gouté," elevated more than 12,000 feet above the level of the sea. On his return, however, to Chamouny, he was seized with a very feverish indisposition, the effect of extreme fatigue, and of the intense cold; but being attended by Dr. Paccard, a physician of the place, he offered, as an expression of gratitude for his attendance, to conduct him to the summit of Mont Blanc. Accordingly, on the 7th of August, these two daring adventurers sallied forth from Chamouny, and reached the mountain of "La Côte," which overhangs the upper part of the glacier of Bolfon. Here they passed the night, and at three on the next morning they pursed their route over the ice, ascended the "Dome of Gouté," passed under the "Middle Dôme," and turning to the exit at the last pyramid of rock, continued along the ridge which is seen from Geneva, and which lies on the left of the summit. Here cold and fatigue discouraged Dr. Paccard; but being animated by his companion, he determined to advance, struggling with a very violent and piercing wind, till at length they attained the summit which no one had visited before. Here they remained about half an hour, when they found the cold so intense, that their provision was frozen in their pockets, the ink congealed in their inkhorns, and the mercury in Fahrenheit's thermometer sunk to 184 degrees. They spent 15 hours in ascension; but found great difficulty in their ascent, their feet being much debilitated by the reflection of the snow. On their return to Chamouny at eight in the morning, their faces were exorciated, their lips much swelled, and Dr. Paccard was almost blind. These adventurers prepared the way for the observations and discoveries of future naturalists, and particularly of Saunfure, whose indefatigable zeal would not allow him to rest, till he had reached the top of Mont Blanc, and made those experiments, which have served in a very considerable degree to elucidate the theory of the atmosphere.

Having arrived at Chamouny, a village at the base of the mountain, M. de Saunfure was detained by continual rains for four weeks; after which, he set out on the 1st of August 1787, accompanied by a servant and 18 guides, who carried the philosophical instruments and the tents, and other apparatus necessary for the intended experiments. Although the distance from the priony of Chamouny to the summit of the mountain is little more than two leagues, or about 2 miles, in a straight line, it requires nevertheless 18 hours to gain the summit, on account of the difficulties of the road, as well as the necessary circuits. In the evening, they arrived at a hut constructed for them on the top of the mountain of "La Côte," about a mile perpendicularly above the village. Their second day's journey was attended with many difficulties, owing to the wide, deep, and irregular chasms intersecting the ice-valley on the side of the hill, which can only be crossed by means of bridges naturally formed of snow, and often very slender; extended, as it were, over an abyss. In this perilous valley, they were obliged to pursue a winding road, so that they were three hours in crossing it, though in a straight line its breadth is not above three-quarters of a mile. At length, however, they reached the chain of rocks that border on the perpetual snows which cover Mont Blanc, and then mounted, in a serpentine direction, to a valley filled with snow, and running from north to south, to the foot of the highest pinnacle. The surface of the snow in this valley has numerous figures penetrating to a great depth, and considerably broad; presenting to view, by their broken sides, the faceted horizontal layers of snow, which are annually formed. In this situation the guides wished to pass the night; but Saunfure, observing that the loftiest of these rocks is at least 1,400 yards perpendicularly lower than the summit of the mountain, wished to proceed, and at length prevailed with the guides to accompany him. At four in the afternoon, they arrived at the second of the three plains of snow, which they had to pass; but as the day was far advanced, and they were apprehensive of exposing themselves to the "Avalanches," which are frequently tumbling from the summit of the mountain, they determined to proceed no farther. Here they encamped at the height of 9,312 feet above the priony of Chamouny, or 12,762 feet above the level of the sea. For this purpose, they dug a deep hole in the snow, of sufficient width to contain the whole company, and covered its top with the tent-clot. In this situation the barometer had fallen to 17.00 inches, 10 lines 375; and they all felt the effects of the rarefied air. Seven or eight hours' walk, which they had just performed, laid not in the least affected these robust and hardy men; but they had fearly raised five or fix shovels of snow, in forming their intended habitation, before they were under a necessity of
of defiling from labour, and of taking breath at very short
intervals. M. de Saussure himself, though accustomet
ed to the atmosphere of mountains, and finding himsef,
fe; as he says, much better in it than in the air of plains,
now felt exhausted with fatigue, only by observing his meteorological instru-
ments. This uncomfortable sensation was heightened by an
acute thirst, and water could not be procured, except by
melting snow; for the water which they had seen during
their ascent, would by this time be congealed; and the
small chaffing-dish which they had taken with them, very
slowly supplied 20 people languishing with thirst. From the
middle of this snowy plain, near below the top of Mont
Blanc, the snow exhibited the most dazzling brightness,
and formed a singular contrast with the sky, which, in these
elevated regions, appears almost black. No living creature
was seen here, nor the least trace of vegetation. The
moon shone with the brightest splendour in the midst of a sky as black as
ebony. Jupiter, rayed like the sun, arose from behind the
mountain in the east; and the light of these luminaries
was reflected from the white plain, or rather in action, in which
they were situated, and by their dazzling lufure, eclipsed
every star, except those of the first and second magnitude.
Whilfte they were composing themselves to sleep within their
tent, incommodef by heat and vitted air, they were soon
alarmed by the noise of an immense mass of snow, or “An
valanche,” which fell from the top of the mountain, and
covered part of the slope over which they were to climb the
next day. The next morning they departed at even for the
third and last plain; turning to the left in their way to the
highest rock, which is on the east part of the summit, they
found the ascent in some places so steep, that the guides
were obliged to heave their feet upon with hatchets.
Their progress was slow, and it took them two hours to
climb a hill about 1500 feet high. Having arrived at this
half rock, they turned to the west, and climbed the last ascent,
about 900 feet high, and inclining about 28 or 29 degrees.
Here the air was so rarefied, that Saussure could not take
15 or 16 steps without flopping for breath; and at inter-
vals he found himself faint, so that he was under the necessity of
fitting down, until, with the return of respiration, his
strength was revived. On his arrival to the summit, at
11 o’clock, a slight vapour, suspended in the inferior regions
of the air, prevented him from beholding the lower and
more dilant objects; such as the plains of France and Lombard;
but he had the least reason for regretting this loss, as
he was agreeably surprized by a most distinct and compe-
prehensive view of all these elevated summits, with the organi-
zation of which he had so long desired to be acquainted.
He thought himself dreaming, when he saw beneath his feet
many majestic peaks, especially “Aiguilles,” “Le Midi,”
“L’Argentiere,” and “Le Géant,” the bafes of which he
had found it so difficult to ascend. He feized in his mind
their mutual proportion and connection, their form and
structure; and a single glance removed doubts, and afforded
information much more satisfactory, than whole years of
previous study. During this time, his guides pitched his
tent, made preparation for his experiments; but in at-
tempting to dipose his instruments for this purpose, he was
obliged, almost at every instant, to deit, and wholly to oc-
cupy himself about the means of respiration. Considering
that the barometer floated at only 16 inches, 1 line, or 15.145
inches English, and that the air, consequently, polifhed
little more than half the density of that on the plains, it is
manifest that the deficiency was to be supplied by more
frequent intakes of fhort breath. This frequent recurrence of
conqueled air, the circulation of the blood, more especifally as the arteries,
on the surface of the body, were no longer actuated from
without by the pressure which they usually experience.

When M. de Saussure remained perfectly quiet, he only felt
rather uncomfortable, with a light disposition to be fick;
but in any exertion, or when he fixed his attention for a few
successive moments, and particularly when, by flooping, he
comprifed his cheek, the necefity occurred of refiting himfelf,
and refpiring for two or three minutes. His guides also
experienced similar fenations. They felt no appetite, and
had no inclination to take wine or brandy, having found that
strong liquors increafed the above indifpoftion; without
doubt, by quickening the circulation of the blood. No-
thing but fresh water was covered and refilled, and yet both
time and exertion were required to light the fire, without
which it was impoffible to obtain the fame. In this fimation,
Saussure and his companions continued 42 days; and in their
deficient they found fewer difculties than they expefted.
They arrived the next morning at the valley of Chamouny,
without the leaft accident; and as they had taken the pre-
caution to wear veils of crape, their faces were not exccoriated,
nor their fight debilitated.

M. de Saussure has given an ample detail of his obfervations
on the fummit of Mont Blanc, in the 4th volume of his
“Voyages dans les Alpes;” and a translation of this account
by professor Martyn of Cambridge, forms an appendix to his
Sketch of a tour through Switzerland. We fhall here flant
a few particulars. We learn from this narrative, that the fummit
of the mountain is a ridge, nearly horizontal, lying east and
well; the flope at each extremity inclining from 28 to 30 de-
grees, the fourth fide between 15 and 20, and the north about
45 or 50. This ridge is fo narrow, as fcarcely to allow two
people to walk abreast, especially at the well end, where it re-
sembles the roof of a house; it is wholly covered with snow;
and an any bare rock to be seen within 150 yards of the top.
The surface of the snow is scanty, and in fome places covered
with an icy crust, under which the snow is difty, and without
confistency. The higherrocks are all granites; thoje on the
east fide are mixed with rafites; thoje on the fouth and
well contain a large quantity of fchofier, and a little lapis
cornutus. Some of them, fpecially thoje on the eft, which
are about 150 yards below the fummit, feem to have been
lately filvered with lighting. M. de Saussure saw no ani-
mal on the mountain, except two flets, a few phalans, and a
“Mystetius,” which he fupposet must have been driven
there by the wind. At the elevation of 11,372 feet above
the fea, he observed the “Silene Acaulis,” or moss campion,
in flower; and still higher, on the moft elevated rocks, the
“Lichen Sulphureus,” and “Lichen Rupefris” of Hoff-
mam. He has given us the height of the barometer on the top of
the mountain viz. Aug. 3, at noon, 16 inches 0 line, and
438 of a line, French measure, i.e. 16.181 English;
and Reaumur’s thermometer was 2.5 below the freezing point,
or 27 of Fahrenheit. M. Senneber, at the fame time,
obferved, at Geneva, the barometer 27 inches 2 133 lines, or
29.020 inches English, and the thermometer 22.6 above
freezing; or 82 of Fahrenheit. From these data he makes the
height of Mont Blanc 2218 toifes, or 14,180 English
feet, according to M. de Luc’s rule, and 2272 toifes, or
14,525 English feet, according to M. Trembley’s.
To these heights 13 toifes, or 83 feet, the height of M. Senn-
neber’s room above the lake of Geneva, must be added, to
give the height of the mountain above the level of the lake
14,525 feet, according to M. de Luc, and 14,608 feet,
according to M. Trembley. Sir George Shackmude made the
height of Mont Blanc, by trigonometrical measurement,
14,479 feet above the lake, which is almost the mean
height of the mountain. The refult of the obfervation
made at Chamouny, co-temporaneous with M. de Saussure’s,
agrees effe matter nearly with Sir George’s measurement.
The general mean result makes the fummit of Mont
Blanc
Blanc 2450 toises, or 15,673 English feet, or nearly three English miles above the level of the sea. By M. de Saussure's experiments with the hygrometer, the air on the top of Mont Blanc contained six times less humidity than that of Geneva, and to the extreme dryness of it he attributes the burning thirst which he and his companions experienced. But the result of his experiments seems very different from the system of meteorology, published by M. de Luc. See Hygrometer. It requires half an hour to boil water on the top of this mountain; whereas 15 or 16 minutes are sufficient at Geneva, and 14 or 15 by the sea-side. Water boiled at 68.993 degrees of a thermometer, which riffs to 80 with the barometer 27 French inches high. By experiments with the electrometer, M. de Saussure found, that the electricity of the air on the summit of the mountain was positive. The wind on the summit was north, and very piercing; but southward of the ridge, the temperature of the air was agreeable. The experiments with line-water, and with the caustic alkali, showed that the air was mixed with atmospheric acid, or fixed acid.

The difficulty of respiration, experienced by M. de Saussure and his companions, has been ascribed to some fatigue, and not to the rarefaction of the air; but his observations prove, that the latter was the cause both of the difficulty of breathing, and the quickness of the pulse. This, indeed, was so considerable, that the pulse of one of the guides, after continuing four hours on the summit, was 98, of the servant, 112, and of M. de Saussure himself, 100 in a minute; whereas at Chamouny they were 49, 60, and 72 respectively.

M. de Saussure's observations confirm an opinion, which is very common, with respect to the change of the senses of smell and taste, caused by taking place on high mountains. He tried the experiment on different mountains, and both the taste and smell of bread, wine, meat, and fruit, appeared to him and to his attendants not at all different. As to found becoming weaker, this circumstance is not to be attributed to any impaired state of the organ of hearing, but to the rarefied air, which both refills the ears and vibrates them. Besides, on an inflated balloon there are no echoes, nor solid objects to repel the sound. These concerning causers rendered the founds on the top of Mont Blanc remarkably feeble; the report of a discharged pistol being equal in strength only to that of a small Chinese crack，并 let off in a room.

Soon after M. de Saussure's expedition, Mr. Beaufoy, an English gentleman, succeeded in an attempt to ascend Mont Blanc; but it was attended with peculiar difficulty, arising from the enlargement of the chasms in the ice. An account of this enterprise was communicated to the Royal Society, in 1787.

Blanc, Mont, gives denomination to a department formed of Savoy. It is bounded on the north by the departments of Leman and of Ain; on the east, by Piedmont; on the south, by Piedmont and the departments of Upper Alps and of Iere; and on the west, by those of Iere and of Ain. Its superficial is about 1,254,760 square acres, or 642,427 hectares; and its population about 283,166 individuals. It is divided into four communal districts, viz. Chambery, its capital, Annecy, Moutiers, and St. Jean de Maurienne.

Blanc-en-Ber, Le, a town of France, and principal place of a district, in the department of the Indre, containing 3,856 inhabitants. The population of the canton amounts to 10,602; and its territory comprehends 337¾ kilometres and 10 communes; 6 leagues W. of Argenton.

Blanc-Courton. Herald, created by patent on the revival of the most honourable military order of the Bath, 1725, "to attend the first and principal companion of the order for the time being." He enjoys all rights, privileges, and immunities as any other herald; and his office is annexed, united, and perpetually consolidated with the office of genealogist of the said order. See Genealogist of the Bath.

Blanca, in Geography, a small island in the West Indies, north of Margarita, low and uninhabited; having faults of large grains, plenty of guamas, and some trees of lignum vitae; but chiefly remarkable for its turtle fishery. N. lat. 11° 26', W. long. 62° 16'.

Blanca, or Blanche, an island in the gulf of Mexico, near the coast. N. lat. 25°. W. long. 62° 14'—Alfo, a river in the province of Chiapa, in the Audience of Mexico, in New Spain. Its water, though clear, is said to have a petrifying quality.

Blancard, Stephen, in Biography, was son of Nicholas Blancard of Leyden, by whom he was initiated into the knowledge of philosophy and medicine. At a proper age he went to Breda, and thence to Franeker, where he took his degree of doctor in medicine, about the year 1678. We know after him he settled at Amsterdam, where he dedicated his time to the practice of his art, but principally to writing or compiling a great variety of anatomical and medical works, of which the most valuable, Haller says, is his "Anatomia practica rationalis, s. variarios cadaverem morbis denaturatorum anatomiis inspiciens," published 1688, 12mo. But he has, even in this work, introduced many observations taken from other writers, without acknowledging it. The cafes here described are 200 in number, and in general, curious and deferring notice. Geolikes, however, not only accuses him of plagiarism, and of mutilating and spoiling the observations taken from other anatomists, but he blames him for publishing so many of his works in the Dutch, his native language, which cannot fail, in the end, he says, of being highly injurious to the profession of medicine, by enabling persons to practice who have not previously received a liberal education. This is, however, now done pretty generally all over Europe, and necessarily at the call in this country, where there are so many persons practicing in every branch of medicine who are incapable of reading any other language than their own, the law here authorizing any persons who may chuse it to practice medicine, without examination, excepting physicians and surgeons residing in the neighbourhood of London, or of the two universities. We shall only mention one of the writer's multifarious productions; his "Lexicon Medicum," containing explanations of all the terms used in medicine, surgery, and anatomy, first published in 1679, 8vo. This has passed through numerous editions, and lately, in 1777, by the care of Juc. Fred. Henflam, is increased nearly treble its original bulk, making two large volumes, 8vo.

Blancards, a name given to certain linen cloths thus called, because the thread used to weave them, has been half-blanched or bleached before it was used. They are manufactured in Normandy, particularly in the places which are in the district, or under the jurisdiction of Pont-Audemer, Bermary, and Lifoues.

Blancat, St. in Geography, a town of France, in the department of the Upper Garonne, 4 leagues W. N. W. of St. Gaudens.

Blanch, a cape on the French coast, N. W. of Calais, almost opposite to Dover, on the English coast.

Blanch, or White Island, one of the large islands on the coast of France, lying along the shore of the projecting coast, to the N. E. of Morlaix.

Blanch ferme, or Blank farm, in Law, a white farm, that is, where the rent was to be paid in silver, not in cattle. In
In ancient times, the crown-rents were many times referred to be paid in "libris abis" called blanche fermes: in which case the buyer was held accountable; viz. his life money or coin, worse than standard, was melted down in the exchanger, and reduced to the fineness of standard silver; or instead thereof he paid to the king 12d. in the pound, by way of addition. In Scotland, this kind of final payment is called "blanch holding," or "reditus abis fermes."

BLANCH-Lyon Pursuivant of Arms. This officer took his title from the arms and supporters of the Moray's, dukes of Norfolk (being ruby, a lion rampant, pearl). Thomas Howard, duke of Norfolk, instituted the office of blanche fermes. 29 Hen. III. He attended at the funeral of queen Jane. Blanch-lyon was also a name to an officer of the crown in the reign of Edward IV.

BLANCHE Pursuivant of Arms, was a pursuivant created by Edward IV, and so denominated from the distinguished badge of the house of York.

BLANCHE-Saghir Pursuivant of Arms. This office was instituted by Richard duke of Gloucester during the reign of his brother Edward IV, in allusion to his badge or cognizance being a white boar.

BLANCARD, William, in Biography, an advocate in the parliament of Paris, was admitted to the bar in 1674, and much employed. Notwithstanding his professional labour, he found leisure for literary researches, and in 1687, published a chronological table of the ordinances of the French kings of the third race; which was republished, with improvements, under the title of "A Chronological Collection, containing a collection of the ordinances, edicts, declarations, and letters patent of the kings of France, relative to public justice, police, and the finances, from the year 987 to the present time," 2 vols. fol. 1715. The work abounds with accurate researches; and to a supplement to it was preparing by the author, when he died in 1724. Moreri.

BLANCHARD, Jacques or James, a painter of history and portrait, was born at Paris in 1666, and having been instructed in the first principles of painting in his own country, he travelled into Italy, where he studied for some time at Rome and Venice, and acquired, from particular attention to the works of Titian and of the Venetian school, distinguished excellence in the art of colouring, so as to have obtained the flattering appellation of the "French Titian." He was employed a considerable time at Turin by the dukes of Savoy and afterwards painted several pieces at Lyons. Upon his return to Paris he was much engaged, and by his devotion to the Holy Spirit, and a St. Andrew kneeling, gained high reputation. Colouring was his peculiar excellence, and he was distinguished for his judicious management of lights and shades. His principal works, besides those already mentioned, are a gallery at the hotel de Bouillon, of subjects from the heathen mythology, and the bacchanals in the saloon of M. Morin, with some pieces at Versailles and Trionon. To Blanchard is ascribed the good taste for colouring which obtained in France. He is said to have etched several plates from his own compositions. He died at Paris in 1685, and left a son Gabriel, who was also a painter of eminence. D'Argenville. Strutt. Pilkington.

BLANCHE, in Ornithology. Somnini describes a kind of tern, or brondelle de mer, under this name, in his additions to Buffon's History of Birds. The plumage is entirely white; with the legs and bill black. It inhabits the cape of Good Hope, and may be placed in the Indian and southern families. It also calls itself the bird firmes alba.

BLANCHE-Carre. See CARTE.

BLANCHE-Coeur, or BLANCHE-COEFF, in Ornithology, is the corvus cyanus of Gmelin and Latham, in Buffon's History of Birds. It is likewise called in the same work gray de Cyanus, and by Latham the Cyanine jay.

BLANCHE-RAIS, synonymous with sturnus des terres magellaniques, names given in Buffon's History of Birds to the Linnean surnus melibarus, a native of Falkland island.

BLANCHE, Fr. for a minim, in Music, or a white note with a tail to it. See Musical Characters, and Time-tables.

BLANCHERS, a name given to mechanics employed in blanching, i.e. the art or manner of bleaching or whitening.

BLANCHET, Thomas, in Biography, a painter of history, perspective, and portrait, was born at Paris in 1617, and first manifested a genius for sculpture; but on account of the weakness of his constitution he was advised to direct his attention to painting. Accordingly, having practiced for some time at Paris, he travelled for further improvement into Italy. By the counsel and assistance of Poullin and Andrea Sacchi, he applied to history painting; and on his return to Paris, he painted several pieces, particularly a picture at Notre Dame, much admired. At Lyons, where he afterwards settled, he became director of an academical school. During his absence from Paris, he was admitted, in 1676, into the academy of painting. Blanchet designed well, and understood the principles of perspective and architecture. His composition was rich, and his colouring natural; and though he was not always correct, his deficiency in this respect is imputed more to the fire of his genius and the rapidity of his execution, than to want of skill. His master-piece was the ceiling of the great hall in the hotel de ville at Lyons, which was unfortunately consumed by fire; and the accident is said to have affected him so deeply, as nearly to have cost him his life. The magistrates of Lyons rewarded him with a pension, and with apartments in the hotel de ville. His character was amiable, and his conversation lively and interesting, so that his company was much sought and valued. He died at Lyons in 1689. Some few of his pieces have been engraved. D'Argenville. Pilkington.

BLANCHET, in Ichthyology, the familiar French name of a species of salmon that inhabits the American seas; salmo saltans of Linnaeus.

BLANCHET, in Zoology, l'Amphibia blanchet, a kind of amphibious known among the French naturalists of the present day by this name. The species is described as being a white colour, without any spots; the body as containing of 230 annulations, and the tail of 16; on the head are fix large scales, and about the vent eight very small tubercles. The length is 18 inches, exclusive of the tail, which measures an inch and an half. This is a native of South America, where it feeds on ants and other insects.—Bofc, from whom the above detail is copied, we are convinced, can mean no other than the amphibius alla of Linneus, when he describes this species. The Linnean character states the number of rings on the body of this kind at 223, in which particular alone the two descriptions seem to be at variance; and the inconformity of that character is too well known to justify the opinion of their being distinct, for that reason only.

BLANCHING, in Gardening, is the art of rendering the leaves and stems of various sorts of plants, as endive (cichorium), celery (apium), &c. white, tender, and succulent. It consists in producing a kind of vegetable dexterity or dicide, by depriving them of the stimulant effects or influence of light, and is accomplished either by carting them well up, or completely covering them, when perfectly dry, by boards, tiles, or other similar means, as will be more fully
fully explained in treating of the different plants that require this fort of management.

 Blanching also denotes the operation of covering iron plates with a thin coat or crust of tin. See Latten.

 Blanching of copper for sale, in imitation of silver; or mixing blanched copper with silver, or expelling the same to sale; or any mallable composition or mixture of metals, or minerals heavier than silver, and which looks, and touches, and wears like gold, but is manifestly worse than flardard, is made felon'y, 8 and 9 W. Ill. &c. 26.

 Blanching of wax. See Wax.

 Blanching, in Coinage, the operation of preparing the pieces before striking, to give them the requisite lustre and brightness.

 The blanching, as now practiced, is performed by steeping or heating the pieces in a kind of pan or fowle, with a wood-fire, in manner of a reverberatory furnace, so that the flame pusses over the fowle. The pieces being sufficiently heated, and cooled again, are put successively to boil in two copper pans, wherein are aqua fortis, common salt, and tartar of Montpellier; when they be well-drawn of this fire, water in a copper fowle, they throw sand and fresh water over them, and when dry, they are all well rubbed.

 The ancient method of blanching was, by putting the pieces, after heating, in a large vessel of common water; and some ounces of aqua fortis, but in different proportions for gold and silver. The method is now diluted, partly by reason of its expensive nature, and partly because it diminishes the weight of the metal.

 BLANCIJAUNE, in Ichthology. Salmo niloticus, of Limneus, a fith of the falmone tribe found in the Nile, is called blane jaune by some French authors.

 BLANCKAMER, in Geography, a town of Brabant, 2 miles S. of Breda.

 BLANCKENBERG, Blakenburg, or Blakenberg, a town of Germany, in the circle of Upper Saxony, and county of Schwartzburg-Rudolstadt, seated on the Rinne, 4 miles S. W. of Rudolstadt.

 BLANC-NEZ, in Zoology. Under this name the Linnean Simia petraurita is described, both in Buffon's Natural History, by M. Allamand, and Soumin, and in the history of Apes, published recently in Paris by Audubert. The pervading colour of this animal is a very dark olive; the visage is black, with the exception of the nose; a remarkable snow-white spot of a triangular form being situated on the latter, which gives the creature a very singular appearance. The appellation of blanc-nez or Guenon blanc-nez, is very well applied, and might be rendered into English with much propriety, the white-nose monkey, if that name had not been previously applied to another species by Mr. Pennant and Dr. Shaw. In the Zoology of the last writer we are informed, that the distinguishing character of his white-nose monkey (Simia nieihami, Linus,) is the tip of the nose, which is milk-white, while the face itself is black. Dr. Shaw observes, however, shortly after, that the white-nose, in this species, is not absolutely peculiar, but is found in another; alluding, as we imagine, to its vauluting monkey, which answers to that description. The last mentioned animal he confiders as the Simia petraurita of Linnæus, and blanc-nez of Allamand's edition of Buffon's quadrupeds, as Gmelin states them; and so far he countenance of the French naturalists appears in favour of his opinion. But, perhaps, it will admit of some doubt how far we may be authorized in believing still further with Dr. Shaw, that the Guenon blanc-nez of Allamand, and Soumin, in Buffon's Natural History, and Guenon à nez blanc prédominant of the Supplement of that work, are of the same species. Dr. Shaw thinks the eif of this male be the female, and the other the male. Virey, and like-wise Audebert, are perfueded that they are certainly distinct species. Guenon blanc-nez, they consider as the Linnean; Simia petraurita, and Guenon à nez blanc prédominant, as Simia niloticus of the same author.

 BLANCO, in Geography, the name of a cap of Africa, on the north coast of the kingdom of Tunis, called the “White Promontory,” or, with the fame meaning by the inhabitants, “Ras-el-ahed,” and supposed to be the “Promontorium caniculun” of Pliny; and the “Promontorium pulchrum” of Livy, where Scipio landed in his fift African expedition. N. lat. 37° 49’. E. long. 10° 16’.—Alfo, a small point to S. E. of cape Corlo, in the ifland of Corfica.—Alfo, a cape on the western coast of Africa, in Negro-land; first discovered by the Portuguefe in the year 1441. N. lat. 20° 55’ 32° W. long. 17° 10’. high water 9’ 45’.—Alfo, a cape on the western coast of the territory of Télémé in Athens Turkey, opposite to the southern point of the island of Sicío. N. lat. 38° 20’. E. long. 25° 5’.—Alfo, a cape of South America, on the coast of Brazil, between cape Roque on the north, and cape St. Augustine on the south. N. lat. 6° 50’. W. long. 35° 37’.—Alfo, a cape of South America, on the western coast of Patagonia, north of port Defcada. S. lat. 47° 20’. W. long. 64° 42’.—Alfo, the north-western point of the bay of Salinas, on the coast of Nicaragua, N. W. from Panama-bay. N. lat. 9° 20’. W. long. 85° 48’.—Alfo, a cape on the north-west coast of America in New Albion, southward of the mouth of the river called “the river of the weff,” between cape Gregory and point St. George, and at a further distance between cape Foulweather and Mendocino. N. lat. 43° 20’. W. long. 128° 20’.—Alfo, a promontory of Peru, in South America, on the coast of the South Sea, 120 miles S.W. of Guayaquil. S. lat. 3° 45’. W. long. 83°.

 BLANCO, an island on the south-eastern part of the peninsula of Yucatan in New Spain. N. lat. 24° 10’. W. long. 88° 5’. See Blanca.

 BLANDA, in Entomology, a species of Buprestis, that inhabits South America. The wing-cases are attenuated, ferrated, and furrowed; colour brassy-green, with the furrows copperry. Fabricius.

 BLANDA, a species of Tenthredo, found in England. The colour is black; abdomen rufous in the middle; posterior thighs marked with a white spot. Fabricius, &c.

 BLANDA, in Ancient Geography, a town of Hispania Tarraconensis, mentioned by Melis, Ptolemy, and Pliny, situate on the coast of the Lactani, south of Garumna.—Alfo, a town of Italy; in the country of the Brutii, according to Pliny and Melis, but called "Blande," by Livy, and placed by him in Lucania.

 BLANDFORD, commonly called Blanford-forum, in Geography, is a market town of Dorsetshire, England. It is seated on the eastern banks of the Stour, and on the great post road from London to Exeter, Cornwall, &c. In the Dome-day book no less than nine parcels or parishes are included under the name of Blanford or Blanford, of which this is the most considerable, and was Sierra a borough in some ancient records, though it does not appear to have been represented in parliament more than twice; once in the reign of Edward I. and again during the reign of Edward III. James the first granted it a charter, and made it a free borough with certain corporate privileges and immunities. The town is governed by a bailiff and six capital Burgesses; a part of whom is invested with the power of determining suits not exceeding 10s.

 Here is a small manufacture of shirt and waistcoat buttons, and another of thread, but the principal trade of the town depends upon its neighbourhood, and the passage of travelers. The town has been destroyed several times by fire. In
In Camden’s time it was wholly burnt by accident, but was soon rebuilt in an improved manner. The years 1676, 1713, and 1731 are recorded as peculiarly calamitous to this town, and in the latter year, nearly the whole of it was destroyed. The church, town-hall, almshouses, free-school, and all the houses, but forty, were consumed. Many lives were lost, and the distressing calamity was greatly augmented by the small-pox, which raged in above fifty families. The computed damage was valued at 100,000L. but the direftes, terror, and misery that prevailed at the time, and refulted from the direful catastrophe, far exceed all calculation, and defy the powers of verbal description. The town has since been rebuilt, and its appearance much improved by some respectable houses, a new church, town-hall, &c. The latter is a neat building composed with Portland stone, and contravened on columns of the Doric order. Within the building is a pump which was erected by John Baffard, who having been a confiderable sufferer by the late fire, had this pump contravened to supply the town with water, and thereby to prevent another similar difalter. The new church, built in the Grecian styie of architecture, confines of a body, two ailes, a chancel, and a tower. Its interior is very neatly ornamented, and contains some handsome marble monuments.

The charitable donations to Blandford are numerous and valuable, and are appropriated to endow an almshoufe, to apprentice and clothe poor boys, to erect and support a charity-school, two free-schools, and for other beneficent purposes. Blandford is 125 miles W. S. W. from London, and contains 408 houses, with 2326 inhabitants; at the eft end of the town are the remains of a handfome old building, called “Darnley-court,” which has been poftfefted by many noble and distinguished perfonages.

Blandford is the birth-place of many celebrated characters: among whom the following are the moft diftinguifhed: George Ryves, who was warden of New College, Oxford, in 1599, and Vice-chancellor, in 1601; Bruno Ryves, author of the Mercurii Ruflicus, a fignular book, recording many of the events of the civil wars. He also affifited in publishing the Polyglot Bible, was dean of Chichefter and Windfor, and died at the latter place in 1677, aged 81 years; William Wake, archbishop of Canterbury, &c. was born here in the year 1657, and died at Lambeth in 1736; Thomas Creede, the tranflator of Lucretius, and other ancient chaffe authors, was born here in 1659; Cbriopher Pitt, another tranflator, dates his birth at Blandford, where he was buried in 1748.

About one mile south of Blandford-forum is Blandford St. Mary, a village noted in the annals of literature as the birth-place of Browne Willis, the celebrated antiquary and topographer (see Willis). At the diftance of one mile west of this town is Brainstone-houfe, the elegant and commodious mansion of Edward Berkeley Portman, esq. This house was erected from the designs of James Wyatt, who has displayed much judgment and taste in the difposition of the apartments, the arrangement of the offices, and in the two principal façades. The river Stour winding in a broad flet through the grounds, with the plantations, and diluent feenes, combine to render this a charming and delightful residence. Hutchinson’s History of Dorfhire, second edition, vol. 1796.

Blandford, a township of America, in Lincernburgh county in Mahon bay, Nova Scotia, fettled by a few families. — Alfo, a township in Hampfhire county, Maffachusetts, west of Connecticut river; about 25 miles, S. W. of Nor- thampton, and 116 W. of Bolton; containing 233 houses, and 1446 inhabitants. — Alfo, a town in Prince George county, Virginia, about 4 miles N. E. from Peterburgh, and within its jurisdiction. It contains 200 houses, and 1200 inhabitants, and is pleasantly situated on a plain, on the easter branch of Appamatux river. Here are many large fhores, and three tobacco warehouses, which receive annually 6 or 7000 hogheads. It is a thriving place; and as the markets in its vicinity are drained, the trade of this town, and alfo that of Peterburgh, is much meliorated.

Blandina, in Entomology, one of the Fabrificus fpecies of Papilio, in the Nymphales fection; the wings of which are dentated, black, and marked with white spots; at the bafe of the anterior pair a blue flanke, and another along the margin of the polferior ones. This rare insect inhabits India. Vide Donou. Inf. Ind. Obf. There is another fpecies of the Papilio genus, that bears the fame name, that ought by no means to be confounded with the above mentioned insect. This is also defcribed by Fabrificus in his “Entomologia Systematica,” in the fition “Satyr;” the wings of this kind are dentated, the colour brown, with a frous occluded band; posterior pair beneath fuccefsus with a cinerous stripe. This is papilio ligea of Seopoli, etkipts of Elper, and melius of the Vienna Catalogue. It inhabits feveral parts of Europe, but has not been hitherto difcovered in Great Britain. The fame fpecific name again occurs in Cramer’s Papiliones, a ftrong variety of the Gmelinian pap. melicetia, being fo named by that author.

Blandrata, George, in Biography, a phyfician and divine of the 16th century, was born in the marquisate of Salufies in Italy, and practifed phyfick in Poland and Tranfylvania; but upon his return to Italy, he was obferved by the inquisition to fly, on account of his religious opinions, from Pavia to Geneva, where he declared himself a Catholic. Here, however, his sentiments, which then inclined to Arianism, excited the fuspicions of Calvin, which obliged him first to return to Poland, and afterwards, in 1565, to remove to Transylvania, where Sigismund, at that time sovereign of the country, appointed him his phyfician. After the death of Sigismund he retaining the fame office to Stephen and Christopher Battori, and to the former when he obtained the crown of Poland. By his credit and infuence the doctrine of Socinus, which Blandrita feems to have now adopted, made its way from Poland to Transylvania; and it was by his means that Paulus Socinus was brought thither from Basel in 1578, to second his arguments and efforts in counteracting Francis Davides, who zealously opposed the custom of offering up prayers and divine worship to Jesus Chrift. It is faid, that Blandrita, either through natural levity, or under the infuence of an avaricious disposition, abandoned the interefts of the Unitarians, and he is accufed by Socinus with inclining towards the Jefuits, who had obtained credit and infuence at the court of king Stephen. His wealth, however, tempted his nephew to trangle him in his bed, at fome period, not aflowered, between the years 1585 and 1592; and this unfortunate termination of his life has been chartantly interpreted, both by the orthodox and heterodox, as a divine judgment. Of his character as a writer the theologifts of Geneva express a contemptuous opinion; and his conftitute forms to have been chargeable with a degree of unfaithfullness and duplicity, which has been partly attributed to the perfecuting spirit of the times in which he lived. Gen. Diet. Mor. Eccl. Hift. vol. iv. p. 513, 525. Toilomin’s Life of Socinus, p. 6, &c.

Blanes, or Blandi, in Geography, a fee-port town of Spain, in Catalonia, on the Mediterranean, 35 miles N. E. of Barcelona. N. lat. 41° 43’. E. long. 2° 45’.

Blangis, or Blangy, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Neufchatel. The population of the town includes 17,490 persons, and that of the canton 12,879. The territory comprehends 2471 kilometers, and 31 communes: 14 miles
BLANKHEIM, a small town in Germany, and capital of a county of the same name, in the circle of Wettphalia, and archbishopric of Treves. The prince, resident here, pays 62 florins a month, and 72 rix-dollars, and 544 kreutzers to the imperial chamber: 36 miles N. N. E. of Treves. In the French arrangement, it is the principal place of a canton in the district of Prums, and department of Sure. The population of the place includes 520 persons, and the canton 323. Its territory comprehends 72 communes.

BLANKENSEE, a lake of Germany, in the circle of Upper Saxonay, and middle mark of Brandenburg, 6 miles E. of Berlin.

BLANKENSEN, a town of Germany in a prefecture of the same name, in the circle of Wettphalia, and county of Mark, seated on an eminence near the Rhein, 17 miles E. N. E. of Dusseldorf.

BLANKET, in Cammeray, a warm woollen sort of stuff, light and loose woven; chiefly used in bedding. The manufacture of blankets is principally confined to Witney in Oxfordshire, where it is advanced to that height, that no other place comes near it. Some attribute a great part of the excellency of the Witney blankets to the abstinence its water of the river Windrush, whereby they are scoured; others think they rather owe it to a peculiar way of wool spinning, which the people have about that place. Be it as it will, the place has ingrossed almost the whole trade of the nation for this commodity; informuch that the wool fit for it centres here, from the farthermost parts of the kingdom. Platt. Hist. Oxon. chap. ix. § 103.

Blankets are made of felt wool, i. e. wool from off sheep-skins which they divide into several sorts.

Of the head wool, and bay wool, they make blankets of twelve, eleven, and ten quarters broad; of the ordinary and middle sort, blankets of eight and seven quarters broad; of the belt tail wool, blankets of six quarters broad, commonly called cuts, serving for seamen's hamscocks. See Hynes.

Blanket, stuffing in a, a ludicrous kind of punishment, of which we find mention in the ancients, under the denomination fogatio. Martial describes it graphically enough.

"Ibis ab excusco, millas ad alta, iapata."

A late writer represents it as one of Otho's imperial delights. But this is turning the tables; that emperor's diversion, as related by Suetonius, was not to be the subject, but the agent in the affair; it being his practice to frolic out in dark nights, and where he met with a helter-skelter, drunken man, to give him the advantage of the blanket.

BLANKOF, John Teunis, in Biography, a Flemish painter, was born at Alkmaar in 1628. After having spent some years in receiving instruction from Arent Tiebing, Peter Scheyenburg, and Cesar van Everdingen, he went to Rome, where he diligently copied the works of the best masters, and was admitted into the society of Flemish painters, called Bentogells, by whom he was distinguished by the appellation of Jan Maas, signifying, in Dutch, mate or companion, and under which appellation he is most generally known. His subjects were landscapes, with views of rivers, or sea shores, havens, or ports, which he executed with a light, free pencil; and in the representations of forms and calms, he particularly excelled. Thefe of his pictures that are principally commended, are the Italian sea-ports, with vesels lying before them. And his most capital performance is a view of the sea-shore, with the waves retiring at ebb-tide; which Houbraen describes as admirably beautiful and natural. His imagination was lively, and his execution rapid. He died in 1670. Pilkington.

BLANQUEFORT, in Geography, a town of France, in the department of the Charente, and county of Poitou. It is a town of the commune of the department, and its territory comprehends 72 communes.
in the department of the Gironde, and chief place of a canton, in the district of Bordeaux, five miles north of Bordeaux. The place contains 2003, and the canton 9934 inhabitants. The territory comprehends 2724 kilometers and 9 communes.

BLANQUILLE, in Commerce, a small silver coin, equivalent to about 11.5 florins, current in Morocco, and on the coasts of Barbary.

BLANZAC, in Geography, a town of France, in the department of the Charente, and chief place of a canton, in the district of Angouleme, 4 leagues S. S. W. of Angouleme. The place contains 545, and the canton 10,440 inhabitants. The territory includes 2424 kilometers and 20 communes.—Also, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzes, 3 miles S. S. W. of Uzes.

BLAPS, in Entomology, one of the Fabricius genera of coleopterous insects, the palp of which are elavated, and four in number; jaws straight and bifid; lip membraneous and eleft; and the antennae moniliform at the tip. Fabricius includes in this genus some of the tendrines of Linnaeus, such as tendris gagei and mortifaga. Gmelin adopts the genus only as a subdivision of Pinheia, in the Syll. Nat. See Pi.

BLAPSIGONIA, compound of Βατρίς, I bart, and γων, brood or ify, a kind of diseake, or defect in bees, when they neglect or fail to produce young, being wholly employed in making honey.

BLARE, in Commerce, a small copper coin, containing a little mixture of silver, struck at Bern, and valued at much the fame with the RATZE in other places.

BLARINGHEM, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Hazebrouch, 2 leagues S. E. of St. Omer.

BLARNEY, a small market town of the county of Cork, and province of Munster, Ireland. Situated on a river of the same name, about 4 miles W. of the city of Cork.

In the reign of queen Elizabeth, its castle was reckoned one of the strongest fortresses in Munster, and it has often proved very troublesome to the inhabitants of Cork. It belonged formerly to the earls of Clancarty, but at present is the property of Mr. Jeffries, whose father built the town, and established several manufactures, of which Mr. A. Young has given a detail in the account of his tour through Ireland. These establishments, however, as too generally happens in like cafes, have not been successful, and Blarney is not at present the flourishing town, which Mr. Young's account would lead us to expect. A paper-mill, a stamping-mill, a bleach-green, and one or two cotton manufactures still exist; and many flockings made in the neighbourhood are sold at the weekly market and in Cork, but all may be considered as on the decline. The castle and the grounds about it have been considerably improved, and the country around, as well as the park, is well watered. There is a stone at one of the corners of the top of the castle, which is fixed to the drangers, on account of a laving, that any person who has killed it is privileged to lie and flatter. The origin of this laving, which is often referred to, and from which Blarney has become a vulgar synonyme for flattery, the writer has not been able to discover. In the castle there is an original painting of Charles 1st of Sweden, at full length, drawn in the style of nature by Vollbehr, and brought over by the family who had been envoy to that monarch. The adjoining country is mostly under corn and pasture; the soil is a yellowish clay, and is mostly mauled with lime-dine; of which there is a vein that supplies large quantities. Smith's Cork.

BLASISTR, a cape on the coast of the North Pacific ocean, Vol. IV.

near which, to the S. E., lies the town of Compostella, in the province of Galicia, in New Spain. N. lat. 21° 30'. W. long. 105° 12'. See BLAISE.

BLAS, a term, in the Helmontian philosophy, denoting the local and alternative motion of the flars; from whose influence proceed changes of weather, floods, storms, and the like.

In imitation of this bliss fellarum, the same author framed another in animals, either natural, whereby each visus is framed according to the model of its particular; or voluntary, which is directed to motion by the will.

BLASCON, in Ancient Geography, the island of Gaul, mentioned by Pliny, situate at the mouth of the Rhone.

BLASE, S., in Geography, a town of Germany, in the archduchy of Austria, 8 miles S. W. of Steyr.

BLASENDORF, or Balsapula, a town of Tran-

fylvania, in the district of Weissenburg, the residence of the bishop of Walachia.

BLASIA, from Blasio Biagi, an Italian monk, in By-
ter and Halifax. It flowers in the beginning of May.

BLASII ZELLA, in Geography, a small town of Ger-
mny, in the circle of Upper Saxony, and principality of Gotha, separated in 1640 from the bailiwick of Reinhard-
brunn, and added to that of Schwarzwald, and famous for its foundery of fire-arms; 16 miles S. of Gotha.

BLASIMONT, a town of France, in the department of the Gironde, and chief place of a canton, in the district of La Reole, 7 leagues E. of Blanmont, or 3 ½ N. of La Reole.

BLASIUS GERARD, in Biography, son of Leonard, physician at Amsterdam, who received pupils into his house, to instruct them in the knowledge of medicine, particularly in the anatomy of brute animals, of which he dissected a great variety. It was this which probably inclined Gerard to this branch of study, and gave birth to several of his works; such as his "Zoometize, seu Anatomies variarum Ani-
malium," published 1676; "Observatia anatomica, in homine, simia, equo, vitulo, tefudine, echino, glire, ferpe, arde, varifque animalibus aliis," Lugduni, 1674, &c.

After making some progres under his father, he went, for further improvement, to Copenhagen, and at length to Leyden, where he commenced doctor in medicine, about the year 1646. He then returned to Amsterdam, where he ac-
quired to much credit and reputation for his skill in his pro-
fi lion, that in 1660 he was made professor in medicine in the schools of that city, and soon after physician to the hospital.

Besides a variety of original works, Bladius published new editions of parts of the works of Primerofe, Th. Bartholine, Lieitus, Bellini, Borelli, and Willis, to mont of which he gave notes and additional observations, containing such discoveries on the subjects treated of, as had been made since those works had been originally published. Of his original works, besides those mentioned above, we shall notice his "Oratio de noviter inventis," Adl. 1659, 4to. "Observa-
tiones in diversae variarum, accedit triplicis monstri historia," Adl. 1667, 8vo. In six books, containing accounts of the defilection of numerous morbid bodies, in one of which, the spleen, and in another the gall bladder, were found to be misplaced; in one two stomachs were found, in another three tefticles. "Anatomiae animalium terrellium variarum volatilium, aquatilium, serpentium, infeclorum, ovomurane 4 A

structuram"
fructuram naturalem proponentes." Ann. 1601, 4to. The greater part of this work is collected from Severinus, Harvey, Malpighi, Willis, Bartholome, and other writers and journals. The work has, however, its utility, by bringing into a small compass a great number of curious facts, and observations, which were only before to be found by recourse to a variety of publications. In a letter published in the third century of Th. Blakett's epistle, it claims the discovery of the ductus falivaris, which he says he first showed to Steno, then a young man. This has not, however, prevented the discovery from being attributed to Steno, the duct taking his name. For the titles of the rest of the works compiled or edited by Blakett, see Haller. Bib. Anat. Med. et Chirurg. et Eloy's Dict. Hist.

BLASKET Sound, in Geography, lies on the west coast of Ireland, between the Great Blasket island and Dunmore head, on the mainland of the county of Kerry. In this sound there is ten fathom water, and in the summer time and moderate weather a vessel may float off the east end of the Great Blasket; but the ground will not hold well in blowing weather. In passing through this sound, it is necessary to attend to a pretty strong tide, and to a rock not far from Dunmore point, which is covered at high water.

BLASKETS, BLASQUETS, or FERRITIR islands, a cluster of islands on the west coast of the county of Kerry, Ireland, being the most westerly land in the European part of the British empire. They are five in number, besides several rocks, some of which are always above water, and others are covered by high tides. These islands were given by the earl of Desmond to the family of Ferriter, from which one of their names is taken; but at present they belong to the earl of Cork and Orerry. The largest called, Imlymore, i.e. the Great Island, and more commonly the Great Blasket, was visited by Dr. Smith, who found it inhabited by five or six families, and speaks in high terms of the fertility of its air. Ruins of churches, and cells or hermitages, are found in some of the others, but when Dr. Smith was there, they were not inhabited. The small rocks are frequented by sea-fowl, the feathers of which are collected by the people of the neighbouring coast. The hawks which are found here are remarkably good, and were formerly in much esteem. Amongst other sea-fowl the florny petrel, (procellaria, Linn.) is common here. The Greater Blasket is 9 leagues S.W. by W. from Loophead, the north point of the Shannon, and 5 leagues north of the Skelligs. The whole chister lie between 16° 17', and 16° 31' W. longitude, and between 51° 58', and 52° 3' north latitude. Smith's Kerry. McKenzie.

BLASPHEMY, blasphemia, or blasphhemium, in Middle Age Writers, denotes simply the blaming or condemning of a person or thing. The word is Greek, βλασφημία, from βλασφημεῖν, to talk evil of words of evil omen, or that pertended something ill, which the ancients were careful to avoid, substituting in lieu of them other words of foster and gentler import, sometimes the very revolts of the proper ones.

BLASPHEMEY is more peculiarly restrained to evil or reproachful words spoken of the Deity. Angullin says, "Jam vulgo blasphemia non accepit nisi mala verba de Deo dicerint." According to Lindwood, blasphemy is an injury offered to God, by denying that which is due and belonging to him; or attributing to him what is not agreeable to his nature.

By the Mosaic law, blasphemy was punished with death. Levit. chap. xxiv. ver. 13-16. As also by the civil law. Novel. 77. In Spain, Naples, France and Italy, the pains of death are not now inflicted. In the empire, either amputation, or death, is made the punishment of this crime. By the canon law, blasphemy was punished only by a solemn penance, and by cultus, either by a pecuniary or corporal punishment. By the English laws, blasphemies against God and religion, as denying his being, or provoking and all contumelious reproaches of Jesus Christ, &c. to which may be also referred all profane scoffing at the holy scripture, or exposition it to contempt and ridicule, are offences by the common law, and punishable by fine, imprisonment, and pillory. 1 Hawk. P.C. And by the statute law, he that denies any one of the persons of the Trinity to be God, or affrets there are more Gods than one; or, having been educated in, and having made profecion of the Christian religion, denies, by writing, printing, teaching, or advised speaking, Christiainity to be true, or the holy scriptures to be of divine authority, for the first offence is rendered incapable of any office or place of trust; and for the second, adjudged incapable of bringing any action, being guardian, executor, legatee, or purchaser of lands, and to be imprisoned for three years without bail. 9 and 10 W. III. c. 32. To give room, however, for repentance, if, within four months after the first conviction, the delinquent will in open court publicly renounce his error, he is discharged for that once from all disabilities.

According to the law of Scotland, the punishment of blasphemy is death. The first species thereof consists in railing at or cursing God, and here the single act constitutes the crime. The second consists in denying the existence of the Supreme Being, or any of the persons of the Trinity; and therein obliquely perverting to the half. For reiterated denial does not fully constitute the crime, because the flat. of Charles II. 1661, admits of repentance before conviction as a complete expiation.

This statute of 1661, is ratified by a statute of King William, whereby the calling in question the existence of God, or of any of the persons of the Trinity, or the authority of Scripture, or the Divine Providence, is made penal. For the first offence, imprisonment till satisfaction given by public repentance in sack-cloth. For the second, a fine of a year's valued rent of the real estate, and twentieth part of the personal estate: and the trial in both these cases is competent to inferior judges. The punishment of the third offence is death, to be tried only by the justices.

BLASPHEMY against the Holy Ghost. Divines are not agreed with respect to the nature of the crime thus denounced, Matthew, xii. 31. Mark, iii. 28, 29. Luke, xii. 10. and the grounds of the extreme guilt ascribed to it. On this subject it may be observed in general, that from our Saviour's expression this sin appears to consist, and to be completed, not in our thoughts, nor in our works, but in our words. Nor, indeed, is the epithet "blasphemous," or any synonymous term, ever joined in scripture, as is common in modern use, with doctrines, thoughts, and opinions. It is never applied but to words and speeches. A "blasphemous opinion," or "blasphemous doctrine," are phrases, which, however familiar to us, are as unfuitable to the scripture idiom, as a railing opinion, or "slanderous doctrine," is to ours. It may be also observed, that this blasphemy is not of the constructive kind, but direct, manifest, and malignant. It is mentioned as comprehended under the same genus with abuse against man, and contra-distinguished only by the object; and it is further explained by being called "speaking against," in both cases. The expressions are, in effect, the same in all the gospels, where
it is mentioned, and imply such an opposition as is both intentional and malevolent. This could not have been the case with respect to all who disbelieved the mission of Jesus, and even decried his miracles; many of whom, we have reason to think, were afterwards converted by the apostles.

The learned Grotius, in order to mollify the severity of the sentence denounced against this sin, foegd a, that what our Lord expresses absolutely, must be understood comparatively; and that he only designed to intimate, that it is very difficult to obtain the pardon of this sin, but not that it will admit of no forgiveness. But our Saviour here has expressly of this sin, whatever it was, both negatively, that it shall never be forgiven, and affirmatively, that the perfon guilty of it shall be obnoxious to eternal judgment, confirming the whole with an aievation. Dr. Waterland (see his SerM. vol. ii. No. 9. p. 177—182.) seems to incline to Grotius's opinion; alleging that advenitas signifies only exceedingly difficult. Dr. Hammond comments upon the words with observing, that this sin shall not be pardoned, but upon a particular repentance; but this is true of every sin as well as of the blasphemy against the Holy Ghost. Some have made this crime confit in final impenitency, because that is unpardonable; but it is not only to affign a reason why this should be called the sin against the Holy Ghost. Others have represented it as, in its specific nature, a wilful and obstinate opposition to the truth; others again as a malicious opposition to the truth, on the part of those who know and are convinced that it is the truth; whilst some have supposed it to consist in a renunciation of the truth for fear of suffering, which made Francis Spira think that he had committed this sin. Mr. Wakefield, in his Notes on the Translation of the Gospel of St. Matthew, p. 178, is of opinion, that what is meant by the blasphemy of the Spirit appears from the context to be perversely resisting and bellying with contumacy, against plain and satisfactory evidence, the operation and interference of the holy spirit of God; and he thinks, that those men who reject the Christian revelation, without contemplating its claims with diligence, candour, and exactness, upon a precipitate preformation of its falsity; and those, who refuse their assent to that degree of moral evidence, of which alone those subjécts are capable, and which they would think sufficiently satisfactory in other cases, and in the ordinary occurrences of life, are as much guilty of the sin of blasphemy in our times, as those callowing and hypocritical Pharisees were in the days of Christ.

Dr. Tillotson (vol. i. term. xvii.) maintains, that this sin of which the Pharisees were guilty confit in maliciously attributing the miraculous operations which Christ performed by the power of the Holy Ghost to the devil. This feæe is adopted by bishop Pearce, in his Commentary on the four Evangelists, vol. i. p. 85. But Dr. Whitby, with greater probability, refers it to the dispensation of the Holy Ghost, which commenced after our Lord's resurrection and ascension; and those were guilty of the crime, who periled in their unbelief, and blasphemed the Holy Ghost, representing him as an evil spirit. The crime was unpardonable, because it implied a wilful opposition to the last and most powerful evidence which God would vouchsafe to mankind, and preceded the possibility of a recovery to faith and repentance. Whitby's Fourth Appendix to the Gospel of St. Matthew, in his Paraphrase, vol. i. p. 289.

Of this sin, it is said, it shall not be forgiven, either in this world or in that which is to come. With regard to the meaning of this expression, it is observed both by Lightfoot (Hor. Hebr.) and by Grotius (in loc.), that through a fond imagination of the final happiness of all the seed of Abraham, the Jews supposed, there were some sins that had not been forgiven here, which would be expiated by death, and be forgiven after it; and that our Lord designed by this expression to affirm them, that there was no forgiveness for those who should be guilty of this sin, either before or after death, and that their expectations of forgiveness then would prove no other than a deceitful dream. Dr. Whitby, however, has clearly shown, that this was used as a proverbial expression, and that it only signified, "a thing should never be," when it was said, "it shall not be, either in this world, or in the world to come." Others, however, amongst whom we may reckon bishop Pearce and Mr. Wakefield, have thought that the expressions of "this world," and "the world to come," denote the Jewish and the Christian dispensations. O awxv, and 

blasphemy, signify in the New Testament the Jewish age or dispensation, which continued till the annihilation of the Jewish polity, civil and ecclesiastical, by the destruction of Jerusalem under Titus; and 

blasphemy, or the future age, denoted the Christian dispensation. Bishop Pearce adds, that under the Jewish law, there was no forgiveness for wilful and presumptuous sins; concerning which he refers to Numb. xv. 30, 32. xxxv. 31. Lev. xx. 10. and 1 Sam. ii. 25. With regard to the age to come, or the Christian dispensation, the bishop observes, that no forgivenefs could be expected for such finners as the Pharisees were; because, when they blasphemed the Spirit of God, by which Jesus wrought his miracles, they rejected the only means of forgiveness, which was the merit of his death applied to men by faith, and which under Christianity was the only sacrifice that could atone for such a sin; in this sense, as things then stood with them, their sin was an unpardonable one. But, he adds, it is not to be concluded from hence, that, if they repented of this blasphemy, they could not obtain forgiveness. Mr. Wakefield observes, that the unreferred affirmation in Matt. xii. 32. must he interpreted, as well as the preceding verse, with considerable qualification. Owaous, "will not be forgiven him," must signify, says this writer, "will not be forgiven will not be extermated a common and wilful fault," agreeably to the eastern mode of expression, which constantly requires such limitation. Accordingly he thus gives the general sense of this verse, "Offences of the most heinous nature, even reproach and injustice against the anointed prophet of God, may more readily find pardon, than contumacious blasphemy of the Holy Spirit." This aggravated sin, the result of obstinacy, depravity, and malice in the extreme, will have no title to forgiveness, even from the clemency and mercy of the Christian revelation, a revelation of pardon and peace, in the fullst fæce, and to the whole race of man. See Heb. vi. 4—7. Nevertheless, "will not any sins be pardoned on sincere repentance, and heartfelt purposes of amendment, under that confounding dispensation, which breathes nothing but reconciliation and forgiveness—nothing but favour, mercy, and peace, from God our Father, and our Lord Jesus Christ?"

BLASQUES ISLAND, in Geography, lies on the west coast of Newfoundland, in about 47° 30' N. lat.

BLASS-ENT, in Ornithology. The common wild duck is called by this name in the vicinity of the lake of Constance.

BLASSENTLE, (Fr.) a name synonymous with anus Penelope of Limneus, and common oxymon of English writers.

BLAST, fatus, in the Military Art, a sudden compression of the air caused by the discharge of the bullet out of a great gun. The blast sometimes throws down part of the embra-

A 2
Blast is also applied, in a more general sense, to any forcible stream of wind, or air, excited by the mouth, bellows, or the like.

Blast, in Agriculture, a discharge in grain, trees, &c. See Blight.

The fugar-case in the West Indies is subject to a disease called the blast, and paid to be occasioned by the split of Linneus, which is distinguished into two kinds, the black and the yellow; and of these the latter is the most destructive. It consists of myriads of little insects, invisible to the naked eye, whose proper food is the juice of the cane, in search of which they wound the tender blades, and consequently destroy the vessels. Hence the circulation being impeded, the growth of the plant is checked, until it withers and dies in proportion to the degree of the ravage. It is frequently affirmed, says Mr. Bryant Edwards (Hist. West Indies, vol. ii. p. 215.) that the blast never attacks those plantations where colonies have been introduced of that wonderful little animal, the carnivorous ant, or "forrnia omnivora" of Linneus, called in Jamaica the "raffles ant," from its being supposed to have been introduced there by one Thomas Raffles from the Havannah, about the year 1762. These minute and busy creatures soon clear a fugar plantation of rats; and their natural food items to convict of all kinds of insects and animals.

Fire Blast. See Blight.

Blasts, among Miners. See Damps. See Mines, and Mining.

Blast, the term used at iron foundries to denote the column of air introduced into the furnace for the purpose of combustion. Its velocity is occasioned by the impelling power of the blowing machine forcing the whole contents of the air-pump through one or two small apertures called nose-pipes; and, according to the absolute power of the engine, air of various densities will be produced, so that density and velocity are always intimately connected, and mutually implied.

The well known combustibility of iron, and the indisputable necessity of exciting combustion by the introduction of large quantities of condensed air into the furnace, in contact with ore in various states of maturity as to separation, into contact with iron existing in all the modifications of quality as to carbonation, and into contact with an immense body of ignited fuel, render this subject the most important in the major scale of our manufactures. Unfortunately for art, as well as for science, few practical deductions can be brought forward to establish any one theory of blast; one common principle only is acknowledged, that all reduction in the furnace is in consequence of the combustion excited by the column of air introduced.

To take a proper view of this interesting subject, it will be necessary to submit it to the following divisions.

1st. Combustion, as excited in this particular branch of manufacture.

2d. The nature of the fuel submitted to combustion.

3d. The density of the air.

4th. The quantity.

5th. The properties which follow as a consequence of density and quality.

1st. Combustion in the blast furnace consists chiefly in the rapid reduction of a given quantity of solid fuel, and its accompanying portion of ore, in the shortest possible time. That furnace, and that blast, which can, in a given time, reduce the greatest quantity of fuel, all things else being alike, will always manufacture the greatest quantity of iron.

In common, before the introduction of the blast, the furnace is previously filled with alternate strata of coke, iron-flone, and lime-flone, heated by simple atmospheric pressure to a bright red or white heat, and the iron-flone to a melting heat. This temperature is soon increased throughout the furnace, after the blast is applied. The glowing orifices or tuyeres of the furnace exhibit the fuel increasing in white heat, and the iron-flone rapidly diffusling before the blast, of a blackish colour. At this period, the lava which flows from the furnace, in consequence of the reduction of the ore and lime-flone, is considerably charged with iron, and is of a black, blackish brown, or greenish brown colour. These appearances will continue for twelve, twenty-four, or thirty-six hours, according to the mode of treatment in bringing forward the furnace after blowing. The tuyere (if a bright tuyere furnace) will appear like a blaze of uncommonly pure light, at times very offensive to the eye; it soon, however, becomes accustomable to it, and can with facility discern the individual masses of coke, as they are forced away, with the rapidity of lightning, before the irresistible force of the air. The concrete ore and lime-flone are no longer visible; but a fine metallic spray is constantly descending, and, forced from the fuel, precipitates itself to the bottom of the furnace. The scoria formed by the fusion and union of the lime-flone, with the immetallic parts of the ore, is carried before the blast in a similar manner and form, but easily distinguishable from the fluid metal by its buoyancy, want of velocity when impelled, and by its dull colour.

In this state, the furnace is deemed in excellent smelting order. The iron is generally revived with little loss; and the colour and purity of the cinder or lava sufficiently indicate the perfection of the separation. When at any time the brightness of the tuyere fails, and becomes dull white or reddish white, then a change is indicated; the iron-flone and lime-flone will again appear in the solid unseparated state, and the change of colour in the cinder infallibly betokens an irregularity in the movements of the furnace. These appearances are so general, as scarcely to admit of an individual exception, and are sufficient to warrant the following explanation.

At the introduction of the blast, the interior of the furnace at the tuyere was simply a mixture of ignited masses of coke and iron-flone, the latter partly semifused, but the greatest part merely heated to a bright red heat. In the deficient through the furnace, in contact with ignited coke, the particles of metal in the ore may, by parting with the oxygen, have received a disposition to become revived. The increased temperature creates an additional tendency, by establishing a greater force of affinity between the fuel and the iron. But the metal approaching to its proper state, meeting the current of blast, is immediately subject to a partial combustion. The portion thus oxidized conveys to the lava, in proportion to its quantity and oxygenation, the colour already mentioned.

As soon as the continuation of the blast conveys a higher temperature to the superior regions of the furnace, the appearance of the solid matter at the tuyere ceases. The fusion and separation of the metal from the ore are effected in situations more remote from the blast, or chief source of decomposition, in a temperature more suited to the nature and existence of the metal. The iron, once formed into a fluid, and its fluidity preferred, its defeat to the blast is attended with little or no injury to its carbonation.

To understand this distinctly, it will be necessary to state two curious facts relative to cast-iron in a fluid state; and but for the existence of these properties, the manufacture of the metal in open furnaces or vesseis would be totally impracticable. 1st. Cast iron, while kept fluid, never decomposes atmospheric air, and never itself becomes oxidated. 2d. The degree of carbonation passed upon the metal at the moment
moment it enters into complete fusion, continues without diminution or augmentation throughout the whole operation of the furnace; or, in other words, cast iron neither receives nor looses carbon whilst it preserves its fluidity. The first fact explains the reason why the iron is preserved from combustion, when it defends opposite to the current of blast. The second is a proof that the carbonaceous matter is conveyed to the iron in the furnace by a species of cementation previous to fusion; and that after this point, cast iron will not take up any addition of carbon.

To preserve and establish the relation of cementation and fusion in the furnace ensures uniform products. Combustion in this presents us with a gradation of temperature, diminishing from the tuyere upwards through thirty or forty feet of ignited matter. The inferior temperature towards the top of the furnace heats the materials to redness; an affinity is here commenced between the carbonaceous matter and the oxygen of the ore; the latter is gradually removed, and a second affinity is instituted between the de-oxygenated particles of metal and the carbon: this, as the ore descends to higher temperatures, is rapidly increased, and by and by the saturation of the coal principle is complete. As the saturation of carbon always increases the fluidity of iron, the metal of the furnace enters into fusion at a comparatively low temperature, and speedily precipitates, through the high temperatures in the neighbourhood of the blast, to the general reservoir below.

It is not therefore necessary to suppose, that the great volume of air thrown into the furnace, and the great temperature of course excited, are necessary to the manufacture of the iron, so far as it regards quality; this, it is more than probable, may be injured by it, and even the economy of the manufacture itself. Quantity, however, is in general secured; but this is more the effect of mechanical reduction, than of any necessary operation of the blast upon the ore and materials above.

The quicker the body of cokes can be reduced, which occupy that part of the furnace between the point of separation and the tuyere, the greater will be the reduction of the whole, and the greater the quantity of manufactured metal. To this point the whole force of the blast is directed; here the chief part of the decomposition of the atmospheric air takes place; and here the destruction of the intervening cokes is effected, and that always in proportion to the quantity of air poured upon their highly ignited surfaces.

If we assume, with a blast of a certain density, any two points in the furnace, the one as the point of decomposition, and the other of separation and fluidity of the metal, suppose the former at the tuyere, and the other at the lower end of the botches at A, (See description of Blast furnace,) then it must be allowed probable, that a change taking place in the density, or even in the quantity of the blast, that change will affect not only the points themselves, but also their relative distances. The point of separation may be brought nearer (and perhaps injuriously so) to the level of the blast, the elevation of which is supposed to remain the same. The contrary may with equal truth be inferred; that if the point of separation is carried to a more elevated situation by a change or increase of temperature, the ore may enter into fusion before it has remained sufficiently long in contact with the ignited fuel, and thereby both the quality and quantity may be injured.

2d. Since pit-coal coke became the staple fuel at the blast furnace, the density and quantity of air deemed necessary to ensure combustion and quantity, have been yearly increasing. The various qualities as to hardness or softness, purity and effect, have given rise to a multitude of opinions, which are the most appropriate quantity and density of air for respective qualities of cokes. The blast of the furnace, in consequence, has at different places varied from 1½ to 4 lb. of expansive force upon the square inch of the air vessel. Most of the English works are blown with air not exceeding 2 lb. upon the square inch, as being the most proper medium of density, and beyond which the materials would be overblown. English coal, in general, is soft in its fossil state, but rich in carbon, and free from mixture. In Scotland, where the coal is found in dense strata, and forms heavy coke, the blast is used from 2 lb. to 4 lb. per inch. Those who have adopted dense blasts declare, that quantity of iron is incompatible with a column of air inferior to the measure of their standard. Either the prejudice is very general, or there must exist a direct analogy between the nature of the blast and the density of the coal.

The operations of the charcoal pig manufacture were conducted with blasts of a trilling density, seldom exceeding 1½ lb. upon the inch, and often under this. Dense blast, it was believed, over-ran the furnace, most probably by exciting too great a temperature, and frequently had a tendency to discharge the materials from the furnace top. There never yet have been any direct experiments made to ascertain upon what this variety of pit-coal depends; whether exclusively from its density, or from containing the carbonaceous matter in more purity or greater difengagement. Perhaps both are necessary to be taken into account, before any satisfactory explanation can be given of the facts now stated and generally admitted.

3d. The density of a column of air depends upon the power of the blowing machine, and the proportion of the area of the steam cylinder to that of the blowing cylinder. Tables of the powers of steam engines, and the diameters of cylinders requisite to condense air from 1½ lb. to 4 lb. upon the circular inch, will be found under the article Blowing Machine. It will appear evident from these tables, that steam cylinders of the same diameter, and working at the same power, when employed to raise air of various densities, do not discharge the same quantity of atmospheric air in any given time. The larger the area of the blowing cylinder, the number of strokes being the same, the greater will be the quantity of air discharged into the furnace. The reverse is the case with blasts progressively more dense; so that any part of an engine's power may be employed, not in raising the true principle of combustion—air, but in conflicting a comparatively small body of air, so as to give it additional velocity.

To fix the point, or maximum, of the most profitable density, has hitherto been unattainable. The circumstances, deemed intimately connected with coal, render it necessary to accommodate the blast to the combustibility of the fuel: were this not the case, it would be difficult to overturn the following reasoning, and to exhibit an instance where it might not be found generally applicable. Combustion in the furnace will be excited in proportion to the quantity of air introduced. A blowing machine, that with the same power of steam cylinder threw into the furnace double the quantity of air, though of an inferior density, would reduce a greater quantity of combustible matter than one oppositely constructed; or, in other words, 3000 feet of air per minute entering a furnace would produce greater effects than 3000 feet, although the latter were compressed into nearly half the bulk of the former.

The most plausible theory of blast is to fix upon the lowest density at which the air can be forced into the furnace, and then proportion the diameter of the air-pump to the power of the steam end. Suppose that this could be effected at half the density usually employed, then that part of the engine's
The engine’s power used formerly to compress the air to 3 or 4 lb. would now be employed in a blowing cylinder of larger diameter, raising per minute, or, indeed per stroke, from 200 to 2000 cubic feet of air. Opposed to this there stand two formidable objections, resulting from the necessity of using blow-pipes or nozzles of increased diameters, from which to discharge the additional quantity of air, making it in area what is wanting in velocity to discharge the air in a given time. The first is a reaction of the air, so powerful as to issue back from the tuyere with a velocity little short of that at which it enters. This, with noz-pipes of 2, 2½, and from that to 3 inches, is scarcely felt when the blast is soft, and may be entirely obviated by a judicious arrangement of the tuyere iron and nozzle-pipe; but with pipes from 3 to 4 and 4½ inches diameter, the recoil increases as the squares of the diameters of the blowpipes; and even in dense blasts the recoil increases with the diameter of the discharging pipe. It is therefore probable, that to blow with a nozpipe 4 or 5 inches diameter, so as to have no recoil, a velocity or density of air would be requisite beyond any thing yet in use.

Those who advocate for the use of a soft blast, either upon the plea of their materials, or as being the most advantageous method of using any given mechanical power, frequently fed the full effects of the recoil of a considerable portion of the whole blast. But to obviate this, and to gain the advantage of the whole air, the blowpipe is enclosed in a moveable frame or building, which is made air-tight at every cask, and completely prevents the return of the smallest portion of it. The combination at these furnaces is carried on with equal effect, and the resulting products in iron equal in point of quality and quality to those where blasts of double density are used.

Again, at other furnaces, where a soft blast had been originally preferred, the plan of forcing back the recoiled air, in order to make up in quantity what was now deemed to be deficient in density or velocity, has been in vain attempted. The tuyere iron has become immediately heated, and burnt back with violence. The materials would not admit of the tuyeres being raised sufficiently high to prevent the cinder from flowing back into the bag, which connects the large and small pipes, and destroying it. Even, in more than one instance, the entire tuyere side of a furnace has been lost in endeavouring to establish this plan of blowing, where either the materials would not answer, or from some misconception in the mode of operating. Where a furnace works uniformly with a dark or honey-combed tuyere, this mode of blowing may be attended with the greatest success. In all new erections, however, the blast ought to pafs through itself sufficient velocity not only to enter the furnace, but to ascend through the materials, without admitting of any important recoil.

The second objection, arising as a consequence of the want of velocity, and of being obliged to use pipes of a larger diameter to carry in the full complement of air, arises from a belief that a large pipe never makes the metal of a good quality. This deduction is perhaps not altogether correct; but it seems highly probable, that in the use of a comparatively weak blast, only a small portion of the air passes through the furnace without decomposition. The point of separation may by this means be changed, or perhaps be raised too high for the preservation of the metal, immediately previous to separation. As the increased temperature prevails upwards, the affinity between the particles of metal in the iron-flume, and the carbon of the fuel, may be earlier established, and no ultimate evil consequence, in point of reafloning, ought to ensue. It appears from numerous observations, that the quantity of iron-flume, which a given weight of cokes smelts, and to the metal of which is conveyed the carbonaceous principle, is considerably dependent upon the diameter of the blowpipe. Supposing the ore of equal richness, the smaller the pipe, the greater burden will the coke carry, and the cheaper will the iron be made per ton, so far as materials are concerned. On the contrary, with large pipes, whatever the density of the air may be, the quantity of cokes necessary to manufacture an equal quality of pig iron will be increased, and the cost of the iron is also enhanced. As an equivalent for this, however, the quantity is considerably increased with nearly the same amount of labour; so that it remains a question with the manufacturer, whether the additional cost of cotes is compensated by the extra produce of metal he is enabled to bring to market.

4th. The quantity of air discharged into the furnace, under the application of blast, depends upon the number of strokes or cylinders which the engine makes per minute, and on the area and diameter of the air pump. This is independent of every consideration of density and increase of power in the blast cylinder, so long as the blowing or air cylinder remains the same, and the engine performs the same discharges; the measure of atmospheric air, which enters the furnace, will remain the same. The rapid improvements, which of late years have been made in the blowing machine, have increased the quantity from 1000 to 4000 feet per minute per furnace; and the quantity or produce in iron has been also considerably increased. We by no means, however, find that the increased manufacture of iron has been in the exact ratio of the quantity of blast thrown into the furnace. Many influences of late years have been noticed during the transition from the old to the improved modes of blowing, wherein the proportion has had little or no similarity.

Fifteen hundred feet of atmospheric air in one minute was found in most situations equal to the manufacture of twenty tons of melting iron; in the same situations, 3000 feet in the same time has never exceeded thirty tons per week; and in one particular trial for two weeks, the discharge of 6000 feet, being the whole produce in air of the engine, the produce in iron never exceeded 24½ tons. In the blast cafe, the quality of the iron was irregular, and the quantity of cokes for each ton of metal thus produced was considerably increased, although the iron was of inferior carbonation.

Without recourse to the diameter of the air cylinder, and the particular movements of the engine, the same facts have been frequently deduced from the diameters of the noz-pipes. We have frequently seen air discharged under a pressure of 2½ lb. upon each square inch, but with a pipe of 2¼ inches diameter, reduce materials, and manufacture good melting iron to the extent of 26, 22, and 25 tons per week; and in the same furnace, and with the same materials, the air discharged by 2 pipes, each 2½ inches, under a pressure of 3 lb. upon each square inch, the produce never exceeded 30 tons of metal of an equal quality, but more frequently 25 to 28 tons. One observation full more direct, and made with a blast of a density equal to 2½ lb. per inch, and discharged by one pipe of 2¼ inches diameter, frequently manufactured 22½ tons fine melting iron weekly; another pipe was added to the opposite tuyere of the same diameter, and the quantity of metal weekly was never increased beyond 72 tons, and upon an average of six months only 27 tons. These are various facts relative to the nature and effects of blast, and exhibit the investigation of its principles as a matter of singular importance in the economy of the manufacture.

One remark was made relative to the burden of ore in the luff flated fact, that with the small pipe a given weight of cokes smelted and carbonated the metal in 3 cwt. of iron-flume;
done; but after the two pipes were added, the weight of iron-lone, to produce an equal quantity of gas, was reduced to 23, and afterwards to 2 1/2; producing in the first instance per charge 14 cwt. of iron upon an average, but latterly not above 1 cwt. and 10 lb. of iron of equal qualities. Another observation, in the same case, with every attention paid to the velocity, quantity, and temperature of air, may be adduced as of equal importance, though somewhat different in its mode of application.

Under a pressure of 2 lbs. a 31/4 pipe was found upon the average of 18 weeks to manufacture 20.12 tons; a 3 inch pipe, 20.5. Upon an average of 11 weeks, and a 4 1/4 pipe, 22.17. Their respective areas, and iron produced, will stand in opposition thus:

It is but fair to state that the effects of combustion, so far as it related to the reduction of a quantity of fuel, was not in the same unequal proportion as the quantity of metal to the measure of the air. The quantity of reduction was with the

But the capacity of the fuel to carbonate the original quantity of iron, diminished in nearly the same ratio as the combustion increased; so that the same measure by weight which carbonated 140 lbs. of iron with the 31/4 pipe, was unable to carbonate more than from 96 to 100 lb. of the same quality of iron with the 4 1/4 pipe. This observation was made previous to the one last mentioned, and reasoning upon the subject led to the practice detailed in that experiment. It will appear therefore conclusive, that the same body of blast may, with greater advantage and economy, be introduced through two pipes than through one, and this for two reasons. The reduction is equal, and the quantity of fuel required, forsmelts and carbonates a larger portion of metal per charge; but it will appear from both cases equally conclusive, that the capacity of the fuel to convey carbonate is in the ratio of the square roots of the pipe, or the reduction of the quantity of air.

This is in unison with what was stated under the particular "Combustion," that a large volume of air, so far as it related to the institution of affinity between the coally principle of the fuel, was probably more hurtful to the carbonate than otherwise; but that in so far as it halved the completion of the affinities, the reduction of air, and above all increase of produce, though merely as an agent destroying the superfluous fuel, it may be considered as giving the manufacturer a superiority over his processes by means, the extent of which he never could formerly command.

Tradition has, though rather imperfectly, conveyed to us many words which our forefathers seemed to have understood and practised with better effect than their policy. In operating with charcoal furnaces, and a blast proportioned to the scanty means then in use for the purpose of producing forge pigs, the whole air was conveyed into the furnace by means of a pipe 2, or at most 2 1/2 inches diameter; but when grey metal was wanted, the same body of air was divided and introduced by two pipes, whose joint capacity was equal to the former.

It appears therefore an inquiry of some importance to those embarked in iron foundries, to ascertain how far this tendency of the fuel to increase the carbicaceous principle proceeds in the ratio of the diminution of the blowpipe. If general observation confirmed the particulars here stated, the effects of carbonation might be greatly increased, and the quantity perhaps little reduced, by introducing the same quantity of air by means of four, six, or eight small pipes, whose joint areas should be equal to the original column of blast.

From quantity and density of air, there may and do result peculiar properties of blast, which may affect the operations of the furnaces, and which once fully understood may help to explain the facts hitherto unaccounted for, and which we before noticed. Facts resulting from accurate observation would prove an invaluable source of information upon this subject; and it is with regret that we can furnish no perfect acrological table of the different temperatures of air under different densities or degrees of compaction. The following, we believe, contains the only collection of temperatures hitherto noted; and as it relates to only one degree of compaction, the satisfaction it affords must be only partial.

### Table of 30 observations made in summer upon various temperatures of air before and during the act of compaction, compared with the thermometer in the shade.

</tbody>
</table>
There can arise no doubt, but that heat is extracted by compression from atmospheric air; and that it is further probable, that the quantity of heat thus engaged is in proportion to its condensation. If, therefore, we are allowed to reason upon this subject, we should rate the following as a considerable approximation towards truth. It is universally believed and felt, that combustion in the blast furnace in June, July, and August, is considerably diminished, as a consequence of the increased temperature of the air. The metal, in these months, is frequently debased in point of carbonation, and diminished nearly one half in point of quantity. We shall suppose that this takes place at a temperature of 100, which has been proved to exist under a pressure of 21 pounds. The reverse of this happens in the cool season of the year, and particularly in the winter months. The furnace then yields the largest quantity of iron, and in the most profitable manner. This, with the same probability, takes place at a temperature of 50 found in the table.

It would therefore appear to result from these, that two thirds, or one half of the iron only, is manufactured at a temperature of 100, than in winter at 50. The difference between these degrees of temperature amounts to 50, and most probably in combustion affects the operation as feebly as the human frame is affected by a transition of temperature equal or similar. It is not necessary now to dilate the difference between summer and the drier air of our winter, the circumstances of evaporation and aqueous solution; these shall be particularly attended to in the general process of manufacturing iron. The great difference of temperature arising purely from compression seems to us adequate to explain many phenomena regarding the blast furnace. Our knowledge, however, upon this subject can only be forwarded by a general collection of facts well ascertained, shewing what are the various degrees of heat made sensible by the compression of the blowing machine under every density; what the difference in temperature, the densities being alike, when the air is received over water, in the air-vault, or in the regulating cylinder. From these it might most probably result, that the higher the density of the air, the greater would be the degree of heat manifested; and it might also follow, that in the ratio of this density, or temperature, when the air was received over water, etc. would be the evaporation or quantity of water suspended in the air, and of course discharged into the furnace.

This article may be concluded by the following remarks:—That all iron works are not alike affected by the heat of the summer months. Many iron works preserve the quality of the iron, though at the expense of fuel, and with loss of quantity; but at other places no extra quantity of fuel will compensate, either as to quality or quantity, for the want of cool air. Neither station nor density of blast will explain this curious circumstance; for with blast of equal density and quantity, works situated not 50 feet above the level of the sea have been found to manufacture a greater quantity of soft iron in summer, than at a similar work, not ten miles distant, situated at least 250 feet higher. At both of these works the air is received over water; and no material alteration in the use of that air is or can possibly be applied. The causes of this difference must be sought for in the nature of the coal and iron-stone used at both works, the investigation of which, however interesting, would prove a most laborious undertaking.

**Blast Furnace**, a large conical or quadrangular building used at iron-works for melting iron-stones and ore.

**Blast Furnace, Description of:**

_Plate (Chemistry) II._ fig. 1. represents a blast furnace, and part of the blowing machine constructed upon what at one time was the general plan at iron-works.

A, the regulating cylinder, eight feet in diameter, and eight feet high. B, the floating piston loaded with weights proportioned to the power of the machine. C, the valve by which the air is passed from the pumping cylinder into the regulator; its length 26 inches, and breadth 11 inches. D, the aperture by which the blast is forced into the furnace. Diameter of this range of pipes 18 inches. The wider these pipes can be with convenience used, the less is the friction, and the more powerful are the effects of the blast. E, the blowing or pumping cylinder, six feet diameter, and nine feet high; travel of the piston in this cylinder from 5 to 7 feet per stroke. F, the blowing piston, and a view of one of the valves, of which there are sometimes two, and sometimes four, distributed over the surface of the piston. The area of each is proportioned to the number of valves, commonly they are 12—16. G, a pile of solid stone building, on which the regulating cylinder rests, and to which the flue and slits of the blowing cylinder are attached. H, the safety valve, or cock, by the simple turning of which the blast may be admitted to or shut from the furnace, and passed off by a collar and tube on the opposite side. I, the tuyere.
by which the blast enters the furnace. The termination of the tapered pipe, which approaches the tuyere, receives small pipes of various diameters from two to four inches, called nose-pipes. These are applied at pleasure, as the furnace may be deemed to require an alteration in the volume or denity of the blast. K, the bottom of the hearth, two feet square. L, the top of the hearth, two feet six inches square. KL, the height of the hearth, six feet six inches. L, is the bottom of the boles, which here terminate of the fame size as the top of the hearth, only the former are round, and the latter square. M, the top of the boles, twelve feet diameter, and eight feet of perpendicular height. N, the furnace-top, at which the materials are introduced, or, as it is commonly called, charged; three feet diameter. MN, the internal cavity of the furnace from the top of the boles upwards, 30 feet high. NK, total height of the interior of the furnace, or working part, 44½ feet. OO, the lining. This is done in the nicest manner with fine bricks, from twelve to fourteen inches long, three inches thick, and tapered to suit the circle of the cone. PP, a vacancy which is left all round the outside of the first lining; three inches broad. This is sometimes filled with coke dust, but more often with sand firmly compressed. This space is allowed for any expansion which might take place, either by an increased volume of the furnace itself in heating, or by the exterior and weight of the materials when depending on the furnace bottom. QQ, the second lining, similar to the first. The object of this is to guard against the entrance of the flame into the mass of common building, by rents which may take place in the first lining OO. R, a cast-iron hinged, on which the bottom of the arches is supported, eight feet and a half long, and ten inches square. RS, the rife of the tuyere arch, fourteen feet high on the outside, and eighteen feet wide. SV, the extremes of the hearth ten feet square. This, and the bolting stones, are commonly made from a coarse-gritted sandstone, whose fracture presents large rounded grains of quartz connected by means of a cement of carbon. This serves to prevent the entrance of the flame into the mass of common building, by rents which may take place in the first lining.

Fig. 7. represents the foundation of the hearth, and a full view of the manner in which the false bottom is constructed.

AA, the bottom stones of the hearth. B, a flintem of bedding sand. CC, passages by which the vapour generated from the dams is passed off. DD, pillars of brick. The letters in the horizontal view of the fame figure correspond to similar letters in the dotted elevation.

Fig. 8. AA, horizontal section of the diameter of the boles; the lining and vacancy for stuffing at M. C, view of the top of the hearth at L.

Fig. 9. Vertical side section of the hearth and boles, showing the tym and dam-stones, and the tym and dam plates. a, the tym-stone; b, the tym-plate, which is wedged firmly to the side walls of the hearth; c, dam-stone, which occupies the whole breadth at the bottom of the hearth, excepting about five inches, which, when the furnace is at work, is filled every cast with a strong binding sand. This stone is surmounted by an iron plate of a considerable thickness, and a peculiar shape, d; and from this it is called the dam-plate. The top of the dam-stone, or rather the notch of the dam-plate, is from four to eight inches under the level of the tuyere-hole. The space under the tym plate, for five or six inches down, is rammed every cast full of strong loamy earth, and sometimes even with fine clay. This is called the tym filling.

The square of the base of this furnace is 38 feet. The extreme height, from the false bottom to the top of the crater, measures 55 feet.

VOL. IV.
from 8 to 10 per cent. of water, and coarser-gritted stones
from 10 to 12. Taking the average 10 per cent., then in
a furnace of equal dimensions to the drawing in Plate 11.
fig. 6, the sand lime of which will weigh upwards of 1200
tons, there will be introduced 120 tons of moisture. This
quantity is always considerably increased by the portion
of water necessary to reduce the lime to mortar, and frequently
augmented by the moist state of the weather during
building.

The evaporation of this immense body of water is the
source of all the mischief which takes place in the shell of
the blast furnace; nor is it much to be wondered at, where
every precaution is not used to bring the heat forward in
the moist gradual manner, preparing the glazes of the
vents, and allowing the moisture indifferently to pass away.

In situations where bricks can be obtained, the moisture
of the sand lime is avoided, but the great extra quantity of
lime, which is necessary to build with bricks, introduces
through the medium of the mortar an almost equal quantity
of water, as with sand lime. This has been observed in
part by using loft clay in the interior of the walls; but as
clay seldom binds to any great extent, the general pull of
the furnace must be trusted to good binders from
without.

In the construction of all blast furnaces, a complete vent-
uation ought to be preferred by means of narrow flues, or pa-
flages proceeding horizontally from the middle of the solid
shell, or within two feet and a half of the interior to the
outside. These ought to be connected with a circular chan-
el, or gutter, of the same dimensions, proceeding round
the circumference of the furnace; so that, if any one vent
were choked in the general expansion, the moisture con-
ducted by it might easily vent itself among the other open-
ings. The vents cannot well be too numerous; and as they
f seldom exceed four inches square, the building cannot be
materially weakened by them.

In addition to the horizontal channel of communication,
some builders carry up in the main building of the furnace
four, six, or even eight perpendicular flues, which commu-
nicate with it and the openings that proceed horizontally
to meet the external air. See Plate VIII. fig. 1, 2, 3, 4.

Either of these methods may be considered as just precau-
tions to ensure the existence of the furnace, but adopting
them in the fullest and most complete manner, is not always
accompanied with similar success. If circumstances formerly
noticed concur in occasioning an extra degree of expansion,
the prelude of the lining against the common building of
the furnace often deranges the fyllematic order of the vents,
pushing the bricks into contact with each other, and madders
for a little while, though to gain more fatal effects,
the increasing volume of the vapour.

After such a diversity of opinion upon a subject of such
general importance, wherein each respective class of veterin-
cans boast of complete success from its peculiar plan, it may
be difficult to point out one more generally attended with
good effects than another. The following, however, may
defere the serious consideration of the manufacturer of
pig-iron.

Of whatever materials the furnace is constructed, let them
possess no more moisture than is sufficient for their proper
building. The thickness of the common building not to
exceed, at its greatest breadth, 6½, or 7 feet. In the middle
of the wall, a space of four or six inches ought to be left
clear all the way to the furnace top. Into this vacancy should
be introduced small fragments of sand-lime, about the size of
an egg and under. When the expansion, proceeding from the
free building of the interior, causes the bricks immediately in
contact to pull outwards, the masses of sand-lime are im-
mediately reduced in size, and filling the interstices occasioned
by their former angular shape, actually occupy much less
room; and now present to the flame or fire, should it be in-
cliued to penetrate so far, a solid vertical stratum of sand,
thus diverting the expansion of the furnace to the ex-
tent of some inches. The effects of the prelude are thus
directed from the shell of the building, and lost in the pul-
verization of the fragments of sand-lime.

The advantages resulting from this plan may be nearly
doubled, by using a double lining of fire bricks, as repre-
sented in Plate VIII. fig. 3, between each of which, and the
common building, a similar vacancy should be left; but with
charged sand-lime, containing no more moisture than serves
to compact it into a firm body. As this moisture becomes
gradually expelled in the flow heating or annealing of the
furnace, the sand occupies less bulk, or, which is the same
in effect, is then susceptible of a greater degree of compre-
ssion when the general expansion of the furnace comes on. It
is evident that the force is here also diverted against the sand,
in place of acting immediately, with a tendency to enlarge
the circumference of the building.

Over and above all these precautions, the annealing or
drying of the furnace in a progressive and regular manner
ought to be carefully attended to and continued for two or
three months at least. Many are blown much earlier, from
an anxiety to get to work, and make returns for the great
capital necessarily expended in these undertakings.

The fame variety of opinions exists in the trade, relative to
the determined figure and dimensions of the blast furnace, as
substituted, with regard to the bell mode of building. Its height
has, at different times, varied from 20 to 70 feet; and its diameter,
in the boles, or widest part, from 8 to 15 feet. It will be easy to trace the source of
this indefinite mode of construction, and the uncertainty which
must necessarily pervade operations of so much risk and
importance.

At the time when charcoal of wood was the common, and
indeed, the only fuel used in the blast furnace, the volume
and extent of the blast were proportioned to the very impe-
fieat state of the blowing machinery. Long experience had
taught the manufacturer what were the proper size and di-
ensions of his furnace. Many of them were from 12 to
18 feet high, and some of them, where a good water wheel
blast existed, reached as far as 28 feet in height.

When pig-iron was introduced into the blast-furnace, in the
state of coke, to produce similar effects to the charcoal of
wood, it was soon found, that in furnaces of equal capacity
and height the same effects could not be produced. The ore
required to remain in contact with the ignited fuel for a
longer space of time, in order, unquestionably, to produce,
by attenuated contact, what was deficient in temperature, for
the saturation of the ore with metallic matter. This would
immediately suggest an increase of the height of the blast-
furnace; and if beneficial effects once resulted from a step
of this nature, it became a matter of difficulty to say where
the progression of height would stop.

Hence, in a few years, arose furnaces of 40, 50, 60, and
70 feet in height. Of the last dimensions, one was erected in
Wales. The size of the artificial crater was such, that
the strength of the blast was scarcely sufficient to keep the
existence of flame visible at the furnace top. After in vain
endeavouring to ignite the immense body of materials con-
tained in its vast capacity, the height of the furnace was re-
duced 30 feet by cutting a hole in its side, narrowing the
mouth, and throwing in the materials at the height of 40,
in place of 70 feet from the furnace bottom. This was at-
tended
tended with success, and the operations of the furnace proceeded with their usual facility.

After the application of steam engines to raise and condense air, the quantity and strength of the blast became more a mechanical property in the hands of the manufacturers. It was soon discovered that an increased volume of air, by raising a much higher temperature throughout the furnace, constituted the immediate action of those affinities, which the tall furnace accomplished by a long attenuated contact, and that iron equally carbonized and fitted for the purpose of melting, could be produced by 30 hours contact, as in four days.

The consequence of these gradual discoveries was a general predilection in favour of small furnaces, and at present the bias of the manufacturer seems inclined to this extreme. Where the maximum will be found it is difficult to conjecture, for the ground which the manufacturer now occupies is materially altered from what it was when smelting with coke was first introduced. The perfection to which the blowing machine has attained, forms a striking contrast to the feeble and diminished effects of the bellows in the infancy of the trade. So far as the necessary affinity is increased, and more instantaneously produced in high temperatures, than in those inferior, the manufacturer is differently circumstanced, and commands an extent of means unknown to him in former times. That this inferiority will produce equivalent effects in the modification of the blast-furnace, requires but little demonstration. Two facts illustrative of this may, however, be mentioned. Calf fertil has of late years been formed directly from bar-iron, by a process which only requires an hour or two to complete, and with small quantities of matter the fame may be performed in a few minutes. This is effected by preheating the carbonaceous matter to the iron at a melting temperature. In the usual mode of cementation, blistered steel, by a more attenuated contact and inferior temperature, requires fix or seven days to complete, what is here produced in two hours. The difference of temperature in the two operations is equal to 60° or 70° of Wedgewood. The first operation will be considerably shortened, if the coal fertil is required to hold much carbon; but if this requisite is necessary in the blistered steel, the length of the cementation must necessarily be protracted. Again, a piece of malleable iron may, by preheating it with a proper dofe of carbon, at a high temperature, be converted, in a few minutes, into a mass of the richest carbonated cast-iron, which, in a temperature inferior, would have required several months.

The same facts will apply, in part, to the manufacture of pig-iron in the blast-furnace; but an unanimity of opinion and action on this subject is precluded, as well by the prejudices of individuals, as from circumstances arising out of the nature of the materials operated upon in different places.

A furnace has lately been tried at Muirkirk in Scotland, only eight feet diameter across the boles, in place of its former dimensions, which were ten feet, and 40 feet high. It was soon found, that with the fame volume of blast which was formerly applied to the ten feet furnace, very inferior effects were now produced. The combination apparently was carried to too great an extent, and the materials owing to this circumstance, entered into fusion before the iron had imbibed a sufficient dose of the equally principle from the fuel. Another great evil which resulted from this diminution of diameter, was a fracture, or retardation of the descent of the materials upon the lining of the furnace. This evil was increased and the materials made more buoyant, by the usual volume of air elevating itself in a cone not much more than half its former area. The consequences were, that the whole mixture of coke, iron-oxide, and slime-iron, would have frequently hung for an hour together, or until the blast had cut all the hearth and boshes clear of materials, a slip would have then ensued, and brought with it a large proportion of newly introduced matter. The introduction of this into the fusing point before being properly heated, and long before any affinity had been established between the particles of metal and the carbon of the furnace, invariably changed the quality of the metal, and caused frequent and sudden alterations from grey to white iron.

Upon the subject of height and width of blast-furnaces, it may be finally remarked, that the average height in Britain may be taken at forty feet from the upper surface of the hearth bottom, eleven feet diameter at the greatest width bothings, and three feet and a half for the diameter of the tunnel-head, or furnace-mouth.

If the proportions of height and diameter in the dimensions of the blast-furnace have given rise to a multiplicity of opinions, the internal structure and shape of the cavity have been no less an ample field for speculation and prejudice. At one time this was conceived so essential to the successes of iron-making, that any particular furnace that had made a fortunate run of quantity and quality, was copied with the greatest accuracy of design. The fortunate iron-maker ingeniously attributed to the mechanism of his own construction the rich and superior harvet it heaped in metal, and faw, or fancied he faw, in the curve of a line, or in the inclination of a slope, the talisman of his good fortune. By prolonging the one, or depriving the other, he immediately inferred that ftil superior effects would be produced, and that by obtaining the perfection of art in the mere fahr- cation of structure, every thing that was great and powerful would ensue. This rage continued for many years, and gave rise to an endless variety of shapes, many of which, in their eventual successes, had only the merit of originality to boast.

In the establishment of this important and national manufacture, the great fluctuation of opinion as to structure seems to have been the prelude to a subidence into approved forms, founded upon general principles; and though we may now smile at the indigible forms which our predecessors, or even contemporaries, annexed to the blast-furnace, yet those alterations of shape and structure lay the strongest claim to our respect and gratitude. The path is now opened, and the ground already bare; from the labours of those who have already gone be us, refult the happiest effects; we proceed towards our object, free from the interruption which inexperience always entails; and we may now, by the direct application of principle, perfect with facility what may still be deemed desiderata in this important branch.

The varieties of shape which custom and experiment, from time to time, had annexed to the blast-furnace, may be classified under four distinct kinds. Plate VII. and VIII. The following description, characterizing the resulting properties and dimensions in the form of each class, will be necessary for comprehending the subject thoroughly.

Plate VII. fig. 1. is the vertical section of the blast-furnace cut across the top of the boshes; the internal shape entirely conical; the external figure a quadrangular pyramid. The construction of this furnace is truly singular; and from this alone great advantages were expected to result. The originality of the principle consists in the double square, or trapeze. One immediately above the hearth, not represented in this figure, but similar to the figure in Plate IX. fig. 1. B, and another half way up the cone, four feet in diameter; see A.

4 B 2
B, the top of the boles, 12 feet in diameter.

C, an inferior diameter of 10 feet, previous to the formation of the throat at A.

D, the top of the second row of boles, of the same diameter as B.

E, the furnace mouth, or termination of the second cone, four feet diameter, and proportioned to A.

F, funnel for carrying off the flame occasioned by the blast, so as not to interfere with the workmen in filling the furnace.

The dimensions, as to height, are as follow:

From B to C height - - - - - - 12 feet

C to A ditto - - - - - - 6

A to D ditto - - - - - - 6

D to E ditto - - - - - - 13

Height of the hearth, and first row of boles, not shown in the figure, but being the same as Fig. 1, Plate IX. measure - - - - - - 15

Height of the bottom stones, packing, and false bottoms, - - - - - - - 4

Total height of this furnace from the foundation 56 feet

G, fire brick lining.

bb, space left for packing.

I, the common building either of sand-stone, or of bricks.

Fig. 2. plan and section of the same furnace taken across the boles at B.

AAA, square of the common building 29 feet upon the side, bound by BBEBEBEBB, eight cast-iron binders; the number or fett of these requisite, being proportioned, both in length and dimensions, to the height of the furnace. In common, a full binder is applied every six feet in the height.

The concentric circles represent the various diameters of the interior of the furnace, and are connected each by dotted lines, with their respective places in the elevation.

The reason which we believe led to the construction of this furnace, proceeded from a firm belief that the boles and throat or square of a blast-furnace were of the greatest importance on two accounts. First, because they supported the weight of the materials; and secondly, because they concentrated the heat. These acting conjointly, permitted the least possible quantity of materials to pass, till they dropped away in a state of semi-fusion, or complete separation. In furnaces, however, the cones of which were 30 feet high and upwards, this was conceived impossible to take place for any length of time, to any considerable extent. The height and gravitating pressure of the materials were more than sufficient to counteract the most favourable construction of boles; and as this could not admit of diminution, the fupefliion of the materials, and the concentration of the heat must be effected by some other means. This, at one time, was believed to have been completely effected by the scheme of an additional square, and an extra set of boles; but there is little doubt but that, by converting perpendicular to lateral pressure, the superficiality of the materials was reduced at least to one half of its former intensity.

It was not doubted but that the process of smelting and separation would commence, in part, at A; that what escaped fusion and separation in that quarter, would be easily resolved below; and that the process of combustion intensifiy at work in two different places at once, would greatly facilitate the general reduction, and add greatly to the produce in iron of the furnace. These fangane expectations were unfortunately never realized, the solitary instance of one furnace only being constructed in defence of this theory, and that only for a very temporary endurance, is the best proof of the inutility of the plan.

Fig. 3. is the elevated section of a blast-furnace, of which several were built, and from which it was at one time conveived that the greatest advantages were derived. The numerous minute gradations of diameter exhibited in the construction of this furnace, were at one time held in high estimation by many iron-makers; and a plan of the present furnace circulated from the domains of the lucky projector, with as much care and conscientious of rich acquisition, as an antiquary would remove from Hercules or Egypt, the precious remains of antiquated obscurity.

It will be extremely easy to trace to its source this particular bias to form, so universally believed in at one time, but now confined to that oblivion which experience has taught us it deferred at a much earlier period.

It often happens, that when repairing or re-lining a blast-furnace, the manufacturer avails himself of the time thus obtained, to overhaul and repair his engine and blowing machine. The former movements of the machinery may have discovered to him many errors both in movement and construction, which the constant requisite motion rendered impracticable for him sooner to remove. In this way, considerable improvements on the engine and blowing apparatus are frequently made; and when again in motion, may, by increasing the length and number of the thumbs in a given time, or by conferring a higher additional working power on the beam pillow, increase at the same time both the volume and density of the blast. If the produce of the furnace is increased, which it is highly probable will be the case, then the superior effects are attributed to a few unimportant circles and lines added to the interior of the cone, the scum-leafs and proportion of which do not survive the blowing of the furnace three days.

In like manner, if a work entirely new, commence operations with a greater advantage of blowing power, and with something original in the shape of the furnace, the consequent effects of the former are indubiously attributed to the fortunate construction of the latter, and the grand essentiaal blast is entirely overlooked, and its next important associates coal and iron-stone.

The dimensions of the present furnace are as follow:

Diameter of the cone at A - - - - - - 3 feet

ditto at B - - - - - - - - 4

ditto at C - - - - - - 8½

ditto at D - - - - - - 9½

ditto at E - - - - - - 10

ditto at F - - - - - - 11

ditto at G - - - - - - 10

From G to F, the distance in height measures 1 foot

Increase of diameter - 1 foot

E to F, the distance is - - 12

Diminution of diameter - 1 foot

D to G, the distance is - - 1½

Diminution of diameter 6 inches

C to E, the distance is - - 6

Diminution of diameter - 1 foot

B to C, the distance is - - 2

Diminution of diameter - 4½

A to B, the distance is - - 4½

Diminution of diameter 1

Height of the hearth and boles not represented in the plate - - - - - - - - 13

Total height of the cavity of the furnace or place occupied by the materials - - - - - - - - 40 feet

The former descriptions will suffice and apply to this plate,
plate, with equal propriety as to the former, regarding the lining, packing, common building, &c.

Fig. 4. is a plan and section of the same furnace at F in the elevation.

The inner circles represent the various diameters of the interior of the cone, the letters in each corresponding. The two external circles describe the packing and lining; and the circle N exhibits the circumference of the common building of the furnace, which, at this particular section, is 26 feet in diameter.

Plate VIII. fig. 1. is the elevation of the interior of a furnace of a plain construction, and at one time very prevalent at founderies. This fashion was deemed to polence its peculiar merits, and still maintains its form unaltered at some ironworks where the regular tapering cone is not yet admitted. Its inferiority, as to height, is amply made up by an enlarged capacity arising from its diameter.

Diameter at the mouth of the cone A - 3 feet
ditto at the bofhes C - 12 feet

Height from C to B - 11 feet
Height of the bofhes and hearth not represented in the figure - 11 feet

Total height of that part of the furnace occupied by the materials - 37 feet

FF, represents a view of the vertical method of carrying off the moisture and steam from the masts of building, by means of vents. The number of upright flues vary from four to eight, and have regular communications by means of horizontal openings with the external air, GG. They are generally carried up parallel to the lining, and incline with the general diminution of the cone. The former, or vertical openings, are six inches square, and the horizontal communications four inches square.

Fig. 2. is a plan and section of fig. 1. in which are represented the lining, the vacuity for packing, and eight vents or openings corresponding to those in the elevation. The letters in each figure correspond, and the two dotted circles are meant to shew, that occasionally all the vents communicate with each other by means of a horizontal gutter, or channel, carried quite round the building. This precaution is used lest any of the tubes were to fill up and choke the free circulation of the vapour, that its appropriate quantity may get easily discharged amongst the other openings.

Fig. 3. is an elevated section of a furnace, the interior shape of which has now almost become universal. The regular and uniform descent of the materials which follows, as a consequence of the gradual enlargement of the cone, fully justifies the general partialty in favour of this shape.

Diameter at the mouth, or opening A - 3 feet
Diameter at the top of the bofhes B - 10 feet

The height from B to A - 31½ feet
Height of the hearth and bofhes not seen in the plate - 11½ feet

Total height of this furnace - 43 feet

This form of furnace is not only constructed with a double lining of fire-bricks, CCCC, and two openings for introducing fuel for packing bbbh, but has also an opening DD, from top to bottom, about the centre of the common building. From this, in all directions, proceed small vents, which communicate at a short distance with the open air, as may be seen along the sides of the building.

Fig. 4. is a plan and section of fig. 3. cut across at B.

B, diameter over at the bofhes 10 feet.
C CCC the two circles of fire brick-lining, as seen in the elevation.

bhh, spaces for receiving packing.

DD, circular vent, or general gutter, from which ramify the horizontal openings.

These are repeated at intervals of four feet in the height, as may be seen in the elevation. In building, DD is filled with fragments of soft sand-stone, which are easily reduced in the expansion of the furnace, and tend, by diverting its real preflure, to preserve the body of the building entire.

A similar want of unanimity of opinion subsists among iron-makers, relative to the general construction of the bofhes, their particular height, and most benefical range. Some contend for flat, others for bofhes more vertical, while others again concede the exertions of those equally successful, who adopt the mean of the two extremes. At different places, and to every possible range, have been attributed the most important consequences in the subseuent procels.

Plate IX. fig. 1. represents bofhes of the sleeppet construction.

Diameter at A - 10 feet
Perpendicular height from A to B - 8 feet
Square at - P - 2½ feet

The opinion relative to this form is, that at first blowing, the bofhes are productive of a very proper degree of suspension of the materials; but as the preflure of the deficient bears in every direction upon the under, or bottom part next the square at B, it becomes increas'd too much, that the weight of the incumbent materials early begin to press too much towards the bottom of the hearth, counteract the regular precipitation which should take place, and impede the ascent and full effect of the blast.

Fig. 4. is a section of bofhes approaching to, or indeed may be considered as the oppolite extreme. Here the reverie of the fact attributable to No. 1. takes place. The preflure of the descending material is equally distributed over the very flat inclination of the bofhes, and there is no more weight deemed to be on the square at A than is equal to a full column of the materials of similar dimensions, left by the direct tendency which the strengh of the blast to keep them in a flate of partial buoyancy. To counteract these advantages in part, very serious defects are here also imputed. If circumstances unite to increse the tear and wear at A in any uncommon ratio, either by fowing, or from a deficiency in the quality of the flone or bricks, the whole of the upper part of the hearth at B B is immediately exposed, and, though compefed of a superior quality of sand, will soon follow the direction of the descending current. A preflure of materials then takes place, equal to the whole of the increased space, while the effect of the blast to bear them up is considerably diminished by the enlargement of the original diameter. It will be seen from the plate that the weaknefs of flat bofhes at the top is ill calculated to withstand any accumulating preflure, and that by confining their part of the procels to the hearn, the latter may soon, by a fimilar widening, be entirely devoured.

Those who wish to fleer clear of extremes, or profit by the more adventurous spirit of their neighbours, more generally adopt a mode of bofthing that occupies the mean of the two former extremes. This is represented by fig. 3.

Diameter of the bofhes at A - 10 feet
Perpendicular height from B to A - 5 feet
Diameter of the square B - 2½ feet

In general, the bofhes of blast furnaces are made of the same sand flone with the hearns, but of late fire bricks have been introduced with a considerable indication of advantage and
and permanency. When bricks are used, it is found of utility to make the whole part of the building solid, back as far as the external square of the hearth, so that if the boffins fail in part as to displace one layer of bricks, another surface, equally fresh and entire as the former, presents itself to the action of the fire.

Fig. 2. Ground plan of the top of the boffins of fig. 1. A and B correspond to the same letters in the elevation. The dotted square C describes the form and dimensions of that part of the hearth immediately above the tuyere, as seen in the elevation C C. The large dotted square D D is the external size of the hearth, as seen also in the elevation D D.

Fig. 5. Ground plan of the square and boffins of fig. 4.

While we prosecute the detail and history of the construction of the blast furnace, the same diversity of plans formerly noticed comes under review, in every department of the erection. The importance of the hearth is admitted by every class of reasoners upon this subject; and to devise a form better calculated for melting than another, has been an object of general concern with the manufacturer. Much as may be deemed to depend upon its form and construction, infinitely more benefit is derived from a proper quality of stone, to refit for a given length of time the powerful effects of a continued and unremitting blast. To both of these important desiderata much of the manufacturers attention has been from time to time directed.

The first singularity that strikes us forcibly in the figure of the hearth, is, that in place of being circular, like the upper parts of the furnace, it is constructed of a square funnel-form, with angles as acute as represented in Plate IX. of this work. It is this narrowing form that is continued on three sides, and the square to the bottom of the hearth, where it generally measures from 22 inches to 24 inches. The top of the hearth, at B or A, fig. 1. and 4. is, as it is commonly called, the square, is never less than 30 inches, nor more than 33. The height of the hearth from E to B, Plate IX. fig. 1. 7 feet, and none are made higher. From C to B, fig. 3. 6 1/2 feet, which is now reckoned the most advantageous height; and from C to A, fig. 4. the hearth measures 6 feet, under which height there are no hearths ever attempted.

The structure of a hearth, properly speaking, consists of three solid sides only, the fourth, or front, is filled up by the tympanum, or key-hole. Plate IX. fig. 1. The block E is generally in one piece, and from four to five feet long, according to the height of the hearth. It descends towards the bottom till within two feet or two feet four inches, and then leaves an opening of similar dimensions as to height, into the centre of the hearth or funnel, as at letter F.

As the square form in which the hearth is figured cannot last a day after the blast is introduced, and is even frequently destroyed in the act of annealing, or heating, it cannot be essentially necessary to the making of iron. The hearths of all furnaces when blown out, are entirely round, or if vaulted more upon the tuyere sides, oval. The general use of the square must have been derived from long acquired habit, or perhaps from the convenience of working and finishing those immense blocks of stone which are still deemed necessary to the perfection of a hearth. The interior of charcoal of wood furnaces was at one time entirely square from top to bottom, so that in the progress of the trade, from smelting with wood to the use of pit-coal, although the general shape of the furnace has been altered, the square figure of the hearth has been retained.

Whatever may have been the utility of this general pre-

...
happens but a considerable portion of time is sacrificed, besides the expense of the bag.

In common, the surface of the tuyere plate is laid eight inches above the cinder, or, which is the same thing, above the level of the dam-bronze. Some blow at a distance of four inches, others at six and eight, and some again as high as twelve and fourteen inches. However, under some circumstances, the height of the tuyere is determined by the nature of the materials. In these cafes, if the tuyere is only raised one inch above its proper height, the bottom of the furnace lumps up immediately, and will invariably rife in the fame progressive manner in which the tuyere is heightened.

Plate X. fig. 1. represents the relative proportions of height battwixt the dam, tuyere, and tymf, in ordinary cafes.

G, the dam, or notch of the dam plate, 17 inches above the level of the bottom at H.
I, the centre of the tuyere 26½ inches from the surface of the bottom, and 9½ inches above the level of the dam.
K, the bottom of the tymf plate, 23 inches from the bottom of the furnace, and 6 inches above the level of the dam.

At iron-works where different opinions exist as to the proper or working height of the dam, very different relative heights ensue, regarding the tymf and tuyere. The former should always regulate the other two. The height of it is seldom used less than 16 inches, nor more than 28 above the bottom.

Considerable advantages result from placing the tuyere, as to its horizontal position, at a judicious distance from the front or back wall. This is, as in the case of height, often regulated by the nature of the materials. If the furnace, owing to this circumstance, tends to work cold and languid, behind, with a propensity to lump at the back wall, the blow pipe ought to be directed as near to the extremity of the hearth backwards as it is possible to get in the tuyere iron; Fig. 4. Plate X. letter a; but where the operations of the furnaces proceed with ease and facility, the centre of the tuyere should more generally approach the centre of the hearth, as at b.

Of late years a new mode of blowing has been introduced, which, from its great prevalence and good effects, seems to bid fair to come into general use. Furnaces till lately were only erected with one arch, or tuyere side, and the blast or column of air introduced by means of one blow pipe; now most of the new furnaces are built with double tuyeres, with two sets of main conducting pipes, and the blast introduced by means of two pipes in place of one.

The general effects and supposed properties of this mode of blowing are attended to under the article blast.

In the mean time, the proper height and distance of the tuyeres, and their relative position to each other, have been subject to endless disputation. Fig. 4. Plate X. a and b shew how, in common cafes, the tuyeres are placed to each other in their horizontal range: a is placed with its centre three inches from the extremity or back wall of the furnace, and b at the distance of nine inches from its centre. That there should be a difference of distance in their horizontal position none are inclined to dispute; but that this should take place in their vertical situation, is by some contended; while others insist that the difference ought never to be less than four inches.

Some find fault with this, and with many evidences of found reasoning on their side, that if the blast is introduced into the furnace, and at a proper distance, to keep the back wall clear, those nice distinctions as to inches go for nothing,
in a region where an inflammation increase of volume mult destroy all repulfion or mechanical contact. This philo-

sophical reason is flatly denied, and the contrary minutely and gravely asserted, that were two pipes placed every way immediately opposite to each other, the action of the opposite columns would retard the velocity of the air, and diminish the real elevated quantity in the furnace, by locking up in mutual opposition a portion of their respective quantities in the laying pipes. There might be some foundation for this conjecture, were the respective nozzles or blow pipes brought into actual contact, or inserted into each other; but to those who consider, that in most furnaces there is never less than four feet of distance between nozzle and nozzle, and the most of the intervening space filled with a column of cemented materials, ignited to the highest pitch of whiteness, this supposition will appear to rest upon very unsatisfactory grounds.

A lefs scrupulous class of observers and reasoners upon this subject even go so far to assert, that the tuyeres ought to be put in direct opposition, and that this, so far from being detrimental, would be found to possess unqualified advantages. This it is said would result from a certain degree of coolness which the extremity of each column of air confers upon its opposite tuyere iron, and prevent the same from heating and burning. To whatever cause it is attributable, the fact stands in many instances unquestioned, that not half the tuyeres are lost or burnt out with the double blast, that was formerly destroyed, where the single blast was in use.

Fig. 7. Plate X. represents a tuyere iron, 16 inches wide, and 12 inches high at the wide end, 18 inches long and narrowing at the other end to 4 inches wide, and 44 inches in height. Fig. 6. is a plan of the under surface of the tuyere iron. Fig. 5. represents the size and dimensions of the tuyere plate, which when bedded receives upon its surface the tuyere iron, Fig. 7. This plate is first laid upon a bed of fire clay, with its narrow end towards the hearth, and inclined to rise a little. The tuyere is then introduced upon its surface, height and distance being attended to in the disposition of the plate, and the space between its surface, and the sand-bronze of the furnace, rammed very perfectly with balls of good fire-clay mixed with small fragments of fire bricks. When about to blow, the nose or inner end of the tuyere is covered with a very plastic clay, to prevent it from heating and burning away. This is always carefully attended to, and the blast put off at any time to replace it. Should it be neglected at any time, the iron would inflame with such rapidity, that an opening would be instantly made, by which the coals and ignited matter of the furnace would be recoiled with the greatest violence imaginable.

Fig. 2. Plate XIII. The dam-brone. This is actually the dam, or barrier, which prevents the fluid contents of the furnace from advancing, and making their escape into the sand of the casting house. It is generally made from the same stone as the hearth, but is found still more difficult to stand for any length of time the action of the fluid iron, than the hearth to resist the ravages of the blast.

Fig. 3. dam plate. This is laid against the dam stone with a bed of fire clay interposing, and closes the front of the furnace. Its form is double, so that by turning it serves the purpose twice. It often fails, owing to the constant current of lava palling over the curvature a, and deepening it, till the iron flows over along with the cooler.

Fig. 4. the tymf plate. This embraces the under end of the tymf stone, and the sides of the furnace hearth for three feet up. The thickness at bottom, called the heel, or end, is preferred from the action of the fire by a strong stopping of clay.
This is replaced at least every call, and prevents the flame and heated materials of the furnace from being blown forward.

Plate IX. fig. 4, is a ground plan of the arch pillars, hearth, tuyeres, and vents of a blast furnace.

A, the hearth, or particular spot where the fluid metal is collected.

B, the dam-done.

c, the fall, or opening, by which the metal is discharged.

After the last it is filled with sand, which soon hardens and presents a very close texture to the fluid metal within. At the following call it is cut carefully down, till the bar penetrates to the quick. A circular incision is then made, and the metal flows out of the orifice in a connected round stream, into the runner or channel made in the sand.

d d d d, four vents or openings which communicate with the false bottoms. Plate I. fig. 2. These serve to convey the damp from the furnace bottom, and by being run out into the external air, two in the front of the hearth, and one at each tuyere, indicate by their temperature, and the quantity of steam or vapour which they emit, the real state of the bottom below.

D D, the two pillars which support the front arch; they, at the same time, serve as abutments to one leg of each of the tuyere-arches. The arch at the front is 15 feet wide and 15 feet high, and inclines to the centre of the furnace, in the same manner as the side walls of the pillars approach.

E, main or back pillar built entirely solid.

F F, vent holes six inches square, carried up from the foundation, and brought forward to meet the open air every four or five feet.

G G G G G G, tops of the pillars covered with cast iron plates, for receiving three large cast iron lintels, 10 feet long, and 10 inches square. These serve to give solidity to the arch, and support the lining and boles of the furnace.

Fig. 8, 9, different forms of tuyere pipes.

Blas - Furnace.—History of its Origin and Progress.

In detailing the progressive history of the blast furnaces, it is necessary to premise, that in this country it has undergone a revolution, of which we meet with no similar instance in other countries.

The most natural and abundant fuel which prevents itself to mankind in their progress towards civilization, is that furnished by the numerous and extensive forests, which generally occupy the surface of a wide and uncultivated country. These, in the history of all nations, have been early appointed to domestic uses, and to the comfort of individuals. As a country became more populous, and the spirit of civilization increased, other advantages resulted from the general use of wood as fuel. The civilization of climate, and the clearing of large tracts of land, making it subservient to the purposes of agriculture, were not the smallest benefit thus derived. As the progress of knowledge began to devolve and establish regular manufactories, to supply the wants of the thriving community, the same sources of combustion were opened to the manufacturer and the artisan. These, as they became successful, were only preludes to other establishments more extensive, more lucrative, and entailing more difficult to supply. Among others the finding of metals was no doubt of early origin, and equally dependent on the woodland countries, in the immediate neighbourhood of the ores. In this class we can trace no metallurgical operation fo hostile to the existence of wood, as an extensive manufacture of iron. If this manufacture, owing to the great and unprecedented prosperity of the country, in place of remaining stationary, or exhibiting symptoms of decline, arising from a want of consumption of the article, has increased in capital, in extent, and riches beyond all precedent, wood, the base of the manipulation itself, depending only upon it, is rapidly declining, the existence of which was frequently incompatible with the views and interest of the landed proprietor, must soon have been annihilated, and the art of making iron lost to the community.

In this singular situation was Great Britain placed from the reign of Charles II. to the middle of the last century. The increasing manufactures, commerce, and general prosperity of the country called loud for an additional supply of articles fabricated from iron, while wood, the foundation of the whole art, was rapidly declining in point of quantity, without the most distant prospect of ever being again renewed. Pit coal had been long before the latter period suggested as a substitute, but prejudice, intercrossed views of established capitalists, and above all, a want of command of mechanical power, had prevented any successful operation from being established in this new department of iron making. No sooner, however, were these barriers to improvement broken through, and a change of fuel in the blast furnace found to be attended with profitable effects, than the languishing state of the trade began to revive, and improvements succeeded each other, with a facility new and astonishing. In fifty years the revolution was complete, whether the consideration regards the increase of the manufacture, the general use of pit coal in the blast furnace, or the almost total annihilation of the charcoal mode of making iron.

It is uncertain at what period the manufacture of iron commenced in Britain. It is probable, that the working of the tin mines of Cornwall, by the Phenicians, would introduce into the country a class of men skilled in the then known metallic ores, capable of appreciating their true value, by converting the riches of an unexplored country, either to their own immediate necessities, or to the conveniences of the skilful inhabitants. The invasion of England by the Danes, and their consequent establishment, would most likely add to the former flock of knowledge, in the art of mining and furnishing iron ores. Whatever truth there may be in this conjecture, the fact stands unquestioned, that in several counties in England large heaps of scoriæ are found, with an accumulation of coal sufficient to bear large trees. These have been from time immemorial called “Danes cinders.” So early as 1620, Dudley remarks, that large oaks were then found in a state of decay upon the tops of these hills of scoriæ. It is not, however, probable, that these cinders were the product of the blast furnace. At a period remote as that, wherein these heaps of scoriæ must have been accumulated, the labours of the iron maker were chiefly directed to the fabrication of small portions of malleable iron in foot furnaces and bloomeries. The art of moulding and casting in iron was either totally unknown, or so very rude, as to excite no interest in favour of prosecuting this fine branch of art. If pig or bell metal was at all formed, it was merely of the most inefluate nature, for being speedily converted into malleable iron. It was not till long afterwards, when improvements had taken place in the rude machinery of the times, and a division of labour seemed to be productive of many advantages, that different furnaces existed: one for the making of pig iron, and another for the conversion of it into malleable iron. This first gave rise to the blast furnace. Which, properly speaking, was an improvement resulting from the knowledge of the advantages derived from a division of labour. After the application of the blast furnace to the exclusive manufacture of pig iron, the manufacturer would soon discover, that the products of his
his furnace were frequently different from each other. Experience and observation would soon enable him to decide, from whence this had its origin. A small additional quantity of fuel, beyond that he formerly used for forge-pig-iron, he found, would confer a degree of flexibility upon the metal that immediately pointed out the practicability of casting it into plates. Moulding from thence would most likely enucle, and become equally an appellation to the blast furnace as was the bar-iron forge. As this new manufacture became familiar to the proprietor, he would immediately find his interest in dividing the product of his blast furnace into grey melting iron or into forge pigs, as the exigencies of his moulding shop, or forge required.

If credit could be given to the "Metallum Martin" of Dudley, in the 12th year of James, anno 1615, there were at that period not less than 300 blast furnaces for melting iron-ore with charcoal, each of which had fuel, upon an average, for 40 weeks per annum. The average produce in pig-iron at each furnace of 15 tons per week, or 600 tons per annum, makes the total yearly quantity 180,000 tons, being a greater quantity than has ever since been manufactured in Britain.

However much this quantity may be exaggerated, yet it is highly probable, that even at this early period, the iron business in general, and the particular operations of the blast furnace, had obtained an eminent rank in the manufactures of the country. The progress of agriculture, and the increase of population under the reign of the peaceable James, had taught the husbandman and the proprietor the value of cultivated fields. The great consumption of wood for the navy and iron-works had greatly exhausted the principal forests of supply; tracks of country became cleared, and as the spirit of cultivation increased, the annual quantity of fuel for the manufacturing of iron diminished.

It is probable that Mr. Dudley, in eliminating the quantities produced from each furnace, formed his average from the winter and spring months, when water was plentiful, and he seems not to have made sufficient allowance for the occasional hoppages in summer, during the time of cutting and collecting the wood for the ensuing wet season. If, therefore, in place of making 600 tons yearly, the furnaces of these days are supposed to have made each, upon an average, five tons per week, or making a little allowance, 250 tons yearly, which is surely nearer the truth, this still leaves an annual amount of manufactured pig-iron equal to 75,000 tons, which, exclusive of the operations of the forge, forms a very respectable staple at that early period of the history of our manufactures.

The period of prejudice, so unfavourable to innovation in the iron business, was followed by one more general and more calamitous for the nation: amidst the distraction occasioned by civil war, neither innovation nor improvement could be expected. Patents, however, were granted to some during the common-wealth, for the exclusive manufacture in the new way, in one of which it was at the time believed, that Cromwell was a partner: these partially shared the fame with the full inventor, and none succeeded in establishing a manufacture either of extent or certainty. In 1665, we find Dudley applying for his last patent, and setting forth, that at one time he was capable of producing seven tons of coal pig iron weekly, with an improved furnace 27 feet square, and bellows, which one man could work for an hour without being much tired.

It was not, till impelled by necessity, arising from the rapid decline of the annual growth of timber, that pit coal became an object of universal estimation. When improvements in machinery had attained a pitch of certainty, and experience had taught the mechanic the manifold advantages of the beam engine; the adventurous manufacturer found he possessed an extent of means to which he was formerly a stranger. Small furnaces, supplied with air from leather bellows, blown by oxen, horse, or human labour, became exploded, and an increase of size took place, together with an increase of the column of blast necessary to excite combustion.

At this eventful era in the history of the blast furnace, when the ameliorating hand of agriculture was progressively sweeping before it, what remained of the once immense tracts of woodland dedicated to the supply of the blast furnace; when the general improvement in machinery, and the introduction of the beam engine threatened to give new life and impulse to manufactures in general, the iron-busins flewed dwindling into insignificance and contempt. The demand of the country increased for the manufactured article, particularly bar-iron, while every year saw a gradual but steady diminution of the annual quantity. Recourse to foreign markets was had for a supply of that article, of which this country once was the greatest exporter, and the immense annual importations from Russia and Sweden may date their origin from that period. The flourishing and extensive detail of Dudley no longer existed, and the 300 blast furnaces of his day were now diminished to 59 in all; the total amount of whole annual produce was 17350 tons, or nearly 3200 tons to each furnace.

**LIST of the Blast Furnaces in England and Wales immediately before the introduction of pit coal, as a substitute for the charcoal of wood; the particular counties in which they were situated; the collective quantity of iron manufactured in each county, and the product of each particular blast furnace.**

Annual average for each furnace 294.

By this statement it is evident, that the manufacture of pig-iron had diminished during one hundred and thirty years preceding, upwards of 50,000 tons annually. Fortunately for the existence of the trade, the application of good going, and what, at that time, would be reckoned powerful steam engines, about the year 1750, for raising and comprefling air, were introduced at some places where abundance of materials was found without water for turning machinery. The manufacturer now found that his produce could be increased by enlarging the diameter of his steam cylinder, or perfecting the vacuum under the plunger; and it was soon discovered, that these increased effects alone were requisite to the formation of pig-iron, in profitable quantity from the coke of pit coal; nor is it to be wondered that this secret remained so long a mystery. The small quantity of air that was formerly requisite to ignite a charcoal furnace, whether from the great inflammability of the fuel, or the smallness of its capacity, was constantly before the eyes of the manufacturer. He had more often felt the effects of over-blowing, than under-blowing his furnace; and it is highly probable, that pit coal, being deemed every way inferior,
inferior, an unusual timidity would precede any movement that might have for its object the enlargement of the column of air or the increase of its density.

This, however, once done away, there seemed no end to the quantity of air that a coke blast furnace could with propriety receive before any bad consequences ensued. Denitity, however, was found imitable to quantity, and the same law was at last discovered to hold good regard the pit coal as with wood, that the latter qualities could be overthrown, while the more dense and compact flake remained undiminished before a heavier blast.

The celebrated foundry of Carron was begun about the year 1760, and as was the custom of the times, the operation of blowing was performed by large bellows moved by means of a water wheel. Pit coal was the flake fuel in view, but the scanty supply of air and its want of density, seldom permitted the produce of the furnace to exceed 10 or 12 tons weekly, and frequently, in summer, the quantity was reduced even below this. The company collected immense quantities of charcoal wood, and found their blast much better calculated for the operation of melting with it, than the unflameable pit coal obtained in their neighbourhood. Experience, however, gradually unfolded means of adopting machinery, more calculated to the nature of the coal fuel, and more powerful wheels were constructed, the bellows was abandoned, and in their place large iron cylinders were introduced blowing both up and down. A larger column of air of triple or quadruple density was obtained, and effects equivalent to those great improvements followed at the blast furnaces. The same furnaces that formerly yielded 10 and 12 tons weekly, now sometimes produced 40 tons in the same space, and on the average in one year not less than 1500 tons of metal.

From the period (1750 to 1760) that pit coal coke was applied as a substitute for wood charcoal in the blast furnace, the iron trade began immediately to revive, and its progress in England and Wales, in a period of 30 years, was truly astounding. The general use of pit coal, most unquestionably, occasioned an earlier relinquishment of many of the charcoal works, than would have otherwise been the case, but the collective manufacture had so much increased, as to render this an object of trifling importance.

The following is a correct statement of the annual manufacture of pig-iron in England and Wales in the year 1788:

</table>

Total of charcoal furnaces 24 13100

Average produce from each furnace 545 16 2
Former average produce 294 1 1

Increased produce per furnace, from the year 1750 to 1788, attributable entirely to the general improvement of machinery, and the introduction of the steam engine, 251 tons, 15 cwt. 1 qr.

About the year 1750 the annual quantity of charcoal pig-iron manufactured in England and Wales amounted to 17350

In 1788 the same was 15100

Decrease in charcoal iron between 1750 and 1788 attributable chiefly to the decrease of wood, but also in part owing to the use of pit coal as a substitute in the furnace.

Total quantity of pig-iron manufactured in Scotland 8 7000

Average produce for each furnace annually 875 Tons.

Total quantity of pig-iron made in England and Wales 77 61300

Annual quantity manufactured immediately preceding the introduction of pit coal for furnace fuel 59 17350

Annual increase in 30 years 26 50950

The period of 1788 or 1790 may be called a new era in the manufacturing of pig-iron. The double power engine of Mr. Watt had now become more general, and was yearly
yeaM finding its way into blast furnace works. The regular and increased effects of this very powerful machine were soon felt in most of the iron counties. The produce of the furnaces in metal greatly increased as to quantity, and as they became more prosperous, stimulated others to engage in similar undertakings. New works were yearly projected, and several blowing furnaces annually added to the former list: so that in eight years the manufacture of pig-iron had nearly doubled itself.

The following table is a curious illustration of this fact. It was drawn up as an authentic document of the returns made from all the blast furnace proprietors in Britain, of the number of their furnaces, and the annual quantity of pig-iron manufactured at their respective foundries. These returns were made at a time when it was in the contemplation of the legislature to impose a tax upon pig-iron, and are copied from Dr. McNab's letter to the chairman of the committee of the house of commons upon the subject of the coal trade.

Average Produce of each of the English and Welsh furnaces, 1048 Tons per Annum.

Ditto of each of the Scotch Furnaces, 946
The demand for iron articles of all kinds in this country not only continued unabated after the period of 1796, but kept increasing in a greater ratio than formerly; so that, in the short space of five years, situations were occupied for nearly 50 additional furnaces, or additions made to established works of that extent. Between 1801 and 1802, it was ascertained that the following new furnaces were either building or actually in blast, in England, Wales and Scotland.

In England and Wales.

Total of new Blast Furnaces 22 25

Blowing and building in Great Britain; the produce of which supposing them all to have gone to work at the rate of 1000 tons per annum, from each furnace, would amount to, from Manufactured at, and previous to 1796, in

| 47 furnaces, 47,000 tons |

121 furnaces, 125,079 tons |

168 furnaces, 172,079 tons.

The respective proportions of this refining produce in pig iron manufactured in England and Wales, and in Scotland, will stand thus:

About
About the year 1620, charcoal pig iron sold for 6l. per ton.  
1788, ditto for melting, - 81.  
1798, ditto - 91. 10s.

Coke pig iron, when first invented by Dudley, was sold at 4l.  
In 1788, it sold for - 51. 10s.  
1798, ditto - 71. 10s.  
1802, melting iron was - 81. 10s.

And smooth-faced No. 1, fold at - 91. 10s.

One thing is here worthy of remark, that in a period of 170 years one ton of coke pig iron sold in value only 32s.  
i.e. between 1620 and 1798; but that in the short period of 14 years following 1798, an advance of 4l. per ton took place.  
One thing only may be offered in extenuation of this immense rise, that part of it was owing to the misfortunates that took place between this country and some of the Baltic powers, which was no sooner adjusted than pig iron fell in price. The article still, however, maintains itself at 81. 10s. per ton, being double the rise in point of value in fourteen years that took place in the one hundred and seventy preceding the commencement of that period.

To point out proper channels, whereby to account for the annual consumption of such an immense quantity of raw materials, would prove a satisfactory source of information.  
The endless detail into which the foundery trade has now branched itself, the almost universal fabrication which it embraces, and the extensive diffusion of the diecises of manufactories themselves, preclude the possibility of obtaining this with strict accuracy. The following statement, however, will tend to throw some light upon the subject.

It is reckoned, that the bar iron forges in Britain manufactured annually from pig iron 40,000 tons of finished bars, which, at the rate of 33 cwt. of pigs for every ton of iron bar produced, will account for - 70,000

Confined yearly in the erection of new furnaces, forges, machinery, &c. - 5,000

Purchased by the board of ordinance in the state of cannons, mortars, carronades, shot, and shells, &c. on an average of 1794, 5, 6, - 10,935

Waste in melting from the pigs, boring, &c. - 1,350

Purchased by the navy board in the state of ballast, &c. - 2,664

India Company's annual supply in guns, shot, shells, canes, &c. - 5,000

Waste melting, boring, &c. - 700

Merchant guns, carronades, shot, &c. for arming trading vessels - 10,000

Waste in melting and boring - 1,000

Ballast for Merchantmen and India men - 5,000

Tons 111,599

For the difference between this and the total manufacture, recourse must be had to the large exportation to Ireland, and to the numerous and extensive casting founderies of London, Liverpool, Manchester, Birmingham, Worthington, Newcastle, Edinburgh, Glasgow, &c. none of which reflect under 2000 tons yearly, and many of them from 4 to 5000 tons of melting pig iron.

We shall now leave this interesting subject with some general observations upon the origin and progress of the pig iron manufacture, and its early use in the fabrication of castings.

It appears from Dudley, that towards the close of the reign of queen Elizabeth, blast furnaces had been constructed of size, and with machinery sufficient to produce upwards of two tons of charcoal iron per day. Such great products in iron were most probably confined to situations where there was abundance of water, and where water-wheels and belows of a considerable magnitude were used. The more common modes of operation were confined to furnaces of an inferior size, which were supplied with air by means of hand-bellows, excited by cattle, or the labour of men. At the same period England enjoyed a considerable export trade, arising from her superior manufacture of iron guns, mortars, &c. As pig-coal had not been applied in any branch to the manufacturing of iron, it is probable, that these articles would be cast from the large blast furnaces; the flame of wood possessing but feeble effects compared to that of pig-coal, would render the application of the reverberating furnace, if then known, of no use in the casting of guns and mortars.

The non-application of pig-coal in every department of the melting foundery, would greatly retard the perfection, or even improvement of the art of moulding, and casting smaller and more general articles. The want of it, as the smelting fuel in the blast furnace, was long severely felt by the general backward state of the art of moulding and casting in this country, and allowed other nations with fewer advantages to get the start of us. It is highly probable, that long before the period formerly alluded to, the application of pig-coal had been speculated upon, either as an auxiliary, or as a substitute in every branch of the iron business. Its well known inflammability and tendency to form a cinder, and the general decay of wood, would furnish ample grounds for what, to many at the time, would be considered as idle and visionary speculations. The advantages arising from the trade, as it was then situated, had been rigidly ascertained, and fully appreciated by the established manufacturers. The business, in point of extent, seemed only limited by the supply of wood. New erections, for want of a proper supply of materials, became impracticable; those already engaged were more anxious to preserve their supply, however much inferior, than to extend innovation, which, by substituting pig-coal for the charcoal of wood, would likely give to the speculator a great superiority in the market. It is also highly probable, that many of the iron works then established were at a considerable distance from pig-coal, the general introduction of which would prove fatal to their interests.

In this view of the subject, the adventurer with capital had every thing to hope, the established manufacturer every thing to fear, by change. Under these circumstances, the discovery, or rather the assertion of the practicability of making iron with pig-coal, was announced by Simon Sturtevant, Esq. in the year 1612, who, upon application, was favoured with a patent from king James, for the exclusive manufacture of iron with pig-coal, in all its branches, for the long period of thirty-one years. In return, the said Simon Sturtevant bound himself to publish a faithful account of his discoveries, which afterwards appeared in quarto, under the title of his Metallicus. It is uncertain to what causes his failure was at the time attributed, but in the execution of his discoveries upon a large scale, he found difficulties amounting to utter impracticability; for in the year following, he was obliged to make a surrender of his letters of monopoly.
The second adventurer in this unexplored path we find to have been John Ravenston, esq., who, like Sturtevant, was successful in obtaining a patent for the new manufacture, but, like him also, was inadequate to the completion of it upon a profitable scale. Ravenston was also enjoined to publish his discoveries under the title of his "Metallica," which was printed for Thomas Thorp, anno 1613. Several other adventurers leaped forth, all of whom had the mortification of relinquishing their patents, without having contributed to the success of their arduous undertaking.

In 1619, Dudley obtained his patent, and declared, that although he made only at the rate of three tons per week, he made it with profit.

This discovery was perfected at his father's works at Pentfent, in Worcestershire. This gentleman's success in the various manufactures of iron with pit-coal, had united not only all the proprietors in the charcoal iron trade, but many new adventurers, who wished to share in the emoluments, or to acquire part of the fame of the new discovery. Their interest was sufficient to limit the duration of Dudley's patent from 31 to 14 years. During the greater part of this period, according to his own statement, he continued to make pig and bar iron, and various callings; all of which he sold much lower than the charcoal manufacturers. In the article of callings he must have had greatly the start of the charcoal foundries, as the quality of melting coke pig iron is far superior to that of charcoal, particularly that made in this country for the general purposes of casting. Nor was the superior genius of Dudley always an object of passive indifference in the narrow estimation of the new adventurers and the established manufacturers. The envy occasioned by his uncommon success, produced at first a spirit of combination, which terminated in a bold attack upon his devoted works. His improved bellows, furnace, forge, &c. all fell a prey to a lawless banditti, betwixt whom and its furious leaders no shades of distinction were visible, but those of avarice, ignorance, and the most contemptible prejudice.

To evade the mode of operation discovered by Dudley, or to introduce the making of coke pig iron with greater advantages, a new plan was adopted by captain Buck, major Wildman, and others, in the forest of Dean, where they erected large air-furnaces, into which they introduced clay pots resembling those used at glass-houses, filled with the necessary preparations of ore and charcoal. The furnaces were heated with the flame of pit-coal; and it is probable, that by tapping the pots below, it was expected that the separated metal would flow out. This rude process of affaying on a large scale, was in the end found utterly impracticable; the heat was inadequate to perfect separation; the pots cracked; and, in a short time, the process was abandoned altogether.

The misfortunes which befell the fangue, but unfortunately Dudley, were an irreparable loss to the perfection of the coke pig process. The hostile rivalhins he had to encounter, in consequence of the new ground he had occupied as a manufacturer, together with a zealous attachment to the royal cause during the civil war which followed his discovery, completely prevented his improvements from attaining a pitch of permanency and general utility. The refusal of a new patent after the restoration, prevented him from again entering the laborious paths of discovery and improvement, although it appears, that his former application to the perfecting of this branch of manufacture had not been unsuccessful, for in place of three tons of coke pig weekly, in his petition praying for a renewal of his ancient rights, he states, that he could now manufacture seven tons by means of a large furnace, and an improved bellows.

No greater pitch of improvement took place for nearly one hundred years after this period. The practicability of the manufacture was discovered; but the mode of obtaining quantity, to ensure in general a profitable return, depended upon other circumstances than the proportioning of the raw materials together. Had machinery received the same improvements in the time of Dudley, it is more than probable that the rapid progress of the coke pig trade would have dated its origin from that period. But this great era in the history of our manufactures was referred for a much later date: and in the improvements of the steam engine, we see new life and existence conferred upon every species of art that can be made subject to motion or mechanical control.

**Blast Furnace Works.** are large and expensive buildings for the manufacturing of pig iron. An erection upon the smallest scale must consist of a furnace, casting-house, bridge-house, and blowing engine. The latter is sometimes, though seldom, worked by means of a water-wheel. The most universal mode of blowing is by means of a steam engine. See **BLOWING Machines**.

There is no general plan laid down for building a blast furnace work. The singular situation which should be occupied, to infuse every convenience, renders this dependent upon the nature of the ground.

It is always reckoned a great advantage to place the blowing machine at as short a distance as possible from the furnace or furnaces, that the air may have the least possible travel in the conducting pipes. When this cannot be conveniently effected, the diameter of the pipes ought to be made sufficiently large to admit of the blast passing without any material friction.

The usual appendages to blast furnaces are mines of coal, iron-stone, and lime-stone. And these form no inconsiderable portion of the whole expense.

In situations where blast furnace building materials are at a moderate price, and where no uncommon difficulty occurs in the progress of the general operations, 15,000l. of sunk capital may be deemed requisite for one furnace; and for every furnace after this, 10,000l. may be added.

This great capital for many years kept the trade in the hands of a few; but of late, since capitalists have become more common, the number and extent of the blast furnace erections have become truly astonishing.

The following descriptions of plates illustrative of the plan and arrangement of blast furnace works will convey a tolerable idea of the nature of these buildings.

**Plate XI. Blast Furnace Works,** represents the ground plan of an entire fabric, consisting of

A. Steam-engine for blowing two furnaces.
2. Blast furnaces.
2. Bridge-houses.
1. Casting-house.
1. Boiler-house.
2. Boilers.
1. Chimney for boiler flues.
A. Engine-house, 40 feet long, 18 feet wide.
B. Pedestal for steam cylinder; 7 feet square at base, and 4 feet at top.
C. Pedestal for blowing, or air cylinder. Base 10 feet square, top 7 feet square. These are generally built of solid hewn stone, and bedded with the greatest accuracy. From centre to centre of the two pedestals is 24 feet, which is also the distance betwixt centre and centre of the steam and air cylinders.
D. Door or opening through the lever wall. This wall at bottom is built 5½ feet thick, but is occasionally reduced
in point of thickness to 3$\frac{1}{2}$ feet at top, as may be seen at the corresponding letter in the section.

F, Door or opening from the engine into the boiler-house.

An opening above this serves to conduct the steam pipe from the boiler to the steam apparatus at the cylinder.

G, The boiler-house, 40 feet by 50 within the walls.

As this is excavated from the solid hill to the depth of 30 feet, it is requisite to have the walls uncommonly strong. Those in the plan are 6 feet thick at bottom, and are reduced at three different heights in thickness, as reprefented by the interior lines.

H H, Two boiler feats for boilers, 18 feet long, 5$\frac{1}{2}$ feet high, and 7 feet wide.

I I, Fire-places, 6 feet square.

K K, Dead-plates before the bars or grates.

L L, Openings where the furnace doors are hung.

M M, Semi-circular openings formed beyond the dotted line, or termination of the boiler, in which the flame from the grates rises to enter the iron flue or tube, which is placed in the centre of the boiler.

N, Chimney, 2$\frac{1}{2}$ feet square within, and 50 feet in total height; from the bottom of the flue 42, and 8 feet from the foundation.

O O, Coal pits for containing small coal for the engine's supply. These are 8 feet by 6 at bottom, and widen gradually as they approach the surface of the coke yard. The coal is there emptied from the cart into the receivers, and the engine-man easily supplies his wants from the small openings which communicate with O into the boiler-house.

P P, Bridge-houses for containing cokes, iron-lime, and limestone, for filling the furnace. Measurement within 42 by 40 feet.

Q Q, Doors or entrances from the coke yard into the bridge-houses.

R R, Openings from the bridge-house, which is here connected with the furnace, by means of an arch and parapet walls. This is more fully seen in the elevation section P. Along this bridge the materials are carried or wheeled into the mouth of the furnace.

S S, Two blast furnaces, 34 feet square in the base.

T, Cafting-houfe 102 feet long by 48 in width, from the front wall or arch of the furnace, or 88 feet wide from the front wall of the engine and bridge-houses, and 24 feet high in the side walls.

W, Water receiver for receiving and equalizing the column of blast. Length 40 feet, and breadth 18 feet.

V, The space in which the equivalent column of water rises, 3 feet wide. The exterior line denotes the inverted iron chead; the interior lines, the different basements formed by the flue work laid upon the chead to prevent it from rising when the engine is at work.

Y, Termination of the blast conduct pipes from the air cylinder into the iron receiver, 2 feet 6 inches diameter.

Z, Position for the horizontal range of pipes to branch off, which are meant to convey the blast to the opposite tuyeres, a a, betwixt the back wall of the furnace, and the bridge-house.

A A, The two tuyere sides next the water pressure. From Y proceeds a straight pipe along the centre line b, for conveying the blast to that side of the furnace.

\(ce\), Front arches, under which the furnace workmen perform all the labour of tapping, cafting, and cleaning the furnace.

Vol. IV.

The spaces inclosed within these dotted lines are called pig beds. They are kept constantly filled with sand, and in them the operation of moulding and running the pig metal is constantly performed.

Plate XI. Blast Furnace works.

Elevated section of the ground plan, Plate XI. through N F B D C E and X.

A, Inside of the blast engine-house.

B, Steam cylinder peddial.

C, Blowing or air cylinder peddial. Both of these are built upon 4 or 6 inch planking, laid upon strong logs, which are again supported upon the solid stone buildings, a a, running from the lower wall along the side wall of the engine-house, to the wall perpendicular to E. The binding down bolts that pass through the flanges of the cylinders are strongly keyed upon the underside of the logs, and are at all times easily accessible.

D, The lever wall and opening of communication between the steam and blowing end of the engine-house.

F, Door or opening into the cafting house and water regulators.

G, The boiler-house.

H, One of the boiler feats.

I, One of the boilers, 18 feet long, by 9$\frac{1}{2}$ feet, 7 high.

K, Manhole door for entering the boiler.

L, Thorough arch in the foundation of the chimney.

M, Throat, or opening into the chimney, for the passage of the flame and smoke.

O, Coal pit for containing fuel for the engine.

P, Arched passage of communication between the bridge-house and furnace mouth. The opening in the bridge-house is more distinctly seen at R, Plate XI.

S, Side view of one of the blast furnaces, as connected with its corresponding bridge-house.

W, Water vault, or chamber, for receiving the inverted chead. In rocky foundations this is cut out of the rock, but is soft ground the excavation is made and lined with well jointed mason work, puddled behind with clay to prevent the loss of water.

T, Cafting-house and roof.

b, The tuyere arch.

c, The low, or lintel of caft-iron, 12 inches square.

d, The orifice at which the blast enters, called the tuyere.

s, Spring beams of the engine house, A. These are composed of two logs 14 inches square. The main gudgeon, feet, and beam rest upon these.

f, Stay logs for the steam cylinder.

\(g\), Ditto, for the blowing cylinder.

Description of Plate XII. Blast Furnace Works.

Cross section and elevation of Plate XI. through S Y S.

S S, Section of two blast furnaces, and their situation connected with the blowing apparatus.

Y, The branch pipe for communicating the air to the inside tuyeres of the furnace. This pipe has another branch of communication behind, which connects it to the blast pipes which descend from the blowing cylinder at A, and to the double column of pipes which are carried round behind the furnace to the opposite tuyeres.

C C, View of the pipes which convey the air to the opposite tuyeres, where double flues are in use.

D D, Front wall of engine and bridge-houses.

X, Iron chead inverted in the water receiver, and connected with the blast pipes.

VV, Opening all round for the water to ascend, as it is conveyed from the chead by the impelling force of the blast.
O, Logs on which the chimney is inverted, to preserve the floor of the water receiver, from 12 inches to 18 of space.

Description of Plate XIV. Blaft Furnace Works.

Ground plan of an extensive blast furnace foundery, consisting of four furnaces and two blast engines. The peculiar construction of this plan is, that only one furnace may be erected at a time, and afterwards the whole number; still preserving that regularity and uniformity of design which will at any time make the blowing machinery of one part subservient to the whole, in case of accidents, floppages for repairs, &c.

A, Engine house, with cylinder, peddals, lever, wall, openings, &c.

B B, Two boiler-facts and boilers.

Cc, Water regulators for the blast, which conveniently communicates, by means of pipes, with the blowing cylinders, placed upon the peddals behind A, I.

D D, &c. Centre line of the whole blast pipes. This extensive column may be so arranged, as to enable the furnaces to be blown each with two tuyeres; and the blast of one engine made to pass through the whole. The general communication is effected by carrying the chief column either behind the furnaces, or, as in the plate, through the main pillar of the furnace, by means of an arched opening 3 feet wide.

E, Ground plan of the hearth, squares, and pillars of four blast furnaces.

FF FF, Bridge-houses for materials, and filling or charging the furnace.

GGGG, Openings into the furnace top.

H, Casting-house.

I, Second blast-engine, upon the same plan as A. Each of these two engines ought to be calculated to blow two furnaces, and occasionally, when any thing goes wrong with one, the blast of the other could be easily distributed for a time among all the furnaces.

Blastral, in Antiquity, something struck with a blast.

Among the Romans, places blasted with lightning were to be consecrated to Jupiter, under the name of bidunata, and patacla. It was also a ceremonial of religion to burn blasted bodies in the fire.

Blaasting of flumes, in Agriculture, the operation of tearing asunder large flumes or rocks, which are in the way of the plough or other instruments employed in breaking up ground, by means of gun-powder. The method of performing this business is by boring a large hole, eight, ten, twelve, or more inches deep, according to the nature and size of the flume or rock to be blasted, by means of a chisel for the purpose, and then introducing a sufficient quantity of gunpowder, and afterwards carefully ramming the hole up with small fragments of flume or other solid materials, only leaving a very small aperture, by placing a firm pricker of sufficient length and suitable dimensions, with a handle at the top, at first into the powder, and frequently turning it round while the hole is ramming up. After the hole is quite filled, by forcing the hard materials in with a proper instrument, the pricker is withdrawn, and the aperture left by it filled to the top with gun-powder, and then a match of tow, straw, or other light inflammable material laid to it, and set on fire.

It is observed by Mr. Hendrick, in the second volume of "Communications to the Board of Agriculture," that in order to perform this operation properly some experience is necessary, and that a skilful workman can frequently rend flumes into three equal pieces, without causing the fragments to fly about. This, he says, depends upon the depth and position of the bore. It is also remarked, that a small portion of quick-lime, in fine powder, is bound to increase the force, and consequently to diminish the expense of blasting flumes. On these grounds the following is offered as a substitute for gun-powder, which is now become very expensive, though, as is freely confessed, without any experience of its effects. Supposing fig. 1, Plate III. (Agriculture) to be a large flume to be blasted or rent at a, a bore being dug down into it in the usual manner. This bore being then well cleaned out and dried, it is to be filled from b to c with the purest quick-lime, or such as swells most in flaming. That it may be perfectly quick, it should be taken red hot from the kiln, or the small furnace where it has been burnt; being then rammed in hard with the jumper or punch ace, the upper part of the bore is to be crammed with rotten rock in the ordinary way. The pricker being removed leaves the aperture at b; a k, a small pipe of copper, of less diameter than the needle or pricker, having an orifice about the dimensions of the straw, used to convey the fire down to the gun-powder, with a funnel d to receive water, is introduced into the aperture. Perhaps a straw or small reed fluck in the lower part of the funnel, among tallow or beeswax, might serve the purpose of a copper-pipe. Things being thus prepared, pour water into the funnel d; and if the pipe be not too high, so as to prevent the air from escaping from the aperture, left by the pricker, it will descend and cause the lime to flame in the bore c. Every one knows how irreducibly the purest quick-lime attracts water, and with what prodigious force it expands in flaming into three or four times its former bulk. From these data it is therefore inferred, that the flaming of lime, in such circumstances, would burst or rend the flume f in pieces; but the success of such an experiment, it is observed, must depend entirely upon using lime of the utmost purity, and having it very hot, and perfectly cautious when it is put in.

It is further remarked, that if the bore c be filled with water, and the aperture afterwards rammed up, the water being made to freeze by cold, would rend the flume; for when water pusses from a fluid to a solid form, it expands with irresistible force, though frost cannot be depended upon in this climate.

Blastology, from blasto, bud, and hoo, I gather; the regular and slanted pruning of vines.

Blatna, in Geography, a town of Bohemia in the circle of Prachatitz, near which is an inland lake, which is the source of the river Ulava.

Blatta, in Middle Age Writers, denotes a purple in the wool or silk, dyed with the liquor of the blatta.

This was otherwise denominated blatta serica, or blato fritum; whence also blattarius, used in ancient writers for a dyer in purple.

Blatta, in Entomology, a genus of hemipterous insects, called in England cock-chaffers, or black beetles. The head is inflected; antennæ fuscous; feelers unequal and siliform; wing-cages and wings subd, the former somewhat coriaceous; thorax flattish, orbicular, and margined; legs formed for running; abdomen terminating in two articulated appendages above the tail.

The blatta, considered in a collective point of view, are a very troublesome race of insects. Certain kinds, that are happily for us still peculiar only to the hotter parts of the world, are so formidable both in respect of number and talents for doing mischief, that they are really considered as a pest to society in those countries which they inhabit. These noxious creatures enter houses and commit various depredations on the furniture, dour provisons of every kind, teas or gunn holes in clothes, torment the inhabitants with their bite, and otherwise do considerable injury. The sort of blatta most abundant in England
England was originally a native of the eastern parts of the globe, or, as some suppose, of America, from whence it was long since imported into Europe, and is now completely naturalized to our climate. This is the blatta orientalis, or common cockroach, so frequent in London, is.

The blatta orientalis, when exhibited internally, renders the body soluble, softens the spoken, and discloses peccant humours. When used externally, by way of fumigation, it restores epileptic patients, and women labouring under a frangulation of the uterus. In other disorders its effects are the same with those of most teflaeatus substanies.

BLATTARIA, in Botany. See Ceilsia, Lythrum, Pentapetes, and Verbascum.

BLATTERIAE, Affinis. See Lysimachia.

BLATTITNUS, in Entomology, a species of fiphaliphysus that inhabits Austria; the colour is black; thorax broad; wing-cases and the legs teflaeatus and glossy. Slench. Inf.

BLATUM-BULGUM, in Ancient Geography, a province of Britain, mentioned in Antonine's itinerary, concerning the situation of which antiquaries have entertained different opinions. Camden, Gales, Baxter, and some others, have fixed it at Bouloges, on the coast of Solway firth, at the end of Severus's wall; yet Mr. Horfey assigns its situation at Middleby in Annandale. Here, as at the most remote limit of the province of Britain, Antonine commences his second route. A military way led from Blatum-Bulgium to Lugubalum, or Carlisle.

BLAU, in Geography, a river of Germany, in the circle of Swabia, which rises near the foot of a hill in the Blautopf, as it is called, and runs into the Danube at Ulm.

BLAUBEUREN, a town of Germany in the circle of Swabia and duchy of Wirttemberg, in a small district of the same name, seated on the river Blau, 7 miles W. of Ulm.

BLAUDRUSELUS, in Zoology. (obtusif. phala criffata) of Erxleben and Gmelin, and hooded feet of Pennant.

BLAuENThAL, in Geography, a town of Germany, in the circle of Upper Saxony.

BLAUE-Bock, in Zoology, one of the names given by authors to the blue antelope, antilope kucephala. Vide Kole Vorgeb.

BLAVET, in Biography, a celebrated performer on the German flute, the first, perhaps, who greatly distinguished himself by that instrument after it superseded the common flute, and became in general use. He was born at Befancon, and coming to Paris in 1723, soon acquired a great reputation. The prince of Carignan, who knew his merit, enframed him in his service; gave him an apartment in his hotel, and a pension. He was afterwards appointed superintendent of the comte de Clermont's band, and remained in that nobleman's service to the end of his life.

To his admirable talents, Blavet joined the respectable virtues of society; his manners and conduct were blameless, his temper tranquil, and his probity unexampled. He married at eighteen, and lived upwards of fifty years with his wife in uninterrupted harmony and felicity. We are always glad when such great professional abilities, such an estimable character can be joined.

Blavet's excellence on the German flute had been heard of all over Europe, before the character of Weideman was established in England, or that of Quantz in Germany.

About the end of 1765 he was attacked with the stone, which was a malady then more dangerous than it became afterwards, by the skill, experience, and success of eminent surgeons; but determining too soon, like our poor countryman Dr. Worgan, to submit to the operation, he died under it in 178, leaving behind him the esteem and regret of all who knew him.

BLAVET, in Geography, a river of France, which runs into the sea opposite Belle Isle. This forms a good harbour and spacious road.
BLAUFELCHEN, in Ichthyology, the name under which Salmo wartmani of Bloch and Gmelin is described by Wartmann Bech. Berl. Natur. Fr. 3. p. 184.

BLAVIGNAC, in Geography, a town of France, in the department of the Lozère, and chief place of a canton in the district of St. Chely d’Apezcher; 6 miles south of St. Chely.

BLAUKOPFJE, of the same name, is a village in the department of the Lozère, and chief place of a canton, near its confluence with the Dordogne. Its citadel is situate on a high rock, and it is defended by a fort constructed on an island in the river, which is here 1500 toises wide; and on the other side of the river, in the country of Mendoc, is another fort. All ships that are going up the river to Bourdeaux, deposit their arms and cannon at Blaye, before they pass the river, and take them up on their return.

The town contains 3586, and the canton 13,819, inhabitants.

The territory comprehends 160 kilometres, and 14 communes. It is distant 200 miles north from Bourdeaux.

N. lat. 45° 9'. W. long. 4° 45'.

BLAYMARD, or Blevyland, a town of France, in the department of the Lozère, and chief place of a canton, in the district of Mendoc. The place contains 546, and the canton 11,822, inhabitants. Its territory comprehends 3475 kilometres, and 11 communes; 3 leagues east of Mendoc.

BLAZE, in the Manager. See Star.

BLAZEGNIES, in Geography. See Malplaquet.

BLAIZEY DAY, a day in the English channel, on the south coast of Cornwall, between Fowey and Deadman point.

BLAZING STAR. See Comet.

BLAZON, or Blason, in Heraldry. To emblazon is a term signifying the description of things borne in coat-armour, in such manner as they ought to be represented, according to the rules of heraldry. To blazon, originally signified the blowing or winding of an horn by the heralds, at jousts and tournaments, when they proclaimed and recorded the achievements of the combatants.

Blea, in Vegetables, is that part of a tree, which lies immediately under the bark, and between that and the hard wood, and is the first progres of the alteration of the bark into wood by the natural growth and strengthening of the fibres. See Botany.

While the blea remains yet soft, and retains something of the nature of bark, it may maintain a feeleable vegetation; but when it is grown absolutely hard and woody, it can contribute nothing to the growth of the tree. The vegetation of the young branches of trees is the most lively and vigorous, and the only one that goes as far as the flowers and fruit, because these branches are little else but bark.

BLEACHING. The art of bleaching consists in removing the coloured matters intermixed with vegetable and animal substanices in their natural state, or such as they have subsequently imbied by accident, or some artificial process. Edward Hussey Delaval, Esq. F.R.S. has shewn, by a number of accurate experiments on the caufe of the permanent colours of opake bodies, published in the second volume of the second edition of the Memoirs of the Literary and Philosophical Society of Manchester, "that when the colouring matter of plants is extracted from them, the solid fibrous parts, thus divested of their covering, disply that whiteness which is their distinguishing character. White paper and linen are formed of such fibrous vegetable matter, which is bleached by dissolving and detaching the heterogeneous coloured particles." He further observes, "it appears that the earth, which forms the solid substanice of plants, is white; that it is separable from the colouring matter by several means; that whenever it is either pure and unmixed, or diffused through transparent colourles media, it exhibits its whiteness, and is the only vegetable matter which is endowed with a reflective power; that the colours of vegetables are produced by the light reflected from this white matter, and transmitted from thence through the coloured coat or covering, which is formed on its surface by the colouring particles; that whenever the colouring matter is either discharged or divided by solution into particles, too minute to exhibit any colour, the solid earthy substanice is exposed to view, and displays that whiteness, which, as before noticed, is its distinguishing character.

He states that in all those animal matters which do exhibit colours, the colouring particles are endowed with the same properties, and are regulated by the same laws, which prevail in vegetable substances.

A reference to the original paper can only do justice to the observations of this excellent philospher, confirmed by numberless experiments; but what is already said will be sufficient to give an idea of the nature of the procceds of bleaching, and that it depends on the removal of the matter interposed between the air and this white substanice.

The national importance of bleaching is so great, that it comprehends nearly the whole of the cotton and linen manufacture, and goes to an extent beyond most other arts.

Its operation in these branches may be considered under two points; viz. 1st, the separation of extraneous substanices from linen and cotton, which is effected by steeping, fermentation, or weak alkaline leys; 2d, the separation of the constituent or inherent colouring matters of those substanices, which is effected by different modes, and by various modifications of each method, as exposure to the air, light, the use of alkaline leys, soap, oxygenated muriatic acid, combinations of oxygenated muriatic acid with other matters, sulphuric acid, hepar sulphuris, &c.

To impress upon the mind the nature of the bleaching business, it will be proper first to describe the vefsels ufed in the fundry operations of steeping, boiling, bucking, washing, and then proceed to the management of each process, with some observations on its effects; and, lastly, how to make or procure the articles neccessarily employed in this art, and the method of ascertaining the qualities of each, adding some observations on the theory of the operations.

Bleaching of goods, particularly cotton manufactures. See Bleach, or Steeping.

The vefsels generally ufed in bleaching are made of such wood as will not communicate any colour to the liquors they are to contain, and therefore deal or fir wood is preferable to most others. The vefsels employed for steeping the goods when received from the loom are usually of the form A, fig. 1. Plate 1. Bleaching. The goods when received from the weaver contain not only the natural colouring matter of the cotton, which is of an oily nature, and which prevents the cloth from easilly imbibiing water, but also a substanice called fowins, being a paste made of flour and water, ufed during the weaving, and applied with brushes upon the warp, in order to give a firmness to the threads by glueing or
or parting together the loose fibres of the threads, and thus allowing them to pass more freely through the reed and harness. To remove this substance, and to open the fibres of the cotton, so as to give full effect to the subsequent operations, it is proper to steep the goods in a vessel of the above form in lukewarm water, till a gentle fermentation takes place, which will usually be effected in 24 hours. The cloth should then be taken out, and well washed in a current of clear water, which will thus separate a considerable quantity of lint without the expenditure of using alkaline leys; and the cloth is then ready to be boiled or bucked as may be preferred by the bleacher.

2d, On Boiling.

For boiling, a copper vessel is to be preferred, and the goods prepared, as above mentioned, by steeping and washing, are put into the vessel containing hot water only, or warm alkaline ley; a winch is placed over the vessel, and the piece goods attached to the ends of each other, are, when put in motion by the handle of the winch, dragged or rolled over it till the whole are passed; the winch is then turned with a retrograde motion, and the cloth gradually thus returned back, in order that every part of each piece may be thoroughly impregnated with the liquor, which is raised to and kept at a boiling heat, as long as it appears to extract any colour or matter from the cloth; the goods are then taken out and well washed in water.

Fig. 1. Plate IV. shows a section of the boiling pan A, of copper, fast in brickwork B, the winch C, with its handle D; E, uprights of wood, on which the winch turns; F, a cock to impart the spin; G, the fire-place; H, the ash-hole.

The use of this process depends upon the properties which alkaline leys have of uniting with the oily and resinsous matters which are either attached to or are a constituent part of vegetable fibres, and which contain their colouring particles, forming with them a sapopaneous matter, soluble in water, and by that means easily extricated from the cloth.

3d, On Bucking.
