As this is one of the most general operations in bleaching, it will be necessary to describe it more particularly. Fig. 1. Plate I. under the word bucking, shews at A the form of the bucking tub or kien, in which the goods are to be laid; B is an iron boiler, in which the alkaline salts, as pot-ashes or pearl-ashes, are to be dissolved in boiling water; C is the fire-place, in which a fire is constantly kept up; D is the ash-hole; E, a cock through which the boiling ley is let out upon the goods closely placed together in the bucking tub, A. A sufficient quantity of boiling ley is let into the bucking tub, till all the goods in the tub are thoroughly impregnated with it; the ley liquor is then allowed to pass by a cock at H into an iron vessel placed in the ground at F, and from thence raised by the pump G into the iron boiler B, and thence returned hot again upon the cloth. This operation is continued for several hours, till the ley, by the separation of the colouring matter in the cloth, acquires a colour alomost black, a very offensive smell, and nearly the confidence of molasses or treacle. The cloth is then taken out, well washed from its impurities, and, in the old mode of bleaching, it is then laid upon the ground to be whitened by exposure to the atmosphere, but, in the new mode of bleaching, is submitted to the action of the oxygenated nitric acid, to procure a familiar whitehead. It may be proper here to notice, that the old and new methods of bleaching are yet much the same; as formerly, only in the substitution of the use of the oxygenated nitric acid in those parts of the processes, where a long exposure to the atmosphere was formerly employed after the alkaline leys.

The operation of bucking acts on a similar principle to that of boiling, but in a much more forcible manner, as a greater quantity of ashes is added in proportion to the water made use of, and more heat is received and retained in the large bulk of cloth placed in the bucking tub, which expands the fibres of the cotton, and admits the more powerful action of the alkali, as is easily demonstrated by observing the very dark colour of the alkaline leys which have been used in bucking, in comparison with those which have been employed in boiling goods. To those persons who wish for a full and clear account of the absorption and power of heat, we recommend a perusal of Count Rumford's interesting essays on the subject of heat.

The black alkaline ley which remains after bucking should be preferred, as it will answer, after evaporating and calcining, as hereafter mentioned, to form again fresh alkaline salts of good quality. With a view to preserve as much of the ley as possible, it will be advisable to wring it out into a tub from the cloth or yarn, after it is bucked, by the method shewn in Plate IV. fig. 3. where R R are two strong pots, fixed firm in the ground, S T two wringing hooks, upon which the cloth U is twisted, to force out the liquor, by W, a winch handle, which turns the hook round on the post R. The two hooks are kept at a proper distance from each other, one by a collar at X, the other by an iron pin at Y, which runs through a hole in the square part belonging to the hook T, which square has several holes in it to bring this hook nearer to the hook S when required.

4th, Souring.

This proceeds in immebr, for the space of twelve hours, or more, the yarn or cotton in a mixture of water and sulphuric acid; well incorporated; the proper strength of which mixture is about the acidity of lemon juice, and is usually directed by the tafie. The four kettles should be made of lead, of a form which can be heated; the heat of the liquor should not be greater than the hand can bear with ease. This four kettle should be half sunk within the ground, as shewn in Plate IV. fig. 2. where M is a section of the four vessel; N, the level of the ground; O, the brickwork; P, the fire-place, which is a half circle, or arch, without any grate; I I, a space filled with dry ashes, between the lower part of the four vessel and the brickwork, in order to preserve the heat of the liquor in that part of the vessel below the surface of the ground; K, a brick hearth, on which part of the fire is made; L, a cast iron plate, bending in the form of the four kettle, which is intended to prevent the fire placed on the floor at P K, from acting upon the lead of the four vessel; Q, the space betwixt the vessel and brick-work, through which the smoke goes to the chimney.

The construction of this apparatus is upon the same principle as the warm vats made use of by the blue dyers, the intent not being to make the liquor boil, but to keep it at a degree of heat which the hand can long and easily bear. There are no grate or bars necessary in this fire-place, as the coals will burn with sufficient rapidity without them.

The goods may be put into this acid liquor either in a wet or dry state. The bell plan is to immerse the goods in the evening in the acid liquor cold, let them remain covered with it all night, then in the morning make a fire and bring the liquor to a blood heat, in which state having a winch over the vessel, similar to that represented at C, fig. 1. give the goods a few turns over it, that every part of them may be exposed to the action of the liquor. The goods may then be lapped round the winch to drain a little, to prevent an unnecessary waste of the acid liquor, and afterwards carried to the wash-wheel, or river, to be well washed from the
BLE.

the acid, so that the cloth may be perfectly tasteless to the tongue. It is a remarkable circumstance, that cloth may remain immered a very considerable time in a strong acid liquor without rotting, but that if exposed to the air or heat of a flame, if a very small portion of acidity remains in the cloth, it becomes so concentrated by heat, as to damage the cloth immediately; therefore too much attention cannot be paid to this point.

The use of the acid liquor above-mentioned is to dissolve any earthy or metallic matters inherent in the cloth, or which may have been communicated to it accidentally, or which it may have derived from the impurity of the alkaline falls used in the backing or boiling. The quantity of the acid liquor may be preserved by palling the goods which have been stripped through a tub of clear cold water, previous to washing them, and replenishing the four kettles with this acedulated liquor, rather than water only.

5th. Washing.

After every operation in which acids or alkaline substances are used in bleaching, it is necessary that the goods should be well washed in clear water; it is therefore of the greatest consequence that the water of a bleach ground should be pure, and in considerable quantities, and, for instance, as is perfectly transparent, will not curdle with soap, nor yield any degree of blackness with powdered gall nuts, or, which is a more accurate test, with a tincture of galls by infusion in spirits of wine.

Various methods have been invented for the purpose of washing out the impurities of the articles to be bleached; such as cleansing them in a large current of water by shaking them with the hand in the stream, beating them on blocks of wood with a flat paddle, or hand-brush, beating them on a large flat stone with long wooden levers, flattened underneath, passing them over winches placed above velices of water, or rivers, as fig. 1. and 3. Plate II. palling them betwixt plain or fluted rollers, as fig. 5. and 6. putting them under falling mills, or falling blocks, as fig. 7. or within wash-wheels, as fig. 1. and 2. and by many other modes, few of which are equal, and perhaps none superior, to those of which engraving is here given, for doing the business simply, equally, and with ease to the workmen; the latter point of which is of consequence to be attended to, as it will be universally found in every mechanical employment, that if the least additional labour or care is required from the workmen, however great the effect produced, prejudice or indolence will prevent their doing justice to the invention. Under these circumstances, the wash-wheel represented in Plate II. fig. 1, 3, 4, is the bell machine for general use, and the leaf liable to occasion damage to the goods. The front of the wash-wheel represented at A, fig. 4, is supposed to be eight feet diameter, exclusive of the buckets B, shown by dotted lines on its periphery, which give it motion from the water falling into them. This wheel, divided into four parts or quarters, by the strong arms projecting from the flats D, to the outer circle; in each of these separate quarters or boxes, represented by dotted lines, one or more pieces of goods which require washing, are put loosely folded together through one of the holes C, of 14 inches diameter.

Fig. 2. shews the back part of the said wash-wheel, which is made of solid planks, excepting a grate of slender iron bars marked R, which encircles the wheel underneath the separation boards or bottoms of the buckets; the use of this grating is to admit within the wheel a current of clear water from the pipe Q, When an equal number of piece goods have been introduced into each of the four divisions of the wheel by the holes, C, &c. above mentioned, a current of clear water is permitted to run through a cock from the pipe Q, against the grating R, which allows it to flow freely through into the boxes, or those parts of the wheel which contain the goods; a valve is then opened from the through P, communicating with a large reservoir or stream of water, a sufficient quantity of which is let into the inside buckets from the valve, to give the proper motion to the wash-wheel containing the goods. In every revolution of the wheel, the goods in each quarter of it are thrown twice, by the simple motion of the wheel, with great force against the arms which form the four divisions of it; viz. once in going down, and once in rising up. The ear can distinguish by the firmness of the sound when the wheel moves with proper velocity; and a greater or less quantity of water is allowed to act upon the buckets till that is attained, which usually is when the wheel makes 15 or 16 revolutions in a minute. During the whole time the wheel is in motion, the stream of clear water from the pipe Q, flows upon the goods within the wheel in every direction; and the dirty water, produced from thus washing the goods, runs out of the wheels from a number of holes bored through the wood-work near the axle, and a few made in the front near the outer circle of the wheel. Fig. 4. shews an end view of the wash-wheel, about thirty inches wide, with the manner that the bucket-work is made.

It has been found to answer equally well to make use of a greater number of wash wheels of a smaller size, as six feet diameter and two feet wide, of which several may be put in motion at once by a large water-wheel, horsies, or a steam engine.

The goods, when taken out of the wash-wheel, are to be unfolded, and taken to the river to be streamed, or may be washed from any impurities which may remain in the folds by means of a winch N, fig. 1. and 3. Plate II. where six pieces of cloth are represented in the action of washing in a large wooden box divided into six partitions, to prevent the pieces of goods entangling with each other. Fig. 1. is a side view of the operation, where the dotted lines represent the partitions which separate the goods; I. a trundle wheel, which being put in motion by the cogs, H, of the wash-wheel, turns the winch on its axle, which winch may at any time be detached from it by the handle M drawing the catch K from the hook, as is shown in the top view fig. 5. where also is explained, at the letters OOOOOO, the manner in which each piece of goods is kept in its proper place on the winch, by the partitions above mentioned, and by angular slips of wood nailed to the back and partitions.

To assist the drying of the goods after washing, they are usually passed betwixt two small rollers, commonly called squeezer, represented at fig. 5. where C is a solid wooden frame, containing two wooden rollers, each from 10 to 16 inches long, on an iron axis, which rollers receive a proper preface by means of the two screws T, acting on an iron bar V, which reaps on the two ends of the axis of the top roller, as shown by the dotted lines. In proportion as the screws press the iron bar upon the axle of the top roller, it brings that roller closer in contact with the bottom roller, and occasions more water to be pressed out of the cloth, which is passed betwixt them loosely drawn together, something like a rope, and the goods therefore require less time in the subsequent drying. In this plate the squeezer are connected with the wash-wheel above mentioned by a square iron socket, which, as is shewn at F, slides occasionally upon the figures of both axles. Fig. 4. shews at S the buckets of the wash-wheel, on which the water falls to give it motion; H, the cogs round its axle, which work the trundle wheel I.

Fig. 6. Plate II. shews two views of another machine used for cleansing cotton goods, consisting of two flinted or grooved
grooved roller, in the fiction of which $a$ represents the fills, or bottom timbers; $b$, the two supports or side pieces; $c$, one of the upright pieces in which the axes of the rollers are placed; $d$, the two crosses pieces to secure the frame work below; $e$, the two rollers with grooved channels which fit to each other; $f$, one of the levers, which, from a point $g$, drawn by dotted lines, preludes on the round end of the axle of the top roller, more or less, according as the weight $k$ is placed on the lever further from or nearer to the axis of the roller.

In the geometrical elevation of the frame machine, $e$ shows a front view of the two rollers; $f$, the winch to turn it, with a hollow wood handle upon the iron work; $g$, the axis of the upper roller projecting beyond the side timber, fo as to admit one of the levers $h$ above mentioned to preludes upon it.

The vet goods, by being passed backwards and forwards through these fluted rollers, which are constructed at such a length as the goods can be cleasted, but not so perfectly as by the wash-wheels above mentioned.

Fig. 7. Plate II. explains another mode of cleansing goods, and is applicable to cotton, linen, or woollen goods, but more generally to the two laft, as, without great care in its management, it is very apt to tear or damage cotton goods. This machinery is usually termed falling flocks, or falling hammers. No. 1. is the axe of the water-wheel, in which are fixed tappets at 2, to raise alternately the levers 3, 4, furnished with large wooden mallets or hammer heads 6, 8, channelled at the lower part as at 8. These lever hammers or fallers, work from a pin fixed in the upright at 7; 9 is a strong piece of timber hollowed out at 10, to receive the goods to be cleansed; 11, a piece of timber fixed a-fiant to keep the fallers in their proper place, and direct their motion; 12, a chain fastened to each faller, serving by means of the hook 13, to lend the faller whilst the goods are put in or taken out of the cavity 10.

When the goods to be cleansed are placed in a loose bundle in this cavity, the hammers are let down upon them, and put in motion alternately by the tappets 2, in rotation, which raise the levers to a certain height, and then quitting them, the hammer heads by their great weight, fall with great force on the goods in the cavity below them; and a current of clear water being admitted upon the goods from a cock above them, the dirty water runs out at a hole in the bottom of the cavity. The falling of the hammers gives a flow circular motion to the goods in the cavity, so as to expose the several parts in rotation to the action of the hammers.

Having noticed the vessels made use of in bleaching, and the general nature of the several operations, we shall now proceed to mention the origin of the several improvements made in this art, and their application to practice.

Under the operation of steeping, we have shewn the method of removing the colouring matters not natural to the vegetable, but acquired in the manufacture, and which may probably be best done by water alone, though sometimes some of the old leys, which have been previously used to other cloth, are employed to this purpose. After the steeping, and indeed after every application of bleaching agents, it should be laid down as a general rule, that the cloth or goods be carefully washed in cold water.

In the old method of bleaching, alkalies, such as pearl or pot-ashes, were, after steeping, applied by bucking or boiling, with the utmost exposure to the atmosphere.

Alkalies acting in this manner, and being at the same time rendered caustic, and their power materially augmented. But in order that no inconvenience may arise from causticity, after mixture, the whole is allowed to settle, and from the pure liquor thereof the work is afterwards hulled; the bleacher, in drawing it off, reducing it by the addition of water to the different strengths which the goods may require.

The ley being prepared, the bleacher proceeds to apply it to the cloth by bucking or by boiling.

In bucking, the alkaline ley is put into the boiler before described, near to and below which is the wooden vessel called a kier, in which the goods are loosely and regularly arranged. After this, fire is put under the boiler, and beginning whilst the ley is yet cold, it is made to circulate through the cloth in the kier, from which it runs into the wooden vessel placed in the ground, from this it is pumped up into the boiler, and again returned upon the cloth in the kier; and this circulation is maintained, and the heat at the same time increased, until the ley be so far concentrated by evaporation, as at half to remain almost wholly in the cloth. This is generally the operation of a day, and the cloth is allowed afterwards to remain thus impregnated with the concentrated ley until next morning.

In boiling in alkaline leys, the mode of which has been before described, the operation is continued from one hour to five or six hours, but it is more tedious and less effectual than bucking, where much buffing is to be done.

After bucking or boiling, the goods were, by the old bleaching procexes, exposed for at least a week to the air, before they were again submitted to the action of alkaline leys, and this process alternately repeated many times, till the goods were perfectly white, and the goods at last foured and washed off.

To explain the old method of bleaching more particularly, we shall add the following process for bleaching linen cloth.

Steep your raw linen cloth in a wood vessel all night, then change the water, and add fresh till you perceive the water to be no longer discoloured by it; raise, wring, and lay it on the ground, and water it if you have opportunity. When it has thus lain on the grass three or four days, and is dry, take hold of each piece one after the other by the felpvedge, and draw the cloth to you, still holding it in the most even manner you can, until you get the further end, with the corners of which further end you tie the cloth very loofly in the middle of the folds, and so lay it in the bucking tub, with two felvedges upwards.

Thus proceed till you have placed as much cloth in your tub as will cover the bottom of it, taking care not to pack the cloth so close but that your ley may penetrate every part equally. When you have laid the first range of cloth in your tub, pour upon it as much milk-warm ley as will sufficiently soak through all parts of your cloth. Then lay another range in the same manner upon the first, and pour on more ley till that be soaked as the other was, and continue so to do till your bucking tub be full of cloth.

That done, you must begin to buck for twelve hours together, the remainder of your ley having been put in the pan with a flow fire underneath. For the first five hours the ley should not be of a boiling heat; you must from time to time allow some of the ley to run out of the pan upon the cloth in the bucking tub; then increase your fire gradually and florinly, so as in four hours more to bring it to a boil, continuing to put on the ley by a little at a time, and draw it off your cloth in small quantities at a time. When your ley begins to boil, you must let it boil on for three hours, during the whole time
time pumping your ley up to the boiler from the reservoir, into which it runs from the cloth, and returning it boiling hot upon the cloth, so that the hot ley may act powerfully and equally upon every part thereof.

After each bucking your cloth must be laid upon the grafts in the bleach-field for some days. The bucking, and exposure on the ground, must be repeated about ten times successively, according to the nature of your cloth; it should then be dried up, foured, and washed well in clean water; if the water is rather warm, the better.

Your two first buckings ought to be from a strong caustic ley of pot-ashes; but afterwards you should abate of that strength, lest it should injure your cloth. Mild ley, or pearl-n, should be used for the latter buckings, as the cloth becomes nearer white.

This was the management during the summer months; but for four months in winter bleaching was suspended, the operations being periodically interrupted, and the capital of the manufacturers or proprietors of the goods locked up. Even during the bleaching months, their property was long in preparing for sale; as cotton goods, which required from four to six applications or repetitions of alkaline keys, continued so many weeks in bleaching, that linen, which could not be bleached by less than from twelve to twenty applications, could not be brought in a marketable state to the proprietor hardly in six months.

Such was the state of bleaching till Mr. Scheele, a Swede and eminent chemist, discovered the properties of oxygenated muriatic acid, procured by mixing manganese with marine acid, in rendering vegetable matter white; and M. Berthollet, the celebrated French chemist, improved this operation, and actually applied its powers in bleaching cotton goods by interpreting its action between the different alkaline operations instead of the tedious exposure of the goods to an uncertain atmosphere; the same effect being produced by immersion of the cloth in this acid, as by laying the goods upon the grafts in the bleach-field, exposed to air and light.

Discovery of and Variations in the Mode of procuring the Oxygenated Muriatic Acid.

By the addition of vitriolic acid to common salt, an eaf- tic aeriform fluid, or muriatic gas, is difengaged, from which with water a marine acid is produced. The mineral substance manganese, or what the modern chemists call oxv of manganese, contains what was formerly denominated vital air, pure air, or dephlogisticated air, but now named oxygen. Manganese yields oxygen, when marine acid is added to it, and submitted to distillation; the liquor produced by the contact of this oxygen with water, is the oxygenated marine or muriatic acid discovered by Mr. Scheele, about the year 1774, when he observed and applied its effects in rendering colourless vegetable substan
ces of various kinds. More as a matter of curiosity than anything else, it was used for bleaching the wool. M. Berthollet, in the year 1786, improved the process of its preparation, applied its power to bleaching or destroying the vegetable colours natural to cloth, the result of which experiments he gave to the world in the year 1789; but, without derogating from the merit of this excellent chemist, it is justice to state, that, previous to any publication by M. Berthollet, Mr. Scheele communicated to Mr. Kirwan the properties of the dephlogisticated marine acid in whitening vegetable substan
ces, and Mr. Kirwan, then refiding in Newman-Street, London, suggested to Mr. C. Taylor, the present secretary to the Society of Arts, &c. the probability of its use in bleaching; and a whole piece of calico, in the state received from the boom, was, in the spring of 1788, actually bleached white, printed in permanent co-
lours, and produced in the Manchester market ready for sale, having undergone all these operations in less than 48 hours, by the joint efforts of Mr. Cooper, Mr. Baker, and Mr. Taylor, which is perhaps the first entire piece, either in France or England, that fully ascertained the real merits of the new mode of bleaching, and a certainty that it might be generally useful in commerce. This experiment was imme-
diately followed by the establishment of a large bleaching concern by Mr. Cooper, Mr. Baker, and Mr. Horridge, at Raikes, near Bolton, in Lancashire, and before any con-
derable bleaching work was actually at work in France.

The ingenious Mr. Watt we believe to be the first person who simplified the procress of preparing the oxygenated muriatic acid, by means of a mixture of common salt and man-
ganeef, previous to the addition of the vitriolic acid. Soon afterwards the operations of the bleachers were further facilitated by the substitution of large and commodious flills of lead, instead of glass vessels, and both these improvements have since been in general use.

We shall now proceed to mark the various treatment of the oxygenated muriatic acid when obtained, and the different methods which have been adopted to fit it for application in bleaching.

It having been found in the earlier stages of distillation that common marine acid was produced instead of the dephlogisticated or oxygenated muriatic acid; and from the violence of the ebullition, that manganese itself was sometimes thrown over from the still, M. Berthollet had recourse to an intermediate vessel, containing water, to absorb the marine acid gas, and stop other impurities which might contaminate the oxygenated muriatic acid in its passage through this vessel to the receiver.

It will here be necessary to discriminate the various modes in which the oxygenated muriatic acid has been treated, after passing the intermediate vessel last mentioned.

Mr. Scheele seems generally to have operated with the acid in the state of gas; but M. Berthollet thought of condensing it in water, with which he filled his receiver, or wooden vessel, and which water he kept agitated during the distillation, to accelerate the solution or combination of the gas.

The oxygenated muriatic acid, thus prepared, was drawn from the receiver into kiers, or large wooden vessels, where its strength was regulated by the addition of water; after which, the goods to be bleached were immersed therein from fix to twelve hours, but most frequently during the night; and though these periods may seem short, they were sufficient to allow the cloth to become more white than could be done by as many days’ exposure to the atmosphere and a summer’s sun, and were then ready for a fresh application of the alkaline keys.

Such was the bleaching liquor of M. Berthollet; but it was found in practice yet defective, as the volatility of the gas occasioned its speedy evaporation from the aqueous solu-
tion; a decomposition even by light alone in glass vessels took place; a rapid loss in the strength of the liquor when exposed; and much danger to the health of the workmen from its suffocating quality; at the same time, that in ex-
tracting the natural colours of the cloth, it also tended to discharge the colours dyed in the yarn, and were along with the gray cotton an imperfection which precluded its use in an infinite variety of British manufactures.

Similar circumstances probably led some bleachers resident at Javelle, in France, to add a solution of caustic alkali to the water in the receiver, and by this means to remedy many of the defects complained of.

But M. Berthollet continued to recommend his processes, confiding such substance as impairing the bleaching powers;
BLE

An idea that was generally maintained by the chemists, but contradicted by the bleachers, whose experience taught them, that though the acid thus combined whitened with some what less rapidity, yet it was not eventually in an inferior extent; and the advantages of preferring the colours dyed in the yarn, compelled them to have recourse to the expensive addition of pot-alkys, in preference to M. Berthollet's mode.

Here we shall observe, that, according to the doctrine of the modern chemists, the oxygenated muriatic acid bleaches in consequence of yielding to the colouring matter of the cloth that oxygen which, in the diffusion, the acid absorbed from the manganee; or, in the language of Stahl and Becher, that the dephlogisticated marine acid absorbed the colouring matter from the cloth, and was restored to its original state of common marine acid, by regaining that phlogiston which it had, in its preparation, yielded to the manganee.

In the mixture of an alkali with the acid, we have noticed that the bad consequence arising from its volatility have been corrected, and the requisite protection afforded to dyed colours; yet still that its power of whitening cloth was not diminished, nor much more time taken up by the operation; yet, in part, from deference to M. Berthollet's opinion, and in part owing to the expence of the alkali, other means to produce the effect were attempted.

One of the first of these, practised by the bleachers of cotton-hose, at Nottingham, was to receive the dephlogisticated muriatic gas into a small air-tight chamber, in the upper part of which the goods were suspended from a frame, whilst at some distance below was water, sometimes impregnated with ley of pot-alky, and sometimes with lime-water, or water mixed with lime. The gas was introduced betwixt the fluid and the goods, amongst which it ascended and mixed; at the same time, by occasionally immersing the goods in the fluid below, it was sought to modify the action of the acid. This was effected by means of a pole, or long lever, connected with the frame on which the goods were suspended, the centre of which pole moved on a swivel fixed in a hole in the partition, occasionally stopped with clay, and enabled a person to let the goods down into the fluid, not always however without inconvenience, which occasioned it the name of the Bedlam Process.

Respecting the above processes it must be observed, that the acid is much more powerful or active in the state of gas than in any other way; and though the occasional immersing of the goods into the fluid below, connected in some degree its violent effects, yet the dyed colours disappeared more rapidly in this than in any other process, and the fabric itself was sometimes injured.

The next process attempted by the bleachers, was to put into the receiver, filled with water, a quantity of pulverized lime, then the goods themselves, and the whole agitated during the admixture of the gas; the consequence of which was, that the goods thus mixed with lime were partially coated with it; and this coating being unequal, the action of the acid upon it was irregular, leaving at the same time the parts uncoated to receive the whole action of the bleaching powers; hence inequality of bleaching ensued, and an insurmountable difficulty in preserving the dyed colours of the goods to be bleached.

Having noticed the imperfections of the two last processes, we shall observe that lime-water, or a pure chemical solution of lime in water, has been sometimes substituted instead of a solution of alkalis in the receiver, but was not, when used in that manner, found to answer so well as the alkaline solution.

Vol. IV.

BLE

That lime-water could produce no valuable effect beyond what was derived from M. Berthollet's mode, or from simple water, must be evident, when it is considered that water can diffuse no more than 4/5th part of its weight of lime, a quantity wholly insufficient in neutralizing the oxygenated muriatic acid for the purpose of the bleacher; nor could pulverized lime, merely thrown into the water of the receiver, serve a better purpose, since, from its being specifically heavier than the water, all beyond the quantity in chemical solution diffused and remained nearly useless at the bottom of the receiver.

It has been already mentioned, in noticing the application of alkaline leys in bleaching, that the more intelligent bleachers, in preparing their alkali-leys, made use of quicklime to augment the power of the alkali, when such alkali was in a mild state, or, in other words, combined with fixed air, or, as it is now termed, carbonic acid; the attraction of caustic lime for the carbénie acid being stronger than that of ashes. Hence, on caustic lime being thrown into mild alkali-ley, the carbonic acid, by which the ashes were rendered mild, abandons the alkali to combine with the lime, leaving the ashes in their caustic state.

But, although the attraction of carbonic acid is stronger for lime than for alkali, the operation is the same with the oxygenated muriatic acid, as it abandons the lime to combine with ashes, leaving the lime to precipitate.

This observation is made in order to guard the ignorant bleacher from mistakes, who, from having mixed lime with his alkali-ley in the receiver, in the preparation of the oxygenated muriatic acid, may suppose its acts in a similar manner; but not a particle of lime is acted upon by the acid, whilst ashes remain to combine with it; the only effect of the lime there, being to subtract from the ashes any fixed air they may contain, and so dispose the alkali to absorb more of the oxygenated muriatic acid.

Besides the processes above mentioned, the bleachers attempted to unite the oxygenated muriatic acid with clay; but as the clay has scarcely any affinity with it, the liquor thus made was little, if at all, superior to that of M. Berthollet.

Such were the attempts made from the year 1785; and the oxygenated muriatic acid combined with pot-alky was in general use by the bleacher until 1793, when Mr. Tennant, of Glasgow, by a well-conducted series of experiments, formed what may not improperly be called a new era in bleaching.

Mr. Tennant, having seen so long a period elapse without any material improvement in bleaching, and the alkali, though an expensive ingredient, regarded by the bleacher as an indispensable article to unite with the oxygenated muriatic acid in the receiver, made some trials with the earths, from which barytes and barytes, and with success. Their solubility in water enabled him to combine them with a sufficient quantity of oxygenated muriatic acid to serve the purpose; but the scarcity of barytes, and the difficulty of separating barytes from the vitriolic acid, with which it is usually found in combination, rendered these discoveries rather objects of curiosity than use.

Mr. Tennant had previously made experiments to combine the oxygenated muriatic acid with lime and lime-water, in the modes above-mentioned; but found they were not adequate to the purposes intended; the lime in general remaining at the bottom of the receiver uncombined with the gas, which was the necessary consequence of the lime being specifically heavier than the water, and the gas much lighter; the water, by its interposition betwixt the two substances which ought to be combined, namely the oxygenated muriatic gas and the lime, preventing their union. To bring the pulverized lime into contact with the gas as quickly as
it entered the receiver, became then the object of his attention; and for this purpose he found it was necessary to keep the lime floating, or diffused through the fluid, which he succeeded in accomplishing by two different methods; one of which was by increasing the specific gravity of the water in the receiver, by the addition of common salt, and thus regarding the lime from subsiding; the other mode was by constant agitation of the lime in the water in the receiver, to keep the lime diffused through the fluid, during the time the oxygenated muriatic gas was introduced; and by this means he succeeded in uniting and retaining a much greater quantity of gas with the mixture, than by any method heretofore used, and without the addition of any ashes or alkaline fulmines.

A very material advantage was gained by this discovery; namely, that it uniformly afforded security to the dyed colours in a superior degree to the alkaline ley.

It is well known, that in the alkaline of commerce, such as pot-ash or pearl-ash, a large and very irregular proportion of neutral salts is intermixed, which are soluble along with the alkalies in water, whereby far more contaminating the ley, that the bleacher is always uncertain what quantity of pure and active alkalies it contains. In buckering or boiling cotton goods, the detriment from these neutral salts is not so great, as a repetition of the process may compensate for those admixtures in the ley; but in the bleaching liquor formed by the mixture of the oxygenated muriatic gas with such ley, if there is a deficiency of alkalies, the uncombined oxymuriatic acid immediately attacks the dyed colours of the goods, and discharges them; and thus considerable damage frequently occurs before the real origin of the evil is ascertained and corrected. The bleacher is kept in a constant state of alarm respecting the quality of the ashes he makes use of, besides the great coot of their purchase. In using lime for the same purpose, the expense is a mere trifle; what is not combined with the oxymuriatic acid precipitates, after the agitation is over, leaving a pure liquor free from all uncombined acid.

Simple as the combination of the lime with the oxygenated muriatic acid may now appear, yet it was a long time attempted in vain; but this, perhaps, will not be so much a matter of surprise, when we reflect that the French chemists, whose opinions were regarded generally as law by the common bleachers, and whose treatises on the subject of bleaching were almost the only accounts published, considered lime as no further useful in bleaching, than in absofbing the carbonic acid or fixed air usually combined with alkalies or ashes; and thus rendering the alkaline ley more disposed to unite with the oxygenated muriatic gas, when exposed to its contact in the receiver, to form, as it is called, the liquor de Javelle; or, when intended for use as a mere alkaline ley, to render its action more powerful on the oily particles in the vegetable fibre, on a similar principle to the formation of soap.

An excellent treatise on the subject of bleaching, in the English language, viz. The Report on Experiments made by order of the right honourable the trustees of the linen and hemp manufactories, to ascertain the comparative merits of specimens of oxygenated muriatic bleaching liquors, published at Dublin in the year 1791, in claim of a bounty offered by the trustees, appears to convey no further knowledge of the use of lime in bleaching at that time, than in promoting the separation of the carbolic acid from the ley, whether they were afterwards to be used alone, or in the preparation of the oxygenated muriatic acid. Mr. Roff's experiments in this report contain, however, much useful information, which we shall further notice.

The simplicity of Mr. Tennant's invention of retaining a greater quantity of the oxygenated muriatic gas, by agitation of a sufficiency of lime in the water of the receiver, should be no derogation to its real merit. In substituting lime for pot-ash, an article, not only of foreign produce, but expensive, he has benefited this country to an extent almost beyond conception; it having been proved upon oath, that by the use of Mr. Tennant's process, the consumption of ashes at a single bleaching-green has been reduced three thousand pounds férder in value in one year. A patent for Mr. Tennant's invention was granted him in the year 1798; but, as frequently happens in patent cases, on a late trial of its validity, some circumstances arose, from which the jury thought themselves justified in reverting the patent; we have therefore, with considerable pains, collected for the public benefit an account of his process, and the most approved mode of putting it in practice, either on a small or an extensive scale, as will be seen by a reference to Plate I. of Bleaching hereafter described.

Mr. Tennant's method of using calcaceous earth for neutralizing the muriatic acid gas, and forming the oxy-muriatic of lime employed in bleaching, is as follows; viz.—In a receiver capable of containing one hundred and forty gallons wine measure, diffuse thirty pounds of common salt, which appear useful only in giving an additional degree of specific gravity to the water, and by that means making it easier to keep the lime to be afterwards added, in suspension; when this salt is dissolved, add sixty pounds of finely powdered quicklime, and into the retort of the apparatus put thirty pounds of powdered manganese, mixed up with thirty pounds of common salt, upon which pour thirty pounds of sulphuric acid (oil of vitriol), previously diluted with its bulk of water, and the usual precaution of letting the reflex be taken, proceed to distillation. When the gas begins to appear, the agitation of the lime and water in the receiver must commence, which should be continued by means of a wooden paddle or rake, or similar contrivance, without intermission, until the materials in the retort, after heat being employed as usual, will not yield any more oxygenated muriatic acid gas. Then the whole should be allowed to remain at rest for two or three hours, when the clear liquor in the receiver may be drawn off for use, and mixed with water in such proportions as may be found necessary, previous to the immense lion of the goods to be bleached.

The principal point of attention in preparing this oxygenated muriatic of lime is, to obtain a complete diffusion of the lime through the mixture, or a mechanical interpenetration of it in the water during the operation, so that every particle of the lime may, by agitation, be exposed to the action of the gas, instead of merely its upper surface, as had been formerly practiced. By the present means, the oxygenated muriatic acid gas is absorbed with ease, and meets with a sufficient quantity of lime to produce a strong solution of oxygenated muriatic of lime, without any uncombined oxygenated muriatic acid; a thing which could not be otherwise effected. The addition of the common salt in the receiver may even be omitted, without prejudice, if the agitation of the lime be well managed.

Plate I. fig. 2. of Bleaching, shews a longitudinal section of a method, which has been practiced in Ireland for distillation of the oxygenated muriatic acid, and the formation of the oxygenated muriatic of lime. a, the ash-hole; b, the fire under the iron pot or vessel; c, the aperture through which it is supplied with coals; d, the entrance to the ash hole, which may be provided with a flopper of burnt clay, or earthen ware, to regulate the draught of the fire, by means of the handle shown by dotted lines; e, a cast-iron pot or vessel.
wessel, nearly filled with water, in which the leaden retort is placed; ½, a tripod of iron, on which the retort stands; ½, the leaden retort, from which the gas is to be diffused; ½, a tunnel of bent lead, through which the gas of vitriol (sulphuric acid) is to be introduced into the retort; ½, a leaden cover, fitted and luted to the neck of the retort, having three apertures, viz. for the introduction of the tunnel, the rod of the agitator, and the tube of the condenser; ½, the agitator, formed of a rod of iron coated with lead, having some arms at its lower end to stir the materials within the retort. At the part where the rod passes through the cover, a leaden collar or cap is fitted, to prevent the agitator from descending too low; these two parts are made in a conical form, to fit exactly, and thus prevent the escape of the gas; ½, a leaden tube or pipe, of three inches bore, to conduct the gas into the tubed lead retort; ½, the lead retort, formed upon the principle of Wolfe’s apparatus; the tube, ½, divides by the first aperture, ½, to the bottom of the retort, which is about three feet high.

The small portion of sulphuric acid, which rises in distillation, unites with the water; the oxygenated muriatic acid, which traverses this water, passes by the pipe, ½, into the receiver or condenser, ½, which is a wooden vessel, in the middle of which is placed an agitator, ½, the arms of which rising up the lime cause it to combine with the gas, in proportion as it arises in bubbles from the lower extremity of the leaden pipe, ½.

The projections of wood, oubles, fixed to the flanges within the tub, counteract the rotatory motion of the arms of the agitator, and thus affl the combination of the gas with the lime and water. The cover of this tub is fixed close upon the edge of it at ½; the cover having a groove in it to unite them together; ½, a cock to draw off the liquor, when sufficiently impregnated for use; ½, a wooden handle to give motion to the agitator. The joints may be luted with clay, to prevent the escape of the gas.

Fig. 3, and 4, shew Mr. Tenant’s improved machinery for preparing the oxy-muriatic of lime. The outline, A, (fig. 3) is the still, made of lead, of a circular form, having a double flange at the top, which is filled with water, to prevent the gas from escaping in that direction. B, the leaden cover of the still, having a flange on the under side, which goes into the double flange of the still, and having a dome flange on the upper side, which is filled with water; the inner part of this double flange consists of a short tube, which goes quite through the cover, opening by this means a communication with the still, and allowing the gas to escape through the long lead pipe inflected into it, and thence into the receiver, as explained at fig. 4, where there is a section of the still, furnace, and receiver; ½, the still; ½, an iron pan in which the still is placed on an iron stand; this pan is then nearly filled with water; ½, the fire-place; ½, the furnace door; ½, the ash-hole; ½, double flange filled with water; ½, the cover, with flanges on the upper side filled with water. D, the receiver, made of wood, and lined with lead; ½, a double flange filled with water, the interior pipe communicating with the inside of the receiver, and bent horizontally as at ½, from whence the gas issues into the receiver; ½, two short pipes inflected in the top of the receiver, through which the rods of the agitators have a free motion; ½, ½, a stopper in the top of the receiver, closed when the receiver is at work, but sufficiently large, if removed, to admit a person into the inside to repair or cleanse it, when necessary; ½, ½, two paddles, or agitators, generally of a square form, and of a similar construction to the head of a churn half; ½, ½, the rods of the agitators attached by iron pins to the lever, ½, which lever has balls at the place of junction, to allow the rods to rise and fall perpendicularly; ½, the fulcrum or support of the lever; ½, the lever, which, by a proper motion communicated to it, alternately raises and depresses the agitators in the receiver; ½, a rod connecting the lever, ½, with the lever, ½, which latter lever is put in motion by the wheel E; ½, a balance weight placed at the other end of the lever; the beam supporting the fulcrum of the lever being near the letter E. E, the wheel to be put in motion by water, or in any other way, having a crank, ½, communicating by an upright shaft with the lever ½.

It will be found that the flanges, filled with water, preclude the necessity of the application of any lute, and occasion the operation to be conducted in a cleaner, cheaper, and more expeditious mode, than formerly employed.

To describe the proportions of the several articles used in the process of bleaching, would carry us far beyond the bounds which can be allotted in the present publication; we shall, therefore, give the following short but clear account of the mode we recommend to be practiced, to procure the most perfect and durable white on cotton goods, after their being taken from the water; which is, first, to wet them thoroughly in cold water; then to allow them to steep in cold, or lukewarm water, from 12 to 36 hours, according as they are of a strong or thin fabric; then to wash them well in cold clean water; afterwards to buck or boil them in a caustic alkaline leys; then to wash the goods well in clean water, and afterwards immerse them in diluted oxymuriatic of lime, and wash them, repeating the operations of the alkaline leys, and the oxide of lime; till the goods are perfectly white; then to pass the goods through the diluted sulphuric acid liquor, washing them well afterwards: lastly, to pass them through a weak ley of pearl-ashes, or of soap, and again through clean water, before drying and finishing them; which finishing of the goods consists in bleaching, bluing, rolling, or callendering them as fashion directs, or the particular market for which they are intended, may require.

It is to be remarked, that the immersion of the goods in the vitriolic fours, and also in pearl-ashes, or soap liquor, is necessary at the end of the process, to prevent a brown hue which the clothes that are bleached white from the oxygenated muriatic acid, without such precaution, are apt to revert to.

By experiments made at Rouen on cotton thread, with a view to ascertain whether the old or new mode of bleaching was more prejudicial to the fabric, it was proved that the cotton thread bleached in the new mode was, without breaking, considerably more weight than that bleached in the old method, and was less injured in texture.

In the report on experiments, made by order of the trustees of the linen and hempen manufactures at Dublin, in the year 1791, with a view to ascertain the comparative merits of several speciments of bleaching liquids sent for their examination, the following mode of bleaching appeared to be the best for linens, and though executed on a small scale, will convey the principal necessary information.

May 11th, 1791. The linen was dipped, in the flate received from the loom, into water of a heat sufficient to bear the hand, and left in the vellit.

May 16th. The linen was washed out of the liquor, in which a pretty strong fermentation was observed to have taken place.

May 17th. Finished making a mother-ley, which was made in the following manner: three pounds and a half of lime were flaked, and mixed with ten gallons of water; fourteen pounds of Dantzic pearl-ash were dissolved in some of this water; then mixed the whole; when it had settled, it was
was filtered through a coarse cloth, and the residuum washed repeatedly in four gallons of water, to obtain the whole strength of the alkali; the whole fourteen gallons being then carefully mixed, the ley proved, by very accurate weighing, to contain twelve ounces of caustic alkaline salt to the gallon. From this, a ley was made from the work, by adding five parts of water to one of the mother-ley; thus each gallon of the working ley contained one ounce, five drachms, and forty-three grains of caustic alkali.

The boiler being charged with this ley, the linen, which had been flatly washed, was steeped in it cold for one hour; then brought up by a very gentle heat to a simmering boil, which was continued for three hours; the cloth was then well washed out, and left in steep for that night.

May 18th. Washed out the above linen in fresh water; hung it on cards in the open air, watering it several times in the day.

May 19th. Finding the cloth not so well cleared as could be wished, the boiler was again charged with one of mother-ley, to four of water, which made the strength two ounces, three drachms, twelve grains of caustic alkali to the gallon. In this was boiled another piece of linen which had been flat washed as the others; and after it was boiled, it was well washed out.

May 20th. Steeped the whole of the linens for five hours in the liquid prepared with the oxymuriatic acid of the several claimants; afterwards washed them well out, and left them steeping in cold water all night.

May 21st. Washed out all the above linens, and when dry, boiled the whole parcel as before in one of the mother-leys, to five of water, containing two ounces of caustic alkaline salt to the gallon; washed them well out of the ley, and left them to steep in pure water till Monday morning, the 24th instant.

May 24th. Steeped the linens for the second time in the oxymuriatic acid for five hours; then washed them out, and left them to steep all night in cold water.

May 25th. Having charged the copper with a ley made from one of mother-ley, to fix of water, containing one ounce, five drachms, and forty-three grains of caustic alkali, all of which was boiled in this for the third time, with a very gentle simmering heat for three hours; they were then washed out, and left to steep.

May 27th. Steeped all the linens for the third time five hours in oxymuriatic acid as before; washed them out, and left them in water all night.

May 28th. Immerged all the linens which had been steeped yesterday in the oxymuriatic acid, in a weak vitriolic acid for four hours; then washed them out, and left them steeping in cold water.

May 29th. Washed and dried the linen cloth which had been fouled yesterday.

June 1st. Boiled all the linen which had been fouled in a strong lather of soap.

June 2d. Soared and washed out all the linen which had been boiled in a soap lather yesterday. This operation finished that experiment, in which the above linens were first steeped in water; then boiled in caustic alkaline ley, and steeped in oxymuriatic acid alternately four times; then foured in vitriolic acid, foamed and foured again.

The above experiments were made, with various others, by Mr. John Arbuthnot, and Mr. John Clarke; and on the trials of the different specimens of the oxymuriatic acid, the preference was given to that prepared by Mr. Robert Roe, of Bing's End, on the principle of the javel liquor mentioned by Mr. Bartholomew, by adding a solution of alkali in water in the receiver. Mr. Roe's boil prepara-

...
HOURS: at the end of which time, any common salt it contains will be found crystallized in regular cubes at the bottom of the vessel; pour off the clear liquor, and repeat the process, till no more cubic crystals are produced. If it is desired to be very accurate in the analysis, before the common salt (muriate of soda) thus procured is weighed, some muriatic acid may be poured upon it, in order to take up any of the pure pot-ash which may have adhered during its crystallization. The muriatic acid, with such of the alkali as it has dissolved, may be then drained off and thrown away, and the muriate of soda dried and weighed.

The sum of the impurities being then subtracted from the weight of the specimen, the quantity of the pure pot-ash is ascertained.

To show what quantity of mere alkali is contained in 100th. avoirdupois of several different alkaline salts examined by Mr. Kirwan, we shall add the following table, published by him in the Irish Transactions, in 1789.

It is much to be regretted, that confining the immense quantities of pure marine alkali which could be procured at a cheap rate from the East Indies, that so little attention should be paid by the East India Company to an article which would be so profitable a branch of commerce to them, and prevent a considerable sum being paid to other nations. The mineral alkali procured from the East Indies, is much purer than what is obtained from Barilla; and a preparation exactly similar in appearance and quality to the Alicant Barilla, may be made with great advantage to the manufacturer, from a mixture of the East India mineral alkali with the common Scotch kelp, for the purposes of the bleacher, the soap maker, or the Turkey-red dyer. To shew the importance of this object, the following table of the imports into Great Britain are annexed for seven years.

When it is considered that 20 pounds of the mineral alkali brought from India in a powder'd state, as it usually is, will, by mere flection in water, yield 1500 lbs. of the crystallized soda; if the soaps of the alkali are dried in the fiery, it will be seen, that the purbahe of the mineral alkali from the East India company, will be an object well deserving the attention of the bleachers and soap-boilers; and far preferable to the use of Spanish kelp or Barilla.

Mr. Kirwan, by means of muriatic acid, precipitated the colouring matter from an alkaline ley, saturated with the colouring matter of linen yarn, and found it to possess the following properties. When suffered to dry for some time on a filter, it assumed a dark green colour, and felt somewhat clammy, like moist clay. His observations in the Irish Transactions for 1789, are as follow:

"I took, says he, a small portion of it, and added to it 60 times its weight of boiling water, but not a particle of it was dissolved. The remainder I dried in a sand-heat; it then assumed a shining black colour; became more brittle, but internally remained of a greenish yellow, and weighed one ounce and a half."

"By treating eight quarts more of the saturated ley in the same manner, I obtained a further quantity of the greenish deposit, on which I made the following experiments:

18. Having digested a portion of it in rectified spirits of wine, it communicated to it a reddish hue, and was, in a great measure, dissolved; but by the action of distilled water, the solution became milky, and a white deposit was gradually formed; the black matter dissolved in the same manner.

20. Neither the green nor the black matter was soluble in oil of turpentine or linseed oil, by a long continued digestion.

3. The black matter being placed on a red hot iron, burned with a yellow flame and black smoke, leaving a coaly residuum.

4. The green matter being put into the vitriolic, marine and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the latter, but did not seem at all diminished.

"Hence, it appears, that the matter extracted by alkalis from linen yarn, is a peculiar sort of resin, different from pure resins only by its insolubility in essential oils, and in this respect resembling lacs. I have proceeded to examine the powers of the different alkalies on this substance, eight grains of it being digested in a solution of crystallized mineral alkali, saturated in the temperature of 60°, instantly communicated to the solution a dark brown colour; two measures (each of which would contain eleven pennyweights of water), did not entirely dissolve this substance. Two measures of the mild vegetable alkali dissolved the whole."

"One measure of caustic mineral alkali, whose specific gravity was 1.053, dissolved nearly the whole, leaving only a white residuum."

"One measure of caustic vegetable alkali, whose specific gravity was 1.335, dissolved the whole."

"One measure of liver of sulphur, whose specific gravity was 1.170, dissolved the whole."

"One measure of caustic volatile alkali dissolved also a portion of this matter."

The colouring matter of cotton is much more soluble in alkali, than that of linen: hence the greater facility with which cotton is bleached.

The theory of bleaching vegetable matter, as we have before observed to have been deferred by Mr. Delaval, depends on removing the colouring matters, whether natural or accidental, which cover their solid fibrous parts, which are the only parts endowed with a reflective power.

Raw cotton or linen, boiled in a diluted solution of caustic alkali, gives to the liquor a deep brown colour, and destroys its colorability; and fresh portions of clear ley applied a second or third time, will produce a similar effect, but in an inferior degree. If the cotton or linen be now plunged into the oxymuriatic acid, and allowed to remain a short time, they will become white; and if they are then plunged into an alkaline ley, the liquor will again become brown, and lose its colorability.

On saturating either the frith or leaft of the alkaline solutions with an acid, a similar precipitate is obtained from each, of a dark coloured matter, almost insoluble in water, but soluble in caustic alkali.

Hence.
In this apparent, that after raw cotton or linen has been acted upon by alkalis for two or three times, they have no further effect upon it, till the cloth comes in contact with oxygen or pure air, either by immersion in the oxygenated muriatic acid, or by exposure to the atmosphere; and it is on account of the speedy action of the acid, in comparison with that of the atmosphere, that the new mode of bleaching is now generally adopted.

M. Berthollet, and the modern chemists suppose, that the colouring matter of linen is composed principally of carbon and hydrogen; and they conclude, that linen, bleached by the oxygenated acid, becomes yellow, on this principle, that when the oxygenated acid renders linen white, a quantity of oxygen has combined with the colouring particles; but that this oxygen gradually enters into a combination with the hydrogen, and forms water which paffes off; that then the carbon becomes predominant, and the linen, in consequence, assumes a yellow colour.

The old chemists, on the principles of Stahl, would say, that a part of the dephlogisticated marine acid, (oxymuriatic acid,) after the cloth had been acted upon by the alkali, absorbed such phlogistic colouring matter from the cloth, as the alkali had no affinity for; and thus became diluted common marine acid, which has a great attraction for cotton or linen, and, if exposed to a moderate heat, will act upon the texture of the cloth, and render it of a yellow colour.

We notice this circumstance in two different points of view, that the bleacher may be aware of the necessity of applying, in either cafe, a weak key of pearl-ash, ultimately after the use of the muriatic acid, to prevent this yellowness from occurring; and also that the reader may comprehend the reasoning of Home, and other perfons who have written upon the subject of bleaching, previous to Mr. Scheele's discovery.

To recover the pure alkali from the black coloured leys which have been used in bleaching, and to render them equally proper for the same purpose, has been for a considerable time a material object in the neighbourhood of Manchester, and practised with great success.

To effect this, the black or brown brown leys, which have been left after bucking linen, or cotton yarn, or goods, orfaved after wringing them, is put into an oblong flat shallow iron pan, made of plate-iron, rivetted together. (See Plate IV. fig. 4. 5.) Under this pan a fire is made, and the old leys gradually evaporated, till they become of a confence nearly resembling tar; the matter is then put into cakes, and carried to the reverberatory furnace, Plate IV. fig. 6. 7, where it is laded or poured into the cavity or bed within the furnace; the fire being then made, acts powerfully on the alkaline mafs; gradually dries the water left amongst it; then acts on the colouring matter the key has abstracted from the cloth, which is partly dissipated in a black, offensive smoke, and partly destroyed by combustion; the calcination of the ashes is affisted from time to time, by taking them up with a long iron rod, in order to exp accelerate the flame to the heat is continued and increased till the inflammable matter amongst the alkali is dissipated, and the ashes brought to a perfect fluid state; they are then let out by an aperture in the side of the furnace, into an old iron pot put into the ground, and when cold, broken into small pieces for use, being frequently in a purer state when first imported.

Fig. 4. Plate IV. is a section of the evaporating pan for the waste leys, where A represents a flat iron pan, of an oblong square form, about six inches deep, and of a size proportionate to the quantity of leys to be evaporated; B, the fire-place; C, the ash-hole; D, the flue in which the fire as under the pan; E, the chimney for the smoke; F, the brick work.

Fig. 5. Plate IV. is a bird's eye view of the same evaporating pan, which is made of plates of beaten iron rivetted together, as shewn in the plan; the fire-place underneath it is marked by dotted lines at B, and the chimney flue at E.

Fig. 6. Plate IV. represents a longitudinal section of the reverberatory furnace used in the preparation of ashes, or solid alkaline salts from the old leys after evaporation, to a proper consistence; a, the brick work; b, the ash-hole; c, a channel, or passage under the furnace, to admit a free current of air; d, the fire-grate; e, the fire-place; f, the inner part of the furnace; g, the bed of fire-proof brick, on which the matter is calcined; h, the alkaline key to be calcined; i, a door through which the fire is introduced by an iron tacle into the furnace, and through which door the matter, during calcination, is filled from time to time; k, the passage for the smoke, or chimney, which chimney should be from 20 to 30 feet high; l, the upper part of the furnace, arched like an oven; n, the reinforcement between the fire and matter to be fluxed or calcined.

Fig. 7. Plate IV. represents the upper plan of the furnace, of which fig. 6. is a section; a, the outer wall; b, the ash-hole and draught-hole; c, the iron grate of the fire-place; g, the bason in which the leys are calcined; m, the door through which the coal is thrown into the fire-place; n, an iron tube through which the ashes in fusion flow out of the furnace when sufficiently calcined; o, an iron pot into which the melted ashes flow, and where they are suffered to cool; p, a wall of fire-brick between the fire-place and bason, over which wall the fire paffes; r, the flues leading down to the ash-hole.

It is necessary to remark, that all the interior part of the reverberatory furnace should be made of Welsh brick, or such as will withstand the action of a strong fire; the whole building should be well bound together by iron bars, or cramps. If so constructed, it will last for several years; and when it then needs repair, the ashes, which will be found accumulated in the interstices of the brick-work, will defray the expense of such repairs.

Having shewn the methods generally used in bleaching linen and cotton, we shall now proceed to the discovery heretofore, viz. Mr. W. Higgins of Dublin, for the sulphur and lime, as a substitute for pot-ash in bleaching. The sulphur is prepared in the manner following, viz. sulphuret or brimstone in fine powder, four pounds; lime well slaked and fluid, twenty pounds; water sixteen gallons; these are all to be well mixed, and boiled for about half an hour in an iron vessel, straining them briskly from time to time. Soon after the agitation of boiling is over, the solution of sulphuret of lime clears, and may be drawn off free from the precipitate, which is considerable, and which rests upon the bottom of the boiler. The liquor, in this state, is nearly of the colour of small beer, but not quite so transparent.

Sixteen gallons of water are afterwards to be poured upon the remaining precipitate in the boiler, in order to separate the whole of the sulphuret of lime; the matter is then well agitated and mixed, when settled, be drawn off, and mixed with the first liquor; to these again thirty-three gallons more of water may be added, which reduce the liquor to a proper standard for steeping the cloth.

Though either lime or sulphur, separately, are very little soluble in water, yet this sulphuret of lime is highly soluble.

This preparation has been applied, in the following manner, to the bleaching of linen in Ireland.
The linen, as it comes from the loom, is charged with the weaver's paute or dreffing, to discharge which, the linen must be steeped in water for about 48 hours, and afterwards taken out and well washed; in order to separate the religious matter inherent in the vegetable fibre, the linen must then be steeped in the cold solution of sulphate of lime (prepared as above), for about 12 or 18 hours; then taken out and well washed; when dry, it is to be steeped in the oxymuriate of lime, prepared by Mr. Tennant's process, for 12 or 14 hours, and then washed and dried. This process is to be repeated by six alternate immersions in each liquor, which are sufficient to whiten the linen.

Though we must confess, that we have some doubts respecting the application of sulphate of lime to superde the use of ashes, in bleaching goods intended to remain perfectly white, yet we think it incumbent upon us to state, that for goods previously bleached for dying, it possesses advantages over those where alkalies have been used, and which has been actually proved above 50 years ago, by the practice of Mr. Peter Henry Otterfen, communicated by him to the late Mr. John Wilson, of Ainfworth, near Manchester. Mr. Wilson's memory deferves every mark of respecting from the cotton manufacturers of England, for his numerous improvements in the bleaching, dying, and finishing of cotton goods.

For the ufe of private families, where the linen is dirtied by perspiration or grease, it will be of great service towards rendering it white, to steep it for some time in a clear liquor, made by mixing one quart of quicklime in ten gallons of water, letting the mixture stand 24 hours, and then using the clear water drawn from the lime. After the linen has been steeped in this liquor, it should be washed as usual, but will require much less soap to be used.

Cotton goods, after bleaching, were formerly dried in the open air, on frames or tenter rails, or on rails in covered buildings, or in large rooms or stoves heated for the purpose, all which modes were attended with great delay and disadvantages.

These difficulties were removed in 1797 by an apparatus, simple in its construction, easily managed, and of singular use in facilitating the procfs of the bleacher. For this useful invention the public are indebted to John Burns, Esq. of Paisley.

By this discovery the bleacher can erect a drying machine, equally useful at all seafons, and in all weathers, at lesfs than one-tenth of the expense of former contructions, for doingbusiness to the fame extent. There is no risk of damage from wind or rain, less chance of injury from servants, owing to the simple manner in which the goods are prepared. They receive a fine gloss during the procfs of drying, the colour is as well preferred as if dried in the open air, and they cannot be injured by the heat.

A contrivance so obviously beneficial and complete, was soon introduced into general practice in the west of Scotland; and so undoubtedly were the claims of the above gentleman to the originality of invention, that the bleachers in the neighbourhood presented him with a handloom donation of silver plate, suitably inscribed, in testimony of their fene of his merit, and as some reward for communicating his plan to the public.

We are more particular in noticing this circumstance, because other persons have subsequently taken out a patent for the same principle, with a little variation in the construction of the machine, but which alteration has not been found to answer the purpose as expected. We shall therefore now more particularly describe Mr. Burns's apparatus for drying.

Fig. 1. Plate III. A is the boiler or steam vesel; B, the safety valve; C, the hollow leaden pipe which conveys the steam from the boiler to the rollers; D, a brass cock hollowed to receive the pivot of the roller, represented in fig. 2, one of which cocks is fixed to the pipe under each roller, and by opening which the steam is admitted into the roller; E represents twelve rollers placed upon the cocks, one of which, next to D, has the cloth upon it in the operation of drying; FFFF, the wood frame in which the machinery is placed; GG, the supporters of the leaden steam pipe, and of the trough HH, which trough is 15 inches broad at top, to receive the water formed by the condensed steam as it drops from the bottom of the rollers, E, and to conduct it to I, a small pipe extending from the trough, to the funnel, K, which funnel has its lower pipe reaching to within eight inches of the bottom of the boiler, to prevent the steam from inflating out at its mouth, and which funnel keeps the boiler supplied with water to its proper height, or flows when any is wanted, as the steam would drive through it if water should be wanting in the boiler.

Fig. 2. Plate III. A shows one of the rollers separate from the frame. It is usually five feet long, one foot in diameter, and made of double tinned sheet iron, and hollow in the middle, for containing the steam; a is the lower pivot of the roller, which is an open tube at the end for receiving the steam conveyed through it from the cock. This pivot rests a foot within the roller, at the under part of the roller; at d is a small hole for allowing the condensed steam to drop into the trough placed below it as above-mentioned; b, the other pivot or axis of the roller, which is fastened to the top bar of the frame by a latch, as represented in fig. 1.; c, a row of teeth fixed into a small slip of tinned sheet iron, folded to the roller, and thereby elevated to prevent the teeth from tearing the cloth.

Fig. 3. Plate III. A machine about three feet in height, for the purpose of lapping the cloth upon the rollers. A, the box in which the cloth is first laid; B, the farthing wooden roller, over which the cloth passes from A, and from thence under the wooden roller C, to the tin roller D, on which it is lapped by turning it with the handle E; F, the cloth passing under the roller C, to the tin roller D, on which, when it is lapped, it is ready to be carried and placed in the drying machine; G, a weight hung from the projection in the frame at H, over the roller E; to keep the cloth sufficiently tight as it passes from the box A, over that roller to be lapped on the drying roller D.

Fig. 4. Plate III. A shows another method of lapping the cloth on the tin roller, previous to its being dried. A, a perpendicular frame in the front of which is placed the tin roller B, with a handle for turning it at C; the cloth D extends from the roller B over the wooden roller E, in a frame F to G, where its other end is attached by a wire run across it to some wrapper or linen cloth, fastened to a board H, fixed below the roller B. L.L. are upright posts fixed to the outer side of the bottom frame K.K., having wooden pegs NN in them, on the side nearest the tin roller B. Rails or rods are laid across from these to similar pegs opposite, to prevent the cloth touching the ground when it is adjusting in the beginning of the operation, and the number of these pegs necessary, therefore, are in proportion to the length of the cloth.

At the commencement of lapping the cloth on the tin roller B, the frame F, movable on small rollers II. running in grooves on the frame K.K., is drawn so far back, that when the cloth is fastened to the wrapper G, one half of the piece reaches to the roller F, the other half passed over that roller, reaches to the tin roller B, to which it is then to be fastened. On turning the handle C, the cloth is gradually lapped round the
the roller B, the moveable frame F being drawn forward by the cloth: for as the cloth is lapped on the roller B, the frame F is drawn towards it by the uprights LL, and by means of a projecting wood forming an inclined plane fixed to M, on each side, near the top of the frame F, the rails O are raised off the pegs NN, and carried forward on the part M of the frame T, without impeding its progress to the tin roller B, till the wrapper G, to which the cloth is fastened, passes over the roller, and the wire at G, which attaches it to the cloth, is withdrawn, leaving the whole of the cloth to be dried on the tin roller B, which roller is then taken out and placed in the drying frame.

To ascertain the strength of the oxygenated muriatic acid used by the bleachers in France, Mons. Deforciauzelles made use of a soltion of indigo in the vitriolic acid, for which purpose he took one part of finely pulverized Guatimala indigo, and eight parts of concentrated vitriolic acid, which mixture should be put in a glass vessel, and kept of a gentle heat by flanding near the fire or in warm water all night, and repeatedly stirred with a glass rod or tube. When the solution is complete, it is diluted with a thousand parts of water. One measure of this solution is put into a graduated tube of glass, and oxygenated liquor is added, until the colour of the indigo is completely destroyed, and the strength of the oxygenated liquor is ascertained by its power in discharging the colour.

Mr. Roff has recommended a method which is better adapted for general use, which is, to have small measures properly proportioned to each other, and when the liquid is strong, to prevent wafte of the indigo liquor prepared as above, and a tedious repetition of measures, let a small measure of the liquor to be tried be put into a measure containing 24 of the same measures of water (it then becomes diluted to a twenty-fifth part); to a measure of this diluted liquor add as many measures of the blue taff as it will discharge, which multiplied by 25 gives its whole strength. It will be proper to have a measure of five for the sake of dispatch, in adding the blue taff liquor. It is necessary that the experimenter should fit to low enough to view his measures horizontally, in order that they may not be overfilled, otherwise he may be deceived.

Great care should be taken in the choice of the indigo and the vitriolic acid employed, for unless the indigo is of the Guatimala kind, or hell East India, and the vitriolic acid highly concentrated and pure, the colour produced will be a greenish brown, instead of a bright blue.

Mr. Chapal has employed the oxygenated muriatic acid to the purpose of bleaching paper, both by applying it to the rags before worked down, and to the pulp or paste; he also redored the white to prints discoloured by time, by immersing them in the oxygenated muriatic acid liquor, or exposing them to the action of its vapour. Several patents have been granted in this kingdom for bleaching pulp or paper, amongst which Mr. Mifia, Clement and George C. Taylor, of Maidstone, in Kent, have obtained one for bleaching the pulp, by inclosing it with a liquor of oxygenated muriate of potasium, in a vessel containing a churn, eight feet diameter at the great end, three feet four inches diameter at the little end, and two feet ten inches in the clear. This vessel revolves upon an axis at each end, and the pulp, by this motion, and projecting parts within the vessel, is constantly exposing fresh surfaces to the liquor, till the whole pulp is sufficiently whitened.

Mr. Bigg, of Iping, in Sussex, has since obtained a patent for bleaching paper, and re-forming white paper dammaged or mildewed paper, by exposing it in close wooden vessels paper, in quantities of six or eight sheets together, on wooden frames placed at small distances from each other, to the action of oxygenated muriatic gas, and after the paper is taken out, pressed, and dried, previous to its being fixed, wetting it in a solution of alum water.

Another method he propoies, is by wetting and soaking the paper in oxygenated muriatic acid liquor, till it is properly bleached; after which it should be well pressured and dried, and wet out in the alum water, as in the other processes.

A patent has likewise been granted to Mr. Elia Carpenter, of Bermondsey, London, for a method of bleaching paper in the water leaf or sheet, and fixing it without drying; he uses for this purpose a stout deal box or case, which must be carefully closed, and capable of containing water or steam within this. The paper to be bleached is to be hung on strips of glass, about 15 inches long, placed in grooves within the box, about four sheets on each strip; the paper is taken for this purpose when preffed in the packs in its wet state, and when the box is filled and closed, it is exposed to the action of oxygenated muriatic gas for eight or ten hours, and when sufficiently bleached, fixed with a preparation made from one hundred weight of pieces of skin boiled in water and strained, then fourteen pounds of alum, seven pounds of white vitriol, and one pound of gum arabic; these ingredients will make fixe enough for about 50 reams of foolscap paper; the paper when fixed and preffed, is finished in the usual way. To prevent the noxious quantities of the gas to the workmen, he directs a solution of pot-ash in water to be placed at the bottom of the bleaching box, to absorb the elastic vapours which would otherwise affect them on opening the box.

Mr. Tennant of Glasgow, subsequent to the patent granted for his bleaching liquid, has obtained a patent for preparing the oxygenated muriate of lime in a dry form, by which means bleachers may be cheaply and conveniently supplied with it by him, and save much of the trouble, expense, and hazard which attend the preparation of the former bleaching liquor.

To bleach silk from its natural yummy state, whether in skin or manufactured, it should be put into a thin linen bag, and thrown into a vessel of boiling water in which good white soap has been dissolved; the silk should boil two or three hours in this liquor, and the bag of silk frequently preffed with a stick, and turned, so that the matter may separate from it, and rise to the surface of the liquor, from whence it should be skimmed off, and thrown away; the bag should then be taken out, and if it contains silk goods, they should be well washed in clean cold water, to prepare them for printing or dyeing; but if the bag contains silk in the skin, after it has been well washed in clean water, beaten, and sharply wrung, it may be put the second time into the copper vessel, filled with cold water mixed with soap, and a little indigo blue, if you wish it tinged a little of the blue hue.

The silk, when taken out of the second water, should be wrung hard with a wooden peg, to press out all the liquor; then shaked, to separate the threads; then suspended on poles, in a clofe room or room where sulphur is burnt, which improves the whiteness of the silk.

Woollen cloths or stuffs may be bleached and made white by soap and water; by the vapour of sulphur; or by chalk, indigo, and sulphuric vapour. In the first case, after the stuffs have been cleaned at the fulling mill, they are again worked in warm soap and water, to render them whiter, and afterwards washed in clear water and dried; in this state they are fit for drying any light colours.

To delroy or remove the reddish hue arising from boiling printed cottons in madder decoctions, which prevents the printed
printed colours appearing to advantage, the goods are
fingly boiled for some time in bran and water, and then ex-
pofed to the air, by laying them on the grats, and throwing
upon them clear water from time to time. Mr. Grimshaw,
in the year 1756, obtained a patent for clearing printed goods
coming from the madder copper, by using the grains after
brewing malt liquors, instead of bran; the plan he recom-
mands is, that the grains should be previously four, and that
three or four baths thereof, more or less, according to the
colour of the cloth, should be put into a copper of hot water,
containing 200 gallons or upwards, and four or five pieces
of the printed cotton goods then immured therein, and
worked over a which backwards and forwards, for ten
or fifteen minutes; the pieces are then taken out of
the copper, and well washed in clear water, and laid straight
upon the ground for two or three days, till the parts which
should be white become clear. The same liquor, with
the addition of a few grains, will serve to clear other printed
goods, until the whole number wanted to be cleared, have
been completed; a sufficient quantity of clear water being
added to replenish what has been absorbed by the goods,
or evaporated in boiling. After either of the operations
above-mentioned, the immersion of the printed goods in
dilute oxygenated acid, will awfar the purpose of the ex-
posure to the air.

**Bleaching of Books, Prints, and Paper.** See Books,
&c. and Bleaching; limpa.

**Bleaching of Hair.** See Hair.

**Bleaching of Wax.** See Wax.

**BLEA,** in Ichthyology, the English name of Cyprinus
Alburnus, a species distinguished from the other fishes of
its genus by having twenty rays in the anal fin.

The bleak is a very abundant fish in many of the English
rivers, and in those of the northern countries of Europe in
general. The flesh is in some esteem; but it is chiefly taken
for the sake of the beautiful silvery scales, which artist
make use of in the manufactory of artificial pearl. The
credit of this invention is claimed by the French; and it is
said, that they have arrived at such a degree of perfection
in this art, that, independent of the plain silvery hue of the
beads in common, they can vary the colour to blue, green,
or any other vivid tint they may desire. The process is very
short; the scales are scraped off, washed, and then reduced
to a fine powder; this is diluted with water, and introduced
into a thin bubble of glass, where it forms an internal coat-
ing; the cavity is then filled with wax, through which a
hole is bored, and the bead is finished.

Gmelin speaks of this species being from four to ten
inches in length; but these do not commonly exceed six
inches. This fish is infested in the summer-time with a crea-
ture of the vermes tribe, that lives in the intestines, and
which oftentimes increases to such a vast size as to occasion
the death of the bleak. Fishes so infested rise to the surface
of the water, where they leap and tumble about in the
greatest agonies, and in that state are well known to the
fishermen by the name of mad bleaks. The white bait taken
in the Thames at Blackwall and Greenwich, in the month
of July, is believed to be the fry of this species. Vide Do-
nov, Brit. Fishes, pl. 18.

**BLEB,** a small blister, or bubble.

Naturalists have observed small purple blebs on all the
plants of the Hypuricum kind. Phil. Trans. No. 224. Thick
pieces of glass, fit for large optic glasses, are rarely to be
had without blebs. Ibid. No. 4.

**BLECHINGLEY,** or BLECHINGLEY, in Geography,
an ancient but small borough town of Surrey, in England; it had
the privilege of returning members to parliament from time
immemorial. The right of voting was vested in burgage tenure;
and the lord of the mayor's bailiff was the returning officer till
1723; when, by a revival of the house of commons, he
was deprived of that office; and the borough has now the
reversionary of sending two members to parliament, without a
mayor, constable, or any other legal returning officer. Sir Ro-
bert Clayton is the proprietor of the borough, and has con-
stantly the power of appointing the representatives.
The town occupies 31 miles south from London. The town and
suburbs within the parishes, contain 156 houses, and 1544
inhabitants.

**BLECHNUM,** in Botany. Lin. gen. n. 1175. Reich.
1292. Schreb. 1627. Clavis, cryptogamia flsces, or ferns.
Gen. Char. Fructifications dispersed in two lines, ap-
proaching to the rib of the frond, and parallel.

*Species, 1. *B. occidentale, South American B. "Fronds
pinnate; pinnas lanceolate, opposite, emarginate at the base." This species rises by a simple undivided stalk to the
height of 13 or 18 inches; leaves long and narrow, many
pinnas, with two small auricles at the base. A native of
the West Indies islands, and the continent of South America.
Introduced here about 1777. 2. *B. orientale,* Chinese B.
"Fronds pinnate; pinnas linear, alternate." Frond three
feet long; fronds covered at the base before, with large grey
briils; the anterior side frose with three longitudinal
grooves; leaflets linear-lanceolate, sessile, smooth, entire,
fringed at an acute angle, the length of the finger.
Found in China by Olbeck, and also in the Society isies.
3. *B. affinis,* Cape B. "Fronds pinnate; pinnas sub-
lanceolate, cordate-lanceolate, quite entire, the lowest oppo-
site. Stipes a foot long, green; fronds entire, about the edge
rugg'd; the barren ones with broader pinnas, truncate at
the base; the fertile, with lanceolate pinnas, heart-shaped
at the base; having two branches of fructification, longitudinal,
and distant both from the edge and rib. A native of
the cape of Good Hope. Introduced here, in 1774, by Mr. F.
Maffon. 4. *B. virginicum,* Virginian B. "Fronds pin-
nate; pinnas multifid." Having the stature of polypodium
filix mas or male fern; frond smooth; pinnas lanceolate, sessile,
femini-pinnatifid, acut; divisions obtuse, quite entire. A
native of Virginia and Carolina. Cultivated, in 1774, by Dr. John
Fothergill. 5. *B. japonicum,* Japanese B. "Frond bipin-
natifid; pinnules ovate, obtuse, ferrated." Stipe convex at
the back and smooth, before flat and fringed; the whole
smooth, flexuose, equal; pinnas oblong, acute, pinnatifid;
the lower subpetioloed, the upper sessile; differing from the
orientale in having an erect frond and blunt pinnules. A
native of Japan. 6. *B. radicans,* rooted-leafed B. "Fronds
bipinnate; pinnas lanceolate, crenulated; the branches of
fructification interrupted." Frond rosecing; pinnas sessile, slightly
concurrent at the base, ferrate with a very fine callus, acu-
minate, more veined beneath; the line of fructification is
next the nerve, but interrupted as it were by long
points. A native of Virginia and Madeira, where it was
observed by Koenig. Introduced, in 1779, by Mr. P. Maffon.

**Propagation and Culture.** The fourth species alone will
abide the open air in England; the first must be kept in the
dark house; the reit require only the protection of the dry
fog, or conservatory; they are increased by parting the
roots. Marty.
BLEDSOE LICK, in Geography, lies in the state of Tennessee, in America, 32 miles from Big Salt Lick Garrison, and 36 from Nashville.

BLEDA, or BLIDA, in Geography, a town of Africa, in the kingdom of Algiers, and province of Titeri, is situate in the interior of the country, over-against the mouth of the Ma-Saffran, at five leagues distance, under the shade of a ridge of mountains, forming a part of mount Atlas. It is about a mile in circuit, encompassed by a wall chiefly of mud perforated by hornets, and tolerably populous, but without much trade; some of the houses are flat-roofed, and others tiled; it is well-watered, as a branch of an adjacent rivulet may be conducted through every house and garden, and it is surrounded by very fruitful gardens and plantations. As Bleda and Medea (see Medea) lie nearly in the same meridian, and are situated at a proper distance from the Hamam Mercega, the Aque Calida Colonola of the ancients, and as their modern and ancient names resemble one another, Dr. Shaw supposes that we may take one for the Bleta Colonola, and the other for the Lamida of Ptolemy. That part of mount Atlas which lies between these towns, and reaches as far as mount Jurjura, is inhabited by numerous clans of Kabyles; few of which, from their rugged situation, have been made tributary to the Algerines. The Beni-Sala and Hadel overlook Bleda, and the rich plains of Mettjah whilst the Beni-Selim and Balalefa sometimes descend into the fertile ground, near the banks of the Bibfelhab, or river of fennel, of which a great quantity grows on its banks. Shaw's Travels. P. 36.

BLEEDING, or BLOOD-LETTING, in Medicine, a species of evacuation frequently resorted to, as a principal remedy in inflammatory affections, such as pleurisy, peripneumony, phrenitis, quinsy, enteritis, acute rheumatism, &c.; and in disorders accompanied with plethora, such as mania, apoplexy, &c. See these difeases separately. In all these cases, the earlier this remedy is employed the better, and especially in those inflammatory disorders, such as phrenitis and peripneumony, where, from the great vascularity of the part, the progress of the inflammatory action is extremely rapid, and the injury done to organs so essential to life, often becomes irreparable.

Nor is the timing of this remedy the only circumstance that requires attention. Other circumstances of equal moment are to be attended to; viz. the quantity of evacuation, and the fluidness with which it is effected. The quantity must be regulated by the degree and seat of inflammatory action, and the age and constitution of the patient. The appearances of the blood, when drawn (see Blood), are commonly regarded as a good criterion for regulating the repetition of the lancet, and the quantity to be taken away each time; but the state of the pulse affords a much better guide; and venefaction will often be found necessary in cases where the bloody coat or bloody appearance of the blood is not present in any considerable degree.

The impchipion produced upon the system is very different, according as the blood is drawn from a large or a small orifice; i.e., according as it is evacuated suddenly or slowly. The former method is to be practised in all violent inflammations of parts essential to life; such as the brain, the lungs, the stomach, &c.; for thus the increased action of the vascular system is subdued almost on the spot; a momentary delirium is induced (a flatte the opposite to that in which the morbid condition consisted), from which the most beneficial consequences result.

Provided equal quantities of blood be drawn in equal times, it matters not whether it be taken from the right or the left arm; in other words, supposing, in the case of pleurisy, the seat of the pain and inflammation to be in the right side, those symptoms will be as speedily removed by taking away in the whole thirty ounces of blood at three different times from the left arm, as they would be, if the same quantity were taken away from the right arm, in the same number of times, and from orifices equally large; because in both cases there is the same quantity abstrated from the whole mass of blood, and consequently from the quantity circulating through the lungs, and their invading membranes; whence the general and local effects in both cafes are ultimately the same. Hence the futility of the doctrine of Resolution, about which such warm disputes were at one time carried on.

Hitherto we have merely hinted at the general effects produced upon the system by blood-letting. It will now be expected that we should specify what they are. The first and most obvious effect is upon the heart and arteries. The blood is to them a stimulus; consequently, by withdrawing a quantity of that fluid from them, we withdraw a proportionate quantity of stimulus, and bring down their action so much nearer to their natural standard. The abforbents partake in this change; whence a lefs impeded exhilaration takes place. At the same time a diminution of the animal heat succeeds. Of course the cerebral system and the vascular system, in particular, are often in a state of excitement, that the one cannot be materially affected without producing a corresponding effect upon the other. This is proved by the deliquium and convulsions which succeed to a sudden and profuse hemorrhage.

From this view of a remedy so powerful and so extensive in its operation, it is easy to conceive what mischievous and even dangerous consequences must result from its abuse. Being the most speedily debilitating of all remedies, it is obvious that what is termed general bleeding ought never to be resorted to, but in cases where the pulse denotes an increased degree of strength, as well as excessive activity. It has been from attending merely to its increased activity, and the accompanying accumulation of heat, without a due estimation of the strength of the pulse, in fevers and other disorders supposing to be inflammatory, that so much abuse has been committed in the employment of the lancet. See Fever; under which article, the propriety and impropriety of blood-letting will be fully considered, with remarks on the practice of Fernebus, Botallus, Sydenham, Pringle, and other celebrated physicians, who pursued this remedy to an extravagant length.

Although general bleeding be only admissible under the conditions above mentioned, yet partial bleeding may be sometimes employed with good effect in cases of partial inflammation, existing in flutes of the body where vigour in the fluale at large is wanting; especially when the fluids belonging to some organ essential to life, are obstructed, overloaded, or inflamed.

Bleeding was formerly employed for the purpose of proscribing phlegmatic and inflammatory conditions of the body. Hence many of the old writers recommend it to persons in health both in spring and autumn, to pregnant women, &c.; but this practice is very properly discontinued, and other modes of counteracting a tendency to over-repletion are adopted in its place, such as a vegetable diet, regular exercise, occasional purging, and the like.

BLEEDING.
Bleeding, or Blood-letting, in Surgery, is the artificial extraction of blood from an Artery or Vein, for medicinal purposes. The operation of cutting an artery is named Arteriotomy; that of opening a vein is called Phlebotomy.

The instrument used in this country for bleeding the human subject, is denominated a Lancet; though a phleome or femor, was formerly employed, and is still very commonly used by farriers in England, and even by the belted surgeons in Germany, &c. See the Plate of Surgical Instruments. The lancet, on these occasions, is used singly; but where the intention is to puncture numerous small blood-vessels at the same instant, rather than any one considerable vein or branch of an artery, surgeons have recourse to an instrument containing many lancets, which is known by the name of Scarificator.

Lecches are often applied to a part of the body requiring the local evacuation of blood; and in this case, as well as in phlebotomy, the operation is termed local bleeding, in contradistinction to general blood-letting by the lancet.

Some nations, especially those which have scarcely emerged from a state of barbarism, are accustomed to draw blood by making one or more incisions or punctures at random, with a knife, a bone, a tooth, or a needle. See Acupuncture, Phlebotomy, Arteriotomy, Leeches, and Cupping.

The art of bleeding may be traced back to the remotest antiquity, and seems to have been common among the Egyptians, Assyrians, Scythians, &c. at a time when anatomy had never been cultivated. The Greeks boast that Podaliarius, the son of Eucalus, was the first who practised bleeding, soon after the reign of Troy; but the fact itself is related by only one author (Steph. Byzant. in voc Syrre), who lived too long afterwards to be credited implicitly. It is therefore much more likely, that bleeding had been performed previously to the time alluded to. Pliny, indeed, supposes that physicians first learnt this operation from having observed the hippopotamus draw blood by pulling sharp reeds into its body (Hist. Nat. lib. viii. cap. 15); but this is a very improbable thing, as there is very little analogy between the arterial opening of a vein with a lancet, and the random wounding of an animal by friction against a broken reed.

We shall, however, not enlarge on the history of this practice, but proceed to describe the common modes of opening a vein in several parts of the body; after which we shall treat of Arteriotomy.

When we resolve to perform venesection, we must, besides the instruments required for that operation, have in readiness one or two well-rolled blood-letting bandages, or tapes, from four to eight feet in length, and of two fingers breadth, with pins, or cleft needles and thread. Thoese bandages are, by foreigners, reckoned the best, which have narrow fraps at their ends.

In general, venesection is practised at the bend of the elbow, or upon the foot. When the patient is to be bleed at the arm, we place him, with his face towards the light, upon a chair of a moderate height; draw his shirt as high as is necessary above the elbow; let him extend his arm to a certain degree, but not too much; after which, the surgeon, in order that the veins may become turgid by checking the circulation, applies a bandage (which is often made of fine red cloth), of the breadth of three or four fingers, twice round the arm above the elbow, with the ends of which, after having previously drawn them moderately tight, he ties a bow with a single knot, at the posterior part of the arm.

Whether this bandage has been properly applied, we know by the circumstance, that the veins become elevated and turgid, whilst the pulsation of the artery at the wrist is distinctly perceptible.

We then choose a vein in the bend of the elbow, which must be done with caution. The upper is the cephalic vein, and this a beginner ought, if possible, always to choose; a little or no danger is to be apprehended from opening it; but it is very seldom to be seen or felt, and commonly is too small. The median vein is most easily seen and felt; but generally the tendon of the biceps muscle is situated under or at the side of it, which we must take great care not to puncture. The inner vein of the arm, or the basilic (which in the right arm is by some termed the hepatic vein, and in the left the splenic), is instead commonly very easy to be seen, and full more easy to be felt; sometimes, however, it is also very small, or lies so close upon the artery as to render it hazardous to open it.

Some recommend blood-letting upon the back of the hand, although this is an inconvenient place, and, in certain cases, not very safe for the operation. But if it is to be performed, we tie the red bandage two fingers breadth above the wrist, round the fore-arm; and, in order to raise the vein, let the patient then hold his hand in warm water. The most common vein upon the hand is the cephalic of the thumb, which lies between the bones of the carpus, with which the thumb and the fore-finger are joined. But the vena valutalata of the middle finger, which lies between the two metacarpal bones with which the middle and the ring fingers are joined, is at present but very rarely opened, and only when no other is to be seen; especially as it does not discharge much blood, is difficult to be tied, and, if cut quite through, forms a thrombus.

In bleeding these veins, the patient must be placed in a somewhat oblique position against the light; so that when the hand is half closed, and laid upon the edge of the vessel, the fingers are directed towards the light, in order that the instrument may throw no shade upon the place of the vein where we intend to open it.

Bleeding at the foot is generally performed upon the vena saphena, which lies upon the first metatarfal bone, connected with the great toe, running along it and the tarsus, over the inner angle. Where it lies close upon the ankle, it is inconvenient to open, and we must be very careful not to cut through it and injure the peroneum, or even thrust the thumb or lancet into the bone itself. If possible, it will be better to open it one, two, or three fingers' breadths farther from the ankle towards the great toe. We may also open a branch far forwards, almost close upon the great toe; and here we are required often to open it with pregnant women who have swelled legs.

The other pretty safe vein upon the foot is the cephalica pedis, that lies between the two tendons which extend the great and the second toes; only we must be cautious not to injure the tendon lying beside it. The other veins situated upon the back of the foot should never be opened, but in cases of extreme necessity; for the operation is attended with danger, on account of the contiguous tendons; besides, they do not discharge a sufficient quantity of blood, and they almost always form a thrombus, which a beginner should be careful to avoid.

When we bleed at the foot, the patient should first place the limb in a pail of warm water, in order that the veins may be seen and felt; and if it is necessary with small veins to apply the red bandage, which, however, in order that the purpose of checking the flow of the blood may be attained, and no inconvenience occasioned, must be applied in the middle of the calf, especially where lean persons, in
the same manner as on the arm; but the bow and its knot must not lie upon the tibia.

On the arm, therefore, we choose either the cephalic or the median vein, and, if the tendon lying below it should occasion irritation, the bicipital, especially if this lies more convenient and superficial. When the surgeon, then, has brought his eye to the proper distance from the vein, he rests the point of his middle finger, prefixed gently with this finger upon the vein at the places where he thinks he can best open it, and accurately marks the place with which he was satisfied in trying by the feel; after which he suffers the arm to fall down again into the patient's lap. In the same manner he chooses a vein upon the hand.

For blood-letting at the right foot, the patient is placed upon a chair of a moderate height, in the most elevated part of the room, with his face directed towards the window, and his feet immerged in a vessel filled with warm water, so that the water covers all the veins of the whole foot. When therefore the foot is warm, and the veins sufficiently tumid, the surgeon holds hold of the foot with his left hand, and places it with the middle of the sole upon the edge of the vessel which is the most remote from the body, in such a manner, however, that the foot is not extended, but forms a right angle with the leg. With the middle finger of the right hand he examines those veins which lie the most elevated, and makes, according to the rules before laid down, a scientific selection; but he must always direct his attention to the vein saphena.

The most convenient attitude for the surgeon is when he kneels down with one knee; as in this position the eye is near to the vein, the position is firm, and can be better supported for the requisite length of time. If any other vein besides the saphena be chosen, the patient is directed to move his toes, whilst we are examining the vein, in order that we may feel how near a tendon may be situated below it; and here the caution should be observed, not to make all the fingers wet, for the warm water diminishes the sense of touch, and consequently renders it indistinct. We therefore use at first only one hand, because, in case of a failure, or from some other cause, we may be under the necessity of taking also the other foot.

The vein may be opened either longitudinally, that is to say, in the direction of its course, or we open it rather obliquely or transversely. The first is the saphenous, cephalic, and most convenient method; but it is admissible only with large veins, and when we foresee that during the operation they will not slip or twit, as it were, out of the way of the instrument. Commonly the veins are open somewhat obliquely, and in this manner we may generally open the veins on the arm, and in most cases upon the foot. But when the veins are too small, there is reason to apprehend that we may not hit them, or that they will not discharge a sufficient quantity of blood; and when their situation requires it, as is the case with the cephalic of the foot (where it lies over the tendon that elevates the great toe), the orifice must be made quite transversely.

When therefore we have properly examined the vein with the moist finger, we hold the plume in readiness (if we use this instrument); that is to say, we draw up the spring, take it in the right hand, so that the thumb lies upon the fiddle, the forefinger upon the bridge, and the middle finger upon the prehenser, exactly over its spring, and the ring finger upon the round part of the bottom plate. With the forefinger and thumb of the left hand, which are moistened with a little salve, we move the iron as high up in the groove as we think it necessary to make the orifice deep; and place the box (after having again elevated the arm, or taken the foot or hand out of the water, and supported them, in the manner above described, upon the margin of the vessel) in such a manner upon the skin, that the iron has exactly the proper direction toward the place where the orifice is to be made, and then, by a gentle pressure with the middle finger, let the spring fly loose.

If a part should be so fat as to render bleeding impracticable, and with such it is at least very difficult to do it on the foot, we may in some measure attain our purpose, if we direct the patient, as he gets out of bed, to hold his foot or hand in warm water; after which the veins will generally become sufficiently perceptible to the eye or touch of an experienced surgeon.

But though the phleum is used for blood-letting, especially in Germany, it is however an universally acknowledged truth, that the lancet is the safest and best instrument for the purpose. We run less hazard with it of doing damage, and the surgeon is always able, according as the circumstances require, to make the orifice either small or large. When therefore we let blood with the lancet, we place it so that the handle forms a somewhat acute angle with the blade. The surgeon next lays hold of the limb upon which he is to perform the operation, supposes the right arm, with his left hand; and at the same time presses with the left thumb upon the vein, about two fingers' breadth below the place which is chosen for the orifice: he then takes the lancet between the thumb and fore finger of the right hand, so that something more of the blade is uncovered than he thinks necessary to introduce. At the same time he lets his hand rest upon the middle, ring, and little finger, which must be placed as conveniently as possible below the vein that is to be opened. He then pressures the point of his lancet carefully through the skin and integuments into the vein, and carries the instrument in an oblique direction a little forwards, till the orifice is sufficiently large. But, during the introduction of the lancet, the operator must hold the point as steady and even as possible, in order that it may not penetrate into the subjacent parts. Should he, however, not be able to depend sufficiently upon the fingers of his hand, he will do well to leave no more of the point of the lancet uncovered than is to penetrate into the vein. The surgeon having withdrawn his right hand, at the same time removes the thumb of his left hand from the vein, in order that the blood may flow out freely.

If the blood will not flow properly, notwithstanding the vein has been properly hit, either the orifice is too small, or fat perhaps gets into the orifice of the integuments and stops it. The fist is to be prefixed back, by stroking with a wet and warm sponge, or by means of an instrument. The impediment, indeed, may lie in the motion of the part; when, for example, the arm is bent obliquely, or the foot is placed in the water, the orifice of the vein may easily be displaced, and some of it be closed by the found part of the flail. But, finally, the circumstance may also be occasioned by the cold confluence of the blood. To this latter case it is often to be attributed, after the first few minutes; on which account it will be proper to wipe the arm, over the orifice of the vein, with a sponge moistened with warm water, and let the hand rest in a somewhat higher situation than the orifice, upon a flail, which the patient may also turn round, or press firmly with his fingers.

When a sufficient quantity of blood has flowed from the vein (for example, in the arm), and we are to tie it up, we take the sponge, moistened with warm water, in the right hand, the handkerchief in the left, and the linen compress between the thumb and middle finger of the same hand; we hold against the vein with the sponge, and with the left hand...
remove the red bandage and hang it over the chair, or the
shoulder of the patient. The assistant takes away the vessel
into which the blood has been received, and the operator
now with a moderate pressure draws the sponge from the
vein towards the hand in a right line with the orifice that
has been made; and it will be proper, whilst he brings the
lips of the wound together, with the thumb of his left hand
from the side, to repeat the wiping with the sponge once
more, in order completely to remove the blood that may
have been left in the orifice.

When the surgeon now sees the vein well closed, he lays
upon it the compres, with the fingers of his right hand,
whilst he draws it towards the thumb of the left hand upon
the skin; and when the middle of it is upon the orifice, he
prefers it down with the fore and middle fingers of the right
hand, and immediately changes the for the thumb of the left
hand. With the right hand he washes the blood from the
limb, by means of the sponge; after which, he lays the
sponge aside. He then takes the bandage out of his left
hand, lays hold of it with the fore and middle fingers of the
right hand at the inner part of its head, and the thumb upon
the outer, and places it upon the compres in such a manner
that the fingers of the left hand make way for it, whilst
the two fingers of the right hand continue the pressure in
their place. But, immediately after, these are again changed
for the left, fore, and middle fingers, which now press at
the same time upon the outer turn of the bandage and the
compres. The right hand carries the bandage cross-ways
round the arm, whilst the fore fingers of the two hands
always alternate, till the last, when both ends of the
bandage are either fewed, tied, or pinned together.

Notwithstanding we have given these very precise direc-
tions, a young surgeon will learn better by seeing the
operation performed by a skilful hand, than by any verbal
directions.

Tying the vein upon the thumb is performed in the
following manner:—Pressing with the compres, which
here must be pretty narrow and thick, is like that performed
on other veins; and therefore, whilst we hold it fast upon
the wound of the vein with the two fore fingers of the left
hand, we let the bandage, (which is rolled upon one head,
with a breadth of four inches in length from the end to the
place where it touches the compres), hang down about half a
foot from the bandage over the back of the hand, obliquely from the wrist
outwards; carry the head of the bandage, after pressing
it over the compres with two fingers of the left hand,
through between the thumb and the fore-finger, over the
palm of the hand; and, proceeding over the back of the
hand, cover the end of the bandage; then go round the
wrist, again over the back of the hand, under the thumb,
and now round the ball of the thumb; again over the turn
that has just been made across the back of the hand; and after
having once more carried it half round the wrist, pin both
ends together on the back of the hand. We may also apply
this bandage with varied turns. In a similar manner, with
turns round the little finger, and circular turns round the
wrist, the bandage is applied, when the vena palvata is
opened.

With the veins of the foot, the common bandaging is
made by the STAPES, which, however, sometimes requires
a peculiar method, that every one will easily be able to
adapt according to circumstances. The bandage may be
applied somewhat tighter than upon the arm; however, on
account of the injurious consequnces, which may even be
attended with danger, the bandage must not be drawn too
tight; but it will be better some hours after to examine it
again, and if necessary, draw it somewhat tighter. Upon
the whole, it is to be recommended, if possible, in all blood-
letting operations, especially in arteriotomy, that the sur-
gen should see the patient again some hours after; as he
may observe several small inconveniences, which afterwards
frequently occasion unpleasant complaints.

Venection is more rarely performed upon the frontal
vein, from veins under the tongue, and upon the neck. For
the frontal vein, when it requires to be opened, we apply a
bandage, or a garter or cloth, round the neck, lay the mid-
dle of the bandage upon the back of the neck, carry both
extremities over the throat, and round again to the back of
the neck, where an assistant takes one end in each hand.
This the patient may also perform himself: only then the
middle of the bandage must be applied to the throat, the
two ends carried round the neck till they meet at the
throat again; there the patient holds them with both his
hands, and, according to circumstances, draws the bandage
tighter, or relaxes it, so as to fill the air-space for respiration.
A still more convenient mode of distending the
veins of the neck, &c. is to pass the bandage over the sides
of the neck, and under the opposite arm-pits, so as not to
press upon the trachea, which may impede respiration; then
roll the swollen vein down with the thumb or finger of your
left hand, a little below the part allotted for the operation.
The incision is to be made, when the vein is sufficiently
puffed, with a lancet.

In order that the blood may not run down upon the face,
we press a card bent crooked under the orifice upon the skin,
and thereby conduct the blood into a vessel. After a suffi-
cient quantity of blood has been discharged, we remove the
bandage from the neck, when the bleeding generally ceases
immediately, and the orifice is secured with fleshy plaster,
or, if it should be necessary, with a compres and Discri-
men bandage.

When we have to open a subclavian vein, we must pro-
mote the efflux of the blood, as in bleeding at the forehead,
by the application of a cloth under the arms and across the
sides of the neck. The orifice is made with the lancet, and
the incision is continued till it forms large enough. In order
more conveniently to get at it, we hold back the tongue
with a wooden fork, or spatula. We may draw a silk
thread through the wound, in order to clear it from the
blood, which here easily coagulates, and at the same time
to prevent the lips of the wound from adhering together,
and consequently to obviate whatever might impede the flow
of the blood. When its flow must be stopped, we take off
the bandage, and let the patient hold some spirit of wine, or
common brandy, in his mouth. If the blood flows more
copiously, we may dispense with the thread, and immedi-
ately remove the bandage from the neck; also, when it is to
be stopped, apply a little alum or agaric to the wound, and
press it down for a time; or apply Lampre's compresfory,
described in I. Val. Heinr. Kocher's Anleitung zum Ver-
bande, &c. Leipzig, 1796, 8to. Tab. VI. Fig. 5.

To bleed at the external jugular vein, the bandage is
likewise applied round the neck; against the clavicle, and
upon the vein that is to be opened, a thick compres is
placed, and the bandage drawn somewhat together. The
thumb is placed upon the compres which lies upon the vein,
and the fore-finger over it, in order to secure it and to stretch
the skin; we then take a pretty large lancet, and with it
open the vein in the ordinary manner; only with this dif-
culty, that we must introduce it deeper, and make the ex-
ternal orifice larger. To catch the blood, we make use of a
card, as in bleeding at the forehead. When a sufficient
quantity of blood has been drawn, we remove the bandage;
after which, the lips of the wound generally close sponta-
neariously.
necally. But should a bandage be necessary, we may secure a compress upon it by means of two circular turns round the neck. As this bandage, on account of the pressure upon the trachea and vesicles, &c., of the neck, is always very troublesome; and also the pressure, as it never must be strong, is frequently insufficient; we may most conveniently use the instrument invented by Mr. Clabert for compressing the veins of the neck. In want of it, we must let an adfiant clofe the orifice by pressure with his finger, till the danger of hemorrhage is over.

Some moiben the comprefles with brandy, vinegar, &c. and thereby, on account of the irritation, occasion none incon- venience at the orifice of the vein, in which sometimes inflammation, and even a suppuration is excited. It is better to apply the compres dry, or to fllick upon it a piece of gold-heater's skin, whereby the lips of the wound, if they have been well brought together, are retained in that file, to that the bursting open of the vein is more effectually prevented.

Easy and insignificant as some young surgeons think the operation of phlebotomy, it nevertheless often requires the greatest accuracy, and is on that account one of the most delicate operations. To a true surgeon, therefore, it is always of importance, and the more so as his honour and reputation are endangered by committing an error in it. Frequently the faults which the patient commits during and after the operation, such as inconstant motion of the limb, whilst the operation is performing, violent exertion of it, drawing on boots, &c., after blood-letting at the feet, are ascribed to the negligence or ignorance of the surgeon. Inasmuch also as no operation occurs so frequently as this, and as it so very often endangers the life of a man, or at least an error committed may give rise to such danger; the surgeon must well consider the symptoms which occur in it, and may superinduce more important consequences dangerous to health, in order that he may timely obviate or remove them.

Sometimes there arises, as the most common bad con- sequence of blood-letting, as inflammation of the external integuments, and of the subjacent cellular substance. Sometimes it is chronic, but little painful, suppures slowly, and produces a circumscribed abscess. Sometimes it is more dif- fused, and has the appearance of an erysipelas inflammation; sometimes it is violent and acute, and resembles a phlegmon. This generally occurs when the instrument is a bad one, and rather tears than cuts; when the patient is of a very-writable habit, and much difposed to inflammation; when the requisite precautions for healing the wound by the first intention are neglected, and the arm is suffer'd to be moved; when the wound is externally rubbed, pressed, &c. The nature of this inflammation cannot be mitaken, and it must be treated like a common wound.

It may sometimes happen, that when the wound of the vein does not soon close, an inflammation of the vein takes place, which however varies with respect to its violence, its extension, and progress. In a milder degree, this inflammation is followed merely by a slight swelling of the vein, and an adherence of its sides. A violent inflammation induces suppuration. The common method of treatment is the anti- phlogistic. As the internal membrane of the veins is continued to the heart, and as inflammations in such membranes spread cally and rapidly, where they are not prevented by an adherence of the sides of the vein, it is in most cases adva- lible to produce such an adherence by the application of external pressure at some distance above the orifice. If, as may very easily happen, such an inflamed vein should pafs into suppuration, it would (if known) then be necessary to cut open the vein, in order to prevent the pus from mixing with the circulating fluids.

When a vein has been cut entirely through, the pain is not greater than common, nor does the patient experience any inconvenience whilst the blood is flowing; but a greater or less quantity of it descends under the vein into the adi- pos membrane, remains there inclosed, and during the first twenty-four hours occasions a tension. The external orifice of the skin may be displaced from the orifice of the vein, likewise, when the orifice of the integuments is smaller than that of the vein; when the patient moves the arm too much, in consequence of which some blood is indeed discharged from the wound, but more penetrates between the vein and the skin into the cellular texture; and when the operation has been absurdly performed where two veins anastomose; from all these causes an effusion of blood may take place, in consequence of which the part acquires a blueish black co- lon, and sometimes an ecchymoma, sometimes a suppuration, and at other times a thrombus is produced. Although the appearance frequently seems to indicate greater danger than really exists, the speedy application of remedies is nevertheless necessary.

In the first case, cataplasms, with warm vinegar, wine, and other spirituous or efficient remedies, are serviceable. When such extravasated blood is not again taken up, or when the vessels are inadequate to its re-absorption, on account of its great quantity, an abscess is generally formed, which must be treated according to the rules of art, and the spirituous remedies laid aside. See Abscess. In the fu- gillation, we must endeavour to remove the obstacles that may impede the circulation of the blood: these are either external ones, such as a too tight bandage, by loosening which the complaint is removed; or they are internal ones, and occasioned by a contraction of the vessels. In a recent fugillation, we may combine the refulent means above-mentioned with mild altringents; and when the flagrating blood has been again disloved and removed, we at last apply cold, difcent, and spirituous remedies.

When an aponeurotic part (for example, the facia of the fore-arm) is wounded, the patient sometimes experiences a more violent pain than usual; especially when he moves the limb; and this he feels presently after the blood-letting has been performed. A compres, moistened with cold Goerland's water &c. is of service, whilst at the same time the bandage is left applied for three or four days, and the limb kept completely at rest, and wetted many times a day with such remedies. When this is neglected, there very often takes place a serious inflammation, which must be treated according to the antiphlogistic plan. Repose of the limb, which is to be kept in a bent position, and relaxation of the inflamed parts by means of warm emollient applications, are abso- lutely necessary. As soon as the inflammation abates, it is proper every day to attempt moving the joints, in order to prevent a stiffness. But if the tebodium and inflammatory symptoms run very high, it may even be requisite to divide the facia completely.

When a nerve is injured, the patient experiences a still more violent pain, which extends itself throughout the whole limb, and the patient is also apt to faint, the muscles of the affected part contract, and the blood sometimes does not flow so freely as usual, although the vein has been well opened. The orifice of the vein does not become violently inflamed, and the pain continues. In order to prevent in- flammation and other symptoms, a larger quantity of blood must be let run out, the limb must at least for some days be left completely at rest, and we must take care that the mus- cles of the part remain as much relaxed as possible. More-
ever, we must treat the patient antiphlogistically, prescribe a
mild diet, and alch, if the case should require it, administer
opiates and laxatives. For lesions of the nerves, the applica-
tion of warm spirit of turpentine is commended; but it
would probably be useful only in cafe the nerve should lie
above, but hardly when under, the vein. Over the orifice
we apply some lint and a mild plaster, and over this and
the whole limb, emollient and diuretic cataplasmis, with which
anodyne remedies are mixed.
If, notwithstanding this treatment, the symptoms should
become more violent, the lips of the wound acquire a hard-
ness, and become more inflamed, affected with pain and tu-
mor, with a full and quick pulse, blood must be drawn by
leeches, or at another place by venesection. Instead of the
warm emollient fomentations and cataplasmis, which are
recommended in such cases, Mr. B. Bell extolls, from his own
experience, cooling affurgentic remedies. Preparations of
lead he has found most serviceable. The parts which suffer
the most may be covered alternately with cloths wetted with
a solution of ficcatemum Saturni, and with pledgets spread
with ceratrum Saturni. The fever must also be particularly
attended to, and the above mentioned cooling treatment
continued. When the pains are so violent, that they en-
tirely deprive the patient of sleep and rest, we must use an-
timony and opium; but in order that the opium may prove
serviceable, it is administered always in considerable doses.
The limbs must also be kept continually at rest, and in a
horizontal posture.
But frequently the first affection is neglected, or improper
remedies are employed, so that opium, and all the remedies
that have been mentioned, have not the smallest effect. This
is particularly to be supposed, when the nerve is cut in such
a manner, that only a part of its fibres still remains entire, and
these are preternaturally stretched; in which case the whole
body suffers, and the most violent convulsive affections take
place, which indicate the most imminent danger. The only
remedy under these circumstances is the division of the nerve
by a transverse incision above the inflamed part, that is to say,
higher than the orifice of the vein. As the nerve certainly
lies within the breadth of the orifice of the vein, the incision
needs not be long, and it must penetrate only down to the
edge of the orifice, for all its cutaneous branches always lie
on the outside of this edge.
Mr. Benjamin Bell has given very extraordinary directions
on this subject, which have (mutt unaccountably) been tran-
scribed by many surgeons in France and Germany: he directs,
among other things, an extensive transverse incision to be
made through the original wound, and even down to the bone!
which Mr. Abernethy has very properly reproved as "dangerous and unnecessary." When the branch of an artery has been wounded, the pa-
tient does not feel more pain than usual; but the surgeon
immediately concludes from the colour and spouting of the
blood what fault he has committed. See Anemurism.
In venesection, a bone may also be injured, chiefly with lean
persons, who generally have very thin veins, especially on the
feet; which, though they are very visible, lie, however, so
close upon the bones and tendons, that the instrument passes
through and injures the subcutaneous bone. In such cases, this
only occasions a pain which the patient feels during the opera-
tion, and no bad consequences ensue. Frequently the sur-
gen himself would not know it, did he not find, on examin-
ing the instrument, that the point is entirely wanting, or at
least bent round, and its edge foaked. This, however, ap-
plies only to the case where none of the iron is left in it; but
when this happens the case is worse. We may know that it
has taken place from the cutting blade being wanting, or in
part broken off; from the pain which the patient feels, and
which is generally of a pulsating kind; from the divided
stream of the blood; from the feel with the fingers, when
this are frothed over the orifice of the vein, and from the re-
bounding which the surgeon feels in the fingers at the stroke.
If it is not staved very firmly, the stream of blood generally
drives it out, if we draw the orifice gently afunder with two
fingers. But when it is more firmly staked, we must endeav-
uour to draw it out with a fine pair of forceps as cautiously
as possible, that it may not break in extractions, and the point
reain flicing in the bone. When it has been successfully
extracted, we must endeavour to prevent the symptoms, such
as inflammation, tumor, &c., by moistening the compres
and the bandages with a diuretic lotion, and afterwards also
keep the bandages moistened with such remedies throughout
the day. This accident is only liable to occur in using the
flam.
But the breaking off the blade may also happen with mus-
cular subjedcs, md this the surgeon can certainly in general
prevent, by always inspecting his instrnents carefully, and
providing them with good blades. The blut blades are tho-
se which are very sharp and finely polished, and these are
generally very thin, and consequently most liable to fly off. Be-
fore we use any blade, especially a thin one, we ought always to put
it to the following test. We fcrew the new blade into the
plume, and let it fly two or three times without any object
opposed to it. If the blade remains as it shouild, we are then
luckily on the sure side, and if not, the blade is too thin, or
the orifice of the vein is too large, or the bandages too wide.
Sometimes a lymphatic vein is wounded; in which case
the patient experiences no extraordinary pain, nor does the
surgeon foresee the injury that is still to arise, and conse-
quently cannot be immediately discovered. After the ban-
daging, the vein heals up, no inflammation is left behind, but
there daily flows out of the orifice of the skin a quantity of
clear pellicid lymph, which continually keeps the dressings
wet. This inconvenience often gives the surgeon much
trouble. Here we may apply with advantage Goulard's
faturnine water, or a solution of alum, or mere cold water.
The cure is best completed by means of dry lint, applied daily
once or twice in the form of a tent. We may also sprinkle
pulverized alum, or apply a strong pressure upon the ve\n; and sometimes we may use the lapis infernalis with advan-
tage. Mr. Jaeger, however, thinks (Funzif. chirurg. prakt.
Cantilen. &c. Frankf. a M. 1788, p. 9) that the cure may
most speedily be effected by immediately promoting fup-
putation.
It may happen, that in letting blood at the arm a lymph-
atic vein becomes inflamed; in which case we feel upon
examination, a hard absorbent veefel both above and below
the wound of the vein, which laft, however, is not yet healed,
but generally uninflamed; if the affected limb is used, the
pains become more violent, and sometimes extend themselves
into the axilla, where also the glands swell; generally the
fore-arm likewise swells and becomes painful, and at last abs-
cesses take place in different parts. Besides keeping the
affected arm at rest, we must cover the wound with an
emollient ointment, and apply to the hard veefels and tumors,
cataplasmis of emollient, diuretic, and anodyne remedies,
upon which they are generally disfigured. When absesses
have already been formed, they must be opened and healed,
according to the rules of the art. See Abscess.
The most common symptom consequent upon blood-letting is fainting, which, however, is in most cases unattended with danger, especially when it does not arise from a too copious evacuation of blood. It may often be prevented, by keeping the patient engaged in conversation, by letting him take a powerful alkali, or a glass of cold water into his mouth or sprinkling him and washing his hands and face with it. But if it nevertheless supervenes, we must immediately place the patient in a horizontal position, throw open the chamber window, and apply strong stimulating substanves, such as volatile alkali, to his nostrils; and when he has come to himself, we may give him a glass of wine, provided it be not contra-indicated by his ill state of health.

With persons who always faint whenever they are bled, and who on this account, however necessary the operation may be for them, always dread it, the best method of preventing their fainting, is to lay them immediately in a horizontal position, with the head low, and at the same time frequently to stop the discharge of blood by holding the vein. This caution is particularly to be recommended with pregnant women, as faintings and convulsions in them, if they continue too long, may prove very injurious to the fetus, or produce an abortion.

We have hitherto confined our remarks to the opening of a vein; it therefore now remains for us to describe the operation of arteriotomy, which is the artificial opening of an artery.

This operation was very frequently practised by the ancients; who, perhaps, from having incorrect ideas of the nature of these blood-vessels, were not always aware of the dangerous consequences which follow from this practice, if injudiciously managed. Those who are deficient in reading a full account of the ancient practice in this branch of surgery, may peruse what Oribanush has collected from Galen and Antyllus; to which they may add the observations of Paulus Aegineta, and Profer Alpinus, the latter of whom describes the operation as it was performed in Egypt.

The supposed advantages of opening an artery, rather than a vein, are 1st, that the blood flows with greater velocity than from a vein; and therefore affords a larger quantity in a given time: 2dly, that it prevents the accumulation of blood in any local inflammation more effectually, because it intercepts the fluid in its passage towards the affected part: 3dly, that its salutary effects more speedily follow, on this account, than from the operation of phlebotomy; and, therefore, it is preferable in cafes of a very urgent nature, such as apoplexy and phrenitis, arising from the pressure of blood upon the brain.

But these advantages are speculative, rather than practical, for the following reasons: 1st, No surgeon who is acquainted with the serious consequences of opening a large branch of an artery, and the difficulty of restraining the effusion of blood in many instances, will perform this operation in the same part of the body, and in the same manner, as the ancients did. And in opening only very small branches, (suppose of the temporal artery,) it rarely happens that the blood flows rapidly, and never with the same freedom as it does from a large vein: 2dly. That we may sometimes, by this means, intercept the blood as it paffes towards an inflamed part is certain, by cutting through the principal artery which conveys the blood; but this advantage is not, often obtained, because we dare not divide any considerable ramifications, and there are always more arterial branches than one to supply an important organ: 3dly. We admit, that in certain cafes, (in ophthalmia, or inflammation of the eyes, for example,) the good effects of blood-letting by arteriotomy near the affected part, is far more useful than by phlebotomy, in a remote part; but, unfortunately, the surgeon cannot always evacuate a sufficient quantity of blood by this means, on account of the difficulty of finding a suitable branch of an artery, which may be easily as well as safely incised.

Therefore, considering all the disadvantages of this operation, it is now very rarely practised, except in the temples, where the pulsation of a small branch of the artery may be often felt with ease; and there is little or no danger in attempting to divide it. If we do not succeed in our attempts, or do not procure so much blood as is requisite, the operation of phlebotomy may then be had recourse to. It should, however, be mentioned as an undoubted fact, that acute inflammations of the eyes, are more efficaciously relieved by arteriotomy, (when it properly succeeds,) than by opening a vein in the arm; and that the execution of four ounces of blood in this way, is as useful as twenty or even thirty ounces taken from the venous system.

As arteriotomy is now scarcely ever performed in any other part of the body besides the temple, we shall content ourselves with describing the operation alone. In that situation, the artery lies near enough upon the cranium to be compressed readily, when we wish to stop the current of blood; though, in general, the blood does not flow so freely, as to cause any difficulty in restraining it by moderate pressure.

The patient being placed in a good light, the operator feels for a pulsating vessel in the temple, nearly opposite the outer angle of the eye. When he has discovered it, he endeavours to trace the direction in which it runs; and then he places the two forefingers of his left hand upon the artery, leaving a space of about half an inch between them for the place of the incision. The vessel is so small, in general, that it cannot be opened by an oblique, or a longitudinal puncture, as in bleeding the veins of the arm; but must usually be cut across, by a single stroke of the lancet, or scalpel. A lancet is not so convenient as a small knife for this purpose, because its fine point is apt to be broken; and it will be found best to draw the instrument over the artery, instead of endeavouring to strike it with the point, (which Dr. Butfer, Mr. B. Bell, and others, direct to be done,) as in phlebotomy. It may be convenient to make a little impression with the finger-nail, or with ink, on the exact spot we determine upon for the incision, lest we lose our object in operating; for a surgeon cannot always ensure the division or wounding of the artery on his first attempt, especially if the incision be made with timidity, or hesitation.

When a sufficient quantity of blood has flowed, (which it does by a florid and falient stream,) we close the wound, and apply a long bandage over a very firm, thick compress of linen, in which may be included a piece of coin, or some other hard substance. It is a matter of small importance whether or not we first use an adhesive plaster, except when the bleeding is likely to prove troublesome; but the different modes of applying arterial hemorrhages, are described under the articles Hemorrhage, Ligature, Stypitic, and Anseurism.

Frequently it is necessary that the surgeon should make himself acquainted with the state of the blood, and often also it is required of him to pass his opinion upon it. As long as the blood is warm and flows out of the vein, it exhibits a pretty uniform red colour, and has a sickly glairy feel; but when it grows cool, it coagulates into a mass varying in colour and density. After some hours, there gradually exudes from this coagulated mass a fluid, which separates the more solid parts from the fides of the vessel, so that it swins in it. This water is called serum, but the coagulated red cake is named crust or crum.amentum.
Good venous blood, exposed to the air, is of a dark red colour: when it cools, it separates a thin and almost colourless serum, and a thick cake, which has no crust of a different colour from the blood below it; and of which the serum forms a proportion, amounting to between the third part and the half. Such blood has no preternatural acrimony, or saline quality; and in it are found all its constituent parts in the proper proportions. From this condition of the healthy blood, we may form a judgment of its preternatural state, if it be materially changed.

When the blood remains fluid that it will not coagulate, it indicates a deficiency of the gelatinous part, and a great redundance of serum. Such blood is to be found in many fevers, especially in malignant ones, or when the patient is in a very debilitated condition.

If there be too much serum in the blood, dropisy and other similar diseases are to be apprehended; for such di- folved blood always indicates a weakness of the vessels, and of the muscular fibre.

When the serum is yellow, it indicates an obstructed flow of the bile, and its regurgitation into the mas of the circulating fluids.

When the blood has much serum and little of the red part, the blood is overloaded with mucus, and it indicates that a cachetic disease is impending; especially when the serum has various different colours, and the texture of the serum is very flenser.

If the blood has its proper and sufficient redness and fluidity, but at the same time exhibits a greasy pallicle, it indicates a superfluity of oleaginous particles.

When it separates and yields a very compact, tenacious, yellow, or bulby surface, it is too thick; and if the serum be at the same time small in quality, it flows a great degree of vascular action and inflammation. This is a fact very generally admitted.

Finally, it is to be observed, that we need not be alarmed when the thicker part of the blood seems to swim in a milky fluid; for it commonly happens, in drawing blood only a few hours after a meal, when it proceeds from the chyle, which, about this time, is imperfectly mixed with the blood.

We have thrown out these few hints for the attention of practical surgeons; but they are by no means to be regarded as complete or absolutely incontrovertible. There is a great deal of fallacy in judging from the colour, and other superficial qualities of the blood; and the moderns have, therefore, learnt to give their opinion with diffidence. This subject is considered more at large in a subsequent article. See Blood, and its properties.

**BLEEDING a Horse.** A frequent operation in the Veterinary Art, principally intended to diminish the mafs of blood, and thereby destroy the too great fulness or over-action of the heart and arteries.

When this operation is intended to affect the general system, the evacuation is usually made from the jugular vein. For the relief of particular parts, the vessels which belong to it, or which are adjacent to it, may be opened: as the vein running down the inside of the fore-arm is commonly opened when it is conceived the shoulder is affected; the necessity of this operation, on account of injuries of this part, is less frequent than is generally imagined; the vein itself in general gives out but little blood, and is very apt to swell after the operation.

Afflictions of the foot are more frequent, and we have often opened the coronary veins with obvious good effects: by puncturing with a lancet various parts of the coronary ring, the blood flows copiously, and at length stops of itself without the least ill concomitances.

The vein which encircles the coffin bone is also, without much difficulty, opened in inflammations of this part; the blood flows freely, the artery which accompanies it being in general opened along with it. It is necessary, in performing this operation, to remove the horn covering the vessels with a drawing knife till the blood-flows in sufficient abundance. The horn round the point of incision should be thinned considerably, to prevent irritation, and mild refuse dressings should afterwards be laid over the part, to exclude the air, &c.

This operation we have heard condemned by some, as producing ill concomitances, and a sore difficult to heal. We have only to remark, after having frequently performed it, we have not met with an instance of these ill effects following it.

The angular veins of the eye are often opened with good effects in inflammations of this part, as also the vesseis which are seen falling over the sclerotic coats of the eye, and over the duplicature of the membra na conjunctiva on the inside of the eye-lids, both of which admit of easy incision with the lancet.

The temporal artery also presents itself very conveniently for opening in the horse; and in inflammations of the brain, or its coverings, or where a sudden depletion of the system is desired, it is productive of manifest good effect.

If this vessel should bleed too freely, and apprehensions are entertained of the loss of too much blood, it is most easily stopped by pressure, or by a deep incision, which completely stops the vessel: in this case its ends soon retracting, stop the farther effusion of blood.

The veins of the palate are conveniently situated for opening, by making a transverse incision in this part with a lancet, and this is often made recourse to in the relaxation of the palate, termed lampons, and with apparently good effect. Some are deterred from the operation, by having experienced a difficulty in stopping the flow of blood; a circumstance that in a few times when we have performed this operation, has not occurred to us.

We shall now briefly state the mode of operating, and the concomitances which sometimes follow the opening of the jugular vein in horses.

It is most usual to bleed with the ftream, or the lancet; the former, on account of the thickness of the skin of the horse, and the resistance afforded by the hair, is generally had recourse to. It is also next to impossible to drive the blade into the neck so deep as to be injurious, on account of the shoulder to which it is affixed: it is perhaps, on this account, the safest and most certain instrument, especially in the hands of grooms and helpers in stables, as it cannot be much abused. In the structure of it, the back should be particularly attended to; for in general this is too narrow, incommodous, that the instrument being fixed, it presses into the channel of the vein, the prominent muscles of the neck receive the stroke, and the vein is not opened. To remedy this, which is a very common inconvenience, the back of the stream should be at least three quarters of an inch broad, in which case the operation very rarely fails.

The lancet is also very convenient in thin-skinned horses, and performs the operation very well. It requires, however, on account of the resistance of the skin and hair, to be used rather boldly, as to the length it is presented with, and the force employed, at least when a copious flow of blood is desired.

It is usual to wet the hairs over the part intended to be punctured,
puncheated, and then if they are drawn parallel to the direction of the vein, the lancet passing between them, there is less resistance than if they presented themselves transversely to the blade, in which case they must necessarily be divided before the incision can take place.

The jugular vein, after bleeding, often ulcerates, and is attended with the most serious ill consequences, the mischief extending in both directions along the internal surface of the vein, from the point of the incision; the cavity of the vein, or its canal becomes obliterated, and the irritation occasions a thickening of the cellular membrane surrounding the vein, often to some inches in depth. This, in general, if no external irritation happens, subsides gradually, and disappears without any farther ill consequences, and the vein is totally lost on that side: at other times, an oozing and discharge of thin lymph takes place from the injured part, and a slough forms, running molly against the course of the vein up the neck, which, being freely opened, soon heals without further inconvenience. At other times, considerable abscesses form, which are opened without danger, and the thickening of the cellular membrane gradually subsides, and the part heals. Again, in others, the inflammation and ulceration extend along the course of the vein to the head, forming abscesses, which burst and discharge blood, and the ulceration extending to the head becomes fatal.

As prevention is often much safer than cure, to avoid this accident great care should be taken to use a clean instrument, with a smooth, keen edge, not to strike where the vein has been already opened, where very often is an enlargement, and the vein becomes thinner in that part, and more extended, not to include any thing but the skin in pinning it up, and not to leave the pin remaining in the neck too long, to become cankered and ruly, and thus produce irritation. The pin should be elipt as short as possible, to prevent the horse rubbing it out against the manger, &c.

The wound will in general close of itself after a few minutes, if all pressure upon the vein be removed, and sufficiently firm to stop the escape of the blood, if the lips of the orifice are pressed together, without any pinning, and the horse's head, to render it more certain, should be tied rather high to the rack for a short time; where, however, the orifice is very large, or the veins very tumbid, and dispensed to bleed, pinning is the surest practice.

Lancets are often made with a spring, suddenly to plunge them into the vein, and are usefully and commodiously employed for this operation, as they do it with great suddeness and effect, more fo than the hand or the blow of a blood-flick. The only objection is, that the instrument, from the pressure against the neck required in using it, cannot be fo suddenly withdrawn as might be desirable, so that if the horse plunges at the moment he might severely cut himself, which we have seen happen. To prevent the possibility of such an occurrence, the instrument might be provided with a second spring to bring back the lancet to its sheath, or cafe, immediately after the stroke, which would render this instrument very useful and perfect.

Bleeding from the nape. See Epistaxis.
Bleeding from the lungs. See Hemoptysis.
Bleeding by means of, is where an account is taken of the quantity as it flows from the vein, in order to put a stop to the flux when the requisite portion is had.
Bleeding at large, where the flux is continued without regard to the quantity, till such time as some expected effect is perceived. This method is sometimes used in cases of apoplexies, comata, &c.

Bleeding of a corse, cruciatio cadaveris, is a phenome-
and confined in prison for eight years. Released at length from his confinement, he went and settled at Avignon, where he continued to the time of his death, about the year 1722, being 70 years of age. Haller, Bib. Chirurg. Anat. et Med. Elér, Diet. Hill.

BLEICHERODE, in Geography, a town of Germany, in the circle of Upper Saxony, county of Hohenstein, and lordship of Lora; though small, it is populous and thriving, has some manufactories, and carries on a good trade; 20 miles north of Milhausen.

BLEIDENSTATT, a town, or large village of Germany, in the circle of the Upper Rhine, and principality of Nassau-Saarbruck-Ulfsingen, seated on the Aar, 9 miles N.N.W. of Mentz.

BLEISTEIN, or Bleistain, is a town of Germany, in the circle of Bavaria, and principality of Newburg, with an annexed lordship, a fief of the kingdom of Bohemia; 22 miles E.N.E. of Amberg.

BLEKEDER, a small town of Germany, in the circle of Lower Saxony, and principality of Luneburg-Zell, seated on the Elbe, to which belongs a toll on the river of considerable produce; 20 miles E.N.E. of Luneburg.

BLENINGEN, called by the Swedes Blekingby, by the Danes Bleking, and by the inhabitants Bligen, a province of Sweden, bounded on the north by Smoland, on the south and east by the Baltic, and on the west by Scania, Schonen, and Skone, is about 100 English miles in length, and about 26 in breadth. It is a mountainous country, but various parts of it are more pleasant than any other provinces of the kingdom. It abounds with forests of oak, beech, pine, and birch trees, and carries on a considerable trade in potash, tar, tallow, hides, leather, beams, deal-boards, and masts. The inhabitants also employ themselves in fishing and hunting. The shallow soil does not admit of much tillage, but the pastures afford the best cheese in Sweden; the cattle, however, are of a smaller size than those of Schonen. This country has several lakes and five principal rivers, which furnish good fishers; its islands belonging to this jurisdiction are numerous, and the whole province contains 29 parishes. The clergy are subject to the see of Lund. As to its political division, it is subdivided into four cantons, or districts, and its principal town is Carlshonna, which is capital.

BLEMISH, or Blenheim, a term by which this disease is understood by many physicians, and by which the horse is disfigured. As broken knees, a blind eye, tears of various kinds, &c. The term blenheim, by some, may be extended even to any ugly natural markings of the horse. These blennishes, however, for the most part are considered as in no wise of themselves constituting an unsoundness.

BLENISH, a term in Hunting, used when the hounds, or beagles, finding where the chase has been, make a proffer to enter, but retreat.

BLEMYS, or Blemyes, among the Ancient Geographer, a fabulous sort of people, supposed without heads; having eyes and mouths on their breasts; said to have inhabited part of Ethiopia, on the borders of Egypt.

Some authors imagine, that this fable had its origin in a custom which prevailed among this people of depriving their heads between their shoulders, which they forced upwards, so that their necks were very short, and their heads were concealed partly by their shoulders, and partly by their long and thick hair. To this purpose it is alleged, that the Egyptian, or bearded Bacchus, has the head sunk in his breast. We learn from Vopiscus, that some Blemmyan captives, taken prisoners by Probus, in an expedition against them, about the year of Christ 278, made a very odd appearance at Rome. But at this time they could not be quite unknown at Rome, as some of them had appeared there before, on occasion of Aurelian's triumph. In the time of Diosclerus, the number of the Blemmys, scattered between the island of Menoe and the Red sea, was very considerable, their disposition was unwarlike, and their weapons rude and offensive; yet, in the public disorders, these barbarians, whom antiquity, shocked with the deformity of their figure, had almost excluded from the human species, prevailed to rank themselves among the enemies of Rome. With a view of opposing to the Blemmys a suitable adversary, Diosclerus, in his attack on the rebellious Egyptians, A.D. 286, permitted the Nubians, or people of Nubia, to remove to their ancient habitations in the desert of Lybium, and assigned to them an extensive but unprofitable territory above Syene, and the cataracts of the Nile, with the stipulation, that they should ever respect and guard the frontier of the empire. We find, however, that at a subsequent period they sent ambassadors to the court of Constantine. The Blemmys were subdued by Florus, the lieutenant of Marcellus, A.D. 450.

Bochart derives the word Blemys from δαμας, which implies a negation, and δαμας, brain; in which sense, the Blemmys should have been people without brains. See Strabo, I. xvii. p. 172. Pomponius Mela, l. i. c. 4. His words, in describing these savages of Ethiopia, are curious: "Intra, si crederis libet, vix homines magisque femenides; Aegipianes, et Blemymes, et Satyris." BLENNAU, in Geography, a town of France, in the department of the Yonne, and chief place of a canton in the district of Oigny, containing 1655 persons; the number of people in the canton amounts to 5976; the territory comprehends 290 kilometres and 9 communes; 2 leagues N.W. of St. Fargeau.

BLENCH, in Law, a sort of tenure of land; as to hold land in blench is by payment of a sugar-loaf, a couple of capons, a beaver-hat, &c. if the same be demanded in the name of blench, i.e. nominis alte firma. See ALBA FIANA.

BLENE, in Mineralogy, called also black-jack, or pseudo-galena, the native sulphur of zinc. See ZINC, ores of.

BLEND-Metal iron, a coarse sort of iron from the Staffordshire mines, used for making nails and heavy ware; in some places also for horse-hocks.

BLEND-water, a distemper incident to black-cattle, which comes several ways. 1. From blood. 2. From the yellows, which is a ringleader of all diseases. And 3. From the change of ground: for being hard, it is apt to breed this evil, which if not remedied in six days, will be past help.

BLENHEIM, in Geography, a village of Germany, in the circle of Bavaria, and principality of Newburg, 2 miles N.E. of Hockstedt, famous for a victory obtained there by the English and their allies over the French and Bavarians, August 13th 1704. For an account of the battle, see HOCKSTEDT.

BLENHEIM, a new town of America, in the state of New York, in Schoharie county, incorporated in 1797.

BLENNA, or BLENA (from) in Medicine, a term used by Hippocrates, and subsequent medical writers, to denote a phlegm or mucus excreted from the nostrils. This sort of excretion occurs not unfrequently in acute diseases, and is generally a favourable symptom.

BLENNIUS, in Ichthyology, a Linnaean genus of jugular fibres,
Galen, in Surgery, was the first to describe the symptoms and treatment of blennorrhagia. He divided it into four sections: the first including those with a head crusted (blennus occidentalis Linn.), and the blennic physis, because these have two dorso fins, and filaments or appendages upon the head. The second division, comprehending those with only one dorso fin and filaments upon the head, includes the blennic mediterraneen (gadus mediterraneus Linn.), the blennic gattorugine (gadus fuscus Linn.), the blennic coquaille (blennia generale Linn.), the blennic fanter (a species discovered by Commeron in the South seas), and the blennic sarini (blennia eritrita Linn.). The third and fourth section has no appendage upon the head, but are distinguished from each other by having either two dorso fins, or only one. Those with two are the blennic gadoidae (gadus albus Linn.), the blennic belette, and the blennic triacule. Lastly, in the fourth section are the blennic pholis, the blennic bofide, of Lacépède, the blennic ovovipare (blennia oviparum Linn.), the blennic guncel, the blennic pointile of Lacépède, the blennic garamit, (gadus soliaris of Forkal), the blennic lumpsé, and the blennic torfs.

BLENNORRHAGIA, in Surgery, is a term lately introduced to express the varieties of a morbid affection, more generally called Gonorrea. This term is derived from gloss, mucus, and gen, gens; and is therefore equivalent to the Latin word Muscosus; but it is distinguished from Blennorrhea, which denotes the symptom usually called Gleet. The author who has principally endeavoured to introduce this new epithet, is Dr. Schwedauer. His classification is as follows:

**Classis, Localis.**
Ordo, Phlegofes, or Muscosus.

**Genus, Blennorrhaia.** Angl. Claph; Germ. tripson; Gallé, Chaud Pisse; Ital. Gonorrhoea.

**Characters in Viribus.**—Titillatio, praecipue in urethra parte anteriori in lacuna Morgagni sub frangulo; subsequente pote biduum aut quattuoridum, philogofi locali, cum ardo et dolore in mingendo; accedente filliciado materiei purulentae vel puriformis ex urethra; corpore cavernofo urethra præternaturaliter turgescente, plerunque cum erexitium membra virilis folio frequentioribus dolorificis.

In Femininis.—Titillatio ad orificium vaginum externum; subsequente pote biduum aut quattuoridum dolore, rubore et tumore præternaturali, praecipue (ad rapham) prope commifuram labiorum uliorem inferiorem; accedente ardo et dolore ejufdem partis in mingendo; cum fillicicio materiei puriformis ex vulva.

**Gonorrea**

BLENNUS, in Ichthyology, a name given by Schonfelt to the \textit{fuguwhath tymphe} of Linnaeus, and shorter pipe fish of English writers.

BLENNY. See BLENNUS.

BLENOD, in Geography, a town of France, in the department of the Meurthe, and chief place of a canton, in the district of Toul, 5 miles south of Toul.

BLEONNE, a river of France, which runs into the Durance near Meez, in the department of the Lower Meuse.

BLERA, in Ancient Geography, Gravina, a small town in Italy, in Apulia, east of Venula. The Blera of Ptolemy is a place in Etruria, near Tarquinia.

BLE'RE', in Geography, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Tours, containing 2519 inhabitants; the population of the canton is 13185; and the territory comprehends 472.4 kilometres, and 15 communes; 4 leagues E.S.E. of Tours.

BLERGIES, a town of France, in the department of the Somme, 8 miles S. W. of Poix.

BLEMCHINO, a town of Bohemia, in the circle of Konigingratz, 3 miles east of Konigingratz.

BLE'SLE, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Brioude, seated on the Allagnon, and containing 1329 inhabitants; the population of the canton is 5706; the territory comprehends 167.1 kilometres and 12 communes; 3 leagues W. of Brioude.

BLESS, Henry, in Biography, a painter of history and landscape, was born at Dovine, near Dinant, in 1480, and, without any instruction, rendered himself eminent in his art, by his own genius, and a diligent study of the works of Petenier, particularly by his landscapes. His style of composition, in historical subjects, resembled the style of the Flemish artists of that age, and crowded several subjects into one design; and yet his pictures were so delicately pencilled and finished, and his landscapes so agreeably varied and well executed, that even in Italy his works were highly esteemed, and distinguished by the appellation of the owl pictures, for he fixed an owl, as his peculiar mark, in every picture he painted. He died in 1550. Pilkington.

BLESSINGTON, in Geography, a market town in the county of Wicklow, and province of Leinster, Ireland, which, before the union, sent two members to parliament. It is pleasantly situated on a rising ground near the Liffy, 14 miles S.W. of Dublin; and was founded by primative Boyle, one of whose descendants, the marquis of Downshire, is the present proprietor. The number of inhabitants, according to Mr. Frazer, does not exceed 400. N. lat. 53° 9' 45''. W. long. 6° 34'. Dr. Beaufour. Frazer's Wicklow.

BLEST, or BLESTIO, in Ancient Geography, a place of Britain, in the county from Ica to Caleva, according to the itinerary of Antoninus, between Burrium and Ariciumn, suppos'd by Mr. Horley to be Monmouth. Mr. Camden, and Mrs. Gale, and Stukeley, have placed this station at Old Town, in Herefordshire.

BLESTRISMUS, in the Ancient Physic, (\textit{strepisus}, \textit{fractos}) a term employed by medical writers to express those refleffines and toasting about the body, which takes place in febrile disorders.

BLETA ALBA, a barbarous term employed by Paracelsus to denote a milky appearance of the urine in some distempers of the kidneys.

BLETTERAND, in Geography, a town of France, in the department of Jura, and chief place of a canton, in the district of Lons-le-Saulnier, 6 miles N.W. of Lons-le-Saulnier; containing 732 inhabitants. The population of the canton is estimated at 10,007; the territory comprehends 150 kilometres, and 13 communes.

BLETTERIE, John Philip René de La, in Biography, a distinguished professor of the congregation of the oratory, was born at Rennes; and quitting the congregation, he removed to Paris, and obtained the rhetorical chair in the Royal College, and a seat in the Academy of Belles Lettres. Among his most esteemed works may be reckoned his "History of Julian the Apostate," Paris, 1735, 1746, 12mo.; "History of the emperor Julian, and a translation of some works of the emperor Julian," Paris, 1748, 2 vols. which Gibbon (Decl. and Fall of the Rom. Emp. vol. iv. p. 206.) characterizes as "a work remarkably distinguished by elegance of style, critical disquisition, and religious prejudice." The abbé de la Bletterie also published a translation of the "Life of Agricola," and the "Manners of the Germans," of Tacitus, and a life of that historian, his favourite author, in 1755; and a translation of the six first books of the "Annales," in 1768. The style of this work has been charged with the vulgarity of religious sectarianism; for the author had adopted the opinions of the quietist Quenel, and published a defence of the famous madame Guyon. He died in 1772, at an advanced age, with an excellent character for both understanding and morals. Nov. Dict. Hift.

BLETUS, in the Ancient Physic, (\textit{staton}, from \textit{bala}, to stirke.) This term is used by Hippocrates and other medical writers to signify a livid appearance or ecchymosis on the sides of the chest, as if from a blow, which sometimes occurs in those who die of pleurisy. The epithet \textit{bala} has also been applied to those who die suddenly (as if struck by lightning) in acute diseases.

BLEU, in Ichthyology, the French trivial name for the species of fish called by Linnaeus \textit{paltus glaucescens}.

BLEUET, in Ornithology, is the name by which the common king's piper, \textit{alcedo ipida}, is called in Provence.

BLEUVERT. The \textit{merops caroldus} of Latham is known among the French naturalists by this title.

BLEVY, in Geography, a town of France, in the department of the Eure and Loire, 3 leagues S.S.W. of Dreux.

BLEXEN, a town of Germany, in the circle of Westphalia, and county of Oldenburgh, 3 miles N.N.E. of Oldenburgh.

BLEYL, a village of Bohemia, near the town of Bregnitz, in the circle of Sazau, or Saaz; famous on account of its manufactury for the preparation of sulphuric acid, by separating it from sulphat of iron by distillation. The manufactury has two sheds for this operation; one with three galleries, each containing 20 retorts on each side; the other with two galleries, each holding on each side 21 retorts. In the galleries of this manufactury there is likewise a distillation of aqua fortis, or nitric acid.

BLEYMARD. See BLYMARD.

BLEYNE, in Farriery, a French word, now obsolete in the English language, for a sand crust, which fee.

BLEYSWELCH, in Geography, a town of Germany, in the circle of Westphalia, and bishopric of Paderborn, 4 miles S. of Wunnenberg.

BLEYSWICK, a town of Holland, 8 miles north of Rotterdam.

BLIARUS, or MEMBRIARUS, in Ancient Geography, an island of the Mediterranean, near that of Thera, laid by Steph.
B L I

Steph. Byz. to have derived its name from one of the companions of Cadmus.

BLIEGG, in Ichthyology, a name given by the Germans to the fish we call the bleak. See BLEAK, and A ROUSUS.

BLIESCASTEL, in Geography, a town of France, in the department of Strasburg, and chief place of a canton, in the district of Sarrebuck; containing 12,484 inhabitants; the population of the canton includes 10,084 persons; and the territory has 30 communes.

BLIESNA SALES.S, a harbour on the coast of Lapland, between the rivers Kola and Kildainy island.

BLIGHT'S CAP, a name given by captain Cook, on account of its shape, to an island in the southern Pacific ocean, near Kerguelen's land, before called by Kerguelen "the island of Rendezvous." It is a high round rock accessible only to birds. S. lat. 48° 2'. E. long. 68° 4'.

BLIGHT, in Agriculture, a general name for various diseases incident to corn and fruit-trees.

It affects them variously, the whole plant sometimes perishing by it, and sometimes only the leaves and blossoms, which will be scorched and shrivelled up, the rest remaining green and flourishing. Some have supposed, that blights are produced by calmer winds, which bring vast quantities of insects' eggs along with them from distant places. These being lodged upon the surface of the leaves and flowers of fruit-trees, cause them to shrivel up and perish.

Mr. Knight, however, observes, that blights are produced by a variety of causes: by insects, by an excess of heat or cold, of drought or moisture; for these necessarily damage and destroy the delicate organization of the blossoms; but he believes the common opinion, that they arise from some internal or external quality in the air, or from lightning, to be totally unfounded. The term blight is very frequently used by the gardener and farmer, he remarks, without any definite idea being annexed to it. If the leaves of their trees be eaten by the caterpillar, or contracted by the aphid; if the blossoms fall from the ravages of insects, or without any apparent cause, the trees are equally blighted; and if an east wind happen to have blown, the insects, or at least their eggs, whatever be their size, are supposed to have been brought by it.

The true cause of blights seems to be, continued dry easterly winds for several days together, without the inter- vention of showers, or any morning dew, by which the perspiration in the tender blossoms is stopped; and if it do happen that there is a long continuance of the same weather, it equally affects the tender leaves, whereby their colour is changed, and they wither and decay.

The best remedy, perhaps, is gently to wash and sprinkle over the tree, and, from time to time, with common water; and if the young shoots seem to be much infected, let them be washed with a wet woolen cloth, so as to clear them, if possible, from this glutinous matter, that their respiration and perspiration may not be obstructed. This operation ought to be performed early in the day, that the moisture may be excluded before the cold of the night comes on; nor should it be done when the sun shines very hot. Mr. Forthyn recommends that their being washed well with urine and soap-suds, as soon as possible after the diff sic appears.

Another cause of blights in the spring, is said to be sharp, hoary frosts, which are often succeeded by hot sun-shine in the day-time. This is the most sudden and certain destroyer of fruit that is known. The chief remedy to be depended upon in this case is, that of protecting the fruit-trees during the night-time with nets. This mode, where regularly and correctly performed, has been found highly beneficial.

But, in order to cure this disease, some have advised the burning of wet litter on the windward side of the plants, in order that the smoke of it may be carried to them by the wind, which they suppose will affright and destroy the insects and therby cure the mischief. Others direct the use of tobacco-dust, or the washing of the trees with water in which tobacco-dust has been infused for twelve hours, which they say will destroy those insects, and recover the plants. Pepper-dust, scattered over the blossoms of fruit-trees, &c. has been recommended as very useful in this case; and there are some who advise the pulling off the leaves that are affected.

What is termed the blight is frequently, however, no more than a debility, or dissembler in trees. Mr. Forthyn observes, that "this is the case when trees, against the same wall, and enjoying the same advantages in every respect, differ greatly in their health and vigour, the weak ones appearing to be continually blighted, while the others remain in a flourishing condition. This very great difference, in such circumstances, can be attributed only to the different constitutions of the trees, proceeding from want of proper nourishment, or from some bad qualities in the soil; some dissembler in the flock, buds, or seats; or from some maimagement in the pruning, &c. all of which are producive of dissemblers in trees, of which they are, with difficulty, cured. If the fault be in the soil, it mult, he says, be dug out; and freshly mould be put in its place; or the trees must be taken up, and others, better adapted to the soil, planted in their room. It will be found absolutely necessary always to endeavour to suit the particular sorts of fruit to the nature of the soil; for it is vain to expect all sorts of fruit to be good in the same soil. If the weakness of the tree proceed from an ill-kept dissembler, it will be advisable to remove it at once, and after renewing the earth, to plant another in its place." But if the weakness is brought on by ill management in the pruning, which is frequently the case, he would advise a more attention to the method of pruning and training.

Besides this, "there is another sort of blight that sometimes happens pretty late in the spring, as in April or May, which is very destructive to fruit-trees in orchards, and open plantations, and against which we know no effectual remedy. This is what is called a fire-blister, which, in a few hours, hath not only destroyed the fruit and leaves, but often parts of trees; and sometimes entire trees have been killed by it." This, Mr. Forthyn observes, "is generally thought to be occasioned by certain transparent flying vapours, which may sometimes take such form as to converge the sun's rays in the manner of burning-glasses, so as to sear the plants they fall upon; and this, in a greater or less degree, in proportion to their convergency. As this generally happens in close plantations, where the vapours from the earth, and the perspiration from the tree, are pent in for want of a free circulation of air to disperse them, it points out to us the only way, yet known, of guarding against this enemy to fruits; namely, to make choice of a clear healthy situation for kitchen-gardens, orchards, &c. and to plant the trees at such a distance, as to give free admission to the air, that it may disperse those vapours before they are formed into such flames as to occasion these blights." But blights may also be occasioned by the reflection of the sun's rays from hollow clouds, which sometimes act as burning mirrors, and occasion excessive heat. Against this there is no remedy yet discovered.

Mr. Marshall, in the Rural Economy of midland counties, observes, that it is well known that this disease is most injurious

BLI

5. In the humour of the eye. By their defective quantity; by the turbid state, or imperfectly transparent condition, of the humours; by the loss of any one of them, through accident or violence; by an altered figure of the crystalline lens.

4. In the brain or optic nerves. By compression, producing palsy or Guttai Serena (which fey); by a state of debility or inertia of the visual organs, so as to require an uncommonly strong light; by too great sensibility in the optic nerves, endearing but a very feeble impression from the light, and transmitting only a confused perception of visible objects to the mind; by some unknown change in the nervous power, causing depraved vision, and exciting imaginary fancies, which no person can observe besides the patient himself.

It has been generally supposed, that blind persons have not any idea of visible objects, though they can distinguish them by the touch: thus the gentleman coughed by Mr. Cheffelden, though he knew the colours to be in a good light during his blind state; yet when he saw them after considering, the faint ideas he had of them before, were not sufficient for him to know them by afterwards. Phil. Trans. N° 403.

P. 447.

It was even a considerable time before he could remember which was the cat and which the dog, though often informed, without feeling them. Add, that he had no idea of distance; but thought all the objects he saw touched his eyes, as what he felt did his skin.

But a cafe is recorded by Mr. Ware in the Philosophical Transactions (read to the society June 11th, 1801), which does not accord with Mr. Cheffelden's observation on this subject. It was the cafe of a young gentleman, who (by a surgical operation) recovered his sight when seven years of age; after having been deprived of it by catarrh, before he was a year old. Mr. Ware gives the following account of the facts in question: "I performed the operation on the left eye, on the 29th of December last, in the presence of Mr. Chamberlayne, F.A.S. Dr. Bradley, of Baldock college, Oxford, and Mr. Platt, surgeon, in London. It is not necessary, in this place, to enter into a description of the operation. It will be sufficient to say, that the child, during its performance, neither uttered an exclamation, nor made the smallest motion, either with his head or hands. The eye was immediately bound up, and no inquiries made on that day with regard to his sight. On the 30th, I found that he had experienced a flight sickness on the preceding evening, but had made no complaint of pain, either in his head or eye. On the 31st, as soon as I entered his chamber, the mother, with much joy, informed me that her child could see. About an hour before my visit, he was standing near the fire, with a handkerchief tied loosely over his eyes, when he told her that under the handkerchief, which had slipped upward, he could distinguish the table by the side of which she was sitting: it was about a yard and a half from him; and he observed that it was covered with a green cloth (which was really the cafe), and that it was a little farther off than he was able to reach. No further questions were asked him at that time; as his mother was much alarmed, lest the fife thus made of his eye might have been premature and injurious. Upon examination, I found that it was not more inflamed than the other eye; and the opacity in the pupil did not appear to be much diminished. Distress, however, to ascertain whether he was able to distinguish objects, I held a letter before him, at the distance of about twelve inches, when he told me, after a short hesitation, that it was a piece of paper; that it was square, which he knew by its corners; and that it was longer in one direction than it was in the other. On being desired to point to the corners, he did it with great precision, and readily carried his finger in the line of its longest diameter. I then showed him a small oblong hand-box covered with red leather, which he said was red and square, and pointed at once to its four corners. After this, I placed before him an oval silver box, which he said had a shining appearance; and, perfectly afterwards, that it was round, because it had not corners. The observation, however, which appeared to me most remarkable, was that which related to a white stone mug; which he first called a white basin; but, soon after, recollecting himself, said it was a mug, because it had a handle. Thee experiments did not give him any pain; and they were made in the presence of his mother, and of Mr. Woodford, a clerk in his majesty's treasury. I held the objects at different distances from his eye, and inquired very particularly if he was sensible of any difference in their situation; which he always said he was, informing me, on every change, whether they were brought nearer to, or carried farther from him. I again inquired, both of his mother and himself, whether he had ever, before this time, distinguished by sight any sort of object; and I was assured by both that he never had, on any occasion; and that, when he wished to discover colours, which he could only do when they were very strong, he had always been obliged to hold the coloured object close to his eye, and a little on one side, to avoid the projection of the nose. No further experiments were made on that day. On the ist of January, I found that his eye continued quite free both from pain and inflammation, and that he felt no uneasiness on the approach of light. I showed him a table knife; which at first he called a spoon; but soon recollected the mistake, giving it the right name, and distinguishing the blade from the handle, by pointing to each as he was described. He afterwards called a yellow pocket-book by its name, taking notice of the silver lock in the cover. I held my hand before him; which he knew, but could not at first tell the number of my fingers, nor distinguish one of them from another. I then held up his own hand, and desired him to remark the difference between his thumb and fingers; after which, he readily pointed out the distinctions in mine also. Dark-coloured and smooth objects, were more agreeable to him than those which were bright and rough. On the 3d of January, he fave, from the drawing-room window, a dancing-bear in the street; and distinguished a number of boys that were running round him, noticing particularly a bundle of cloths which one of them had on his head. On the same evening, I placed him before a looking-glass, and held up his hand: after a little time he smiled and said he saw the shadow of his hand, as well as that of his head. He could not then distinguish his features; but, on the following day, his mother having again placed him before the glass, he pointed to his eyes, nose, and mouth, and seemed much gratified with the sight.

Having thus stated the principal observations that were made by M. W. I shall now make a brief comparison between this statement, and that which is given in the XXXVith volume of the Philosophical Transactions, of M. Cheffelden's patient, who was supposed to be born blind, and obtained his sight when he was between thirteen and fourteen years old.

It should be observed, that though M. W. was six years younger than Mr. Cheffelden's patient, he was remarkably intelligent, and gave the most satisfactory answers to every question that was put to him. Both of them, also, if not born blind, lost their sight very early, that, as Mr. Cheffelden expresses it, "they had not any collection of having ever seen."
My first remark is, that, contrary to the experience of Mr. Cheffelden's patient, who is stated “to have been so far from making any judgment of distance, that he thought all objects touched his eyes, as what he felt did his skin,” Muller W. distinguished, as soon as he was able to see, a table, a yard and a half from him; and proved that he had some accuracy in his idea of distance, by saying, that it was a little further off than his hand could reach. This observation, so contrary to the account we have received of Mr. Cheffelden's patient, would have surprised me much more than it did, if I had not previously, in some similar instances, had reason to suspect that children, from whom cataracts had been extracted, had a notion of distance the first moment they were able to feel. On the contrary, in the instance particularly of a young gentleman from Ireland, fourteen years old, from each of whose eyes I extracted a cataract, in the year 1704, in the presence of Dr. Hamilton, physician to the London hospital, and who, before the operation, assured me, as did his friends, that he never had seen the figure of any object, Dr. Hamilton and myself were much astonished by the facility with which, on the first experiment, he took hold of my hand at different distances, mentioning whether it was brought nearer to, or carried further from him, and conveying his hand to mine in a circular direction, that we might be the better satisfied of the accuracy with which he did it. In this case, however, and in others of a like nature, although the patient had certainly been blind from early infancy, I could not satisfy myself that they had not, before this period, enjoyed a sufficient degree of sight to imprint the image of visible objects on their minds, and to give them ideas which could not afterwards be entirely obliterated. In the instance of Muller W., however, no suspicion of this kind could occur; since, in addition to the declaration of himself and his mother, it was proved by the testimony of the surgeon who examined his eyes in the country, that the cataracts were fully formed before he was a year old. And I beg leave to add further, that on making inquiries of two children, between seven and eight years of age, now under my care, both of whom have been blind from birth, and on whom no operation has yet been performed, I find that the knowledge they have of colours, limited as it is, is sufficient to enable them to tell whether coloured objects be brought nearer to, or carried further from them; for instance, whether they are at the distance of two inches or four inches from their eyes; nor have either of them the slightest suspicion, as is related of Mr. Cheffelden's patient, that coloured objects, when held before them, touch their eyes. But the judgment which Muller W. formed of the different distances of objects, was not the only instance in which he differed from Mr. Cheffelden's patient; who, we are informed, “did not know the figure of any thing, nor any one thing from another, however different in shape and magnitude;” for Muller W. knew and described a letter, not only as white, but also as square, because it had corners; and an oval silver box, not only as shining, but also as round, because it had not corners: he likewise knew, and called by its name, a white stone mug, on the first day he obtained his sight, distinguishing it from a bason, because it had a handle. These experiments were made in the presence of two respectable persons, as well as myself; and they were several times repeated, to convince us that we could not be mistaken in them. I mention the circumstance, however, with much diffidence, being aware that the observations not only differ from those that are related of Mr. Cheffelden's patient, but appear, on the first statement, to oppose a principle in optics, which I believe is commonly and justly admitted, that the senses of sight and feeling have no other connection than that which is formed by experience; and, therefore, that the ideas derived from feeling can have no power to direct the judgment, with respect either to the distance or form of visible objects. It should be recollected, however, that persons who have cataracts in their eyes, are not, in strictness of speech, blind, though they are deprived of all useful light. The instances I have adduced prove, that the knowledge they have of colours is sufficient to give them some idea of distance, even in their darkest state. When, therefore, their sight is cleared by the removal of the opaque crystalline, which intercepted the light, and the colour of objects is thereby made to appear stronger, will it be difficult, or unphilosophical, to conceive that their ideas of distance will be strengthened, and so far extended as to give them a knowledge, even of the outlines and figure of those objects with the colour of which they were previously acquainted? The miferies of blindness are feelingly described both by Homer and Milton, in the following impressive passages. The venerable father of epic poetry, who is said, in the person of Democritus the Phœnician bard, to have described his own situation, proceeds thus:

"The wise who touch the sense, do not see.

The dark, and up to re-ascend,

Though hand and rare; then I revisit fate,

And feel thy fav'rent vital lamp: but thou
Reviv'st not these eyes, that roll in vain
To find thy piercing ray, and find no dawn:
So thick a drop hereath quench'd their orbs,
Or dim suffusion veil'd.

Yet not the more
Cace I to wander, where the muses haunt
Clear spring, or shady grove, or sunny hill,
Smit with the love of sacred song: but chief
Thee, Dion, and the flow'ry brooks beneath,
That wash thy hallow'd feet, and warbling flow,
Nightly I visit; nor sometimes forget
Those other two, equall'd with me in fate,
So were I equall'd with them in renown,
Blind Thamyris and blind Meonides,
And Tiresias and Phœnus prophets old:
Then feed on thoughts, that voluntary move
Harmonious numbers; as the wakeful bird
Sings darkling, and in shadelet covert hid
Tunes her nocturnal note. Thus with the year
Seafsons return; but not to me returns
Day, or the sweet approach of ev'n or morn,
Or light of vernal bloom, or summer's rose,
Or flocks, or herds, or human face divine:
But cloud instead, and ever during dark,
Surrounds me, from the cheerful ways of men
Cut off, and for the book of knowledge fair
Prefent'd with an universal blank
Of nature's works to me expugnd and ras'd,
And wisdom at one entrance quite shut out."
Blind among enemies, O worse than chains, 
Dungeon, or beggary, decrepit age. 
Light, the prime work of God, to me is extinct, 
And all her various objects of delight
Annull'd, which might in part my grief have eas'd, 
Inferior to the vilest now become
Of man or worm. The vileness here excels me: 
They creep, yet fee; I dark in light expos'd 
To daily fraud, contempt, abuse, and wrong, 
Within doors, or without, fill as a fool, 
In power of others, never in my own;
Scarce half I feem to live, dead more than half.
O dark, dark, dark, amid the blaze of noon, 
Irrecoverably dark, total eclipse
Without all hope of day!
O first created beam, and thou great word, 
Let there be light, and light was over all;
Why am I thus bereav'd thy prime decree? 
The fun to me is dark, 
And silent, as the moon
When the deforms the night, 
Hid in her vacant interlunar cave. 
Since light so necessary is to life, 
And almost life itself, if it be true 
That light is in the soul, 
She all in every part; why was the fight 
To such a tender ball as thine eye confin'd? 
So obvious, and so easy to be quench'd? 
And not, as feeling, throughout all parts diffus'd, 
That the might look at will through ev'ry pore? 
Then had I not been thus call'd from light, 
As in the land of darknes, yet in light 
To live a life half dead, a living death: 
And buried; but yet more miserable! 
Myself the leprous, a moving grave; 
Bury'd, yet not exempt 
By privilege of death and burial 
From word of other evils, pain, and wrongs, 
But made hereby obnoxious more 
To all the miseries of life.

The degree in which the calamity of blindnes is felt and lamented by those to whom it occurs, may be also partly guessed at by the extatsies into which perons have fallen on their recovery from it.

Mr. Boyle mentions a gentleman, who, having been blind, and brought to fight at eighteen, was very near going distracted with the joy. See a remarkable case of this kind, Tatler, N° 55. vol. i. Boyle's Works abr. tom. i. p. 4.

We find various recompenes for blindnes, or subtitUttes for the use of the eyes, in the wonderful fagacity of many blind persons recited by Zahnus in his "Oculus Artificialis," and others. In fome, the defect has been supplied by a most excellent gift of remembering what they had seen; in others, by a delicate nofe, or the fene of smelling; in others, by an exquisite touch, or a fene of feeling, which they have had in fuch perfection, that, as it has been faid of fome, they learned to hear with their eyes; as it may be faid of thofe, that they taught themselves to fee with their hands.

Some have been enabled to perform all forts of curious and fubtle works in the niceft and moft dexterous manner. Aldrovandus speaks of a fculptor who became blind at twenty years of age, and yet ten years after made a perfect marble statue of Cosimo II. de Medici; and another of clay like Urban VIII. Barbarin tells us of a blind fculptor in Denmark, who diftinguifh'd perfectly well, by mere touch, not only all kinds of wood, but all the colours; and F. Grimaldi gives an infance of the like kind; besides the blind organift living in Paris, who is said to have done the fame.

An infance no lefs extraordinary is mentioned by Dr. Bow in the Tracations of the Manchefter Society.

It is that of a perfon, whose name is John Metcalf, a native of the neighbourhood of Manchefter, who became blind at an early age as to be altogether unconfeious of light and its various effects. His employment in the younger period of his life was that of a waggoner, and occasionally as a guide in intricate roads during the night, or when the common tracks were covered with snow. Afterwards he became a projector and surveyor of high-ways in difficult and mountaneous parts; and in this capacity, with the affiftance of a long ftaff, he traverses the roads, ascends precipices, explores valleys, and investigates their feveral extents, forms, and situations, fo as to acqur his purpose in the beft manner. His plans are delineat'd, and his estimates formed, with fuch accuracy and confidence, that he has been employed in altering most of the roads over the Peak in Derbyshire, particularly those in the vicinity of Buxton, and in constructing a new one between Wilmflew and Congleton, fo as to form a communication between the great London road, without being obliged to pafs over the mountain.

Although blind perons have occafion, in a variety of respects, to deplore their infelicity, their misery is in a considerable degree alleviated by advantages peculiar to themfelves. They are capable of a more fixed and steady attention to the objects of their mental contemplation, than thofe who are diftracted by the view of a variety of external scenes. Their want of light naturally leads them to avail themfelves of their other organ of corporal fenfation, and with this view to cultivate and improve them as much as poftible. Accordingly they derive relief and affiftance from the quickness of their hearing, the acutenef of their fenn, and the fenitiveness of their touch, which perons who fe are apt to difregard; and many infances have occurred, that feem to verify the opinion of Rochester:

"That if one fene should be fuppof'd, 
it but retires into the reft." 

To this pofe we may obferve, that Democritus is said to have put out his eyes, that he migbt think more intenfly.

Many contrivances have also been devis'd by the ingeneous for supplying the wants of light, and for facilitating thofe analytical or mechanical operations, which would otherwife perplex the moft vigorous mind and the moft retentive memory. By means of these they have become eminent proficients in various departments of science. Indeed, there are few sciences in which, with or without mechanical helps, the blind have not diftinguifh'd themfelves. The cafe of professor Sawander at Cambridge is well known. His attainments and performances in the languages, and also as a learner and teacher in the abftrac mathematics, in philofophy, and in music, have been truly afoivating; and the account of them appears to be almost incredible, if it were not amply attested and confirmed by many other infances of a fimilar kind, both in ancient and modern times. Cicero mentions it as a fact scarcely credible, with refpet to his mafter in philofophy, Diogenes, that "he exercifed himself in
in it with greater affinity after he became blind; and, which he thought next to impossible to be performed without light, that he professed geometry, and described his diagrams so accurately to his scholars, as to enable them to draw every line in its proper direction. Jerom relates a more remarkable instance of Didymus in Alexandria, who, "though blind from his infancy, and therefore ignorant of the letters, appeared to great a miracle to the world, as not only to learn logic, but geometry also to perfection, which feems (he adds) the molt of any thing to require the help of light." Professer Saunderfon, who was deprived of his light by the small pox, when he was only twelve months old, feems to have acquired molt of his ideas by the fene of feeling; and though he could not distinguih colours by that fene, which, after repeated trials, he faw, was pretending to im- possibilities, yet he was able with the greatest exactnes to discriminate the minutest difference of rough and smooth in a surface, or the least defect of poliſh. In a fet of Roman medals he could distinguih the genuine from the falle, though they had been counterfeited in fuch a manner, as to deceive a connoiflfer who judged of them by the eye. His fene of feeling was fo acute, that lie could perceive the least variation in the state of the air; and it is faid, that in a garden where observations were made on the fun, he took notice of every cloud that interrupted the observation, al- most as jufly as thoſe who could fee it. He could tell when any thing was held near his face, or when he paffed by a tree at no great distance, provided the air was calm, and there was little or no wind: this he did by the different pulse of air upon his face. He profefled a fenfibility of hearing to fuch a degree, that he could distinguih even the fifth part of a note; and by the quicknelf of this fene he not only diftinguished perfons with whom he had once con- vefed fo long as to fix in his memory the found of their voice, but he could judge of the fize of a room into which he was introduced, and of his diftance from the wall; and if he had ever walked over a pavement in courts, piazzas, &c. which reflected a found, and was afterwards con- ducted thither again, he could exaftly tell in what part of the wall he was placed, merely by the note which it founded. See SAUNDERSON.

Sculpture and painting are arts which, one would imagine, are of very difficult and almost impracticable attain- ment to blind perfons; and yet infaences occur, which fhew that they are not excluded from the pleafing creative and expenfive regions of fancy. We have known cafe in which the form and features of the face have been delineated wholly by the touch, and in which it has been moulded with the utmost exactnes. De Piles (Cours de Peint. p. 329.) mentions a blind sculptor, who thus took the likeness of the duke de Bracciano in a dark cellar, and made a marble figure of King Charles I. with great infence and elegance. However unaccountable it may appear to the fromed philo- sophers, yet nothing is more certain in fact, than that a blind man may, by the infpiration of the mufes, or rather by the efforts of a cultivated genius, exhibit in pofture the moft natural images and animated defcriptions even of visible objects, without defervedly incurring the charge of plagi- rism. We need not recur to Homer and Milton for attesta- tions to this fact; they had probably been long acquainted with the visible world before they had loft their light; and their defcriptions might be animated with all the rapture and enthusiasm which originally fired their bosoms, when the grand and delightful objects delineated by them were immediately beheld. We are furnished with instances in which a fimilar energy and transport of defcription, at least in a very confiderable degree, have been exhibited by thoſe on whose minds visible objects were never impressed, or have been entirely obliterated. Dr. Blacklock affords a surprizing inftance of this kind; who, though he had loft his sight before he was fix months old, not only made him- felf master of various languages, Greek, Latin, Italian, and French, but acquired the reputation of an excellent poet, whose performances abound with appropriate images and animated defcriptions. See BLACKLOCK.

Another infance, which deferves being recorded, is that of Dr. Henry Moyes in our own country, who, though blind from his infancy, by the arduous and affiduity of his application, and by the energy of native genius, not only made incredible advances in mechanical operations, in music, and in the languages, but acquired an extensive acquaint- ance with geometry, optics, algebra, astronomy, chemistry, and all other branches of natural philosophy. From the account of Dr. Moyes, who occasionallv read lectures on philosophical chemistry at Manchester, delivered to the Manchester society by Dr. Bews, it appears, that mechanical exercises were the favourite employment of his infant years; and that at a very early age he was so well acquainted with the ufe of edge-tools, as to be able to construct little wind- mills, and even a loom. By the found, and the different voices of the perfons that were prezent, he was directed in his judgment of the dimensions of the room in which they were assembled; and in this respect he determined with fuch a degree of accuracy, as feldom to be mistaken. His me- mory was fingularly retentive; fo that he was capable of recognizing a perfon on his firft fpeaking, though he had not been in company with him for two years. He deter- mined with surprizing exactnes the nature of thefe with whom he conversed, by the direqtion of their voices; and he made tolerable conjectures concerning their difpositions, by the manner in which they conducted their conversation. His eyes, though he never reccolled his having seen, were not totally infensible to intenfe light; but the rays refracted through a prifin, when sufficiently vivid, produced distinguihable effects upon them. The red produced a disagree- able fenfation, which he compared to the touch of a law. As the colours declined in violence, the harleines lefened, until the green afforded a fenfation that was highly pleasing to him, and which he described as conveying an idea similar to that which he gained by running his hand over smooth polished surfaces. Such surfaces, meandering arcs, and gentle declivities, were the figures by which he expressed his ideas of beauty; rugged rocks, irregular points, and bofillerous elements, furnished him with expressions for terror and difguift. He excelled in the charms of conversation; was happy in his allusions to visual objects; and difcoursed on the nature, composition, and beauty of colours, with pertinence and precifion. This infance, and fome others which have occurred, seem to furnish a presumption, that the feeling or touch of blind perfons may be fo improved, as to enable them to perceive that texture and disposition of coloured surfaces by which fome rays of light are reflected and others absorbed, and in this manner to distinguih colours. But the fact is still undecided; and further trials are neceffary, in order to fet aside high authorities to the contrary, and absolutely to decide it. Dr. Reid, in his "Inquiry into the Human Mind on the Princlipes of Com- mon Sense" (ch. vi. § 2.), deduces evidence from acknowledg- ed facts, as well as reafoning, in order to fhew, that there is very little of the knowledge acquired by finight, that may not be communicated to a man born blind. One who never saw the light may be learned and knowing in every science, even in optics; and may make discoveries in every branch of philosophy. He may understand as much as
another man, not only of the order, distances, and motions of the heavenly bodies, but of the nature of light, and of the laws of the reflection and refraction of its rays. He may understand distinctly, how those laws produce the phenomena of the rain-bow, the prism, the camera obscura, and the magic lantern, and all the powers of the microscope and telescope. Nevertheless, as to the appearances of colour, a blind man must be more at a loss, because he has no perception that refle\(\text{}\)ms it; though, by a kind of analogy, he may supply even this defect. To th\(\text{e}\)se who see, a scarlet colour signifies an unknown quality in bodies, that exhibits to the eye an appearance which they have often observed, and which they well know; but to a blind man, it denotes an unknown quality that exhibits an appearance, with which he is unacquainted. But he can conceive the eye to be variously affected by different colours, as the nose is by different smells, or the car by different sounds; thus, he can conceive scarlet to differ from blue, as the sound of a trumpet does from that of a drum; or, as the smell of an orange differs from that of an apple. It is impossible to know whether scarlet colour has the same appearance to me which it has to another man; and if its appearances to different persons differed as much as colour does from sound, they might never be able to discover this difference. Hence it is plain, that a blind man might talk for a long time about colours distinctly and pertinently; and if you were to examine him in the dark about the nature, composition, and beauty of them, he might be able to answer, so as not to betray his defect. After all, as a blind man has never had any sensation of light and colour, his knowledge concerning them, however extensive and accurate, must be the result of previous instruction; it must depend on the force of genius, or on the strength of memory; and his language concerning coloured objects must be like that of a parrot, without any precision of meaning, and without any corresponding ideas. On this disputed subject the reader may derive information from Diderot's "Lettre fur les Aveugles a l'usage de ceux qui voyent," or "A Letter concerning the Blind for the use of those who see," in his "Works," vol. ii.; and they also may consult Cheffelden's "Anatomy," and Locke's "Essay on the Human Understanding."

With regard to the scientific and practical departments of music, every age has supplied numerous in\(\text{\}}\)flues of blind persons who have attained to great excellence. They will occur among the articles of musical biography in the course of this work.

Of the contrivances that have been devised for the assistance of the blind, we have already mentioned those of professor Saun\(\text{d}er\text{f}\text{on}, and of Mr. Grenville, under the article Palpable Arithmetic. We shall here subjoin, from a letter addressed by Dr. Moyes to the editor of the "Encyclopedia Britannica," an account of the palpable notation generally used by him for twenty years, for the purpose of affisting his memory in numerical computations. With this view he made use of a square piece of mahogany, a foot broad and an inch thick, represented by A B C D (Plate I. Algebra, fig. 3); he divided each of the sides A B, B C, C D, D A, into 24 equal parts; joined each pair of opposite divisions by a groove cut in the board of sufficient depth to be felt with the finger; and perforated the board at each intersection with an instrument 1/24th of an inch in diameter. Having thus divided the surface of the board into 576 small figures, perforated at each of their angles, he fitted to the holes in the board three sets of pegs or pins, resembling those in the plate, figs. 4, 5, 6, in such a manner, that when fixed in them they keep their position, and required some force to turn them round. The head of each peg belonging to the full
fylematic plan for this purpose was proposed by M. Hailey in an "Essay on the Education of the Blind," printed at Paris in the year 1786, under the patronage of the Academy of Sciences. An English translation of this essay is annexed to "Dr. Blacklock's Poems," printed at Edinburgh in 1793. 4to. The object of this plan is to teach the blind reading, by the affilance of books, in which the letters are rendered palpable by their elevation above the surface of the paper; and by these means to instruct them, not only in the liberal arts and sciences, but likewise in the principles of mechanical operations, such as spinning, knitting, book-binding, &c.; so that those who are in easy circumstances may be capable of amusing employment, and those of the lower ranks of life, and such as have no genius for literary improvement, may nevertheless, become respectable, useful, and independent members of society, in the situation of common artisans. By these palpable characters, they are taught to read, to write, and to print; and they are likewise instructed, according to their several talents and dispositions, in geometry, algebra, geography, and every branch of natural philosophy. The institution encourages and cherishes a taste for the fine arts; it teaches the blind to read music with their fingers, as others do with their eyes; and it does this with so much facility, that though they cannot at once feel the notes and perform them upon an instrument, yet they are capable of acquiring any lesson with as much exactness and rapidity, as those who enjoy all the advantages of sight. Of this curious and interesting essay, now before us, we shall give such an account as may serve to gratify those of our readers, who are concerned in the support of plans, somewhat resembling that which it describes, in our own country. The author, after stating the object of his plan, and obviating the scruples of those who denounce against allowing its general utility, in the two first chapters, proceeds, in the third chapter, to illustrate the method of reading, as adapted to the practice of the blind. This method consists, as we have already observed, in the use of typographical characters, whose elevation above the surface of the paper renders them obvious to the touch, without the intervention of sight. From the perception of typographical characters, the transition is not difficult to that of written characters; i.e. of characters not written with ink, but formed by impressions made upon strong paper with an iron pen, whose point is not flit. The characters, thus produced, are distinctly separated and inverted; and they are marked on the face of the paper contrary to that which is read, and in such a manner that the position and order of the letters may appear right and in relief, when the page is turned. The blind may thus be able to form and decipher musical characters, mathematical diagrams, and all the necessary processes of arithmetic and geography, as well as those that are printed and written. In the fourth chapter the author replies to several objections that are urged against the method of reading he has proposed. The fifth and sixth chapters contain an account of the art of printing, as it is practiced by the blind, for their peculiar use, and also as it is performed for the use of those who see. In the process of printing, the blind compositor has a box for every alphabetical character in use; on the outside of these boxes are palpably marked the peculiar character belonging to each; these are filled with types, which he feels and sorts as they are wanted, but in a contrary position to that in which they are read. When the types have been arranged and fixed, a page of very strong paper is moistened, so as to be capable of receiving and retaining impressions, and laid upon the types; and then by the operation of the press, or by the easy strokes of a small hammer frequently repeated over the surface, the impression of the type is made to rise on the opposite side of the paper; and it continues, when dry, not only obvious to the sight but to the touch, and is not easily effaced. On the upper side of the paper the letters appear in their proper position; and by their sensible elevation above the common surface, the blind may easily read them with their fingers. The seventh chapter explains the method of teaching the blind to write; which we have already noticed. The eighth chapter shews how they are taught arithmetic; for this purpose they are provided with a board pierced with different lines of square holes, proper for receiving moveable figures, and bars for separating the different parts of an operation. To render this board more useful, a sieve is added, composed of four rows of little boxes, which contain all the figures proper for calculation, and which are placed at the right hand of the blind person while he operates. In order to obtain characters for expressing all the possible fractions, to simple denominators are call'd, in the order of the figures 0, 1, 2, &c. to 9 inclusively, and likewise to simple numerators in the same order, moveable, so as to be adapted at the head of the denominators. By means of this combination, the blind are able to express any fraction. The ninth chapter treats of geography; and in teaching it, M. Weissenbourg and Mad. Paradis marked the circumference of countries by a tenacious and vivid matter, and covered the different parts of their maps with a kind of sand mixed with glafs, in various modes; and distinguished the order of towns by grains of glafs, of a greater or less size. M. Hailey satisfies himself with marking the limits of the maps, for the use of the blind, by small iron wire rounded; and it is always a difference, either in the form or size of every part of a map, which affists his pupils in distinguishing the one from the other. For the purpose of teaching music, the subject of the tenth chapter, musical characters are call'd; and these are so numerous, as to represent upon paper, by elevations on its surface, all the possible varieties that occur. The eleventh chapter contains an account of the mechanic arts, in which the blind are employed, and of the method in which they are formed for such occupations. Accordingly they have been successfully employed in spinning, in making pack-thread of the thread they have spun, in weaving girts with this pack-thread, in making nets, in fewing, in binding books, &c. In the twelfth chapter we have a view of the proper mode of instructing the blind, together with a parallel between their education and that of the deaf and dumb. This operation, it is said, is easy in itself, and requires in a mediator more courage than knowledge. "By the aid," says M. Hailey, "of our books in relief, every one can teach them to read. Upon the musical works found in our prefs, every professor of that art may give them lefions. With an iron pen, with plates and moveable characters, executed according to our models, the first matter in writing may teach them that art, and arithmetic." The thirteenth chapter contains a brief account of the elementary books of languages, mathematics, and history, which should compose the library of the blind person. The essay terminates with an historical summary of the rife, progress, and actual state of the institution for blind children. The success of this institution has fully answered the expectations of its founder, and amply compensated the expense bestowed upon it by the liberal and well-disposed. We are happy to add, that institutions of a similar kind have been established in our own country; and to render our particular tribute of respect to the founders and supporters of the "School for the Indigent Blind," instituted in London in 1795. It is now situated in St. George's-fields, but will speedily be removed to Gray's Inn-lane, as soon as the necessary buildings for its accommodation are erected. The object, with a view to which this school was founded, is unquestionably one of the most important and interesting kind that
that can excite compassion, or demand encouragement. It
provides instruction for the indigent blind, in a trade, by
which they may be able to provide, either wholly or in part,
for their own subsistence; and thus, instead of being alto-
gether a burden to the community, they will be of some ser-
vice to it; and instead of being depreded and cheered them-
elves, under a sense of their total dependence, and for want
of regular employment, habits of industry will relieve their
spirits, and produce the most beneficial effects on their state
and character. The children of this institution, amounting
in the present year (1804) to 34, are completely clothed,
boarded, lodged, and instructed, gratis. The articles at
present manufactured in the school are shoemakers’-thread,
fine and coarse thread, window fad-line, and cloaths’-line
(of a peculiar construction, and made on a machine adapted
to the use of blind persons), by the females; and window and
fad-line, cloaths’-line, hampers, and wicker baskets, by the
males. The success that has crowned the efforts of the
friends of this institution, since its first establishment, affords
sufficient evidence of the degree in which the situation and
faculties of the blind are capable of improvement; and a
view of it in its present prosperous state, must be gratifying
to persons of humane and compassionate feelings. Here they
will not find the scholars sitting in little’s indolence, which
commonly the cafe with the blind, or brooding in silence
over their own defects, and their inferiority to the rest of
mankind; but they will behold a number of individuals, of
a class hitherto considered as doomed to a life of sorrow and
difficent, and to be provided for in alms-houses, or
by donations of charity, not less animated in their amuse-
ments, during the hours of recreation, and far more cheer-
fully attentive to their work in those of employment, than
persons perfectly fitted for fight. This important and useful
institution is under the direction of a president, eight vice-presi-
dents, a treasurer, and a committee of 24 members. A sub-
scription of one guinea annually, or of not less than 10
guineas at once, or within one year, constitutes a member.

To this article we shall subjoin the following directions
given by Mr. Thickenos, for teaching the blind to write:

"Let any common joiner make a flat board, about 14
inches long, and 12 wide; in the middle of which let a
place be firk, deep enough, when lined with cloth, to hold
only two or three sheets of fool’s-cap paper, which must
quite fill up the space; over this must be fixed a very thin
false frame, which is to cover all but the paper, and fastened
on by four little pins, fixed in the lower board; and across the
lower frame, just over the paper, must be a little flider,
an inch and a half broad, to flip down into several receffes
made in the upper frame, at a proper distance for the lines,
which should be near an inch aflunder; and this ruler, on
which the writer is to rcl his fourth and little finger, must
be made full of little notches, at a quarter of an inch distant
from each other; and these notches will inform the writer,
by his little finger dropping from notch to notch, how to
avoid running one letter into another. When he comes to the
end of the line, he must move his finger down to the
next groove, which may easily be fo contrived with a spring
to give warning that it is properly removed to the second
line, and fo on."

Blindness, in the Veterinary Art, a disease very fre-
quently happening to horses. The eye of the horse is sub-
ject to various diseases which may occasion blindness, as the
cataract, the gutta serena, opacity of the cornea, or its cover-
ings, &c.

The disorder, however, generally inducing blindness among
horses is the cataract, and the inflammation of the external parts
of the globe of the eye, which precedes the obscuration of
the crystalline, is termed blindness, as though the disease was
really confirmed; and horses so affected are considered as
such, and denominated blind, though at this period of the
disease the sight is only very imperfect.

This destructive disorder, in general, commences with an
inflammation of the outer coats of the eye, as the membra-
na conjunctiva, or cornea, or both together, and extending gra-
dually to the interior, inflames and destroys the transparency
of the crystalline, and obstructs the admission of light.

These attacks of inflammation not unfrequently disap-
pear for a time, or, at least, become much less disfigur-
able, and then return again, observing something like
regular periods of accession and remission; and from hence
the disease has been termed by some the moon blindness,
and these changes were considered as under the influence
of this planet, and corresponding with the periods of its
change; there are, however, other causes more powerful
in their influence, to which these changes in this disorder
may, with more appearance of truth, be attributed, as in-
proper exposure to excessive cold, or drafts of air; to
a close, low, over-heated stable, or sudden alternations
from the one to the other; violent exercise and sweating;
then washing with cold water, leaving the hair drenched
with it; acid volatile salts nailing from the dung; over-
feeding with too hot, dry, and stimulating food, and all
other causes inducing an increased action of the heart and
arteries, naturally tend to induce a recurrence of this com-
plaint.

As this disease is one of the most interrelling in the ve-
tinary art, and the most necessary to be well understood,
as well by professional men, as by dealers and poffeffors
of horses, we shall describe at some length the appearances by
which it is known to exist, and the means that have
hitherto been employed, as far as they have come to our
knowledge, for the removal of it. Thofe who may desire to
be acquainted respecting the information polled by the
ancients of this complaint, and their practices for its cure,
may be referred to the writings of Abyllyus and Vegetius:
the latter, in his elegant work de arte Veterinaria, lib. 2,
cap. xvi. de fissurarum oculorum, has divided this disorder
into three kinds, under the titles feuces-borinias, protocoryphias,
hypho-chorias; by his definitions, however, of thefe three
kinds, it appears that he only meant the different flages
of the formation of the cataract, from the first inflam-
mation of the eye, to the crystalline becoming perfectly
opaque and burfting its capsule; rushing to the anterior
chamber of the eye, and refting, like a white oapule ball,
against the cornea; occafioning a total los of fight, and
which he compares to the yolk of an egg burfing from
its situation in the centre of the egg, and to which it can
never be again reduced. He considers the caufe of this com-
plaint to be the rupture of the membrane containing the
fight; by excessive heat, or more certainly from the fatigue
of a long journey, or the neglected injury of the eye, from
the intattention of the matter. His hypho-chorias, which
appears to be the firft flage of this disorder, he fays, de-
sides from the head, and often fwcys itself in one eye, and
then migrates to the other, and is attended with a flow
of water or tears. His treatment, in this cafe, is to
bleed often from the eye-brow, or rather the eye-bids,
and from the temples; to foment frequently with warm
water in which rue and fenmel seeds have been boiled; to
anoint the eye with "cum collyrio apposito et opolbafamino." He
also recommends applying the actual cautery to the
temples above the veins. This author, in another chapter,
recommends, in this complaint, that you fhould infeft the
notirl on the fame fide with the morbid eye, and you will
find
find a small opening, through which, by inserting a pipe, you may fill the eye with wine, and relieve the disorder; a remarkable proof of the minute and accurate observation of the ancients. The existence of such an opening (for it is, in reality, the opening of the lacrimal duct that is alluded to), is not known to many who profess to practise on the diseases of horses at this day.

Abystus, a Greek writer, who lived about the reign of Constantine the Great, and prior to Vegetius, recommends, in this disorder, and which he calls 

inflammation of the cornea. It should be cured with an awl, and a piece of white helble.

The following we venture to give as a more natural and true description of the appearances of the eye, during the presence of this complaint, than what has before been exhibited; though, no doubt, subject to many omissions and imperfections, which future observations may lead us to rectify.

The earliest indication of this disease is exhibited by the external transparent parts of the ball of the eye becoming obscured, assuming a blackish glassy hue; sometimes blue, or brown, or a dull white, and streaked with blood, according to the degree of inflammation or dilution of the blood-vessels; admitting, according to their capacity, the different parts of the blood which are not transparent; and this inflammation, it may be remarked, takes place more frequently in young horses of five or six years old, than in those of a more advanced age, and the upper half of the cornea generally appears more obscured than the lower; this, however, may be a deception, arising merely from the point of vision, the observer being placed below the eye, and seeing directly through the lower part, and more obliquely through the upper. The blood-vessels also may be observed increased in number and size, passing over the opaque white surface of the sclerotics, to the cornea and conjunctiva; for it has not, as far as we know, been ever ascertained from actual dissection or experiment, whether it is the cornea that is inflamed, or the conjunctiva, or both; nor is it absolutely necessary for the treatment, that this should be known.

The eye and eyelids feel hotter to the hand than usual; and often times there is a deposit of a white matter resembling pus, in the bottom of the anterior chamber of the eye, which, perhaps, proceeds from the vessels of the ciliary fringe, or uvea, which are large in the horse.

After this opacity of the cornea has existed some time, the eye of itself, or still more certainly if antiphlogistic means are used, returns to its natural brilliancy, and the disorder seems removed; a few weeks or months may elapse before its return; and if these remedies are had recourse to very early, the disorder may even be permanently removed; it very frequently, however, returns, and again disappears, and this several times before the inflammation of the crystalline, and the destruction of light take place. In other subjects, one uninterrupted course of inflammation, without any interval, takes place, till the cataract is fully formed.

When this morbid process begins in the crystalline, the inflammation of the exterior parts of the eye often disappears, and they assume their usual brightnesses, and afford us an opportunity of distinctly observing the changes which take place in the lens.

And, with respect to the cataract itself, or this opacity of the lens, we may remark, that the whole crystalline shall assume this milky appearance at once, or a small speck only near the centre shall be seen, which often remains for years, without the least perceptible increase, and without producing blinding, or any sensible detriment to the animal: again, in other cases, no speck is observable but whitish lines which reflect the light, stretching like rays from the centre of the lens to its circumference; and sometimes the capsule containing it is laid to be only affected.

The cataract, as it is called, being fully formed, the complete opacity of the lens being established, and light no longer admitted, the iris begins to lose its properties, nearly closing up the opening of the pupil; from its relaxation, the whole eye becomes diminished, and apparently sunk in the head; and the capsule, especially in draft horses, bursts, and the lens is forced from its situation, and falls to the anterior chamber of the eye, resembling, as we have before observed, an opake white ball.

As perfect cleanliness and distinctness in all parts of the eye, with a due contraction of the pupils, are the most certain indications of its good health, so the slightest dulness or opacity in the external coats, or diminution of the pupil, should lead the purchaser to be cautious; for it cannot be too often observed, that this opacity, after it has been of some standing, is almost certain destruction to the eye; and there are no remedies at this time known that can prevent its fatal termination, though numerous attempts and experiments have been instituted with this view; and the operation for the cataract is useless in the horse; for if it succeeds, the vision is still so imperfect, that blindfolds itself is preferable.

Though various useful offices can be found for horses that have lost their sight; yet it is of importance, for most of the purposes to which they are applied, that it should be preferred. We cannot recommend with too much force, the necessity of an early recurrence to the preferred remedies for destroying the inflammation; for, at its very commencement, it has probably only the characters of common inflammation, and might be entirely and effectually subdued as in other parts; but neglected, this disorder soon assumes its peculiar properties, arcing, perhaps, from the particular structure and functions of the parts affected, and in a short time becomes perfectly beyond the reach of any remedy; for though, no doubt, there are a few insulatd instances where this disorder has been removed, yet, as the termination of the generality of cases is of an opposite nature, it would be unwarminable to make a conclusion from such cases of the general possibility of cure in this complaint.

Where the inflammation has not yet received the specific properties above described, the following remedies will frequently remove it; and in more confirmed cases, we shall mention the means that have been successfully employed to remove it, that we may shew the insufficiency of such attempts, and promote further experiment and research respecting it.

In the commencement of this complaint, the use of abstinence from heating food, or hard exercise; exposure to stables of cooler temperature, and well aired, not from partial drafts, but their loofiness only; exclusion of too much light, or the light altogether; diluent drinks, and purgatives; such may be employed to the general system. To the part itself, washes of cold water, or ice and water, or latharge water, or with a small portion of opium dissolved in it; others think more favourably of stimulating, or cautic washes, as weak solutions of vitriolated zinc, very dilute acids, and even spirits and water.

Blister applied to the cheek, or over the malleter muscle, produce an irritation which is very successful in removing this inflammation, and, in particular, the insertion of a ferret or two in the muscular parts surrounding the eye, care being taken that the fæula over the muscle is divided, otherwise
otherwise there is no suppuration; these will tend, as we have experienced, powerfully to carry off an attack of this disorder. Diving with a hot iron has also been employed with the same view, on the surrounding skin; and likewise blood-letting from the jugular vein, or from the temporal artery, or locally from the vessels proceeding from the inner canthus, or anterior angle of the orbit; as also the vessels passing over the fleshy coat, which become very much enlarged and visible in this disease, as well as those in the lining of the lids.

Mr. Coleman, the very ingenious professor of the veterinary college, feared up the vessels of the fleshy coat with a hot iron, forming an entire circle round the ball of the eye, at some distance from the cornea, to prevent all access of blood to this part, and so endeavour, mechanically, to put a stop to the inflammation; it was found, however, insufficient to destroy the disorder, and we believe that any hope of relief from this mode of treatment has since been abandoned; and for this reason, perhaps, this experiment has proved insufficient, that when communication is flopped from the external vessels, there are others whole trunks are short of these, which supply the substance of the cornea; and others again, out of our reach, on the inside of the cornea; but above all, the habit in the parts to discharge, and the disposition in the futten to generate it, are not overcome, and the morbid tendency is not thereby destroyed.

The farriers, who practice medicine, in treating this complaint, often remove the lacrimal gland, which they call the law, from its supposed resemblance to this fruit; and as this part partakes of the inflammation, and is much swelled, they mistake it for the source of the disorder. The removal of it, which is easily done, by drawing it out with a hook, and cutting it off, occasions a copious discharge of blood, which, in flight attacks, relieves the eye, and encourages them in this practice; but from our own personal experience we have learned, that in cases of any duration, it is totally inadequate to the removal of the complaint, and the eye must obviously suffer from the loss of a part that is necessary to its well-being; and means less injurious to the eye may be equally well employed with as much success, such as we have before pointed out.

An infusion of the Polygonum hydropiper injected into the nostrils, so as slightly to inflame the membranes, produces very good effects in this complaint.

It has been observed, that in the human eye, long continued inflammations of the exterior coats rarely produce cataracts, as they do in the horse; and the reason that has been assigned for this is, that the same blood-vessels which supply the tunica conjunctiva and cornea, also supply the lens and the humours of the eye, which they say is not the case with the human, as these parts are supplied from the ciliary and integuments; there is, however, in the horse, a singular similarity to inflammatory complaints, and to this disposition, perhaps, it is rather to be attributed.

In the inflammation of the cornea, which is attended with a black, glossy appearance of this part, there is seldom any increased discharge of tears from the eye and nose; but in the other kinds which we have before enumerated, there is, in general, a considerable increase of this secretion. When blood-freaks, or blotsches appear, it is probable that the vessels are ruptured, and that this blood is really in a state of extravasation.

BLINK of the ice, in Sea Language, denotes that bright, white appearance produced by the ice near the horizon, and perceptible, in approaching the ice, long before it itself seen. This phenomenon has been often remarked by mariners, and is particularly mentioned in Pipps's (lord Mulgrave's) voyage to the North Pole, p. 70.

BLINKS, in Botany. See MONTIA.

BLINKS, among Ancient Sportsmen, denoted boughs broken down from trees, and thrown in the way where deer are likely to pass, to hinder their running, or rather to mark which way a deer runs, in order to guide the hunter.

BLINKING of beer, in Lincolnshire, signifies letting the wort stand for some time in the vat, till it hath acquired some degree of acidity, in order to dispose it to fine, and be the sooner ready for drinking.

BLISSOM, among Husbandmen, corruptly called bloss, is the act of a ram when coupling with an ewe.

BLISTER, in Pharmacy. Blisters are raised on the surface of the body for medicinal purposes, by applying, for a number of hours, some of the most active of the animal or vegetable stimulants. Of these, by far the most convenient, and that which is almost universally employed, is the cantharis, or Spanish fly, (Meloe variatorius). These insects are found in Spain, Italy, and the south of Europe; they have a long body, beautifully brilliant with green and gold. They are gathered, by shaking the trees which they frequent, and are killed by the vapour of spirit of wine burnt beneath them, or by the fumes of vinegar, after which they are dried in a stove. In this state they are brought over without further preparation.

Cauterizations poelis so much ceremony, that in reducing them to powder, the face should be covered with a mask, to prevent the troublesome sneezing and exorrhization of the fucusses, from the finer dust flying about. Taken internally, in an over-dose, they inflame the whole intestinal canal, in a greater or less degree; and they have a peculiar tendency to irritate the urinary organs. Applied to the skin, they first inflame the part, but often, with scarcely any attending pain; after which they produce a very copious blister of clear, yellowish serum beneath the cuticle, which rises in a large bag. This effect appears to poelis this vesicating property in a much larger degree, in proportion to the pain excited, than any other stimulant; and hence its peculiar utility in producing this eous discharge with the least possible inconvenience to the patient. It is not exactly known in what part of the insect the vesicating property resides, or whether it does not equally belong to every part. It is not easily destroyed, or impaired by long keeping, if the insect be unbroiled, and preferred in a dry place.

For blistersing the skin, the cauterizations are first finely powdered, and then incorporated, with some labour, with a simple mixture of wax and resin melted together, to which some add a little vinegar, and allowed to grow nearly cold before the flies are added. This is a necessary precaution, since it is certainly known that a considerable heat impairs the blistering property. The platter, thus made, should be of such a consistence, as readily to soften with a moderate heat. When used, it is generally spread uniformly upon leather, of the requisite size and shape, by the assistance of an iron spatula, warmed fiercely more than the hand can bear.

To increase the effect, some apothecaries sprinkle the platter with powdered cauterizations, after it is spread on the leather, but this is not necessary, where the platter itself is good; and the powder is apt, after vellution, to lodge on the tender cuts, and produce much needful irritation. As the blistering platter adheres very closely to the skin, it is useful in applying it to children, to maulialc persons, and wherever it is danger of being too soon pulled off, to surround the blister with a margin of strong adhesive plaster.
The plaster of cantharides seldom fails to produce a large blister, in ten or twelve hours; but its operation continues sometimes longer, so that it may be conveniently suffered to remain for twenty-four hours, the large cuticular bags being punctured to let out the fluid. When the plaster is taken off, and the serum mottly discharged, the blistered part should be dressed with spermaceti, or some other mild ointment, unless it be intended to keep up the serous discharge by stimulating applications.

The pain produced by the action of cantharides varies greatly, according to the part affected, the thickness of the skin, and the general irritability of the constitution, and in particular of the surface of the body. Most frequently the pain is very slight, often amounting to no more than a sense of heat on the part. When very acute, it is of great service to remove the plaster, when it has been on about two hours, to anoint the part with oil or cream; and about an hour or two after, to replace the blistering plaster, which will then often proceed to vesiculate without much further irritation.

The operation of cantharides is much affected by the thickness of the skin beneath; and hence the scalp refits vesication more than the weaker skin of the abdomen; and particularly by the heat of the body, so that the plaster should be stronger, and its influence foster, when applied to an unusually cold surface.

Sometimes, though rarely, the symptoms of strangury produced by this active medicine, follow even its external application.

A more active vesicatory is supposed to be made, by adding other stimulating substancces to the cantharides plaster.

In the Paris Pharmacopoeia, euphorbium (the root of all the medicinal gums) is added in equal quantity with the cantharides: in the Edinburgh, verdigris, nut, and black pepper are used.

It is often of advantage to keep up a discharge from a blistered part for a considerable time. It then becomes gradually purulent. For this purpose, a milder form of cantharides is highly useful, and a softer confidence is given to it. This may be done by mixing a small portion of the fluid in powder, with any simple ointment; but this is liable to act unequally, and the entire particles of the fly sometimes create trouble, by lodging upon the tender cuts. To remedy this, the London college use a watery infusion of cantharides, mixed with a stimulating fluid ointment, melted, and continued over a low fire, till all the water is evaporated, leaving a small portion of extractive matter of the flies, equally diffused through the ointment, and strongly increasing its stimulating power.

A few other substancces have been occasionally used to produce vesication. One of these is the inner bark of the mezer, (Daphne mezereum) and of another plant of the same genus, the Thymus latifolius, or Spurge Laurel, (Daphne laureola) both shrubby plants, well known in gardens. The use of the latter (which will equally apply to the mezereum) is thus directed in the Paris Pharmacopoeia. Small twigs of the plant, about the size of a pen, and smooth, are selected, and cut transversely into portions of the requisite length. These are steeped in milk-warm water, or in vinegar, for about half an hour, to loosen the bark, which is then peeled off with a pen-knife, and the wood is thrown away. This bark is applied to the skin to be blistered, previously rubbed with vinegar.

In twenty-four hours a perfect vesication is produced, with little pain, and without the possibility of those symptoms of strangury, which now and then attend the use of cantharides.

BLISTERED, bulla, in Botany, is applied to the surface of a leaf, which rifes high above the veins, so as to appear like blisters.

BLISTERING of horses, in the Veterinary Art, a remedy much in use for promoting the removal of a great variety of disorders; more especially, however, in reducing morbid enlargements of bone, or morbid thickenings of any of the softer parts, where its utility is principally obvious.

The vesication of the skin of the horse is attended with some remarkable circumstances, in which it differs from the human, especially in the greater irritability of the skin; for the cuticle of the horse is raised by a blister of less strength, than is required in raising the human cuticle; whence, perhaps, it may be inferred, that its sensation also is more acute. It is probable that the skin of animals covered with hair are, in general, more irritable than naked skinned animals; the spirits of turpentine producing a most painful irritation, both in the horse and the dog, when applied to the skin, but not so in the human.

Irritants, however, of the skin, without any blistering, or vesication, may be had recourse to with very great advantage, in the veterinary art, as they can, without injury to the parts, be very frequently renewed, and with the happiest effects.

The mildest applications of this description, are the animal and vegetable oils; as hog's-lard, and the oil expressed from linseed, or olives: where more irritation is thought requisite, the addition of the essential oil of orgeaum, or the spirits of turpentine, will readily afford it.

Lard alone, rubbed on the skin of the horse, we have often observed to produce a sensible irritation and increased warmth in the part, so inexpressible is this part in these animals; and many have as a basis from which we may proceed to the higher degrees of stimulus, firing the skin with the actual cautery, in lines more or less close, being the highest degree of irritation to which we can or ought to proceed.

That irritation which is produced by the cantharides, is, of all others, we believe, the most useful in its effects. It should be applied, mixed with lard, or olive-oil; to which it is useful to add the dried juice of the euphorbium; as, however, it is ever desirable to avoid unnecessary complication in the remedies we prefer, by which our effects are rendered more certain, and the indications more easy and clear, so we propose to try this medicine by itself, to ascertain its precise effects; and being mixed with olive-oil, it was applied to the skin of the leg of the horse; no distinct vesication of the part followed, but it produced a considerable heat, and formed a brown scab, with very little discharge of serum; but, on the contrary, was particularly dry and irritating to the horse. We have since omitted it in the blister, and, we believe, without the slightest detriment to its operation; for the cantharides, when they act properly, and are not applied too strongly, produce a plentiful vesication, and a copious discharge of thick serum, almost of the confidence of honey.

We have found also the pyro-ligneous acid, or the acid obtained by the distillation of wood, in close vessels, and properly concentrated, a cutaneous irritant, of very useful qualities. After the skin has been simply wetted with it, it slightly inflames it; and the cuticle, after two or three days, comes away dry, bringing with it any foulness of the skin, for the removal of which it is most particularly serviceable.

We have known some, from motives of economy, omit the cantharides in their blister, and use, instead of it, vitriolic acid. It, in general, as far as we have seen, forms a dry, black scab, and is by no means so agreeable in its effects as the former.

Bli
BLI

It is a common habit with farriers prating medicine, to mix corrosive sublimate with their blister; and, where it may be defiable to destroy the skin, this should be used, but not otherwise; for it is very remarkable, but a most violent caustic, soon destroying any living matter with which it comes in contact; and we have seen, from the ignorant use of it, the most deplorable effects, by bringing off extensive floulings of the skin, and even penetrating to the parts beneath, and so injuring them, as ever after to render the horse unserviceable.

There is an effect produced by the cantharides on the skin of the horse, which, as far as we know, has not met with much attention; though it is very remarkable, and not analogous to its effects on the human skin: It is that prodigious thickening of the integuments, after the operation of the blister, which sometimes does not subside for many weeks, being a great delightment: a blister, therefore, if one could be devised not producing these effects, would be a desirable thing in the veterinary Pharmacopoeia. This effect, we should, however, remark, is not confined.

BLITAS, Las, in Geography, a cluffet of small islands in Nicaragua lake, in Spanish North America.

BLITH. See BLYTH.

BLITHE, a river of England, which runs into the Trent, 4 miles N. E. of Litchfield.

Species 1. B. capitatum, berry-headed straw-berry blite, Lin. Spec. 6. Reich. ii. Hall. helv. n. 1571. Morocarpus capitatus. Scop. Carn. n. 3. Atripllex. Bauh. pin. 119. n. 7. Prodr. 58. b. 2. Ger. emac. 526. n. 8. Park. 748. f. i. Mor. hiff. 2. 666. f. 5. t. 32. f. 11. Rau. hiff. 197. n. 57. "Heads fisked terminal." An annual plant, with leaves resembling those of Spinach, and stalk rising, in gardens, about 2 1/2 feet high; but in a wild state, upright and only about a foot high; flowers on the upper part siling in small heads at every joint, and terminated by a calyx of the same; when the flowers are pale, these heads swell to the size of wood-strawberries, and when ripe have the same appearance, full of a purple juice, which stains the hands, and formerly much used in cookery, for colouring puddings, &c. feed black when ripe: commonly called strawbery blite, strawberry spinach, or bloody spinach, and, by some, berry-bearing orach. A native of Switzerland, the Grisons, Austria, the Tyrol, Spain, and Portugal; cultivated by Parkinson, in 1633. 2. B. virgatum, Bender-branched straw- berry blite, Lin. spec. 7. Reich. 12. Gmel. flb. 3. 16. Atriplex. Bauh. pin. 119. n. 6. Mor. t. 32. f. 10. Rau. hiff. 197. n. 6. "Heads scurred, lateral." Schlom growing more than one foot high, with smaller leaves than the former; flowers produced from the axis, almost the whole length of the stalk; small, and collected into little heads, smaller than the first, and not so deeply coloured, but of the same shape. A native of the south of France, Spain, Italy, and Tartary. 3. B. tatarian. Mill. Dict. n. 3. B. fragiferum maximum polyspermum. Amm. ruth. "Leaves triangular, sharply toothed; heads simple, lateral." Rifling near three feet high; flowers axillary, in small heads; fruits of the same shape and colour with those of the first, but smaller; differing from it in the shape and indumentes of the leaves; and in having leaves placed between the fruits the whole length of the stalk, not terminated by heads, as the first, but having leaves above the heads. Probably a variety of the second sort. The seeds were sent to Mr. Miller by Dr. Amman, professor of botany at Peterburgh.

Propagation and Culture. All are annual plants, which drop their seeds, that will produce plentifully the following spring; or if the seeds of any one of them be sown in March or April, upon a bed of common earth, in an open situation, the plants will come up in a month or six weeks, and remaining in the same place, will require no other care besides being kept from weeds, and thinned out to the distance of six or eight inches apart; and in July the plants will begin to flower their berries, which will make a pretty appearance. By many they are transplanted into the borders of the flower garden, and by others planted in pots, so as to be ready for removal into the court-yard, or for being placed upon low walls for ornament. When these plants are desired to be removed, they should be transplanted before they shoot up their flower-foms, for they will not bear transplanting afterwards; and when planted in pots, they must be watered in dry weather; and, as the flower-foms advance, they should be supported by sticks. Martyn.

BLITUM. See Achyranthes, Amaranthus, Chenopodium, and Gunnera.

BLOATED, fihi, or berring, in our Statutes, are those which are half dried. Vide Stat. ann. 18 Car. II. c. 2.

Bloated herrings are made by keepring them in a peculiar brine, and then hanging them in a chimney to dry.

BLOATING, in Medicine. See Leucopilegmatia, and Oedema.

BLOCH, Mark Eleazar, in Biography, a Jewish physician at Berlin, and a celebrated ichthyologist, was born at Anspach in France. His parents were in a condition to observe and dictate, that they were scarcely able to maintain him during his infancy, and much less to procure for him any suitable means of education. At the age of 15 he understood neither German nor Latin; and as he had read only a few Rabbinical books, he spake a kind of Francian gibberish, intermixed with the Jewish jargon. About this time, however, he was taken into the house of a surgeon at Hamburg, who was a Jew, and employed by him in the instruction of his children; and in this situation he acquired a competent knowledge of the German language. The savings of his scanty salary enabled him to procure attendance in the study of Latin. Having also gained some knowledge of surgery, he repaired to Berlin, where his relations lived, with a view of prosecuting the study of anatomy. After struggling with various difficulties, he was admitted as doctor in the university of Franckfort, and returned to Berlin for the exercise of his profession. Here he became acquainted with M. Martini, who recommended him to be elected a member of the Society of the Friends of Nature. In order to promote the objects of this institution, he undertook a natural history of the herring, and finally, at eight, as it was supposed, only in the lakes of Pomerania. He also began to form a cabinet of natural history; and having made a considerable collection.
of aquatic animals from all parts of the globe, he determined to write a natural history of fishes; and in this design he was encouraged and aided by obtaining possession of the original MSS. of father Plunier, who had made three voyages to America, and brought with him many objects highly interesting to the natural historian. M. Bloch first published, in German, four numbers of an "Economical Natural History of Fishes, particularly those in the states of Prussia, with figures from original drawings;" Berlin, 1781 and 1782, large 4to. In the following years appeared an "Economical Natural History of the Fishes of Germany," in 3 volumes, consisting of 108 plates, and including the three numbers already mentioned. He afterwards published, in 9 volumes, "The Natural History of Foreign Fishes," to that his whole work was reissued in 12 volumes, and contained 432 plates. The last appeared in 1795. He also, at his own expense, procured a French translation of his work, by C. Laveaux, then at Berlin, which he published under the title of "Histoire general et particuliere des Poissons," Berlin, 1785-1788, in 6 vols. folio, with 216 plates. In order to defy the expense of this work, his only son, a young man distinguished by his talents, undertook a tour through France and England for the purpose of procuring subscriptions; and in the prosecution of his journey died at Paris, in 1787. This loss, and the embarrassment of his circumstances, preyed upon the spirits of this ingenious naturalist, and funk him into the deepest affliction. However, he still continued to employ himself in his favourite work, the history of fishes, and having completed it, undertook a journey to Paris. He died at Carlbod in Bohemia, August 6th 1799. Besides the above voluminous works, Mr. Bloch published many memoirs on subjects of natural history, in the transactions of different societies. That on the onuron, in the Memoirs of the Friends of Nature, has been already mentioned; he also communicated, in the same Memoirs, "Observations on the regular depredations in vitriform fishes;" "On the worms in the intestines and lungs of birds;" "An Essay towards the natural history of the worms which live in other animals;" "On worms of the bladder;" "Description of the buffard, and some kinds of birds found in marines;" "On the oil of herrings;" "On the vulgar opinion that the organ of generation in the ray and lizard is double;" "On the myxna glutinosa of Linnæus;" &c.

BLOCK, Daniel, an eminent portrait-painter, was born at Stettin in Pomerania, in 1595, and educated for his profession under Jacob Scherer. As a painter of portraits, he gained great reputation, and had the honour of painting the portraits of Christian IV. King of Denmark, and of Gustavus Adolphus, king of Sweden. His merit recommended him to the prince of Mecklenburg, in whose service he was retained for 44 years, and for whom he painted the portraits of his whole family, at full length, as large as life, and in the antique habit. By the agreeable manner of his colouring, and the easy attitudes of his figures, he obtained so much employment, as to enable him, before the decline of his life, to amass a large fortune; of which, however, he was unfortunately deprived by a plundering party, preferring, with great difficulty, his own life. He died in 1661. Pilkinson.

BLOCK, Jacob Roger, was born at Gouda, where he acquired the art of painting, particularly in reference to perspective and architecture, which he principally cultivated. Having spent several years in Italy, where he imbibed that taste of grandeur and elegance in his compositions, by which he was advanced in the public esteem above all his contemporaries, he returned to his own country, and was appointed state-painter to the archduke Leopold, whom he attended in all his campaigns; but whilst he was passing a small rivulet, over a bridge of planks to view the fortifications of St. Vinox in Flanders, his horse slipped, and he was unfortunately drowned. Whilst he lived at Gouda, he was visited by Reubens, who, having examined his works, testified to his honour, that he had not seen any painter in the Netherlands, who could stand in competition with him for the subjects he painted. The time of his birth and death are not ascertained. Pilkinson.

BLOCK, Benjamin, son of Daniel Block, was born at Lubeck in 1631, and, with a view of improving himself in colouring and design, resided for some time at Rome, Venice, and Florence. Having thus acquired a good taste, and a pleasing tone of colouring, he was introduced to the court of Saxony, where he painted several portraits of the elector and prime nobility; and he also painted several altar-pieces for the churches and convents of Hungary, which are much commended. His capital performance is the portrait of Kircher the Jesuit, which, even at Rome, was exceedingly admired. The time of his death is not ascertained. Pilkinson.

Block is used for a piece of marble as it comes out of the quarry, before it has assumed any form from the hand of a workman.

Block, in the Mechanic Arts, a large piece of solid wood, whereon to fallken work, or to fashion it; strength and flatibility being the requisite properties.

In this sense we say a chopping block; a sugar-nner's block; a smith's block, on which his anvil is fastened; an executioner's block, on which the criminal's head is laid to be struck off.

BLOCK, Mounting. See Anabathra.

BLOCK, among Cutters of Wood, is a form made of pear-tree, box, or other hard and close-grained wood, free from knots, on which they cut their figures in relief, with knives, chisels, &c. The like are in use for card-making: and from the same first arose the modern art of printing. Phil. Trans. N° 310. p. 2398.

BLOCK, among Bowlers, the mark which is aimed at, being a small-sized bowl laid on the green for this purpose; it is called also the jack.

Block, in Falconry, denotes the perch wherein a bird of prey is kept. This is to be covered with cloth.

BLOCK Island, in Geography, called by the Indians "Manitimes," lies about 21 miles S.S.W. of Newport, in Newport county, and slate of Rhode Island. It was erected into a township, named "New Shoreham," in 1672. This island is 46 miles in length, and its extreme breadth is 15 miles. It has 632 inhabitants, including 47 slaves. It is famous for cattle and sheep, butter and cheese; and round its coasts are caught considerable quantities of cod-fish. The southern part of it is in N. lat. 41° 8'.

Block, in Naval Architecture, denotes an eight square, or round part below the keeling of the main and fore topmasts.

Blocks are short pieces laid under a mast to raise it from the ground.

Blocks are also pieces of wood belonging to ships, in which the shivers; or sheaves, of pulleys are placed, and where in the running ropes go. Accordingly they polysse the properties and powers of pulleys, and they have from one to eight sheaves. The blocks in general use are the single block, the double block, the treble block, and the four-fold block; but when heavy weights or bodies are to be raised, or moved, blocks with a greater number of sheaves are applied, the increasing power being as two to one for every sheave moving with the object. See Pulley.

Blocks differing from the common shape are the bee-block, the check-block, the long-tackle-block, the main-sheet-block, the monkey-block, the nine-pin-block, the rack-block, the

shoe.
the heave-hole, the shoulder-block, the fisher-block, the snatch-block, the strap-bound-block, the vlo-th, and the warping-block. The principal parts of blocks are their shells, shoes, and pins, which are of various sizes and powers, according to the effect which they are to produce. The dimensions of the shells, and the thickness and number of the sheaves, are proportioned to the size of the ropes working in them, and the powers required. The sheaves turn abreast of each other in the shell, on one axis or pin, or one above another, on separate pins. The shell is made of elm or ash, and hollowed between the cheeks, with one or more sheave-holes to receive the sheave or sheaves. On the outside of the cheeks of blocks that are to be strapped, one score is cut towards the ends, in which part of the strap it is buried; if they are double-strapped, they have two scores. A hole is bored through the centre to admit the pin; which, passing through both sides of the shell, forms the axis for the sheaves. The sheave is a solid cylindrical wheel, and round its circumference is a groove, one-third of the thickness of the sheave deep, in which the rope works. It is commonly made of lignum vitae; but for laborious purposes, it is cored in the middle with metal, or else made of cast metal; if the sheave is iron, it is coated with brass, and if of brass, with the hardest bell-metal. The hole in the centre is somewhat larger than the pin. The pin is made of lignum vitae, copper, green-heart, or iron; and it is the axis on which the sheaves turn.

The proportions for single, double, treble, fourfold blocks are as follow: viz. the length is eight times the breadth of the sheave-hole, which is one-sixteenth of an inch more than the thickness of the sheave; and this is one-tenth more than the diameter of the rope for which it is intended, and the diameter of the sheave is five times the thickness. The breadth of the block is six times the thickness of the sheave, and the thickness of such one half the length. Flat thin blocks are three-eighths of the length thick; but all blocks, having more than one sheave, are increased in thickness more than in the above proportion by the additional number of sheave-holes, and middle-parts or partitions; the thickness of each partition being one-sixth less than the breadth of the sheave-hole. These dimensions are variable, according to the uses for which blocks are intended. Very large and four-fold blocks are formed of separate pieces, as the cheeks, partitions, &c.; and when thus made, they are denominated "made-blocks." The shells of blocks are first fawed to their length, breadth, and thickness; and the corners or angles are taken off. The workman then gages the size of the sheave-hole in the middle, one sixteenth larger than the thickness of the sheave, and once the thickness longer than the diameter, for a single-sheaved block. In blocks of two sheaves, the partition is kept in the middle, and is one-sixth less than the sheave-hole; each sheave-hole is gauged equally on each side, and fo for all blocks with a greater number of sheaves. The blocks are then jambed up edgewise with wedges in a clave, and the sheave-holes are made in this manner: the length and breadth are first gouged out, and holes are bored half way through the block, along the part gouged out, with an augre of the size of the sheave-hole; then the sheave-hole is gouged and bored on the opposite side in the same manner, so as to meet the opposite holes. Blocks from 10 inches and upwards have one hole bored at each end, and cut through with a chisel; and the wood is faved out with a rive-faw. All blocks have the sheave-holes cleared through by chisels, and by burns at the corners. Blocks that are to have iron straps, should have the strap fitted on before the wood is cut out of the middle. The hole for the pin is bored through the middle of the block, one-tenth less than the diameter of the pin. The outsides and edges of the shell are next rounded off by the block-sheave, and neatly finished by the spoke-sheave. In the royal navy, blocks are left thick upon the edges of the checks; but in the merchant-ships, the edges are sometimes thinned off to a small square, and sometimes roundt off. The scores for the straps are gouged out along the outsides of the checks, and taper in depth from nothing at the pin to half the thickness of the strap at the ends of the block, for a single score, and the same on each side of the pin for a double score. The scores are gouged down, across the breadth of the block, to half the size of the strap, in order to allow for the fearing. After the score is cut, the sheaves are fitted; they are one-tenth thicker than the diameter of the rope intended for running on them, and five times that thickness in diameter. The hole for the pin should be bored through the centre by a bit fixed in the mandrel of a turning lathe, or with a rock and bit; and reamed with an augre one sixteenth larger than the diameter of the pin, that it may easily turn; they are then put in a lathe and turned smooth, and the outer circumference hollowed one-third of its thickness, that the rope may embrace it closely. The diameter of the pin is the thickness of the sheave, and is turned in a lathe, except its head, which is left square, to prevent its turning in the block, and is driven through the holes in the block and sheaves. After the sheaves are fitted, the inside of the sheave-hole, at the end of the block, is gouged hollow, to admit the rope, and correspond with the sheave; and a small neat chamfer is taken off the edges.

Blocks, Brail, in rigging the mizen-yard, are strapped together in one strap, and lie over the yard, and fize together underneath; the throat-blocks next the sheets to the mast; the middle-blocks in the middle between the throat-block and peak; the peak-blocks about three or four feet within the sheets at the peak.

Blocks, Bank-line, are hauled in rigging the lower-yards like the lee-clerk blocks in the middle between them and the flaps of the yard. Thence, in rigging the top-sail yards, are spliced around the ftrap of the top-sail-tye-block upon the yard.

Block, Cat, is employed to draw the anchor up at the cat-head. See Cat-heats.

Blocks, Check, or half-blocks, are made of elm-plate; the length being twice and a half the depth of the top-mast head; the breadth is seven-eighths of the depth of the top mast head, and the thickness half that depth. The depth of each tenon, and thickness of the check, when the sheave-hole is cut, is each three-eighths of the whole thickness; so that the remaining two-eighths are the sheave-hole. The three tenons are each two inches square, one in the middle, and one at each end; and the length of the holes is more than the breadth of the block, by the thickness of the sheave. The back of the block is divided into three parts, and one-third on each side is bearded down to one-third the thickness of the check on each edge. Pins of iron are made for fallen-
flying them to the top-mast head, and for durability the sheave-holes are coppered. Cheek-blocks are bolted to the thwart-ship sides of top-mast heads, close up under the cap, the bolts serve as the pin or axis for the sheaves to work on; the jib-sheet and halyards, and fore-top-mast stays, fail-sheets, and halyards reeve through the check-blocks at the fore-top-mast head, and the main-top-mast fail halyards, and middle-top-mast fail-sheets, and halyards reeve through the check-blocks at the main-top-mast head.

Blocks, Cer-rane, serve to draw the clines, or lower corners of the courses up to the yards, and are fastened to the clines of those fails. In rigging the lower-yards, these halyards pass through the eyes upon the yard; the blocks hanging underneath, four feet without the middle cleats on each side. See CLEW-REN.

Block, Clew-line, in rigging the sprit-fail yard, are frapped with two eyes, and are lashed through those eyes round the yard, three feet without the flings; the lashing to be upon the yard. In rigging the sprit-fail top-fail yard, these blocks are frapped with two eyes, and are lashed through those eyes round the yard, about two feet without the flings. The clue-line blocks, in rigging the top-fall yards, are frapped with two lashing eyes, and lashed upon the yard three feet without the flings; the blocks hanging underneath the yard, through which the clue-line reeves, and is frapped with a knot, and leads down upon the deck. In rigging the top-gallant yards, these blocks are frapped with two lashing eyes, and lashed upon the yard three feet without the flings. The blocks hang under the yard, through which is reeved the clue-line, which is flopped with a knot. The leading-part leads down the mall, and into the lower hounds. Some loops and light-rigged hounds have no clue-line blocks; they lower the yard.

Blocks, D, are lumps of oak in the shape of the letter D, from twelve to sixteen inches long, and eight to ten inches wide. They are thir'd and bearded on the back, and the edges beaded. A sheave-hole is cut through the middle fore and aft. It is bolted to the ship's side, in the channels, to reeve the lifts. &c.

Blocks, Deep-seat-line, are the same as a wooden snatch-block (which 8c) only smaller; generally from nine to eleven inches long.

Block, Derrick, in rigging the mizen-yard, is frapped with eyes, that go round the yard, and lashed underneath, between the flings and the outer yard-arm or peak; the other block is cross-frapped into the flap, has an eye spliced in each end, and lies upon the mizen cap, and soizes or hangs through the eyes under the cap, or upon the upper side of it.

Block, Fijle, is hung in a notch at the end of the davit, and serves to haul up the sluices of the anchor to the ship's bow.

Blocks, Girt-line, in rigging the fore-mast, and main and mizen masts, are lashed round the mast-head, above the flop of the cap, one to hang on each side. The girt-lines that reeve through them lead down upon deck, for hoisting the rigging-tops, and cross-trees, and the perons employed to place the rigging over the mast-head.

Blocks, Latch-line, in rigging the lower yards, are lashed round the yard, and through the eye of the flap, ten feet within the cleats on each yard-arm; the blocks hang on the fore part of the yard.

Blocks, Lift, in rigging the lower yards, are spliced into the flap of the top-fall-sheet blocks; the lifts reeve through the block in the flap round the mast-head, between that and the top-mast, then lead down abreast the hounds, and reeve through a block fastened to the side, and so are there belayed. In rigging the top-fall-yards, the lift-blocks are frapped with an eye to the side of the yard-arm. The lift reeves through the lower sheave in the filler-block in the topmast-fernords, and through the block on the yard-arm. The flanding part blocks to a becket round the topmast-cap, and the leading part leads down the side of the mast, and belays to the dead-eyes in the lower hounds.

Block, Long-tackle, resembles two single-blocks joined together endways; one being two-thirds less than the other. The sheel is made of ash or elm, two-thirds longer than the proportion for a single block. These blocks are used for tackles, and are made according to the size of the rope, as other single blocks. They are used in the Royal Navy and East India Service as yard-tackles; but in the merchant service as leading tackles.

Blocks, Mule, have the shell formed of several pieces of clap-planks, fitted to the thickness of the sheaves, sheaves-holes, and middle parts, and are strongly bolted together with three bolts at each end, driven through and clenched on a ring at the points. These blocks have flatter sheaves and more square edges than other treble and fourfold blocks. Of this sort are large treble and four-fold blocks, for lowering down ships, or other heavy purchases. Smaller made blocks, of modern invention, are formed of two pieces, joining in the middle; the pin working on patent rollers, let into the side of the sheaves, which are bolted or riveted together at the ends. These blocks are thought too complex for the Royal Navy, and are not so easily remedied in case of failure.

Block, Main-sheet, is used for the sheet-tackle of the main-fall-fooms of small vessels, and is single or double; the sheet or fall being always belayed round the pin. The shell is made of ash or elm, one half longer than the proportion for single or double blocks; the additional length is tapered, and a hole bored through between the sheaves and the end, to admit the flap; the length of the pin is the length of the block, and is similar to a belaying pin, for which purpose it is sometimes used.

Blocks, Monkey, are sometimes used on the lower yards of small merchant ships, to lead (into the mast or deck upon deck) the running rigging belonging to the falls. The sheels are made of ash or elm; some are only small single blocks, attached by a flap and iron twisted into iron-flaps that embrace and nail to the yard, the block turning to lead the small running-ropes in any direction; others are nearly square, with a roller working in the middle, the same as a sheave, with a wooden faddle beneath, to fit and nail to the yard.

Blocks, Nine-pin, are used to lead the running-ropes in an horizontal direction. The sheels, made of ash or elm, resemble the form of a nine-pin, though flared on the sides; their lengths are generally confined to the place in which they are fixed, and this is for the most part under the cross-pieces of the fore-castle and quarter-deck huts. The breadth of the block, sheave, &c. is governed by the rope, and tapers from the ends to three-eighths of the breadth of the middle; the pin at each end, serving as a vertical axis, is two-thirds of the thickness of the end. The thickness is five-eighths of the breadth. These blocks may be turned in a lathe, and flared afterwards with a spoke-shave.

Block, Quarter. See Thick and thin Block.

Blocks, Rack, are a range of small single blocks, made from one solid, by the same proportion as single blocks, with ends, in form of a dove's tail, for the lashing, by which they are fastened athwart the bowsprit, to lead in the running ropes. They are seldom used.

Blocks, Shove, are two single blocks, cut in a solid piece, tranversely to each other. They serve for legs and falls of the bunt-lines, but are seldom used.

Block, Shoulders, is a large single block, left nearly square at the lower end, or ark of the block, and cut sloping
in the direction of the sheet. Shoulder-blocks are used on the lower yard-arms, to lead in the topfall-yards; and, on the topfall-yards, to lead in the topgallant-yards; and by means of the shoulder, are kept upright, and prevent the sheets from jamming between the block and the yard: they are also used at the outer end of the boomkins, to lead in the fore-tacks.

**Blocks, Sjffer,** are made of sbr, similar to two single blocks, and are turned out of a solid piece, about twenty inches long, one above the other; between the blocks is a score for a middle seizing: a round head is turned at each end, and hollowed underneath, to contain the end-seizings; along the sides, through which the pins are driven, is a groove, large enough to receive part of the topgallant-shroud, in which it is seized. In these blocks receive the lifts, and reef-tackle-pendents, of the topfall-yards.

**Blocks, Slib-lair,** in rigging the lower-yards, are frapped with a short lafing-eye, that fixes to the span of the quarter-blocks underneath the yard.

**Blocks, Snatch,** are proportioned by the rope, as a single block, leaving twice the length for the score and lafing; they taper from the lafing to the lafing end, to half the breadth and thickness at the lafing; one side of the shell is cut across above the lafing, large enough to admit the rope or fall. In the Royal Navy, snatch-blocks are iron-bound, terminating at the small end with a twivel-hook, or an eye, large enough to receive several turns of lafing; that part of the frap, over the notch in the side, lifts up with a hinge, and is confined down, when the rope is in the block, by a small iron hook, or latch, that hooks in the eye of a toggle-bolt, and that secures the upper end of the frap; the hinged part of the frap goes over the bolt, with a hole in the end; the frap is let into the block its thickness, and is confined by the pin and nails; they are used for heavy purchases, and where a warp, or hawser, is brought to the capstern. Snatch-blocks, not iron-bound, have a large hole bored through the tapering end of the shell, for the lafing. They are used for the main and fore sheet blocks of square-rigged vessels.

**Block, Spring,** a new kind of block, invented by Francis Hopkinson, eqq. of Philadelphia, and designed to affix a vessel in foul weather, by increasing the acting spring of her rigging. It is proposed to apply it to all foul parts of the rigging as will admit of it with safety and convenience, and where its operation will be most advantageous; but particularly to the sheet ropes, and, if practicable, to the dead-eyes, in lieu of what are called the chains. A (see Plate of Ship) is a block made in the usual manner, having a ring, or eye, D, at one end. C, is a spiral spring, linked at one end to the hook DE, and at the other to the ring F, which is to be annexed by a staple to the timber-head, or by some other means to the place where it is to be applied. The spring C must be of well-tempered steel, and proportioned in strength to the service it is to perform. Within the cavity or pipe, formed by the spiral spring, there must be a chain of suitable strength, called a check-chain (represents separate at G), connected by the links to the hook DE and ring F. When the spring is not in action, this chain is flack; but when the spiral spring is extended, by the force of the wind, as far as it can be without danger of injury, the check-chain must then begin to bear, to prevent its farther extension, and if strong enough, will be an efficient security against failure.

Fig. 2. represents part of the gun-ward of a loop, with the spring-blocks in action, one of them hooked to a staple in the timber-head, and the other to the corner of the jib. The inventor of this machine apprehends, that a vessel thus furnished will be less liable to heel; and that the will receive the impulsive of the wind to better advantage, and fail with a more lively and equable motion than if rigged in the common way. Transactions of the American Philosophical Society, vol. III. art. 40.

**Blocks, Strap-bound,** are single blocks, with a shoulder left on each side, at the upper part, to admit the frap through, a little above the pin. These blocks are used at the clutches of the square-falls, for the clue-garments or clue-lines, and under the yards; the shoulder prefers the frap from chafing.

**Block, Thick and thin, or Quarter,** is a double block, with one lafing thicker than the other, and is used to lead down the topfall-yards and clue-lines. In the merchant service they are used single, thick and thin. In rigging the lower yards, they are frapped with a long and short leg, with a lafing eye spliced in the ends, and laf to the yard within the cleats, in the middle of the yard, the block hanging downwards. The long leg comes up the aft-sides, and meets the short leg on the fore-side, and there lafes through the eyes. Although these are used for the topfall-yards, and intended for the clue-lines, a single block would be cheaper and better; as the thin lafing is seldom used for the clue-line, it being found rather to impede than to facilitate. Small ships, in the merchant service, have a double block lafied in the middle of the yard, as the quarter-block, through which the sheets receive, and lead down on opposite sides. Large ships, in the merchant service, have a single block lafied on each side of the middle of the yard, and the sheets receive on their respective sides, and lead down by the main. A quarter-block, in rigging the crows-jack-yard, is frapped with a double frap, with an eye in each of the four ends, and is lafied upon the yard in the middle between the cleats.

**Block, Top,** See Top-Rope. **Blocks, Top-Gallant-Sheet,** in rigging topfall yards, are frapped with two lafing-eyes, and laf upon the yard, close within the clue-line-blocks on each side.

**Blocks, Topfall-Sheet,** in rigging the lower yards, are put over the yard-arms, frapped with an eye of the size of the yard-arm.

**Blocks, Tricing,** for the yard-tackles, are frapped with a short lafing-eye, that fixes round the yard about one third of the length within the arm-cleats; the blocks hanging under the yard.

**Blocks, Tyre,** in rigging the topfall-yards, laf on the topmast-head close up to the rigging, under the collar of the stay, as the lower ones; and the blocks on the yards laf under the fore-part of the yard, as the lower ones, and receive with a double tye, in large ships, and with a single tye, like the lower, in small ones. The flanking parts of the double tyes clinch round the mast-head, then receive through the double block upon the yard, and up again, and receive through the block on each side of the mast-head. The blocks are then spliced in their lower ends, and connected by their halyards to a single block, that is frapped with a long frap, with a hook and thimble, that hooks to a twivel-eye-bolt in the channel on each side; the leading-part comes in through a block lafied on each side; the foremost ones abaft the forecastle, and the after ones on the quarter-deck.

**Block, Veyal or Viol,** is a large single lafied block; the length is ten times the thickness of the lafey-hole, which is three-eighths more than the thickness of the lafey; the thickness of the lafey is one tenth more than the diameter of the viol, and the diameter of the lafey is seven times the thickness. The breadth of the block should be eight times the thickness of the lafey, and the thickness two-sevenths of the length. This block is double faced, the
the sheave is coated with braids, and the pin is iron, and nearly as thick as the sheave. It is used in bearing with the anchor. The vio paffles round the jier-cap, and through the block, which is lathed to the main-mall; and the cable is fastened in a temporary manner to the vio in several places. It is seldom used except in the largest ships of the Royal Navy.

Block, Wallpings, is made of elm or ash board, shaped like the body of a bellows; the sides or cheeks are 8\" inches broad in the middle, and tapered to 2 inches broad at the ends; the block, or longer cheek, is 16 inches long, and 5\"ths of an inch thick, with a hole bored through the upper end to receive a leathern slrap; the upper cheek is 12 inches long, and 3\"ths of an inch thick, except the lower end, which is 15 inches thick, and forms the sheave-hole. The sheave is 1\½ inches thick, and 7\½ inches in diameter, made of lignum vitae, coated with braids; it is let into the cheeks one eighth of an inch, to prevent the yarn from getting between the sheave and the cheeks. The cheeks are faftened together at the lower end with three screws and nuts; and the pin, which is iron, is seven inches long, driven through the middle of the block, with a shoulder on the upper side, and clinched at the point on the lower side of the shell; the upper part of the pin is tapered small, and a wooden handle riveted upon it. The sheave has a broad chamfer round the outer edges; the inside edges, and inside of the block above the sheave, are lined with thin iron neatly screwed on, to prevent the block from wearing. This block is faftened in a wayer manner than blocks in general, and is seldom used but by rope-makers, to warp off the yarn into hauls for tarring.

Blocks, Single, double, or triple, in Rope-making, are frapped with a hook and thimble, and reived with a rope, and of the tackle-fall, which is used to stretch the yarn to its full extent, before the press is put on, by a caplern, or crane, at the lower end of the rope-walk. The fall is then belayed, until every yarn is have through the fraps and brought down, so that the rope may not exceed the circumference intended. For other blocks, see Bulls-eyes, Dead-eyes, and EuPhroes. See Plates of Ships.

Blocks, Strapping of. A seventeen-inch block has a five-inch rope slrap, and every inch in length above or under, to a twelve-inch block, has half an inch more or less fixed rope allowed for the slrap; a 1\½ inch block has a 3-inch slrap; a 10 and a 9-inch block, 2\½ inches; an 8 and a 7-inch block, 2 inches; a 6-inch block, 1\½ inch; a 5-inch block, 1 inch; and a 4-inch block, 2\½ inch of an inch. The core round iron-bound blocks is taken out to the size of the iron slrap, sufficient to bury it, except at the pin. Iron slraps are from 4\½ to 4\¼ inches in thickness; and nearly three times the thickness in width; the thickness of these should correspond to the slraps which they are to refit. The cast-block must have a strong slrap and large iron hook, which hooks the rings of the anchor in casting. The top block should have a stout iron binding, with a strong short hook. Top tackle blocks have strong iron bindings, the upper block with a tackle-hook, and the lower block with a twine-hook. The twine, in iron-bound blocks, serves to turn it occasionally, in order to untwist the parts of the rope that form the tackle, as the mechanical power is greatly reduced thereby.

In rigging, the whole length of all the different sizes of block-frapping is got upon the stretch, and have out tight for worming and serving; it is then wormed and served, and cut into shorter lengths, to suit the different blocks. The frapping of jeer-blocks is wormed, parcelled, and served; frapping of 4 inches diameter, and above, is wormed and served; and all under four inches is only served with spun yarn; except the sprit-sail brace, bunt-line, and leech line blocks, that are lashed under the tops, which are only served with spun-yarn over the splice, and the tail left half a fathom in length. Jier-blocks are double scored, and the double and treble blocks are frapped with a double slrap, thus: it is spliced together at the ends, and, when doubled, to be the size of the block and circumference of the yard; it is then doubled, and the block feized in the sight, with a long and short leg; the splice lying in the arse of the block.

The scores of all blocks are to be well-tarred, and the pin and sheave examined, before the slrap is put on. The block is set well into the slrap with wedges, thus: the four parts are frapped together with rope-yarn under the block, with a chock between, and the wedges are set between the breasf of the block and chock. Then the slrap is rippered, with a heaver, round the block; the wedges, chock, and frapping, taken away, and the block hung upon the flake-head, or post, and the slrap well feized together, close under the block, with nine under and eight riding turns, every turn strained tight round by a heaver, and croffed each way with two turns.

Jier-blocks, for the mast-heads, are frapped with long eyes, to receive many turns of the lathing; and the block is feized into the slrap as before, as are all feizing blocks, in proportion to their fizes. The fraps are cut according to the following table.

A TABLE of the Dimensions of Straps for Lathing and Seizing Blocks.

Blocks, frapped with eyes or thimbles spliced in the ends, are feized tight into the bight, and the legs left long enough to haft through the eyes, round a mast, yard, &c. as the top-fall-eyes, ches, garnets, and spritfall-ches, &c.

Blocks frapped with a thimble, or hook and thimble, have the slrap spliced together at the ends. The block is fixed in one bight, for the splice to lay on the arse of the block, and the thimble is in the other bight; the feizing is put on, between the block and thimble, with eight under and fix riding turns, according to the size of the block, each turn strained tight by a heaver; the turns double croffed, and the end flop with a wall-knot crowned.

Blocks frapped with double tails, are fixed in the slrap, similar to blocks with eye-slraps; and those with a single tail are spliced in, and served with spun yarn over the splice.

Girtline blocks are frapped in the house, and the girt- lines recived. See Elements and Practice of Rigging, &c. vol. i.
Block-and-Block, in Sea-Language, denotes the situation of a tackle, when the effect is destroyed by the blocks meeting together.

Block-wood, is a name sometimes given in our laws to logwood. 3 Edw. c. 9.

Blockade, in the Military Art, signifies the method adopted in cutting off all communication between a town which it is intended to reduce by famine, and the neighbouring country. It is effected by posting troops on all the passages and avenues leading to and from the place; preventing any supplies of provisions or reinforcements from being thrown in by the enemy, and, thus, in course of time, starv- ing the garrison into a surrender. A blockade differs from a regular siege, inasmuch as there are no trenches or attacks. Blockades are principally formed by the cavalry. The term probably owes its origin to the German expression blocken, or blockhaufig, a bulwark, or house of wood; or to the Gaulish blocat, a barricade; though others derive it from the Latin baculares, signifying to stop a passage.

The word is sometimes used in speaking of the commence ment of a siege, when detachments are sent forward to feke the principal avenues, and occupy the ground on which the besiegers intend to fix their quarters.

To raise a blockade is to force the troops, which keep the place blocked up, from their posts.

The only method of reducing fortresses in the more remote ages of antiquity, was by blockade. The town was completely invested by a wall of masonry confined around it, and furnished at certain distances with redoubts and places of arms; or the besiegers contented themselves in surrounding it with a deep ditch and intrenchment, well pallisaded, to prevent the garrison from making sorties, or any succour or provisions from being introduced by the adversary without. In this situation the investing army tranquilly waited until famine brought about what at that period art and force were unable to accomplish. From hence proceeds the extreme length of those sieges chiefly spoken of in the more early pages of profane history; that of Troy, which lasted ten years; that of Azotus, by Pammelitnus, which continued twenty-nine; and that of Babylon, by Cyrus, who, according to Xenophon (Cyrop.); would have been much longer detained before its walls, if a lucky surplice had not rendered him master of the place. See Babylon.

The ancient Greeks, on foreseeing that the siege of a fortress would prove a work of time, often changed it into a blockade. They environed the town with a sallie and rampart against the attempts of the garrison, and drew another ditch round it towards the country, to oppose such troops as might advance to succour the place. The besiegers established their camp between the two lines, and thus, in course of time, starved their adversaries into a capitulation.

In the instance of the blockade of Plataia, carried on during the third year of the Peloponnesian war, the works constructed by the Lacedemonians were of a more complex nature. They consisted in two walls of solid masonry, built at the distance of sixteen feet from each other, of a reason able thickines, and covered in at top by a kind of roof or platform. The intervening space formed a suite of apartments, in which the troops, defined to carry on the blockade, were lodged during the winter. Each of these walls was furnished with a parapet and battlements, and, at the distance of every ten of these huts, was erected a turret with a flat roof, of the breadth of the whole terrace, and capable of making resistance at the same time against an enemy from within or without. The only method of communication between the different chambers, was by travelling these towers.

The approach to the walls on either side was defended by a deep ditch, the earth of which had been used in constructing the rampart. During the night, guards were kept on the several towers; centinels were established at different polls round the whole extent of the circumvallation; and a corps de reserve of three hundred men remained always under arms, ready to march on the first signal wherever there might be occasion for their services.

This is the most remarkable instance of a blockade we meet with in the Grecian history. Notwithstanding, however, all the precautions above related, and the forming impracticability of flight, the intrepid garrison of Plataia found means to elude the vigilance of their besiegers, and, by a well concerted fortiss, about one half of them effected an escape across the formidable works of the Pelopon nians, and reached Athens in safety. The event is related in a very interesting and circumstantial manner by Thucydides in his second book. The Romans first imitated, and finally surpassed the Greeks in this as well as in every other branch of scientific warfare. As early as the siege of Agrigentum, in the first Punic war, we find them dividing their forces, and forming two encampments to block up the place on both sides; connecting their encampments by lines of circumvallation, and braving within these defences every effort made to relieve the town by the enemy from without. But these lines were equally badly guarded against a forte with those of Plataia. The Carthaginian garrison, imitating the former example, succeeded in a like manner in forc- ing a passage by night over the intrenchments of the besiegers. (Polyb. lib. i. c. 17.)

The famous blockade of Lilibuxum, during the same war, which lasted for nearly ten years, is a remarkable instance of Roman perseverance in military undertakings, although, the place being open to receiving supplies from the sea, the activity of the besiegers was not attended with much complete success as it deserved. By degrees, however, the Romans improved in the art of reducing fortresses by blockade. Syracuse, which the abilities of Archimedes rendered impregnable by open force, had been thus reduced by Marcellus, but for the treachery of a townman, which in a great measure abridges his labour; and all the military science and manoeuvre of the formidable Hannibal was in vain exerted for the preservation of Capua, during the twelve months the siege lasted. (Polyb. Lib. iv.)

The works constructed by Scipio Africanus for the reduction of Numantia, exceeded in magnitude all which had been raised on any former occasion, and besides surpassing them in length, embraced a much greater extent of ground, than the intrenchments of the Lacedemonians before Plataia. Numantia was eighty-four itches, or nearly a league in circuit. Scipio, after having invested it, drew a circle including twice the area of the circumference of the town; and this work being completed, he threw up his lines of circumvallation and contravallation at a reasonable distance from each other. Each of these fortifications was composed of a rampart eight feet thick, and ten in height, defended by sharp pallisades, and flanked with turrets at a hundred feet distance from each other. We can hardly comprehend or credit the immense labour of such a circumvallation; but nothing can be better attested than these facts. (Appian. de Bell. Hisp.)

Among the numerous exploits of Cornelius Sylla, the blockade of Prunella, during his civil war with the party of Marius in Italy, is not to be reckoned the least. The in flexible audacity, with which it was kept up during a long period of time, and preferred unbroke against the bloody and almost uninterrupted attacks of several hostile armies, superior in number to his own, conveys the highest idea of his
his martial abilities. It was, however, under the auspices of Julius Caesar, that this branch of military science attained its highest point of perfection among the Romans; and whether we confide the annals of ancient or modern warfare, we find no example to equal the talents displayed by that unrivalled general, in the formation of his immense works before Aleia, and at Clyrachium, which have defervely excited the wonder and admiration of posterity.

In the former instance, he undertook the arduous task of blocking up an army of 80,000 Gauls, doubly superior in number to his own forces, commanded by a general of the greatest military knowledge, Vercingetorix, and entrenched under the walls of a fortified city, situated itself on an almost inaccessible mountain. Caesar's line of contravallation, extending nearly eleven miles, was composed of a ditch fifteen feet broad, and as many deep, defended by a rampart twelve feet in height, furnished with a parapet, and fortified all round by turrets, at the regular distance of eighty feet. The front of the rampart, looking towards the town, was protected by a pallisade of sharp flake and boughs of trees, interlaced, cut sharp, and pointing outwards. Before the fosse were planted five different rows of cippi, or large branches sharpened at the ends, fixed in trenches five feet in depth, and so strongly interwoven, as not to be removed or plucked up, without infinite labour. In front of these were arranged eight other rows of lilias, or pits, three feet deep, disposed in the form of a quincunx, flanked thick with strong sharp flake, and covered over with bushes to deceive the enemy. Before these again were strewed an and down numerous flakes of a foot in length, fastened in the earth, and headed with barred iron hooks, called by the Romans flaminulae. Farther advanced than these last, at 400 paces distance from the rampart, Caesar drew another ditch, twenty feet broad and deep, to keep the garrison at a distance, and prevent them from annoying his soldiery while employed on the contravallation. Not contented with such immense labours, he constructed the like fortifications towards the country, for the purpose of frustrating any attempts the expected Gaulish succours might make for the relief of their besieged countrymen. Between the lines, a space of nearly half a mile in breadth, was disposed the investing army, and their principal encampment was pitched in the most convenient situation for communicating with every part of the contravallation. Behind these defences did Caesar labour, the utmost efforts of a new army of 250,000 Gauls, sent to extricate Vercingetorix; and, after a series of the most brilliant achievements ever recorded, obliged the town of Aleia, and the army inclosed within its walls, to surrender at discretion. Cæs. de Bel. Gal. lib. vii.

No less famous in history, though not productive of equal succours, were the celebrated lines at Dyrachium, carried over a tract of fifteen miles, and which, Caesar flattered himself, to surround, and compel to a capitulation, an army exceeding his own in strength, and commanded by the great Pompey. But in this instance, the conqueror of Gaul had to do with Romans, and the enterprize proved too vast for his strength. Pompey, by a sudden and well-directed effort, broke through the blockade, when it was on the very point of being completed; and had he briskly followed up the advantage, might, according to Caesar's own confession, have converted his adversaries' hopes of success into total defeat. Cæs. de Bel. Civ. lib. iii.

The works thrown up by Augustus at Perusia, and the entrenchments within, which Stilico at Fufcula enclosed, and destroyed an inundation of 400,000 Goths, are proofs that in after ages the Romans retained a remembrance of the means by which Caesar had triumphed at Aleia, and were still capable of practising them for the extermination of their numerous enemies. App. de Bel. Civ. Zozim. Prop. Marc. Chron.

In modern warfare, there are two ways of forming blockades. The first, and most simple, consists in fortifying and occupying different positions at a small distance from the place, principally upon all the highways and avenues, and along the banks of rivers, both above and below the town. These posts are guarded by disjoint corps of infantry and cavalry, who take care to keep up an easy communication with one another, and to prevent all supplies of provisions from being conveyed into the fortresses blockaded. This, by degrees, reduces the garrison to great necessity, causes them to desert, and frequently occasions such murmurs and mutinies among the inhabitants, as to force the governor to a premature capitulation. Such a species of blockade is extremely tedious; for it is almost impossible to prevent provisions from being sometimes introduced in small quantities, and reviving the courage and patience of the besieged. But it is of advantage, after having thus for some time invested a town at a distance, to convert the operations into a regular siege, as the garrison are then generally unprovided with the materials necessary for protracting their defense.

The second kind of blockade is much closer and nearer. It is effected by means of lines of circumvallation and contravallation, between which the army lies encamped, and is adopted only in particular cafes. If, for example, after the loss of a battle, the enemy should retire into a town which is well known not to be over-abundantly supplied with provisions, and, it is presumed, must be obliged to surrender in a few days. But as it would be the height of imprudence in a beaten general to expel the remains of his army to certain ruin, by shutting them up in a place so ill-circumvallated, (a fault, notwithstanding, committed by marshal Wurmer in 1796, after the loss of the battles of Baffano and Roveredo, and which all the importance attached by the imperialists to the preservation of Mantua can hardly excuse,) this kind of blockade is seldom put in practice.

It is rarely a fortress is reduced to surrender, by the mere proceeds of blockading; but sieges are often greatly accelerated by it, on account of that scarcity of necessaries, whether for the subsistence or defence of the garrison, which, in a greater or less degree, is its never failing consequence.

The blocking up of towns by corps principally of cavalry, posted in the neighbouring places of strength, is more convenient than any other method; because the troops forming the investiture, are not so fatigued as they would be in occupying open positions, and unfortified villages. In the latter case, it is necessary to be always on the alert, not only against the garrison, who, by a well directed fortie, may interrupt the communication, and cut off some of the detachments; but, against the enemy from without, who, by secretly marching a strong force, may surprize, beat up one of the besieger's quarters, and introduce a convoy, or reinforcement into the town. On account of the inconvenience, it is essentially necessary to ascertain the quantity of provisions and stores contained in the magazines of a place blockaded, in order to compute how long it may hold out, and to have an army in the field sufficiently strong to protect and cover the blockade. For, should the enemy succeed in surprizing and cutting off one detachment, its defeat might occasion the premature destruction, or capture of all the others, before they could assemble in competent force to repulse the collected attacks of an enterprising and vigorous adversary. (Fuequieres, Mem. chap. xxii. p. 377.)

It is chiefly, since the contest for the imperial succession in
in 1749, that the expedient of blockading fortresses of the most formidable strength, has been preferred to the less tedious, but more destructive plan of carrying them by a regular siege. In the latter case, every outwork belonging to the place must be taken, or battered down inch by inch, with an immense loss to the besieging army, and frequently at the hazard of its being reduced in numbers, as not to be capable of undertaking any action of moment during the remainder of the campaign. On the other hand, a blockade, well kept up, must, sooner or later, reduce the garrison to the last extremity for want of provisions, or ammunition. The number of troops engaged in the enterprise is comparatively small. The loss of men, necessarily considerable in the frequent and bloody attacks on the fortifications of a well defended place, is entirely avoided; and the major part of an army is still at liberty to continue its advances into the heart of the enemy's country, and to follow up a previous success, without the tedious process of stopping to reduce every strong hold in its way. The inconveniences which might otherwise result from leaving a hostile garrison in the rear, are, in a great measure, obviated, if the blockade is kept up with proper acclivity and elongation. The enemy within the town have enough to do to attend to procuring provisions for themselves, without troubling the convoys designed for the main army of their besiegers; and by this means, the operations of a campaign on the latter side being removed, are frequently accelerated, by having recourse to a blockade. Had the allied powers, instead of montering away their armies before the walls of Mayence and Valenciennes, and afterwards completing their ruin, by the impotent and bloody attempts upon Dunkirk and Maubeuge, adopted this method during the summer of the year 1793, they possibly might have made greater impression on the territory of the French republic. Had, on the contrary, the generals Jourdan and Pichegru endeavoured, in 1794, to carry Landrecy, Valenciennes, Condé, and Luxemburg, by regular sieges, instead of contending themselves with leaving those fortresses in a state of blockade, it is very evident that the successes of the French, during the latter part of that memorable campaign, would have been by no means so rapid and important as they actually turned out.

When the directory formed, in 1796, the revolution of invading Germany, their armies made no attempt to attack in front the towns of Manheim, or Mayence, but proceeded to effect a passage over the Rhine, at a distance from those places; and, instead of confining their time, and waiting their strength in long and tedious sieges, they advanced rapidly into Swabia and Franconia. They wished to become masters of Ehrenbreitstein, Mayence, Manheim, and Philipplburg, by the same method by which, in 1794, they had recovered the towns of Landrecy, Quefnoy, Valenciennes, and Condé, and to achieve, by a single manoeuvre, that which would, in former times, have been the result of two or three successive campaigns. Pursuant to this system, they forbore to undertake any siege, and ventured to leave fortified places at a great distance behind them. Their generals foresaw, that by carrying the war away from these towns, they should, by force, detach the enemy from them; and judged that if they could obtain and keep possession of the country situated beyond these fortresses, they would, in the end, fall into their hands perfectly undamaged, and without having cost them either blood or treasure. They proposed to acquire the fortified places, by making themselves masters of the surrounding country; and formerly these countries were secured by getting possession of the fortified places. These had hitherto been the means of conquest; they now meant to make them its reult. This method, by which the French acquired so great a number of fortified towns in 1794, met not with the same success in 1796; but their failure did not arise from the strong places which they left behind them; and as the French had not impeded the progress of Jourdan and Moreau, neither were they the causes of their first disfaters. If the troops of the republic had been victorious at Amberg, or at Wurzburg, the fortresses of Ehrenbreitstein, Manheim, Mayence, and Philipplburg, would, no doubt, have ultimately fallen, as Luxemburg did in 1795. Hill. of the Camp. of 1795, Lond. 176, 680.

As a proof of the little danger attending this method of carrying on war, we shall only add, that the garrisons of Philipplburg and Mayence remained so closely blockaded by a small part of the French forces, as not to be capable of affording the archduke any essential assistance in cutting off the retreat of the invaders, notwithstanding the rapid and disorderly manner in which more particularly that of Jourdan was conducted. During the same year, Buonaparte, although the reduction of Mantua was the principal object of the campaign in Italy, did not for a moment discontinue his other operations in the field. On the contrary, this did not hinder him from carrying his arms into the middle flates of that beautiful country; from laying Parma and Modena under contribution; obliging the pope and duke of Tuscany to agree to a neutrality; forcing the English from Leghorn, and fighting the imperialists almost incessantly, on every point of a very extended line, to the destruction of no less than four of their armies successively detached against him.

Notwithstanding the tardy proceedings of a blockade are far from being congenial to French vivacity, yet, where the strength, or peculiarly inaccessible situation of a fortress, have precluded all hopes of success from a coup de main, they have often had recourse to this means. That they are professed of sufficient perseverance on these occasions, the three blockades of Luxemburg, Mantua, and Ehrenbreitstein, in 1795, 1796, and 1798, are convincing proofs.

The most famous blockades which, during the last century, have distinguished the military history of Europe, are the following: That of Prague by the Austrians in 1742, is renowned for the gallant defence made by the French forces under the marquis Belville and Broglie, for the space of five months, during which time they were driven to the last necessity for want of provisions; and for the daring retreat by which the former of these generals preferred the remain of his army from falling into the hands of the enemy. The late war has produced several remarkable instances. The two already mentioned of Luxemburg and Ehrenbreitstein reflect equal honour on the besiegers, whom no obstacle could deter from continuing, with invincible patience, their plan of reduction; and the garrisons, whose resistance was in the highest degree meritorious.

In 1796, public attention was every where engrossed by the blockade of Mantua, which gave occasion for the utmost exertion of that military talent by which the first confu of Frances has so eminently distinguished himself, and for the veteran marshal Wurmer to add fresh laurels to those he had already acquired, and draw even from his conqueror a flattering acknowledgment of the ability he had displayed in its defence. The different exploits of these generals; the entire destruction of four imperial armies, in vain attempts to relieve the place; the bloody battles of Castiglione, Roveredo, Arcole, and Rivoli, the refult of those attempts; and the conquest of all Italy by the French,
French, the consequence of its fall, secures to the blockade of Mantua everlasting fame.

The conduct of general Maffena, when blockaded up in 1800 within the walls of Genoa, may justly be compared with the most glorious actions of the war. Surrounded on all sides by enemies; cut off from every hope of succour by land or sea, and almost delitute of provisions or ammunition, he maintained, for sixty days, a post the Austrians had flattered themselves to reduce by famine in six; destroyed immense numbers of them in his different attacks on their posts; and having defended the place to the last extremity, obtained a negociation (for Maffena would not suffer the word capitulation to be inserted in the treaty), equally honourable to himself, and advantageous to his country. It was advantageous, inasmuch as it obliged the enemy to divide and scatter their forces, entangle themselves among the defiles of the Apennines, and, besides losing a number of men before Genoa, drew them to such a distance from what the French government intended to make the principal feat of action during the campaign, as enabled the first confuf to pass the great St. Bernard unopposed, occupy the plains of Piedmont, throw himself in the rear of general Nicias, and, by the battle of Marengo, extingufh at once the hopes of the Austrians in Italy.

BLOCK-battery, in the Military Art, denotes a wooden battery on four wheels, moveable from place to place, whereby to fire en barres, or over the parapet; sometimes also used in galleries and cafemates, where room is wanted.

Block-brush, a term used in Heraldy, to express a bundle or bunch of knee-holm, or halford myrtle, formerly used by butchers to clean the surface of their chopping-blocks, which forms a part of the armorial emblems assigned to the company of butchers of London.

Block-carriage, in the Artillery, denotes a carriage used for conveying mortars and their beds from one place to another.

Block-house, in the Military Art, a kind of wooden fort or battery, either mounted on rollers, or on a vefsel, and serving either on the water, or in some counter-scars and counter-approaches. The name is sometimes also given to a brick or stone fort, built on a bridge, or the brink of a river, serving not only for its defence, but for the command of the river, both above and below. Such was that noted block-house anciently on the bridge of Dreden, since demoliﬁed on enlarging the bridge.

Block-printing. See Printing.

BLOCKING, in Middle Age Writers, denotes a kind of burial used for persons dying excommunicated.

Blockings, circular, in Architecture, are bases to the dome, repreffented in the Plate of Archit. (title Basile) QQQ; which, by their apparent solidity, seem to strengthen the dome, and at the same time taking from its height, add a peculiar gracefulness to its appearance.

Blockings, square, are repreffented at S (title Basile), in Plate of Archit. Thefe, when enriched with base and cap, obtain the appellation of festaels.

Blocking-course. See Course.

BLOCKLAND, Anthony de Montfort, in Biography, a painter of history and portrait, was born of a noble family at Montfort in 1532, and acquired his art in the school of Francis Floris, in which manner he always followed. By endeavouring principally to imitate the fable of the Roman school in deign and composition, he became a distinguished artist. He well understood the principles of perspective, and he difpofed his figures with judgment and accuracy. The style of his colouring was agreeable, and his pencil mellow. He designed every object after nature, and gave to the contours of his figures considerable elegance. His genius was best adapted to great compositions, of which he designed many, both at Delft and Utrecht. Several of his works, particularly a Venus, and the history of Joseph and his brethren, are in so good a taste, that they seem to have been painted by a master educated in the school of Florence, Pilkington.

BLOCKLEY, in Geography, a township in Philadelphia, in the county of Pennsylvania.

BLOCKY, among fculptors, a name given to a diamond when its fides are too upright, by its table and collect being larger than they ought to be.

BLOEMAERT, Abraham, in Biography, the moft distinguished of a family of Dutch artists, was the fon of Cornelius, an architect, engineer, and excellent ﬂatuary of Dor- drecht, who, during the troubles of the low countries, removed to Utrecht. He was born at Gorcum in 1567; and re- fided chiefly at Utrecht, where he probably died, A.D. 1647. In his youth, he diligently copied the designs of Francis Floris; but the excellence to which he attained was chieflie owing to his own genius, which enabled him to acquire a style of painting peculiar to himself. He painted history pieces, sacred and profane, landscapes, and animals; but though he possessed a facility of invention, and free-spirited touch, and well understood the chiaro-furo, his table and style are said to have too much of the Flemith, and he is charged with having indulged his own fancy, and deviating from nature in his figures. The historical picture of the death of Niobe and her children, gained him great reputation; the figures in the composition being, as large as life. Some fligh, masterly etchings are attributed to this artist, which are executed in a manner imitating drawings with a pen, from his own compositions. He also published some spirited chiaro-furos, the outlines of which, contrary to the usual custom, were not cut on blocks of wood, but etched upon copper. Of this kind are two large prints by him, repreffenting Moses and Aaron, both sitting figures.

He left four sons, all artists. His fon Frederic, worked chiefly from his father’s designs, and imitated his style in his etchings and chiaro-furos. He also, conjointly with his father, made a large drawing book, conﬁscating of figures, animals, landscapes, &c. Henry and Adrian, were both painters; and they are also mentioned as engravers: the moft eminent, as a painter, was the latter.

Cornelius, the moft distinguished as an engraver, was Abraham’s youngest son, and born at Utrecht in 1603. Devoting himself wholly to the art of engraving, he ﬁrst studied under Crispin de Paes, and then went to Rome, where he died, at a very advanced age. The manner of engraving adopted by this artist was original, and the source of that style, in which the best French masters excelled, or those of them who worked merely with the graver. He covered the lights upon his designs, and the other parts of his plates which required tinting, with great care: whereas, before his time, the lights on the distant hills, trees, buildings, or figures, had been left quite clear; and by fo many white spots, scattered in various parts of the fame deign, the harmony was disturbed, the subject confused, and the principal ﬁgures prevented from relieving with any striking effect. By this judicious improvement, Bloemaert gave to his prints a more clear and ﬁnished appearance, than all the laboured neatness even of Jerom Wierix had been able to produce. He drew correctly; but as he executed entirely with the graver, the extremities of his figures are heavy; and his heads are not always beautiful or expressive. In the mechanical part of the work few have excelled him,
either as to clearness, or freedom of execution. His great fault, however, is want of variety. The naked parts of his figures, the draperies, and the back ground, are equally neat, and engraved precisely in the same manner. Hence the effect is flat, and the flesh, for want of distinction, appears cold and slivery.

His works, which are numerous, are justly held in high estimation, and cannot be easily procured. The following are particularly noticed, and the first impressions of some of them are very rare: the "Chalify of Joseph," from Blankert; the "Adoration of the Shepherds," from Raphael; the same subject from Pietro de Cortona; the "Holy Family" of the "Spectacles," as it is called, from Joseph's holding a pair of spectacles in his hand, from Annibale Caracci; another "Holy Family," from Parmigianio; the "Virgin and Child," the child sleeping, from Guido; the "St. Luke painting the Virgin and Child," from Raphael; the "St. Peter raising Tabitha from the Dead," from Guercino; the "St. Marguerita" leaning on a pedestal, and setting her foot upon the dragon, after Annibale Caracci; the "Four Fathers of the Church," from his father A. Bloemaert; "Christ appearing to St. Ignatius," from the same; "Mekager presenting the boar's head to Atalanta," from Rubens; several "prints for a misfial," after Ciro Ferri and others; a few small prints of "Rutlics, &c." from his father; the "Heads" from the same; &c. &c. Pilkinson and Strutt.

**BLOMEN, JOHN FRANCIS VAN, a painter of landscapes, called by the Italians, from the delicate manner in which he painted his distances, "Horizonti," or "Orizonti," was born at Antwerp in 1655; and as he studied at Rome, and always resided in some part of Italy, he is generally considered as an Italian artist. His works have been very much admired in every part of Italy, and bought at very high prices by the boldest judges. His first manner resembled that of Vander Cabel; but he afterwards made nature his model, and more particularly the views about Tivoli, the subjects of many of his landscapes, in which he represents, with extraordinary truth and beauty, the mists arising from the agitated surface of the river below. His pictures are generally well designed and well executed; and those of his best time are now considered as an ornament to the most select cabinets in Europe. A very capital picture of this excellent artist, in which the figures were invented by Sebastian Conca, is in the collection of the earl of Moira. By this artist we have five small etchings, probably done for his amusement. They are "perspective views," apparently near Rome. Pilkinson and Strutt.

**BLOMEN, PETER VAN, brother of the preceding, was born at Antwerp, and after living several years with his brother at Rome, studying the works of the greatest masters, returned to his native city, where, in 1699, he was appointed director of the academy. The subjects of his pictures are the marchings of squadrons of cavalry, encampments, artilleries, battles, Italian fairs, markets, and festivities, in which he manifests correctness in design and drawing, and an elegance in the manner of dressing his figures. His horses are designed in an admirable style, and in his battles they exhibit great spirit, graceful attitudes, and an expression full of life and nature. His landscapes are enriched with elegant architecture, with balto-relieves, and mutilated statues, in a noble taste; and they are rendered the more agreeable by a good tone of colour, animals of different kinds, and excellent figures. His best works are admired in all parts of Europe, and afford high prices; but some of them are too laboured, and less valuable. Pilkinson.
power soon terminated; for, upon the banishment of the archbishop A. D. 1168, he left the court of Sicily, and returned into France. From France he was invited into England, by Henry II. who employed him as his private secretary, made him archdeacon of Bath, and gave him some other benefices. After having spent a few years at court, he conceived a disgust at that mode of life, and retired into the family of Richard, archbishop of Canterbury, who made him his chancellor, about A.D. 1176. After the death of this prelate, A. D. 1183, he acted as secretary and chancellor to archbishop Baldwin, his successor; and was deputed by him on an embassy to Rome, A. D. 1187, in order to plead his cause before pope Urban III. in the famous controversy between him and the monks of Canterbury, about the church of Hackington. When Baldwin departed into the Holy Land, A. D. 1190, he was involved in various troubles in his old age, the causes of which are not distinctly known, and died about the end of the 12th century. From his works, which may be justly reckoned among the most valuable monuments of the age in which he flourished, and some of which may even now be read with profit, he appears to have been a man of approved integrity and piety, as well as of a lively inventive genius, and uncommon erudition. He is said to have dictated letters in Latin to three different scribes, on different subjects, and to have written a letter in the same language himself, at the same time. His printed works consist of 183 letters, which he collected together at the desire of Henry II.; of 65 sermons, delivered on various occasions; and of 17 tracts on different subjects; "Opera P. Blefien. Paris, edit. A. D. 1667," fol.; and afterwards printed in the Bibliotheca Patrum, tom. 24. Cave Hill. Lit. vol. ii. p. 333. Henry's "Hill," vol. vi. p. 147, &c.

BLOKZYL, in Geography, a town and fort of Overfyl, situated at the mouth of the Steenwyck, or Old Aa, where it enters the Zuyder Meer, a harbour capable of containing 200 vessels; defended by six bastions, and erected by the Dutch, at the commencement of their republic, to defend them from the invasions of the Spaniards. N. lat. 52° 45'. E. long. 5° 45'.

BLOMARY, or BLOMARY, the first forge in an iron-works, through which the metal passes after it is melted out of the ore. (See iron.) They are also called blomary-hearths.

BLOMBERG, in Geography, a town of Germany, in the circle of Welsephalia, and county of Lippe, which possessed its first privileges, in the beginning of the 14th century, from count Simon I.; 8 miles S.E. of Lemgo.

BLOMESHOLM, a manor of Sweden, in the district of Bohus, about 3 Swedish miles from Stramfald, in which is a very ancient monument, confituting of large stones, set up perpendicularly, and arranged in the form of a ship.

BLONAI, a barony and castle of Swifferand, near Vevay, and about 1½ mile from the lake of Geneva.

BLOND, LE, CHRISTOPHER, in Biography, a painter, was born in 1670, but little noticed in the more early part of his life. He became known at Rome in 1716, and established his reputation in Italy, as a good painter of portrait in miniature. At Amsterdam he distinguished himself by painting small portraits, for bracelets, rings, and snuff-boxes, first in water colours, and a very lively and natural colouring, and afterwards in oil. From the Low countries he came over to England, and projected a new manufacture for improving colours on paper with copper-plates, which promised to be advantageous, but in the end proved detrimental to himself and his associates, to which his own disinterested and manners very much contributed. His scheme was to copy the most capital pictures in England, of the greatest masters, to give his prints the appearance of paintings in oil. Many of his prints were very well executed, are full extant, and are held in estimation. It is said, however, that he was not the original inventor of this method of managing colours; but that he took it from Lalman, and others, who, with equal capacities and more different conduct, had undertaken it before him, but failed of success. Pilkington.

BLONDEL, DAVID, a French protestant minister, eminent for his acquaintance with ecclesiastical and civil history, was a native of Chalons in Champagne, admitted minister in 1614, and settled at Houay near Paris. His first work in favour of the Protestants was printed at Sedan in 1619, under the title of "Modell Declaration, &c," or, "A Modell Declaration of the sincerety and truth of the reformed churches in France;") and intended as a reply to the invectives of the party of the bishop of Luzon, afterwards cardinal Richelieu. This work established his reputation among the Protestants, and occasioned his being much employed in their synods. He was not distinguished as a preacher; and his style, as a writer, was perplexed, and encumbered with parentheses; but his judgment was penetrating, his memory tenacious, and his erudition extensive. As an honorary professor, with a pension, to which office he was appointed by the synod of Chartern in 1645, he had opportunity to devote his time to literature; but though he undertook to refute Baronius's annals, it does not appear that he did much besides writing a few notes in his own copy of the work. His works were "Explanations on the Eucharist," a treatise concerning "The Primacy of the Church:" "Pseudofilocteron et Tharrius Vapulans," against the Decretal epistles; a "Treatise on the Sibyls," disproving the truth of their oracles, and refuting the ancient practice of praying for the dead; and a treatise "De Epistola Prebytcrii." By his treatise against the story of pope Joan, which he rejected as fabulous, he offended some Protestants, who did not wish to be deprived of this topic of satire against the Romish church. Among Blondel's works on civil history, we may reckon his "Genealogy of the kings of France against Chifferet," written in Latin, and printed at Amsterdam in 1654, 2 vols. fol. which is said to have been undertaken at the desire of chancellor Seguier; and his piece "De formula regnante Christo." On the death of Gerard Vossius, he was chosen to succeed him as professor of history in the school of Amsterdam, and took possession of his office in 1656; but his affluvity in the prosecution of his studies, and change of air, occasioned the loss of his fight, after which, it is said, that he dictated his work intitled "Genealogy, &c." At Amsterdam his situation was rendered uneasy by a charge of Arminianism; and he died in 1657. Gen. Diet.

BLONDEL, FRANCIS, an eminent mathematician and military engineer, was born in 1617, at Ribemont in Picardy. In 1652, he was travelling governor to the young count of Brianne, and after a tour of three years he published an account of it in Latin. After his return he was advanced to considerable posts both in the army and navy, and he was employed in various negotiations with foreign princes. In 1659, being deputed by Louis XIV. as his envoy-extraordinary to Conflantinople, he visited Egypt; and at the termination of his embassy, he was appointed counsellor of state, tutor in mathematics and belles-lettres to the dauphin, and one of the mathematical professors at the royal college. In 1665, he began to display his talents for architecture, when the court employed him to construct a bridge over the Charente at the town of Saintes. In 1669, he became member of the Academy of Sciences; and in 1709 he was honoured
honoured with letters patent from the king for the superintendence of all the public works in Paris. To him were intrusted the repair and decorations of the gates of St. Anthony and St. Bernard; and the gate of St. Denis, one of the most finished pieces of French architecture, was designed and erected by himself. In the office of director and professor of the Academy of Architecture, established in 1671, he gave "A Course of Architecture," which was published in large folio, in 1698, and which was long considered as a standard book. In 1675, he presented to the king his treatise "On the art of throwing bombs," printed in 1685, 4to. and "On a new method of fortification," which procured for him the rank of marshal de camp. His other works were "Notes on the architecture of Savot;" the "Resolution of four principal problems of architecture," Paris, 1676, fol.; "A Course of mathematics," Paris, 1683, 4to.; the "History of the Roman calendar," Paris, 1682, 4to.; and a "Comparison between Pindar and Horace." He also communicated several ingenious pieces to the Royal Academy of Sciences, which are inserted in their Memoirs, particularly for the year 1666. He died at Paris, Feb. 2, 1686. Gen. Dict.

BLONDEL, Francis, was admitted doctor in medicine at Paris, the place of his birth, in 1532. As he had acquired considerable reputation as a scholar, he was engaged, on the death of Chartier, to assist in completing his magnificent edition of the works of Hippocrates and Galen, three volumes of which were left unfinished. He was an avowed opponent to the admission of antimony, and of all chemical preparations, into the practice of medicine, coinciding in that respect with his contemporary and coadjuver, Guy Patin. In 1648, he was made dean of the faculty of medicine, which office he held the following year. In 1660, he published "Statuta facultatis medicinae," Paris, 12mo.; and in 1665, an epistle to Alliot, "De cura carcinomatis, abaque ferro et igne," 4to. Alliot used for the purpose a medicine prepared from the arsenicum rubrum, dissolved in aqua fortis, and precipitated with the acetum saturni. The precipitate was then washed, by repeated affusions of warm water, and its causticity further mitigated by burning spirits of wine, in which it was immerced, until the powder became perfectly insipid. Blondel died Sept. 5th, 1682. Haller. Bib. Chir. et Med. Eloy. Dict. Hist.

BLONDEL, Francis, born at Liege in 1613, studied medicine at Cologne, and was for some time physician to the elector of Treves. On the death of that prince, in 1572, he went to Aix, and was appointed physician and superintendent of the baths in that city. In 1662, he published "Lettre de Francis Blondel a Jaques Didier, touchant les eaux minérales chaudes d'Aix, et de Bordelet, et les cures qui se font faites par fum' haine," Brux. 12mo. and in 1671, "Ther- marum, aquifgranenfium, et porceanarum decripta," which was reprinted in 1688, 4to. with engravings, and considerable additions. He died in 1703, much regretted by the inhabitants of Aix, having, by his writings, so recommended the waters, as considerably to increase the resort of patients there. Eloy. Dict. Hist.

BLONDIL, James Augustus, a French family, hitherto in England, and admitted licentiate of the college of physicians in London about the year 1720; published, in 1727, "The strength of imagination in pregnant women examined, and the opinion that marks and deformities in children arise from thence, demonstrated to be a vulgar error," 12mo. Though Dr. B. had not put his name to this work, yet his neighbour and colleague, Dr. Turner, discovering that he was the writer, and considering it as an attack upon what he had said on the subject, in the 12th chapter of his treatise on the diseased of the skin, in which he gives numerous instances of marks and deformities in the bodies of children, impressed on them by the disturbed imaginations of the parents, thought himself called upon to explain and to defend what he had there advanced. He therefore, in an appendix to his treatise on the affections, published the following year, gave some additional observations on the subject, in further proof of the influence of the affections of the mother over the fetus in utero. To this Dr. Blondel replied, in 1729, and with much humour, as well as argument, flewed the absurdity and fallacy of the opinion maintained by his antagonist; who, if he insisted on his point, must admit that animals, and even plants, are under the influence of the same affections; their figures being frequently produced equally defective and monstrous as those of the human species. The answer is entitled, "The power of the mother's imagination over the fetus examined, in answer to Dr. Daniel Turner's book, entitled, "A Defence of the 12th chapter of his treatise, de morbis cutaneis." This drew a more serious reply from Dr. Turner, addressed immediately to his opponent, under the title of "The force of the mother's imagination upon the fetus in utero still further considered, in the way of a reply to Dr. Blondel's last book, by Digo," 1730, 8vo. But though the doctor supports himself with the authority of Schenckius, Hardimus, Horfius, and many other collectors of wonderful and extraordinary stories, the good sense of his antagonist prevailed, and he has the merit of having contributed very largely towards removing the prejudices on this subject, which had prevailed for ages, and, with them, the solicitude and anxiety which never failed to torment the minds of such women as had the misfortune, while pregnant, to see or hear any thing, strongly affecting their imaginations, left their offspring should be born with some defect or deformity. It is now pretty generally known, that no such consequences follow, and that the few cases in which children are produced defective, with redundant parts, or in any way deformed, happen indifferently, where the mother has or has not, in the course of her pregnancy, received some shock or alarm. The power of the imagination in marking, distorting, or deforming the fetus in utero is van- ished, with the witches, ghosts, and hobgoblins, formerly equally objects of diffidence and terror. Haller. Bib. Chir. et Med. Pract. Eloy. Dict. Hist.

There is another writer of the name mentioned by bibliographers.

BLONDIL, Jaques, surgeon of Liége in Flanders. He translated the Chirurgia militaris of Nicolas Godin, under the title of "La Chirurgie militaire, tres utile a tous ceux qui veulent fuivre un camp, en tems de guerre, parcelliment a tous autres en condition pellique ou dyfenterique, ecrite en latin, par Nic. Godin," Anvers, 1558, 8vo.

BLONDIL, John Francis, was born at Rouen in 1705; and was known, not only as architect to the king, member of the Academy of Architecture, and royal profavor of the art at the Louvre, but by several useful publications, and the "Discours sur l'architecture," 12mo.; "A Treatise on the decoration of buildings," 1738, 2 vols. 4to.; "A Course of Architecture," 6 vols. 8vo. 1771-1773. The two last were published in 1777, 3 years after his death. M. de Balliste also published, in 1774, a poetical work of Blondil, entitled, "L'homme du monde éclairé, par les Arts," 8vo. 2 vols. Blondil was the author of the articles relating to architecture in the Encyclopedie. He died Jan. 9, 1774. Encyc.

BLONDIN Peter, a native of Picardy, born Dec. 18th 1682, was a disciple of Tournafort, by whose advice he travelled over Picardy, Normandy, and the ile of France, to improve himself in botany. In the course of his excursion, he difco-
discovered upwards of an hundred and twenty plants, which had not been before described, and several others, which had been supposed peculiar to America. In 1708, he was admitted doctor in medicine at Rheims; and, in 1712, he was received into the French academy, in quality of eleve of M. Renanune, an honour he did not long enjoy, being cut off in the following year, by an inflammation of the lungs. M. Fontenelle, who spoke his funeral oration, attributed to him a small work, published in his life-time, in which he had made some corrections in Tournefort's arrangement of certain species of plants; he also says, he left some curious memoirs on the subject of botany, intended for publication, and which were prevented being printed by his premature death. But his name does not appear in Haller's Bib. Botan. nor in the catalogue of botanical works contained in the splendid library of Sir Joseph Banks, lately published by Dr. Dryander. Eloy Dict. Hist.

BLONDVAURY, in Geography, a town of France, in the department of the Charente, 5 leagues east of Confolens.

BLOUNDUS, or BRONDI, MICHAEL ANGELO, in Biography, was born at Venice, May 4th 1497. After studying under Anguifina Niphus, a celebrated teacher of that time, he settled at Naples. He was a voluminous writer. The titles of the most distinguished of his works follow. "Epitome ex libris Hippocrates de nova et prifca arte medicce de diebus decemtoris," Rome, 1528, 1535, 8vo.; "Libellus de morbis puerorum," Venetius, 1539, 8vo.; "De partibusictu fectis etutine fananys, et medicamento aqve, nuper invento. In plurimum opinionem de origine morbi Gallici, deque ligni Indici ancipiti proprietate," Venetius, 1542, 8vo. For wounds made with a cutting instrument, and recently inflected, he recommends the application of simple water, as a most valuable and useful remedy. He does not admit that the venereal disease was a new complaint, originating in the West Indies, but believes it to have been known to Hippocrates, and other ancient physicians, and described in their writings. He had used the lignum sanctum in his attempts to cure the disease, but ineffectually; the disease returning, he says, after discontinuing the medicine, with increased violence. He placed his principal dependence on mercury, but does not give the rationale, or method of using it. This work is inserted by Conrad Gesner in his "Collectio scriptorum optimorum de chirurgia," 1555, fol. For the titles of the remainder of his works, see Eloy's Dict. Hist. Med. Alfruc. de Morb. Vener. Haller. Bib. Med. Pr. et Botan.

BLONSK, in Geography, a district of Poland, belonging to the territory of Warsaw, in the palatinate of Czersk, or Masovia.

BLOOD, is the nutritive fluid of animals. In the human subject it circulates through the arteries and veins (see Circulation), being of a scarlet colour in the former, and of a purple colour in the latter; it is of confiderable confluence; of a slightly saline taste, and peculiar smell; its specific gravity is estimated at 1.0257. When blood is drawn into a bason, it first coagula into a tremulous, jelly-like mass; and then spontaneously separates into a solid, heavier substance termed the claffamentum, or clot, or the clot of the blood, and a supernatant pale liquor called the serum. If the claffamentum of the blood be washed with water, all the red colour may be washed out of it, and a firm whitish substance will remain. This substance, which did exist in a state of subsile fluidity, so as to be capable of permeating the minute vessels of the body, and which thus spontaneously concretes, has been, therefore, called the coagulating lymph of the blood. If the blood be filtered with a wip, this substance concretes in a fibrous form round about it, and it was in consequence formerly termed the fibrous part of the blood. By this latter denomination, it is also now generally known and described. Thus it appears, that there are three parts readily distinguishable in the blood; the serum; the fibrous part or basis of the claffamentum; and the colouring matter; to the more particular consideration of these we now proceed.

Of the Serum.

The Serum of the blood is of a light greenish yellow colour, and its mean specific gravity is estimated at 1.0287. It is used in about 162° Fahrenheit's thermometer, the juice when becomes converted into a tremulous fluid fibula, which being cut in pieces and compressed, can be squeezed out of it a muddy and somewhat glutinous fluid, which is termed the ferosity of the blood. If the remainder be boiled, part of it will be found to be insoluble; and this has all the properties of albumen, or that infusible matter which is contained in the white of the egg; for an account of which, see the article Albumen. That part of the serum which is dissolved in boiling water, becomes a jelly, if the water be evaporated to a certain degree, and it is suffered to become cold. It is again soluble, if more water be added. This modification of animal matter is now termed gelatine, and to that article the reader is referred for a more full account of its properties. The ferosity of the blood appears to contain animal mucilage, but no accurate chemical examination has as yet been made of it. The serum of the blood turns the syrup of violets green; which effect is owing to foda, that is contained in it. If coagulated serum be heated in a silver vessel, the silver becomes blackened by being converted into a sulphate; in consequence of the serum containing sulphur. If the parts of the serum be dissolved in boiling water, and afterwards crystallized, they are found to be carbonat of soda, muriat of soda, phosphat of soda, and phosphat of lime.

Of the fibrous Matter of the Blood.

This matter spontaneously concretes in open and in close vessels, in the temperature of the animal, or in a much lower degree of temperature, though with some little variation as to the time in which the coagulation happens. Dilution of albumen by water prevents its coagulation, even by those chemical agents which suddenly and firmly coagulate it in its natural state, such as heat, spirit, and acids. No dilution of the blood by water has hitherto prevented even the spontaneous coagulation of its fibrous part. The basis of the claffamentum, or fibrous part of the blood, is found to be a whitish solid elastic substance, of greater specific gravity than the serum. This substance, which is insoluble in water or alcohol, and which resembles the muscular fibres in its chemical properties, has been denominated by the French chemists fibrine or fibrina, to which article the reader is referred for a more particular account of it. It is right however here to remark, that chemical analysis ultimately converts all animal substances into azot, hydrogén, and carbon; and that the proportion of the former is greater in the fibrous part of the blood than in albumen, or perhaps in any other animal compound.

Of the colouring Matter of the Blood.

The colouring matter of the blood has an attraction to water and diffuses in it, forming a transparent red liquor. This attraction is perceived in macerating flesh in water; for the colouring part, which is specifically heavier than any other part of the blood, and readily sinks in the serum, yet rises up and becomes dissolved in the water. The watery solution of this part of the blood turns the syrup of violets green, and contains both foda and albumen. If the red part
part of the blood be incinerated by fire, it is found to contain much iron, which Fourcroy and Vauquelin discovered was combined with phosphoric acid in the state of subphosphate of iron; and this is the only part of the blood which is found in analysis to contain any of that metal. Fourcroy examined the blood of the fetus, and found that the colouring matter was darker and more abundant than in the adult subject. He also found that the blood of the fetus contained no fibrine, but much more gelatine than in the adult.

The colouring matter of the blood is found, by examination with the microscope, to be composed of very minute globular particles. They were particularly attended to by Leeuwenhoek, and afterwards examined and described by others, chiefly by Senac, Heath, and Fontana. They are so small as scarcely to admit of an accurate examination in this climate by the common microscope. This affinity will probably be readily admitted, if it be granted that they do not exceed a 200,000th part of an inch in diameter; yet such dimensions may be stated as the average estimate of their size, drawn from the accounts of various observers. Haller says, that he found them as large as peas by the polar microscope, and it was by the aid of that instrument that we are enabled to give the following account of them. A drop of blood, much diluted with water, was put upon a micrometer or piece of glass, ruled by a diamond in figures of 

A

\[
\text{th of an inch, and put before the lens of the polar microscope. The figures were magnified upon the screen to eight inches diameter. The globules of the blood were seen un}
\]

dulating to and fro in vast numbers; they all appeared exactly of the same size; and a few which were separated from the rest were attentively examined. These had all the appearance of globules; they were circular in their disk, and were regularly illuminated on one side, and shaded on the other, with the prismatic colours arranged in the middle or greatest convexity; the violet being next to the light, and the red next to the shade. On varying the focal distance of the lens, indeed, an alteration of appearance took place, some figures appearing in the middle just in the manner represented by Fontana. Upon again varying the position of the lens, the globules appeared as at first. This shadowy appearance in the middle probably led Mr. Heath to suppose that they contained a central solid particle. It is, however, generally admitted, that the colouring particles of the blood are spherical; and if their size be calculated from the preceding account, they will be found to be less in diameter than the 200,000th part of an inch.

If, for instance, the figure of \( \frac{1}{8} \) th of an inch be magnified to a figure of eight inches, and the globules appear \( \frac{1}{4} \) th of an inch in diameter, then 64 may be placed in a line on one side of the figure, and 64 x 64 = 4096, is the number which will stand within that figure. Now, this figure is but \( \frac{1}{4} \) th of an inch, magnified on the screen to a figure of 8 inches; then, multiply 4096 by 50, and it gives 204,800, as the number of thees globules which would stand in the figure of one inch.

The preceding account of the blood, imperfect as it is, yet affords us much satisfactory information. We perceive that there are contained in the blood, in a state of subtile fluidity, the materials of which the body is constituted, and which are capable of becoming solid fibres of various degrees of solubility. We find in it also that aqueous liquor which fills all the interstices of the solid parts. It is true, that we find in the animal body many substances which do not exit formally in the blood, and which are new compounds of matter made out of that fluid; and for an account of which the reader is referred to glandular secretion.

With respect to that change which the animal matter undergoes from a fluid to a solid state, and which is called coagulation, little is satisfactorily known. It seems to have been a problem amongst chemists. Scheele attributed it to the agency of caloric; Fourcroy, to that of oxygen; and Dr. Thomson has of late accounted for it, without supposing the addition of any other sublimate to the coagulated matter.

With reference to the latter opinion, it should be observed, that in coagulation, a change in the chemical properties of the coagulated sublimate takes place, which implies, that a chemical alteration has also taken place; and that even if the theory were true with respect to albumen, it will not account for the coagulation of the fibrine of the blood. Where chemistry fails to explain phenomena incident to living bodies, it is fair to inquire if life may not have some share in their production.

Mr. Hunter thought that the coagulation of the blood depended on its living powers, and supported his opinion by many ingenious arguments. To remove any objection which might be made to a fluid or unorganized sublimate being alive, he adverts to what happens with respect to the yolk and white of the egg, which, in consequence apparently of its possessing a principle of life, are preferred from putrefaction during incubation, and which refulg the effects of heat and cold in a degree and manner similar to the lower kinds of animals. His chief arguments in evidence of the coagulation of the blood depending upon life are, that in some cases where death has been caused by lightning, or by violent fatigue in running, as in animals who are hunted to death, or by blows on the stomach, the irritability of the muscles has been destroyed, and the blood has remained fluid, and never coagulated. Mr. Hunter also mentions, that he mixed infusions of bitter vegetables, which are generally considered as tonics, with blood, and these did not retard its coagulation, but that a solution of opium had that effect.

As a prosecution of this hint, the writer of the present article caused blood to be much diluted with water, and infusions of noxious vegetables to be fired into it; yet in these experiments the fibrine still coagulated, and that in a sudden manner.

The vegetable infusions were those of opium, tobacco, and the atropa belladonna. It may be proper to relate the particulars of these experiments, in order to give a general idea of the whole. Eight ounces of blood were drawn from the arm into ten pints of water of 95° of Fahrenheit's thermometer, containing a strong infusion of the atropa belladonna. It was fired with a glafs rod; the two fluids appeared transparent and homogeneous. In eight minutes, the temperature being 94°, a considerable quantity of flocculent coagulum at once Suddenly formed, and no additional coagulation afterwards took place. The thermometer was attentively observed, but no change was remarked in it during this coagulation. The gentleman who performed these experiments, willing to repeat them with some variety in the mode of conducting them, observed, however, that heat was given out during the coagulation of the blood, as will be seen in the following experiment.

Ten ounces of blood were drawn into a wooden bowl, in which a thermometer was held. The temperature of the blood, while flowing from the vein, was 93°. In five minutes the thermometer had sunk to 89°, and coagulation commenced on the surface; on elevating the bulb of the thermometer to the coagulum on the surface, the quicksilver rose to 90 and 1/2; on depreling it to the bottom of the bowl, it sunk to 89. This was repeated twice with nearly the same result, and on the third trial the quicksilver rose to 91°; and on depreling it again, it was perceived that the blood was coagulated.
coagulated throughout. After this, the quicksilver regularly continued to ascend, and was no longer influenced by changing the situation of the bulb of the thermometer.

With respect to the use of the red particles, Boerhave supposed, that they might tend to keep the diffusible parts of the blood incorporated, as shot agitated in a mixture of sand and water would prevent the fulness of the former from the latter. It seems, however, no improbable opinion, that this is the matter which has the very peculiar properties of forcibly attracting oxygen gas, even through the medium of the blood vessels, and combining with it, and being in consequence of a scarlet colour, yet of holding it so lothly as to part with it in the round of the circulation to carbon and probably to hydrogen, and thus contributing to the production of animal heat. The writer of the present article is of this opinion, because he has exposed the red parts of the blood to air containing oxygen gas, and always found the oxygen gas diminished in proportion to the quantity of blood which had acquired a scarlet colour by exposure to it. On the contrary, he has exposed the serum of the blood to similar kinds of air, and never perceived a diminution of oxygen gas by that fluid. Thus probably we discover the principles of nutrition of the body and the cause of its heat. For a further account of the effects of respiration on the blood and its consequences, see Lungs, function of.

Haller's elements of physiology may be consulted for an account of all that had been done respecting the investigation of the nature of the blood till his time; the works of Mr. Hewfon and Mr. Hunter may be referred to for additional information on this subject; the works of Tournefort, for microscopical observations; and for novel chemical experiments, the writings of Tournefort, Vanquiain, &c. In the Annales de Chimie, and those of Deyen and Parmentier in the Journal de Physique, and Dr. Thomson's excellent summary contained in his System of Chemistry.

Blood, transfusion of. See Transfusion.

Blood, injecting liquors into it. See Injection.

Blood, bleeding of. See Hemoptysis.

Blood, cooling of. Lord Bacon has suggested that the prosecution of experiments on this subject might possibly lead to the means of prolonging life. But this great philosopher appears to have entertained erroneous notions respecting the animal economy, on this and some other points. Nothing accurate was known, in those days, on the subject of animal heat. If the blood were cooled below a certain standard, disease and death, and not longevity, would be the consequence. However, when the quantity of animal heat exceeds what is natural, the excess is carried off by an increased evaporation from the surface of the body, in other words, by perspiration. And in this way, or by the direct application of water of a low temperature to the skin, the blood, as well as every other part of the body, may be said to be cooled, and disease prevented or removed. But this is not what lord Bacon meant in his proposal for cooling the blood.

Blood, Deperation of. See Secretion.

Blood, Flux of, is called an Hemorrhage. The periodical ones of women, Menses. Tho' after child-birth, Lochia. That ordinarily happening on the first coition is by some called and considered as the tclk of virginity.

Blood, cannibalizing of. See Stypic.

Blood, vomiting of. See Hæmatemesis.

Blood, morbid alterations of. The alterations which the blood undergoes in various diseases, are such as claim the attentive observation of physicians. But, in order to form a just conception of them, it is necessary previously to consider what are the component parts of this vital fluid, and their relative proportions, in the natural and healthy state.

By the accurate analyses of modern chemists it has been proved, that, besides water, and various saline matters (such as soda, phosphates of lime, of soda, and of ammonia, and muriates of soda and ammonia), the blood contains of what is termed fibrin, albumen (coagulable lymph), and a colouring principle, viz. oxyd of iron combined with phosphoric acid. These several materials constitute the fluid blood, which, in its natural state, is kept in constant motion, under a temperature of 98° or 100° (in some animals the temperature is rather higher) of Fahrenheit's thermometer. A large proportion of fibrin, some albumen, and the colouring matter, constitute the eror, or crassamen; while the serum is composed of water, with a large proportion of albumen, and the saline substances above mentioned.

Now, it is probable, that considerable alterations take place in the relative proportions of these ingredients, whenever the living body, whether of man or brute, becomes long or violently disturbed in its action, and especially (as Mr. Hewfon has shown) whenever the energy of the vascular action is much increased. But, in accounting for any remarkable alterations in the blood, there are several other circumstances, besides that of vascular action, which require to be noticed; and particularly the circumstances connected with respiration, such as the temperature, and purity or impurity of the surrounding air, its greater or less degree of humidity, &c. These, by their chemical agency, must have a considerable influence in the production of the various morbid alterations which take place.

Many variations, however, in regard to the relative proportion of the constituent parts of the blood, and other chemical changes in its qualities, which in all probability frequently take place, are not obvious to the senses, in some diseases, whilst in others they are very conspicuous: for instance, in pleurisy, peripneumony, acute rheumatism, &c. In these disorders, the blood drawn from the veins, and suffered to stand in the cup until it is cold, becomes covered with a tough, bilious, or fihce, and is usually called inflamed, or inflammatory blood. This fihce is formed (says Mr. Hewfon) by the coagulable lymph (which consists of albumen and a portion of fibrin) being fixed or coagulated, after the red particles have subfused. The blood in these cases does not appear to be thicker, but on the contrary thinner than natural. It is flower in coagulating than healthy blood. The coagulation is owing to the action of the a and acid. Perhaps in pleurisy, acute rheumatism, and other disorders belonging to the phlegmatic of nofological writers, some chemical change is produced in the fibrous matter of the blood (see Fourcroy, Connuifances Chimiques, article Sang), whereby it is preternaturally softened or liquefied; or there may be an over-proportion of albumen, and that of an altered quality. Whatever be the real chemical differences, we cannot think with Mr. Hewfon, that it is wholly occasioned by the increased force or energy of vascular action, since it sometimes occurs in cases where the action of the heart and arteries is not more vigorous than natural, and even where their action appears to be below the natural standard. Thus a fihce has been sometimes observed upon the blood drawn from patients affected with typhus (Parrmentier and Deyen in Fourcroy, as above referred to), and even on the blood taken from scurvy patients. (Ibid.) And Mr. Hewfon himself remarks, that it is a common occurrence in pregnant women. Increased energy of vascular action is doubtless a principal cause of the changes observed.
Blood, mechanical and commercial uses of the, are chiefly in agriculture, where it is found an excellent manure for fruit-trees; among lapidaries; in the manufacture of sugar, &c.; in building, boards are sometimes rubbed with blood to turn them brown. Some also pretend it has recently been used in the mortar of old walls. Blood is the basis of that noble colour called by painters Prussian Blue. See Prussian Acid.

Blood, eating of. This practice appears to have been prohibited to Noah (Gen. ix. 3.), and observed by the Jews, principally with a view to the use of sacrifices in divine worship, and as a token of respect to the altar, at which the blood of every victim was presented before God. The prohibition was repeated by the apostles at the council of Jerusalem (Acts, xx. 28, 29.), confirmed and defended by all the fathers except St. Augudin, and the universal practice both of the eastern and western churches till his time; and in many churches, even of the West, much longer, as long as the middle of the 12th, some say the 11th and even the 12th century. The practice of the primitive Christians seems to intimate that they understood the apothecary prohibition to be absolute and perpetual, as they abstained from the use of blood for many centuries. When they were charged with meeting in the night, and drinking blood, by way of binding one another to secrecy, in some immoral practices, Tertullian replies to this charge, that it was well known that no Christian would eat blood at all; infomuch, that it was usual with heathens, when they wanted to know whether any person was a Christian, to set blood-puddings before him as a very sufficient test. Moreover, blood is not eaten by Christians in any part of the East, or by the Greeks, or Russians, who are of the Greek church, to this day; and it has been alleged, that the use of blood was not introduced into this western part of the world till a very late period. When the Pomeronians were converted to Christianity, in 1120, they were particularly enjoined to abstain from blood, as a badge of their profession. It was not allowed to be eaten in the West in the time of Bede, or a century afterwards; and blood was not eaten in any part of Switzerland, till Calvin introduced the practice from some other place. Dr. Lardner, however, says (ubi infra), that little regard was paid to these regulations of the apothecary decree by the Latin Christians, from the end of the fourth century.

The question is, whether the apothecary precept to abstain from blood, should be considered as only temporary and occasional, a fort of accommodation to the weakneces of the Jewish converts; or perpetual, founded on moral principles, and consequently ill obligotry. The former opinion seems the more probable, and is the most generally received. For the prohibition in the law of Moses, two reasons have been assigned; one, is, that the blood was appointed to make atonement on the altar for offence against the law. The prohibition, according to this reason of it, must be restricted to Jews and others circumcised after the manner of Moses; for no other persons could offer sacrifices, or be cut off for transgressing the Levitical laws, but such as were of that people. The other reason is thus expressed: "It is the life of all flesh; the blood of it is for the life thereof" (Lev. xix. 14.); that is, as some have interpreted the passage, it is the nourishment of the animal, and not fit for your nourishment; and because it was not fit for food, and was useless and offensive, therefore it was to be poured out upon the earth, or covered with dust, that it was buried in the earth; and this order is frequently repeated. Lev. xvii. 15. Deut. xii. 24, xv. 23. Hence we may account for the command...
BLO

duct of David, when his three warriors brought him water from the well of Bethlehem, at the extreme hazard of their lives (1 Chron. xi. 13); considering the water as if it were their blood, which they hazarded to obtain it, he refused to drink it; and there being no rule or reason for offering such water upon the altar, he did what seemed to be next to offering it; "he poured it out before the Lord." The Jewish ordinance answered two obvious ends; it served, with other regulations and restrictions, to keep the Jewish people separate from other nations; and it also promoted their bodily health and vigour. But there is no foundation, either in the reason of the thing, or in the prohibition, to support the opinion of those who imagine the eating of blood to be an immoral thing; if this had been the case, God would not have permitted the Israelites (Deut. xiv. 21.) to fell a creature that died in his blood to an alien or stranger, that he might eat it. If, therefore, the eating of blood cannot be reckoned an immorality, the prohibition in the apostolical decree cannot be binding upon all men in all times, but only at some seasons, when the circumstances of things render forbearance or abstinence expedient. Accordingly, if blood be thought disagreeable and unwholesome, as food, the use of it may be avoided, for the sake of health; but we are not obliged to abstain from it upon a religious account, or in virtue of this decree, which would be no better than superstitution. It has been supposed, by some approved writers, and especially by Dr. Lardner, that this was only a temporary provision, designed to prevent giving offence to the believing Jews, and to facilitate civil concord and religious communion between believing Jews and Gentiles. Dr. Lardner also supposes, that the decree is not to be understood as a precept or commandment, but as delivering advice and counsel concerning some matters of prudence and expediency, considering the circumstances of things and persons in that time. It has been farther urged as an argument against the perpetuity of the apostolical decree, that the apostle Paul never quotes, or alludes to it in his writings.

On the other hand, it has been argued, that the prohibition to eat blood, given to Noah, seems to be obligatory on all his posterity; and as it accompanied the first grant of animal food, it seems to be referred, by way of acknowledgment to God, as the giver of life, and of the food which supports it. This respect paid to blood, which is shed when animals are killed for food, and which is the most apparent vehicle of life, may also be intended to inculcate a respect for life, as the most valuable gift of God, and to warn us not to deprive any animal of it, and much less man, without necessity. It has also been pleaded, as an additional argument for abstinence from blood, that it is not a wholesome aliment, especially in hot countries, promoting leprous and scrofulous disorders. The advocates of this opinion further argue, that blood is prohibited because it tends to make men savage; that the prohibition is joined with that of fermentation, which is an immorality in the common sense of the term, but which Dr. Lardner understands as denoting marriage with heathens, from which the apostle Paul so earnestly diffuses the Christians at Corinth; and that God has enjoined abstinence from blood on all Christians, in order to manifest his supreme dominion over all their enjoyments. Selden, de Jure Gentium, &c. l. vii. c. 17. Shackford's Conn. vol. i. p. 97, &c. Lardner's Remarks on Dr. Ward's Differtations in Works, vol. xi. p. 329, &c. Priestley's Institutes, vol. ii. p. 1259, &c.

Blood, religious use of.—Among the ancients, blood was used for the sealing and ratifying of covenants and alliances, which was done by the contracting parties drinking a little of each other's blood; for appeasing the mases of the dead, in order to which blood was offered on their tombs, as part of the funeral ceremony. Thus we read, that twelve youth were sacrificed at the funeral of Patroclus; and eight at that of Pelias. Homer. I. 0. ver. 27. Virgil. Æn. li. x. ver. 518.

The blood of victims was the portion of the gods, both among Jews and Heathens; and accordingly was poured or sprinkled on the altars, in oblation to them.

Some have asserted, that the Romans offered human blood to appease their deities, which is denied by others.

The priests made another use of blood, viz. for divination: the streaming of blood from the earth, fire, and the like, was held a prodigy, or omen of evil.

The Roman priests were not unaccompanied with the use of blood in miracles; they had their fluxes of blood from images, ready to serve a turn; witnesses that had to have streamed from the statue of Minerva at Modena, before the battle at that place. But in this their successeers have gone beyond them. How many relations in ecclesiastical writers of Madonos, crucifixes, and wafers bleeding! At least the liquefaction of the blood of St. Januarius, at Naples, repeated annually for so many ages, seems to transcend by far all the frants of the Grecian or Roman priesthood. But the chemists are got into the secret, and we find M. Neumann at Berlin performed the miracle of the liquefaction of dried blood, with all the circumstances of the Napolitan experiment. See JANUARIUS.

Blood, in the Roman Church, is used in speaking of the wine in the eucharist; which they suppose miraculously converted, by the priest's consecration, into the real blood of Christ. See TRANSUBSTANTIATION, &c.

Blood is also used abusively for the sap of plants; as having much the same office in the vegetable, as the other in the animal economy. In a sense not unlike this, wine is sometimes also denominated the blood of the grapes.

Blood is also applied, in Pharmacy, to certain vegetable juices, tears, &c. as dragon's blood gum. Dragon's blood, Sanguis Draconis, is also used by the Arabs for the juice of the anchusa.

Blood, sactyron, a ruddy liquor produced from the roots of Sactyron, baked with bread; and liquefied, as it were, into blood, by a long digestion.

Blood, in Chemistry and Alchemy, is a denomination given to several artificial compositions, chiefly on account of their red colour.

Blood is more peculiarly used by the alchemists for the tincture of a thing. In which sense we meet with blood of mercury, denoting the tincture of it; dragon's blood, denoting the tincture of antimony.

Blood, Dragon's. See Sanguis Draconis.

Blood is also used, in Middle Age Writers, for supreme jurisdiction, exercised by the lord of the fee, in cases where blood is spilt. This is also called "judgment of blood," "judice of blood," sometimes "cognizance of blood."

Blood, assayer of, among the Jews, was the next of kin to the person murdered, who was to prosecute the murderer. Ecclesiastical judges retire when judgment is to be given in cases of blood, because the church is supposed to abhor blood: it condemns no person to death; and its members become irregular, or disabled from their functions, by the effusion of blood.

Blood of Christ, is the denomination of a military order instituted at Mantua, in 1608, by Vinc. Gonzangua IV. Its device was "Domine profulisti me," or, "Nihil hoc triste recepto." Hermant speaks of this order, and observes that it took its name from some drops of the blood of Christ.
BLO

Blood, in Farrery, denotes a distemper in cattle's backs, which makes them in going draw their heads aside, or after them; the cure is by cutting the length of two joints under the tail, and thus letting the beast bleed plentifully. If he bleed too much, the farriers knit his tail next the body, and then bind felt and nettles bruised on the part.

Blood-running itch, is a species of itch in a horse, proceeding from an inflammation of the blood by over-heating, hard riding, or other forced labour; which getting between the skin and flesh, makes the beast rub and bite himself; and, if left alone, sometimes turns to a grievous mange, highly infectious to all nigh him.

Blood, field of, in Syria, Acedana, was a field purchased by the Jews, with the thirty pieces of silver which had been given to Judas for betraying his master, and which he had restored. It still serves for a burial-ground, in which all pilgrims, who die in their pilgrimage at Jerusalem, are interred. See Acedana.

Blood-flower, in Botany. See Hamanthus.

Blood-begot, See Hound.

Blood-letting, See Bleeding.

Blood, precious, in Ecclesiastical History, a denomination given to a reformed congregation of Bernardine nuns at Paris, first established under that name in 1661.

Blood, Prince of the, in France, are those descended from the blood royal.

Blood-fixed, in Surgery, a dillerem of the eye, where-in the blood-veins are greatly distended, so as to make the eyes appear red. See Ophthalmia.

Blood-flone. See Haematites.

Blood of sulphur, fanguis sulphuris, is a preparation of liver of sulphur, ground with the oil of tartar per deliquium, then digested with dulcified spirit of nitre. It is reputed a good pectoral and diuretic, but rarely preferred.

Blood-veins, in Anatomy, usually include only the veins and arteries, though, in a larger sense, all the vessels in the body, as the nerves, lymphatics, &c. to the very hair, may be comprehended under the denomination. See Artery, and Vein.

Blood-fleck. See Blood-Snake.

Blood-wine, in Ancient Law Writers, signifies blood, and a customary amercement paid as a composition for the shedding or drawing of blood.

The word is also written bloodwit, bloodwita, bloodwyte, bloodwit, bloodwcit, and blodwit; and is formed from the ancient Saxon blod, blood, and wit, or wise, a fine or penalty.

The word also denotes an exemption from this penalty, granted by the king to certain persons and communities, as a special favour. Thus, king Henry II. granted to all tenants within the honour of Wallingford—"Ut quieti sint de hidagio et blodwita et bredwita,"

Bloodwood. See Hamatoxylon.

Bloodwort, or Bloody Dock, in Botany. See Rumex.

Blood, inheritable, denotes such a regular defect as gives a person legal right to inherit the estate of an ancestor. See Attainer, Escheat, Inheritance, &c.

Blood, Royal, is applied to the regular descendants of the royal family. See Royal Family.

Blood, whole and half; a kindman of the whole blood is he that is derived from the same pair of ancestors; whereas a person of half blood descends from either of them singly, by a second marriage. Blackl. Com. vol. ii. p. 227. See Descent.

BLOODY Crime, Sanguinum Crimen, in Rlriters of the Middle and Barbarous Age, that which is punished with the blood or life of the offender.

BLOODY Fine, in Medicine. See Dysemeny.

BLOODY Hand, in Law, one of the four kinds of trespases in the king's forcell, by which the offender being taken with his hands or other part bloody, is judged to have killed the deer, though he be not found either hunting or chasing. In Scotland, in such cases, they say, taken in the fact, or with the red hand. See Backward.

BLOODY Hand Cock. See Cock.

BLOODY Island, in Geography, an island in the harbour of Port Mahon, in the island of Minorca.

BLOODY Point, a cape on the south-west coast of the island of St. Christopher's. N. lat. 17° 24'. W. long. 60° 41'.

BLOODY Bay, a bay on the north side of the island of Egmont, or New Gonerby.

BLOODY-False Point, a remarkable head-land on the northern coast of the county of Donegall, Ireland, nearly opposite to Tory island. N. lat. 55° 9'. W. long. 8° 11'.

BLOODY Rains. See Rain.

BLOODY Urine, in Medicine. See Hamaturia, and Urine.

BLOOM, in the Iron Works, a term used by the miners for a four-square mass of hammered iron, about two feet long, and three quarters of a hundred weight, made from part of a few of cull iron. The bloom, however, is not yet become iron fit for the smith's tite, but must undergo many hammerings, and be first made what they call the anomy ; which fee.

Bloom, half, a round mass of metal, which comes out of the finery of an iron-work. See Bloom.

Bloom, in Sea Language, hot burning winds, blowing from the land to the sea. See Heisser.

BLOOMFIELD, in Geography, a township of America, in Ontario county, New York. By the late census of 1726, 151 of the inhabitants were electors.

BLOOMING VALE, a tract of land, in the township of Manlius, and slate of New York, or Butternut creek.

BLOSSOM, in a general sense, denotes the flower of any plant. See Flower. In a more proper sense, the word is restrained to the flowers of trees, which they put forth in the spring, as the forerunners of their fruit, otherwise called their bloom. The office of the blossom is partly to protect, and partly to draw nourishment to the embryofruit, or feed. Phil. Trans. Nof. 39. p. 329.

Blossom, in Botany, denotes one of the parts of a flower. See Corolla.

Blossom is also used, in the Manage, for the colour of a horse, which has lfs hair white, but intermixed all over with forcell and bay hairs, called also peach-coloured.

Horses of this colour generally are hard and inoffensive, both in the mouth and the flank; so that they are little valued; besides they are apt to turn blind.

Blossom, in respect of heep. See Blossom.
BLÖT, BLOTTING PAPER, a species of paper, made without size or thinning, serving to imbibe the wet ink in books of account, and prevent it setting off, or blotting the opposite page.

BLÜNT,THOMAS, in Biography, a learned English writer, was born at Bordesley, in Worcestershire, in 1619; and, without the advantage of an university education, made a considerable progress in literature. By profession he was a barrister of the Inner Temple. Upon the breaking out of the popish plot in the reign of Charles II., he was much alarmed on account of his being a zealous Roman Catholic, and feized with a palsy, which terminated in his death, in 1679. His works were numerous, and are as follow: viz. "The Academy of Eloquence;" "Glosiographica, or a dictionary interpreting such hard words, Hebrew, Greek, Latin, Italian, &c. introduced into the English tongue," 1656; 8vo; "The Lamps of the Law, and the Light of the Gospel, &c.;" "Baboon, or the History of his Majesty's Elaps after the battle of Wrothcester," 1660; 8vo; the second part was printed in 1651, 8vo; "The Catholic Almanac for 1661, 62, 63, &c.;" "Booker refuted," or "Anadverberions on Booker's Ephemera," 1667, 4to; "A Law Dictionary," 1671, fol.; "Anadverberions upon Sir Richard Baker's Chronicle, &c." 1672, 8vo; "A World of Errors discovered in the New World of Words, &c." 1673, fol.; "Fragmenta antiquitatis, ancient tenures of lands, &c." 1679. Biog. Dict.

BLÜNT, SIR HENRY, was born at the seat of his father Sir Thomas Pope Blount, at Tittenhanger, in Hertfordshire, in 1622; and having completed his education at Trinity college, Oxford, he commenced the study of the law at Gray's Inn. Being resolved to travel, he set out on his tour in 1634, and visited the Turkish dominions in Europe, and also several parts of Egypt. After a long stay at Grand Cairo, he returned to England, in 1636, and published an account of his travels under the title of "A Voyage into the Levant, &c." London, 1636, 4to, which had a rapid sale, though it was not held in high estimation by the most competent judges. Charles I. appointed him one of the band of pensioners; and, on his father's death, in 1638, he succeeded to the family seat at Blount's hall in Staffordshire, and a considerable estate. In the civil war he joined the royal party; but, abandoning the royal cause, he was well received in London by persons of power. In 1651, he became one of the committee for reforming the practice of the law; and he was very zealous against tythes, and for the reduction of the stipends of all parish ministers to an equal and moderate provision. His general knowledge recommended him to the office of one of the commissioners for advancing the trade and navigation of the commonwealth. His brother's death, in 1654, made way for his succession to the Hertfordshire estate. At the Restoration he was favourably received by the king; and in 1661 he served the office of high-sheriff for the county of Herts. From this time, till his death in 1682, he lived as a retired English gentleman; but he seems to have acquired from his travels an inclination to freedom of opinion, and to have adopted several singular and paradoxical notions. Six comedies, entitled "Court Comedies," and published under the name of John Lilly, have been ascribed to him. Biogr. Brit.

BLÜNT, SIR THOMAS POPS, eldest son of the preceding, was born at Upper Holloway, near London, in 1649, and educated under the immediate inspection of his father. Having established an early reputation for learning and worth, he was created a baronet by Charles II. in 1679. He reprefented first the borough of St. Alban's, and afterwards the county of Herts, and was always esteemed as a friend of liberty, and a true patron of literature. Of his edition he gave evidence in his learned work, entitled, "Centuria Selectorum," printed at London, in 1659, folio, and reprinted at Geneva in 1694, and 1710, 4to. This work is an accurate and useful compilation, containing an account of the characters and writings of both ancient and modern authors. His work "De Re Pooitica," published in 1604, 4to, is a similar compilation, comprehending an account of ancient and modern poets. His "Natural History," printed 1693, 12mo, is a kind of common-place book, containing observations, many of which are uncommon, selected from the bell modern writers. Of his talents as an original writer, we have a specimen in his "Elays on several subjects," 8vo, in which he discourses many curious points; such as the influence of the priesthood; the regard due to the ancients; the variety of opinions; the uncertainty of human knowledge; the effects of custom and education, &c. He died at Tittenhanger in 1697, and left a numerous family. Biogr. Brit.

BLÜNT, CHARLES, brother of the preceding, was born at Upper Holloway in 1654, and possessed distinuidulous talents, which were, affiduously cultivated by his father, who, directed the direction of his studies. As he was the favourite of his father, he encouraged his marrying and settling in an independent estate at the early age of eighteen years. If we except a little treatise, published without his name, and entitled "Mr. Dryden vindicated, &c," his literary career commenced in 1678, or 1679, with the publication of his "Animis Mundis, or an historical narration of the opinions of the ancients concerning man's soul after this life, according to unenlightened nature;" in the composition of which he is said to have been assisted by his father. This work contained free opinions, which gave great offence; and though it had been previously licensed, was suppressed by order of Compton, bishop of London; and during his absence burned by some officious zealot. Several answers to it were written; and it was particularly animadverted upon in the second volume of Nichols's Conference with a Theif. In the same year Mr. Blount published some extracts from Hobbes's Leviathan, in a single sheet, entitled "Mr. Hobbes's hit Words and dying Legacy;" and intended to expel, probably, the political principles of this writer. To these, his ardent zeal for liberty rendered him peculiarly adverse; and his zealous attachment to this cause was soon after manifest in a pamphlet, under the signature of "Junius Brutus," designed to alarm the nation with regard to a popish plot, and the prospect of a popish successor to the crown. In 1680 he published his translation of "the Two First Books of Philolatra, concerning the life of Apollonius Tyanaus, with philological notes on each chapter," fol. which being considered as a dangerous attempt to reproach and prove the Christian religion, was immediately suppressed; so that
few copies of it could be obtained. This was followed, in the same year, by a work entitled "Great is Diana of the Ephesians, or the Original of Idolatry, together with the political institutions of the Gentiles' Sacrifices," which, though professedly written against the impostions of the Heathen priests, was thought to be aimed at the Christian priesthood, and indirectly against all revelation. The author was now confounded as the head of the Deistical sect, and he is charged with having taken great pains, by conversation and correspondence, to propagate and defend his opinions. In a letter to Dr. Sydenham, however, he acknowledged, that in point of precision Deistical is far more satisfactory than the Christian scheme. The clamour raised against him by his former publications made him somewhat more cautious and reserved; and accordingly he stolidly concealed his being the author of a treatise, entitled "Religio Lacici," published in 1683, and said, by Dr. Leland, in his Deistical writers, vol. i. p. 37, to be little more than a translation of Lord Herbert's work, under the same title; and he also abandoned the design which he had formed of writing a life of Mahomet. From this time he seems to have changed the objects of his study; for in 1684, he published "Janus Scientiarum; or an Introduction to Geography, Chronology, Government, Hillory, Philosophy, and all genteel arts of learning;" Svo. which was intended to afford young persons at an early age in the acquisition of principles of philosophy and science, without pursing the tedious course that had been usually preferred to them in schools.

Mr. Blount was one of those who cordially concurred in the revolution; and in a letter addressed to W. Lefeyon Gower concerning corporations, and inserted in the "Oracles of Reaion," he expresses his wish, that those counsellors of the late king, who had injured the independence of parliament, might be punished, justly considering the purity of representation as the essence of a free constitution. About this time he wrote his treatise entitled "A Just Vindication of Learning, and of the Liberty of the Press," in which he endeavored one of his best performances, and a summary of all the principal arguments that can be urged upon this topic. In his zeal for the cause of king William, he wrote a pamphlet in 1693, intended to prove the right of William and Mary to the crown, on the ground of conquest; and in explanation of this design, so different, one would imagine, with his principles, and no less obnoxious than ill-founded, he declares that he wrote "with an especial regard to such as have hitherto refuted the oath, and yet allow of the title of conquest, when consequent to a just war." By this performance he gave such offence, that, on a complaint being brought before the house of commons against this pamphlet, entitled "William and queen Mary Conquerors," it was ordered to be burnt by the hands of the common hangman; and in the same cen sure was involved a pastoral letter of bishop Burnet, in which the same notion was advanced, probably with the same views.

Mr. Blount, having lost his wife, became ardently enamoured of her sister, a lady of great beauty and merit, who seemed disposed to return his affection; but as the ecclesiastical laws opposed their union, he drew up a suit strongly argued, and referred it to certain divines, who of course gave their opinions against his wishes. As the lady refused to comply, after such a determination, Mr. Blount took into despair, and at length shot himself through the head.

After this act of perversity, he languished for some days, receiving no nourishment but from the hands of the object of his affection, till at last death relieved him, April 1693. Many of his private letters and some small tracts were published, together with a preface, by Gildon, in 1699, before the author's death, in a work entitled "The Oracles of Reason," which was afterwards re- printed, with some additional pieces, after his decease, in 1695, in a collection of "The Miscellaneous Works of Charles Blount, esq." by the same Mr. Gildon, who prefixed to it an account of the life and death of the author. The learning of Mr. Blount is unquestionable, and he seems to have polished a strong and ardent mind; but his early dislike of superstition precipitated him into some very considerable errors, and inclined him to believe all revealed religion to be pietistic, because he perceived that some priests had converted religion to their own secular advantage. His sentiments on the subject of religion were divulged in his writings without disguise, and sufficiently warrant our referring him to the class of deists; but the charge of atheism alleged against him by some foreign divines, is certainly unfounded. See an account of Mr. Blount's writings by Dr. Leland, in the fourth letter of his View of the Deistical Writers, vol. i. by this author we are informed that Mr. Gildon, who published the "Oracles of Reason," and communicated them to the world, was afterwards, upon mature consideration, convinced of his error, and in 1705 published his retraction in a book, entitled "The Deist's Manual." The greatest part of this book is intended to vindicate the doctrines of the existence and attributes of God, his providence and government of the world, the immortality of the soul, and a future state. And his avowed reason was, because many of the deists, with whom he was well acquainted, did really deny those great principles, which he laid at the foundation of all religion, or, at least, represented them as doubtful and uncertain. And their not admitting natural religion in its just extent, formed some of their principal prejudices against the Christian revelation. See the Biog. Brit. Blount, in Geography, a new county of the State of Tencove, in America.

BLOUNTSVILLE, a town of America, in North Carolina, on the post-road from Halifax to Plymouth, 49 miles from Plymouth, and 55 from Williams town.

BLOW, in a general sense, denotes a stroke given either with the hand, a weapon, or instrument. The effect of a blow is estimated like the force of perusion, and accordingly it is expressed by the velocity of the body multiplied by its weight.

In fencing, blows differ from thrusts, as the former are given by tilting, the latter by pulling. We say to give, to return, to parry a blow. (See PARRYING.) Blows on the sword make a kind of purr, called BEATING.

Blow, blind, ilius ursus or exunus, is that which does not appear, or is not attended with effusion of blood; in contradistinction from that followed by a wound, discolouring, tumor, or the like, called ilius apertus or openus, an open blow.

In the ancient laws, we find blows for remembrance, given to make persons remember some transaction, and enable them to become better witnesses of it in future times.

Blow, military, ala militari, that given with the sword on the neck or shoulder of a candidate for knighthood, in the ceremony of dubbing him. The custom seems to have taken its rise from the ancient ceremony of manumissio.

In giving the blow, the prince used this form: "ello bonus miles;" upon which the party rose a complete knight, and qualified to bear arms in his own right. Sometimes a double or even triple blow was given, called trina percylio.

Blow, Dr. Johnson, in Biography, born at North Colling- liam, in Nottinghamshire, was one of the first set of children of the chapel royal after the restoration, that was brought up under captain Cook. He likewise received instructions from
BLO

BLO

from Hiexelton, domestic organist to Oliver Cromwell, and Dr. Christ. Gibbons. In 1673, he was sworn one of the gentlemen of the chapel; and in 1674, upon the decease of Humphrey, appointed master of the children. In 1683, he was nominated one of the private music to king James II. and in 1687, he was likewise appointed almoner and master of the choir-schol in the cathedral of St. Paul; but, in 1693, he resigned this last place in favour of his scholar Jeremiah Clark.

Blow had his degree of doctor of music conferred on him by the special grace of archbishop Sancroft, without performing an exercise for it in either of the Universities. On the decease of Purcell, in 1695, he was elected organist of St. Margarets, Westminster; and, in 1699, appointed composer to the chapel of their majesties, king William and queen Mary, at a salary of 42l. a year, which afterwards was augmented to 73l. A second composer, with the like appointment, was added in 1715, when John Weldon was sworn into that office; at which time it was required that each should produce a new anthem on the first Sunday of his month of waiting.

That Blow was a composer of anthems, while a singing-boy in the chapel royal, appears from Clifford's Collection of the Words of the Services and Anthems used in our collegiate and cathedral churches, 1664; for among the ecclesiastical composers mentioned in this book, amounting to upwards of sixty, are included the names of Pelham Humphrey, John Blow, and Robert Smith, children of his majesty’s chapel. Humphrey was born in 1647, and Blow in 1648; so that at the restoration, the first being only thirteen, and the second but twelve, their composing anthems fit for the chapel royal, before they had attained the age of sixteen or seventeen, would now be regarded as wonderful proofs of precocity, if Purcell, soon after, at a more early period of his life, had not produced compositions that were still superior to theirs.

Dr. Blow died in 1708, at sixty years of age; and though he did not arrive at great longevity, yet, by beginning his career, and mounting to the summit of his profession so early, he enjoyed a prosperous and eventful life. His compositions for the church, and his scholars who arrived at eminence, have rendered his name venerable among the musicians of our country.

Though his church music was never collected in a body, yet, besides the three services and ten full and verse anthems printed by Boyce, in Dr. Tudway's MS. collection, nineteen of his choral productions have been preserved; and in Dr. Aldrich's collection in Chirl-church there are five more. The aggregate of which, amounting to upwards of forty different compositions of this elaborate kind, is but a small part of what might be found in the chapel and choir-books of our cathedrals.

Some of his choral productions are doubtless in a very bold and grand style; however, he is unequal, and frequently unhappy, in his attempts at new harmony and modulation; but, as a composer who ranked so high among our most classical masters should not be praised or censured indiscriminately, we shall point out a few instances of his great, and, to our conceptions, unwarrantable licentiousness, as a contrapuncti.

We are as sorry to see, as to say, how confused and inaccurate a harmonist he was; but as it is necessary to speak of an artist so celebrated and honoured by his contemporaries, to dissemble his faults would furbish censure, and incur the censure of ignorance and partiality; for it is a common duty of an historian to blame as to praise, when justice and integrity require it. Indeed, upon whatever subject a man writes, he should aspire at nothing so much as speaking truth, if he wishes for the approbation of his confidemce, which is not only the most comfortable of all praises, but, luckily, the most within his own power. The abilities of the dead, we can have no interest in depreciating; and if our opinion should be unjust, the mischief will recoil on ourselves; for the dead have more friends than the living, who are ever ready to vindicate such wrongs.

Though there are strokes of pathetic and subjects of fugue in Blow's works that are admirable; yet we have examined no one of them that appears to be wholly exceeeptionable, and free from confusion and crudities in the counterpoint. Of the two-part anthems with choruses, "Lord how are they increaced," the first movement is very plaintive and expressive; but there are licences in the harmony which look and found quite barbarous. Indeed, these crudities are so numerous as to throw a doubt on his learning, as well as genius. Whether they are notes of passion, effusions of an unruly spirit, or of ignorance and affectation, we will not venture to determine; but, to our ears, they have the full effect of jargon and profanities.

It does not appear that Purcell, whom he did himself the honour to call his scholar, or Crofts, or Clark, his pupils, ever threw notes about at random, in his manner, or inflected the ear with lawless discords, which no concords can render tolerable.

In an anthem, "Torn thee unto me, O Lord," printed by Henry Playford in the second collection of Divine Harmony, there are so many wanton violations of rule, particularly in the last chorus, that it would be endless to point them out; but they seem such as no rule, authority, or sect, can justify; 7ths resolved on the 8th, ascending and descending; 2ds treated with little ceremony; 3ths. Indeed, we never saw to fowly a score in print, and it may, in general, be said of his faults in counterpoint, that there are unaccounted millions of them to be found in his works.

He has been celebrated by Dr. Boyce, for his "success in cultivating an uncommon talent for modulation;" but how to excellent a judge he is, correct and pure harmony could tolerate his licences, or reconcile them to his monumental character, and the additional praise he has himself bestowed upon him, is a unaccountable as any thing in Blow's compositions, considering the knowledge and known probity of the late worthy editor of Cathedral Music.

Many of his ballads, though only in two parts, are full of crude discords unprepared and unrefused; the caufe of which, in some measure, may be ascribed to the ground-bases, on which it was now the fashion to write: for melody being scarce, both that and the harmony were frequently inured by this Gothic restraint. But the pafing-notes and notes of embellishment of the composers, in general, of this period, were uncouth in melody, and licentious in harmony. Perhaps those of the present times, in less than a century, will be equally unpleasing to the ears of posterity; and yet we fancy that both melody and harmony have received their last polish.

The ballads of Dr. Blow are in general more smooth and natural than his other productions, and, indeed, than any other ballads of his time; there is more melody than in either of Henry Lawes, or any composer of the preceding reign; yet it is not of that gracefull kind in which the Italians were now advancing towards perfection, with so great rapidity. It is either of a Scots call, or of a languid kind, that excites no other sensation than fatigue and drowsiness.

His pastoral, "Since the Spring comes on," is, however, as elegant as any mongrel mixture of Scots, Irish, French, and English, that has been since compiled.
BLO

The shoe-lamp (more distinctly represented in fig. 2.) is so called from its resemblance to a shoe. It is made of tinned iron, and consists of two parts; the exterior, a, serves to hold the proper lamp, and to retain the oil, which occasionally drops from the wick; the lamp, b, has a fixed cover, except at the tip, where a circular aperture is left for the wick, d, which consists of a bundle of cotton threads, about an inch in diameter; at e is a hinge, by which that part of the lid nearest the wick may be raised, in order to pour in fresh oil, or to renew or raise the wick.

The glass-worker's blow-pipe is, however, not sufficiently portable for the use of the chemist and mineralogist, and it was a happy thought of Swab, the Swedish mineralogist, to substitute the lungs for the bellows. Calun, Engelroth, and Bergman suggested various improvements in the construction of this instrument, which now appears to have attained as great a degree of perfection, as it is perhaps capable of.

The common chemical blow-pipe consists of five parts; (Chemistry, Plate XI. fig. 3.) the mouth-piece, a; a plain tube, b; a bulb, c; a curved tube, d; and a nut, e.

The mouth-piece (more distinctly represented by fig. 5.) is made of ivory, the seat of the apparatus being of brass, and is closely fitted into the pipe, b, so as to be air-tight; the bulb, c, is divided into two hemispheres, which screw into each other, and is designed to collect and condense the moisture of the breath; into the lower hemisphere is fixed the recurved tube, d (as represented in fig. 4.), in such a manner as to prevent the condensed vapour from escaping out of the bulb; the nut, e, is a hollow cylinder sufficiently wide at one end to receive the extremity of the curved tube, and perforated at the other with a small round hole, to allow a passage for the air; each blow-pipe has generally three or four nuts (fig. 6.), with apertures of different sizes, the largest of which does not exceed the diameter of the smallest pin.

In using the portable blow-pipe, the only difficulty is to keep up a constant stream of air; which is to be done by performing the function of respiration through the nostrils alone, diverting from time to time a portion of the expiration into the mouth for the supply of the blow-pipe, and forcing it through the tube by the action of the muscles of the cheek. This knack is by some acquired in an infant, while others are a long time in making themselves masters of it. To those who experience any difficulty in the free use of this instrument, the following directions may be of service. First, let the learner accustom himself to breathe freely with the mouth shut; then in making an expiration, let him transfer the air into the mouth, till the cheeks are moderately inflated, and retaining it there, let him dischage the surplus of the expiration through the nostrils, and then make two or three easy inspirations, and expirations through the nostrils, without allowing the air in the mouth to escape. When practice has rendered this easy, which may be effected in half an hour, let the nut with the smallest aperture be fixed on the curved tube of the blow-pipe, and introduce the mouth-piece within the lips; then inflate the cheeks by an expiration, and continue breathing easily through the nostrils, till nearly the whole of the air has passed out of the mouth through the tube; then renew the air as before, and, after a few days' practice, the muscles of the mouth will be accustomed to this new mode of exertion, and an uniform uninterrupted stream of air may be kept up for half an hour without any extraordinary fatigue. A wax candle, f, having burnt long enough to allow the wick to be turned down, in the manner represented in the plate, the nut of the blow-pipe is to be applied to the arch of the wick, and the air, as it comes through, will bend the flame into a neat horizontal cone, the exterior part of which is yellow, and the interior

BLO

piled. The first movement, particularly, seems to have been the model of most of the Vauxhall songs of the last fifty years.

"Fill me a bowl," p. 52, has the same kind of merit.

The collecting of his secular compositions into a folio volume in 1700, under the title of "Amphion Anglicus," was doublets occasioned by the great success of the "Orpheus Britannicus," a similar collection of Purcell's dramatic and miscellaneous songs, published by his widow, in 1698. But whether Dr. Blow was stimulated to this publication by emulation, envy, or the solicitation of his scholars and friends, by whom there are so few left than fifteen encomiastic copies of verses prefixed to the work, the ungrateful public seems to have remained always insensible to these strains of the modern Amphion, which were not only incapable of building cities, but even of supporting his own totering fame.

Some of his innumerable deformities from the Amphion Anglicus are added to those of his church music, in the third vol. Gen. Hist. Muf. "Go perjured man," is the bell of all his secular productions; but that, in an imitation of a duct of Carulli, "Dite, O riche," is overloaded, in his "Amphion Anglicus," with a laboured and unmeaning accompaniment. p. 44 and 46 of this collection, contain two of his bell ballads, "Sabina has a thousand charms," and "Philander do not think of arms." In these ballads the union of Scotch melody with the English, is first conspicuous. The subject of a song, p. 168, "Oh, heila's bright eyes," is likewise broad Scots.

BLO

Blows, flys, the one of flies deposited on flesh, or other bodies proper for hatching them.

Blow, in 4t. Sea Language: when the wind increases from a moderate breeze, it is said to blow; and, according to the various degrees of strength with which the wind blows, it receives different apppellations.

Blow-pipe, Tubus ferramentarius, Lat.; Lëbwyber, Blether, Germ.; Chalumau, Fr. A blow-pipe is a wooden instrument for the purpose of increasing the heat of a candle or lamp, in the same manner as a pair of bellows is employed for raising the temperature of a common fire or furnace. It is not known at what time or by whom this very useful instrument was invented, but it appears to have been employed by glass-workers, enamellers, and jewellers, long before it was adopted as a part of chemical apparatus. The first intimation of its value to the chemist is to be found in Kinkel's treatise on glass-making.

The common glass-blower's lamp is represented in Plate X. fig. 1. (Chemistry). A, i. a wooden table, within the frame of which is fixed a pair of double bellows B, that are worked by the foot of the artist; from the nozzle of the bellows proceeds a pipe of lead, or tinned iron, CC, which, first rising perpendicularly, is then brought under the top of the table to D, where it penetrates the wood, and terminates on its upper surface, in a recurved hollow cone E, the apex of which is pierced with a minute round hole. A shoe-lamp, F, is placed on the table, so that its wick is somewhat below, and about half an inch distant from the aperture of the pipe; the bellows being then worked, a constant stream of air is thrown upon the wick of the lamp, producing a long conical horizontal flame, G, of very considerable intensity. The increased heat of the flame appears to depend, in part, on a more rapid and complete combustion of the oil, and in part, also, on the concentration of the flame, by the action of the blast. The flame, upon examination, will be found to consist of an exterior yellow cone, including another of a lighter yellow colour, at the extremity of which lies the focus of greatest heat.
interior blue. The substance under examination being reduced to the size of a peppercorn, is to be placed in the platina spoon, fig. 7, or into a shallow cavity in a piece of compact charcoal, and being first gradually heated by the yellow flame, is afterwards to be exposed to the full intensity of the blue focus, b.

An important use of the blow-pipe in the laboratory is to soften glass-tubes, &c. in order to bend them to any shape that may be required, for which purpose the blow-pipe just described is not very well qualified, the flame not being large enough, and, from its intensity at the blue focus, acting very unequally. It may, therefore, in theory, and similar cases, be advantageously superceded by the alcohol blow-pipe.

This instrument, the invention of which is due, we believe, to M. Paul and professor Picquet of Geneva, has received some improvements from English artists, and is figured in Chemistery, Plate XI. fig. 1 and 2. It is made of brass, and consists of the following parts: A is an oval base, in which are two round holes, for the reception of the two spirit lamps, B, and C, the latter of which has a considerably thicker wick than the former. D is a pillar that screwes into the base, and supports a moveable brass collar, E, which may be retained at any convenient height by the screw, F. L is the boiler hanging loosely, but securely, in the collar, E; M is a screw accurately closing an aperture in the boiler, through which it is filled with alcohol; I is a conical plug, serving as a safety-valve, the repletion of which to the expansion of the vapour is regulated by the feel spring H, compressed between the screw nuts G and K; O is the delivering pipe, seen more particularly at fig. 2. It consists of a plain tube, e, somewhat longer than the depth of the boiler, of a shoulder and screw, b, by which it is fixed in the bottom of the boiler, of a ball and socket joint (composed of the sphere, d, in- cluding the perforated bulb and item e, f), and of the nut g, terminated by a small aperture, &c. screwing on the item, f. N (fig. 1) is a hollow cap, screwing into the boiler, and receiving the head of the tube, a, to prevent any liquid alcohol from being thrown into it. This blow-pipe works in the following manner: The boiler being filled with alcohol, and the ferewes and valve secured, the lamps, B and C, are lighted. The alcohol in the boiler being brought to ebullition by the lamp B, the vapour ascends into the cap N, whence it passes down the tube O, and is discharged at P, upon the wick of the lamp C, producing a long bulbous horizontal flame Q, whose extreme temperature is nearly equal to that of melting copper, and is admirably fitted for the working of glass.

Mr. Benjamin Hooke, lately an ingenious mathematical instrument-maker in Fleet Street, has made some improvements in the blow-pipe by alcohol; for a description and drawing of which we refer to Nisbolen's Journal, vol. iv. p. 106, 8vo.

The blow-pipe is of considerable use to the mineralogical chemist, from its being very portable, and flowing, in a few minutes, upon a very small quantity of any mineral substance, the effect that would be produced by its exposure to the heat of our most powerful furnaces. It is also a valuable instrument in the analysis of minerals, by indicating their principal contents, rudely and imperfectly indeed, yet so as to afford a clue to the chemist in his subsequent operations.

The efficacy of the blow-pipe, in fusing the most refractory substances, is, however, greatly increased by charging with common glass, a heat is thus produced, fully equal to that of the folds, by the heat of the mouth-piece taken out, and connected to a gazometer, by a flexible tube of elastic gum; the curved tube and terminating nut of the blow-pipe ought, however, to be made of platina, the heat produced being so intense as frequently to fuse and inflate those parts of the instrument, if made of brass. The operator should also be careful to wear spectacles of green glass, in order to protect his eyes from the intolerable white glow, which is so intense as to cause even the flame of a common wax candle to cast a very sensible flame. Sometimes a double blow-pipe is made use of in experiments with oxygen gas, by which the effect is considerably increased. A representation of this is seen in Chemistery, Plate X. fig. 5. The part, a, which joins the tube of the gazometer, turns in a collar, b, in the end of the tube, b, c. On this tube are two brass boxes, d, e, into which are fitted the tubes, f, g, which also turn in air-tight sockets, for the purpose of enabling the operator to move the blow-pipes, b, i, nearer to or further from each other. The blow-pipes, b, i, are also moveable at t, l by which the direction of the blast may be varied, so as to meet on the charcoal, m, at any angle that may be required.

The caue of the great heat which is produced by the blow-pipe, has generally been attributed both to a concentration of the flame in a small focus, and a more rapid combustion than usual. Count Rumford, however, (Effays, vol. ii. p. 69.) supposes that the effect of this instrument is entirely due to the consumption of the gases; and in support of this hypothesis, he mentions the results of some experiments made by himself, which, he says contradict to daily experience, and were conducted in a more inaccurate manner, as to defer, in our opinion, very little confidence.

He begins by saying, "A current of air cannot generate heat, without, at the same time, being decomposed; and, in order to its being decomposed in a fire, it must be brought into actual contact with the burning fuel, or at least with the inflammable vapour which issues from it. But can it be supposed that there can be any thing inflammable, and not actually inflamed, in the clear, bright, and perfectly transparent flame of a wax candle? A blow-pipe has, however, as sensible an effect when directed against the clear flame of a wax candle, as when it is employed to increase the action of a common glass-worker's lamp." To this it may be replied, in the first place, that flame is not transparent; and, secondly, that a considerable quantity of "uninflammable inflammable matter" is contained in the flame, as is evident from the foot that may be collected by holding a plate of glass or metal over it, so as to touch the summit. The count proceeds to relate that carbonic acid being driven by a blow-pipe through the "clear, brilliant flame of a wax-candle just finished," melted a small tube of glass in the same time as when the pipe was charged with atmospheric air, or even with oxygen gas. We have repeated these experiments, and observed, that when the blast was directed to the whitest part of the flame, no well defined horizontal cone was produced by any of the three gases; that when carbonic acid, or the breadth, was passed through the flame just above the wick, a well defined cone was produced, the interior of which was of a light blue, and the exterior of a pale yellow; when atmospheric air was employed, the whole cone was of a bright yellow; and, with oxygen gas, the whole flame was of a dazzling white. The effect of the second in melting glass was greater than that of the first, and the last was much more powerful than the second. Nerii, art de la Verrerie, Bergman's Eff. vol. ii. Philosophical Magazine, vol. viii. p. 525.

BLOWER, feuillear, an appellation of contempt, sometimes given to an alchemist.

In the French King's kitchen, there was a species of an op-
BLOWER, among dealers in horses, a term used for such horses as wheeze much, without wanting wind. See Wheezing.

BLOWING, in Medicine. One method of administering medicines is by inflation, or blowing them into the part by a tube: thus is it they sometimes convey powders into the eye, and sometimes up the nose, for the cure of a polyposis.

BLOWING, respiro:atria, was also a ceremony in the ancient administration of baptism, whereby the catechumen, upon rehearsing the renunciation, blew three blasts with his mouth, to signify that he rejected or call the devil absolutely off.

Something like this is still retained in the Ruffian church. In the sacramentary of St. Gregory, the priest who administers baptism is enjoined to blow thrice on the child's face, making the sign of the crofs with his hand, and pronouncing the words exi ab eo Satan. Justin Martyr, Tertullian, St. Cyril, and St. Augullin speak of this ceremony as used in their times.

BLOWING of a fire-arm, is when the touch-hole is run or gulled, and become wide, so that the powder will flame out.

BLOWING, also used in speaking of the natural motion or courfe of the wind.

In the Sea-Language, the wind is said to blow home, or blow through, when it does not cease, or grow lefs, till it comes paff the place where the speaker is. To blow through is sometimes also used to denote, that the wind will be fo great as to blow afunder the fails. When a wind increafes fo much that they cannot bear any top-fails, they fay, they were blown into their courfes, i.e. they could only have out the fails so called. To exprefs an extraordinary great wind, they sometimes fay, it will blow the fay out of the boltropes.

BLOWING is also used in speaking of the force and effect of kindled gunpowder on bodies which happen to be over it. In this fence we fay to blow up a house. Engineers at fiesges make mines wherein to blow up walls, baflions, and other defences. Powder-mills are apt to blow up by the iron gudgeons growing hot, and fetting fire to the powder duff flying about.

BLOWING, among Gardiners, denotes the action of flowers whereby they open and difplay their leaves. In which fence, blowing amounts to much the fame with flowering and blooming.

BLOWING of Glass, one of the methods of forming the divers kinds of works in the glafs manufacture. It is performed by dipping the end of an iron poftegho, or blowpipe, in the melted glafs, and blowing through it with the mouth, according to the circumstances of the glafs to be blown.

BLOWING of tin, a term used by the Cornith miners for the fusion or reduction of tin-ore to the metallic flate, after having been roasted to get rid of the sulphur and arsenic.

BLOWING. Manufacturing is used in metallurgical operations on a great fcale, for the purpose of exciting combustion in furnaces appropriated for the finifhing and reducing of ores.

The history and improvement of machinery of this nature have kept pace with the other branches of our national manufacture, and, in many inftances, may be juftly faid to have gone beyond them.

In the finifhing of lead and tin ores, the size and powers of the blowing machine have been left a subjeft of alteration and improvement, than those used at furnaces and works where iron ore is smelted.

The natural fulhibility and easy volatiliation of the former metals, in temperatures beyond a bright red heat, have prefcribed the size of the furnace, the meafure of the blast, and the nature of the ore used.

In the manufacture of copper, air furnaces are generally used, except where precipitated oxyd of copper is revived in small blast-furnaces, refembling those called cupolas, used at iron founderies.

The conflagration of a lead smelting machine, or what is commonly called a "Lead Mill," is extremely simple. A water wheel is erected in the middle of a square building. To the shaft of this wheel are attached four small wheels of cast iron, about 18 inches diameter. Four pairs of bellows, two pairs on each side of the shaft, are placed at equal distances, and supported upon a strong frame of wood. As the water wheel shaft revolves, the small wheels are carried round, and alternately, or two and two together, depress the extremity of a lever attached by an iron chain to an equipoised beam. The defcent of this lever elevates the opposite end of the beam, to which is also attached, by means of another iron chain, the upper or moveable furface of the bellows. The blast produced in this way is in general soft, much inferior in point of either quantity or denfity to what is found necessary at iron furnaces. The bellows in common measure 10 feet in length, and 5 or 6 feet across the breach, moving about 30 strokes per minute.

In the manufacture of iron it has always been, particularly since the introduction of pit coal, the unceafing object of the iron-maker to improve his blowing apparatus; for uniformly he has found, that in proportion as he can raife air, and make it enter the furnace, so will his weekly quantity of metal be increafed.

In the early history of this interesting manufacture, when charcoal of wood was the matter of fuel made use of, the affinities between the latter and the ore were established with more facility. Small furnaces, called bloomeries, were sufficiently large, and deemed of profitable capacity, if they produced a bloom or two of iron per day, of 50 to 120 lbs. each.

Hand bellows, and what were called fuel bellows, were sufficiently large for the minor operations. After the general introduction of the refinery furnaces, and the division of the manufacture into the making of pig iron, and the refining of this into bar or malleable iron, the advantages of a powerful blast were immediately perceived. Water wheels, working two pairs or more of leather bellows, were found to produce powerful effects, and, in consequence, almost every situation that presented a command of materials and a waterfall, became the feite of an iron-mill.

The simple mode of blowing furnaces by means of a trompe, was at the fame time introduced; but in general it was found, that much greater advantage could be derived from the defcent of water upon a wheel, either as to denfity or quantity, than by means of the belt contracted trompe.

The use of water wheels and leather bellows continued general throughout the iron businefs, until the principles and mechanism of the steam engine were effabliffed upon unerring grounds. This wonderful invention was soon applied with the happiest effect in many situations rich with mineral treasures, but to which nature had denied the advantage of water fufficient to turn machinery. Cylinders, comfounded of wood, firmly jointed and hooped, were first introduced as a substitute for leather bellows; these were foon after replaced by bored cylinders of cast iron; and with
with this great discovery and application of the art of ca-
ning, the blowing machine assumed a general and well-pro-
portioned form.

This took place nearly 40 years ago, and continued with
a few temporary deviations until the introduction of Bolten
and Watt's highly improved engine. The following may ser-
ve for an outline of the old blowing iame engine.

A team cylinder, working with atmospheric pressure from
1 to 2 lbs. upon every square inch of the area of the piston.
The diameter of the cylinder for one furnace varied from
25 to 36 inches, and for two furnaces from 36 to 50 in-
ches. Upon the opposite of the main or working beam, some-
times at equal, and sometimes at unequal distances from
the centre, was placed the air-pump or blowing cylinder.
This was, in common, equal to four or five times the area of
the former; and, with the small working power of the team
piston, seldom conveyed the air beyond 1½ to 1¾ lbs. per
square inch. The air-pump was commonly constructed open
below, as may be seen in Plate II. fig. 1. (Chemistry).

The plan was sometimes deviated from, and the cylinder inverted.
The blowing piston was loaded with weights, and the air ex-
pelled by its deficient. In this mode of working, the act of
the team piston, depending in vacuum, raised the air-
pump piston loaded with weights. Upon the return of the
stroke, or while the team piston ascended in the cylinder, this
piston loaded with weights funk the whole length of the
stroke, and by means of this loading, proportioned to the
powers of the engine, forced the air either into the regula-
ator or the furnace.

Above, or parallel to the air-pump, was placed the regu-
lating cylinder, as may be seen in the plate above mentioned.
This has a valve of communication, which opened every
stroke the engine made, and admitted the whole discharge
of air. The piston of the cylinder, frequently called the
fly piston, was loaded with weights, and kept constantly vib-
rating; so that when any deficiency of pressure arose
from the remitting action of the air-pump piston, the blast
was comparatively equalized by the preffure of the fly piston
upon the included air. The size of the cylinder was gene-
rallv in the proportion of 5 to 6 of the air-pump.

The chief objections to this mode of blowing, even when
in univcrsal use, were founded upon the great inequality of
the blast, and a very considerable waste of air that took
place at the short, or safety valve, to prevent the fly piston
being blown entirely out of the cylinder. The fly piston
was an opening made in the top of the air-pump cylinder, on
which rested a heavy iron valve, faced with leather stuffed
with wool; this was, by means of an upright iron rod, at-
tached to a lever, which run across the top of the regulating
piston. As soon as the fly piston arose to a certain height,
a block of wood, or other contrivance, lifted the one end of
the lever, and along with it the valve, to a certain height,
and permitted a quantity of the denfified air to escape, suf-
cient to insure the safety of the piston. Notwithstanding
these precautions, many accidents and flaws ensued; the
breaking of a pin, or the loosening of a key, frequently ejected
the piston from its cylinder, though loaded with several
tons of weight.

Some iron matters, more ingenious than others, contrived
to take the spare or waste air from the short, to receive it in
an inverted chest above water, and blow to its extent smithy
and flnery fires. Endeavours of this kind to husband and eco-
nomic air, raised and condensed at a great expense, were
sufficient proofs that a method was still wanting to complete
the blowing machine, to render its motions steady and uni-
form, and to equalize the density of the blast throughout the
whole stroke.

This was completely accomplished by inverting large chests,
or cylinders, in citerns of wood, stone, or iron. The space
between the inner and outer citerns was constructed of suf-
cient capacity to oppose to the expansive force of the blast
a column of water of equal or superior reliability.

This invention was called the water blast, water preffure,
water regulator, &c. The dimensions differed materially
from each other; this circumstance being much regulated
by convenience, opinion, and the size of the engine.

Plate XIV. fig. 1. (Chemistry) represents a ground plan of
a very capacious water regulator, sunk in the ground, and built
of stone and bricks.

A, the inverted chest made of plates of cast iron, 40 feet
long, 12 feet wide, and 12 feet high. The square super-
ficies of this chest is equal to 480 square feet, and its cuhical
contents are 7200 cubical feet. Its weight will amount to nearly
30 tons.

B, the opening to which the air-pipe is attached; 2 foot
diameter.

cccc, open space between the inverted chest and stone
cistern, for the column of water to ascendl; 3½ feet wide.

DDDD, stone or brickwork, of which the great
chest is built. This work requires to be well jointed, as
the motion of the water has a great tendency to open the
spaces between the stones. This cistern is 47 feet long,
19 feet broad, and 14 feet high; its cubical measurement
amounting to 12,500 feet, and capable of containing
93,500 gallons wine measure.

eed, an opening of one foot in breadth left in the
middle of the building. This is compactly filled with well
red clay, called pudding, and prevents the escape or circu-
lation of water through the building. Beyond this the
common building extends to a sufficient thickness to give
general security to the whole.

Fig. 2. is a cross section of the water regulator at B,
fig. 1. The letters in this view correspond with those in the plan.
F, the blast pipe from the cylinder entering the chest,
and branching to the two blast furnaces.
GG, large hewn stones, on which the chest is supported,
about two feet from the bottom of the citern, at inter-
vals of six feet from each other.
H, loading of hewn stone, which for this citern requires
to be equal in all to 90 tons. If the chest weighs 39, then
60 tons of loading will be requisite. This is supposing
that the power of the blowing machine is calculated to pro-
duce equal to 3 lbs. upon every square inch, which many of them
are constructed to perform.

To comprehend distinctly in what manner the water regu-
lator performs its functions, and upon the supposition
that the compreffing power of the engine is equal to 3 lbs.
upon every square inch, we shall suppose the engine at
rest, and water introduced into the regulator, till it rise to
the level of the dotted line b, 5 feet from the lower edge of
the chest, and 7 feet in total depth of water. As soon as
the engine is set to work, the compreffion of the air im-
mmediately sets the water in motion; every stroke making
the water rise in the space CC, and proportionally falling
towards GG, in the interior of the chest.

When the inverted chest becomes filled with air, and the
condensation has reached the maximum of the power of the
blowing machine, the water will be found elevated 3½ feet
to i, and the gauge will exhibit a depression in the interior
of the chest, from b to k, 3½ feet, making in all 7 feet
from k to i.

At every turn of the engine stroke, the water maintained
at i falls a few inches, and elevates itself above k in the in-
terior
terior of the chett, a similar height. This description takes it for granted, that the spaces C C are equal to the area of the inverted chett; so that every inch of water forced out of the chett adds exactly one inch to the height of the column.

A blowing machine, capable of blowing to purpose two blast furnaces, ought to have the inverted chett of the regulator equal to three or four hundred square feet of area. There cannot arise any error from having this large enough; the want of space and capacity frequently proves a real detriment.

In calculating the proportions and dimensions of water regulators in general, the principle is, to allow the space around the inverted chett equal in point of superficial measurement to the area of the interior of the chett, that the defcending column of water may displace no more in the perpendicular ascent, than it is elevated absolutely depressed.

If the area or space, in which the water rises and falls, is only equal to half the area of the inverted chett, then for every foot of water which is depressed in the bottom of the chett, a column of two feet will be raised and maintained on the outside. On the contrary, if the outside space for water be equal to twice the area, then every foot of water depressed in the chett will only elevate the external column six inches.

It will appear evident from these general facts, that a considerable latitude may at any time be affumin in constructing the water regulator, particularly in old established works, where local circumstances and convenience confine its situation to one spot.

Where it is not inconvenient to use a high perpendicular column of water, the inverted chett may be increased one half, double, or even triple the superficial measurement of the outside space; so that if the power of the blowing machine is equal to 3 lbs. upon the square inch, the water in the chett will be depressed 3/4 feet nearly, and raised in the perpendicular column 5 feet 3 inches in the first, 7 feet in the second, and 10 1/4 feet in the last cafe. This plan to suit former establishments may be adopted with considerable modifications, always keeping in mind, that every foot of area gained upon the surface of the water is a material acquisition to the equalizing powers of the regulator.

One imperfection attends this want of equilibrium on the two spaces for the action and reaction of the water. Whatever space the waters would fall, at the return of the stroke, supposing the inside and outside columns exactly balanced, would in this case be increased one half, double, or triple.

Again, where situation does not admit of the perpendicular column being raised beyond, or not even to the extent of the depression, that takes place within the inverted chett, and where an additional space cannot be procured for an increase of its diameter, an inverted chett of much less height than common may be used, loaded with a material of great weight, such as iron. The water in that case would distribute itself over the surface of the chett, instead of rising in perpendicular height.

One serious objection, however, is made to chetts or cyinders, where the education pipe approaches within a short space of the surface of the water; namely, water rising in the pipes, and being conveyed along with the air into the furnace. This may take place in two ways; by an insensible and uniform discharge of water into the furnace, making the blast at the tuyere visible, like the respiration of the human body in a frosty day; or in quantity, threatening utter destruction to the furnace buildings. The former is occasioned by the air from the education pipe, at the com-

menement of the stroke, impinging violently upon the surface of the water, and raising a portion of it in the state of spray. This is directly dissolved or entangled in the mists of condensed air before the return of the next stroke, and becomes expressed along with the blast into the furnace. The other hazardous consequence is occasioned chiefly by undulation in the column of water, when the blowing machine is, by derangement or accident, working under its proper power or number of strokes. In these cases, when the pause at the end of the stroke is prolonged, an exhaustion sometimes takes place in the air-pipes, the water rises and is carried in a stream through the blow-pipe into the furnace.

The same casualties may more readily occur, if the surface of the water is upon a level, or nearly so, with the tuyere.

In judicious erections this is most carefully avoided; the surface of water in the inverted chett or cylinder is kept at least 8, 9, and 10 feet under the level of the tuyere, even at the half period of return, when the water has risen to its greatest height within.

This very proper precaution ensures an advantage of much importance. A large space is obtained betwixt the top of the chett and the depressed surface of the water; this becomes a spacious reserver for the condensed air, and, by generating a considerable portion of effluvium, prevents any violent perturbation upon the water at any period of the stroke. The increased distance betwixt the surface of the water, and the pipe which conducts the air from the cylinder, has a complete tendency to prevent the elevation of the aqueous particles, and always ensures a quantity of air comparatively free from moisture.

Upon the principles formerly noticed, it is possible to construct a blowing apparatus of this nature, wherein there could be little or no visible motion in the perpendicular column of water even with the same engine.

Let us suppose a machine of this nature at work, with an accurately balanced column of water, the fall of which, at the return of the stroke, was equal to 12 inches. It is evident, that if the outside space was enlarged so much over its surface as to contain this foot of water, without adding any perceptible height to the column; that included within the chett would, at the return of the stroke, be fed from a more capacious limb, rise a foot, without any sensible diminution taking place in the perpendicular height of the external fluid. It is equally obvious, in this as in every cafe with water regulators, that the rise and fall of the inside column of water will remain the same, under every modification and form, while the pace and powers of the engine remain the same.

The application of water regulators to blowing machines was soon followed by an attempt to further improvement, by the introduction of the air-vault; the principle of which was to form a receiver of such capacity, that the elasticity or spring of the condensed air would be sufficient to ex-pel and equalize the blast during the return of the stroke.

To effect this, an immense magazine was requisite; to erect which of any metallic substance would have been ruinously expensive, and, if constructed of wood, insufficient for retaining the air. It became therefore requisite to try the experiment upon building, or by excavation from the solid rock. In both these ways has the air-vault been tried, and found to produce an excellent effect, as to equalizing the density of the blast; but it has been conceived with such indifferent consequences as to quantity, that the plan is for the present given up.
Air-vaults were constructed both at the Clyde and Muirkirk iron works in Scotland, and a constant current of air produced; but nearly one half the quantity lifted by the air-pump escaped through the walls and arches of the building. This was at any time made visible by rubbing soapy water upon the external walls.

At Devon iron works in Scotland, an air-vault was excavated from the solid rock, 72 feet long, 14 feet wide, and 13 feet high; equal to 13,000 feet of cubic measurement. This immense excavation was made comparatively air-tight, by caking the seams and fissures of the rock, plastering and then covering the whole with alternate layers of pitch and clove weed paper.

This was the most perfect experiment ever tried upon the air-vault; and if an opinion is to be formed of the perfection of the apparatus by the quantity of iron at one time manufactured, a very trifling portion of air indeed must have been lost.

It has been frequently noticed in Scotland, that at works where the materials were in any degree similar, 3000 to 3500 cubic feet of air per minute will, in the course of a week, produce from 30 to 35 tons of pig iron, whatever may be the density at which it is thrown into the furnace.

The Devon furnace at one time averaged 33 tons weekly for 9 months running, and consumed of air, per data furnished by Mr. Roebeck in his paper published in Nicholainson's Journal, vol. iv. nearly 3400 cubic feet per minute, under a pressure of 25 lbs. per square inch. Notwithstanding this powerful demonstration, strong prejudices were entertained to its disadvantages; and many believed, that had any other mode of regulator been attached to the blowing machine, abundance of air would have been obtained to have blown two furnaces equally well. That this idea was incorrect, may be easily gathered by calculation from the area of the air-pump, the length of the working strokes, and the number of strokes per minute, all of which are particulars stated by Mr. Roebeck.

For the general construction of an air-vault formed by building, see Plate XV. (Chemistry.)

Fig. 1 is a section of the vault constructed under the bridge-house, or place where the materials are proportioned, previously to their being thrown into the furnace. One half a blast furnace outline, is seen as connected in point of situation and blast to the air magazine.

A, the termination of the blast pipes that convey the air from the blowing cylinder into the receiver, 3 feet diameter; the length depends upon the contiguity of the engine to the vault.

B B B B, four vaults, 13 feet wide each, 25 feet deep, and 10, 11, 12, and 13 feet high to the springing of the arches; total height to the crown of the arches, 163, 173, 183, and 193 feet. These cells communicate with each other by arched openings in the crofs-walls, which may be diftinctly seen in the ground plan at L.

C C, the eduction pipes that carry the air to the furnace; 18 inches diameter.

D D, end view of the range of laying pipes at the tuyere of the furnace. The dotted lines betwixt D and C are meant to represent the horizontal range of the pipes.

E E, part of the outline of a blast furnace to shew its proper situation to the air vault.

F F F F, floor of the respective vaults, composed of a mixture of two parts of burning dust, two of fine riddled lime, and one part of fine roasted iron flue, mixed up into plater with water containing a considerable portion of salt.

G G, end walls of bricks or stone, four feet thick.

H H H, lining of brick-work, built in the most accurate manner, with fine riddled mortar, and run every second or third course with mortar made thin and very liquid. These walls are two feet and a half in thickness, are carefully plastered, and afterwards covered with several layers of strong paper and pitch, to prevent the escape of air. The roofs of the vaults are finished in the same manner.

I, door arch into the vaults; entrance obtained by means of a ladder or wooden flaps suspended within.

K K, space above the arches; entrance obtained by means of a ladder or wooden flaps suspended within.

L L L, openings of the cross-arches, which communicate the vaults with each other.

The cubical contents of a vault, constructed according to these dimensions, will amount to 20,000 feet.

In general, it may be remarked upon the construction of the blowing machine, that since the period of the introduction of Mr. Watt's engine, the air-pump, or blowing cylinder, has been constructed so as to discharge a cylinder full of air every second and decent of the piston. This, instead of travelling 4 to 5 feet per stroke, more generally moves 5 feet; and the number of cylinders per minute arc seldom under 24.

Formerly, in the common atmospheric engine, the movement of the piston from top to bottom, and back again, produced only one cylinder full of air from the air-pump, and the number of cylinders discharged per minute seldom exceeded 16. A steam cylinder of 40 to 44 inches diameter, and an air-pump of 6 feet diameter, the piston moving about 5 feet per stroke, were deemed sufficient in the construction of a blowing machine for two blast furnaces. The quantity of air pumped up and thrown into the furnaces by such an engine seldom exceeded 3000 cubic feet per minute. This, and even a larger quantity, is now thrown into one furnace, and the produce by such means increased from 15 to 25 tons weekly.

The first set of tables following are calculated to shew the quantity of air that would be discharged by blowing cylinders of various diameters, the length and number of the strokes being given.

The second set, to shew what diameter of blowing cylinder is requisite, with a given steam power, to raise the air to a certain density per square inch. See ENGINE, WATER REGULATOR, and REGULATING VAULT.

Note: The table continues with similar entries for various areas and steam capacities, illustrating the relationships between different parameters for steam engines and machinery.
In heredity, a fleur de lys is said to be blown, effanoui, when its leaves are opened, so that buds appear among the fleurons. The arms of the city of Florence are argent, a fleur de lysblown, gules.

Blowing-planks, in zoology, a name given by the people of Virginia to a species of serpent much resembling the European viper, but considerably larger, and very remarkable for its inflating and extending the surface of its head before it bites. Its wound is very fatal.

Blown red, in the manufacture of porcelain. See red.

Blubber, in physiology and trade, the fat which invests the bodies of all large cetaceous fish, serving to furnish an oil.

The blubber is properly the adipose of the animal; it lies immediately under the skin, and over the muscular flesh. In the porpoises, it is firm and full of fibres, and invests the body about an inch thick. In the whale, its thickness is ordinarily six inches; but about the under lip, it is found two or three feet thick. The whole quantity yielded by one of these animals ordinarily amounts to forty or fifty, sometimes to eighty or more hundred weight. Phil. Trans. No 77: p. 2275.

The use of the blubber to the animal seems to be partly to poise the body, and render it equiponderant to the water; partly to keep off the water at some distance from the blood, the immediate contact whereof would be apt to chill it; and partly also for the same use that cloaths serve us, to keep the fish warm, by reflecting or reverberating the hot streams of the body, and so redoubling the heat; since all fat bodies are, by experience, found less sensible of the impression of cold than lean ones.

Its use in trade and manufactures is to furnish train-oil, which it does by boiling down. Formerly, this was performed abroad in the countries where the whales were caught; but of late the fishers do not go abroad, they bring the blubber home, boiled in casks, and boil it down there.

Blubber-fish. The livers of cods, which having been barrelled, yield spontaneously a considerable quantity of oil, which being skimmed off, the residue are called blubber-livers, to be boiled down for more oil.

Blu

Blowing of a flower, among florists, an artificial process in order to bring a flower to display itself with greater perfection and beauty than it would arrive at in the natural way of blowing. The usual method is thus: about April, when the flower stems begin to put forth, or unfold, as the gardeners call it, they place by each flower a frail flick four feet long, and tie the sundries to it as they float. As soon as the flower-buds appear, they leave only one of the last-mentioned, and thus, in its due course, each flower-bud to blossom. About ten days before the flowers open themselves, the round-ended kinds will begin to crack their husks on one side, when the careful gardener, with a fine needle, splits or opens the husk on the side opposite to the natural fission; and about three or four days before the complete opening of the flower, cut off with a pair of scissors the points on the top of the flower-pod, and supplies the vacancies or openings on each side of the husk with two small pieces of vellum or oil-cloth, slipped in between the flower-leaves and the inside of the husk; by such means, the blossom will display its parts equally on all sides, and be of a regular figure. Besides this care, when the blossom begins to show its colours, they use to shade it from the extreme heat of the sun with a trencobl-like board, or other device of the like nature, fastened to the flick which supports it; for the flowers, as well as fruits, grow larger in the shade, and ripen and decay sooner in the sun.

In heredity, a fleur de lys is said to be blown, effanoui, when its leaves are opened, so that buds appear among the fleurons. The arms of the city of Florence are argent, a fleur de lysblown, gules.

Blowing-planks, in zoology, a name given by the people of Virginia to a species of serpent much resembling the European viper, but considerably larger, and very remarkable for its inflating and extending the surface of its head before it bites. Its wound is very fatal.

Blown red, in the manufacture of porcelain. See red.

Blubber, in physiology and trade, the fat which invests the bodies of all large cetaceous fish, serving to furnish an oil.

The blubber is properly the adipose of the animal; it lies immediately under the skin, and over the muscular flesh. In the porpoises, it is firm and full of fibres, and invests the body about an inch thick. In the whale, its thickness is ordinarily six inches; but about the under lip, it is found two or three feet thick. The whole quantity yielded by one of these animals ordinarily amounts to forty or fifty, sometimes to eighty or more hundred weight. Phil. Trans. No 77: p. 2275.

The use of the blubber to the animal seems to be partly to poise the body, and render it equiponderant to the water; partly to keep off the water at some distance from the blood, the immediate contact whereof would be apt to chill it; and partly also for the same use that cloaths serve us, to keep the fish warm, by reflecting or reverberating the hot streams of the body, and so redoubling the heat; since all fat bodies are, by experience, found less sensible of the impression of cold than lean ones.

Its use in trade and manufactures is to furnish train-oil, which it does by boiling down. Formerly, this was performed abroad in the countries where the whales were caught; but of late the fishers do not go abroad, they bring the blubber home, boiled in casks, and boil it down there.

Blubber-fish. The livers of cods, which having been barrelled, yield spontaneously a considerable quantity of oil, which being skimmed off, the residue are called blubber-livers, to be boiled down for more oil.

Blue, sea, a denomination given by our navigators to the artica marina, or sea-nettle. Phil. Trans. N° 319.

Bludentz, in geography. See incident.

Blue, one of the seven primitive colours of the rays of light, into which they are divided, when refracted through a glass prism. See colours, and refraction.

Ancestrally blue was the symbol of the sea; for which reason, in the Circenian game, the combatants who represented the sea were clad in blue; and those who had distinguished themselves by any notable exploit at sea, were rewarded with a blue cushion.

Mr. Boyle has given us the following method of making transparent blue, nearly equal to ultramarine. The principal ingredient of this beautiful colour is the cyanus, or blue corn-bottle flower, which abounds almost in every corn-field, and may easily be had during four of the summer months. It may be gathered by children about the verges of cornfields, without doing any damage to the corn. This flower has two blues in it, one of a pale colour in the large outer leaves; and the other of a deeper blue, that lies in the middle of the flower. Both these will do, being separated from the buttons or cafes in which they grow; but the deep blue leaves in the middle produce much the better colour: this may be observed by rubbing the leaves while they are fresh upon a piece of writing-paper, so hard as to express the juice, which will yield an excellent colour, that by the experience of two or three years has not been found to fade. A sufficient quantity of these middle leaves being procured, let the juice be press'd from them; to which a little alum being added, will give a lasting transparent blue, scarcely inferior in brightness to ultramarine. It is very probable, that if the chives of these flowers were cured in the same manner with tallow, they would produce a much greater body of colour, from which a tincture might be drawn with more ease than when pressed fresh from the field.

Mr. Boyle also recommends another fine blue, produced from the blue leaves of rue beaten in a flan mortar with a wooden pestle, and then put in water for fourteen days or more, washing them every day until they are rotten. These beaten up at last, water and all, until they become a pulp, and then dried in the sun, will make a fine blue for shading.

Blue Aftes, cendres bleues. See verditer.

Blue bis, is a colour of good brightness, next to Prussian blue; it is also a colour of a body, and flows well from the pencil. See Bice.

Blue, in dying. See dying, Indigo, and Wood.

Blue black. See black.

Blue enamel. See auber Enamel.

Blue, Flanders, is a colour seldom used but in landscapes, as being apt to turn green. The French call it cendres violets, or green athes.

Blue for painting or staining glasses. See glass.

Blue Japan. See Japaning.

Blue Indigo. See indigo.

Blue Lithmus, or Lithmus. See Lithmus.

Blue, Painters', is made differently according to the different kinds of paintings. In liming, fresco, and miniature, they use indifferently ultramarine, blue athes, and finial; these are the natural blues, excepting the last, which is partly natural, partly artificial. See each under its proper head. In oil and miniature they use indigo, blue bis, blue verditer, laps argent., finial, and Lithmus, also a counterfeit ultramarine. Enamellers and painters of glafs have blues peculiar to themselves; each preparing them after his own manner. See enamelling, painting on glass, and Neumann's Chem. Works, by Dr. Lewis.

Blue,
BLUE

**Blue, Prussian.** See Prussic Acid.

**Blue, Saxony,** a solution of indigo in sulpheric acid. See Indigo.

For an account of the proceeses for obtaining blue liquors from oak-duct and vitriol, from log-wood and verdigris, from log-wood and blue vitriol, from an effential oil and volatile spirit; see Dr. Lewis’s Commercialis Philosphico-Technicum, ed. 4to, ann. 1773, p. 382. 457. 456.

**Blue, Stone, or Powder,** used in washing of linen, is the same with smith, either in the lump, or powdered. When the film is taken from the pot, it is thrown into a large vessel of cold water: this makes it more tractable and easily powdered. Afterwards, when examined after cooling, it is found to be mixed with a greyish matter resembling ashes, which they call sebula. This grey matter it separated by washing, and then the blue substanse is powdered and sifted through fine sieves, to bring it to what we call powder-blue. Phil. Trans. No. 396. See Cobalt.

**Blue, Turnbull,** is a blue used in painting on wood, made of the feed of that plant. It is prepared by boiling four ounces of turned in a pint and a half of water wherein lime has been flaked. See Ternsol.

**Blue, Ultramarine.** See Lazuline.

There is a blue sufflance, something like what Kentman mentions under the name of *calceum patraenia.* It was discovered in a peat-moss in Scotland. This earth is at first of a white colour, and only grows blue by being exposed to the air. It has also some resemblance to what Mr. de Colfa in his Nat. Hist. of Foss. p. 103, calls *acrida friabilis cartula.* It is describ’d very minutely by Mr. Douglas, who gives an account of his various experiments upon it, and recommends it as a cheap paint in gum water, particularly as it is levigated and prepared by nature. See Phil. Trans. vol. viii. No. 27. an. 1768.

Many similar specimens of blue earth have been discovered in England and Ireland, and several parts of the continent.

**Blue-ball,** a name given in some countries to the Corn-Wheat.

**Blue-bottle,** in Botany. See Centaurea.

**Blue-Cap,** in Lithology. See Blew-Cap.

**Blue,** the common appellation, among the Derbyshire miners, of Fluor-Spar.

**Blue Mantle Pursuivant of Arms.** This officer is by patent a member of the corporation of heralds. Sir Henry Spelman conjectures, that the title was taken from the colour of the mantle of the French kings. This office is said to have been instituted by King Henry V., and probably might be coeval with that of Garter, and erected with reference to that order; but although the catalogues place John Wexworth and others by this title under the reign of Henry V.; Anthony Wood ascribes the creation of this office to Henry VI., in whose 26th year Bluemanite Pursuivant waited on Bruges, Garter king of arms, into France, and also on the bishop of Chichester and others, ambassadors thither. Previous to that date there are not any entries on record relating to this officer; but from thence to the present time the succession hath been carried on without any interruption.

**Blue Nuns, filles blues,** those of the order of the Annunciation.

**Bluefield’s Bay,** in Geography, a bay in the island of Jamaica, lying S.E. of Savannah-la-Mar, and having good anchorage for large vessels. N. lat. 18° 10’ 30’’. W. long. 78°.

**Bluefield’s, or Bluefield’s Bay,** a bay on the western coast of Nicaragua, in New Spain, into which a river of the same name is discharged. N. lat. 11° 40’’. W. long. 83°.

**Bluehill,** a township of America, in Hancock county and district of Maine, on the west side of Union river, 344 miles N.E. of Boston, and 13 E. of Penobscot; having 274 inhabitants.

**Bluehill Bay,** a bay of America, formed by Naiscag point on the west, and Mount Defart island on the east, and extending northly to a mountain on the east of Penobscot river, which, from its appearance at sea, is called “Bluehill.” Union river discharges itself into this bay.

**Blue Hills,** a range of mountains in New England, the first ridge of which in New Hampshire passes through Rochefur, Barrington, and Nottingham.

**Blue Mountains,** are mountains of America, in Northampton county, and state of Pennsylvania, extending from S.W. to N.E. and through a small interval across the Delaware.—Alfo, a range of mountains, which run from S.E. to N.W. through Surry county, in the island of Jamaica. Blue mountain peak is said to rise 7431 feet above the level of the sea; and the precipices are interperfed with beautiful savannahs.—Alfo, a mountain in Ruffia, part of the Aitay mountains. See Sinnaia Sopka.

**Blue Ridge, or South Mountain,** is the first ridge of the Alleghany mountains in Pennsylvania, Virginia, and North Carolina, distant from 130 to 200 miles from the sea, and, measured from its base, about 4000 feet high. Between this and the north mountain is a large fertile vale. The passage of the Potowmack river through this ridge is one of the most rupendous scenes in nature. See Alleghany Mountains, and Potowmack River.

**Blue Licks,** lie on the main branch of the Licking river in Kentucky, and are situated about 8 miles westerly from the Upper Blue Licks. Both of them are on the N.E. side of the river; and the latter is about 15 miles N.E. of Millers.

**Blue Spring,** lies between Big Barren and Little Barren river, southern branches of Green river, in Mercer’s county, Kentucky, about 22 miles south-westerly from Sulphur spring, and 13 south of Craig’s fort, on the north side of Green river.

**Blue Stone Creek,** a small western branch of the Great Kanawhaway.

**Blueness,** that quality which denominates a body blue, depending on such a size and texture of the parts that compose the surface of a body, as dispose them to reflect the blue or azure rays of light, and those only, to the eye.

With respect to the blueness of the sky, M. de la Hire, after Leonardo da Vinci, observes, that any black body viewed through a thin white one, gives the sensation of blue; and this he ascribes as the reason of the blueness of the sky, the immense depth of which being wholly devoid of light, is viewed through the air illuminated and whitened by the sun. For the same reason, he adds, it is that foot mixed with white makes a blue; for white bodies, being always a little transparent, and mixing themselves with a black behind, give the perception of blue. From the same principle he accounts for the blueness of the veins on the surface of the skin, though the blood they are filled with be a deep red; for red, he observes, unless viewed in a clear, strong light, appears a dark brown, bordering on black: being then in a kind of obscurity in the veins, it must have the effect of a black; and this, viewed through the membrane of the vein and the white skin, will produce the perception of blueness.

In
In the same way did many of the early writers account for the phenomenon of a blue sky; such as Fromondus, Fucceans, Otto Guericke, and many others: their opinion long prevailed, and has been adopted by some in more modern times, especially by Wolfius and Mushenbroek. But in the explanation of this phenomenon, Sir Isaac Newton observes, that all the vapours, when they begin to condense and coalesce into natural particles, become first of such a bigness as to reflect the azure rays, before they can constitute clouds of any other colour. This, therefore, being the first colour which they begin to reflect, must be that of the finest and most transparent flakes, in which the vapours are not arrived to a groviness sufficient to reflect other colours.

M. Bouguer, without having recourse to the vapours diffused through the atmosphere, in order to account for the reflection of the blue-making rays, ascribes it to the constitution of the air itself, whereby these fainter-coloured rays are incapable of making their way through any considerable tract of it. And he accounts for those blue shadows, which were first observed by M. Buffon in the year 1742, by the aerial colour of the atmosphere, which enlightens these shadows, and in which the blue rays prevail; whilst the red rays are not reflected so soon, but pass on to the remotest regions of the atmosphere.

The Abbé Mazas, in a Memoir of the society in Berlin, for the year 1752, accounts for the phenomenon of blue shadows by the diminution of light; having observed that, of two shadows which were call upon a white wall from an opaque body illuminated by the moon, and by a candle at the same time, that which was enlightened by the candle was reddest, and that which was enlightened by the moon was blue. However, the true cause of this appearance seems to be that assigned by M. Bouguer, which agrees with the solution given of it about the same time by Mr. Melville. But instead of attributing the different colours of the clouds, as Sir Isaac Newton does, to the different size of those globules into which the vapours are condensed; Mr. Melville supposed, that the clouds only reflect and transmit the sun's light; and that, according to their different altitudes, they may assume all the variety of colours at fun rising and setting, by barely reflecting the sun's incident light, as they receive it through a shorter or longer track of air: and the change produced in the sun's rays by the quantity of air through which they pass, from white to yellow, from yellow to orange, and lastly to red, may be understood agreeably to this hypothesis, by applying to the atmosphere what Sir Isaac Newton says concerning the colour of transparentliquors in general, and that of the infusion of hydrogen sulphuricum in particular. Edinb. Eff. vol. ii. p. 75; Bouguer Traité d'Optique, p. 268, Newton's Optics, p. 228; or Priestley's Hist. of Vition, &c. p. 436—440.

BLUFF-HEAD, or Bluff-headed, in the Sea-Language, is when a ship has but a small rake forward on, being built with her stem too straight up.

Bluff-headed ships are opposed to those that are sharp-headed. They are shorter, less masted, and fail cheape.

BLURING of IRON, a method of beautifying that metal sometimes practised; as for mourning buckles, fwords, or the like. The manner is thus: take a piece of grind-flone, and whet-flone, and rub hard on the work to take off the black scurf from it; then heat it in the fire, and as it grows hot, the colour changes by degrees, coming first to a light, then to a dark gold colour, and lastly to a blue. Sometimes they grind also indigo and fallad-oil together, and rub the mixture on the work with a woollen rag, while it is heating, having it to cool of itself.

Among sculptors we also find mention of bluing a figure of bronze, by which is meant the heating of it, to prepare it for the application of gold leaf, because of the bluish color it acquires in the operation.

BLUM, JOACHIN CHRISTIAN, in Biography, an esteemed German poet, was born at Rathenau, in 1739, and received the early part of his education in his father's house, from a lady, who was the governess of his sisters. At the age of eleven years he lost his father, and became master of a library, of which he availed himself to great advantage. During his residence with his mother and sisters, he amused himself with writing hymns on the harpsichord, and with reading moral authors, and reciting odes, which he did in a manner so affecting as to cause his hearers to find tears. His mother concluded, that he had an inclination to become a clergyman, and with this view placed him, in 1754, at a school in Brandenburg, where he manifested by his course of reading, and also by his performances, a strong turn for poetry. In 1757, he removed to the gymnasium at Berlin; and giving up all thoughts of the ministerial office, he devoted himself to the study of philosophy and the belles lettres, indulging himself occasionally in his favourite pursuit. From Berlin he proceeded, in 1759, to Frankfort on the Oder, where he studied for some time under Baumgarten, for whom he professed the highest respect; but when this city fell into the hands of the Russians, he retired to the house of his mother; and as his health was in an invalid and declining state, in consequence of an accident which had almost proved fatal to him in his youth, he determined to continue with his mother, and to devote the remainder of his days to the muse in his native place. Here he closed his life, Aug. 28, 1790. His poetical works were "Lyrical Poems," and "Idylls," published at various periods after the year 1757. A dramatic piece, in praise of his native town, entitled "Rathenau delivered," was often represented at Berlin with applause, but forbidden in compliance with the request of the Swedifh ambassador. Blum's poetry is said to be characterized by loquacity, simplicity, and correctness, and he ranks among the best poets of Germany. He also published some volumes under the title of "Walks," two volumes of "Orations," and a collection of "German Proverbs." His works in general were much read, and approved by persons of the first distinction. The late king of Prufia, Frederick William, honoured him with a very particular token of favour. As Blum's health required his residence in the country, he purchased, in 1787, a small estate, upon which was a mansion in a very ruinous condition; but having in the purchase exhausted almost the whole of his property, he could not repair his house without assistance; and, therefore he addressed a poetical epistle to the king, in which he introduced the following lines:

"O aid thy poet, gracious prince,
And free his bread from care;
All that he asks is competence
His mansion to repair.
Those mould'ring walls, which long have stood
Offensive to the eyes,
A temple then to gratitude,
Shall renovated rise.
His groves, near yonder wand'ring stream,
Whole banks with reeds are crown'd,
Thus consecrated groves fill'd with fame,
And shine the hallow'd ground!"

With this address his majesty was so much pleased, that he ordered for him 1200 rix-dollars. Blum expressed his gratitude: in a second epistle, to which the king returned his best
BLÜ

BLA

wishes. Besides the Greek and Latin, he well understood the French, Italian, and English languages; and he had studied with great attention the history of the Christian church. Gen. Bog.

BLUMBERG, in Geography, a small town of Germany, in the landgrave of Baar.

BLUMENAU, a bailiwick of Germany, in the principality of Calenberg, feated on the Leine.

BLUMENFELD, a town of Germany, in the circle of Swavia, and commandery of Minau, feated on the river Ach; 8 miles N.N.E. of Schaaffhausen.

BLUMENFRAST, J. DEODATUS, in Biography, took his degree of doctor in medicine in Leyden. Returning thence to Russia, his native country, he was soon distinguised by the emperor, who made him archi- torial and principal physician to his court. He had also the honour of being appointed the first president of the Royal Academy of Sciences at Petersburg, which had been instituted, Haller says, by his exertions. He died at Moscow at an advanced age, in April 1755, leaving only one publication, which was first printed in the year 1700, 4to. "Medicus Calendens Exercitui Moscovitatum." Haller Bib. Med. Pract. Elyot, Dict. Hist.

BLUMENTHAL, in Geography, a bailiwick of Germany, in the duchy of Bremen.

BLUMIS ALP, a majestic eminence of the Alpes, in the canton of Bern, in Switzerland, terminating the valley of Lauterbrunnen, and having at its feet a large glacier, which fretches towards the valley of Gifter. The Blumis Alp, and also the feet of the Alpichelenhorn, are covered with black schilfus; but the granite is not apparent, except at a considerable height. The sides of the Blumis Alp, bordering the glacier, are black slate, in which have been found several belemnites, and a fragment of a Corru Ammonis, a foot in diameter.

BLUNDERBUS, in the Military Art, a short fort of fire arm, with a large bore contrived to carry a number of musket or pilote bullets at once. The blunderbus is pro- per to do execution in a crowd, or to make good a narrow pallsage, as the door of a house, Rair-cafe, or the like.

BLUNT, in Fencing. To fight with blunts, is to exer- cise or parade with weapons without points or edges.

BLUNTING the angle of a batalion, in the Military Art, signifies to retrench the four corners, and turn the square into a bason. This is done in order to give an opportunity for presenting the pikes, or firing on all sides, and was a military evolution formerly much in use, but now difused.

BLUSHING, a suffusion or redness of the cheeks, ex- cited by a fent of flame, on account of conceitfulness of some failing or imperfection. See ENCHYMOMA.

Blushing is supposed to be produced from a kind of con- fent or sympathy between several parts of the body, oc- casioned by the fume being extended to them all. Thus the fifth pair of nerves being branched from the brain to the eye, ear, muscles of the lips, cheeks, palate, tongue, and nose; a thing seen or heard, that is shameful, affects the cheeks with blushing, driving the blood into the minute veins thereof; at the same time that it affects the eye and ear. For the fame reason it is, as Dr. Derham observes, that a favoury thing seen or smelt, affects the glands and parts of the mouth; if a thing heard be pleasing, it affects the muscles of the face with laughter; if melancholy, it exerts itself on the glands of the eyes, and occasions weeping, &c. And to the fame cafe Dr. Willis ascribes the pleasure of killing.

BLUSTERING, which is that where the wind blows with various degrees of strength, attended with a dark sky, rain, snow, &c.

BLUTEAU, DON RAPHAEL, in Biography, a religious theatre, was born of French parents in London in 1698. After having distinguished himself in sacred and profane literature, he visited Portugal and acquired such knowledge of the language as to be able to preach in it with applause. From Portugal he returned to Paris, and was for some time preacher to Henriette-Maria, queen of England. Upon revisiting Portugal, he obtained an office in the inquisition, and became member of the Royal Academy of History. Of his works, the most esteemed is "A Portuguese and Latin Dictionary," in 8 vols. fol. Continua 1712—1721, to which he added a Supplement in 3 vols. fol. Lisbon, 1727, 1728.

He died at Lisbon in 1734, at the advanced age of 56. Morevi.

BLUTFINK, in Ornithology, one of the synonymous names of voisza pyrhril, the common bullfinch. Frisch.

BLY, in Geography, a river of South Wales, which runs into the Tivy, about 3 miles S.S.E. of Card- digan.

BLYTH, in Geography, a small market town of Nottinghamshire, in England, has been the seat of a castle and a priory; but these buildings, with their endowments and pri- vileges, being entirely demolished at the dissolution, the town also sunk in the general wreck, and has never since been renovated. The whole parish consists now only of 157 houses, and 589 inhabitants. Here is a small market on Wednesdays, and two annual fairs. The church is a large handsome structure, and contains several ancient monuments. Some of the Creffy family built an hospital here, which bears the name of Blyth-spittle.

BLYTH, or South Blyth, a small sea-port town of Northum-berland, in England, is a place that has obtained its folk con- sequence since the restoration; for, previous to that period, here were scarcely any houses. In the year 1728, its trade had so much increased that above 200 vessels were entered in the custom-house books as failing from this port. It is con- sidered as a creek to the port of Newcastle, and its principal trade is in coals. Blyth is 14 miles N. E. of Newcastle, and 288 miles N. of London. The township contains 193 houses, and 1170 inhabitants, of whom 234 are em- ployed in trade. Here is a small market on Saturdays. About three miles south of Blyth, is Scaton Delaval, a feot belonging to lord Delaval, whose grandfather, sir Francis Blake Delaval, was an able admiral in the beginning of the last century. He was often projecting some improvements in the ports near his seat, and after surmounting great difficulti- es, contructed one upon a new plan, which now bears his name.

BMI, in Mysie. See GAMUT.

BOA, in Zoology, a genus of the Serpent race, distin- guished by having plates, or undivided fepta, both on the belly, and beneath the tail; the latter of which, unlike the croatil, does not terminate in a rattle.

Such is the Lincean character of this genus, the species of which are not very numerous. Ginellin enumerates the following kinds in the Syllena Nature: contrarix, canina, hipnale, constrictor, cenchris, ophiys, cynphis, minura, fytale, and hortulan. But in addition to these, we are to mention a few other species described by Dr. Patrick Ruffel in a recent publication on the serpents of India, with the observations of Dr. Shaw upon the newly dis- covered kinds, and several others lately spoken of by con- tinental writers.

Dr. Ruffel, in the work above cited, has four new species of
BOA

of boa, called, in the Indian language, lungarum fanab, budain coote, geidi paragando, or in the young flat cobra mouil, and horatta pan. These are the species, falcicata, viperea, lineata, and horatta of Dr. Shaw's zoology. Dr. Shaw has likewise increased the number of the box by the addition of a fifth species, crotalus mutus of Linnaeus, which he is induced to remove from the crostai to this genus, because it is not furnished with a genuine rattle like the rest of that tribe.

But the French writers of the present day have regarded the arrangement of the Swedish naturalist in the amphipithic class of animals with much less indulgence, their alterations tending to little else than the subversion of his system. The box genus, as established by Linnaeus, is obviously defective, in one point at least, where nature had herself preferred those characters which ought not to have escaped the discrimination of the naturalist. Nothing, we must admit, can be more improper, if it could have been avoided, than to include in the same natural family both the venomous and inoffensive kinds of serpents; or, in other words, to unite, under one head, those which, having fangs for the conveyance of poison into the wound inflicted with their bites, are highly dangerous, and such as have no fangs for this purpose, and are therefore comparatively harmless. The first innovation upon the Linnaean genera was made by Lacépede, whose method has been followed by others; and lastly, by Latreille, with some improvements, in his Natural History of Reptiles.

Latreille retains among his box those only of the Linnaean species which have no venomous fangs; for the reception of the remainder he establishes the new genus Scytale. This genus forms an intermediate link between the two Linnaean genera boa, and crotalus; having, in common with both, the abdominal plates, and either plates alone, or plates and scales beneath the tail; the poisonous fangs removing them from the box, and the naked tail from the crostai, or snakes that have a rattle at the extremity of that part. The box of Latreille contain the following species: le boa devin (constrictor, Linn.), le boa gient (a species hitherto confused with the former), le boa bojoti (boa canina, Linn. and Lacépede), le boa bipala (bipala, Linn.), le boa cenobrit (cenobrit, Linn.), le boa enbyre (enbyre, Linn.), le boa epahrie (ophrias, Linn.), le boa fystale (fystale, Gmel. Scheuchzer), le boa brodi (brotula, Linn.), le boa ratrave (Seba, v. 2. pl. 29. 1.), and le boa tarte, a native of the Greek islands, described by Olivier in his "Voyage dans l'Empire Ottoman."—Thus the Linnaean boa constrictr, a poisonous species, le fystale a grand of this writer, is removed from among the box to the genus Scytale, together with another species not before described, le fystale a tete plate, and the four new species mentioned by Dr. Rüffel belong unquestionably to the same genus, being all of the venomous kind. We have, therefore, six species of the Scytaleas confused with the natural family of boa.

The box, taken collectively, exceed in magnitude all the other tribe of serpents. The powers of certain species, like their future, are prodigious. These enormous kinds are principally the inhabitants of the burning regions of Africa, whose fame, in this respect, was celebrated in ages of remote antiquity. History speaks of these tremendous serpents in terms that stagger credibility; but travellers of our own times, who have had the opportunity of observing these creatures in their native haunts, and whose relations deliver every rational degree of credit, afford so much collateral evidence, that we are not allowed to reject the authority of the ancients in many of the most material points. When Valerius Maximus relates, upon the authority of Livy, the contest between an army of Romans under Attillius Regulus, and an enormous snake, that disputed with them, for a considerable time, the passage across the river Bagdara in Africa, and was at last only overcome, after killing many of the soldiers, by means of the battering machines employed in attacking fortresses, we are inclined to suspect the whole as fabulous. If, however, we reflect at the same time upon the size and power of this monitor, the skin of which, when taken off, was 120 feet in length, we need not be astonished at the resistance it was capable of making. Something must be allowed on this occasion for the luxuriance of fancy, or the fictions of the battle between the Phoenicians, and the faced snake of Mars, would almost shrink from comparison with this surprising adventure.

Tite vulilibilis squamofos nuxibus orbes
Torquet, et inmensos sola munitor in aeras
Ac media plus parte leves eructus in auras
Defpacit omne nemus:----

Nec mora: Phoenicas (five illa tala parabant,
Dive fugam: five ipse timer prohibebat utrumque)
Occupat: boa mora, longis complexibus illos;
Hos recitatis flammea tanti venom.
Ovid.

The serpent mentioned by Livy is believed to have been an overgrown creature of the boa genus, the constrictr of Linnaeus; a kind which, from the ferocity of its size, is emphatically denominated the "King of Serpents." This species, of which we shall speak more largely in another place (vide Constrictor), is found occasionally in Africa, Asia, and South America, from 20 to 30 feet in length, and even more; and of a strength so great, as to be able to destroy most of the larger animals by the violence of its pressure only. We have seen the skins of this particular species almost 20 feet in length, and of a bulk proportionate. Among the articles of Natural History, collected in South America for the National Museum at Paris, but intercepted, and sold in this country, there were several specimens: dried skins of this kind are also preferred in the British and Leverian museums, and in most of the public museums on the continent, which at once remove every unreasonable degree of fascination as to the actual existence of such a monstrous kind of serpent.

If, therefore, according to the ideas of latter writers, the true boa be delirium of poisonous fangs, nature has more than amply supplied the deficiency by the powers they are endowed with for the destruction of their prey. The elephant, the rhinoceros, the hippopotamus, and the lion, are the only animals that can refresh them with success. The flag, the leprous, and even the buffalo, entangled once within the coils of the body of the boa, must fall an easy victim to its voracity. The boas, among serpents, what the elephant and the lion are among quadrupeds: like the elephant, they surpass the rest of the serpent race by their size; and, like the lion, excel them in their address, their courage, and their force. They seldom attack their prey by artifice, decoying their unwary adversary, and, by a wound as sudden as insensible, paralyzing its efforts with the deadly torpor of their poison. Confident in their powers, they attack them openly; oppose their strength to the resistance of their enemy with ardent intrepidity; and when they conquer, it is by the manifest superiority of bodily vigour over that of their opponent.—It should be observed, that these traits of character relate only to the largest of the boa genus, of which no more than two species are correctly ascertained, although there is reason to believe the number must be greater. Much confusion prevails among travellers who have described these serpents: they have entered largely into the prodigies of their history, without paying any due regard to the description
tion of the animals themselves, a circumstance that has hitherto involved this matter in obscurity; and leaves us in considerable doubt as to the real number of distinct species already discovered, and mentioned by those travellers. See Constaev's *Cosmographia*.

Boadicea, in *Ancient Geography*, a place of Italy, on the Aenian way, in the route from Rome to Arclato, through Etruria and the Maritime Alps. Anton. Itin.

Boadicea, in *Geography*, a town and port of Hindoostan, in the country of Orissa, near the Mahanahab river; 35 miles S. E. of Sumulpour, and 100 west of Calcutta. *N. lat. 29° 40'*. *E. long. 84° 10'.

Boadicea, Boudicia (Tacitus), or Boudica (as she is called by Dion), in *Ancient British History*, a queen of the Iceni, celebrated for her misfortunes, and for her formidable, though unsuccessful, resistance to the Roman power in Britain.

At the time when the revolt, of which Boadicea was the principal mover, took place, the southern part of the island had tranquilly submitted to the government of the Caesars. Although scarcely 18 years had elapsed since the invasion of Claudius, Britain was already considered an important acquisition. Several flourishing colonies were founded; numerous settlers flocked from the more distant provinces of the empire, and the only expedition which employed the legions, was that undertaken against the beleaguered island of Mona, the principal remaining fast of Druidical superstition. But amidst this seeming security, the oppression exercised by individuals excited indignation among the natives. The procurator, Catus Decianus, who, in the absence of the proconsul, possessed the exclusive administration of government, behaved with the most insufferable tyranny; and, according to the confession of Tacitus himself, the great men of the nation were treated as slaves, and deprived injuriously of their estates by this upright governor. The fear, however, of incuring the imperial resentment, restrained them from expressing their dissatisfaction otherwise than by murmurs, till the decafe of Praetagus, king of the Iceni, brought matters to a crisis. This monarch, by his attachment to the party of the invaders, had merited the title of friend and ally of the Roman people, and by his last will, had bequeathed his estates as a joint inheritance between the emperor Nero and his two daughters. His policy, if intended as such, failed of the desired effect. The procurator, under pretence of carrying the testament into execution, feized on all the possessions of Praetagus without exception; and as Boadicea dared to murmur against such flagrant injustice, he actually caused herself to be publicly scourged as a slave, and the chastity of her daughters to be violated by his officers.

Such outrages were beyond sufferance. The Iceni to a man rose up in arms, headed by Boadicea in person, who to a masculine spirit joined a gift of natural eloquence calculated to inflame the minds of a barbarous multitude. The Trinobantes, and other neighbouring nations, alike incensed, and an army of 100,000 lancers being rapidly formed, marched directly against Camulodunum, (supposed to have been Maldon,) the metropolis of the Roman colony. As Decianus could only spare a few trollops to affill the inhabitants in its defence, the place was almost instantly consumed, and, with a temple lately erected to the divinity of Claudius Cæsar, reduced to ashes, all within it being previously massacred. The ninth legion, which had ventured to take the field against the insurgents, was next attacked and defeated. The infantry were almost totally destroyed. The commander, Petullus Cerialis, at the head of his cavalry, with difficulty regained his camp, where he carefully intrenched himself; while Catus Decianus, terrified at the consequences of his infamous conduct, made his escape into Gaul, covered with universal odium.

After such a series of ill-fortune, the only hope of the Romans remained vested in the proconsul Suetonius Paulinus, at this time occupied in exterminating the Druids of Mona. On receiving news of the proconsul made by Boadicea, he immediately marched, though by a dangerous route, and through the midst of an hostile country, to Augusta (London), already a considerable place, though not yet dignified with the name of a colony. As he judged this poll untenable, he retired to unite his scattered forces, accompanied by such of the inhabitants as chose to follow his fortunes; but the women and children, the old and infirm, who were left behind, without any other protection than their sex, their age, or their situation afforded, were indiscriminately sacrificed to the fury of the Britons. Verulamium, another colony, shared the same fate. All foreigners were everywhere put to the sword, and the cruelties, paid by Dion to have been executed upon some of the sufferers, are shocking beyond description.

The rebellion had now attained its utmost height. Three Roman stations laid in ashes, and the blood profusely poured of 70,000 of her persecutors, had amply avenged the wrongs of Boadicea. The whole calmer part of the island was in possession of her partisans, and her forces in arms had increased to the amazing number of 230,000, when Suetonius, having taken every measure prudence could suggest in his circumstances, prepared to check this torrent in its course. The proconsul, although accused, and perhaps with justice, of pride and excessive cruelty, yet possessed the molt splendid military talents. During the last reign he had signalized himself, when commander in Africa, by a complete victory over the rebellious Mauritanians. Nero rewarded his bravery by naming him to the government of Britain. The late reduction of Mona had increased his celebrity; and he appears to have been the only general then in the empire, Corbulon probably excepted, equal to the task of reducing the insurrection raised by Boadicea. His situation was, however, extremely critical. It was in vain that he dispatched instructions to Pannius Polithmenus, who commanded the second legion, to march to his assistance. Pannius, in consequence of some difference with his general, or actuated by a secret jealousy, refused to move, in direct disobedience to orders. Thus Suetonius was left in the condition of the troops attacked, and auxiliary cohorts, only amounted to about 15,000 men. With this army, small as it was, he determined on hazarding a battle, and therefore waited the approach of the Britons on a narrow spot of ground, opening in his front into an extensive plain, while his rear was protected by a thick wood. According to the usual disposition observed by the Roman armies, the legionsaries were stationed in the centre, flanked by the light armed and auxiliary cohorts the wings being composed of cavalry. Suetonius did not tarry long in expectation of the enemy. The Britons soon appeared, covering the plain in immense numbers. Their waves and children, who had accompanied them to become spectators of a victory already conferred, the certain, were mounted in heaps on waggons, encircling the field in their rear, like an amphitheatre. Boadicea, with her two daughters, drove in a chariot along the ranks, encouraging her troops in animated language. She renewed the detail of Roman injustice; besought vengeance for the wrongs sustained by herself and her family; magnified the importance of the victory she had already gained, and assured her fol-
Boadicea was described by Dion Cassius as a woman of large stature, strong and well proportioned in her limbs, of a manly
and firm countenance, harle, authoritative voice, and perfec-
ting beautiful golden hair, which reached down below her
waist. That she was possessed of uncommon abilities, or at
least had perils of extraordinary talents to aid her, is evi-
dent from the rapidity with which she cut off the Roman
garrisons one after another; the duration of her forces, so
as entirely to interrupt the communication between the
quarters of the legion; the victory she obtained over
Cereriis, famous for his military knowledge, and the
extremities to which she reduced Suetonius, the greatest
general of the age. Dion is kind in praise of her eloquence,
and puts into her mouth several elaborate orations. We have
preferred the authority of Tacitus, referring, however, such
passages of Dion as are most necessary to elucidate the
narration. The defeat and death of Boadicea are said to have

Dion Cassius, Hist. Rom. lib. xii. cap. 1—12.

Boadicea, in Geography, called also Oren lara, or men of
the sea, are a sort of itinerant fishermen in the East In-
dies, said to come originally from Johon, at the east entrance
of the straits of Malacca, though some are of opinion, that
they must have come either from China or Japan. They
live chiefly in small covered boats, on the coasts of Borneo,
Celebes, and the adjacent islands. Others dwell near the
sea, on these islands; their houses being raised on posts, at
a little distance in the sea, and always at the mouths of rivers.
They are Mahometans; and have a language of their own,
but no written character. Many Boadiceas are settled on
the north-west coast of Borneo, who not only fish, but make
salt, and trade in small boats along the coast. Some of their
boats are from 12 to 18 and 20 tons burden, and carry from
15 to 20 men, and form, in some places, a fleet of a hundred
vessels. Others of them are about 5 or 6 tons burden, which
are managed by women, even in heavy seas. Their method
of making salt is as follows: they gather sea-weeds, burn
them, make a ley of ashes, filter it, and form a bitter kind
of salt in square pieces, by boiling it in pans made of the bark
of the anebong, or cabbage-tree; these pieces of salt are
shipped to market, and passed as a currency for money. Those
that are settled on the north-west coast of Borneo used to
supply the English at Balambangan with rice, fowl, and other
provisions. Many of them are settled at the mouth of the
river of Pallur, who employ themselves chiefly in catching
small shrimps with hand-nets, which they pull through the
mud; the shrimps, after being well washed with water, are
exported to a hot-climate. They are then bound in a mortar,
and made into a kind of palls, called flatshere, which has a
strong smell, and is much in request all over India. These flat
Boadiceas may be considered as stationary or fixed, compared
with those who live always in their boats, and who, as the
monsoon shifts on the islands Borneo and Celebes, shift their
situation to leeward, so as to be always under the lee of the
land, for the sake of fine weather. Most of those who rove
round Celebes, though they change their situation with the
monsoon, consider Macassar as their home. Whillest the
Boadiceas lie at anchor, in boats managed by their women,
they are dextrous in fishing for tringps, i.e. swallows, or
feathered-fish, which they take in seven or eight fathoms water.
When they see the swallow in clear water, they strike it with
an instrument, consisting of four-bearded iron prongs, fixed
along an almost cylindrical fcone, rather smaller at one end
than at the other, about 18 inches long; an iron shot is
fixed at the end of the fcone, next the point of the prongs.
The swallow is dried in the smoke, and sent to the China
market. They also dive for it, the bell being found in deep
water. The black is reputed the best; but there is some of a
lighter colour, found only in deep water, which is more
valued
valued in China than the black, and sold even for 40 dollar a picol; some of the pieces weigh half a pound. The white, caught in shoal water and on the dry land, among coral reefs, is the worst; its value being about four or five dollars a picol. The Boudjous are very useful to the Dutch East India Company, in carrying intelligence speedily from place to place.

442. BOADODA Bafbon, in the Turkish Military Orders, an officer of the janizaries, whose business it is to walk every day about the principal parts of the city, with a number of janizaries to attend him, to keep order and see that all things are regular, even to the doors. This office is for three months, and from this the person is usually advanced to be a fevah.

BOAEE, in Ancient Geography, a town of Peloponnesus in Laconia, at the extremity of the Bracian gulf. Diana was particularly worshipped in this place; Apollo and Eucharis had their respective chapels here. At some flada from this city was a temple of Serapis and Isis. Paunianus.

BOAGRIUS, a river, or rather torrent, of Greece, in the country of the Epicenemidians Loecrines, according to Ptolemy. Strabo says, that it watered the town of Thrion.—Also, a town of the same figure, situated to the west, or the confines of Phocias.

BOANERGES, i.e. Sons of Thunder, in Scripture History, a name given by our Lord to the two apolhs James and John (Mark, iii. 17.), which some have erroneously supposed to be an appellation of reproach, intimating a fierce and furiousness of temper; whereas it is much more reasonable to consider it, with others, as a title of honour, prophetically representing the resolution and courage with which they would openly and boldly declare the great truths of the gospel. When they were made fully acquainted with them. How well they deferred this title, sufficiently appears in the sequel of their history. See JAMES, and JOHN.

BOANS, in Zoology, a species of Rana, or frog, the body of which is smooth, marked with conspicuous spots beneath; and the feet palmed. Gmelin. Two varieties of this kind are described; consisting, having the upper part of the body bluish lead colour, and the with the body inclining to orange. Laurent. Amph. &c.

This kind inhabits America, and differs from rana arborea, the tree-frog, to which it is nearly allied, according to Gmelin, in having all the feet webbed, and the body spotted with white. Much confusion prevails respecting the Linnean species, boas. Dr. Shaw supposes it to be the same as the rana maxima of that author, probably in a younger state. He mentions likewise another supposing variety, the rana virginiana altera of Seba.

BOAR, the wild boar or hog from whence the common hog derives its origin. See Scrofa Sus. The male of the tame hog is also called the boar.

The wild boar is a native of almost all the temperate parts of Europe and Asia, and is also found in the upper parts of Africa. Formerly it was an inhabitant of this country, as appears from the laws of Howel Dda, who permitted his grand huntsman to chase that animal from the middle of November to the Beginning of December. (Leges Wallacie, 41.) There are also many places in Wales that retain the name Penarth, or the Boar's Head, to this day. William the Conqueror punished those who took the eyes any that were convicted of killing the wild boar, the stag, or the roebuck. (Leges Saxon. 302.) And Fitz-Stephen tells us, that the wild boar, which in his time grew on the north side of London was the retreat of flags, fallow-deer, wild boars, and bulls. Charles I. turned out wild boars in the New Forest, Hampshire; but these were destroyed in the civil wars. (Pennant.) In France, Germany, Poland, and other countries on the European continent, they are still common, and the hunting of them is a principal amusement among parties of the gentry. Boar-hunting is a favourite diversion also in other more diffus parts of the world.

These animals are found in the slopes of the Samara and the Volga, in Russia, on the confines of the river Ural in Daoria, and about the Iryth. Between the Ural and the Yamba they are very numerous, and are hunted in winter by the Cossacks, not without danger, with dogs, and sometimes killed with carabinies, and sometimes with lances. Although they feed solely on the roots of tea-wood and fudge, they grow to such an extraordinary size, that they are frequently found weighing upwards of fix hundred pounds; their bacon is nearly four inches thick in fat, though their flesh is in general dry and firm and well-flavoured.

Sonnini thinks it probable (see his Travels in Upper and Lower Egypt, p. 348.) that the wild boars of Egypt are not the same with those in Europe. The great differences of climate, and the still greater difference of situation, must have occasioned at least some varieties in the species of these animals. More multiplied in temperate or cold countries, which appear more fitable to their nature, they inhabit the thick recesses of the forests, where they can find abundance of food. They never leave the woods; but pass from one to another, or to ravage the growing crops, and their predatory excursions are undertaken only by night. In general, they retire to the darkest and closest places at the rising of the sun, the bright stars and heat of which seem to dread. The wild boar of Egypt, on the contrary, has no shelter. Continually exposed to the rays of a burning sun, he roams over the desert lands, where he with difficulty finds a few scattered shrubs, which afford him a scanty subsistence, and fearlessly any shade. He is also frequently seen in the deserts of Nitria, which is the resort of a greater number of animals than any other part of the deserts, on account of the flocks of water it contains, and the plants that grow on their banks. These boars are solitary, though a general want of food sometimes drives them in herds to the environs of the lakes of Natron. As the Mahometans and Copts do not eat the flesh of the wild boar more than that of the hog, and hold both these animals in equal abhorrence, it was impossible, says this writer, to procure a wild boar in Egypt, at least without seeking it in the desert. Upon the whole he concludes, that they are not the same as those of Europe. It is perhaps, he adds, in this sense only that we must understand the passages of Aristotle (Hist. Nat. i. viii. c. 24.), and Pliny (Hist. Nat. i. viii. c. 33.), who have asserted that there are no wild boars in Africa. Wild boars, says Buffon, are as common in Asia and Africa as in Europe. But he has given an account and a drawing of an African wild boar, which is remarkable for several particular characters; and hence there is reason to believe, that the "hazara" of Egypt is the same animal as the wild boar of Africa.

Among huntsmen, the wild boar has several names according to its different ages: the first year it is called a pig of the fander; the second, a hog; the third, a hog-fallow; and the fourth, a boar. When leaving the fander, he is called a fngler, or fngler. The wild boar inhabits woods, living on roots, roots, and other vegetable food. Though glutinous, they do not attack other animals to devour them; but they eat flesh when they meet with it. They have been seen to eat horse-flesh; and the skin of the deer,
deer, and the claws of birds have been found sticking in their stomach, but this may be from necessity. Yet they are fond of blood, since they will eat their own young, or even children in the cradle, according to Buffon. "Wild boars (says this writer) do not separte from their mothers until the third year, and till that age are called by the hunters flock bunches, or batches of company. They never wander alone till they have acquired sufficient strength to resist the attacks of the wolf. These animals, when they have young, form a kind of flocks, and it is upon this alone their safety depends. When attacked, the largest and strongest front the enemy, and by pressing all round against the weaker, force them into the centre. Domellic hogs are also observed to defend themselves in a similar manner. The wild boar is hunted with dogs, or killed by a spear during the night when the moon shines. As he flies slowly, leaves a strong odor behind him, and defends himself against the dogs, and often wounds them dangerously, fine hunting dogs are unnecessary, and would have their nose spoiled, and acquire a habit of moving slowly, by hunting him. Maffets, with very little training, are sufficient. The oldest boars, which are known by the track of their feet, shoud alone be hunted: a young boar of three years is difficult to be attacked, because he runs very far without stopping; but the old boars do not run far, allow the dogs to come near, and often stop to repel them. During the day, the boar commonly keeps in his hole, which is the most secluded part of the woods, and comes out by night in quest of food; and in summer, when the grain is ripe, it is easy to surprize him among the cultivated fields, which he frequents every night.

The boar lives to twenty-five or thirty years, if he escapes accidents. The time of going to rut is in December, and lasts about three weeks. They feed on all sorts of fruits, and on the roots of many plants; the root of fern, in particular, seems a great favourite with them; and when they frequent places near the fen-coat, they will defend to the thores, and demolish shellfish. Their general places of rest are among the thickets bushes that can be found, and they are not easily put out of them, but will stand the bay a long time. In April and May they sleep more soundly than at any other time of the year, and this is therefore the successful time for taking them in the toils. When a boar is routed out of the thicket, he always goes from it, if possible, the same way by which he came to it; and when he is once up, he will never flop till he comes to some place of greater security. If it happens that a fowler of them are found together, when at one breath the rest will follow the same way. When the boar is hunted in the wood where he was bred, he will fear no more be brought to quit it; he will sometimes make towards the fides, to listen to the noise of the dogs, but retires into the middle again, and usually dies or escapes there. When it happens that a boar runs a-head, he will not be flopped or put out of his way by man or beast, fo long as he has strength left. He makes no doubles or crossings, when chased; and when killed, makes no noise, if an old boar; but the fows and pigs will squeak when wounded.

The feaon for hunting the boar begins in September, and ends in December, when they go to rut. 'f it be a large boar, and one that has lain long at rest, he must be hunted with a great number of dogs, and thofe such as will keep close to him; and the huntsman, with his spear, should always be riding among them, and charging the boar as often as he can, to discourage him. Such a boar as this, with five or six couple of dogs, will run to the fire convenient place of shelter, and there stand at bay, and make them as they attempt to come up with him. There ought always to be relays also set for the heft and staunchest hounds in the kennel; for if they are of young eager dogs, they will be apt to fize him, and be killed or spoiled, before the lot come up. The putting of collars with bells about the dogs' necks is a great security for them; for the boar will not so soon strike at them when they have thefe, but will rather run before them. The huntsmen generally kill the boar with their swords or spears; but great caution is necessary in making the blows, for he is very apt to catch them upon his front, or tule, and, if wounded and not killed, he will attack the huntsman in the most furious manner. The places in which the wound is to be given with the spear, are either between the eyes in the middle of the forehead, or in the shoulders; both these places make the wound mortal. When this creature makes an attack, his safety conflicts merely in courage and address; if he flies for it, he is surely overtaken and killed; if the boar comes straight up, he is to be received at the point of the spear; but if he makes doubles and windings, he is to be watched very cautiously, for he will attempt getting hold of the spear in his mouth, and if he does so, nothing can save the huntsman but another person's attacking him behind. He will, on this, attack the second person, and the first must then attack him again. Two people will thus have enough to do with him; and were it not for the forks of the boar-spears, that make it impossible to press forward upon them, the huntsman, who gives the creature his death's wound, would seldom escape falling a sacrifice to his revenge for it.

The modern way of boar-hunting is generally to dispatch the creature by all the huntsmen striking him at once; but the ancient Roman way was for a person on foot, armed with a spear, to keep the creature at bay; and in this case the boar would run of himself upon the spear to come at the huntsman, and push forward till the spear pierced him through.

The hinder claws of a boar are called guards. In the corn he is said to feed; in the meadows or fallow-fields, to root, worm, or form; and in a clofe, to graze. The boar is swarmed with as many teeth as he will ever have; his teeth increasing only in bigness, not in number. Among these there are four called tusks, or tulets, the two biggest of which are of no use to him when he strikes, serving only to whet the two lower, which are his most formidable weapons of defence. As the boar advances in age, he becomes less dangerous, on account of the growth of those tulets, which, when they are very long, take such a curvature, as rather to impede than assist him in wounding his adversary. The Ethiopian boar, or hog, is a still more fierce and dangerous animal than the kind found in Europe. In habits and manners they are pretty much the fame, although specifically different; and, like the common boar, is capable of inflicting the most tremendous wounds with its tulets.

The flesh of the boar was esteemed a delicacy among the ancient Romans; a boar served up whole was a dish of state. The boar was sometimes also the military ensign borne by the Roman armies, in lieu of the eagle. Certain writers of modern date speak of the flesh being wholesome, except to those of athletic constitutions.

A remarkable circumstance concerning the wild boar is related by Sonnini. In the year 1787, an animal of this kind, of a most extraordinary size, was killed in the neighbourhood of Cognac, in Angoumois, which had many times escaped from the hunters, had received many gunshot wounds, and had cut the lives of several dogs and men each time of attacking him. When this animal was at length slain, several bullets are said to have been found be-

Vol. IV.
BOA, between his skin and flesh. Had not the above account been given by hunters of distinguished order, and too well acquainted with these animals to have made any mistake, it might have been imagined, that this formidable creature, which had long charmed its ravens in the park of Cognac, belonged to a different species. It was of an enormous size; with a very long head, a very sharp or pointed snout, and its mouth was armed with teeth of a very singular form. The hairs of the body were white; those of the head yellowish; the neck marked with a black band in form of a cravat; and the ears large and slanting; and what appears surprizing, considering its size, it was of uncommon swiftness. For a further history of this animal, see Scops.

Boar, in the Menage. A horse is said to boar when he shoots out his nose as high as his ears, and tosses in the wind.

Board, a piece of timber sawed thin, for the purposes of building. See Timber.

We say, a deal-board, an oak-board, &c. Boards thicker than ordinary are called planks. Boards formed ready for the cooper's use are called clap-boards. We have also mill-board, and scale-board, shaven very thin, for cafes, band-boxes, &c. Deal-boards are generally imported into England ready shaven, because they are prepared cheaper abroad, by means of saw-mills. Clap-boards are imported from Sweden and Dantzick. Oak-boards chiefly from Sweden and Holland; some from Dantzick. Pile-boards are brought from Dantzick. We also import white boards for shoe-makers; mill and scale boards, palette-boards, &c. for divers artificers. Scale-board is a thinner sort, used for the covers of primers, thin boxes, and the like. It is sawed with mills, and imported from Hamburg.

Board, feather-edged, greening, leg, post, found, trail, wag, weather. See the several adjectives.

Board, is also used for a kind of table or bench, whereon several artificers perform their work.

In this sense, we say a work-board, a shop-board, a tailor's-board, &c.

Board, is also used for a flat machine, or frame, used in certain games, and the like.

In this sense, we say a draught-board, a chefs-board, a shovel-board, and the like.

Boards, in book-binding. See Book-binding.

Board, bureau, is also used for an office where accounts are taken, payments ordered, and the like.

In this sense, we say the board of works, board of ordnance, board of treasury, and the like.

Board of green cloth. See Green-cloth.

Board of Control, was first instituted in 1784, by flat. 24 Geo. III. 2. c. 25, with a view of directing and aiding the East India company, in the executive government of India, and establishing a power of control in this kingdom. This board was further established and regulated by the flat. 33 Geo. III. c. 52, the operation of which commenced in India on the 14 of February 1794. By the former act, six persons were to be nominated by the king, as commissioners for the affairs of India; but by the latter, the number, instead of being limited to fix privy-councillors, is indefinite, depending upon the king's pleasure; of which number the two principal secretaries of state, and the chancellor of the exchequer, are to be three; and his majesty, if he pleases, may add to the list two commissioners, not of the privy-council; and the person first named in the king's commission is to be president. The king may give 1200l. a year among such of the commissioners as he pleases; which, together with the salary of the secretary and officers, and other expenses of the board, are to be paid by the India company; the whole not to exceed 16,000l. per annum. The members of this board and their officers are sworn to execute the several powers and trusts reposed in them, without favour or affection, prejudice or malice. The office of a commissioner, or chief secretary, is not to be deemed a new office, to disable them from sitting in parliament; nor is the appointment of a commissioner, not having a salary, or of a chief secretary, to vacate a seat. Three commissioners must be present to form a board. The powers of the board are to superintend, direct, and control all acts, operations, and concerns, which relate to the civil and military government and revenues of the British territorial possessions in India, subject to certain restrictions. They and their officers are to have access to the papers and records of the company, and to be furnished with copies or extracts of such of them as shall be required. They are also to be furnished with copies of all proceedings of general courts, and courts of directors, within eight days, and with copies of all dispatches from abroad, relating to matters of government or revenue, immediately after their arrival. No orders on those subjects are to be sent by the company to India, until approved by the board, and when the commissioners vary or expunge any part of the dispatches proposed by the directors, they are to give their reasons; and all dispatches are to be returned to the court of directors in 14 days. The directors may refer their objections to any alterations, and the commissioners are to reconsider them; and if they interfere with what the directors deem matters of commerce, the directors may apply to the king in council to determine between them. But the board is restricted from the appointment of any of the company's servants. If the directors, on being called upon to propose dispatches on any subject relating to government or revenue, shall fail to do so within 14 days, the board may originate their own dispatches on that subject. The board is not to authorize any increase of salaries, or any allowance or gratuity to be granted to persons employed in the company's service, except the same shall be first proposed by the company; and their intention and reasons for such grant are to be certified to both houses of parliament, 30 days before the salary can commence. The directors are to appoint three of their members to be a committee of secrery, through whom dispatches, relating to government, war, peace, or treaties, may be sent to or received from India. This committee, and their clerks, are to be sworn to secrery. Orders of directors, concerning the government or revenues of India, once approved by the board, are not subject to revocation by the general court of proprietors. For the further provisions of the acts, appointing the board of control, see East India Company.

Board of Ordnance. See Ordnance.

Board of trade and plantation, was established by king William, in the year 1696. Commercial matters had before this time been generally referred to a fluctuating committee of the privy-council; the obvious inconveniences attending this mode of management, induced king Charles II. to erect a special council of trade in the year 1666, which was soon after laid aside; it was renewed again in 1672, but soon discontinued, and the former method of reference to committees of the privy-council revived. In 1696, a regular and permanent board was established, for settling all disputes and regulations relating to commerce and colonies. This board, beside such of our ministers of state, who only attended on extraordinary occasions, consisted of a full load commissioner, and of seven other commissioners, with an annual salary of one thousand pounds each. This board was abolished in 1780.

Board of trade, bureau de commerce, an office in the French polity,
Board-wagons, denotes a certain annual sum allowed to household servants for maintenance. Board-wagons, granted to the menial offices and servants of the crown, commenced in 1629, when the necessities of King Charles obliged him to retrace the expense of his household, by abolishing the greatest part of the daily tables in his palace, which were eighty in number, and substituting this annual allowance in their room.

Board, or Aboard, in the Sea Language, is used in speaking of things within a ship, or other vessel.

Hence, to go aboard signifies to go into the ship; to have one aboard, is to throw a thing out of the vessel into the sea; to fall by the board, is to fall down by the ship's side; to fall a board of, is to strike or encounter another ship, when one or both are in motion; to keep the land a board, or to keep hold of the land, is to steer near to, or in sight of the land; board and board, is when two ships come so near as to touch one another, or when they lie side by side. Weather-board, is that side of a ship which is to windward. To board a ship, is to enter an enemy's ship in an engagement. See Boarding, infra.

Board denotes the distance run by a ship at one tack; and hence to make a board, or, as it is otherwise expressed, to board it up to a place, is to turn to windward; and to beat sometimes upon one tack, and sometimes upon another; in which it is to be noted, that the farther you stand off to one point of the compass, the better ship you will make; and that it is better making long boards than short ones, if you have sea-room. A long board is when you stand a great way off before you tack or turn; a short board is when you stand off a little; a good board is when a ship does not go leeward of her course, or advances much at one tack, and falls upon a straight line. To leave a land on back-board, is to leave it a stern, or behind; the back-board being that which, in boats or ships, we lean our backs against. A-board main-tack, the order to draw the main-tack; i.e. the lower corner of the main-sail, down to the chefs-tree. See Chess-tree.

Board-Lar, and Starboard. See Larboard, and Starboard.

BoARDED Floor. See Floor.

BOARDING, in Naval Tactics, denotes the art of approaching the ship of an enemy so near as to admit of the grappling, which are fixed on the lower yard-arms, at the forcastle, gang-ways, &c. being thrown into it, for the purpose of securing the vessels together, and of entering her decks with a detachment of armed men. The method of conducting or of avoiding this kind of attack depends upon the relative situation of the contending ships; and varies, as it is to be performed to windward, to leeward, with the wind at large, or when the ship proposed to be boarded is at anchor.

In the first case, when the enemy's ship keeps her wind under an easy sail, and is overtaken in a chafe by those who intend to board her, the vessel of the latter must get on the weather-quarter of the former, within half a pistol shot. She should then begin and continue a brisk action, so that the smoke of the cannon and musketry of both ships may conceal her manoeuvres; and, under the cover of this cloud, she should increase her sail, if she has not way enough, in order to augment her velocity and the rapidity of her movement, that she may more readily lay on board the enemy, on the weather-side, either exactly abreast or a little abaft. This may be easily done, by edging down suddenly upon her, but avoiding being raked by the enemy's first. By this manoeuvre the grapnels will be on board of the adversary ship, before or very soon after she fufpect the design of the boarders.

In this situation, the vessel proposes to be boarded can recur only to one precarious expedient, which, duly observed by the boarder, will be of little or no avail. For when she braces sharp a-back her head fails, to evade the ship's falling off, and squares those aft, to give her stern-way, the boarder, by performing briskly the same manoeuvre, will be as well situated for boarding as before; provided the boarding ship feels the impulse of her falls and hems, which ought to be put a-weather, and kept so till the ship's head-way ceases, when it is to be put alee, to affiet her falling off, in order to board the enemy to lee-ward; for the boarder ought to be on the quarter of the other, since at the moment the two ships were right before the wind, she who was directly to windward, and wished to board, had only to continue her movement of rotation, and render her velocity equal to that of her adversary, by shortening a fall in order not to pass her. If, therefore, the circular motion is kept up by the boarder, which at first caused her to fall off, and now brings her to the wind on the other tack, she will join the enemy to lee-ward; for it is evident that, if this motion of turning be more rapid than that of the ship which wishes to avoid boarding, the boarder will clothe with her before she can range to the wind on the other tack, since the boarder comes round with greater celerity. However, if the ship which fears boarding was pressed thus closely, she could make no other attempt than to throw once more all her falls to the main, by bracing them only perpendicular to the keel to give her stern-way, and putting the helm a-weather, to keep her to the wind, as soon as her head-way ceases; afterwards, as she is to windward, she may be thus driven on the boarder, who watches for her under her lee. But necessity obliges her to adopt this only expedient; because, if she could go a-fern with sufficient velocity, the might let the boarder pass a-head, veer under his stern, and rake him, if he does not anticipate this manoeuvre, and as quickly manoeuvre in the same manner; the great velocity with which he comes to the wind, and goes a-head, his falls being full full, reducing him to this state, which may prevent his performing in the design of boarding. Nevertheless the boarder may attain his purpose, if he throws all his falls a-back at the same time as the ship to windward; because, the attacked ship dropping to leeward, and having stern-way still, approaches the boarder, who has preserved his position on the quarter, and longer kept his helm, by having gone a-fern somewhat later than the weather ship. It should also be observed, that when the two ships are right before the wind, if the vessel which fears boarding moves more quickly to the wind than the one which attacks, she will avoid it, as the retiring ship will be close to the wind before the other, and able to get a-head of her, by making all sail to keep her wind, or to heave in ilays, and get upon the other tack. This last movement, however, is disadvantageous; because it will present the stern to a ship, which will avail itself of that situation, and rake her, and this may be more destructive than a well opposed attack by boarding. After all, if the ship that is inclined to board falls better than the other, she will always have it in her power to execute her purpose, if she proceeds as well manoeuvred as the ship which endeavours to escape.

In the second case of boarding to lee-ward, when close to the wind, the boarder should arrive within pistol shot, close in the
the wake, or, at morn, to the weather-quarter of the ship against which the attack is meditated; taking care to continue steerling, so as not to be raked by any of the guns that belong to the quarter on which he stands. In order to come up with his adversary, he must edge away a little, and range round aft, so close upon the enemy's lee-quarter, that his cat-head may almost touch her quarter-gallery. When the ship has shot sufficiently a-head, and is parallel to that of the adversary, the fore-castle being a-breast of the enemy's main-mast, the mizen and mizen staysail sheets are to be well hauled aft, the helm put hard a-lee, and the head-sheets let fly; then the ship, coming rapidly to the wind, shivers her sails, and closes with the opposing vessel side to side. In executing this manoeuvre, which cannot fail to succeed with the advantage of failing, great attention is necessary; because, if at this moment the weather-ship, which wishes to avoid being boarded, either lets her courses, or lays all those flat a-back which she had let, she may chance to break the grappling, if the falls of the boarding vessel have not been trimmed like those of the other; for, by making more fail, if the wind be a little fresh, she will shoot a-head through the water, and drag the boarder with such force as to break the chains or hawiers by which the two ships are confined together. By laying all flat to the mast the boarded vessel is still more likely to succeed, since the fails of one ship will be full, while those of the other are a-back.

This mode of boarding may be avoided, if the boarder does not pay strict attention to his own manoeuvres, as well as to those of his adversary; and it may be more readily avoided, if the adversary's vessel braces her head-fails sharp a-back, setting only, if necessary, the fore-fail, at the same instant laying to the mast or shivering, according to the necessity for more or less stern-way, all those which are abaft, and putting the helm hard a-lee. This is to be executed, when the boarder is about a ship's length a-fore of the other vessel. The quickness of this evolution, and the rapid veering of the weather-ship, may bring the boarding vessel, which is a little to leeward or a-fore of the other, into the morn dangerous situation, if the does not maneuvre in the same manner, and with equal celerity; as the boarder's fails being full, keep up his velocity, and may, before he can veer, engage his bowsprit in the main shrouds of the enemy, who pays short round on her head. Those who wish to board a ship, and to engage the enemy's bowsprit in their main shrouds, need only to get a little to windward of her; and by running on a ship's length a-head, according to the celerity of that moment's movements; then brace sharp a-back the head-fails, shiver the after-ones, or lay them flat to the mast, with the helm a-lee. This manoeuvre, well performed, and covered by a brisk fire, will commonly succeed; but care must be taken not to come round too soon, but to range very close to the adversary; because, if the boarding vessel be not sufficiently a-head of him, it might fail in boarding, by paying too short round, and its bowsprit get foul of his fore-shrouds, which would be very disadvantageous. The design will be frustrated, if the boarding ship, being too far a-head, pusses under the bowsprit of the enemy, who will thus, however, be exposed to be raked at his head, if he does not manoeuvre in the same manner and equal quickness as the boarding vessel, which has the great advantage of priority. In order to engage the bowsprit of the enemy's ship in the rigging of the boarding vessel, this should be ranged very close to the other; because, if this were attempted at only a ship's length large, and to windward of the enemy, he need merely, upon perceiving the design, to put the helm hard a-lee, and heave in flaps. If this last method be properly executed, the two ships can only range very near each other, and exchange their broadsides; and the lee-ship will immediately gain the wind of her adversary. Consequentiy to execute this maneuvre well, the veelys must be nearly yard-arm and yard-arm.

If the boarder be at a certain distance aft on the weather-quarter, the ship wishing to avoid boarding must have in flaps, as soon as the other vessel is in the act of veering, in order to clove with her to leeward. By this maneuvre they will come head to head, so that they may reciprocally fire their broadsides, in palling on opposite directions, and the lee-ship will get to windward.

In the third case, when two ships engage with the wind large, the boarding vessel should keep as close as possible on the lee-quarter of the ship in order to attack by boarding, that she may execute her purpose by coming rapidly to the wind, and being careful not to pass a-head of her opponent. The weather-ship, in order to avoid being boarded, must act according to circumstances, in the manner directed in the last case. A ship may be boarded on the weather-side, by conforming to the instructions relating to boarding to windward. When two vessels are engaged with the wind right afg, the boarder ought to drop a-fore of the enemy, in order to run up close along-side of him, if the boarder has the advantage of failing; for, as the then advances towards her adversary, the adversary can only endeavour to range rapidly to the wind on the other tack, as soon as the bowsprit of the boarder is a-breadth of her stern, and thus gain the wind, in order to be in a situation to extricate herself more easily by a good maneuvre. The boarding vessel should be allowed to come a-breadth of the stern of her adversary, before he hauls her wind; because, if this were done sooner, the ship a-stern, at a small distance, would board her perfectly well, even if she failed with equal celerity, since the boarder would be to windward, would run large longer than the other, would range more slowly to the wind, and continue to a-head of the flying ship. This will appear more evident by considering, that the boarder coming from windward prefers his velocity longer, trimming his fails only as the ship comes to the wind, and cuts the course of his adversary with a line a-fore curved than that described by the retreating ship. If, by coming too soon or too fast to the wind, the boarder chose to abandon his design, he might do so by veering a few points on the other tack, and shortening fail; so that the retreating ship will shoot her stern, and the boarder can then rake her by passing under her stern.

In attacking a ship closely to leeward, the boarder should keep away a little when abreast of her, and feem to yield under her fire. If the enemy's ship should be induced to veer, in order to bring the boarder more under her guns, the latter should heave rapidly to the wind, by putting the helm a-lee, trimming all sharp astir, and unfurling the effect of the head-fails; which should be done at the instant when the enemy is perceived to be bearing down. The two ships will, by the quickness of this maneuvre, and the priority of the movement thus gained on the enemy, soon close, and, with proper attention, the enemy's bowsprit may be entangled in the fore or main rigging of the boarding vessel, which would be a favourable circumstance in the attempt to board. However, it may happen that no attempt can be made to board, if the weather-ship, instead of bearing away, pusses more and more to windward; for this faint maneuvre may take the boarder too far oit to leeward of the adversary. If the boarder should chance to be a ship's length to leeward, and about the same distance a-head of the enemy's vessel, it may, under cover of a heavy fire, heave in flaps; and thus come right athisart the enemy's haewe, rake him fore and aft, and board him, his bowsprit being
right over the enemy's gang-way; nor can he possibly avoid a broadside; for if he have all a-hack and make a-tern board, which is his only resort, he may avoid being boarded, but his situation will be very perilous.

In the last cafe of boarding a ship, which is at anchor, riding head to wind, it must be executed under fail; for if the boarder cannot approach the enemy except by towing a-head, he will never be able to board the latter against his will; because he will be always able to annoy the boats which are laying out the tow-lines. It should not therefore be attempted, unless the boarder be under way. In order to perform it with success, the boarder must be sufficiently to windward to approach the enemy by a little falling off, without expuling his stern to the fire of the latter, which in this situation might be played on with great advantage. If the boarder, then, should be thus to windward, so as to be able to approach the enemy at anchor, he ought to dip his head-way, by taking a-back his mizen top-fall and fore staysail; and when about a ship's length from the vessel proposed to be boarded, let go an anchor, and then work, so that, as soon as the mizen top-fall is taken a-back, the mizen clove aft, the top falls clued up, and the fore-topmaft staysail hauled down, he may come head to wind, and veer away cable, till, by falling off, he comes board and board with his opponent, who is still riding at his moorings, and who at that instant ought to be also raked by the boarder. This is the only method of manoeuvring to which the boarding ship can recur; because, as soon as the anchor is gone, the ship acquires stern-way, and when the cable is checked, she runs head to wind, in which she is much afflicted by the mizen and mizen top-fall, which impel her stern to leeward, till the wind is right in the direction of the keel; and, as the cable is veered away, till exactly alongside the ship at anchor, her own anchor being right a-head of the vessel she means to board, it follows that, as soon as the boarding ship comes head to wind, she is in a proper situation to throw her grapnels, and send her crew on board of the other, if they are the stronger.

The ship at anchor should never wait for the enemy in that situation, which is always disadvantageous, and as there is much greater probability of escape when under way. But if it be necessary for the enemy to continue at anchor, he should take advantage of the boarder's ship letting go her anchor, to cut the cable by which he rides; and by this manoeuvre fall athwart, rake the boarder, avoid being boarded, and bring up with the lee-anchor. If time allow, two springers should be call'd out, one on each side of the cable by which the ship rides, if there have been no previous opportunity for laying out two anchors, and thus guard against surprize, in case the ship which attacks has it in her power to pass on either side of the other; and when the tide for which she is determined is perceived, the assailant should hoist on the spring which is on the same side the has let go her anchor, if she be a-head, and on the opposite, if she be a-tern, veering out at the same time the other spring and cable, till the assailant be brought right a-broad. Then he may be raked at pleasure, as he has no way of escape. His only course to prevent danger would be having aloft a spring and, under cover of a brisk air, veering upon that spring and cable, to lay his enemy handomely on board. But if this precaution should have been neglected, he must cut his cable, and drop on board of the ship to leeward; who, on the other hand, has no mode of avoiding being boarded, but by cutting, to get under way, or to run on shore.

It is always easy to board a ship at anchor, when the wind will allow approaching to her under fail; in which case it is most advicable to run her along-side, or to bring-to to windward of the ship intended to be attacked, keeping her exactly to leeward; then to drift on board of her, by trimming the falls in such a manner as to keep as nearly as possible the broadside of the attacking vessel opposite to that of the adverse ship. In this situation the boarder should annoy the enemy with his guns till he can close with him; and by constantly cannonading, his fire may not be so well served as it otherwise might be. If, whilst a vessel is under way, it be proposed to board a vessel that is moored, an anchor should be let go at the time of boarding; for if the attacked ship should at this moment cut her cables to drive on shore, this would prevent the assailant and the affailed running aground together. Elements and Practice of Rigging and Seamanship, vol. ii. Boude's Manoeuvrers, or Skilful Seaman, &c. translated from the French by Sauceul, 4to. 1783.

boa, BOAR, in Ornithology, the name of a small bird, described by Aldrovandus and others. This is the fig-eater of Albin and Latham; and Motacilla Natrix of Gmelin.

Boarula, a species of Motacilla, called in England the grey wagtail. The colour of this bird is cinerous above, beneath yellow; tail-feathers dark, and pale at the edges. This is an European bird, about seven inches and a half in length, and, like the rest of the wagtail tribe, frequents watery places. They are lively, active birds, perpetually stir the tail, and feldom perch, but rest upon the ground. They feed chiefly upon insects. The neck of this species is made on the ground, and is composed of dried fibres and moss, lined with wool or feather, and usually contains from fix to eight eggs, which are of a dirty white, marked with yellow spots. They breed in the north of England, seldom approaching nearer to the southward than Cumberland, till after the month of October. Linn. Donov. Brit. Birds, pl. 40, &c. Le Bergette, of Belon; and la Bergeronette jaune, of Brison, is of this species.

Obf. A variety of Motacilla Boarula inhabits Java. The colour is an olive brown, beneath yellow; lower part of the neck grey; first tail-feather entirely white; inner and tip of the second and third white.

BOAS, in Entomology, a species of Scarabaeus, that inhabits Sierra Leona. The thorax is retuse, excavated, bidentated; horn of the head recurved and fimple. Fabricius.

BOAT, a small vessel, generally without a deck, managed by sails or oars, or drawn by horses upon canals, rivers, or lakes, for the purpose of conveying passengers, goods, &c. from one place to another. The form, equipment, and names of boats are different according to the purpose for which they are intended, or to the country where they are built. Hence, boats are made flight or strong, sharp or flat-bottomed, open or decked, plain or ornamented, as they may be designed for swiftships or burden, for deep or shallow water, for failing in a harbour or at sea, and for convenience or pleasure.

As boats make always a necessary appendage to ships, it will,
will, therefore, be proper to give a brief account of those belonging to the different classes of shipping.

Ships of war, particularly of the line, have usually six boats, and the number decreases with the rate of the ship. The largest is called the long-boat, and sometimes the launch; and its principal employment is to convey heavy stores to the ship. This boat is generally furnished with a mast and sail, and is occasionally decked, armed, and equipped, for cruising from distances against merchant ships of the enemy, or smugglers, or for impressing seamen, &c. The long-boat is the next least boat, and is particularly appropriated to carry the principal sea officers, as the admiral, captain, &c., to or from the ship; and in consequence of its slender construction, combined with its small breadth, is very unfit for sea. This boat never rows less than ten oars. The jinnae is similar to the barge, but smaller, never rows above eight oars, and is used by lieutenants in going ahore, or coming off to the ship. Cutters are broader, deeper, and shorter than the former; they are employed on almost all occasions, as for going ahore, carrying stores, provisions, boarding ships at sea, &c. Jolly-boat is the smallest boat used in any of the ships in his majesty's service. In Plate VI. of Ships are perspective views of a man of war's long boat, of a barge, and flat-bottomed boat.

In an East Indian there are four boats, the long boat, cutter, jolly-boat, and yawl. The first of these is for conveying stores and goods to and from the ship; the second for going ahore; and the others are employed occasionally.

Ships in the West India trade use boats in number and size according to the islands at which they intend to take in their cargo. Four boats generally belong to a ship in the Jamaica trade. The largest, called a Flatboat, will carry from eighteen to twenty hogheadsh of sugar. The next in size is usually called a ten hoghead boat, from the number of hogheads it carries; these two are left in the country. The next, a boat called a double mofes, or jinnae, carries two hogheads a short distance; and the smallest boat is called the jolly-boat, and is generally suspended from the taffrail.

Ships in the Windward Island trade, loading at Barbadoes, Martinique, Dominica, &c., generally use a flat launch with oars, each about thirty-five feet long, one end being upon the boat's stern, and the other upon the beach, upon which the sugar hogheads are rolled from the beach into the launch. At St. Vincent's, Grenada, and Tobago, a one hoghead mofes is used. At Trinidad a launch as flat as can be built is used. At Demerara, Barbice, and Surinam, they generally use falling craft that will carry from twelve to twenty hogheadsh.

Ships employed in the whale fishery have fix or more boats. These are very narrow in respect to their length, for the purpose of pulling fast; they are strongly built, and sharpen at both ends. Smaller vessels of one hundred tons and under, have in general one boat.

Baceto, a fishing boat on the rivers in France; it is provided with a mast, oars, fishing lines, a flaff, a pole to fatten their boat on the river when they are fishing, &c.

Balsa, or balsa, a boat, or rather raft, composed of five, seven, or nine logs or trunks of trees, used in South America. This boat is so called from balsa or half, the name of the wood of which it is contrived, but which is called puerio by the Darien Indians. The balza is a whitish fanguy wood, and so very light that a boy can easily carry a log four yards long and a foot in diameter. The following account of this boat is extracted from the Relacion Historica del Viaje a la America Meridional, hecho de Orden, de S. Mag. &c. Impresa de Orden de Rey en Madrid, 1748.

The balzas are not only adapted to this river (Guayaquil), but venture to sea, and carry on the trade as far as Payta. Their dimensions are proportionate to their use, or the voyage for which they are intended; some being only for fishing, others for the river trade, bringing fruits, and all sorts of merchandise from Bodega to Guayaquil, and from thence exporting them to Punt, Salto de Tumbes, and Payta; others are yet more commodiously contrived for carrying families, with all their furniture and necessaries, to their plantations or country houses. The puerco trees, of which they are built, are twelve or thirteen foles long, reckoning five feet to the fole, and two feet, or two and a half diameter; so that the whole breadth of nine logs, of which some of them consist, is between twenty and twenty-four feet; and that of fewer or fewer logs are proportionate.

These logs are fastened to each other only by the bejucos or withies, with which the crofs logs are also lathed to them, yet so securely as never to give way, if not worn out by long use, though in their voyage to the coast of Tumbes and Payta the sea runs very high; but the negroes neglecting to examine if the bejucos are not too much worn to fulfill another voyage, before they put to sea, it often happens that the lashing breaks, the logs separate, and both cargo and passengers perish; indeed the Indians, being more active, get upon a log and safely work it to the nearest harbour. One of these melancholy ininfances happened while we were in the jurisdiction of Quito, and are wholly to be imputed to the forlid negligence of the Indians, who seem to have no fenfibibility of danger.

The thickft log of the balza is placed fo as to reach further than the others; at the stern, another log is lathed to this, on each side, and others to these, till the intended number be completed, which is always odd; the large one in the middle being, as it were, the stay and foundation of the others. The larger part of these vessels usually carry about twenty-five tons, without damaging the cargo in consequence of its being too near the water's edge, for the sea never breaks over them, nor does the water fwell between the logs, or ever rise above them, because the whole body of the vehicle accommodates itself to the motion of the water in all weathers.

These rafts work and ply to windward like a keeled vessel, and keep their course before the wind almost as exactly, which is the effect of another contrivance besides the rudder; some large planks, three or four yards long, and half a yard broad, called gures, are set up vertically at the ftern, and also forward between the main logs. By pulling some of these under the water, and taking others a little up, the boat fails large, bears up, tacks, or lies to, according as the machine is worked; an invention which has hitherto escaped the acutenefs of the most ingenious Europeans; and though the Indians have indeed contrived the instrument, yet they are utter strangers to the principles of mechanics, and the caufes of its operations.

Had it been known before in Europe, the lobs of many lives in shipwreck might have been prevented, as appears by the following, among many other infances: in the year 1730, the Genoese flip of war, being lost in the Vivora, the mariners made a jaguada, or raft, to fave their lives, but miferably by committing themfelves to the winds and currents, without any levere; and the frequency of fuch melancholy events induces me to give a minute explanation of this instrument, from a memoir of Don Jorge Juan, relating to it.

The direction in which a flip moves, when under faif, is in a line perpendicular to the faif, according to the demonstrations of Renou, in his Theory of Mammal Arts, cap. ii. art. 1. Bernouilli, cap. i. art. 4, and Pitot, Lect. ii. art. 13. The reaction
re-action being equal, and opposite to the action, the opposition of the water to the motion of the vessel will also be in a direction perpendicular to the fall, from leeward to windward, and the impulse of a longer body exceeding that of a smaller, supposing the motion of both to be equal, it follows that, upon one of the fore gaffes being thrust under water, the vessel will lie to, and bear up again, if it be taken out; and by a parity of reasoning, an after one being thrust under water will cause the ship to bear up and to lie to, on its being taken out. The way used by the Indians, in managing the balza, is to increase the number of gaffes to four, five, or six, to keep her to windward; for it is evident that the more there are under water the greater will be the lateral resistance, which is increased by the lee-boards used in smaller vessels, and for the same purpose. These gaffes so effectually answer the end for which they are intended, that, when once the balza is underway, only one need be worked; and by thrusting it down or raising it up a foot or two, the vessel is kept in a right course. Plate I. of Botes, contains a perspective view of a Balza.

Barge, the second boat in a ship of war, as mentioned above; a vessel employed in carrying merchandise in the river Thames, with one mast. See also the article BARGE.

Bam boat, a small boat employed in cutting vegetables, &c. to vessels lying at a distance from the shore.

Bander boat, a boat at Bombay for carrying off pilots to a ship, and taking passengers ashore.

Chalana, a boat navigated on the river Loire in France; these boats are narrow and low, for the purpose of more easily passing through the locks of canals; they are principally used in carrying wines, and other productions, and merchandise of the provinces, which lie near the Loire and Allier.

Cowbe, a boat employed as a wherry at Bombay; it has one mast, with a considerable rake forward, and falls very flat.

Fechto, is a strong gaffing-boat used in the Mediterranean, having from 10 to 16 banks of oars. The natives of Barbary often employ boats of this sort as cruisers.

Ferry boats, are used for conveying passengers, goods, horses, cattle, &c. across a river or branch of the sea; and, therefore, are of different dimensions and forms of construction accordingly. Fishing boats, are of various sorts; those employed in the salmon fishing, which is generally in rivers, or at the sea shore, and commonly called cods, are narrow at one end, and broad at the other, for the purpose of making up the net upon it, and from which the net is let into the river or sea. Boats employed in the white fishery, that is, in taking ling, cod, haddock, &c. are pretty large; some carrying ten tons and upwards, with two masts, with square or log-gigs, and strong built so as to endure a rough sea; they are usually and equally sharp at both ends, the sharpest end being the bow. Decked vessels called smacks having one mast, or luggers with three masts, are employed in this fishery.

Flat-bottomed boat, is so constructed for taking the beach easily, for the greater convenience of landing troops with their baggage, accoutrements, &c.

Flotter, boats of the matter ferrymen at Paris. The ordnance of that city, made in the year 1752, enjoins them to keep their boats always provided with oars and oars; and to have a sufficient number of boats ready at the places and services appointed by the provost of the merchants and chevins.

Fosset, boats which navigate on the river Seine; they are large, long, and strong; they come from Roan, and from the river Oise, and are commonly used to carry great loads of wood for fuel, also goods, &c.

Gig, a small light boat, usually suspended from the tail-rail of a ship.

Holland, Boats of. In almost all the Seven United Provinces there are boats which serve for public carriages, which set out from every city at all hours of the day, and carry passengers very conveniently from one place to another, at a very small expence. They are long, narrow, and covered, and can contain about sixty persons; each boat is drawn by one horse, and has only two men to manage it, the one attends the helm, and the other takes care of the rope; the horse is generally rode by a boy. In these boats there is a room which can easily contain six persons; this room, which is called a reef, has glads windows, whereas the other openings in the boat are shut with oil cloth in bad weather. A passenger may take a place in this room, or the whole room. These boats which carry goods from Amsterdam to the Hague, and which leave Amsterdam at eight at night, arrive at the Hague next morning. In these boats, however, dedicated for passengers only, a person is obliged to change boats several times. From Amsterdam to Haarlem he must change boats half way, because the canal there is cut by a dyke. At Haarlem, the passengers must cross the town to get to the boat that is to carry them to Leyden. At Leyden, he must again cross the town to meet the boat in which he is to go to the Hague. All this can be performed in ten hours and a half; for, at eight o'clock precisely, a boat sets out from Amsterdam to Haerlem, where it arrives about half an hour after ten; at eleven a boat sets out from Haerlem for Leyden, and arrives there at three in the morning; half an hour after three a boat sets out from Leyden, and arrives at the Hague half an hour after six. There is such good order kept, that at the ringing of a bell the boat must set out immediately, without waiting for any passenger. There are few countries where people can travel so conveniently as in Holland.

Ivahah, a boat or canoe of the Society Islands, of which captain Cooke gives the following description. The ivahah is used for short excursions at ten. These boats are all of the same figure, but of different sizes, and used for different purposes; their length is from ten to seventy-two feet, but the breadth is by no means in proportion; for those of ten feet are about a foot wide, and those of more than seventy are scarcely two feet. They have the fighting ivahah, the fishing ivahah, and the traveling ivahah, for turning in the channels, or crossing one island to another. The fighting ivahah is by far the longest; and the head and stern are considerably raised above the body, in a semicircular form, particularly the stern, which is sometimes fourteen or eighteen feet high, though the boat itself is scarcely three feet. These never go to sea, but to the acts together side by side at the distance of about three feet, by strong poles of wood, which are laid across them, and lashed to the gunwales. Upon these in the fore part, a stage or platform is raised about ten or twelve feet high, and somewhat wider than the boats, which is supported by pillars about fix feet long; upon this stage stand the fighting men, whose military weapons are slings and spears; for, among other singularities in the manners of these people, their bows and arrows are used only for diversion, as we throw quoits below these stages fit the ravers, who receive from them those that are wounded, and furnish fresh men to ascend in their room. Some of these have a platform of bamboo, or other light wood, through their whole length, and considerably broader, by means of which they can carry a great number of men. The fishing ivahahs very long in length from about forty feet to the smallest fixe, which is about ten feet; all that are of the length of twenty-five feet and upwards, of whatever fort, occasionally carry fifty. The travelling ivahah is always double, and furnished with a small seat house, about five or six
fix feet broad, and fix or seven feet long, which is fastened upon the fore part, for the convenience of the principal people, who sit in them by day, and sleep in them at night. The fishing iavahals are sometimes joined together, and have a house on board, but this is not common. Those which are shorter than twenty-five feet, seldom or never carry sail; and though the stem rises about four or five feet, they have a flat head, and a board that projects forward about four feet. The iavahals are the only boats used by the inhabitants of Otaheite.

Life-boat, a boat invented by Mr. Henry Greathead of South Shields, for the purpose of preserving the lives of shipwrecked persons. The following circumstance gave rise to this invention:

In September 1789, the ship Adventure of Newcastle, was stranded on the Herd fand, on the south side of Tynemouth haven, in the midst of tremendous breakers; and all the crew, excepting one, were thrown into the water. The six men, who were stranded, were saved by Mr. Greathead, who immediately directed a boat at the expense of the committee.

This boat went off on the 30th of January 1790; and so well has it answered, and indeed exceeded, every expectation, in the most tremendous broken sea, that since that time, not fewer than two hundred lives have been saved at the entrance of the Tyne, which otherwise must have been lost; and in no instance has it ever failed.

The principle of this boat appears to have been suggested to Mr. Greathead by the following simple fact. Take a sphere, and divide it into quarts; each quarter is elliptical, and nearly resembles the half of a wooden bowl, having a curvature with projecting ends; this, thrown into the sea or broken water, cannot be upset, or lie with the bottom upwards.

The length of the boat is thirty feet; the breadth, ten feet; the depth, from the top of the gunwale to the lower part of the keel in midships, three feet three inches; from the gunwale to the platform (within), two feet four inches; from the top of the flims (both ends being similar) to the horizontal line of the bottom of the keel, five feet nine inches. The keel is a plank of three inches thick, of a proportionate breadth in midship, narrowing gradually towards the ends, to the breadth of the flims at the bottom, and forming a great convexity downwards. The flims are segments of a circle, with considerable roundness. The bottom is constructed to the floor-heads, a curve fore and aft, with the sweep of the keel. The floor timber has a small rive cutting from the keel to the floor-heads. A bilge-plank is wrought in on each side, next the floor-heads, with a double rabbit or groove, of a similar thickness with the keel; and, on the outside of this, are fixed two bilge-trees, corresponding nearly with the level of the keel. The ends of the bottom section form that fine kind of entrance observable in the lower part of the bow of the fishing boat, called the cable, much used in the north. From this part to the top of the flims it is more elliptical, forming a considerable projection. The sides, from the floor-heads to the top of the gunwale, flaunch off on each side, in proportion to above half the breadth of the floor. The breadth is continued far forwards towards the ends, leaving a sufficient length of straight side at the top. The sheer is regular along the straight side, and more elevated towards the ends. The gunwale fixed to the outside is three inches thick. The sides, from the underpart of the gunwale, along the whole length of the regular sheer, extending twenty-one feet six inches, are caulked with layers of cork, to the depth of fifteen inches downwards; and the thickness of this caulking of cork being four inches, it projects at the top a little without the gunwale. The cork, on the outside, is secured with thin plates or flaps of copper, and the boat is fastened with copper nails. The thwarts, or seats, are five in number, double-banked; consequently the boat may be rowed with ten oars. The thwarts are firmly flattened. The side oars are short, with iron tholes and rope grommets, so that the oar will pull either way. The boat is steered with an oar at each end; and the steering oar is one third longer than the rowing oar. The platform placed at the bottom, within the boat, is horizontal, the length of the midship, and elevated at the ends, for the convenience of the steerer, to give him a greater power with the oar. The internal part of the boat next the sides, from the under part of the thwarts down to the platform, is caulked with cork; the whole quantity of which, affixed to the life-boat, is nearly seven hundred weight. The cork indisputably contributes much to the buoyancy of the boat, is a good defence in going along-side a vessel; and is of principal use in keeping the boat in an erect position in the sea, or rather for giving her a very lively and quick disposition to recover from any sudden cast or lurch, which she may receive from the stroke of a heavy wave. But, exclusively of the cork, the admirable construction of this boat gives it a decided pre-eminence. The ends being similar, the boat can be rowed either way; and this peculiarity of form alleviates her in rising over the waves. The curvature of the keel and bottom facilitates her movement in turning, and contributes to the safety of the steerer, as a single stroke of the steering oar has an immediate effect, the boat moving as it were upon a centre. The fine entrance below is of use in dividing the waves, when rowing against them; and, combined with the convexity of the bottom, and the elliptical form of the flims, admits her to ride with wonderful buoyancy in a high sea, and to launch forward with rapidity, without shipping any water, when a common boat would be in danger of being filled. The flaunching or spreading form of the boat, from her floor-heads to the gunwale, gives her a considerable bearing; and the continuation of the breadth, well forward, is a great support to her in the sea; and it has been found by experience, that boats of this construction are the best sea boats for rowing against turbulent waves. The internal shallows of the boat from the gunwale down to the platform, the convexity of the form, and the bulk of cork within, leave a very diminished space for the water to occupy; so that the life-boat, when filled with water, contains a considerable less quantity than the common boat, and is in no danger either of sinking or overturning. It may be presumed by some, that in cases of high wind, agitated sea, and broken waves, a boat of such a bulk could not prevail against them by the force of oars; but the life-boat, from her peculiar form, may be rowed a-head, when the attempt in other boats would fail. Boats of the common form, adapted for speed, are of course put in motion with a small power; but, for want of buoyancy and bearing, are over-run by the waves, and sunk, when impelled against them; and boats constructed for burthen meet with too much resistance from the wind and sea, when opposed
to them, and cannot in such cases be rowed from the shore to a ship in distress.

Mr. Greathead gives the following instructions for the management of the life-boat.

The boats, in general, of this description are painted white on the outside; this colour more immediately engaging the eye of the spectator when rifting from the hulking of the sea, than any other. The bottom of the boat is at first varnished (which will take paint afterwards) for the more minute inspection of purchasers. The oars the ship equipped with are made of fir, of the best quality; having found by experience, that a rope ash oar, that will dress clean and light, is too plain among the breakers; and when made strong and heavy, from rowing double-banked, the purchaser being short, soon exhausts the rower, which makes the fir oar, when made fluff, more preferable.

In the management of the boat the requires twelve men to work her; that is, five men on each side rowing double-banked, with an oar flung over an iron thole, with a grommet (as provided), so as to enable the rower to pull either way, and one man at each end to steer her, and to be ready at the opposite end to take the steer-oar, when wanted. As, from the construction of the boat, the is always in a position to be rowed either way, without turning the boat; when manned, the person who steers her should be well acquainted with the course of the tides, in order to take every possible advantage: the best method, if the direction will admit of it, is to head the sea. The steerman should keep his eye fixed upon the wave or breaker, and encourage the rowers to give way, as the boat rives to it; being then aided by the force of the oars, the launches over it with vast rapidity, without shipping any water. It is necessary to observe, that there is often a strong reflux of sea occasioned by the stranded wrecks, which requires both dispatch and care in the people employed, that the boat be not damaged. When the wreck is reached, if the wind blows to the land, the boat will come in shore without any other effort than steering.

The following additional observations and instructions are given by Mr. Hindewell of Scarborough.

The life-boat at Scarborough is under the direction of a committee. Twenty-four fishermen, composing two crews, are alternately employed to navigate her. A reward, in cases of shipwreck, is paid by the committee to each man actually engaged in the assistance; and it is expected the vessel receiving assistance should contribute to defray this expense. None have hitherto refused.

It is of importance that the command of the boat should be entrusted to some steady experienced person, who is acquainted with the direction of the tides or currents, as much skill may be required in rifting them to the most advantage, in going to a ship in distress. It should also be recommended, to keep the head of the boat to the sea, as much as circumstances will admit; and to give her an accelerated velocity to meet the wave, much exertion is necessary in approaching a wreck, on account of the strong reflux of the waves, which is sometimes attended with great danger. In a general way, it is safest to go on the lee quarter; but this depends on the position of the vessel; and the manner of the boat should exercise his skill in placing her in the most convenient situation. The boatmen should practice themselves in the use of the boat, that they may be the better acquainted with her movements; and they should at all times be strictly obedient to the directions of the person who is appointed to the command.

Plate II. of Boats contains a perspective view of the life-boat riving over a heavy surge, and going out to the assistance of a ship, which appears in the horizon in distress. In the life-boat are ten rowers pulling to get to the ship. At the lower end of the boat, a man is fleering her with a long oar towards the ship; and another perfon is stationed with an oar at the higher end, to fleer the boat on her return; both ends of the boat being formed alike, in order to use either at pleasure in going to or coming from the ship. The fleer, or curve of the boat, riving considerably from the middle to the thero, or ends, is clearly distinguished; also the coating of cork, secured by slips of copper along the outside of the boat, near the part where the rowers are seated.

As every thing relating to this important invention must be interesting to the public, it is, therefore, presumed the following additional information will not be unacceptable, especially as it contains the strongest evidence of the great utility of this boat.

The life-boat having been submitted to a test of twelve years' experience, during which period Mr. Greathead sacrificed a very considerable portion of his time in furnishing plans, and otherwise rendering the invention as extensively useful as he could; on the 25th of February 1802, he presented a petition to the house of commons, the prayer of which was as follows:

"Your petitioner having been instrumental in saving the lives of so many persons; the utility of the boat being now established; and your petitioner having derived little or no pecuniary advantage whatever from the invention, his models having been made public; humbly hopes, that this honourable house will take his cause into their consideration, and grant your petitioner such reward as to this honourable house shall seem meet, &c."

The petition, having been recommended by his majesty, was referred to the consideration of a committee; from which whole report the following is a brief abstract.

"It appeared to your committee to be necessary to direct their inquiries particularly to the three following subjects.

"I. The utility of the life-boat.

"II. The originality of the invention claimed by Mr. Greathead.

"III. Wheter he had received any, and what remuneration.

"And in order to ascertain these facts, your committee proceeded to examine,

"Ralph Hillery, a seaman, who stated, that he had been forty-five years at sea, in the Greenland and coal trade, and has rescued always at Shields. About three years ago, he was in the Northumberland life-boat, which was procured to North Shields by the duke of Northumberland, the first time she went off, which was to the relief of the ship Edinburgh. This vessel was seen to go upon the Hard sands, about a mile and a half from shore; she was brought to an anchor before the life-boat got to her, and the continued striking the ground so heavily, that she would not hold together ten minutes longer, had they not got to her; they made her cut her cable, and then took seven men out of her, and brought them on shore. The sea at that time was monstrously high, so high that no other boat whatever could have lived in it.

"He was then asked, whether he had been out in the life boat on any other occasion; to which he replied, that he had been five times out in her to the relief of different ships; from one ship they saved fifteen men; and in every instance when he, the victors, was in the boat, they saved the whole of the crew of the wrecked ships. Besides the times he has been himself in the boat, he has seen her go off scores of times, and never saw her fail in bringing off such of the crews as layed by the ships. But many times part of the crews of the vessels wrecked have taken to their own boats, and
and have been drowned by the boats' upsetting: whilst the remainder of the crew that continued on board have been saved by the life-boat. And the witnesses declared his conviction, that no other boat that ever he saw could have gone from the shore, and saved the crew, at the times the life-boat went.

"He stated, that in the event of the life-boat filling with water, she would continue still upright, and would not founder, as boats of a common construction do. That about two months ago, he saw her come on shore with a ship's crew, besides her own crew, so full of water, that it ran over each side; the sea had broken several of her oars; and he believes, that no boat of any other construction could have brought the crew on shore so filled with water.

"Captain William Carter, of the ship Providence, of Newcastle, stated, that he had ridden at South Shields twenty-five years, and been fifteen years in the coal and Baltic trades; that on the 28th of November 1779, he commanded the Velocity of 90 tons, riding at anchor on Tynemouth bar, amongst the broken water, when the ship Phanter was driven on shore by the violence of the gale, about one hundred yards from the Velocity; the life-boat came off and took fifteen persons out of the Phanter; and they had scarcely quit the ship, when she went to pieces; they must all otherwise have inevitably perished, as the wreck came on shore almost as soon as the life-boat. He conceived, that no boat of a common construction could have given relief at that time. There were several other vessels in the same situation with the Phanter, namely, the Gatehead, the Mary, and the Beaver, besides a sloop, whose name the witnesses do not know. The crew of the Gatehead, being nine in number, took to their own boat, which sunk, and seven of them were lost; the other two saved themselves by ropes thrown from the Mary. After the life-boat had landed the crew of the Phanter, she went off successfully to the other vessels, and brought the whole of their crews safe on shore, together with the two persons who had escaped from the boat of the Gatehead. He has seen the life-boat go to the assistance of other vessels at different times, and the always succeeded in bringing the crews on shore.

"The witnesses have several times observed her to come on shore full of water, and always safe.

"Captain Gilfred Lawton Reed, an elder brother of the Trinity-houfe, stated, that he had been bred to the sea, and had been a member of the Trinity-houfe nineteen years. He had the management of the life-boat at Lowettzoffe, particularly last year, when he was requested by the subscribers to make any improvement he thought necessary. She was built exactly upon Mr. Greathead's plan, corresponding with the model before the committee. Having fitted her for service as far as he thought proper, he was requested by a number of the subscribers to launch this life-boat; he took an opportunity, when the sea fell very heavy on the beach, and launched her in the presence of at least two hundred spectators. Twenty-four men jumped into her; and when the first mounted the waves, the spectators with one voice expressed their astonishment. He had given the men orders to cross a shoal, that lay about a mile and a half from the shore, upon which the sea broke very heavily; by some mistake one of the plugs was left out of the bottom, and the filled with water before she got to the shoal, which obliged the men to return immediately, and she brought the twenty-four men safe to shore, though when she gained the shore, she was full of water to the gun-wale and midships; yet by her sheer one-third of her at each end was out of the water.

"Being asked, wherein he considered the superiority of the life-boat conflicts over any other boat that has hitherto been invented? he answered, the curvature of the keel, and the slanting sides, which render it almost impossible to be upset. When this boat was afloat and full of water, the men all went to one side of the boat, in order to try the possibility of upsetting her, which they could not effect.

"Mr. Thomas Heiderwell, of Scarborough, ship-owner, stated, that the peculiar nature of the curvature of the keel of this boat is the foundation and basis of its excellence. It regulates, in a great measure, the order with elevation towards the ends. This construction spreads and repels the water in every direction, and enables her to ascend and descend with great facility over the breakers. The ends being reduced regularly from the centre to less than one-third proportion of the midships, both ends are lighter than the body fection. By means of the curved keel, and the centre of gravity being placed in the centre of the boat, she preserves equilibrium in the midst of the breakers. The internal shallowness of the boat in the body section, occasioned by the convexity of the keel and the fierer at the top, leaves a small space for the water to occupy, that the boat, though filled with water, is in no danger of sinking or upsetting. The buoyancy of the boat, when filled with water, is also assisted by the cork being placed above the waterline.

"Mr. Samuel Plumb, of Lower Shadwell, described himself to have been bred to the sea, and to have acted in the capacity of master of a ship from 1777 until within these eighteen months; that he had been chiefly employed in the coal and Baltic trades, and had ridden at Shields the whole of his life till within the last five years. He is acquainted with the Shields life-boats; and from every information he had received, Mr. Greathead has been universally considered as the inventor of them.

"He went out in one of them to the relief of a ship, which was wrecked on the coast near the mouth of the Tyne. The first time they reached the wreck, the rope, which they threw from the wreck to the life-boat, broke, and the boat was drifted to the northward by the violence of the wind and strong current of the tide; they then landed, and by two horses dragged the boat along the sand to the southward, and then launched her again through the breakers to the veil. In the second attempt they succeeded in bringing the crew on shore. The witnesses never saw any other boat in which he would have ventured to the relief of the crew, or which he thinks could have executed the purpose of saving them.

"Mr. William Mafterman, of South Shields, ship-owner, was one of the original committee that ordered the life-boat at South Shields in 1780. He corroborated the evidence given by captain William Carter; and stated, that from the situation of his residence, he has seen the performance of the life-boat more frequently than probably any other of the committee at South Shields, and has frequently seen and assisted in the launching of the life-boat from the beach into the sea during a storm. That this is done with the assistance of low wrights, or what may be called rollers, upon which she is dragged to the water's edge, and by means of hands proportioned to the weight of the boat, she can be launched with as much ease as any other boat. He remembers the instance stated by Mr. Samuel Plumb, in which the life-boat, being drifted to the northward by a strong tide, was landed, and again launched to the southward, opposite to the wreck, and in the face of a very heavy sea. When the Gatehead, Phanter, and other ships were wrecked, it was first discovered that the life-boat could act with perfect safety above the sea; and since that time, the boat has been rowed above the sea, or otherwise, indifferently, as
as the object to be relieved required it; and that she goes with the same safety from one object to another, in a broken sea, as an ordinary boat would pass from one ship to another in a smooth sea. He is confident, since the establishment of the life-boat, that there have been at least 300 persons brought off shore from ships in distress, and wrecks off Shields, the greatest part of whom mult otherwise have perished. And the witnesses added, that it was his opinion, founded upon experience and the observations he had been enabled to make, that no sea, however high, could overtop or sink the life-boat.

The originality of Mr. Greathead’s invention is thereby proper certificates and attestations; and the remuneration that he had received, over and above a profit of from ten to fifteen pounds each, upon building a few boats, are stated to be,

From the Literary and Philosophical Society of Newcastle, five guineas.
Royal Humane Society, a medalion.
Corporation of the Trinity House, 100 guineas.
Society of Arts, a gold medalion and 50 guineas.

The vote of parliament, on the 3d of June, in consequence of the foregoing report, was, “That a sum not exceeding 1200 pounds be granted to his majesty, to be paid to Henry Greathead, of South Shields, in the county of Durham, boat-builder, as a reward for his invention of the life-boat, whereby many lives have already been saved, and great security is afforded to seamen and property in cases of shipwreck.”

The subscribers at Lloyd’s, on the 29th of May, voted to Mr. Greathead the sum of 100 guineas, “as an acknowledgment of his talents and exertions in inventing and building a life-boat,” and 2000 pounds “for the purpose of encouraging the building of life-boats on different parts of the coasts of these kingdoms.”

At the beginning of 1804, Mr. Greathead received a very valuable diamond ring from the emperor of Russia, whose munificence to ingenious men of all countries is well known.

The following extract from the Tyne Mercury of the 26th November 1803, is another proof of the great utility of the life-boat.

The Bee of Shields, John Houlton master, having put to sea (21st Nov.) in an easterly wind, had not proceeded far, when it began to blow strong from the south-eaft, which obliged him a few hours after to put back. In taking Tynemouth bar at the last quarter ebb, in a very heavy sea, she struck the ground, and unhitched her rudder. Being now completely unmanageable, she drifted towards the north side of the bar, and at length drove on the Black Middens. They who have witnessed the tremendous sea which breaks on the north-east part of this harbour, in a south-easterly wind, may form a conception of the dreadful situation in which the crew of the vessel were situated. In the midst of rocks, where the sea runs mountains high, so as frequently to obscure the ship, and where any vessel might be expected immediately to go to pieces; their only refuge from being swept into the gulf, was to climb up into the throuds, which the captain, with six men and boys, being the whole crew, instantly effected. The dangerous situation in which they were placed, immediately attracted an immense number of spectators from both North and South Shields. The shores in every direction were lined with people, who expressed, by their anxious looks, the most sympathetic apprehensions for their safety. The making use of the life-boat was by most people thought impossible; and at all events, the attempt was attended with extreme danger, owing to the tremendous sea, and the immense rocks which lay where the vessel was stranded. So confident, however, was Mr. Greathead, the inventor, of the life-boat being able to live in any sea, if properly navigated, that he, without hesitation, and with the greatest alacrity, volunteered his services to bring off the men from the brig. This intrepid offer operated like electricity among the sailors; and immediately the Northumberland life-boat was launched, and manned with Mr. Greathead and South Shields pilots. In the course of a few minutes they reached the vessel, without much difficulty, and picked off the men from the throuds shivering with cold, and almost perished by fatigue. One man, in making too much haste to enter the boat, fell into the breakers, but was immediately recovered. When the whole crew was in the boat, they rowed towards the shore, and in less than an hour from the time the boat was launched, did they return in safety to South Shields, without a single accident!

Upon the 1st of August 1777, some trials were made on a boat, or sloop fit for inland navigation, coasting voyages, and short passages by sea, which is not, like ordinary vessels, liable to be overtop or sunk by winds, waves, water-spouts, or too heavy a load, contrived and constructed by Monsieur Bernieres, director of the bridges and canaueys in France, &c. at the gate of the invalids in Paris, in the presence of the provost of the merchants, of the body of the town, and of a numerous concourse of spectators of all conditions.

These experiments were made in the way of comparison with another common boat of the same place, and of equal size. Both boats had been built ten years, and their exterior forms appeared to be exactly similar. The common boat contained only eight men, who rocked it and made it incline so much to one side, that it presently filled with water, and sunk; so that the men were obliged to save themselves by swimming; a thing common in all vessels of the same kind, either from the imprudence of those who are in them, the strength of the waves or wind, a violent or unexpected shock, their being overloaded, or overpowered any other way.

The same men who had just escaped the boat which sunk, got into the boat of M. Bernieres; rocked and filled it, as they had done the other, with water. But, instead of finking to the bottom, though brim-full, it bore being rowed about the river, loaded as it was with men and water, without any danger to the people in it.

M. Bernieres carried the trial still farther. He ordered a maff to be erected in this same boat, when filled with water; and to the top of the maff had a rope fastened, and drawn till the end of the maff touched the surface of the river, so that the boat was entirely on one side, a position into which neither winds nor waves could bring her; yet, as soon as the men, who had hauled her into this situation, let go the rope, the boat and maff recovered themselves perfectly in less than the quarter of a second; a convincing proof that the boat could neither be sunk nor overturned, and that it afforded the greatest possible security in every way. These experiments appeared to give the greater pleasure to the public, as the advantages of the discovery are not only of sensible, but of the first importance to mankind.

Marinen boats, so called from being employed on the river Marne in France. They are flat, and carry wine, corn, timber, &c. from the province of Champaigne.

Norway boat, or yawl, is sharp at both ends, and of various dimensions. This boat, from its construction, is admirably adapted for enduring a high sea, and will often venture
tire out to a great distance from the land, when some ships can fearlessly carry any fail.

Pahie, a boat of the Society islands; it is bow-sided, and sharp-bottomed. The pahie, according to captain Cook, is of different sizes, from thirty to sixty feet long, but like the ivahah, is very narrow. One that was measured was fifty-one feet long, and only one foot and a half wide at the top; in the widest part it was about three feet, and this is the general proportion. It does not, however, widen by a gradual swell, but the sides being straight and parallel for a little way below the gunwale, it swells abruptly, and draws to a ridge in the bottom; so that a transverse section of it has somewhat the appearance of the mark upon cards, called a spade, the whole being much wider in proportion to its length. These, like the larger ivahahs, are used for fighting, but principally for long voyages. The fighting pahie, which is the largest, is fitted with the flage or platform, which is proportionably larger than those of the ivahah, as their form enables them to sustain a much greater weight. Those that are used for sailing are double, and those of the middle size are said to be the belt sea-boats. They are sometimes out a month together, going from island to island, and sometimes, as is credibly reported, they are not frequently a fortnight, or twenty days at sea, and could keep it longer, if they had more stowage for provisions, and conveniences to hold fresh water.

When any of these boats carry sail, they make use of a log of wood which is fattened to the end of two poles that lie across the vessel, and project from six to ten feet, according to the size of the vessel, beyond its side; somewhat like what is used by the flying proa of the Ladrone islands, and called, in the account of lord Anson’s voyage, an Outrigger; to which the throns are fattened.

Some of them have one mast, and others two; they are made of a single flick, and when the length of the canoe is 30 feet, that of the mast is somewhat less than 25 feet; it is fixed to the frame that is above the canoe, and receives a fall of matting about one-third longer than itself; the fall is pointed at the top, square at the bottom, and curved at the side, somewhat resembling what is called a shoulder of mutton fall, and used for boats belonging to men of war; it is placed in a frame of wood, which surrounds it on every side, and has no contrivance either for reeling or furling; so that if either should become necessary, it must be cut away, which, however, in these climates, can seldom happen. To the top of the mast are fastened ornaments of feathers, which are placed inclining obliquely forwards, the shape and position of which will be conceived at once from the figure in the plate of Boats.

The oars or paddles that are used with these boats, have a long handle and flat blade, not unlike a baker’s peck. Of these, every person in the boat has one, except those that fit under the awning, and they push her forward with them at a good rate. These boats, however, admit so much water at the seams, that one person at least is continually employed in throwing it out. The only thing in which they excel is landing and putting off from the shore in a furf; by their great length, and high flerns, they could land every day, where the English boats could scarcely land at all; they have also the same advantages in putting off by the height of the head.

The exact dimensions of a pahie, given from a careful admeasurement, will do very materially contribute to the elucidation of the subject frequently given, as to the manner and particular form in which this class of canoes is built; that they might perhaps enable an European draughtsman, to construct one so nearly resembling them as to create some difficulty in pointing out the true from that which was fictitious.

| Extreme length from stem to stern, not reckoning the bowing up of either | 51.0 | Feet, Inches |
| Breadth in the clear of the top forward | 1.2 | |
| Breadth in the midships | 1.6 | |
| Breadth aft | 1.2 | |
| In the bilge forward | 2.8 | |
| In the midships | 2.2 | |
| Aft | 2.9 | |
| Depth in the midships | 3.4 | |
| Height from the ground on which the vessel stands | 3.0 | |
| Height of the head from the ground without, including that of the figure | 4.4 | |
| Height of the figure | 6.0 | |
| Height of the stem from the ground | 8.9 | |
| Height of the figure | 2.0 | |

To illustrate the description of the manner in which these vessels are built, it will be necessary to refer to fig. 2.

Plate II.

The first flage or keel under a a, is formed of a tree hollowed out like a trough, for which the longest trees are chosen that can be procured, so that there are never more than three in the whole length; the next flage under b b, is formed of straight planks, about four feet long, fifteen inches broad, and two inches thick; the third flage under c c, is like the bottom, made of the trunks hollowed into its bilging form; the hat is also cut out of trunks, so that the moulding is of one piece with the upright. To form these parts separately without saw, plane, chisel, or any other iron tool, may well be thought no easy task; but the great difficulty is to join them together.

When all the parts are prepared, the keel is laid upon the blocks; and the planks, being supported by flanches, are fewed or clamped together with strong thongs of plaiting. These are palled several times through holes that are bored with a gauge or anger of bone, which performs its office with tolerable exactness; and the nicety with which this is done, may be inferred from their being sufficiently water-tight for use without caulking. As the plaiting from rots in the water, it is renewed, at least, once a year, in order to which the vessel is taken entirely to pieces; the head and stern are rude, with respect to the design, but very neatly finished, and polished to the highest degree.

These pahies are kept with great care in a kind of house, built on purpose for their reception; the houses are formed of poles set upright in the ground, the tops of which are drawn towards each other, and fastened together with their strongest cord, so as to form a kind of Gothic arch, which is completely thatched quite to the ground, being open only at the ends: they are sometimes fifty or sixty paces long.

Pitter-boat, a boat employed in the river Thames in fishing. They in general fail well, and are good sea-boats.

Pleasure-boat, a vessel employed by gentlemen in excursions upon the water, for their amusement. Their size and manner of equipment are very various, being from a few tons barthen, to upwards of two or three hundred tons, and having one or more masts.

Pull-boats, are boats established on the river Loire in France, for the convenience of the public. They are long in respect to their breadth, and go very fast. There are also two on the Rhone, which go from Lyons to Avignon in 24 hours.

Proc; see that article.

Pinn, a sort of flat-bottomed boat, whose floor resembles the platform of a floating stage. It is used by the naval artificers,
BOA

artificers, either in caulking, breasting, or repairing the bottom of a ship.

Sampan, a Chinese boat without a keel, appearing almost like a trough; they are made of different dimensions, but are mostly covered. There are passenger sampans, to carry people backward and forward, between the town and ships. These boats are as long as sloops, but broader, almost like a baking trough, and have, at the end, one or more decks, made of bamboo-ficks; the cover, or roof, is also made of bamboo-ficks, arched over in the shape of a garter, and may be raised or lowered at pleasure; the sides are made of boards, with little holes, and shuttered instead of windows; the boards are fastened on both sides to posts, which have notches like steps on the outside, that the roof may be let down, and rest on them; on both ends of the deck are commonly two little doors, at least there is one at the stern. A fine, white, smooth carpet, spread up as far as the boards, makes the floor, which, in the middle, consists of loose boards; but this carpet is only made use of to sleep on. As these boats differ from those of Europeans in shape, they are likewise rowed in a different manner; for two rowers, seating themselves at the back end of the sampan, work it forwards very readily by the motion of two oars, and can almost turn the vessel just as they please; the oars, which are covered with a little hollow quadrangular iron, are laid on iron fivisels, which are fastened in the side of the sampan. At the iron the oars are piece, which makes them look a little bent. In common, a rower sits before with a short oar, but this he is forced to lay aside when he comes near the city, on account of the great throng of sampans; and this inconvenience has confirmed the Chinese in their old way of rowing.

Sampan's of burden are the largest boats, by which all porcelain, silk, and other commodities, are conveyed from Canton to the European ships. But these boats do not serve for the above-mentioned purposes only, but are used, besides, as houses for whole families, which are born, marry, and die in them. They commonly have, besides, hogs, some chickens and dogs, and some flower-pots, containing Guinea pepper, or some other plants, in these boats.

Duck sampans, are boats in which they feed four or five hundred ducks. They have on both sides a bridge, which may be let down. In the daytime the ducks feed in the river upon herbs and fish; at night their master carries them into his boat; they immediately obey him, and come on board as soon as he lets down his bridge.

Fishing sampans, are the smallest of all, narrow, like some European fishing boats, and have either a very small deck of straw, or bamboo, or are even without that poor convenience. Bad as these boats are, yet parents, and their naked children, are seen to get their livelihood in them, both summer and winter, by fishing, and picking up what has been thrown overboard from other vessels. For this purpose they tie several hooks to a cord, and throw them out in different places, almost in the same manner as fishermen lay their eel-hooks. They have better or worse fortune, as it happens. There is nothing so filthy but what these people will use as food; and the hogs, which having died are thrown overboard, when they begin to putrefy, float in a few days, and often become the occasion of quarrels, which end in battles. The reason why the Europeans fluke the hogs, which die on board their ships, is, that the inhabitants of this place may not fall upon them; for it is said that the Chinese, when they go on board any ships, will give pepper to the hogs, which they think is poison to them, that they may get them again if they should die. It is certain, that numbers of hogs die in possession of the Europeans whilst they stay in China.

Mandarin's sampans are greater or less red-painted boats, ornamented with dragons, and such like figures, or with little flags.

The passage-boats, called in French, bateaux coches, and more commonly coches d'eau, water coaches, are large covered vessels, which serve, particularly on the river Seine, for the convenience of the travellers, and for carrying all sorts of merchandizes. The names of them are the passage-boat, or water coach of Seiss, of Auxerre, of Montereau, and of Fontainebleau, or Valain.

Tilt-boat, one with a cover, to defend the passengers from rain, &c.

Treat-boat, a boat employed in a canal in conveying passengers, &c. from one place to another. This mode of travelling, though not expedient, is indeed very pleasant, and certainly much cheaper than by any land carriage. From Grangemouth to Port Dundas, a distance of nearly 30 miles, the fare is only one shilling, or eighteen pence.

Well-boat, a boat having a well in the bottom, to preserve fish alive.

A Wherry is a light sharp boat, used in a river or harbour, for carrying passengers from place to place.

The boats, or wherries, allowed to ply on the Thames about London, are either skillets, wrought by a single person with two oars; or oars, wrought by two or more persons, with each an oar.

The following are some of the terms used in the management of a boat.

Bale the boat, is to throw out the water which remains in her bottom, or the well-room. See Bale.

Fend the boats, to have her from beating against the ship's sides.

Mau the boat, an order to those appointed to manage her to go on board the boat immediately.

Moor the boat, the order to fasten a boat with two ropes, so as that the one shall counteract the other.

Trim the boat, the order to fit in the boat in such a manner as that the boat shall float upright in the water, without leaning to either side.

Wind the boat, the order to bring her head the other way.

The ship's gang, includes those who are employed for rowing in the boat; such as the coxswain and his gang, to whom the charge of the boat immediately belongs.

A bold-boat is that which will endure a rough sea well.

To preserve boats from foundering at sea when ships founder.

Take any sail, yard, boom, &c. that may be found floating from the ship; the longer the better; make fast to each end of the boom a rope about twice its length; and bend one end of another rope, about ten fathoms long, exactly in the middle of the span, and the other end is to be made fast to the foremost part of the boat, so that she may drive item on to the sea. When this misfortune happens far from land, and the storm ceases, in moderate weather the drift boom may be towed end on to the boat's item, that they may either row or fail towards land.

Mr. Hutchinfon, in his treatise on practical seamanship, gives an account of a boat being preferred by this method, as follows. The Bafl, in her passage from the West Indies, took up ten men in a small boat, twelve feet long, which was preferred from foundering after the vessel had founded, by having a rope fast to a log of wood, as they called it, and tied to the boat's bow, which kept her to drive end on with the head to the waves, and broke their violence so much as to preserve her from filling with water, when one half of them was obliged to lie down in the bottom of the boat, to prevent her being top-heavy. By particular inquiry of the
matter and mate of the Bafli, Mr. Hutchinson was informed, that those people belonged to a schooner bound from Bermuda to the West Indies; that it was after a hard gale of wind when they met with the boat, which had two oars for masts, and two blankets fet upon them for sails, and was steering for Bermuda, when they were fortunately taken up; and that the log of wood, as it was called, they drove by, was their foresail-fall-yard, spanned with a rope to each yard-arm, and a rope about ten or twelve fathoms long bent to the middle of the span, and made fast to the boat's bow, to drive by. The mate of the schooner told the mate of the Bafli, that they had been fair in this manner in a boat once before, by driving to leeward of a mast, in a hurricane in the West Indies.

In order to account for this wonderful effect of the drift-boom, in preventing the broken water from swamping the boat, it may be observed, says Mr. Hutchinson, that waves never break till their tops are forced forwards by their great velocity beyond the perpendicular of their base; then that water falls down forward, and inclines and compresses a quantity of air, which, by the power of its elucidity, blows this fore-part of the waves to pieces, forwards and upwards, in an oblique direction, and makes it appear like froth. They then have no buoyant power to lift a boat; but when they are high, they fill and sink her. And they break more in shallow water than in deep, in proportion as their bottoms or base are more obstructed in their velocity by the ground than their tops; hence, in very shallow water, they are continually breaking, so that they make nothing but what is called broken water, by which shoals may be seen and known at a great distance in clear weather.

If we endeavour to account for the wonderful effect of so small and simple a machine, to preserve such a small boat, deeply laden as the mast be with ten men, from being filled with water in such a storm; in our opinion, it is owing to the boat driving end on by the drift boom, that keeps it always swimming on the surface, broadside to the wind; and the waves that are running towards it, within the length of the drift boom, muffle certainly obstruct the velocity of the upper part of these waves, so as to lessen their increase in height, and prevent the top from running beyond the perpendicular of the base, or bottom of these waves, that occasion their breaking, as has been described, and spend themselves without breaking. These reasons, we hope, will be thought sufficient to recommend this method to be tried and brought into practice on such dreadful occasions: and we cannot help thinking, that the same method should be tried, when under the dreadful necessity of saving lives by boats landing on a lee shore in a storm, where broken waves run high.

The only difference we would recommend in the management, is to proceed with the boat's stern to the drift boom, and her head to the shore, to be ready to row and steer for the belt apparent landing-place; and if it is a long flat shore, as soon as the boat strikes the ground, cut or flip the drift boom rope, that it may not haul the boat off the shore again by the back sweep of the waves.

Upon landing a boat in a surf. Before the boat comes near the shore, pour a little oil on the water, which will prevent its breaking, and greatly alay the swell, so that the boat may approach the shore without the dread of being swallowed up in the breakers.

M. Danzel has lately invented an hydraulic machine for making a flip or boat advance during a calm, and even against a current.

The mechanism of this machine is very simple: it consists of a long pole, to the anterior extremity of which an apparatus, shaped like a drawer without back or front is attached in such a manner, that when pulled forwards it folds itself back under the pole, to which it (as it were) adheres, and presents to the water the thin cutting surface of its three edges, viz. of the bottom and two sides, which can neither oppose to the water a resistance capable of preventing the pole from penetrating farther, or of making the flip recede. When the pole, which is pulled forwards from the vessel, has attained to its full reach, the drawer, as soon as the pole is pulled back, assumes a vertical position, and presents to the water its whole cavity. By these means it embraces a column of water, which, without finding means to escape, refuses on a surface much larger than that of a common oar, and keeps the drawer immovable; so that those who draw the pole towards them, instead of making the vessel to recede, cause it to advance. This machine, which may be multiplied more conveniently than oars, has this visible advantage over the latter, that it opposes to the water a resistance infinitely superior, while the passive re-action of this resistance renders the labour of the mariners less laborious and more effectual.

De Chales proposes the construction of a boat, which, what burden ever it bear, shall not only move against the current, without either falls or oars, but also advance so much the faster, as the rapidity of the water is greater. Its make is the same with that of the others, excepting only a wheel added to its side, with a cord, which winds round a roller as fast as the wheel turns.

Something of the like kind has also been since done by M. Pitot. Vide Mem. Acad. R. Scienc. an. 1739. p. 359, and p. 540.

M. de la Hire has given us an examination of the force necessary to move boats, both in flagrant and running water, either with ropes fastened to them, or with oars, or with any other machine: wherein he shows, that the larger the surface of the oars plunged in the water, and the smaller that of the boat presented to the water, is; and again, the longer that part of the oar between the hand and the places where the oar redds on the boat, and the shorter that between this last point and the water; the freer will the boat move, and the greater effect will the oar have. See Oar.

Hence it is easy to calculate the force of any machine that shall be applied to rowing; v. gr. if we know the absolute force of all the men who row, it must be changed into a relative force, according to the proportion of the two parts of the oar; i. e. if the part out of the vessel be double the other, and all the men together can act with the force of 500 pounds, we compute first, that they will exert 300; which 300, multiplied by the surface which the vessel presents to the water, gives a solid water of a certain weight; which weight may be found, and of consequence the velocity impressed on the vessel by the oars. Or, the velocity of the oars may be found in the same manner, by multiplying the 300 pounds by the surface of all the parts of the oars plunged in the water. Nor would there be any difficulty in finding first the relative forces, then the absolute ones; the velocities either of the oars, or of the vessel, being given, or the proportion of the two parts of the oar.

Boats fail more slowly and heavily over shallow than over deep waters. See an account of experiments for explaining this, in Dr. Franklin's Letter to St. John Pringle. Experiments, &c. 4to. 5th ed. p. 510.

Boats, Confirmation of. In order to illustrate this by an example, let it be required to lay down the several plans of a long boat, the extreme length being 31 feet, and breadth moulded 9 feet.
Draw the straight line PO, fig. 1. (Ship-building) equal to 32 feet, the extreme length of the boat, and also to represent the upper edge of the keel. Let $\Theta$ be the location of the midship frame. From the points P, Q, and O, draw the lines PT, $\Theta$M, and OS, perpendicular to PO.

Make $\Theta$M, $\Theta$N, equal to the upper and lower heights of breadth respectively at the main frame, PT, the height of breadth at the transom, and OS, the height at the stern. Describe the curve TMS to represent the sheer, or extreme height of the side, which, in a ship, would be called either the upper height of breadth line, or the upper edge of the wale. Through the point N draw a curve parallel to TMS, to represent the breadth of the upper thole of the boat, or lower edge of the wale, if in a ship. The dotted line TNS may also be drawn to represent the lower height of breadth.

Set off the rake of the post from P to $\rho$, and draw the line $\rho\kappa$, to represent the aft side of the post; then $\rho\kappa$ will represent the round up of the transom. Set off the breadth of the post from $\rho$ to $\kappa$, and from $\kappa$ to $\lambda$, and draw the line $\kappa\lambda$ to represent the foreside of the post, which may either be a curve or a straight line at pleasure. Set up the height of the tuck from $\rho$ to $\lambda$. Let $\lambda\kappa$ be the thickness of the transom, and draw the line $\kappa\lambda$ to represent the fore side of the transom.

There is given the point S the height of the sheer on the fore side of the item; now that side of the item is to be formed either by sweeps, or some other contrivance. Set off the breadth of the item, and form the aft side of it.

Set up the dead-rising from $\Theta$ to $d$, and form the rising line $\Theta d$. Draw the line KL parallel to PO, to represent the lower edge of the keel, and another to represent the thickness of the plank or the rabbit. The rabbit on the post and item may also be represented; and the stations of the timbers affixed, as $\Theta$, (1), 1, 2, 3, 4, 5, 6, 7, 8, 9; and $\Theta$, (A), A, B, C, D, E, F, G, H; and the sheer plan will be completed.

The half-breadth plan is to be formed next; for this purpose the perpendiculars TP, OS, &c. must be produced. Upon M $\Theta$ produced set off the half-breadth from the line KL to R (fig. 2.), &c. Set off also the half-breadth at the transom from K to $\lambda$, and describe the extreme half-breadth line $\Theta RX$, making the fore part of the curve agreeable to the proposed round of the harpia.

We may next proceed to form the timbers in the body plan. Let AB (fig. 2.) be the breadth moulded at $\Theta$. Erect the perpendicular CD in the middle of the line AD, draw the line in a diametral direction from the half-thickness of the post, and $\kappa\lambda$ the half-thickness of the item. Then take off the several portions of the perpendiculars $\Theta$, 1, 2, &c. intercepted between the upper edge of the keel and the rising line in the sheer plan, and fix them up from C upon the line CD; through these points draw lines parallel to AC; take off also the several lower heights of the breadth at $\Theta$, 1, 2, &c. from the sheer plan; and let them up from C upon the middle line in the body plan; and draw lines parallel to AC, through these points; then take off the several half-breadths corresponding to each from the floor plan; and let them off on their proper half-breadth lines, from the middle line in the body plan.

Construct the midship frame according to the directions mentioned in that article, the form of which will in some measure determine the form of the rest. For if a mould be made on any side of the middle line to fit the curve part of it, and the rising line, or that marked bend mould (fig. 4.) and laid in such a manner that the lower part of it, which is straight, may be upon the several rising lines, and the upper part just touch the point of the half-breadth in the breadth line corresponding to that rising upon which the mould is placed, a curve may then be drawn by the mould to the rising line. In this manner we may proceed so far as the rising line is parallel to the lower height of the breadth line. Then a hollow mould must be made, the upper end of which is left straight, as that marked hollow mould (fig. 4.). This is applied in such a manner, that some part of the hollow may touch the side of the keel, and the straight part touch the back of the curve before described by the bend mould; and beginning aft, the straight part will always come lower on every timber, till we arrive at the midship timber, when it comes to the side of the keel. Having thus formed the timbers, as far as the whole mouldings will serve, the timbers aft them are next formed. Their half-breadths are determined by the sheer and floor plans, which are the only fixed points through which the curves of these timbers must pass. Some form these after timbers before the whole is moulded, and then make the hollow mould, which will be straighter than the hollow of either of these timbers. It is indifferent which are first formed, or what methods are used: for after the timbers are all formed, though every timber may appear very fair when confidered by itself, it is uncertain what the form of the side will be. In order to find which, we must form several ribband and water lines; and if these do not make fair curves, they must be corrected, and the timbers formed from these ribband and water lines. In using the hollow mould, when it is applied to the curve of each timber, if the straight part is produced to the middle line, we shall have as many points of intersection as there are timbers; and if the heights above the base be transferred to the corresponding timbers in the sheer plan, a curve passing through these points is called a rising flange. This may be formed by fixing a point for the aftermost timber that is whole moulded, and transferring that height to the sheer plan. The curve must pass through this point, and fall in with the rising line somewhere abaft dead-flat; and if the several heights of this line be transferred from the sheer to the middle line in the body plan, these points will regulate what is called the beading down of the hollow mould.

The timbers in the after-body being all formed, those in the fore-body are formed in the same manner, by transferring the several heights of the rising and breadth lines from the sheer to the body plan; the half-breadths corresponding to each height must also be transferred from the floor to the body plan. The same hollow mould will serve both for the fore and after-body; and the level lines, by which the water lines to prove the after-body were formed, may be produced into the fore-body, and by these the water lines to prove the fore-body may be described.

Another method of proving the body is by ribband lines, which are formed by sections of planes inclined to the sheer plan, and intersecting the body plan diagonally, as before observed, of which there may be as many as may be judged necessary. In this, four ribband lines are laid down, marked $\Delta\Sigma$, which are drawn in such a manner as to be perpendicular to as many timbers as conveniently may be. After they are drawn in the body plan, the several portions of the diagonal, intercepted between the middle line and each timber, must be transferred to the floor plan. Thus, fix one foot of the compass in the point where the diagonal intersects the middle line in the body plan, extend the other foot to the point where the diagonal intersects the timber, for example, timber 9. Set off the same extent upon the perpendicular representing the plane of timber 9, from the point where it intersects the line KL, on the floor plan; in like manner proceed with
with all the other timbers, both in the fore and after-body, and we shall have the points through which the curve must pass. If this should not prove a fair curve, it must be altered, observing to conform to the points, as nearly as the nature of the curve will admit; and, therefore, it may be carried within one point and without another, according as the timbers will allow. For after all the ribband lines are formed, the timbers must, if necessary, be altered by the ribbon lines; this is only the reverse of forming these lines; for taking the portions of the several perpendiculars intercepted between the line KL, and the curve of the ribband line in the floor plan, andlett ing them off upon the diagonal, from the point where it intersects the middle line, we shall have the points in the diagonal through which the curves of the timbers must pass. Thus the distance between the line KL, and the ribband at timber 3, on the floor plan, where transferred to the body plan, will extend on the diagonal from the middle line to the point where the curve of timber 3 intersects that diagonal. The like may be said of all the other timbers; and if several ribband lines be formed, they may be so contrived that their diagonals in the body plan shall be at such distances that a point for every timber being given in each diagonal, will be sufficient to determine the form of all the timbers.

In flattening the timbers upon the keel, for a boat, there must be room for two futtocks in the space before, or abaft \( \Theta \); for which reason the distance between these two timbers will be as much as that between the other, as the timber is broad. Here it is between \( \Theta \) and (A), which contains the distances between \( \Theta \) and (1), and the breadth of the timber beides.

The timbers being now formed, and proved by ribbon and water lines, proceed then to form the transom, fashion-pieces, &c.; see these articles.

This method of whole moulding will not answer for the long timbers afore and abaft. They are generally casted in the same manner as theohe for a ship. In order to render this method more complete, we shall here describe the manner of moulding the timbers after they are laid down in the mould loft, by a raising square, bend, and hollow mould.

It was shown before how to form the timbers by the bend and hollow moulds in the draught. The same method must be used in the loft; but the moulds must be made to their proper scantlings in real feet and inches. Now, when they are let, as before directed, for moulding each timber, let the middle line in the body plan be drawn across the bend mould, and draw a line across the hollow mould at the point where it touches the upper edge of the keel; and let them be marked with the proper name of the timber, as in fig. 4. The graduations of the bend mould will therefore be exactly the same as the narrowing of the breadth. Thus the distance between \( \Theta \) and 7 on the bend mould is equal to the difference between the half breadth of timber 7 and that of \( \Theta \). The height of the head of each timber is likewise marked on the bend mould, and also the floor and breadth firmarks. The floor firmark is in that point where a straight edged batten touches the back of the bend mould, the batten being so placed as to touch the lower edge of the keel at the same time. The several ruffles of the floor, and heights of the cutting-down line are marked on the raising square; and the half-breadth of the keel set off from the side of it.

The moulds being thus prepared, we shall apply them to mould timber 7. The timber being first properly sided to its breadth, lay the bend mould upon it, so as may best a river the round according to the grain of the wood; then lay the raising square to the bottom of the bend mould, so that the line drawn across the bend mould at timber 7 may coincide with the line representing the middle of the keel upon the rising square; and draw a line upon the timber by the side of the square; or let the line be bored or cut by a tool made for that purpose, called a raising knife; this line so raised will be the side of the keel. Then the square must be moved till the side of it comes to 7 on the bend mould, and another line must be raised in by the side of it, to represent the middle of the keel. The other side of the keel must likewise be raised after the same manner, and the point 7 on the rising square be worked on each side of the keel, and a line raised across at these points to represent the upper edge of the keel. From this line the height of the cutting down line at 7 must be set up, and then the rising square may be taken away, and the timber may be raised by the bend mould, both inside and outside, from the head to the floor firmark; or it may be carried lower if necessary. After the firmarks and heads of the timbers are marked, the bend mould may likewise be taken away; and then the hollow mould applied to the back of the sweep in such a manner, that the point 7 upon it may intersect the upper side of the keel, before set off by the rising square; and, when in this position, the timber may be raised by it, which will complete the outside of the timbers. The inside of the timbers may likewise be formed by the hollow mould. The beading at the keel is given by the cutting down before set off. The mould must be so placed as to touch the sweep of the inside of the timber formed before by the bend mould, and pafs through the cutting down point.

The use of the firmarks is to find the true places of the futtocks; for, as they are cut off three or four inches short of the keel, they must be so placed that the futtock and floor firmarks may be compared and coincide. Notwithstanding which, if the timbers are not very carefully trimmed, the head of the futtock may be either within or without its proper half breadth, to prevent which a half breadth flaff is made use of.

The half breadth flaff may be one inch square, and of any convenient length. Upon one side of it are set off, from one end, the several half breadths of all the timbers in the after-body; and those of the fore-body, upon the opposite side. On the other two sides are set off the several heights of the floor; the after-body on one side, and the fore-body on its opposite. Two sides of the flaff are marked half-breadths, and the other two sides heights of the floor.

The flaff being thus prepared, and the floor timbers fastened on the keel, and levelled across the futtocks, the timbers must next be flashed to the floor timbers; but they must be set firm to their proper half breadth and height. The half breadth flaff, with the assistance of the ram-line, serves to fig them to the half breadth; for as the keel of a boat is generally perpendicular to the horizon, therefore the line, at which the plumb-line is suspended, and which is moveable on the ram-line, will be perpendicular to the keel, whence we may by it set the timbers perpendicular to the keel, and then set them to their proper half breadths by the flaff; and when the two firmarks coincide, the futtock will be at its proper height, and may be nailed to the floor timbers, and also to the breadth ribband; which may be set to the height of the floor, by a level laid across, taking the height of the floor by the flaff, from the upper side of the keel; by which means we shall discover if the ribband is exactly the height of the floor; and if not, the true height may be set off by a pair of compasses from the level, and marked on the timbers.

Juvenal (Sat. xv. v. 126—128,) describes the boats of the ancient Egyptians, as if they were earthen-ware; and it is alleged, that such earthen-ware ships were used on the Nile, and that they were called "pits," painted, because these boats
boats of baked earth were marked with various colours. However, it is much more probable, that the Egyptians formerly, as they have done in more modern times, made use of rafts, which were made to float by empty vessels of earthen-ware fastened under them. The word "pilae," it is suggested, does not denote their being beautified with a variety of colours, but means their being rubbed with some substance that might fill up the pores, so as to prevent the water’s penetrating into the cavity of the pilae, and causing them to sink; for the Egyptian earthen-ware is said to be very porous. These boats, however, were not constructed to put up and down the Nile like boats, or properly designed for carrying goods upon them, but it is an easy mode of conveying their earthen-ware from Upper Egypt, where it is manufactured, to the lower parts of that country, where, when they reach the defined place, the boat is taken to pieces, and sold to the inhabitants. Harmer’s Observations, vol. iii. p. 56.

Boat-hook, an iron hook with a sharp point, having a socket in which a long pole is slung. This is a very necessary appendage to a boat, as by means of it, any thing floating past may be hooked; the boat may be held on to the ship, or pulled along, &c.

Boat-flower. In the whole fishery a person is appointed to each boat, whose express duty is to steer the boat towards the fish, &c.

Boats, bridge of. See the article Bridge.

Boat, removed with steam. An experiment was lately tried on the canal between Grangemouth and Glasgow, to make a large boat or lighter move by the power of steam. As, it is presumed, the series of experiments is not yet completed, the reader is, therefore, referred to the article Steam.

Boat-fswain, the officer who has the care of the boats, falls, rigging, colours, anchors, and cables committed to him, which he receives by indenture from the surveyor of the navy, and is enjoined to use great care in the disposition of them.

It is the duty of the boatman particularly to direct whatever relates to the rigging of a ship, after she is equipped from a royal dock-yard. Thus, he is to observe that the masts are properly supported by their thongs, flays, and back-flays, so that each of these ropes may sustain a proportionate effort when the mast is strained by the violence of the wind, or the agitation of the ship. He ought also to take care that the blocks and running-ropes are regularly placed, so as to answer the purposes for which they are intended; and that the falls are properly fitted to their yards and flays, and well furred or reeded when occasion requires. It is likewise his office to summon the crew to their duty, to assist with his mates in the necessary busines of the ship; and to relieve the watch when it expires. He ought frequently to examine the condition of the masts, falls, and rigging, and remove whatever may be judged unfit for service, or supply what is deficient; and he is ordered by his instructions to perform this duty with as little noise as possible.

The boatman is not to cut up any cordage or canvas without an order in writing from the captain, and under the inspection of the master; and always to have by him a sufficient quantity of small plats for security of the cables.

He is not to sign any accounts, books, lists, or tickets, before he has thoroughly informed himself of the truth of every particular therein contained. His accounts are to be audited and vouched by the captain and master, and presented to the surveyor of the navy; and until such accounts are passed, he is not to receive any wages. If he has cause of complaint against any of the officers of the ship, with relation to the disposition of the stores under his charge, he is to represent the same to the Navy-board before they pay off the ship. Fifteen years servitude intitles a boatman to superannuation.

The Boatman’s Mate has the charge of the long boat, anchors, cables, &c.; he must give an account of his flore; and he is appointed to execute the sentence of a captain or court-martial.

Boats, train of, a number of small vessels fastened to each other, ascending up the Loir in France, by falls when the wind serves, otherwise towed by men, sometimes to the number of seventy or eighty to a single rope.

Boat-flap, in Ornithology, the English name of a species of Cancroma, coccinia. Brown’s Illustrations. Or, more properly, at this time the English name of the Cancroma genus, C. Coccinia being called by the modern writers the crested boat-flap, and C. Cancroma, the white belted boat-flap. There are the two only species known. See Cancroma.

Boat, flap, in Surgery, a species of bandage, used when the crown of the head and the part between that and the forehead are to be bound. It is likewise called tholus diereus.

Boat-fly, in Entomology. See Notonecta.

Boat-fland, in Geography, a small island in the gulf of St. Lawrence, near the south coast of Labrador. N. lat. 50° 1’; W. long. 60° 55’.

Boat Passage, a channel into Facile harbour, in Dufky bay, New Zealand.

Boating, a kind of punishment in use among the ancient Persians for capital offenders.

The manner of boating was thus: the person condemned to it being laid on his back in a boat, and having his hands stretched out, and tied fast on each side of it, had another boat put over him, his head being let out through a place fit for it. In this posture they fed him, forcing him to eat by thrusting sharp iron instruments into his eyes, till the worms, which were bred in the excrements he voided as he thus lay, eat out his bowels, and so caused his death, which was usually twenty days in effecting; the criminal lying all this while in most exquisite torments. On his face, placed full in the sun, they poured honey, enticing the flies and wasps to torment him. Plutarch tells us, that Mithridates, whom Artaxerxes condemned to this kind of punishment, for pretending to have killed his brother Cyrus, lived seventeen days in the unmitigated agony; and that, when the uppermost boat was taken off at his death, they found his flesh wholly consumed, and swarms of worms gnawing his bowels.

Herodot. i. i. c. 133, 140. Plut. in vit. Artaxerxes.

Boating, in Ancient Geography, a town of Gaul, and one of the twelve cities of Novempopulania.

Boats Kids, in Naval Architecture, are long square pieces of timber, extending across the ship from the gang-boards, on which the boat’s spare masts, &c., are flowed.

BoB, or Ball, in Horology, is the metallic weight which is attached to the lower extremity of a pendulum rod, by means of a tapped adjusting nut, at such a distance from the point of suspension as the time of a given vibration requires. (See the articles Centre of Oscillation and Pendulum.) In fixing upon a proper Bob for any pendulum, two things are particularly to be attended to: the shape which is best calculated for meeting with the least resistance from the air; and the weight which is best adapted for preserving the isochronism of the vibrations with a given maintaining power. Each of these considerations has been the subject of much investigation. A sphere is a solid, the surface of which bears the least proportion to its solidity of any other, and a cube is one with great extent of surface compared to its solid contents; consequently, the former shape has
has obtained in cannon balls, intended to pass through the air with as little obstruction as possible, and has sometimes, for the same reason, been applied as a bob for a pendulum. Such a shape is better adapted for a large bob than a small one; for the increase of the surface is in proportion to the square of the diameter, whereas the increase of weight or quantity of matter is as the cube. Mr. B. Martin (Mathematical Institutions, vol. ii. p. 415.) proposed two equal fruits of similar cones, to be joined together at the bases, as a figure approximating nearly to a solid of least resistance, and recommended it as that out of which the middle one of three segments, cut longitudinally, will constitute the bell shape for an appended weight, to answer the purpose of avoiding resistance. Such a section, he conceived, would displace but a small quantity of air in one vibration, and the impuluses of that quantity, being made oblique on the floping surfaces of the ends, would produce but a small effect. The lenticular shape, however, composed of two segments of a large globe joined to the line of section, has been generally adopted by clock-makers, probably because two plates of brals of that shape can be easily folded together, and left hollow, so as to be filled with lead, or other heavy metal, in order to obtain a due degree of weight without adding to the thickness, which is an advantage that brals or copper cannot have of itself in any shape. M. Ferdinand Berthoud (Effai fur l'Horlogerie, tome ii. chap. xix.) made some experiments with bobs of both a spherical and lenticular shape, of equal weights, attached successively to the same free pendulum, from which it appeared, that, in the same temperature, the latter continued to vibrate seconds much longer than the former before they arrived at the quickest rate, which experiment was considered as a proof that the lenticular shape has the advantage in escaping the effect of resistance; it was discovered, however, on a repetition of the experiment, with seconds and half-seconds pendulums, that the friction at the point of suspension occasioned by heavy weights, particularly when vibrating in long arcs, made considerable alterations in the results, and proved itself a second source of resistance to the free motion of the pendulum.

The second consideration to be attended to in making the bob, as has been said, is the weight which a given pendulum requires, with a given maintaining power. No theory is adequate to determine this desideratum of itself, because the diminution of the maintaining power by the friction of the pivots and the flate of the oil, the duration of the impuluses on the pallets, the nature of the escapements in other respects, the resistance of the air, and at the point of suspension, and particularly the nature and quantity of momentum of the pendulum, must all enter into the calculation; and these are data, many of which are constantly varying. The momentum, or whole quantity of motion of any pendulum, is the weight multiplied into the square of its velocity, so that a large arc with a small weight, and a small arc with a corresponding large weight, ceteris paribus, ought to have an equal effect upon the motion provided the pendulum has its momentum, but the theory is not perfect; for first, large circular arcs are deemed considerable from cycloidal ones, which, it has been demonstrated by Huygens and others, are those which have the isochronal property in an uniformly dense medium; and secondly, they require a greater maintaining power than calculation gives: for instance, where the arc is 10° from the point of rest, the addition to be made to the maintaining power beyond calculation is 57 parts in 100, according to Berthoud's experiments, which consideration induces him to conclude, that irregularities in the maintaining power will affect the momentum principally composed of velocity, more than the momentum principally composed of weight; each kind of momentum, however, has its peculiar disadvantages; for

great velocity is subject to great resistance from the air, and great weight to much friction at the point of suspension.

Mr. Alexander Cummings was an advocate for a large arc with a small bob; but modern practice is in favour of a large ball or bob with a short arc of vibration. It seems to be generally allowed, that the momentum of a pendulum ought to be as great as possible for a given maintaining power, provided the latter be sufficient to overcome all obstacles to contant motion; but as the momentum is obtained in two different ways, it may be proper to subsist here an illustration of them.

If a pendulum, moving in an arc of one degree from the quiescent point, with a bob or ball of fix pounds, has its momentum denominated by unity, then the square of any given momentum will give its corresponding weight for another bob, moving in the same arc; or the square root of the given momentum will give the arc of semivibration with the same weight; for instance, a momentum 4 will require $6 \times 4 = 24$ for the weight where the arc remains unaltered; but the root of 4 = 2 will be the arc from the point of rest with the same weight; again, if the momentum be required to be 9 for a given maintaining power, the weight must be 54, or the arc 3° from the point of rest, and in the same proportion for any other momentum; but, in fact, both the weight and arc may be varied according to circumstances, which latitude affords great variety in the adjustment of the bob, and matter for multiplied experiments to determine what weight and arc shall be most defirable, taken conjointly under different circumstances.

The most practicable method of adjustment of the momentum of a pendulum, where a weight is used as the maintaining power, feems to be, to vary this power instead of the weight of the bob or ball, which, when once fixed, is the requisite shape, is not so easily altered. In pendulum clocks, actuated by a spring as a maintaining power, such adjustment cannot indeed be made in the power properly without changing the spring, or altering the fusee after they are adjusted to each other; but as these instruments are not intended to measure time with great nicety, the adjustment of the bob to the maintaining power is exactly done by guess. In Huygens's best clock, the maintaining power was equal to three pounds, falling about 90 inches in 24 hours, and the ball of its seconds pendulum, together with the pendulum itself, was also three pounds; but the nature of his escapement required the vibrations to be performed in long arcs. Cummings tried different weights for his pendulums from 6 to 15 pounds, and various arcs from 3° to 6° from the point of rest; but it does not appear that any other standard has been adopted by clock-makers than what accords with the individual opinion of each. See MAINTAINING POWER.

Bob, in Ringing, denotes a peak consisting of several courses, or sets of changes.

Bob-flay, in Sea-Language, a rope used to confine the bowsprit of a ship downward to the flem, or cut-water, and to countercraft the force of the foys of the fore-mast, which draw it upwards.

It is fixed by thrusting one of its ends through a hole bored in the fore-part of the cut-water, and then splicing both ends together, so as to make it two-fold, or like the link of a chain; a dead-eye is then feized into it, and a lanyard passing through this, and communicating with another dead-eye upon the bowsprit, is drawn extremely tight by help of mechanical powers. The bob-flay is the firth part of a ship's rigging, which is drawn tight to support the foys. With this view, it is usual to suspend a boat, anchor, or other weighty body, at the bowsprit end, to press it downwards during the operation.

Bob-flay-holes, are those holes in the flem, or fore-part of the knee of the head, to which the bob-flay is faftened.

BOBAC.
BOBAC, in Zoology. The bobak of the French and English writers is a fort of MARMOT with small, and somewhat oval ears; tail hairy; a claw upon the fore thumb; and the body grey above, and yellowish beneath. Gmelin calls this animal *ardensy bower*.

There appear to be two varieties of this species, if not more. The bobak of Rassinski (Nat. Hist. Pol. p. 235.) described by Briffon, in his History of Quadrupedals, under the name of *marmota polonica*, is of yellowish colour, inclining to reddish upon the head; but the bobak described by Pallis is of a greyish brown colour, with only the under parts yellow. In every respect, except the colour of the hair, these two varieties agree.

This creature is rather larger than the rabbit, measuring about sixteen inches from the nose to the base of the tail, the latter of which is four inches and an half in length; so that the whole animal measures above twenty inches. Dr. Pallas, to whom we are chiefly indebted for an account of the bobak, tells us, that it is a native of the high, but milder and funny fides of mountainous countries, which abound with fiddle, or free-tone rocks, where it is found in dry situations, and such as are full of springs, woods, or fand. It abounds in Poland and Ruffia, among the Carpathian hills: it swarms in the Ukraine, about the Borilthenes, especially between the Sula and Supoy; and then again between the Borilthenes and the Don, and along the range of hills which extend to the Volga. It is found about the Yaik and the neighbouring rivers; and inhabits the southern defect in Great Tartary, and the Alpae mountains, east of the Irris. It ceases to appear in Siberia, on account of its northern situation, but is found again beyond the lake Bialkal, and about the river Argun and the lake Dalay, in the funny mountains about the Lena, and very frequently in Kamfelafrica, but rarely reaches as high as latitude 55°.

The bobak is not considered as an article of food by the Mahometan tatars. The Coffsacks and the Calkmoks, on the contrary, hunt and kill them for eating; the flesh, however, is very fat, and not in much esteem for the goodness of its flavour. In its manners of life the bobak resembles those of the Alpine marmot, with which it has been apparently sometimes confounded. It inhabits deep burrows, in societies of from twenty to forty-two in each receptacle. Their habitat is lined with the finest hay; and it is said, the quantity found in every such receptacle is sufficient for a night's provender for a horse. In the morning, or the middle of the day, when the sun shines not, they go abroad in search of food, always taking the precaution to flation one of the party at the entrance of their cell as a sentinel, who announces the least approach of danger with a whistle; and all, if within hearing, are enabled to provide for themselves in the best manner circumstances may require, either by returning for shelter to their cell, or remaining at a distance till the danger is over. The marmot, when attacked, rears itself upon the haunches, and defends itself with the fore paws. It eats with the fore paws, in the same posture. The bobak is an animal of a mild and gentle disposition, and may be easily domesticated. They are torpid throughout the winter, unless kept in a warm room. They breed early in the spring, and are said to produce six or eight young. The fat of this creature is used for dressing fur and leather.

BOBAN, in Geography, a town of Arabia, 32 miles S. of Siander.

BOBART, ROBERT, in Biography, curator of the botanical garden at Oxford, which had been lately instituted by lord Danby, published in 1648, "Catalogus plantarum horti medici Oxoniensis," 8vo. The catalogue gives the names of about 1600 plants, many of them from Canada.

BOBART, JACOB, who succeeded his father, as curator of the garden, published, in 1661, the third volume of Morrision's "Plantarum historia universalis Oxoniensis, seu herbarum distributio nova, per tabulas cognitionis, ex natura libro detecta," fol.: making up by his own industry and sagacity what was deficient in the loose and imperfect sketches left by the author at his decease. There is an ingenious paper by this writer in the Philosophical Transactions for the year 1661, on the effects of the great frost, which happened the preceding winter, on trees and other plants.

Many oak, elm, ash, walnut, and other trees, were found, he says, with large rents or cleits in different parts of their trunks, in the large branches, and in such parts of their roots as were not sunk deep into the earth. Parts, he adds, that were so knotted, that they could not have been split but with great difficulty with beetles and wedges, were rent anew by the force of the ice contained within them, making, at the time of bursting, a noise like the explosion of gunpowder. It was supposed, that the trees which suffered were diseased, that some of the vessels were divided or burst, and that the effect was produced by the freezing of the sap or other juices contained in these cavities.

BOBARTIA, in Botany, (named in honour of James Bobart, formerly professor of botany at Oxford), a genus formed by Linnæus for a plant said to grow in the Ealt Indis, with the following essential character:—Glimmes of the calyx numerous; the exterior ones short, univalved; the interior longer, bivalved; glime of the corol. single, shorter than those of the calyx, sitting on the germ, thrivelling. This generic character was first published in the Amoenitates Academicae, vol. i. p. 113. (Ludg. 8vo. 1781.) and in the species Plantarum a reference is given to Schuencher, Gram. 369. Reichard added another supposed synonym from Pluknet tab. 30. fig. 7. Schreber, Julleu, La Mark, and Boîe, have all taken it up from Linnæus; and La Mark, in his Illustrations, has copied Pluknet's figure. Willdenow, in his new edition of the Species Plantarum, has abolished the genus; afferring, on the authority of Schumacher (Ac. Nat. Hafn.), that Linnæus drew up the character of his botarita from a mutilated specimen of moraea fapaecae, first completely described by Thunberg, and adopted by Linnæus the younger in the Supplementum Plantarum, p. 99.

The mistaken synonyms of Schuencher and Pluknet are referred by Willdenow to cyperus arenaria of Retz, of which Pluknet's figure, copied by La Mark, is said to be a good representation. A figure of moraea fapaecae is also given by La Mark under its proper genus.

BOBARTIA. See also Rudbeckia Purpurea.

BOBBIN, in Commerce, a term denoting about ¼ of a hundred of undressed flax.

BOBBIN, or Bobbin, a little piece of wood turned into a cylindrical form, whereon thread is wound, to be used in the weaving of bone-lace.

The French also give the denomination bobine to what among us is more properly called a *pool or quill*. In which they are also followed by several English.

In this general sense, bobbins are used to wind thread, worsted, hair, cotton, silk, gold, and silver; and they are...
of different lengths and sizes, according to the materials which are fpun or wound.

Borsing for Eds., among Fishermen, is an animning method of catching eels, generally practised from the side of a boat, the piers of bridges, wharfs, or other situations, where deep water can be at once reached. The bait made use of may be either foured lob-worms, or garbage of any kind; which bait of whatever kind is throng lengthwise on woofed, so as to completely cover it. Some yards are prepared in this way, which are then tied up in links, making something like a bundle of fripp. So prepared, the bait is suspended from a strong rod or pole by two or three yards of pack-thread, led away from the bank of the road, with mors and lef according to the strength of the current. The bait and lead must be fixed to the bottom, and sufered to remain, when the fish will soon be felt to nibble; but time must be allowed for them to make their hold secure, after which they may be gently pulled up to within a small distance, when a slight jerk will secure them. The mouths of rivers, muddy and deep places, where the tide reaches, are particularly favourable for this sport.

Bobbio, or Boccio, Nobilium, in Geography, a small town of Italy, and capital of a district of the same name; formerly belonging to the duchy of Milan, feated on the river Trebia, the fee of a bishop, suffragan of Genoa, 30 miles N.E. of Genoa. It is now a canton of the district of Alexandria, in the department of Marengo.

Bobsio. See Bribio.

Bobenhausen, a town of Germany, in the circle of the Upper Rhine, and principality of Upper Heife; 17 miles east of Gießen.

Bodenaukirchen, a town of Germany, in the circle of Upper Saxony, and the Vogtland; 6 miles s.w. of Oelfitz.

Bober, a river which runs into the Oder, at a small distance to the west of Croffen in Silefia.—Allo, a town of Lithuania. N. lat. 55° 3′. E. long. 23° 5′.

Boberg, a high promontory in the prefecture of Bohling, and diocese of Ripen, in Denmark, near which the coast is very dangerous, and has proved fatal to many ships.

Boersberg, a town of Silefia, 9 miles S.S.W. of Croffen, and 25 S. of Frankfort on the Oder.—Allo, a town of Germany, in the circle of Upper Saxony, and duchy of Croffen, 6 miles S. of Croffen.

Boi, in Conchology. Adanion gives this name to the variety 3 of ostolat pericula.

Bohisatio, or Bocdisatio, in Mystic, denotes the united of the seven syllables, boi, er, di, ga, lo, mi, ni, to express the seven musical notes in lieu of the fix usual ones introduced by Arete, ut, na, mi, fi, fa, la, as has been sometimes done by the Netherland and German musciians since the beginning of the seventeenth century, to avoid the mutation necessary in the use of these latter.

Boilingen, in Geography, a small town and district of the same name, of Germany, in the duchy of Wurttemberg, situated in a fertile country, and in the forest of Schonbuch, which abounds with game, having a castle seated on an eminence lying above the town. The district contains 12 parishes; and the vicinity produces some wine.

Boir, a river of Lithuania, which runs into the Dnieper; 5 miles S.S.E. of Rohaczow.

Boir, in Zoology, a kind of marine otter, so called by the Russians, who reside at Kamtchatcha, the precise species of which is doubtful. Some have imagined it to be allied to the cafer.

Bobritzsch, in Geography, a town of Germany, in the circle of Upper Saxony, and country of Erzegberg, 4 miles S.E. of Trierberg.

Bobrof, a district of the government of Voronetz, in Ruffia, feated on the Biluk, falling into the Don.

Bobrownik, a town of Poland, in the patalinate of Lublin, 24 miles W.N.W. of Lublin.

Borysle, a town of Lithuania, in the patalinate of Minfs, feated near the river Berezyen. N. lat. 52°. E. long. 29° 1′.

Bobt, a town of Lithuania, in the patalinate of Troki. N. lat. 55°. E. long. 24° 1′.

Boca. See Bocca.

Boca Erymonidia, in Geography, a bay of North America, in the bay of Campeche, on the coast of Yucatan. N. lat. 18° 56′. W. long. 91° 46′.

Boca Grand, a bay of North America, at the mouth of the river Zacu, on the S.E. coast of Costa Rica. N. lat. 19° 50′. W. long. 83° 6′.

Boca Tora, a bay of North America, in the Caribbean sea, on the coast of Veragua. N. lat. 8° 59′. W. long. 83° 1′.

Bobcarito, a town of North America, in the country of New Navarre, 65 miles east of Cinnloc.

Boca-Chica, the first or entrance into the harbour of Cartagegna, in South America; which was filled up since the attack of the English in 1741, who, having made themselves masters of the forts which defended it, entered the bay with an intent of taking the city; but their attempt miscarried, and they were obliged to retire with considerable loss. This event produced orders for opening the old entrance, by which all ships now enter the bay.

Boca-Del-Drago, a fort between the island of Trinidad and Andalufia, in the province of Terra Firma, South America.

Boca, a small territory of France, in Normandy, of which the principal place was Vire.

Bocalieau, a small island near the east coast of Newfoundlaid. N. lat. 48° 15′. W. long. 52° 3′.

Bocamele, in Zoology, the provincial name of an animal of the Mustella tribe, found in the island of Sardinia. This is believed to be the creature described by Aristote by the name of Iris.

Bocana, in Ancient Geography, a town situate in the eastern part of the Isle of Taprobana, Ptolemy.

Bocardo, in Logic, the fifth mode of the first figure of syllogisms, wherein the first proposition is particular and negative; the second, universal and affirmative; and the third, or conclusion, particular and negative. Thus:

BOC Some animal is not man.
AR Every animal has a principle of senation.
DO Therefore something has a principle of senation, that is not man.

Bocas, Las, in Geography, a town of North America, in New Bicay, 120 miles E. of Paranal.

Bocat, the name of a valley in Syria, in which are the ruins of Balbec, of which Mr. Wood says, it might by a little care be made one of the richest and most beautiful spots in Syria; for it is more fertile, he adds, than the celebrated vale of Damascus, and better watered than the rich plains of Edrlacan and Rama. In its present neglected state, it produces corn, some good grapes, but very little wood. Here, it is supposed, was situated "Beel-hamon," which was the marriage portion of the bride of Solomon. Sol. Song, viii. 12. This estate was leased out to a variety of tenants, each of whom paid her a clear rent of a thousand shekels of silver, amounting to about 120l. 16s. 8d. perling. Harmer's Outlines of a New Commentary on Solomon's Song, p. 35. Good's Song of Songs, Pref. p. 13.
But variety was also called "Dekas," which see. See also Balbec.

BOCAUD, John, in Biography, born at Montpellier, where he received his education. In 1549, he was made doctor; and in 1544, on the death of Denis Fontenot, professor of medicine in the university there; an office he is said to have filled with distinguished honour to the time of his death, which happened in 1558. We have only one work published by this writer: "Tabulae curvationum et indicationum cx proximo Galeni methodos, in forma rerum capita contracta," fel. Lyons. Haller. Bib. Med. Pract. Eloc. D'fa. Hill. Med.

BOCCA, in Geography, a town of Italy, in the duchy of Mantua, in the Comestenza, 5 miles N.N.E. of Sabionetta.

Bocca Trevia, a name given by foreigners to the river Pei-kiang of China, near its discharge into the southern sea of China, S. Pe Kiang.

Bocca, in Glass-making, the round hole in the working furnace, by which the metal is taken out of the great pots, and by which the pots are put into the furnace. This is to be flopped with a cover made of earth and brick, and removable at pleasure, to preserve the eyes of the workmen from the violence of the heat.

BOCCACCI, or Boccaccio, Camillo, in Biography, a painter of history and portrait, was born at Cremona in 1511; and, having received instructions in the art of painting from his father, removed to Rome, and assumed the Roman taile. His application was indefatigable, and his improvement so observable, that he was immediately employed in several noble works for the churches and convents. He died young in 1546, when he was making rapid progress towards very high perfection. Pilkingston.

BOCCACCINI, Anthony, a surgeon of Comachio, a town in Ferrara, flourished in the early part of the last century. Revising the practice of Magatus, in the cure of wounds and ulcers, which had fallen into disuse, he advertised no oily or greasy applications in the treatment of them, nor made use of tents or injections in the cure of abscesses, which, by irritating the parts, prevented, he said, their union, and frequently occasioned the orifices to become cavous. His works, illustrating his practice, are "Cinque dillinagini Chirurgici, per la cura delle ferite," Venice, 1713. 8vo. treating of the cure of gun-shot wounds; "Cinque dillinagini Chirurgici, per la cura delle ulcere," Ver. 1714. 8vo. with observations explaining and defending the doctrine of Magatus. Haller. Bib. Chirurg. Eloc. Diet. Hill. Med.

BOCCACIO, or Boccaccio, John, an eminent Italian writer, and one of the refiners of literature in Europe, was born of parents in low condition at Certaldo in Tuscany, in 1312. Declining that mercantile occupation for which he was originally designed, and in which he spent some of his earlier years, he devoted some time to the study of the canon law; but as soon as he had an opportunity of choosing for himself, he pursued a course of literature; and with this view sought instruction from the best masters, and at Florence put himself under the tuition of Leonzio Plato for the Greek language. Beside the advantage he derived in furnishing his mind with stores of literature, and in cultivating a good taste, from conversation with the most learned men of his age, and from collecting and copying the most approved Greek and Latin writers of antiquity, he was particularly indebted for his progress in learning, and for his future reputation, to the infallibleness and patronage of Petrarch, who was eminently useful to him both by his advice and by supplying him with money for aiding the prosecution of his studies, when his own patrimony was exhausted. By a diligent improvement of these advantages, he acquired such reputation, that the republic of Florence conferred upon him the honour of citizenship, and employed him in a variety of public transactions. Among other important commissions with which he was entailed, that of negotiating the return of his friend Petrarch to Florence was particularly agreeable to him. But though his message to this purpose did not succeed, it afforded him an opportunity of establishing a more intimate and confidential correspondence with this patron of his youth. In 1353, two years after his visit to Petrarch, he was sent to pope Innocent VI. at Avignon. At this time he lived freely, and devoted himself chiefly to poetry and compositions of a lighter kind. During his rambling in Italy, he visited Naples, as some have said, in the year 1341, where he was favourably received by king Robert, and where he reeded for some time. Here he fell in love with a young person whom he calls Tiametta, and who is commonly supposed to have been the natural daughter of Robert. In 1359, he had a conference with Petrarch at Milan, the result of which was that he indulging more serious reflections than he had hitherto done; and having received an admonition in 1361, that his life would not be of long continuance, and that he would soon abandon poetry, his mind was so impressed that he immediately determined to relinquish his poetic lucubrations, and even the perusal of profane authors, and, against the counsel and remonstrance of Petrarch, to part with his library. About this time he assumed the clerical habit, and adopted a plan of conduct more guarded and regular than that of his past life. In 1362 or 1363, he again visited Naples; and, without making any long stay there, went to Venice, and passed three months with his friend Petrarch. He was again deputed by his countrymen as ambassador to pope Urban V. at Avignon; and in 1367 he attended the pontiff under the same character at Rome. A public lecture on the "Comedia" of Dante, having been inducted at Florence, he commenced his expositions of that author in October, 1373; but, preferring the retirement of Certaldo, his native place, towards the close of his life, he died there in December 1375. Boccacio was a voluminous writer both in prose and verse. His works in Latin were, a mythological treatise in 15 books, "De Genealogia Deorum," Basil, 1532, fol. esteemed excellent at the time when it was written, but long since superseded by more valuable publications of a similar kind; to this was annexed a "Poeticon on Mountains, Rivers, Seas, Lakes; &c.," with respect to both the he has been charged with plagiarism; "An Abrigement of the Roman History," from Romulus to the year of Rome 724, with a parallel of the seven kings of Rome and of the emperors to Nero inclusively, Coleta, 1534. 8vo.; an historical treatise, in nine books, entitled "De Caesaribus virorum et feminarum illustrium," beginning with Adam, and terminating with John king of France taken prisoner by the English at the battle of Poitiers, in 1356, which work was translated into Italian, Spanish, French, and English, printed at Augsburg, in 1544, and in French at Lyons, in 1483, and at Paris, in 1558, by Claudius Vitart, under the title of "Traité des Méfaventures des Perfonnages figuaires," 8vo.; and another book "De claris mulieribus." He also wrote in Latin a number of elegies. In Italian poetry, his compositions were the "Theside," in 12 books; the "Filistrate," the "Ninfate Fi泷elane," &c. &c. But though he was reckoned one of the three princes of the poets of that age, he is ranked only as the third of the triumvirate, precedence being assigned to Dante and Petrarch. It is said, that he was duly sensible of his inferiority; and that, after having seen the fennets and fongs of Petrarch, he determined to throw his own into the fire. His prose works, which
which are more valuable, are his "Commentary on Dante," printed at Rome in 1544, 1610; and at Florence, in 1576, 8vo.; some romances of an amorous kind, intermixed with verse, as "Il Filococho," "La Fiametta," "L'Ameto," "Il Laberinto d'Amore," &c. &c. But his most celebrated production of this kind is his "Decamerone," or collection of one hundred stories, or novels, assigned to have been recited in ten days by a company of ladies and gentlemen, who had retired into the country from the plague of Florence in 1548. These stories are partly founded on fact, and partly the productions of the author's own imagination; and they present a curious exhibition of characters and manners in all the ranks of society. They abound with satirical strokes levelled against the vices, usuries, and frauds of the priests, and even the mysteries of religion; and the language, in some parts, is so free and licentious, that we may well wonder at their being recited before females of character and condition. However trite and vulgar many of the reflections may now appear, the style in which they are delivered is considered as a model of elegance and purity for the age in which they were written, and places the Italian language far beyond that of any modern nation at fo early a period. No work was ever more popular, or more generally translated, than the Decameron. The stories that occur in this work have furnished materials for some of the most popular pieces of La Fontaine and other similar writers. Boccace affirms the credit of having first brought the writings of Homer and of several other Greek authors from Greece to Tuscany; and he was, without doubt, a most inditribus and indefatiagible copist of the remains of antiquity. His poetry is pronounced by his countrymen to be as feeble and languid in its character, as his prose is exquisite and admirable. His valuable library was bequeathed to a convent in Florence, where it was long preferred. For a further account of his life and writings, see Fabricius's Bibl. Lat. mediæ ævi. tom.i. p. 245. &c.; and Tiraboschi, tom. v. p. 83. 459—451. Gen. Dict.

BOCALE, or Bocal, a liquid measure used at Rome, answering to what among us is called a bottle, being equivalent to about an English quart. Seven boccale and an half make the rubbia.

BOCCALINI, Trajan, in Biography, a fatirical writer of the 16th century, was the son of an architett at Carpi, and born at Loretto in 1556. At Rome, where he principally resided, he had access, by the vivacity of his genius, to several persons of rank, and among others to cardinal Bentivoglio, whom he instructed in geography. Protected from the danger to which his fatirical turn exposed him, by the influence of the cardinals Borghese and Gaetani, he also, by their recommendation, obtained several offices of trust and honour in the ecclesiastical state, and was appointed to the government of Benevento. But his public conduct occasioned complaints, and he became obnoxious to the Spaniards, by exposing with freedom and severity their designs against the liberty of Italy, so that he was under a necessity of retiring to Venice in 1612. In the following year, it is said that he was assailed by four ruffians, who broke into his chamber at an early hour in the morning, and beat him so severely with sand-bags as to occasion his death. Of his works, the most celebrated is his "Ragguaglì di Parnaso," or news from Parnassus, in which, under the fiction of a court in which Apollo presided, he takes occasion to satirize the actions and works of several persons who pass under review; but his reflections frequently betray the want of critical judgment and of regard to truth. A second part of this work, written with the same view, is entitled "The Secretary of Apollo." His "Political Touchstone," levelled against the Spaniards, is of a similar kind. He also wrote the "Political Balance," "Commentaries on Tacitus," and some other works. Tiraboschi. Gen. Dict.

BOCCARELLA, in the Glass-Manufacutures, a small hole or aperture of the furnace, one of which is placed on each side of the bocca, almost horizontally with it. Out of them the fitters take coloured or finer metal from the piling pot.

BOCCAS, in Ichthyology, the Arabian name of a fish belonging to the Scromber genus, observed by Forskal in the Red Sea. Vide Scromber Sansun.

BOCCHERINI, Luigi, in Biography, who, we hope, is still living at Madrid, and whose instrument is the violoncello, though he writes but little at present, has perhaps supplied the performers on bowed-instruments and lovers of music with more excellent compositions than any master of the present age, except Haydn. His style is at once bold, matterly, and elegant. There are movements in his works, of every tyle, and in the true genius of the instruments for which he writes, that place him high in rank among the greatest masters who have ever written for the violin or violoncello. There is perhaps no instrumentul music more ingenious, elegant, and pleasing, than his quintets in which invention, grace, modulation, and good taste, combine to render them, when well executed, a treat for the most refined hearers and critical judges of musical composition.

BOCHETTA, in Geography, a chain of mountains, over which is the high road between Lombardy and Genoa; on the summit of the highest, which is very steep, is a way so narrow that three persons can hardly go abreast, called "The Paf of Bocchetta," defended by forts, and considered as the key to the city of Genoa. In 1746, the imperialists, having made themselves masters of this pass, found little difficulty in proceeding to that capital. In 1778, a magnificent road was made from the Bocchetta to the north of Genoa, through the Polzehvera, which, for the space of three years, employed from 5 to 800 men, by the patriotic munificence of one noble family, the Cambia. The Polzehvera in the Bocchetta yields a beautiful stone, which is ferpentine, of various colours wrought with marble.

BOCCIANICO, a town of Italy, in the kingdom of Naples, and province of Abruzzo citra, 3 miles S. E. of Civita di Chieti.

BOCCARDI, Clemente, called Clementino, in Biography, a painter of history and portrait, was born at Genoa in 1620, and after having been the disciple of Bernardo Strozzi, went to Rome for improvement, by a judicious observation of the ancient sculptures, and the works of the celebrated modern artists. By the efforts of his own excellent genius, and a diligent application to design, he discovered the art of blending the antique and modern gulf in a style both of gracefulness and strength. Most of his works (his portraits excepted, which were lively, natural, and graceful,) are in the chapels of Genoa, Pisa, and other cities of Italy, where they are much esteemed. Pilkington.

BOCCOLD, Bockholt, or Beuvelks, John, commonly called John of Leyden, a journeyman-taylor of Leyden, who, in the earlier part of the 16th century, connected himself with John Matthias, a baker of Haarlem, and with his assistance displayed the astonishing effects of fanaticism and enthusiasm. These two anabaptist prophets, for this was the appellation which they assumed, fixed their residence at Munster, in Westphalia, and at length gained such a number of profelytes, that they became masters of the city, and established in it a new form of government, directed by Matthias, who invested his commands, with the style, and with
with the authority of a prophet. Matthias, having pillaged the city, amassed large hoards of wealth, and reduced all ranks to an equality, provided for its defence, by repairing and extending its fortifications, by forming all his followers, who were capable of bearing arms, into regular bodies, and by endeavouring to add the vigour of discipline to the impetuousity of enthusiasm. After these preparations, he sent out emissaries to the anabaptists in the Low Countries, inviting them to assemble at Munster, which he dignified with the title of Mount Zion, and from thence he proposed that they should set out to reduce all the nations of the earth under their dominion. The bishop of Munster, justly alarmed by these hostile assemblages, assembled an army, laid siege to the town, and slew Matthias, with 30 of his attendants, in their first frantic rally. Matthias, in the same year 1534, was succeeded by Boccold, who, more cautious than his predecessor, satisfied himself with carrying on a defensive war, whilst he waited for the succours from the Low Countries, which he encouraged his deluded followers to expect. But though less daring in action than Matthias, he was a wilder enthusiast, and of more unbounded ambition. Accordingly he marched naked through the streets, and proclaimed with a loud voice, "That the kingdom of Zion was at hand; that whatever was highest on earth should be brought low, and whatever was lowest should be exalted." In order to verify his declaration, he commanded the churches, and the most lofty buildings in the city, to be levelled with the ground; and depriving Cuippedorling, one of the most considerable of their professors of the consulship, the highest rank in the commonwealth, he degraded him to the humiliating office of common executioner. In place of the deposed pontiffs, he named 12 judges, according to the number of tribes in Israel, and referred to himself the authority possessed by Moses as legislator of the people. He further declared to the assembled multitude, that it was the will of God, that John Boccold should be king of Zion, and sit on the throne of David. Accepting this heavenly calling, which he pretended to have received by a special revelation, he was immediately acknowledged as monarch by the deluded multitude, and assumed all the state and pomp of royalty. He wore a crown of gold, and was clad in the most sumptuous garments. A Bible was carried by him in one hand, and a sword in the other; he appeared in public attended by a body of guards, coined money with his own image, and appointed the great officers of his household and kingdom, among whom Cuippedorling was nominated governor of the city, as a recompence for his former submition. As the excesses of enthusiasm have usually led to fateful gratifications, Boccold instructed his prelates and teachers to inculcate the lawful heirs of a plurality of wives, as one of the privileges granted by God to his saints; and he himself set the example of this Christian liberty, as he called it, by marrying at once three wives, one of whom was the beautiful widow of Matthias. He proceeded with augmenting the number of his wives to fourteen, refraining, however, the title of queen to Matthias's widow, and allowing no other to share with him the splendours and ornaments of royalty. The multitude vailing themselves of his example, indulged their desires to the most licentious and extravagant excesses; and polygamy and freedom of divorce universally prevailed. The bishop of Munster, in the mean while, aided by the German princes, pressed closer the blockade of the town into which the siege had been converted; but its fortifications were too strong, and so diligently guarded, that they durst not attempt an assault. But no succours arrived to the besieged; and after a close blockade of about fifteen months, they began to feel and lament the effects of scarcity. However, such was the fascinating influence of Boccold's promises and predictions, that no one seemed inclined, or at least permitted resolution enough, to propose a surrender. One of his wives, intimating a small doubt of his divine mission, was summoned before him as a blasphemer, and commanding her to kneel, he cut off her head with his own hands; his frantic followers at the same time dancing with joy round the bleeding body of their companion. Notwithstanding all the horrors of famine, the people of Munster still refused to capitulate. At length, however, a defterer made his escape to the enemy; and offered to head a party of the besiegers, under cover of the night, to a weak part of the fortifications, and left vigilantly guarded than any other. The proposal was accepted; and the party feasted the walls, seized one of the gates, and admitted the rest of the army. A dreadful carnage ensued; the king and Cuippedorling were taken prisoners. The former, loaded with chains, was carried about from city to city, as a spectacle to the people; but notwithstanding all its frights, he maintained a firm and unbroken spirit; and adhered inflexibly to the tenets of his faith. He was afterwards brought back to Munster, and suffered the most exquisite as well as lingering tortures of death with unflinching fortitude; thus finishing an extraordinary course of delusion, at the age of 26 years. Bayle, Art. Anabaptists. Robertson's Hist. of Ch. V. vol. iii. p. 99, &c. Mallet's Eccl. Hist. vol. iv. p. 452, &c.

BOCCHONE, Pau!., an ingenious naturalist, was born at Palermo, in Sicily, April 24th 1673. He was a wealthy and respected family, originally from Savona in Genoa. To improve himself in natural history, particularly in botany, to which he was early attached, he travelled over Sicily, Corsica, Malta, many parts of Germany, Holland, and England, conversing with the most eminent literary characters in the places he visited, with whom he afterwards kept up a correspondence. In the course of his travels, he was admitted doctor in medicine at Padua, was elected member of the Academ. Nature Curiouf, and made botanist to the grand duke of Tuscany. In 1682, he entered among the Cistercian monks at Florence, and with the habit of the order, took the name of Sylvio, which he affixed to his latter works, but he was still permitted to continue his researches in natural history. Returning at length to Sicily, he retired to one of the houses of the Cistercians near Palermo, where he died, Dec. 22, 1704. As he had been indefatigable in his researches, his collection of plants and other natural productions was very considerable. Sherrard, who lived as a century, published at Venice in 4to, the same year. The catalogue was also published by itself. Several of his works appear to have been printed while he was on his travels. The first of them, "De abrotsano mare mortum," in 1668; and in the same year, "Manifellum botanicum, de plantis Siculi," Cataneae, 4to. By an advertisement at the beginning of the work, he offers to botanists the seeds of many of the curious and rare plants he had collected, at moderate prices. Morrison published an edition of this work at Oxford in 1674, 4to, under the title of "Icones et descriptiones rariorum plantarum Sicilici, Melitae, Galliae, et Italice." Many of the plants, Haller has since perceived new. The figures are small, and in general not well delineated or engraved. His next production was "Recherches et observations naturelles," published at Paris in 1671, 12mo. again at Amsterdam in 1674, and again in 1747, in 8vo. It consists of letters to his correspondents in France, Italy, England, &c. In 1684, in 16mo. "Opera... vazioni
vazioni naturali ove si contengono materie mediche e di botanica," Bologna. The observations are 26 in number, dedicated, or addressed to so many of the author's friends and patrons, among whom are many persons of high rank. He is very profuse in his encomia on the medical virtue of many of the plants, which he praises far beyond their real value. " Tenere operosum," Haller says, "credulus efficiendum, et in viribus mediasi plantarum liberaliter." "Mufeito di fisica e di esperienze decorato di operazioni naturali," Venet. 1697, 4to. The author here assumes the name of Sylvia. The observations are, as in the former work, dedicated to his noble patrons, and contain ample accounts of the medical virtues of various plants. much beyond what, from experience, they have been found to possess. Some smaller dissertations were printed in Mifcel. Nature Curiofs, and in the Journal des Savans. On the whole, Bocconea appears to have been an industrious and intelligent writer, and to be deservedly reckoned one of the promoters and improvers of botany. Haller Bib. Botan. Eloy. Dict. Hist. Med.

Gen. Char. Perianth two-leaved, ovate, obtuse, concave, caducous. Cor. none. Stamens, before the opening of the flower, from 12 to 24, afterwards seldom more than 10; very short. Anthers: linear, very large, as at the very young. Pith, germ roundish, contracted both ways, large, pedicellate. Style one, bifid. Stigma simple, reflex. Pericarp, capsule subovate, attenuated to each end, compressed, one-celled, two-valved. Valves coriaceous, opening at the base; the annular future crowned with the permanent style. Seed one, globular, infiltrated in pulp at its base, fixed to the bottom of the capsule. Obserbo. The capsule refines 2 filiculae in its general shape, and in the permanent future terminated by the style.

Species. 1. Bocconia frutescens, shrubby bocconia tree, celandine, or parrot-weed. "Leaves oblong, sinuate. Wild." An ornamental shrub, 10 or 12 feet high, with a straight, hollow trunk filled with pith, covered with a smooth, white bark, and divided near its summit into several cylindrical branches. It abounds in all its parts with a thick, yellowish juice, similar to that of celandine. Leaves fix or few inches long, and about three broad; alternate, oblong, semipinnatifid; a little sinuate, with oval, unequally toothed segments; green and smooth above, glaucous, and a little tomentose beneath; on short petioles; flowers small, greenish, numerous, in large pyramidal, terminating panicles; bracts lanceolate.

It is a native of Mexico and the West Indies, where its acid juice is used to take off pimpls and warts, and is also said to be employed in dyeing yellow. It has an evident affinity with the celandines in its felicitous qualities and two-leaved caducous calyx, but differs remarkably from them in its incomplete flowers and mononerprous fruit. La Mark conjectures that its want of a corolla is owing to the change of its natural petals into stamens: for, he observes, after the fall of the true stamens, four are constantly left, which continue as long as the calyx. See La Mark. Encyc.

The shrubbery bocconia was first cultivated in England by Mr. Miller in 1739, and has flowered and ripened its seeds in the physic garden at Chelsea. It is propagated by seeds, which should be sown in a pot filled with light fresh earth, early in the spring, and then plunged into a bed of tenant's bark, and occasionally watered. When the plants are come up, they should be transplanted into separate pots filled with light sandy earth, plunged again in the hot bed, and shaded from the sun in the heat of the day, till they have taken root: at first they should be sparingly watered, but when their leaves are become sturdy, they will require a larger supply. In about two months, they should be transplanted into larger pots, and plunged again into the bark. In warm weather they should have a good share of fresh air, but should never be taken out of the house.

2. B. cordata. "Leaves cordate, a little lobed." A native of China. Panicle elongated, with single, not divided, branches. Calyx white, as in the preceding species, but larger. Stamens about 24. Style none. Stigmas blanched, filiform. Willdenow, by whom it was first described, as it should seem, from a dried specimen.

BOCCORE, in Natural History, [B cattle, q. d. first and early fruit, a name given in the kingdoms of Algiers and Tunis, and also in Palestine, to the early fig, which was produced in June, in Palæstine, though the kermoum, or kermouf, the fig properly so called, which is preferred and made up into cakes before August, and sometimes hung upon the trees all the winter. These latter figs continued a long time upon the tree before they fell off; whereas the boccoros dropped as soon as they were ripe, and, according to the appropriate and beautiful allusion of the prophet Nahum, (iii. 12.) fell into the mouth of the eater, upon being shaken. We learn from Pliny (N. H. l. xvi. c. 26.) that the fig-tree was biferca, or bore two crops of figs, viz. the boccoro, as we may imagine, and kermouf; and it is well known, that the fruit of these prolific trees always precedes the leaves; consequently, when our Saviour saw one of them, in full vigour, having leaves, (Mark xi. 13.) he might, according to the common courfe of nature, very justly look for fruit, and happy find some boccoros, if not some winter-figs likewise upon it. The time of the year in which the event referred to in this passage occurred, was undoubtedly three or four days before the paffover, at which our Saviour was crucified, and the paffover in that year fell in the beginning of April. But it has been inquired, how Christ could expect to find ripe figs on the tree at the latter end of March? to which it is replied, because figs were ripe soon in Judaea. It has been satisfactorily proved, that the harvest in Judaea began at the paffover, and ended at pentecost; and as the barley in Judaea was ripe in March, and the wheat in April, we need not wonder, if there were ripe figs in the beginning of April too, or before the time of the paffover. This, indeed, was the usual time for the first ripe figs; and therefore it was natural to expect that there should be figs at this season, more especially as the tree had leaves, before which the fruit came forth; and as the 16th time of figs as bishop Kidder has shown, the same of gathering in ripe figs, was not yet come. When St. Mark says, "for the time of figs was not yet," he does not design to give reason of what he said in the immediately foregoing clause, viz. "he found nothing but leaves," but he gives a reason of what he said in the clause before that, viz. "he came, if haply he might find any thing thereon." And it was a good reason for our Saviour's coming and seeking figs on the tree, because the time of gathering them was yet not come. The transposition above supposed, is not uncommon. See Mark xvi. 3, 4. Gen. xii. 16. John xxii. 22. See Hallett's Notes on Texts of Scripture, vol. ii. p. 115, &c. Harmer's Observ. vol. i.

BOCH, John, in Biography, a modern Latin poet and classical scholar, was born at Brussels in 1555; and having entered
entered into the service of cardinal Radzewil; accompanied him to Rome, and there studied theology under Bellarmine. He afterwards travelled into Poland, Livonia, and Russia, and was in danger of losing his feet by the frost in his journey to Moscow. Upon his return to the Low Countries, the duke of Parma appointed him secretary to the town-house of Antwerp. He died in 1659. His poetical works, consisting of epigrams, elegies, heroic poems, &c. were collected, and printed at Cologne in 1615. He has been highly esteemed as a Latin poet by the critics of his country, and called the "BAGLE Virgil." Gen. Dict.

BOCHART, Samuel, in Geography, a learned orientalist, was the son of a minister of the reformed church at Rouen, where he was born in 1599. Having studied polite literature at Paris, philosophy at Sedan, and divinity, with the oriental languages, at Saumur, and made a surprizing progress at a very early age, he completed his course of oriental literature under Erpenius and Ludolf at Leyden. On his return to France, he settled as minister at Caen. In 1640, he published his "Phagaq" and "Canaan," the two parts of his "Geographia Sacra," a work of very extraordinary erudition and research, in which he investigates the history of the human race as recorded in the Bible, the disposition of mankind, and the origin of nations and languages, together with a variety of collateral subjects. Notwithstanding the charge of fanciful interpretations and chemical conjectures, which has been all-geared against some parts of this work, it has long maintained a high degree of reputation, and furnished an ample supply of materials for modern writers. In the progress of this work, the author was led to pursue a variety of inquiries concerning the animals, vegetables, and minerals mentioned in the sacred writings, on which he intended to have composed distinct treatises; but he only completed that relating to animals, which was printed at London in 1663, under the title of "Hierozoicon." In this work the errors are such as must unavoidably occur at a period when the knowledge of natural history was very imperfect, compared with that of more modern times. In compliance with the invitation of queen Christina, Bochart visited Sweden in 1652, accompanied by the learned Huet, who wrote an honourous and elegant Latin poem on their journey. But finding that the capricious levity of the Swedish queen was not suited to his own grave character, he returned to France in 1653, and resumed his former studies. He was a member of the academy at Caen, and by his moderation and candour, maintained the distinguished reputation which he acquired by his profound erudition, together with the elocution and respect of persons of all parties, till the time of his death, which happened, in consequence of an apoplectic stroke, during a disputation with Huet in the academy, May 16, 1667. But as the learned works already mentioned, Bochart left several disquisitions, particularly one, in which he attempts to prove that Armenia never was in Italy. His works were collected and printed by M. de Villermont at Leyden in 1712 in 3 vols. folio. Gen. Dict.

BOCHOULTE, or BOCHOUT, a town of Flanders, sittuate on a canal cut from the Scheltz; 4 miles N. W. of Sasse-le-Gent.

BOCK, Blauer Bock, in Zoology, a synonymous name of the blue antelope, antelope leucoplea. Kolbe.—Bock also signifies the male of the common goat. G. Thierb.

BOCK, or BOCKAU, in Geography, a mine town of Germany, in the circle of Upper Saxony, and county of Erzgebirg, 3 miles W. of Schwartzenberg.

BOCKENBURG, a town of Germany, in the circle of Westphalia, and bishopric of Minden, one mile from Minden. Bockenheim, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg; 2 miles W. N. W. of Frankfort on the Main.

BOCK FORD, or BOOK-HORD, in Antiquity, a place where books, evidences, or writings were kept.

BOCKHORST, JOHN VAN, in Geography, a painter of history and portrait of the Flemish school, was born at Münftcr, about the year 1610; and removing to Flinders, acquired the art of design and colouring in the school of Jacques Jordans. He designed well; the heads of his women are generally graceful, and those of his men distinguished by character; his tone of colouring sometimes resembled that of Rubens, but more frequently that of Vandyck. His pictures have great force and harmony, and his skillful management of the chiaro-furo produces an agreeable effect. An altar piece at the church of St. James in Ghent, representing the martyrdom of this saint, and a picture of the Annunciation in another church, painted in 1664, are distinguished performances of this master. Defamps. Pilkington.

BOCKI, in Geography, a small town of Poland, in Polandia, in the patalinate of Bielit.

BOCKING. See Braintree.

Bocking herring, in the Dutch Trade, signifies the same with bloated herring among us.

BOCK-KOGO, in Geography, a vast peak of the Brenner mountains in the Tyrol, rising little inferior to Geiform, and in the same latitude, but towards the west.

BOCK-LAND, or BOOK-LAND, formerly denoted that which we now call FRESHFIELD-LAND, or CHARTER-LAND; and it was by that name distinguished from "folk-land," which was COPYHOLD-LAND. In Ancient Law-History, it denotes a possession or inheritance held by evidence in writing. The word was doublets written back-land, qutifi book-land, answering to free land, or land held by book or charter, which was regarded as free property, and defended to the heirs of the possessor. It stood opposed to folk-land, which was that held without writing.

BOCKUM, BÖCHUM, or BoCHEIM, in Geography, a town and patriculate of Germany, in the circle of Westphalia, and county of Mark; seated in a very fertile district, 24 miles N. E. of Duffeldorp, and 35 N. of Cologn.

BOCNA, a town of Poland, in the patalinate of Cracow, famous for its salt-mines, first discovered in 1251. The small river called Raab, that falls into the Visula, runs near this town, which is surrounded with hills and eminences. The salt-mine of Bocna is in a narrow flip of land, about 750 feet in breadth from north to south, and about 10,000 feet in length from east to west, and its greatest depth below the surface is about 1200 feet. The salt lies in veins, and is somewhat finer, especially at a certain depth, than that of Wieliczka. It is cut in small pieces, and put up in casks. Large pieces of black wood have been found in this mine, which are incrusted with salt; and likewise ala-
THE MINES, which are very dry, are under the direction of the magistrates of Wieliczka. The town is 20 miles E. of Cracow.

BOCZEYKOWO, a small town of Lithuanian Russia, in the palatine of Polock.

BODEZUS A. Stapel, John, in Biography, was born at Amsterdam the beginning of the 17th century, where, at a proper age, he was admitted doctor in medicine, but attached himself particularly to botany, in which he acquired considerable celebrity. He died in 1676, at an early age, leaving a work, on which he appeared to have bestowed much labour, prepared for the press, which was published some years after, viz. Joannes Bodanus, a Stapel, in Theophrastii Historiam Plantarum, fol. Amst. 1644. Eloy’s Dict. Hist. Med.

BODAISKA, in Geography, a town of Hungary, 7 miles W. of Patak.

BODDAERTI, in Ichthyology, a name given to a species of Cyprinodon. This has the body variegated with brown and blue bands, and the ventral fins armed with two spines. Schr. der. beil. natur. Gmel. The habitat of this fish is unknown.

BODDAERT, a species of Gobius, found in the Indian ocean. Pallas describes it specifically as having the rays of the anterio dorsal fin cirriform, and the third ray very long. This fish is 6 inches in length; the body blueish brown, pale and yellow beneath, of a convex shape, tapering in a slight degree towards the tail, and covered with small soft scales. The head is thick, blunt, somewhat convex, and spotted with brown and white. Jaws nearly equal. Lips thick and flabby; eyes vertical. Lateral line with scarcely perceptible papillae, and a few snowy white spots. Each side of the back marked with seven black spots, and on the sides below these as many dots of white. Vent nearer the head than the tail; surrounded by a black circle, with a conic peduncle behind. Dorsal fins blue-black, the anterior ones spotted with white, the other with fucate rays, and five transverse white lines between each ray. Pectoral fin rounded. Tail blueish white. In the first dorsal fin five rays, in the second twenty-five; pectoral twenty-one; ventral thirty-four; anal twenty-five; caudal eighteen. Pallas. Gmel. &c.

BODECKEN, in Geography, a town of Germany, in the circle of Welfphalia, and bishopric of Paderborn, 4 miles N. N. E. of Buren.

BODEGAS, a town of North America, in the province of Verapaz, on the north-east coast of Dolce-bay. N. lat. 15° 40’. W. long. 75° 35’.

BODEGNE, a town of France, the principal place of a canton, in the district of Huy, and department of Orthe; the place contains 320, and the canton 7422 persons; the territory comprehends 1072½ kilometres, and 17 communes.

BODEGON, a town of Spain, in Andalusia, 4 leagues from Seville.

BODEKKER, in Biography, a painter of portraits, was born in the county of Cleves, in 1660, and abandoning the profession of music for which his father had intended him, he was placed as a disciple, in the art of painting, under John De Baan, at the Hague. He commenced the exercise of his profession at Bois-le-Duc and Breda with great reputation; and having resided some time at the Hague, he closed his life in 1727, at Amsterdam, where his performances were much esteemed. Fikkington.

BODENBURG, in Geography, a town of Germany, in the circle of Lower Saxony, and bishopric of Hildesheim; 8 miles N.E. of Alfeld.

BODENETZ, a town of Bohemia, in the circle of Chrudim; 10 miles N. of Chrudim.

BODENFELDE, a town of Germany, in the circle of Lower Saxon, and principality of Calenberg, seated on the Wefer, 11 miles E. of the quarter of Göttingen.

BODENHAUSEN, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse, 18 miles E. N. E. of Cassel.

BODENI, in Ancient Geography, a people of European Sarmatia, according to Ptolemy.

BODENLEICH, in Geography, a town of Germany, in the circle of Lower Saxon, and principality of Luneburgh-Zell; 22 miles N. E. of Zell.

BODEN-SEA, a name sometimes given to the gulph of Bothnia, which fee.

BODENSTEIN, Adam, in Biography, a celebrated German physician, son of a famous theologian, called from the place of his residence, Carlstadt, was born there in 1528. He was a pupil, and strenuous defender of the doctrines of Paracelsus, in which he appears to have placed an entire confidence. For a malignant fever raging at Balle, in 1577, he went there, armed with a Thése, composed on the principles of his master, with which he boasted he should be able to subdue the fever; but taking the infection, he fell a sacrifice to his credulity and temerity. Besides editing several of the works of Paracelsus, he left the following, which were collected and published in one volume folio, at Balle, in 1581.

“Epistola ad Fuggeros, in qua Argumenta Alchymiam inruminatam, et curarum adducuntur; quibuscumque arte verifimilis demonstratur.” “De Podagra prefervatione, tracatus.” “De herbis duodecim zodiaci fignis, dicatis, &c.” Adamus records his epitaph, placed on his monument, he says, at his own desire, in which he is said to have died, anno Saluti, 1577, and his tombstone, for seven times seven, or 49 years. Also the following lines, in which Bodenstein is supposed to say:

“Nec omnia, nec omnes milii
Placere: quinam ego omnibus?
Non omnibus coes fexis,
Non eremita fapiguris.
Nam tu viator omnibus.
Deo placere cura. Abi.”

BODENWERDER, in Geography, a town of Germany, in the circle of Lower Saxon, and principality of Calenberg, seated on the Wefer; 16 miles S. of Hameln. It has some trade with Bremen and Hamburg in coarse linen.

BODEN-TEE, a name given by the Germans to the superior lake of Constance, which fee.

BODER, or BODOTIA, in Ancient Geography, an river mentioned by Ptolemy in his description of Great Britain, which is the present Firth of Forth in Scotland.

BODUGUA, in Geography, a town of Alpine Turkey, in the province of Natolia, 28 miles N. N. W. of Kastamonu.

BODIANUS, or BODIANUS, in Ancient Geography, a borough of Italy, which was repeopled by a decree of Julius Cæsar.

BODIANUS, BODIANUS, in Ichthyology, a genus of Thoric fishe, first established by Dr. Bloch, for the reception of such species of the two Lineae genera Sparus and Perca, as have certain characters common to both, and are not therefore sufficiently distinct to be divided into two genera. The character of this new genus, as laid down in the first instance, consists in having the Gill covers fealy, armed, and smooth, or even at the edges. Under this head Dr. Bloch describes
describes ten species only, namely, Bodianus bodianus, bodianus guttatus, bodianus pentacentbus, bodianus banc, bodianus aya, bodianus macrolepidotus, bodianus opus, bodianus macrolepidotus, botianus fyllifer, and bodianus argentens. Lacepede, in adopting the genus Bodianus, considerably augments the number of its species by the addition of others not previously described under either of the Linnaean genera. In his "Histoire Naturelle des Poissons," there are altogether no less than four and twenty species. The generic character is modified, and two sections formed to admit them. Its essential character is thus expressed: one or more spines to the gill covers, the margins of which are neither denticulated, nor jagged; only a little beard, or sometimes none to the jaws; and a single dorsal fin.

The first section of the Bodians include those which have the caudal fin frizzled in the form of a crescent, of which there are fourteen kinds: le bodian mille (bodianus pentacentus), le bodian louti, le bodian jaguar (bodianus pentacentus), le bodian macrolepidote, le bodian argentens, le bodian Bloch (bodianus bodianus), le bodian aya, le bodian tacheté, le bodian vivanet, le bodian Tijcher, le bodian décananthé, le bodian lutian, le bodian grose tête, and le bodian cyliodactyle.

In the second division, the species of which have the tail fin entire, Lacepede describes only ten, le bodian rogaa, le bodian lunaire, le bodian mélanoqueuque, le bodian Jacob Evertsen, le bodian banc, le bodian bistule, le bodian apus, le bodian eciéf, le bodian tétacanthé, and le bodian fix raies.

The genus Bodianus is recognized, and admitted by Dr. Shaw into the general zoology. He includes in this tribe precisely the same species as those described by Dr. Bloch, with five additional species described by Lacepede as Bodianus, namely, perca louti, Gmel. sparus palpebratus, Gmel. perca rogaa, Gmel. perca lunaire, Gmel. and bodianus melanoleucus of Lacepede. But the general definition of the Bodianus, as given by this author, is evidently at variance with that assigned to it by others. The great object of the Ichthyologyst, in establishing the new genus bodianus, must have been to separate from the two genera perca and sparus, such species as do not strictly belong to either; and unless this could be accomplished in a satisfactory manner, it were better to permit them to remain where Linnaeus placed them. By some unusual oversight Dr. Shaw appears to have failed in this respect; his bodiani are not sufficiently distinguished from the Linnaean perca, as the following generic character will shew. "Habit of the genus perca. Gill covers scaly, serrated and aculeated. Scales (in most species) smooth. The gill-covers of the perca, according to this writer, are scaly and serrated, and the scales of the body (in most species) hard and rough. According to this definition: a perch with smooth scales, and the denticulations of the gill covers conspicuously large, may be mistaken for a bodian; and a hard scaled bodian, on the contrary, for a perch. If we are to allow an innovation on the Linnaean arrangement by the insertion of the genus bodianus, its true character seems to be that the plates which constitute the gill-covers are smooth at the edges, and only armed with one or more distinct spines; while the serrated edges of those plates as plainly point out the perch; and if the plates be both serrated and aculeated, we conceive it highly proper to retain them under the old Linnaean genus perca.

BODIN, JOHN, in Biography, a famous lawyer of France, was born at Angers in 1534, studied the law at Toulouse, and preferring the common to the civil law, quit Toulouse and entered at the bar in Paris; but not succeeding to his expectations, he devoted himself to literature. He commenced his career as a writer, with a translation into elegant Latin verse of "Oppian's Cynegetic," or books of hunting, accompanied with learned notes, claimed as his own by Turnebus. His "Method of History," was published in 1566, and his "Discourse on Coins," with an answer to the paradoxes of Madeiroit in 1568; but these were introductory to his great work in French, "Concerning a Republic," printed in 1576, in folio, and frequently reprinted in 8vo. To this work the president Thuanus bears very honourable testimony; it was also much commended by other persons of learning; and obtained for the author a high degree of reputation throughout Europe. It became the text-book of private lectures both at London and Cambridge. His tables of law, entitled "Juris Univeriti Distributio," were printed in 1576, and in the following year his "Demonstratio de Sorceris," to which was annexed A Rationale of the book, de Laminis, of John Wier, physician to the duke of Cleves, who had undertaken to prove that the stories of witchcraft and forcery have chiefly arisen from imposture or delusions of fancy. The literary character of Bodin, who defended this kind of superstition, incurred reproach, and he himself was suspected of being a magician. Before this time he had been invited by Henry III. to his court, who was much delighted with his conversation and treated him with attention and respect. But the royal favour was of no long continuance; for Bodin, who held an office in the prezbifical court of Laon, was sent, in 1576, as a deputy of the third estate of Vermandois, to the assembly of the states-general at Blois; where he remonstrated against the project of alienating the royal demesnes belonging to that province; and this he did with such effect, that Thuanus principally ascribed the defeat of the injurious scheme of alienation to his conduct on this occasion. Bodin also resolutely opposed the party of the Guifers, who were endeavouring to procure a decree for compelling all the king's subjects to profess the catholic religion. By such measures he became obnoxious at court; and he, therefore, accepted a proposal made to him by the king's brother, the duke of Alençon and Anjou, to accompany him to his government of the United Provinces. He afterwards attended him to England, and, it is said, that he advised the seizure of Antwerp, in consequence of which the duke lost both credit and influence. After the death of his patron, Bodin returned to Laon, and discharged the office of chief magistrate with great integrity. In this city he died of the plague in 1596. A work, written by him but never printed, and entitled "Heptapleron, sive de abditis rerum sublimibus arcatis," is said to have been an attack upon religion, and designed to invalidate the authority of revelation. By the seeming advantages which he gave in this work to the Jewish religion, he was suspected of being a convert to it; but it is more probable, that he was a sceptic with regard to religion, and alike indifferent to all modes of faith. A little while before his death he published a Latin treatise, entitled "Theatrwm Universwm Nature," in which he pursues the causes and effects of things to their principles. B. d. was of an ardent and inquietive temper; and his erudition was superior to his judgment. Gen. Dict.

BODLEY, SIR THOMAS, was born at Exeter in 1544, and at 12 years of age removed with his father to Geneva, who took his family thither to avoid the persecution of queen Mary's reign. In the university of that city he commenced his studies; and when his father returned to England, on the accession of queen Elizabeth, he was sent to Magdalen college, Oxford, where he remained for some years, and became fellow of Merton college. Here he read lectures in Greek and philosophy, and officiated as proctor and public orator. In 1576 he went abroad for improvement, and spent
spent four years in his travels. In 1583 he was made gentleman-at-arms to the queen; and having married, he entered into public life, and was employed in various foreign embassies. At the Hague, where he resided several years, his chief business was the negotiation of money-concerns between the States and queen Elizabeth. After his final return to England, in 1577, he found that his further advancement was obstructed by the intrigues and jealousies of persons in power, and he therefore formed a fixed purpose of retiring from all public affairs, devoting the remainder of his life to the laudable employment of refounding the university library at Oxford, furnishing it with books, and enlarging the building. See Library. At the accession of king James, Mr. Bodley received the honour of knighthood. He died in 1612, and was buried in Morton college choir. An annual oration is still spoken in his praise. Biog. Brit.

BODLEY, John, who practised physic in London, in the beginning of the last century, published, in 1741, a critical essay on the works of various authors, particularly on those treating on medicine, with the view of shewing that neither those physicians who wrote the most correct and valuable treatises on medicine, nor those who were the most intelligent practitioners, were usually the most encouraged: fame and success being more commonly the appendages of craft and policy, than of skill and judgment. A similar opinion was held by the late Dr. Samuel Johnson, who thought a judicious history of the fate of physicians might prove both an entertaining and useful work. Something of this kind was done by Perius, in his book "De Literatorum Infidelitate," but on a larger scale, embracing the whole community of letters. Elor. Dict. Hist.

BODINCOMACUM, in Ancient Geography, the name of a borough of Italy in Liguria, where, according to Pliny, the river Eridanus was at its greatest depth; called in his time "Indulitia."

BODIONTICI, a people whom, according to Pliny, Galba annexed to Gallia Narbonenses; but before this time they formed a part of the Ligurians. M. D'Auvillle has placed them in the maritime Alps. Their capital was Duina.

BODKIL, in Geography, one of the channels between Flanders and Walcheren island, in Zeeland, by which great ships may fail in.

BODMER, in Biography, a celebrated professor and writer of Switzerland, was born at Zurich in 1658; and became professor of Helvetic history and politics in his native place. In this office he taught his pupils to think for themselves, and to make such observations on historical facts as might render them intimately acquainted with the human heart. He wrote the history of his own country in the form of dramatic dialogues. Although he became one of the most voluminous of the German poets, and contributed in a great degree to reform the taste of his contemporaries, and to familiarize them to the sublime beauties of Homer and Milton, he had feared to written a verse in the German language before he was 50 years of age, when the first cantos of Klopstock's Messiah fell into his hands, and excited his emulation. His first essays were in epic poetry, the subjects of which he took from the Scriptures, but he afterwards devoted his muse to other topics; and it is observable, that old age, which generally increases austerity of manners, had the contrary effect on Bodmer; insomuch that his last pieces were the most gay, and that when he was 80 years old, he frequently amused himself with Tibullus and Petronius, and also with Boccace and la Fontaine. At the age of 77, he began a translation of Homer's Iliad and Odyssey, which he finished; he was 80, also, when he published his version of the Argonauts of Apollonius Rhodius. He died in 1783, at the age of 85 years. Bodmer has been derogatly styled by the unanimous voice of his contemporaries, "the father of German literature." He wrote just criticisms and correct judgment; he wrote the poetical odes of Klopstock, Haller, and Goecker. Bildhisse, &c. or Portraits of celebrated German Literati, &c. Rome, 1793.

BODMIN, in Geography, an ancient borough and market town of Cornwall, England, is situated near the eastern border of the county, on the confines of Devonshire. This town appears to have been formerly the principal seat of religion in the western district, and contained a priory, a collegiate church, and, according to Hals, thirteen other churches, or free-chapels. The remains and foundations of some of their religious structures still exist; and the sites of others are remembered by the old inhabitants. A mondf These were the priory with its chapel, St. Peter's church, St. Paul's church, on the northern side of the town, of which a solitary square tower remains; St. Nicholas, or the friary. The present town-hall and bishop's house occupy the site, and are constructed with parts of the latter building. The first religious foundation of Bodmin was removed to it from Padstow, a town on the northern coast of the county, which being much infested by the Saxons and Danes, was the resort of the monks for greater protection and safety. Here they established the priory, and its various dependent buildings; all of which gradually decayed after the removal of the see. The town occupies the northern face of a hill, and consists principally of one long street stretching east and west. Near the eastern end of it is the parish church, a large ancient structure, consisting of three ailes, and a tower which is attached to the north side. The chancel part is certainly the most ancient, and was formerly connected with the priory-building. An old chapel, now appropriated to a school-room, still remains near the east end of the church, and a little farther east is a neat modern mausoleum, occupying the site of the domestic part of the priory. A monument richly and curiously sculptured, of one of the priors of this house, is carefully preserved in the chancel. This was made to commemorate the name and official character of Thomas Vivian, who was bishop of Exeter, and died in 1553.

Bodmin is distinguished among the numerous boroughs of Cornwall, as being the only one free from the control of a patron. It was first made a borough in the time of Henry II. and its privileges were afterwards confirmed by king James I, who incorporated it in the 15th year of his reign. In 1799, a new charter was obtained, which vested the government in a town clerk, twelve aldermen, and twenty-four common council-men, who hold the sole privilege of electing two members for parliament. About half a mile N.W. of the town is a regular, commodious county gaol, which was begun building in 1779, from designs by Sir John Cell, who planned it according to the fylde recommended by the philanthropic Howard. Bodmin gave birth to Dr. Richard Lourier, an ingenious physician and anatomist, who made various experiments on the constitution of blood from one animal into another. This town has a market on Saturday, is 235 miles south west from London, and contains 278 houses, and 1951 inhabitants.

BODOBIRICA, in Ancient Geography. See BODOBIRICUM.

BODODO, in Geography, a town of Africa, in the kingdom of Benin, containing about 50 houses, or little cabins, built of reeds and covered with leaves. Here a viceroy has his residence, attended by a council, whose jurisdiction extends over this canton in all civil affairs, levying taxes, and rating duties and imposts on merchandise. In criminal cases
of great importance, the viceroy and council are obliged to send to Benin, the capital, for the orders of the court.

BODOK, a district of Lower Hungary, in the province of Nitra, containing 101 large villages.

BODON. See WIDIN.

BODROG, a district of Hungary, near the Danube, 30 miles S.E. of Colocza, inhabited by Ruffians and a few Hungarians.—Allo, a river of Upper Hungary, which has its source in the Carpathian mountains, and discharges itself into the Theis near Tokay.

BODTY, in Zoology, the name of a certain kind of American snake, supposed to be of the amphibia type, and of which this species is apparently doubted. The same species is likewise called Hibard.

BODUNGEN, Great, in Geography, a market town of Germany in the circle of Upper Saxony, and county of Klettenberg, 5 miles north of Bleicherode. Little Bodungen lies in the bailiwick of Lora, 4 miles north of Bleicherode.

BODWELL’S FALLS, lie in Merrimack river, between Andover and Methuen, in North America, about 5 miles below Patucket falls.

BOD, in Physics, a solid, extended, palatable substance; of itself merely passive, and indifferent either to motion or rest; but capable of any fort of motion, and of all figures and forms.

The word alludes to the Saxon bodige, nature; and to the Belge sboor, a court, q.d. the tabernacle of the soul.

Body is composed, according to the Peripatetics, of matter, form, and privation; according to the Epicureans and Cor-puticilians, of an assemblage of hooked, heavy atoms; according to the Carthagians, of a certain quantity of expansion; according to the Newtonians, of a system or allocation of solid, malleable, hard, impenetrable, moveable particles, ranged or disposed in this or that manner; whence results bodies of this or that form, differing only in this or that name. These elementary or component particles of bodies must be infinitely hard; vastly harder than the bodies compounded of them; nay, so hard as never to wear, or break in pieces. “This,” says Newton, “is necessary in order to the world’s perfecting in the same rate, and bodies continuing of the same nature and texture in several ages.”

Body, affection of. See Affection.

Body, colours of. See Colour.

Body, elements of. See Element.

Body, essence of. See Essence.

Body, existence of. See Existence.

Body, extension of. See Extension.

Body, marks of. See Mode.

Body, motion of. See Motion.

Body, qualities of. See Quality.

Body, solidity of. See Solidity.

Body, solid, that whose particles cohere, or are some way connected with each other. See Solid.

Body, fluid, that whose particles easily slide over each other, and are of a fit size to be agitated by heat; or that whose particles do not cohere, but are easily put in motion by the smallest force. See Fluid.

Body, rough, that whose surface is betted alternately with eminences and cavities, in contradifferentiation from a smooth body.

Bodies, double, those which being stretched do not break, but extend one way as much as they shrink another. Of these some are hard and malleable, as metals; others, soft or viscous, as glues, gums, &c. Mem. Acad. Scienc. an. 1713. p. 268.

Bodies, flexible, those which admit of being bent without breaking: such are thread, wire, fibres, and even glass, when spun very fine. These are contradistinguished from brittle bodies.

Bodies, specific gravity of. See Gravity, and Weight.

Body, dense. See Density.

Body, rare. See Rare.

Body, luminous, or lucid, that which emits its own rays, or shines by its own light.

Body, illuminated, that which diffuses the light of another by reflection, or which shines by borrowed light.

Body, opaque, that which intercepts the rays of light, or prevents their passage through it.

Body, transparent, diaphanous, or lucid, that which transmits the rays of light. See Transparency.

Body, the inertia of. See Vis inertia.

Bodies, homogeneous. See Homogeneous.

Bodies, congruous, those which have neither the same magnitude, nor the same degree of velocity, nor an harmonical proportion of magnitude and velocity.

Bodies, hard, See Hard.

Body, volatile, that which rises by the force of heat. See Volatile.

Bodies are divided into animate and inanimate; i.e. into those informed by a soul, and those which are not; or those that have life and those that have none.

Some consider bodies, either as natural and sensible; viz. as formed by physical causes, and clothed by physical qualities (in which sense, body makes the object of physics); or, as intellectual or quantitative, in the general or abstract; and according to three dimensions: in which sense, body makes the subject of geometry.

Bodies, alkaline, confidant, elastic, fast, heterogeneous, atmosphere of, deficient of, mercury of. See the several articles.

Body, with regard to animals, is used in opposition to soul; viz. for that part of an animal, composed of bones, muscles, canals, juices, nerves, &c. concerned in digestion, circulation, &c.

In which sense, body makes the subject of comparative anatomy. See Anatomy.

Body, faculties of. See Faculty.

Body is also applied by anatomists to several particular parts of the animal fabric.—As, the callous body of the brain, the cavernous or spongy bodies of the penis, &c. Body, reticular. See Reticular.

Body, in speaking of a horse, denotes the chest, but chiefly the flanks.

A horse is said to have a good body, when he is full in the flank; a light body, when he is thin or slender in the flank. If the lat of the short ribs be at a considerable distance from the hock-bone, though such a horse may have a tolerable body for a time, if he be much laboured, he will lose it. It is a general rule, never to buy a horse that is light bodied and fiery, because he will presently destroy himself.

Body of a plant, in Botany. See Botany.

Body of a piece of ordnance, in Gunnerie, that part comprehended between the centre of the trunnions and the cañon. It ought always to be more fortified than the rest. See Cannon.

Body of a pump, in Hydraulics, the thickest part of the barrel or pipe of a pump, within which the piston moves. See Pump.

Body, in Geometry, denotes the same with solid, which see.

Bodies, regular, or Platonic, are those which have all their sides, angles, and planes, similar and equal.
BOE

Of these there are only five; viz. the tetrahedron, consisting of four angles; the octahedron, of eight; the icosahedron, of twenty; the dodecahedron, of twelve pentagons; and the cube of six squares. See Regular bodies; see also Tetrahedron, &c.

Body, in Law.—A man is said to be bound or held in body and goods; that is, he is liable to remain in prison in default of payment.

A woman, though in other respects she cannot engage her person but to her husband, may be taken by the body, when the carries on a separate trade.

Body of the place, in Fortification, denotes either the buildings included, or more generally the inclosure itself. Thus, to constrict the body of the place, is to fortify or inclose the place with balistons and curtains.

Body is also used for an assemblage of several different things collected into one; more particularly a number of persons united into a company or college.

A state or nation, under the administration of one sovereign, is called a body politic. All large empires are unnatural, because the relation between the head and limbs is here too remote. No body, either natural or politic, can long remain sound without exercise. See Corporation.

Body, corpus, in War, is an aggregate or assemblage of forces, horse and foot, united and marching under some chief.

An army, ranged in form of battle, is divided into three bodies: the van-guard, the rear-guard, and the main body; which last is ordinarily the general's spoil.

Body of reffers, in the Military Art, a draught or detachment of a number of forces out of an army, who are only to engage in cases of necessity.

Body, in matters of Literature, a name given to a collection of whatever relates to any particular science; thus we say, the body of the canon law; the body of the Saxon law. King James I. had a design to compile a body of the English law.

The body of the civil law consists chiefly of the Institutes, Pandects, Code, and Novels. A stratified body, is that to which glosses are added in the margin, composed by several lawyers.

Body is also used figuratively for constancy, solidity, and strength. In this sense, we say the body of a cloth, wine, &c.

Vintners have divers arts of increasing or diminishing the body of wine.

Body, among Painters.—A colour is said to bear a body, when it is capable of being ground so fine, and mixing with the oil so entirely, as to seem only a thick oil of that colour; as white-lead, lamp-black, vermilion, lake, indigo, &c. But verdiers, fmalts, &c. will not embody with the oil, but are full apt to separate from it in working.

Body plan, or plane of projection, in Ship-building, is a section of the ship at the midship frame, or broadest place, perpendicular to the keel and half-breadth plans. The several breadths, and the particular form of every frame of timbers, are described on this plane. As the two sides of a ship are similar to each other, it is therefore unnecessary to lay down both, hence the frames contained between the main frame and the item are described on one side of the middle frame, commonly on the right-hand side; and the other frames are described on the other side of that line.

BODZELIN, in Geography, a town of Poland, in the palatinate of Sandomirz, 24 miles south of Radom.

BOE, in Ancient Geography. See BOE.
This "Jacqu. was B. the ufum" the flowers very 1752. Poly-
the tionum appointed adopted by Having
his lecture, "De phalix. Utrum animat hominum his commo-
ventur, necne?" a question much agitated at that period of

BOECLER, JOHN-HENRY, an eminent German philolo-
gist, was born at Cronheim in Franconia, in 1612, and
preferred, at the age of 21, on account of his great learning, to
the office of professor of eloquence at Stralsburg. In 1638 he
was invited to Sweden by queen Christina, and appointed to
the chair of eloquence at Upsal, and to the office of royal
hiatorigrapher; but being obliged by ill health to quit the
country, he became professor of history at Stralsburg. He
was counsellor both to the elector of Mentz and to the em-
peror, and received a pension from Louis XIV. He died in
1692. His principal works are "Commentationes Phianiam," "
"Timur, vulgo Tamerlanus," 4to. 1657; "Notitia S. Ro-
mani Imperii," 1687, 8vo.; "Hifloria, schola princeps;"
"Bibliographia critica," 1715, 8vo.; "Dillertiones Aca-
demicas," 3 vols. 4to. 1710; "Animadversiones in Poly-
bium," 4to. 1681; "Commentatio in Grotii librum de jure
belli et pacis," 4to. 1712. He wrote, besides, Latin com-
mentaries on various ancient authors, and several tracts on

BOEDROMIA, in Antiquity, from boedromos, helper, de-
erived from boevo, I cry, and lomo, I ran, solemn feasts held at
Athens, in memory of the sacrifice brought by Ion, son of
Xuthus, to the Athenians, when invaded by Eumolpus, son of
Neptune, in the reign of Erechtheus. Pindar gives an-
other account of the boedromia, which, according to him,
were celebrated in memory of the victory obtained by Thes-
fus over the Amazons, in the month Boedromion, called by
the Corinthians "Panemos" which was, in the ancient
chronology, the third month of the Athenian year. It con-
filled of thirty days, and answered to the latter part of our
August and beginning of September.

BOEHM, in Biography. See BEHREN.

BOEHLER, PHILIP ADOLPHUS, son of Juftus B. pro-
professor of anatomy at Hall in Saxony, under whom he received
his education; was admitted doctor in medicine in 1726. As
he applied his mind particularly to the study of midwifery,
his gave for his inaugural thesou, "De precavenda polyporum
generations." His next dissertatio, which was published in
1741, in 4to. was "Situs uteri gravidii, ac fetus, ac fede
placenta in utero." In this he has given a critical examina-
tion of the midwifery forcets used in England, which he com-
pares with, and prefers to Leurets. These pieces were added
by the author to his edition of Sir Richard Manningham's
"Compendium artis obstetriciae," published in 1746, 4to.
Having acquired celebrity by these and other works, he was
adopted member of the Acad. Nat.-Curios, and foreign affo-
niate of the Royal Academy of Surgery at Paris. He was also
appointed to succeed his father as professor of anatomy and
medicine in the university at Hall. In 1749 he published
"Institutiones obstetriciae, in usum prefedationum," 8vo.
Haller particularly commends in this work the engravings of
the embryos, and some fetal skeletons. His "Observa-
tionum anatomicae, fecundus primus," folio, was pub-
lished in 1752. Among many rare and curious objects are,
"an engraving of a pregnant uterus, to show the membrana
decidua, and a fetus in one of the Fallopian tubes, with the
plaenter. The second collection, also in folio, published in
1755, contains a smaller fetus in one of the tubes, and a
child with two bodies and only one head. For the titles of
the remainder of his dissertations, see Haller. Bib. Anat. and
his collection of medical thikes, in which the greater part of
them is inserted.

BOEHMERIA, in BOTANY (named by Jacquin in honour of
George Randolph Boehmer, professor of anatomy and bot-
any at Wittenberg), a genus of the elafp or monspelun, eufatandra,
formed by Swartz for three plants, not described by Linnaeus,
natives of the Wett Indics, to which he added two others,
the urtica cylindrica, and the caritus ramiflorus of Linnaeus.
It constitutes a connecting link between urtica and petariata.
Male flowers on the same plant with the female, either distinct
or mixed. Cal. perianth one-leaved, four-parted to the face;
segments lanceolate, acute, somewhat fercet, coloured. Schreb.
(tubular, Jullif. and Boie). Cor. none. Nel. none. Stam-
filaments four, longer than the calyx, awl-shaped, fercet; an-
thers roundish, ovate. Female flowers, Cor. none. Pil.
germ ovate, comprifed; flyle filiform, fercet, permanent,
 stigma simple, papilifer. Pericarp. none. Seed, roundish,
 comprifed, margined. Schreb. (ingle, very small, enclosed in
the permanent calyx. Jull. Boie). The flowers are sepa-
rate from each other by numerous, dense, ovate-acuminate,
branches or scales.

Species. 1. B. candida. Brown Jam. 238. "Leaves op-
opposite, ovate, acute, farrate; racemes very long, pendulous.
flowers diuooes; item fuftrififue." A shrub ten or twelve
feet high. Brown calls it the nettle-tree. 2. B. litoralis.
"Leaves opposite, ovate-lanceolate, farrate; flowers con-
glomerate, axillary, monocarpous, mixed; item herbaceous,
four-cornered." Native of Hispanicla. 3. B. cylindrica.
"Leaves opposite, ovate, acuminate, farrate; racemes filicid,
axillary, fercet, simple." An annual plant, with a lucid,
herbaceous falk, dividing into several branches; leaves with
three longitudinal veins; on pretty long pedicels. A native of
North America and Jamaica. 4. B. ramiflora. "Leaves
alternate, broad-lanceolate, acuminate, farrate, wrinkled;
flowers aggregate, axillary and lateral, monocarpous, difmift.
Males three-flamcnd." A shrub, eight feet high, with short
branches; leaves fickle-shaped, rugged, on very short pedicels
placed towards the ends of the tigols; very different in face,
forme being two inches, and others a foot in length on the
same twig. Male flowers small, yellowish, numerous, aggre-
gate, on the leaflets old branches. Female flowers whith
on the younger twigs to the very end. Native of Jamaica
and other islands of the Wett Indics. 5. B. birta. "Leaves
alternate, ovate, acute, farrate, hirifete; flowers monocarpous,
heaped, axillary, mixed." A native of Jamaica.

La Mark has not inferred this genus either in the alpha-
betic part of the Encyclopedic, or in the subfquent
fystematic series of figures. He follows Linnaeus in referring
the cylindrica to urtica, and the ramiflora to caritus.

BOEL, PETER, in Biography, an excellent painter of
fruit, flowers, and animals, was born at Antwerp in 1655,
and having been a disciple of Snyders, whose widow he mar-
rried, he went to Italy, where his uncle Cornelius de Waal
resided, and in his return through France was much em-
ployed, particularly at Paris, where he continued for some time.
He died in 1680. As an artifte be copied after nature, with
a free and bold pencil, and a tint of colour that was natural
and beautiful. There are some few flight, but spirited,
etchings by Boel, from his own compositions, representing
various animals, &c. Cornelius Boel, who flourished in 1611,
and Coryn or Quirin Boel, who flourished in 1669, both en-
gravers, were of the same family. Tilkington. Strutt.
BOELE-BOELE, in Geography, a district of the island of Cebes, situated in the bay of Boni, at and near a river of the same name. To the west it has Wauwo Woole; to the south, the river Caffi; to the north, the river Tanika; and to the east, the shores of the bay. It is sometimes called Tellihimpos, and has three chief towns: viz. Boele boele, Lamant, and Radja, which are all independent of each other. The kings of Boni consider it as an appendage of their crown.

BOELE-COMBA, a territory of Cebes, which was anciently a separate kingdom, but in later times it was subjugated by the Macufes; and is become one of the provinces belonging to the Dutch East India company. It stretches from the river Kalenkong, which divides it from Bontain, to Bera, or rather to the river Bampang, which runs between them; to the north of it lie the mountains of Kyndang, which separate it from Boni, or rather from the highlanders of Tourayno; and to the south, it is washed by the sea. The land is fertile in rice, and abounds in game and extensive forests; but the timber is not adapted to the construction of houses. When the wet monsoon renders it dangerous for ships to lie in the road before Boele-Comba, they run into the river Kalenkong, near the mouth of which stands the palisaded fort Carolina, in which the resident of the Dutch East India company, who is a junior merchant, has his abode. The province of Bera reaches from the river Bampang eastward, along the sea-coast to the point of Laffem or Laffon, and thence northward to the point of Cadjang; and on the land side, it borders upon Boele-Comba, Tourang, and Kadjang, belonging to Boele-boele. This country belongs to the Dutch company. It is barren and rocky, but has some woods which furnish timber fit for building pros. The men are good warriors both by sea and land; the richest are merchants; and others employ themselves in building pros, and in manufacturing a sort of coarse white cloth from the cotton which the places supphes.

BOELO. See Belon.

BOEN, in Geography, a town of France in the department of the Loire, and chief place of a canton in the district of Montbrison, seated on an eminence near the river Lignon; 6 leagues south of Roanne, and 3 1/2 north of Montbrison. The place contains 1220, and the canton 10,929 persons; the territory comprehends 305 square miles, and 22 communes.

BOENAC, in Ichthyology, a species of Bodianus, described by Dr. Bloch. The body is of a clear olivaceous colour, marked with seven oblique brown bands; and the caudal fin is rounded. This fish is mentioned as a native of the seas about Japan, where it is called ycan boecan.

There are seven rays in the gill membrane of this species, fifteen in the pectoral fin, six in the ventral fin, eleven in the anal fin, sixteen in the caudal fin, and twenty-five in that on the back.

BOENASA, in Ancient Geography, a town of Capadocia, in the interior of the Galatian Pontus. Prolomy.

BOEON, a town placed by Prolomy in the interior of the Tauric Cheroneus.

Boeon, or Boelo, a town of Greece, in the Doric region, according to Thucydides, near mount Parnassus. This was one of the four cities which, according to Phyll, Strabo, and Steph. Byz. gave the name of "Tetrapolis" to the country poffessed by the Dorian, near mount Oeta.

BOEONUS, Dia, an island of India, according to the Periplus of the Erythrean sea, placed by M. d'Anville at the south-west entrance of the "Barygazenian Insus."
for his military talents. It should also be remembered, that Boeotia was the birth-place of Hesiod, Corinna, and Pindar. Its most remarkable places were the Trophonian cave, Thebes, Aulis, the straits of Thermopylae and Thebes, which fee respectively.

The government of Boeotia was altogether monarchical, and peculiarly delphic, the will of the kings being the law; and of these some governed more like tyrants than moderate sovereigns. Plutarch, in his "Morals," mentions an ancient custom that prevailed among them; which was the manner of introducing their new-married women into their new habitations. They were brought home in a kind of chariot, or chair, the axle-tree of which was immediately burnt, thus intimating to the bride, that she was fixed with her husband for life, and must not expect to return to her parents.

The Boeotians, as to their general character, were courageous, inoffensive, and vain; and with them the transition was very short from passion to infult, and from a contempt of law to a total disregard of the dictates of humanity. The smallest expectation of advantage gave occasion to the greatest acts of injustice; and murders were frequently the consequence of the most frivolous quarrels. The women were tall, well-formed, and generally of a fair complexion; and their voice was remarkably sweet and tender; whereas that of men was harsh and disagreeable, and in some measure suited to their character. Of this character for inoffence and ferocity, which generally distinguished the Boeotians, no traces were to be found in a body of young warriors, called the "Sacred Battalion," consisting of 500, who were brought up together, and maintained at the public expense in the citadel. Their exercises, and even their amusements, were regulated by the melodious sounds of the flute. To prevent their courage from degenerating into blind fury, care was taken to inspire them with the nobility and the most animated sentiments. From this band each warrior chose a friend, to whom he remained inseparably united, whom it was his ambition to please, and to share his pleasures and sufferings in life, and his labours and dangers in battle. These 500 warriors were at one time distributed in troops at the head of the different divisions of the army. Pelopidas, who had frequently the honour of commanding them, having made them fight in a body, the Thebans were indebted to them for almost all the advantages they gained over the Macedonians. Philip destroyed this cohort, that had been invincible, at Cheronæa; and the prince, when he saw these young Thebans stretched on the field of battle, covered with honourable wounds, and lyingdead by side by side on the ground on which they had been flattened, could not refrain from tears, but bore a noble testimonio to their virtue as well as to their valour. Plut. in Pelop. t. i. p. 287.

For the succession of the kings of Boeotia, after Cadmus, and the history of the kingdom as a monarchy, see THEBES. The Boeotians, after having expelled their kings, who had reigned in succession from Cadmus to Xanthus, for about 300 years, formed themselves into a republic, of which the chief magistrates were the praetor, or strategos, the Boeotarchi, and the Polemarchi. The authority of the praetor, who was chosen from among the Boeotarchi, lasted only a year, and resembled that which was vested in the praetors of Achæa and Ætolia. The Boeotarchi allièd them with their advice, principally in time of war, and commanded under him; and they constituted the supreme court in military affairs; so that the praetor could not act in a manner contrary to their determinations. They also bore a great sway in the civil administration, and hence derived their title. Their number was uncertain, being 7, 9, or 11; they were chosen yearly, and obliged by law, as well as the praetor, to resign their office, on pain of death, before the first month of the new year was expired. The Polemarchi were altogether civil magistrates; it being their province to maintain peace and concord at home, while the Boeotarchi were employed in the wars of the republic. Besides these officers, there were four councils, in which the whole authority of the state was vested. These were composed of the deputies that were sent by all the cities of Boeotia; and without their approbation, the Boeotarchi could not declare war, make peace, conclude alliances, or transfer the use of any weapons of importance. The Boeotians, and especially the Thebans, were continually harassed by the princes of Macedon; nevertheless, they took part with Philip against the Romans, and could not be prevailed upon by the Athenians and Achæans to desert him, and to join the other states of Greece, till he was entirely defeated in the famous battle of Cynocephalæ. They then, foreseeing their danger, sent deputies to Flamininus, imploring his protection. He received them with great humanity, and put them upon the same footing with the other allies of the republic in Greece. Flamininus, at their request, obtained the release of the Boeotians who served in the Macedonian army; but, notwithstanding this favour granted them by the interposition of the praetor, they neglected to make the necessary acknowledgments, and filled up all vacant offices with persons who were enemies to Rome, and attached to the interests of Macedon. Flamininus was exasperated by this conduct; and Brachyllus, their praetor, was murdered by the friends of Rome. The murderers, however, were discovered, and one of them, Philætus, was put to death. For this murder of their praetor the Boeotians determined to be revenged; and they took occasion to affilliate all the Romans whom they found wandering about in the fields. In consequence of this outrage, Flamininus ravaged their territories; but, upon their consenting to deliver up the offenders, he diffused from any further acts of severity, and the Boeotians, duly appreciating of their lenity, continued ever afterwards faithful to the Romans. But as some of their leading men joined Persæ, king of Macedon, in his wars against the Romans, the whole country was, on that account, treated with great severity; Rome being at this time under no apprehension of an invasion from Antiochus, as the wars between Flaminius and Cyrus justly appeared. At the disolution of the Achæan league, Boeotia, with the rest of Greece, was reduced to a Roman province. See ACHÆANS.

BOER, in Geography, a town of Germany, in the circle of the Lower Rhine, and county of Recklinghausen, 6 miles W.S.W. of Recklinghausen, and 42 N. of Cologne.

BOERHAAVE, Herman, in Biography, a professor of medicine and chemistry, of such eminence as to form a new era in these sciences, was born at Voorhout, about two miles from Leyden, in Holland, the 31st of December 1668. His father, James Boerhaave, the pastor of the village, having nine children, took on himself the care of their education; and, as he intended Harvard for the church, he was careful to ground him well in Greek and Latin. In these languages he made such rapid progress, that when he was only fourteen years of age, his father sent him to complete his education to the public school at Leyden; and, in 1684, he went from thence to the university. His father dying soon after, and in tender circumstances, the progress of our young student's attainments would have been interrupted but for the friendly affiliation afforded him by Daniel Van Alpin, burgomaster of Leyden, who furnished him with the means of continuing his studies. The kindness of this worthy man was remembered by Boerhaave, with gratitude, to the end of his life. He now applied to the mathematics, and to acquire a knowledge of the Hebrew and Chaldee languages; proposing, agreeably to the intentions of
of his father, to qualify himself for the ministry: and that he might receive his patron from a part of his expense, for his sustenance, he gave private lessons to the students in mathematics, and here probably laid the foundation of that excellence in the art of communicating knowledge by lectures, for which he in time became celebrated. In 1690, he took his degree in philosophy, and gave for his inaugural thesis, "De diutius temporibus mitis et corporis," in which he refutes, in a solid and judicious manner, the errors of Hobbes and Spinoza. This, however, did not prevent his being full of Spinozism, which made him quit his intention of entering into the service of the church, and turn his mind to medicine, particularly to the study of chemistry, as more suited to the activity of his disposition. To acquire a knowledge of anatomy, he read the works of Vellanius, Fallopius, and Bartholinus, and attended dissections under Neck. In medicine, he studied Hippocrates, and the rest of the Greek and Latin writers in sculpture, but returned to Hippocrates, whose works were always mentioned by him with veneration. Among the moderns, he gave the preference to our countryman Sydenham, whom he called the Divine Syd-

denham.

Thus qualified, in 1693, being 25 years of age, he was admitted by the university of Harderwyck, in Gueldern, to the degree of doctor in medicine. His thesis on this oc-

casion was "De utilitate explorandorum excrementorum in egris, ut figurum." To the urine he paid the greatest atten-

tion. He now applied to the practice of medicine, from which, however, he is said to have derived but little profit. As his practice, therefore, employed but a small portion of his time, he had leisure for examining all the theories of medi-

cine which had prevailed, in succession, from the earlist time, and of forming from them a theory, if far from per-

fect, much less exceptionable than any that had preceded it; and which, when matured, superceded them, and became the reigning doctrine over all Europe for more than half a cen-

tury. De Meinacourt, who had long been professor of the theory of medicine, dying in 1701, the university of Leyden feized the opportunity this event afforded them of attaching him farther to that place, by placing him in the vacant chair. This they were prompted to by gratitude as well as by pru-

dence; Boerhaave having refused an advantageous offer of settling at the Hague, and, though in no public office or capacity, he had already acquired a considerable reputation, and drawn a great many foreigners to Leyden, to hear his lec-

tures in chemistry. On the occasion of this promotion he read his "Oratio de commendando studio Hippocratico." In Hippocrates, he particularly admired the correctness of his de-

scriptions and histories of diseases, his patience in at-

tending to the indications of nature, or the constitution, to which, with little interference, he frequently committed the cure of the diseased, and his honesty and sincere account of the termination of the disease, whether in health or death. In this he has not been always followed by writers of cafes. In 1703, he was invited to accept a professor's chair at Groningen; but as he had refused, when much less known, an establishment at the Hague, he had no difficulty, now that his fame was more extended, and pupils were flocking to him from all parts, in rejecting this offer. The university at Leyden thought it necessary to reward this fresh proof of his attach-

ment to the country, by augmenting his salary. About this time he delivered his "Oratio de usu ratiocini medi-

cina." These compositions were all published; and as they were drawn up, and polished with care, they doubt-

less contributed in extending the fame of our professor over Europe. On the death of Peter Hotton, curator of the university garden, in 1709, he was appointed his successor, and made professor of botany. He now read his "Oratio qua repurgare medicina faculis affertur simpliciter," shewing that the knowledge of medicine would be easiest obtained by avoiding hypotheses, and attending to facts and observations; and that diseases would be more certainly cured by using only a few choice and simple medicines, than by the hetero-

geneous compositions then in vogue. He now, in addition to his other studies, employed himself studiously in acquir-

ing a more extended knowledge of plants; and this con-

tinued to be his amusement and delight to the end of his life.

Often have I seen," Haller says, "the good old man,

moving slowly along the garden, at a very early hour in the morning, attending to the culture of the numerous exotics he had introduced there, clasping and arranging them for his lectures." One year only after being appointed pro-

fessor in botany, he published "Index plantarum que in horto Lugdunensi Batavo recuperantur," 8vo. This work was re-
published by him in 1720, much enlarged and improved, including a history of the garden, 2 vols. 8vo. In 1709, ap-

peared his "Aphorisma de cognoscendis et curandis mor-

bis," 8vo.; "aurae in fumma brevitate libellus," Haller says. A work universally read and admired, on which baron Van Swieten, his illustrious pupil, who had attended his instruc-

tions for near twenty years, published his Commentaries, in 1742, extending it to five volumes in 4to. About the fame time he published his "Institutiones rei medicinae in ufas an-

nex exercitationes domesticae," 8vo. These two works, the one treating of the history and cure of diseases, the other of the physiology of the human body, improved and en-

larged at different times by the authors, have passed through numerous editions, and have been printed in every country, and translated into every language in Europe. Schulten says, there is a version of them also in the Arabic. Boer-

haave was now in the zenith of his reputation, and had such a confluence of students from all parts of the world, as never probably before occurred to any one professor. He gave lectures on the theory of medicine, in botany, and chemistry, and delivered them with such clearness and precision, as to fill his pupils with equal admiration and delight. Haller, who was two years under his tuition, speaks of him with enthusiasm. "Vix tui parem habuisti," he

said; as if few, and perhaps may never again see his equal. In 1714, he was made rector of the university. On laying down this office at the end of the year, he read his discurso "De comparando certo in physica." It is only to be acquired, he says, by experiment, and by a careful and minute examination of natural objects. Bidloo dying at this time, he was advanced to the chair of professor in the practice of medicine; and, on the death of Le Mort, in 1718, he was made professor of chemistry. He was now at the head of every branch of medicine; and his pupils were be-

come as numerous, Dr. Matty says, that Leyden was fearcely sufficiently capacious to contain them. In addition to these numerous vocations, he was frequently consulted, in cafes of dificulty and danger, by physicians in all parts of the world.

With these advantages, it will not excite surprize, that his wealth should accumulate and become extremely abun-

dant. As his diet was frugal and sparing, and he was plain in his apparel, he has been accused of being too parimoni-

ous; but it should be considcred, that attached as he was to sciences, and immured in libraries of such variety and magni-

tude, he had no time for expense or luxury; except in what regarded the improvement of his pupils. In procuring rare and valuable books, and in collecting plants from distant countries for his garden, he spared, we are told, no expense.

In 1718, Boerhaave had published "De Chemia, fus errores expurgantes," which was all he purposed giving on that subject; but some of his pupils having, at the instigation, he says, of the book-sellers, ventured to print, in his,

name,
B O E

name, transcripts of his lectures, so incorrectly taken as to materially injure his fame, to vindicate himself from the disgrace this might bring upon him, he found himself under the necessity of preparing his lectures for the press; and, in 1732, he published them under the title of "Elementa Chemiae," in publicatio privatique scholis, Hermannus Boerhaave," 2 vols. 4to. The work is dedicated by a most affectionate address to his brother James Boerhaave. The first volume contains the history and the theory of the art, and is furnished with numerous engravings and descriptions of furnaces, and other instruments of chemistry. The second contains the processes, or operations chemical. In the first volume he gives a catalogue of all the works he had published, preceding it, with much modesty, with this declaration: "Sciafque, me nihil didisse unquam, prater sequenti, quae non abique vereundia recenenda puto." At the back of the title-page, he describes "Ut certus sit lectorem, hane librum: a me editum prodire, propria manu adscriptum putavi; nec pro me aegroco,ubi hic adscripto atell, Boerhaave;" uniting, as his custom was, the H and the B.

The character of Boerhaave, as a chemist, is thus given by Macquer, in his Preliminary discourse to his Dictionary of Chemistry. "Next to Stahl we place the immortal Boerhaave, though he excelled in a different way. This powerful genius, the honour of his country, of his profession, and of his age, threw light upon every subject which he treated. To the view which he took of chemistry, we owe the most methodical analysis of the vegetable kingdom; his admirable treatises on air, on water, and on earth, and particularly on fire, which is an all-suficient matter-priest, is so complete, that the human understanding can scarcely make an addition to it." To his moral character, his disciple Haller bears the following honourable testimony: "Some, though few, will rival him in erudition; his divine temper, kind to all, beneficent to foes and adversaries, detracting from no man's merit, and binding by favours his daily opponents, may, perhaps, never be paralleled." In his conversation he was easy and familiar, and in his demeanour grave and sober, but at the same time disdained to be pleasant, and occasionally indulging in good-humoured raillery; so that he was compared to the admirable Socrates, whose body he is said to have refembled in features. By his pupils, whom he regarded with the kindnefs of a parent, he was beloved and respected in a very high degree. Pity formed a distinguishing feature of his character; and devotion was his daily exercise.

As Boerhaave was of an athletic make, he accustomed himself to exercise on horseback, to spend much of his time in the open air, and to use a frugal and plain diet, he had been enabled thus far to endure the extreme fatigue of his professional labours, with only some occasional interruptions from illness; but being grown corpulent, and incapable of riding, his constitution began to be on the decline, so that, in 1729, he found it necessary to resign his offices of professor in chemistry and botany. The speech he made on this occasion, was published under the title of "Oratio cum cathedrae chemiae et botanicae valedictor." 4to. In this he recounts some of the most memorable occurrences of his life, and particularly with gratitude of the patronage and favours he had received from individuals, in enabling him to pursue his walk in life, as well as from the members of his own profession, who had admitted his improvements in the theory and practice of the arts he taught, with more kindnefs and respect than is usually given to innovators of any kind. This doubtlefs arose in part from the great learning and abilities he was known to possess, and from the high reputation he had attained, demanding respect; and partly from his disposition, averse from contention, and thinking but modestly of his endowments. From whatever cause it might arise, there was very little to give a revolution in any science brought about with so little opposition as was made to that produced by Boerhaave. He had before, viz., in 1728, been admitted foreign associate of the Royal Academy of Sciences in Paris; and in 1732, he was elected a fellow of the Royal Society in London. The same year he was again made rector of the university at Leyden. On quitting that office, he read his "Oratio de honore medicorum ferritutum," which was also published in 4to. In this he again insists on the necessity of attending to the method nature takes in curing diseases, or the manner in which they terminate spontaneously, as practiced by Hippocrates. Though this feecession from public employment procured him some reprieve from his labours, he still continued revising and correcting his original works. He also spent much of his time in revising the works of other writers, and published more correct editions than were before extant; as the "Opera Anatomica et Chirurgica And. Vcslini," fol.; Albinus contributed to this work; of Belliniius, "De urinis et pulvis," 4to. 1730; of Prosper Alpinus, "De praefagiendi vita et morte," 4to. 1733; Aretaeus, "De caulis, lignitique morborum," fol. 1731; Linniius, "De lec venera," fol. 1728, and some other works. Still, however, he enjoyed ease and relaxation from the more fatiguing part of his business, and he passed the principal part of his time, during the remainder of his life, at his manor, a small distance from Leyden, in domestic recreations, with his wife and daughter, to whom he was much attached. Here he had a garden well-looked with every thing that could contribute to his pleasure, and here he amused himself with his violin, in which he was a proficient. Towards the end of the year 1737, he became feebly affected with difficulty of breathing, and a sense of suffocation, which incommoded him, whether walking or lying down. This went on increasing; and a small time before his death, he perceived a strong pulsation on the right side of his neck, which he attributed to a polyvous concretion in the aorta. No remedy being competent to combat this dreadful disSAME, he expired calmly, in the midst of his family, on the 23d of September 1738. He was buried in the church of St. Peter's at Leyden, where his fellow-citizens erected an elegant monument to his memory. The pedestal is of black marble, supporting an urn, decorated with emblematic figures, representing the four ages of man's life, and the sciences in which he excelled. On one face of the pedestal is a medallion with the head of Boerhaave, surrounded with suitable decorations, his head hanging under it, on which is engraved his favourite motto, "Simplex figulum veri," simplicity the seal of truth; and underneath, "Sulutifer Boerhavii genio facrum," sacred to the health-reviving genius of Boerhaave.

But in the course of this sketch of the life of Boerhaave, his principal works have been noticed; for a more complete catalogue of them, see Haller's Bib. Med. Præct. Anatomiæ Botanici et Botanici, and Eloy's Dict. Hist.

Boerhaave, Abraham Kaan, professor of medicine in the university of Petersburg, was born at the Hague in 1715. He was the son of James Kaan, and of Margaret the daughter of Herman Boerhaave. After receiving a good classical education, he went to Leyden, where applying to the study of medicine, under the celebrated Albinus Gauuius, and other masters, he was admitted to the degree of doctor in 1738. He had before obtained an honorary medal from the university, for his discourse, "De gaudis Alchimiftrum," though he was more particularly attached to anatomy, which he cultivated with great success. The year following he took the name of his uncle Boerhaave. In
he went to Peterburgh, where his talents soon procured him the situation of professor in medicine in the university there, and of one of the members of the imperial academy. By Portal and Blumenbach, he is called archiater, or stile controller, and first physician to the empress, confounded with his brother, Herkan Kuan B. who about the same time enjoyed that honour. In the course of a fever and tedious illness, from which he with difficulty recovered, he lost his hearing. This happened in 1710. He died in 1733. His works are "Perispicio dicata Hippocrat. per universum corpus anatomice illustrata," Lulg. B. 17/8, 12mo; in which he shews there is a constant inhalation, or absorption, and an exhalation, or perspiration, carried on, not only on the surface of the body, but in all the principal cavities. "Impetus faciens dictum Hippocrati per corpus confluentis, philologice et physiologice illustratum," Lulg. Bat. 1745, 12mo. In this he treat of the action of the mind upon the body, by the means of the nerves; of the fabric and motion of the mucose; on the effects of opium, given to a dog, &c. He also gave the anatomy of an elephant, which he had an opportunity of dissecting, and of two monstrous infants, and a differentiation on what have been called, improperly he says, hermaprodites; no real hermaprodiote having ever been produced. Haller. Bib. Anat. Portal. Bib. Chr.

BOERHAVIA, in Botany, (named by Vailant in honour of the celebrated Boerhaave) Lin. gen. 9. Schreb. 13. Reich. 9, t. 6. Willden. 20. Julifle. 91; a genus placed by most botanists in the class monandra monogynia, though in different species, there are from one to four flowers. Nat. Ord. Aggregate.—Nylegenus. Julifle. Gen. Char. Cal. oblong, tubular and angular, placed beneath the coroll, with a contracted, entire mouth, permanent. Coroll. monopetalous, bell-shaped, upright, obtusely five-leafed, plaited, fixed on the calyx. Nect. flabby, subcylindric, with a mouth slightly toothed, surrounding the base of the germ. Stam. filaments one, two, three, or four, upright, on the margin of the corolla; anthers twin-globular. Fil. germ roundish, pedicelled, the pedicel surrounded by the corolla; style thread-shaped, twined, as long as the filaments; stigma capitate. Pericarp. none; calyx enlarged, closed, encircling the seed. Seed one, oblong, obtuse, angular. Nepae. It is nearly allied to Mirabilis. The toothlets of the corolla are sometimes triangular, very small, and sometimes obsolete.

Eff. Gen. Char. Cal. small, entire. Cor. one-petalled, bell-shaped, plaited. Seed one, encircling with the enlarged calyx. Dahl has judiciously abolished this genus, and placed its species with the Valerian. In the opinion of Wildenow, it belongs properly to the class triandria, and may readily be distinguished from valerian by its entire calyx, 50 minutes, as scarcely to be visible, without the assistance of a lens, on which account it appears to have been overlooked by Linnaeus and La Mark. Professor Martyn, in his edition of Miller, has inadvertently given Calyx none, as part of its effent ill general character; though in the natural character translated from Schreber, he had properly affixed it one. Species. 1. B. ercta, upright hogweed. "Stem erect, smooth; Stamen two." Jacq. and Miller. "Stem tetragonal, smooth, with vious junctions, and flowers in a corimbous panicle." Willden. Stem two feet high, sprinkled with very minute protuberances as fine as hairs. Leaves waved, ovate, acute, rough at the margin, growing by pairs on long petioles from the joints of the stem, which are placed at a considerable distance from each other. Coroll cylindrical, white, with five reddish shades; segments acute, with small teeth interpolated. Stigma capitate. Discovered by Dr. Hoult at La Verca Cruz in 1731, and since found at the Society Isles. 2. B. adflentes. "Leaves oblong-ovate, somewhat flabby; flowers panicked; peduncles two- and three-flowered; stem ascending." Willden. Stem smooth, tetragonal; leaves petiolar, opposite, veined, entire, smooth; the young leaves and the margin and petioles of the older ones hairy; hairs jointed as in veronica aphylla; panicle terminal, spreading, naked; peduncles two-flowered, involved in membranaceous bracts; fruit club-shaped, rough, with small tubercles. A native of Guinea. Willden. 3. B. difusa. "Stem smooth and even, spreading; leaves ovate." Linnae. "Stem round, pubescent; flowers in corimbos head." Willden. Leaves white underneath; flowers purple, with one flamen. A native of the East and West Indies. Cultivated in the royal garden at Hampton Court 1690. Mr. Miller received seeds from Jamaica by Dr. Hoult. 4. B. hiriflora. "Stem spreading, pubescent; leaves ovate, repand, or corperent." Reich. "Stem roundish, hairy; flowers in heads." Willden. Stems a foot high; peduncles axillary, suffusing small club-shaped heads of scarlet diandrous flowers, which generally fall off in about half a day. A native of Jamaica. 5. B. plumbaginea. "Leaves subcordate, orbicular-acute, pubescent beneath; flowers in umbels." Willden. Umbels axillary, on long peduncles; coroll of a pale rosy-coloured; flamen three; fruit turbinate, inflated, crowned at the apex with pedicilled tubercles. Willden. A native of Spain. 6. B. scandens. La Mare, Tab. 4. "Stem erect; flowers two-flowered; leaf cordate, acute." Linnae. "Stem erect, flowers two-flowered, in umbels; leaves cordate." Willden. Stem shrubby, very stiff, smooth, with alternate branches; leaves smooth; umbels of fix green flowers; involucr of five leaves. A native of the rocky coasts of Jamaica and other West India islands. Cultivated in 1691, in the royal garden at Hampton court. 7. B. excelsa. "Stem erect; lower leaves cordate-ovate, upper ones ovate, flowers with three flamen in umbels." It resembles the scandens, but differs from it in its smaller limbs, in its large ovals leaves, in its doubly larger purple flowers, and in the number of its flamen. Native place unknown. Described by Willdenow from a living plant. 8. B. repanda. "Stem erect; leaves cordate, repando-flinate; flowers in umbels, with three flamen." Willden. Rememhbes the scandens, but from it in its herbaceous stem and opposite branches and peduncles. A native of India and China. 9. B. cheroxphyllidae. (Variciana Cheroxphyllides. Smith in. inc. fulc. 3-1) "Leaves bipinnatifid, toothed; flowers with three flamen in umbels." Willden. It has entirely the habit of a Boerhavia, and agrees in all the generic characters, excepting only the style which is triad. 10. B. repensa. "Stem creeping." Linnae. Native of Nubia, between Mocho and Tangos. 11. B. anguliflora. "Leaves linear, acute." Linnae. Native place unknown. 12. B. tetandra. Stem creeping; flowers with four flamen. Forl. Prod. 2. Native of the Society Isles, found by Forster in the island of Hoshine 1774.

These are all the species in Willdenow's edition of the Sp. Pl. La Marek (Idillt.) has made the hiriflora and the repensa the same as the diffusa, and appears to have been acquainted with the adflentes, plumbaginea, excelsa, repanda, cheroxphyllides, anguliflora, and tetandra; but has inserted two others, which, as far as can be determined from their specific characters, seem to be distinct species. B. pani- calina. "Stem erect; leaves ovate, acute; panicle naked, filiform, very viscosus." A native of South America. B. tuberofa. "Stem erect, shrubby; root tuberose, cefulent." A native of Peru. The following may possibly be the hiriflora, though he unites that species with the diffusa. B. ob- tuffolia. "Stem procumbent, spreading, viscidly pubes- cent;
BOE, a native of South America.

Propagation and Culture. None but the first, third, fourth, and fifth, have been cultivated in England: They will not thrive in the open air, but must be raised from seeds, and treated like other tender exotic plants. The first three are annual, and when they grow too tall to remain under a common frame, may be planted in a warm border, where, if the season prove favourable, they ripen their seeds; but a plant or two should always be placed in the flower, to ensure a succession of seeds. The fourth, which is perennial, may be preserved in a warm flower two or three years. See Martyn’s Miller.

BOERNER, Frederic, in Biography, professor in medicine at the university of Wittenburg, in Saxony, and an active member of the Acad. Nat. Curiof. received his education at Leipzig, where he was born, June 17, 1723. He published several dissertations on medical subjects, but his principal work is "Noctes gallicae, five opuscula medicoliteraria," Rollock, 1755, 8vo. He died June 1761. Eloy. Dict. Hilt.

BOERNERIANUS, Codex, in Biblical History, a MS. of part of the N. T. noted G, in the second part of Wetz’s N. T. It belonged to Dr. C. F. Boerner, was collated by Kuffer, and described in the preface to his edition of Mill’s Greek Testament. It contains the epistles of St. Paul, that to the Hebrews excepted, which was formerly rejected by the church of Rome; it is written in Greek and Latin, according to one of those versions, which were in use before the time of Jerome. The Latin is interlined between the Greek, written over the text, of which it is a translation. Stemmler supposes that the Latin was written since the Greek; but professor Matthi, who published this MS. at Meffen in Saxony in 1791, fuggeld, that an uniformity in the hand-writing, and a similarity in the colour of the ink evince, that both the Greek and Latin texts proceeded from the same transcriber. That it is an ancient MS. appears, says Michaelis, from the form of the characters, and the want of accents and marks of aspiration. It seems to have been written in an age when the transition was making from the uncial to the small characters; and from the correspondence of the letters r, s, and t, in the Latin translation, to that form which is found in the Anglo-Saxon alphabet. It is inferred, that this MS. was written in the West of Europe, and probably between the 8th and 12th centuries. This MS. is preferred at present in the electoral library at Drefden; and a copy of it is kept in the library of Trinity college, Cambridge, among the books and MSS. that were left by Dr. Bentley. Michaelis on the N. T. by Marth, vol ii. and iii.

BOERO, in Geography. See Burro.

BOECHOIT, a town of Brabant, on the river Nthe; 12 miles N. E. of Malines.

BOEGEROEN, or BUDGEROONS, three small uninhabited islets of the East Indies, situated in the strait that lies between the island Saleyer and the point of Celebes, called Laffem. These three islands almost block up the passage between the southern part of Celebes and the northern part of Saleyer, the whole space between which is about a league and a half. The strait is palled between the southemmost and middlemost, or between the latter, and the northernmmost of the Budgeroons. This is one of the most dangerous parts of the navigation for ships failing to or from the Molucca, or spice islands; and it cannot be avoided without going round to the south of Saleyer, which is a much more dangerous route, on account of the great number of shoals and sunken rocks, which abound there, and are not accurately laid down in the charts.

BOESIS. See Basippo.

BOETHICUS, in Entomology, a species of Hesperia, (Pleg. Rur. Iinn.) that inhabits India. The wings are tailed, blue-brown, pale ash colour beneath, and dotted with white; a double ocellar spot in the anal angle.

BOETHIUS, Anicius Manlius Torquatus Severinus, in Biography, descended from one of the most illustrious consul families of Rome, lived in the time of the emperor Zeno, near the end of the 5th century. He was born at Rome about 470, the same year with Martinus Capella, another Roman writer on music. He is said to have spent 18 years in the schools of Athens, pursuing the study of philosophy under Proclus; others, however, have questioned this fact, and it has generally been allowed, that the term of 18 years is too long. Nevertheless, his visit to Athens is justified by much internal evidence, adduced by Brucker, (Hist. Crit. Philos. t. iii. p. 524—527,) and by an expression, though vague and ambiguous, of his friend Cato, that he "longe politas Athenas introiit." It is certain, that the erudition of the Latin language was insufficient to satisfy his curiosity, and that he devoted much of his time and attention to the study of Greek science and letters. From a letter of Cato, written in the name of Theodoric, it appears that he had the honour of introducing to the Romans, in their own language, the music of Pythagoras, the astronomy of Ptolemy, the arithmetic of Nicomachus, the geometry of Euclid, the logic of Aristotle, and the mechanics of Archimedes. He alone was esteemed capable of describing the wonders of art, a fun-dial, a water-clock, and a sphere which represented the motions of the planets. He commented upon parts of Aristotle, Cicero, and Porphyry; and from the commendations which he beffows upon the latter, as the best interpreter of the former, he seems to have united the Platonic with the Aristotelian doctrine. Boethius seems to have been the first who applied scholastic philosophy to the service of Christian theology; and he employed himself in defending the orthodox creed against the Eutychian, Ariat, and Nestorian heresies, in a treatise "De Unitate et Uno." In civil life he attainted to peculiar honours; as he was consul in 487, and also in 510; and he was also created patrician, and advanced to the post of master of the offices. He married the daughter of his friend, the patrician Symmachus, and he enjoyed the peculiar satisfaction of seeing his two sons elevated to the consulate together in 522. Few persons passed through life with a greater share of outward respect and honour; and few could be more distinguished by the testimonies that were given to his benevolence and liberality, his virtue and patriotism, as well as to his singular talents and learning. His own afleavations claims our affent, that he had reluctantly obeyed the divine Plato, who enjoined every virtuous citizen to refuse the fiate from the usurpation of ignorance and vice. For the integrity of his public conduct he appeals to the memory of his country. His authority had restrained the pride and oppression of the royal officers; he had always pitied, and often relieved, the distress of the provincials, whose fortunes were exhausted by public and private rapine; and he alone had the courage to oppose the tyranny of the Barbarians, elated by conquest, excited by avarice, and, as he complained, encouraged by impunity. In these honourable contests, his spirit soared above the consideration of personal danger, and perhaps of prudence. In addition to his other learned labours, he had formed a design of translating all the works of Plato and Aristotle into Latin; but was prevented from executing his purpose by a premature death. Having for some years enjoyed the favour of Theodoric, the Gothic king of Italy, he was at length suspected of being hostile to his
his government, and of concursing with others, and particularly with Albinus, who was accused and convicted on the presumption of hoping, as it was said, the liberty of Rome. "If Albinus be criminal," exclaimed Boethius in the presence of the king, "the senate and myself are guilty of the same crime. If we are innocent, Albinus is equally entitled to the protection of the laws." The advocate of Albinus was soon involved in the danger and perhaps the guilt of his client; their signature, which they affixed to be a forgery, was affixed to the original address, inviting the emperor Julian to deliver Italy from the Goths; and three witnresses of honourable rank, but probably of infamous character, attested the treacherous designs of the Roman patrician. Upon this kind of evidence, Boethius was committed to custody, and rigorously confined in the tower of Pavia; and a fervent Senate, at the distance of 500 miles, pronounced a sentence of confiscation and death against the most illustrious of its members. During his confinement, he composed his treatise "De consolatione philosophia," mentioned in the sequel of this article; and at length the executioners of Theodoric's mandate fulfilled the savage commission with which they had been entrusted, or, perhaps, even exceeded it, by the mode of putting him to death. Some say that he was beheaded; but others relate, that a strong cord was fastened round his head, and forcibly tightened, till his eyes almost started from their sockets; and he was then beaten with clubs till he expired. This event happened, according to some, in the year 526, but according to others in 524. Boethius, in his last hours, derived some comfort from the safety of his wife, of his two sons, and of his father-in-law, the venerable Symmachus. But Symmachus, perhaps indifferently in the mode of testifying his grief, was sometime after dragged in chains from Rome to the palace of Ravenna, and there put to death, A. D. 525. Theodoric, it is said, experienced the bitterness of self-reproach, and the anguish of an unwavering repentance for the murder of these two illustrious senators, Boethius and Symmachus. His daughter Amala- funtha is said to have refrained to the sons of Boethius the confiscated estates of their father. His celebrated tract on music, divided into five books, was first printed in black letter, with his treatises on arithmetic and geometry, at Venice, 1499. It is remarkable, that in this copy the Greek of the famous finatus confilium, against Timotheus at Lacedemon, is omitted; though it was afterwards found in a beautiful MS. of Boethius, De musica, 15 B. IX. of the 11th century, in the British Museum, where the infamous chromatic (χρωματική) is said to have been substituted by that musician to their grave and simple enharmonic (εναρμονια), in the same manner as it is printed in the Oxford edit. of Aurelius. (See Differunt. on the Mus. of the Ancients, p. 27.)

It seems necessary here to give some account of this famous treatise on music by Boethius, which, to read, was long thought necessary to the obtaining a musical degree in our universities; and which, with great parade, has been so frequently praised, quoted, and pronounced, by writers on that art, to be of the greatest importance to every musician, yet contains nothing but matters of more speculative and theory, translated from Greek writers of higher antiquity; which, if necessary to be known at this time, would be more profitably studied in the original; but the theory of every art being vain and useless, unless it guide and facilitate practice, the definitions, calculations, and reverses of Boethius, are no more useful or essential to a modern musician than Newton's Principia to a dancer. In the proemium, or introduction to his first book, "De Musica," he treats of the morality of music, and gives us all the old stories concerning its miraculous powers of exciting virtue, repressing vice, curing diseases, &c. And in this book we find whence Zarlini, and all the Italian writers on music, down to Padre Martini, drew their extensive divisions of music into mundane, human, and instrumental. For Boethius says, "Tres eft Musicas," lib. i. cap. 2. So had Arifl. Quintilianus informed us, long before the birth of Boethius. And as far as we are able to divine at present concerning these divisions, the ancients were chiefly divided by mundane music, the music of the spheres. By human, or humane music, the perfect organization of our frame, and the union of soul and body. By the last only, the instrumental, we are brought to real music, by the grateful production and union of tuneful sounds. Then we have definitions, such as are given in Euclid and all the Greek writers, on harmonics and speculative music in Meibomius. After which, we have the doctrines of proportion and ratios, influtuated by Pythagoras, who would not truft to the various and fallacious judgment of the fentences, but had recourse to reason and calculation to settle his doubts. The account of the discoveries and harmonical laws established by Pythagoras, not only influtuated in Boethius, but all subsequent writers, is taken from Nicomachus, one of the seven Greek writers on music in Meibomius. In the fame book, we have a very superficial and unsatisfactory account of the genera. But we are indulged with several chapters on the music of the spheres from "Cicero de Republica." lib. vi. where the supffused analogy between the planets and the septenary, or seven founds in music, is afferted. At the close of this book, chap. xxxiv. Boethius estimates theory and speculation far above practice in music. But what, we may ask, is the use to the world of such a theory as he describes, without practice? Or, indeed, practice, without the support of what is now understood by theory? The speculative theories, confined to meditation and experiment, in harmony, are mere words of music without hearing it; and the mere practician hears it, without understanding it. Boethius allows him only to be a musician who can examine, judge, and give reasons for what is done. Here we have the origin of the verses ascribed to Guido: "

Musiicorum et cantorum,
Magnus est dilexantia, &c.

The whole second book is relative to the dispute between the Pythagoreans and Ariflo Xenians, which is not yet settled, about dividing the scale, whether by the ear, or by numbers. All the musicians in Europe are now disputing whether we should temper our scales on fixed instruments, or adopt the triple progression of Pythagoras, and tune by perfect 9ths. See "Triple Progression, and Temperament." We have here the tone-major and tone-minor to discuss; which we talk about, but never feel or think of the distinction in our modulation or performance. The apothes, comma, and bema, are left for the amusement of speculative harmonists to talk about, and for musicians to practice with their ears and fingers, fant zanger. In the third book, Boethius continues his controversy with the Ariflo Xenians, and proves what has been long settled, that there is no such thing in music as a literal half-note. The octave is said to contain five tones and two semitones; and in the temperament of equal participation, the twelve semitones of the octave must be nearly equal. In book iv. the subject is pursued of splitting of tones; for the ancients could not divide and subdivide a tone from south to south-west fide. We were very much disappointed formerly at the non-performance of a promiscuous made book v. at chap. 2, the title of which is "Musiicorum per Graecas et Latinas litteras notarium nupercum." But Meibomius says the promise does not extend to the Roman notation in the Seldon MS. at Oxford; nor had the Romans any notation of their own
in the time of Boethius; and all the musical terms he uses are Greek, as were those of Vitruvius.

Even the eulogists of Boethius confess, that his work is so purely theoretic, that in reading it we never think of practice. Let us leave it then to philosophers who are content with imaginary fouds. The mention of instruments, or of the voice as employed in singing, never occurs. No allusions to the music of his time, but all is abstract speculation, tending doubtless to the perfection of the art, but seeming little connected with it. The harmony he talks of is more the harmonic mind of Kepler, than that of Hul- del and Haydn. Guido said, that Boethius's work was only fit for philosophers. In the middle ages, so few understood Greek, that those who were curious to know something about the miraculous powers of that music, imagined that they should find it in Boethius's translation, which had been educated at Athens. Such speculations are curious and amusing, in moments of meditation, to scientific and inquiring minds; but practical musicians, whether composers or performers, can afford little time for such sublime and spiritual amuse- ments. Nevertheless, he must be a dull and incurious pro- fessor, who seeks not the reason of things, the principles of his art, and origin of sounds. If he have a mathematical turn, let him read Galileo, Daniel Bartoli, D'Alembert, Holder, Rameau, Tartini, and Smith's harmonies. They are all intelligible, and lead to knowledge which he will be expected to poise; but for any thing useful that he can acquire from Boethius's speculations, or from the Greek theorists, his prototypes, that will make him a better com- poser or performer, the cafe is hopeless. Yet there are, who, after allowing that "it was so little use in practical music, that they never thought of it in reading Boethius;" yet returning afterwards to former prejudices, is infihted on, that "he has communicated to the world such a knowledge of the fundamental principles of the music of the ancients, as is absolutely necessary to the right understanding of our own system."" When we speak of the instability of Boethius's work on music to the musical students of modern times, we premise not to extend our confusions further. The writings of this great and good man on other subjects have been too long held in reverence to be depreciated lightly. His most celebrated production was his ethic composition "De confolatione phi- losophia," and has always been admired both for the style and sentiments. It is an imaginary conversation between the author and philosophy personified, who endeavours to con- fuse and confound the motions of his affections. The topics of consolation contained in this work, are deduced from the tenets of Plato, Zeno, and Aristole, but without any notion of the sources of consolation which are peculiar to the Christian system. It is partly in prose, and partly in verse; and was translated into Saxon by King Alfred, and illustrated with a commentary by Aelfric, bishop of St. David's; and into Eng- lish, by Chaucer and queen Elizabeth. It was also translated into English verse by John Walton, in 1410, of which translation there is a correct manuscript on parchment in the Brit- ish museum. Few books have been more popular, espe- cially in the middle ages, or have passed through a greater number of editions in almost all languages. It has been ob- served by Mr. Harris, in his "Hermes," that "with Boe- thius the Latin tongue, and the loft of Roman dignity, may be said to have sunk in the western world." To the same purpose, Gibbon says, that "the senator Boe- thius is the last of the Romans, whom Cato or Tully would have acknowledged for their countryman." Fabr. Bib. Lat- tom. ii. p. 146, &c. Le Clerc, Bib. Chrof. t. xvi. p. 168 —275. Burney's Hisl. Muf. vol. ii. p. 31, &c. Gibbon's

---

**BOEUF, Le, in Geography**, a place in the north-western corner of Pennsylvania, at the head of the north branch of French creek, and 50 miles distant by water from fort Franklin, where this creek joins the Alleghany. The French fort of Le Boeuf, from whence the place has its name, lies about two miles east from Small lake, which is on the north branch of French creek; and from Le Boeuf, is a portage of 14 miles northerly to Prefque iles in lake Erie, where the French had another fort. N. lat. 42° 14'; W. long. 79° 53' 20".

**Boeuf, in Ornithology**, according to Salerne, the common name of the bulfinch (Leioa pyrrhula) in the canton of So- loigne. The troglodyte, sylivia troglodytes of Latham, is like- wise called by the same name (boeuf) in Switzerland.

**Boeuf de Marais, The French call the common bittern (ardea aldroria), because it frequents marshes, and has a loud cry, and emits a sort of roaring noise that has been com- pared to that of an ox or bull, by this name. "Il n'y a," says Belon, "boeuf qui puit crier si haut."**

**Boeuf d' Afrique, in Zoology.** By this name some French writers distinguished the buffalo; the epithet is misapplied, because that animal is equally common in India, whence in- deed, it is supposed, the African buffalo first originated.

**Boeuf a Boeuf, synonymous with bisson.** By some it is likewise called boeuf des Illinois.

**Boeuf Guerin, Under this denomination the French describe a race of African oxen, which the Hottentots call backsley; the word backsley in their language signifies war, to the purposes of which they are trained up, in the same manner as elephants are by the Indians. War-oxen of this description are instructed also to guard the herds of the common oxen.**

**Boeuf de Mer, in Ichthyology, is the name of the long- beaked ray, roja oxyrinchus of Linneus.**

**Boeuf de Mer, in Zoology, the common French name for any of the Phocæ tribe of animals, corresponding with the general English name of sea-cow.**

**Boffrand, Germain, in Biography, a celebrated French architect and engineer, was born at Nantes in 1667, and having been educated at Paris, he employed himself for some time in sculpture, during the winter, and studied archi- tecture in the summer. His talents at length engaged the attention and patronage of Harcourt-Manfant, an eminent archi- tect, who obtained for him a place in the commission for the royal buildings. In 1709, he became a member of the Royal
Royal Academy of Architecture, and was much employed at Paris, and by several German princes, in furnishing designs for various edifices. His style of building was grand and noble, and formed after the model of Palladio. He was likewise a skilful engineer, and constructed a great number of canals, sluices, bridges, and similar works. As architect to the general hospital of Paris, he gratuitously served the institution; and, as he was disinterested in his temper, he was lively and amusing in conversation; and he indulged his taste for literature by the composition of several pieces, adapted to the purpose of producing temporary gaiety and mirth, for the Italian comedy. His "Book of Architecture," with plates, was printed at Paris in 1745, folio; and contains an account of the general principles of the art, exemplified in his own works. In this work he has also introduced a curious memoir, describing the method of casting the bronze equestrian statue of Lewis XIV. He retained his gaiety of disposition to the age of 87 years, and died at Paris in 1755. Encycl. Hist. Gen. Bog.

BOFIN, Boffin, or Baffin Longb, in Geography, one of those large lakes in Ireland into which the river Shannon expands, situated between the counties of Roscommon and Leitrim.

BOG, derived from the Italian buca, a hole, or rather from the Belgic boggen, to bend, on account of its giving way when trod upon, in Agriculture, a quaggy sort of earth, generally met with in low situations, covered with coarse grasses, but of so little solidity as to be incapable of supporting the tread of heavy animals; caused by the dissolution, decay, and deposition of different vegetable and other afflictances; from the stagnation and detention of the water that oozes along on the clayey or other thin tenaceous flates below, or which springs up through the fissures, or other openings of them. They are of different kinds, depths, and consistencies, according to the different circumstances of the cafe, and the nature of the situation of the ground on which they are formed, as well as that of the earthy material that enters into their composition. Dr. James Anderson, in his treatise on draining bogs and swampy grounds, remarks, that clay is a substance that strongly resists the entrance of water into it; but, when it is long drenched with water, it is, in process of time, in some measure, dissolved thereby, losing its original firmness of texture and confidence, and becoming a sort of semi-fluid mass, which is called bog. And as these bogs are sometimes covered with a surface of a particular kind of grasses, with very matted roots, which is strong enough to bear a small weight without breaking, although it yields very much; it is in these circumstances denominated a swamp.

But, whatever be the nature of the bog, it is invariably occasioned by water being forced up through a bed of clay, as just described, and diffusing or softening a part thereof. A part is only mentioned, because, whatever may be the depth of the bog or swamp, it generally has a partition of solid clay between it and the reservoir of water under it, whence it originally proceeds. For if this were not the case, and the quantity of water were considerable, it would meet with no sufficient resistance from the bog, and would of course, issue through it with violence, and carry the whole semi-fluid mass along with it. This would more inevitably be the case, if there was at first a crust at the bottom of the bog, and that crust should be broken, especially if the quantity of water under it was very considerable. And as it is probable that, in many cases of this sort, the water slowly dilutes more and more of this under-crust, no doubt is entertained but that in the revolution of many ages, a great many irruptions of this kind may have happened; although they may not have been deemed of importance enough to have the history of them transmitted to posterity.

It has been remarked by Mr. King, in the Philosophical Transactions, No. 170, that the springs, with which Ireland abounds, are generally dry, or nearly dry, in the summer time, and that grass and weeds grow thick about the places where they burst out. In the winter, he observes, they swell, run, and, loosen, and loosen all the earth about them. The fward or turf of the earth, which confines of the roots of grasses, being lifted up and made fuzzy by the water, at that season he has seen it lifted up a foot or two at the head of some springs, is dried in the spring, and does not fall together, but withers in a tuft, through which arises new grass, which is also lifted up the next winter. By this means the spring is more and more clogged, and the turf grows thicker and thicker, till at first it makes the appearance which we call a quaking bog; and as it grows higher and drier, and the roots of the grasses and other vegetables become more purified, together with the mud and slime of the water, it acquires a blackness, and grows into that which we call a turf-bog.

It is, however, confessed, that there are quaking-bogs caused otherwise. When, it is observed, a stream or spring runs through a flat, the passage, if not kept open, fills with weeds in summer, trees fall across it and dam it up; then in winter the water flagellates further every year, till the whole flat is covered. Afterwards a coarser kind of grasses shoots up, peculiar to these bogs; this grass grows in tufts, its roots confide together, and its height increases every year, incomparably as he has seen it as tall as a man. This grass rots in winter, and falls on the turf, and with it the feed, which springs up the next year; and so continues making an annual addition. Sometimes the tops of the flags and grasses are interwoven on the surface of the water, and this becomes by degrees thicker till it lies like a cover on it; then herbs take root in it, and by the matting of their roots, it becomes very strong, so as to bore a man. He has gone on bogs which would rife before and behind, and sink where he flood to a considerable depth, under which was clear water. It is further observed, that Ireland abounds in mofs more than any other country; this mofs is of divers kinds, and that which grows in bogs is very remarkable. The light spongy mofs in no time being covered with water, or the threads of this moss, before it is sufficiently rotten; the turf then looks white, and is light. It has been seen in such quantities, and so tough, that the turf-spades could not cut it. In the north of Ireland, they denominate it old-wives tow, being not much unlike flax. The turf-holes in time grow up with it again; and all the little gutters in bogs are generally filled with it. To this he chiefly imputes the red or turf bog; and from the same cause even the hardened turf, when broken, is irongy, though there plainly appear in it parts of other vegetables; and he is almost, from some observations, tempted to believe, that the feed of this bog-mos begets heath, when it falls on dry and parched ground. However, the moss is so fuzzy and quick-growino a vegetable, that it generally keeps the spring, and contributes to thicken the turf, especially in red bogs, where he remembers to have observed this moss particularly. The situations of land may sometimes contribute to the formation of bogs in it, as flat spots of ground lower than the level of an adjoining river or lake; for when that part is filled up by the flime and earth brought from the surrounding grounds, and the rotten plants and animals, which are buried in it, have choked it up, it will become a bog; and then the water will continue to flow into it from the river or lake, especially when either of these is swelled by a fall of rain or melting of snow. These waters may also sometimes have this...
this effect, without a communication above ground, by soaking through a sandy or gravelly foil. And another cause that may contribute to the production of bogs, may be the fall of a number of trees, which, by occasioning a stagnation in the water brought down from higher grounds, may cause the deposition of much earthy vegetable, and other materials, and consequently the production of boggy appearances in the places where such obstructions are met with.

Bogs are discriminated by different titles, according to the nature of the circumstances under which they occur; as peat-bogs, quaking-bogs, spring-bogs, and turf-bogs. The first being that fort of bog which is principally composed of peat-earth. The second such a kind of bog as, when trodden upon, affords an elastic kind of motion, or sinking under the foot. The third is such a bog as arises from the oozing or springing up of water through the fluff or mats of materials on which it is formed. Mr. Elkington, the celebrated drainer, makes two classes of this fort of bog; the first of which is distinguished by the springs rising out of the adjoining higher grounds, in a regular line, along the upper side of the wet surface; while, in the latter, the number of springs that appear are not confined to one regular direction along the upper side, but burst out promiscuously over the whole surface, especially towards the lower side, forming quagmires all round, that shake and bend under the feet like a suspended cloth, over which it is dangerous for the lightest cattle to pass, and which flosh themselves at a distance by the vibration of the grass, which the quags or spots immediately round the springs produce. The lait is a fort of bog constituted of materials which partake of the nature of turf.

Wherever bogs are met with, draining is unquestionably the first step to be taken towards their improvement. For the full accomplishment of this purpose, Mr. Elkington's mode may in many cases be successfully resorted to, and with great and sudden effect; though the improver should not be too fagacious in his expectations, or imagine that it is in every case an easy operation to free this fort of land from an excess of moisture. There are probably some bogs, which cannot, without great difficulty, be drained at all; and others that would cost the value of the land, in drains and machinery, to effect such improvements in them. But notwithstanding unsuccessful trials may sometimes be made, the drainier ought not to be totally discouraged from further attempts, where there is a tolerable prospect of succeeding in the business at last; as the cafes are no doubt very numerous, in which this fort of land may be effectually drained at an easy expence, and thereby brought from a state of inutility to yield considerable profit to the owners and the public. See Draining of Boggy Lands.

It is observed in the appendix to Mr. Johnston's account of Mr. Elkington's mode of draining, that in the improving of bogs, after their being drained, as the great object is to get the ground brought to such a state, as to be fit for being laid down with grass feeds, when it may be considered in such a state of improvement, that any subfrequent crops will require no more than ordinary management to cultivate them; the first thing to be done, while they are extensive, is to have them divided into proper enclosures by open ditches, by which means much surface water may be carried off, as well as by properly attending to the formation of the ridges and furrows in ploughing, and giving them a direction towards the open ditches, by which the rain or surface water may be discharged as it falls; and after this has been effectually done, to have the surface well levelled by means of the spade, as being in most cafes more effectual than by the plough. The better sorts of the materials thus removed may be mixed up with lime or other sublignises, and let upon the land; while those of the coarser kinds are made use of to fill up the inequalities on the surface. Paring and burning, where there is much coarser vegetable matter, may be practiced with advantage. In order to this, whatever earth remains unemployed, in filling up hollows, should be burnt, together with that taken out of the ditches, unless the latter has been already carried off for fuel. The greater quantity of ashes there is, the greater will be the improvement of the soil itself, and the more will the earth be benefited. The ashes, after being well incorporated with the soil by means of light or superficial ploughing, frequently so enrich it, as to produce excellent crops for two years or more. The effects of the ashes and burnt materials have been said, in some cafes, to be increased by the addition of a little lime. When the turfs have been reduced to ashes, spread over the surface of the ground, and turned in with a little furrow, turnips or potatoes ought to be the first crop. If the former, they may be fown broad-cast, and fed off by sheeps, by the dung and urine of which the soil will be greatly benefited, as well as by the refuse of the plants, and the condensation produced by their treading upon it. It will then be in a state for a crop of oats or barley, which should be fown with grass-feeds, and well rolled down. The ploughing after the turnip crop, thus eaten off, should be very light, in order not to bury the enriching materials too deep; in which view oats ought to be preferred to barley. If the soil be full of the roots of rushes, weeds, and coarse plants, a further fallow may be necessary before any crop be taken; and when the ashes have been made in a particular part of the field, they may be spread over the surface before the seed furrow is given, and the roots and tough clods, after being collected and burnt, may be spread along with the ashes.

If the bog be very soft and deep of peat, so as not to admit houses for ploughing the first year, a crop of turnips broad-cast may be got by fowing the seed among the spread ashes, harrowing it in with a light harrow and roller drawn by men. This crop, being cut off as above, will leave the land the ensuing year so much consolidated as to admit the ploughing.

When the surface has not been pared and burnt, following for two years may be necessary to reduce the soil to a proper mould, in the last stage of which the lime or other manure must be applied. In this cafe two white crops, with an intervening one of turnips, potatoes, &c. may be taken before the grass-feeds are fown.

Boggy foil, of whatever kind, after being once broken up and pulverized by village and a course of fallow, should not be over-cropped before being laid down in grass; and, when brought into a good fward of grass, should not be too foon broken up again, but continue so, buit-harrowing and top-dressing it when the herbage begins to moss. Repeated rolling is also necessary in such soils.

It is probably a better practice to feed sheep the first and second years of the grass than to cut it for hay, as it causes the roots of the grass to live more horizontally through the foil, and more closely to cover the surface. With this view a greater proportion of white and yellow clover, and other short grasses, should be fown.

In the manuring of soft boggy lands some caution is necessary; for, though the ploughings, previously to the application of the dung, may be made deep with advantage, the subfrequent furrows should be very superficial, and the dung regularly and uniformly blended with the soil; for, when this is not the case, it is apt to sink down too much, and be of little utility. The same thing takes place with respect to lime; and even when marle is buried too deep it is said to lose its power as a manure.
On soft boggy ground, merely intended for pasture, nothing will produce a more rapid improvement than the application of a thin covering of marl. In order to this, the directions already given, with respect to paring and burning, should be observed.

Marl, which is often found under a gravel or clay, may also be of great service; but if a loamy earth be near at hand, it will, perhaps, be less expensive for the farmer to bring such earth to cover the bog, than it will be to dig up the clay. But of whatever kind the earth be which is laid upon the bog, the quantity should always be sufficient to cover its whole surface four, five, or six inches deep, according to the lowness of the feal fo brought.

Sea-ford, as being frequently mixed with shells, is well suited to this purpose; if the boggy ground be situated near the sea, fo that it can be easily procured. The great weight of these materials tends equally to consolidate the bog, and press out the moisture from the spongy peaty earth; therefore the thicker they are applied the better. A light sprinkling of lime over it will add to the effect, and bring up much white clover and other sweet grasses.

The most barren earths or clays, when used in this way, may have good effects; but lime-dust gravel, where it can be procured, is to be preferred to all others. After the land has been treated in this manner, and in some years in pasture, it may be broken up for tilage, and crops of grain taken before being laid down with grass feeds. By ploughing, part of the natural soil will be turned up, and intimately mixed with the earth, &c. that has been laid upon it, and, if lime or dung be added, will together form a very fertile mould. When boggy grounds are much over run with rushes, and other coarse, four, aquatic plants, scarcely any thing tends more to the full part of its improvement than that of over-flooding it with different sorts of cattle, as soon as ever it is sufficiently solid to bear them with safety; care must, however, be taken not to put them on till it is quite firm, as if that be done they will not only poach the surface, but the coarse herbage will remain without being eaten closely down. The practice of cutting the rushes frequently in their young and tender state, is also of considerable utility. By these means alone a better kind of herbage is speedily brought up, and much improvement produced.

Another considerable means of improving this sort of land, where the situation is such as to admit of it, or when it lies near the side of a large river or stream, of which, by means of proper dams and cuts, a command can be obtained, is that of flooding it with water, a process that, when judiciously managed, never fails to produce abundant crops of grass. And that it is a mode of improvement well suited to this sort of land, is evident from the effects that have been produced in different instances; and from the observavations of Mr. Beofell, that it requires more and longer watering than any sandy or gravelly soil; the larger the body of water that can be brought upon it the better; its weight and strength will greatly assist in compELLing the soil, and destroying the roots of the weeds that grow upon it; neither can the water be kept too long upon it, especially in the winter season, immediately after the after-math is eaten; and the closer it is eaten the better. The manner of conducting the buffets of watering must be suited to the circumstances of the particular cases.

After being thus improved, it must next be determined to what blilling purpose it may be well applied. The too great moisture of these soils, which always be flat, renders them unfit for continued tilage, and their mould becomes so loose by frequent ploughing, that it frequently does not afford sufficient stability to the roots of corn. For this reason barley, oats, and rye do better here than wheat, which requires a firmer footing; but neither of them should be sowed thick, because the fruitfulness of the foil will always make up in the size of the plants, what some might think wanting in their number. The most beneficial method of employing this sort of land is, undoubtedly, that of converting it into meadow, because, when thus prepared, and not injudiciously exhaustcd by crops of corn, it will yield great quantities of excellent grass. It is, however, usual to begin with sowing some kind of grain on this prepared surface, to indemnify the farmer by the plentiful crop which it generally yields; such, indeed, as sometimes defrays at once the whole expense of the improvement. In some cases the most profitable method may be to sow it in the autumn with rape, the leaves of which shading the surface in hot weather, and rotting in the winter, contribute greatly to mellow the earth; the strong roots of this plant open the foil too, and its feed brings a great return when sold for making oil. One or two ploughings after this will prepare it for a crop of wheat. After this is taken off, and the stubble turned down, white clover and grass-feeds should be sown, and the ground laid down for a hilling meadow; or if turpeins be sown, or cabbages planted in the autumn, these in the spring may be succeeded by barley, with which the grass-feeds may be sown.

In crude moor or black peat boggy improved lands, Mr. Marshall remarks, that what is most desirable is a crop that is sown and reaped during the summer months, and which demands neither labour nor attendance in the humid feasons of autumn, winter, or spring; and such a crop is found in rape, which is luckily natural to the climate, and at the same time highly profitable. Trials with this may be made at but a trifling expense on a small portion of the ground, the proof of which anwering, it is observed, "is not whether the plant will thrive as herbage, but whether it will mature its feed on the given foil in the given situation."

After a recoupment has been obtained by crops of this fort, which may be repeated, as there is no danger of exhausting such deep foils, the foundation of more lasting profits is to be laid, which may be effectcd by sowing grass-feeds, with or over the rape crops, or after the foils have been drawn, according to feasons and the circumstances of the land, flocking, as directed above, till such time as the surface becomes sufficiently firm, and the foil has attained a suitable texture for mixed cultivation, which time may be much shortened by the application of fertile substances of the calcareous kind in any period of the improvement.

When either through necessity, for want of other arable land, or out of choice, the farmer intends to continue ploughing his improved bags, the surface must be raised in ridges, and the further management of it may be like that of most other ploughed grounds.

If a foil of this kind happens to be situated near a town, a greater profit may accrue from planting it with garden fruits than from any fort of grain, as beans, peas, cabbages, potatoes, turnips, carrots, &c. are found to thrive exceedingly well in earth of this kind.

Bog moving or migrating. These soft marshes of earth have been sometimes known to move out of their place. An instance of this there was in Ireland, in the year 1697, about Charleville in the county of Limerick. There was heard for some time a noise under ground like that of thunder at a great distance, or almost spent; and soon after this the earth of a large bog in the neighbourhood began to move, and a hill or rising situated in the middle of it stood no longer above the level of the soil, but sunk flat. The bog not only moved itself, but carried with it the neighbouring pastur-
lands, though separated by a large and deep ditch; the motion continued a considerable time, and the surface of the moving earth rose into a sort of waves, but without breaking up or boiling any where. The passage of the earth rose very high, and was carried on with the same motion till it rolled upon a neighbouring meadow, the whole surface of which it covered, remaining fifteen feet deep upon its surface. The whole quantity of the bog was torn from its former feat, and left great gaps in the earth where it had joined, which threw up foul water, and very fishing vapours. Phil. Trans. N. & 233.

The whole country came in to see its strange a fight as this, for it continued moving a long time; but few guessed the true cause of it, which was that a more than ordinary winter
spring occasioned the rising of the bog to a great height in one part, and thence propagated itself through the whole bog; so that the hill in the midst was undermined, and naturally sunk flat; and the more than ordinary weight of this large bog pressing upon the adjoining passage-ground, forced up its foundations, which were only a loose sand. This was pushed on sideways, where there was a defeat from the bog, and at length having given the bog more room, all was quiet and remained in that state. The bog was more than forty acres of ground.

Another instance of this kind occurred, in March 1745, at the bog of Addargole, about a mile and a half from the town of Dunmore, in the county of Galway. In consequence of a violent storm, attended with a fall of rain, resembling a water-spout, the turbary, which the turf-cutters had just left, containing about twelve acres, was put into motion, and floated till at last it subsided upon a piece of low passage of near thirty acres, by the side of the river, where it spread and settled. The moving bog choked up the river, which consequently overflowed the back grounds, and in a little time a large lake of near 55 acres covered the adjacent fields. A passage for the river was formed as speedily as possible; but before it could be finished, and the lake discharged, it was supposed to have covered 300 acres; however, in seven or eight days it gradually decreased to 50 or 60 acres, of which extent it continued. Irish Transactions, vol. ii. p. 4.

Bog, ancient Iphaneis, in Geography, a river of Poland, which rises in Podolia and joins the confluence of the Dnieper or Nieper, a little above Ockazh, about N. lat. 56° 53', E. long. 32° 21'. This river separates Poland and a portion of European Turkey from Russia. By taking up the Igel, the Simucha, and the Guib, besides other streams in its course, it becomes a very considerable river.

Bog berry. See Vaccinium.

Bog moss. See Sphagnum.

Bog blye. See Schoenus.

Bog wood. See Wood subterraneous.

Bog sre. See Iron.

Boga, in Botany, synonymous with Bogus, and Sphag bogus.

BOGAERT, Martin Vanden, surnamed Dejardinian, in Biography, an eminent sculptor, was born at Brux, in Holland, in 1640, and setting in early life at Paris, he became a member of the Royal Academy, at the age of 31 years. The first of his most considerable works was an equestrian statue of Louis XIV. erected at Lyons in the place Bellecour. He also adorned the gate of the church of the Mazanz college with six groups of figures, representing the evangelists and the Greek and Latin fathers of the church; and besides many other works, the most distinguished was the monument erected in the place of Victory, at the expense of marchal du Fauillade, on which the king, crowned by victory, is exhibited in a standing posture, invested with the regal ornaments, and having under his feet a caryatid, to denote his triumph on occasion of the triple alliance. This group is 50 feet high, and was formed by a single cast, under the particular direction of Desjardins. This artificer died rich in 1674. Encyc.

BOGADHA, in Botany and Mythology, a tree held sacred in Ceylon, on account of the imagined preference given by the deity Buddha to the shade of this tree above all others. Wherever it is found throughout the island, perfons are appointed to watch over it, and preserve it from dirt or injury. It is held in the fame estimation among the followers of Bud- dou, as the banyan tree is among the Brahmins. The Can- dians hold their great festival under the shade of a tree of this kind, which stands at Annarodurbar, an ancient city in the northern part of the king of Candy's dominions; and none but his own subjects are permitted to approach this sanctuarv. Tradition says, that the bogadha tree suddenly flew over from some distant country and planted itself in the spot where it now stands. It was intended as a shelter for the god Budin, and under its branches he was wont to repose, while he sojourned on earth. Near this hallowed spot 90 kings are interred, who all merited admission into the regions of bliss by the temples and images they constructed for Budin. They are now sent as good spirits to preside over the safety of his followers, and protect them from being brought into fulmination to Europeans; a calamity against which they continually pray. Around the tree are a number of huts, erected for the use of the devotees, who repair hither; and as every fort of filth and dirt must be removed from the sacred spot, people are retained for the purpose of continually sweeping the approaches before the worshipers, and to attend the priests during the performance of the ceremonies. Percival's Ceylon.

BOGANEU, in Geography, a town of Bohemia, in the circle of Chrudim; 6 miles S. of Chrudim.

BOGAR. See Bokhara.

BOGAROVSKOI, a town of Siberia, 136 miles N. of Tobolik.

BOGAS, or Boshas, a small town of Egypt, at the mouth of the Nile, 3 miles N. of Damietta. See BOGASS.

BOGATOI, a town and district of Russia, in the government of Kursh, rested on the river Pena, falling into the Piel; 48 miles S. S. W. of Kurik.

BOGAZI, a town of Asiatic Turkey, in the country of Diarbekir, 50 miles W. of Diarbek.

BOGAZI, signifying in the Turkish language a "canal," or "futan," a name given by the Turks to two brahs, adjoining to the island of Samos; one, called Little Bogaz, and scarcely half a league broad, separates Samos from the continent of Asia; the other, called the Great Bogazi, and nearly two leagues broad, lies to the west and separates this island from the small Troms islands, so denominated, because, at a distance, they appear like the roofs of ovens; they were anciently called "Corax, infula." This is a passage much frequented by ships falling from Constantinople to Syria and Egypt, and they have here good accommodations.

BOGDANA, a town of European Turkey, in Mol- davia, on the borders of Transylvania; 65 miles S. of Neucecz.

BOGDEN, Martin, in Biography, a favourd pupil of T. Bartholine, and fiercest enemies of his name and opinions, was born at Drudan, about the year 1632. After visiting France, England, and other parts of Europe, to improve
prove himself in knowledge, he took the degree of Doctor in Medicine, at Balde in Switzerland, in 1652, and at the end of four or five years, passed principally with Bartholini, to whom he was strongly attached, he lectured at Bern. His works are principally controversial, defending the priority of the discovery of the lymphatics by Bartholini, against Rudbeck the Swede, who claimed it; and who, if he did not discover them, Hailer says, has the merit of having more fully and accurately defended them, than Bartholini had done. Bogdan, in this contest, displayed much learning, but equal roughness and ill-humour. The titles of his works are: "Rudbeckii insignis flaccus valetudinaries Thomas Bartholini," 4to, and "Apologia pro valetudinaries Bartholini, adversus insignis fercundo flaccus ab Oloa Rudbeck." Hafniae, 1654, 12mo. "Simeonis Seth, de alimentorum facultatibus," Gr. & Lat. 8vo. 1658. "Observationes Medicæ ad Thoman Bartham." The observations, 12 in number, are published in the "Culter Anatomicus," of Lyter; Copenh. 1665. Halter Bib. Anat. Eloy Diet. Hift.

BOGDIKOTZ, in Geography, a town of Russian Siberia, on the Tchulim; 6 miles N. W. of Archinsk.

BOGDINSK0I, or BOGDAH DABASSY, an inexhaustible salt-lake of Siberia, in the steppe towards Tsaritzin; the salt of which, according to Pallas, is better than that of the Elton.

BOGDO, GREAT, the highest mountain of central Asia, according to the reports of the Monguls and Tartars, is properly a central confluence of the Altai chain of mountains, which gives source to the Upper Iryth, and seems to be delineated in Arrowsmith's map of Asia at longitude 94°, and latitude 47°. See Altaï and Belur.

Bogno, Little, is a mountain of Altic Russia, lying to the north of the Caspian Sea, near which is a salt-lake of the same name.

BOGDOMANTIS, in Ancient Geography, a country of Asia Minor. Ptolomy.

BOGDOY, in Geography, a name given by the Russians to the Minchews, or Mandhurs, who inhabit the eastern part of Chines Tartary, an extensive and populous district N. E. of China, and who are subject to the Chinece empire. See Mandhurs and Chinese Tartary.

BOGENSEE, a town of Denmark, in the island of Funen; 12 miles N. W. of Odense.

BOGESUND, a small town of Sweden, in the island of Gothland, 4 leagues S. of Falkoping.

BOGILCUND, a district or circle of Allahabad, in Hindoostan, situate west of Benares.

BOGHASS, a canal or ditch, so called in the language of the country, at the mouth of the western or Balitic branch of the Nile, now called the branch of Rosetta. This passage is not navigable through its whole width; there being only a narrow channel, which, owing to the infallility of the bottom, and the agitation of the sea, is continually shifting. A pilot or master of the Boghass is continually employed in founding this changeable passage, and giving directions to those who navigate it. The increasing danger of this passage led to the operation of cleaning the canal of Alexandria, and thus to facilitate the communication between Alexandria and the Red of Egypt. See Bogas.

BOGIA. See Bouviers.

BOGILLANA. See Baglana.

BOGLIASCQ, a town of Italy, in the state of Genoa, near the sea coast; 6 miles E. of Genoa.

BOGLIO, or BEUL, a mountainous territory of Italy, in the principality of Piedmont, and county of Nice, seated near the Alps; its chief place has also the same name. This country was surrendered to France in May 1756.

BOGLIPOUR, a town of Hindoostan, and capital of a province, in the country of Balur, near the Ganges; 35 miles S. E. of Monghir, and 15 N. W. of Moorheadabad.

BOGLORAY, a town of Poland, in the province of Sandomirz; 24 miles E. S. E. of Sandomirz.

BOGMUTY, a river of Hindoostan, which runs into the Ganges near Monghir, in the country of Balur.

BOGNOR, or HOTHAMPTON, (as it is sometimes called in honour of its founder,) is a pleasant retired hamlet, on the southern coast of England, in the county of Suffolk. This place has only risen into notice within a few years, being, previous to 1796, merely inhabited by a few fishermen. About this period sir Richard Hotham purchased some ground here, where he built a house for himself, and had others erected for the accommodation of bathers. His plan of making this a fashionable bathing place has succeeded, but it was not much frequented till after his death, which happened in 1759. Soon after this event, the ground and houses were sold in different lots. Some of the purchasers have built additional dwellings, and Bognor is now become a place of great resort during the summer months. The adjacent villages of Berfield, Felpham, &c. also receive a number of summer visitors, who resort to this coast for the purpose of its fine beach and mild air. Bognor is 7 miles S. of Chichester, and 67 S. W. from London. It has a good hotel, an assembly-room, a library, and some other establishments for the accommodation and amusement of its visitors.

BOGODUKHOF, a town and district of Russia, in the government of Kharkof, seated on the Merlo, falling into the Vorskla; 84 miles N. W. of Kharkof.

BOGEOE. See Bog.

BOGOGNANO, a town of the island of Corfica, 5 leagues N. E. of Ajaccio.

BOGOLAVLENSKIO, a town of Russia, in the government of Ufa, 48 miles S. of Ufa.

BOGOLAVLENSKOI, or BOGOLAVLINSKOE, a town of Russia, in the government of Archangel, near the coast of the White Sea; 52 miles S. W. of Archangel. —Alfo, a town of Russia, in the same government, near the river Onega, 100 miles S. of Archangel. —Alfo, a town in the same government, on the Pinega; 70 miles E. of Archangel. —Alfo, a town of Russia, in the province of Uiting; 51 miles E. N. E. of Uiting. —Alfo, a town of Siberia, on the Tchulim; 80 miles E. N. E. of Tomsk.

BOGOMIL, or BOGARMITE, in Bogomilic History, a sect spring from the Manichees, or rather from the Manfullians, towards the close of the eleventh century; whose chief, Basil, was burnt alive by order of the emperor Alexius Comnenus. Being condemned to be burnt, he declared that the fire would not hurt him; upon which the Greeks who carried him to execution, first took off his cloak, and flung it into the fire, to try whether it would prove incommbustible; whilst it was burning, the poor fanatic cried out, "Do you not see that my cloak is untouched, and carried away in the air?" upon which they called him also into the fire, where he was soon consumed to ashes. Du Cange derives the name from two words in the Bulgarick language; Bog, Dua, and milo, misera, harse mercy. The Bogomil deified the Trinity; maintaining that God had a human form; that the world and all animal bodies were created by evil angels; and hence they concluded, that the body was the prison of the immortal spirit, and that it ought to be enervated by fasting, contemplation, and other exercises, so that the soul might be gradually restored to its primitive liberty; and that wedlock was
was to be avoided; and they also maintained that it was the archangel Michael that became incarnate. They rejected the books of Moses, and only admitted seven books of scripture; they maintained the Lord's prayer to be the only eucharist; that the baptism of the Catholics was only that of St. John, and their's that of John Chriult; and that all those of their sect conceived the Word, or Logos, as much as the Virgin, denying the reality of Christ's body, which they considered only as a phantom. They also held, that the body, upon its separation by death, returned to the malign- ant maids of matter, without either the prospect or the possibility of a future resurrection to life and felicity. Modif. Eccl. Hist. vol. iii. p. 140. Jortin's Rom. on Eccl. Hist. vol. v. p. 16.

BOGORDSKOI, in Geography, a town of Russia, in the government of Archangel; 8 miles S. W. of Mezen.

BOGORDITZK, a town of Russia, in the government of Archangel, on the Dwina; 44 miles S. S. E. of Archangel.

BOGORDSK, a town and district of Russia, in the government of Mocow, on the Khsina; 28 miles E. of Moscow.

BOGORDSKOI, a town of Russian Siberia, in the province of Tomisk, seated on the Obi. The church belonging to this town is famous for a celebrated picture of the Virgin Mary, called "Odivititia," which was brought every year, on the 21st of May, in procession to Tomisk. There are iron works in this place.

BOGOROSTAN, a town and district of Russia, in the province of Ufa, seated on a river falling into the Samara.

BOGOTA, a town and province of New Granada, in Spanish South America, seated near the river Magdalena. The town is called Santa Fe de Bogota, and is the capital of the kingdom of New Granada; it is situate on the banks of the small river Patti, which runs into the Magdalena. It was made an archbishop's see by pope Julius III. in 1550, and an university was erected here in 1610. It has a sovereign court of judicature, the president of which is governor of the whole province or kingdom of New Granada. Near it are some gold mines, and the chief modern mines of Peruvian emeralds, justly preferred to all others, since those of Egypt have been neglected. Among the numerous cataracts of this country Bouguer mentions that of the river Bogota, which passes the city of the same name, about 8 leagues before it joins the Magdalena, said to be a vertical fall of more than 1200 feet. N. lat. 4° 22'. W. long. 75° 43'. When the Spaniards took possession of this part of South America, they found in Bogota a nation more considerable in number, and more improved in the various acts of life, than any in America, except the Mexicans and Peruvians. The people of Bogota subsisted chiefly by agriculture. The idea of property was introduced among them, and its rights secured by laws, handed down by tradition, and obferved with great care. They lived in large towns; they were decently clothed, and their houses, compared with those of surrounding tribes, might be termed commodious. Government had assumed, in this state of civilization, a regular form, and a jurisdiction was established, which took notice of different crimes, and punished them with rigor. They were acquainted with the distinction of ranks, and their chief reign'd with absolute authority. He was attended by various officers and guards, carried on with much pomp in a fort of palanquin, and the road was swept before him and fleeced with flowers. For the support of this expense taxes were levied on the people, who regarded their prince with veneration, and seldom approached him but with an averted countenance. One of the chief causes of that obfuscious spirit, which prevailed among the people of Bogota, was the influence of superstition. The respect they paid to their monarchs was inspired by religion; and the heir apparent of the kingdom was educated in the innermost recess of their principal temple, under such austere discipline, and with such peculiar rites, as tended to fill his subjects with high sentiments concerning the dignity of his character, and the dignity of his station. This superstition, which, in the rudest period of society, is either altogether unknown, or wafes its force in childish unmeaning practices, had acquired such an ascendant over those people of America, who had made some little progress towards refinement, that it became the chief instrument of bending their minds to an untimely servitude, and subjected them, in the beginning of their political career, to a delusion hardly less rigorous than that which awaits nations in the last stage of their corruption and decline.

The people of Bogota (as well as the tribe of the Natchez) had advanced beyond the other uncultivated nations of America, in their ideas of religion, as well as in their political institutions. The fun and moon were the chief objects of their veneration. They had temples, altars, priestes, sacrifices, and that long train of ceremonies, which superstition introduces wherever the has fully established her dominion over the minds of men. But the rights of their worship were cruel and bloody; they offered human victims to their deities, and many of their practices resembled the barbarous institutions of the Mexicans. Robertson's Hist. Am. vol. ii.

BOGRA, an uncultivated mountainous tract on the north of the barony of Muthery, in the county of Cork and province of Munster, Ireland. It is upwards of ten miles long, and in some parts six miles in breadth; and is a common to the adjacent estates. In winter it is for the most part deep, marshy, and impassable; but in summer hard and firm, producing grass and heath, and is then grazed by vast herds of cattle, which are removed to the lower lands when this season is over. Large quantities of turf are also procured from it. Dr. Smith has applied to it these lines of Thomson:

"The brown burnt earth
Of fruits and flowers, and every verdureโท
Darren and bare, a joyless dreary waste
Thin cottaged; and in time of trying need
Abandoned."

Many considerable streams flow from this high and wild tract, which discharge themselves into the Lee or Blackwater, as their direction is south or north. Smith's Cork.

BOGRUSH, in Ornithology. The Anthus Selanninus. Linna. and Red Worbler of Latamn, is described under the name in the Arctic Zoology.

BOGUE, in Ichthyology, the French name of a fish of the genus Sparus. Sparus, of Linnaeus.

BOGUE, Bely, in Phyology, the white god to whom the Slavonians paid their adorations. His flate, imsered with blood, was covered with flees. His rites consisted in diversions, games, and feasts. He was a beneficent deity, corresponding to the good principle, the "Ormazes," of the Persians. The black god, "Toberry Bogue," corresponded on the contrary to the evil principle, the malignant being Arimas. He was worshipped by bloody sacrifices, and the prayers of his votaries were addressed to him in a mournful and plaintive voice.

BOGUSLAW, in Geography, a town of Poland, in the palatinate of Kieio; 32 miles S. E. of Bialacziowski. N. lat. 49° 30'. E. long. 41° 12'.

BOGUTCHAR, a town and district of Russia, in the govern-
government of Volozetz, on a rivulet of the same name, falling into the Don.

BOGWANGO D., a town of Hindustan, near the Ganges; 11 miles N. of Moorheadabad.

BOHABOL, in Ancient Geography, a town of Asia in Syria.

BOHADCHIA, in Botany. See Peltaria.

BOILLIN, in Geography, a town of France, in the department of the Aisne, and chief place of a canton, in the district of St. Quentin; 10 miles N. N.W. of St. Quentin. The place contains 2132, and the canton 13184 inhabitants. The territory comprehends 1724 kilometers, and 14 communes.

BOHAR, in Indo-Bengal, a species of Sclere, described by Forcall, as a native of Arabia. The colour is red, linedal, and clouded with white. Turke. Fn. Arab.

This bears a strong affinity to another fish described by the same author, as an inhabitant of the same country, Kufina. Gmelin expresses a doubt whether it does belong to the Sclera genus. The body is of an oblong form, and covered with smooth scales. When alive there are two large spots on the back, which disappear after the fish is dead. There are two short cirri, or beards before the nostrils: in the upper jaw two tuberculate teeth, which project beyond the lower, the two middlemost of which are placed remote. The lateral line runs nearer to the back. Doral and anal fins rounded behind, and the marked part of both scaled, the finca of the latter growing gradually larger; ventral connected by an intermediate membrane. Tail bifid. Gmelin.

BOHAROWCZE, in Geography, a town of Poland, in the palatinate of Kamieniec; 60 miles N.W. of Kamieniec.

BOHANICE, a town of Bohemia, in the circle of Chrudim, which has the privilege of holding fairs.

BOHEA, in Botany. See Thea.

BOLEMIA, in Geography, called in German Böhm, Böheim, Bohim, and corruptly Boumen, that is, the habitation of the Boi (see Boi); a kingdom of Europe, in the Austrian dominions; bounded on the north by Mähia, Lusatia, and Silsea; on the west, by the circle of Erzgebirg, the Vogthland, the margravates of Cumbach, and the Upper Palatinate; or, in general, by Fraincia; on the south, by Bavaria and Austria; and on the east, by Moravia, Silsea, and the county of Glaz. Bohemia is environed on all sides by high mountains and large forests; towards the south it is separated from Austria by a ridge of considerable elevation, which poises to the north-east of Bavaria; and on the north-west, it is parted from Saxony by a chain of metallic mountains, called the Erzgebirg, a word denoting hills that contain mines. On the west of the river Elbe, near its junction with the Elbe, stands the mountainous group of Mlad, near which is Dommberg, supposed to be the highest in the province; and on the north-east is the Sudetic chain, which branches from the Carpathian, and divides Bohemia and Moravia from Silsea and the Prussian dominions. This country was formerly remarkable for an extensive forest, a remain of the ancient Hereyua Sylva, which extended from the Rhine to Sarmatia, and from Cologne to Poland. The Gabreta Sylva lay on the south-west of the same country, where a chain of hills now divides it from Bavaria.

Bohemia, as we have already observed, derived its name from the Boi, who, under their leader Segovesia, settled in that country about 500 years before the Christian era. The Boi were driven after expelled by the Marcomanni; and thefe, being weakened by their wars with the Romans under the conduct of Tibiris, were Lubbed by the Sciavi (see Sclavi-

VORIIANS), who, like the other Scythians, wandered from place to place with their families and cattle; and, as Strabo informs us, even in the time of Augustus Caesar, lived promiscuously with the Thracians. Afterwards, spreading themselves westward, in a few centuries they polishing Illyrians, Poland, Moravia, and Bohemia. But retaining their ancient manners, they neglected to build cities, and, inhabiting the country in detached hordes, they regarded only the pasture and the care of their flocks. The first ruler, or chief, mentioned by historians, was one Czechus, from whom the natives derived the appellation of Czechs, or Chech, who, quitting Croatia, migrated first to Moravia, and from thence to Bohemia, about the middle of the fifth century, which he founded covered with wood, and poissed rather by herds of wild cattle than by men. Here he settled his small colony, and taught the few inhabitants of the country to cultivate the lands, and to sow corn. After his death, the Bohemians remained for several years without a ruler or judge; but being now assembled in villages, they were anxious to obtain a more settled form of government than that which they had found effectual during their pastoral life. With this view they chose for their governor a young man, whose name was Croc, distinguished by his prudence, who restored peace and order, and maintained the authority of the laws. He was succeeded by the younger of his three daughters, Lybba, who was respected for her skill in the art of divination; and who, about the close of the seventh century, married a country labourer of the name of Premilfaus, who, being called from the plough to the dignity of governor, carried his cloak and shoes along with him, as memorials for his poverty, to prevent their being elated with the prosperity of their condition. This Premilfaus is said to have founded the city of Prague, to have distributed the people into different ranks, and, after quelling some temporary insurrections, to have reigned peaceably till his death. He is said to have been the first duke, though others trace the origin of the ducy to an earlier period, and say that Czechus was the first who bore this title. The government afterwards to have continued hereditary in his family, though with some form of election; and a descendant, whose name was Boriviarus, or Borizivirs, embraced Christianity about the close of the ninth century, and, after some opposition, introduced it into his dominions. On this occasion several churches were built, and schools erected; but upon the death of his son Vratisslaus I., in the beginning of the tenth century, his wife Dramethuna, who assumed the government during the minority of her sons, manifested her hatred against the Christians, massacred about 300 of them in one night, burnt their temples, and ordered them to deliver up their arms. However, upon the accession of her son Wenceslaus II., A. D. 916., the Christian religion was again encouraged; and, in order to prevent disputes with his brother Boleslaus, who had been educated under his mother, he ceded to him that part of Bohemia, which lay beyond the Elbe. Wenceslaus, having obtained a victory in a duel, a challenge to which he accepted for the purpose of sparing the lives of his rebellious subjects, was invited by Otto the Great to the east at Worms, where he offered him the title of king, which Wenceslaus declined accepting. In the year 922, Wenceslaus was murdered by his brother Boleslaus I., who named the Cruel, who, succeeding him, conducted his administration with great cruelty, persecuting the Christians, and expelling them the kingdom. His son and successor, Boleslaus II., named the Hands, founded and endowed 20 churches, and obtained leave from pope John IX. to create a bishop at Prague. His subjects formed a conspiracy against him, on account of some reforms which he attempted to introduce;
introduces; and encamping on a mountain in the vicinity of Prague, they were expelled thence by the Christians, with the assistance of the Jews, and obliged to remain in peace. In consequence of this service, the Jews were allowed to build a synagogue at Prague. In the eleventh century, Bretislau, the son of Uladricus, having obtained the government of Moravia, kept possession of it by repulsing the Poles who invaded it; and, succeeding to the government of Bohemia, on the death of his father, A.D. 1023, he again defended it against Hungarian robbers, by whom it was ravaged; and having concluded a perpetual peace with Casimir, king of Poland, he died, leaving five sons, of whom the eldest inherited Bohemia; and Moravia was divided among the four youngest. Wenzelius II. succeeded his brother, A.D. 1061; and, in 1086, was honoured with the regal tite by the emperor Henry IV., who also invested him with the domains of Lusatia, Moravia, and Silesia. This dignity, however, was merely personal; and the constant title of king only commences with Premislau II. in 1199. He, and his immediate successors, were styled Otto- cavi, or Othogari, on account of their attachment to the interest of the emperor Othon. Upon the death of Wenzel- laus IV. A.D. 1157, his son Premislau Othogari succeeded him; and having settled his affairs in Bohemia, took possession of Austria, Stria, part of Carinthia, and other provinces to the south, and carried his arms into Prussia for the defence of the Christians; and having defeated his opponents in several engagements, he prevailed on many of the people to abandon Paganism. After his return to Bohemia, in 1171, he is said disdainfully to have rejected the imperial crown, which was afterwards given to Rodolphus, count of Hapsburg; but Othogar refusing to do him homage, and to take from him the investiture of his fiefs, alleging that he owed him nothing, and that he had paid him his wages, Rodolph having been great marshal of his court, was at length obliged to comply, and to deliver five standards to the emperor for the five fiefs which he possessed. A reconciliation, however, afterwards took place, and Othogar received the investiture of Bohemia and Moravia, on condition of renouncing Austria, Carinthia, and Stria. Wenzelus V. succeeded his father in 1178, and was elected king of Poland; but refused the sceptre of Hungary, that was offered him, in favour of his son. In 1190, the ancient league failed; and John, the son of the emperor Henry VII. of the family of Luxem- bourg, who had married the youngest sister of Wenzelus VI., obtained possession of the kingdom of Bohemia. John, having resigned Bohemia to his son Charles, and procured for him the imperial dignity, proceeded with him to France, to the assistance of Philip against the English, and was slain in the famous battle of Crécy, in 1346. Charles IV. emperor, having succeeded his father, created his brother John marquis of Moravia, erected an university at Prague upon the plan of that at Paris; and engaged pope Clemens VI. to erect the see of Prague into an archbishoprie, with this privilege annexed to it, that the archbishop should have the honour of crowning the king of Bohemia. He enlarged and beautified his capital, by adding what is called the New City, in which he founded the college of Carlziue. With the assistance of several learned persons, he reduced the laws of the kingdom to writing, which are still extant, under the name of "Caroline Constitutions." He greatly extended the boundaries of his hereditary dominions, and cau fet his son Wenzelus to be crowned king, in the second year of his age. He also prevailed with the electors to choose him king of the Romans, in the sixteenth year of his age; and having commenced the junction of the Moldau with the Danube, he died before he had executed his design; and in 1378, was succeeded by his son Wenzelus VII. In the reign of this prince, who was notoriously diffusive, profuse, and sanguine, and who, by his licentiousness and cruelty, incurred the hatred of his subjects, John Huss and Jerome of Prague introduced the doctrines of the reformation into Bohemia. See HUSS, and JEROME. Wenzelus died suddenly in 1419; and before his brother Sigismund, who succeeded him as king of Bohemia and emperor of Germany, could come from Hungary to take possession of the crown, the Hufites, under John Zilca, had acquired great strength, and, up to his approach to the kingdom, they sent deputies to him, degrading liberty of conscience; but, instead of granting their requests, he only declared, that he intended to govern the kingdom as his father had done. A civil war ensued, in which the troops of Sigismund sustained several defeats; and which, after a continuance of sixteen years, occasioned by his breach of faith to Huss and Jerome, terminated in several concessions, and in his admission into Prague with great solemnity and rejoicing. Upon the death of Sigismund, in 1438, Albert of Austria, who had married his daughter, received the crowns of Bohemia and Hungary. The succession was, however, afterwards disputed and infringed by George Podiebrad, a Hufite chief; by Uladlins, son of Casimir, king of Poland; and by Matthias, king of Hungary. Uladlins ultimately succeeded, being elected, in 1471, by the majority of the estates, and soon after receiving the investiture from the emperor. Upon the death of Uladlins, in the 45th year of his reign over the Boemians, and the 23d over the Hungarians, he was succeeded by his son Lewis in both the kingdoms of Bohemia and Hungary, A.D. 1516; but, in 1526, he engaged the Turks at Mohacs, and being utterly defeated, was drowned in the Danube, in his flight. After the death of Lewis, his dominions fell to Ferdinand, archduke of Austria, infant of Spain, and afterwards em- ployed, who had married Anne, the only daughter of Uladlins: and both the empire, and the kingdom of Bohemia, have ever since continued in the house of Austria. Ferdin- and, at a diet of the states held in 1547, declared the king- dom hereditary and absolute; and when Ferdinand II., in 1610, had routed the army of his rival Frederick at the White Mountain near Prague, Bohemia was reduced fully to the condition of an hereditary kingdom; so that from that time the estates had no concern with the right of suc- ceSSION. The crown, however, is conferred with some appearance of election, which right the estates of that kingdom pretend to claim; although, by the treaty of Wolfenbittel, Bohemia is declared hereditary in the house of Austria. The king of Bohemia is the first secular elector, and as such pays homage to the emperor and the empire for his fiefs; and with this exception, he has a right to exercise, through all his dominions, the royal authority agreeably to the laws of the kingdom, which prohibit his raising contributions or taxes otherwise than at the time when the fiefs are as- sembled, the appointment of which is entirely in their own power. He gives his opinion, as elector, after the elector of Cologne, and formerly affiliated at the assembly of the electors only at the election of an emperor, nor did he appear always at the diets of the empire. He is arch-butler, or arch-cup-bearer, of the holy Roman empire; and on this office his right to choose a king of the Romans is said to de- pend. It has been alleged, that Bohemia has been of old time a genuine fief of the Holy Roman Empire, without contributing to its taxes, which was a privilege conferred upon him by Frederick II. in 1212, who at the same time exempted it from the jurisdic- tion of the supreme judicatory of the empire. In 1788, it was acknowledged by the three colleges of the empire, at an act of the diet called "the admission," that the king and elector of Bohemia has an undoubted right of seat and voice in all its assemblies; in consequence of which the emperor pro-
mized, that, on account of his hereditary kingdom of Bohemia, and of the countries belonging to it, he will pay an electoral proportion of all taxes and imposts of the empire and circle, and also 300 florins yearly to the chamber-judicatory; the collective body of the empire engaging at the same time to take the kingdom of Bohemia, and the countries united with it, under protection and defence.

Bohemia, ever since the time of Charles IV., has been divided into twelve circles, besides Prague, which is considered as a distinct territory. These are Kauzimer (comprehending Great Prague), Pilzner, Leutmeritz, Konigingratzer, Rikonowitz (including Beraun), Chrudimer, Pachiner, Slaner (comprehending Little Prague), Bunzlauer, Szatzer, Czflauer, and Becliner. Each circle has two head-men, or captains, appointed annually, for the administration of the government, one from the state of lords, and the other from that of knights. The duchy of Silesia, the marquisate of Moravia, and that of Luftata, formerly held of this crown, but at present only Moravia, which is incorporated with the kingdom of Bohemia, and is in possession of the house of Austria. In 1742, the county of Glatz was ceded to the king of Prussia, and by him added to Silesia. The government of Bohemia is managed by six different courts; viz. the council of the regency, or great royal council, in which resides the great judge or burgomaster of Bohemia, who has under him 18 lieutenants of the king, and other stewards of the council, or superior chamber of justice, at which the great matter of the kingdom is decided; the chamber of lieutenants; the new tribunal, to judge the appeals of the German vassals, with its president, vice-president, and stewards; the royal chamber of finances, with its president and vice-president; and the chancellery, which always follows the court. The states, confiding of the clergy, nobility, and gentry, and representatives of the towns, met at Prague, where a commissioner from the sovereign points out the necessity of granting such supplies as the court demands, which, however exorbitant, are granted without hesitation or examination, though not sometimes without subsequent complaint. The clergy are composed of the archbishop of Prague, several bishops, provosts, and abbots, besides the inferior clergy. The nobility consist of princes, counts, barons, and knights; the others are burgheers, husbandmen, and peasants.

The established religion of Bohemia is popery; but there are many protestants among the inhabitants, who are now tolerated by the wise regulations of Joseph II., in the free exercise of their religion. The Jews at Prague are indulged also with toleration. The archbishop of this city is born legate of the holy apostolic see of Rome, and crown the king of Bohemia; he is also a prince of the holy Roman empire, prince of the kingdom, and perpetual chancellor of the university of Prague. The suffragans are the bishops of Leutmeritz and Konigingratzer. The government of the church and clergy is vested in the archiepiscopal confillery, from which an appeal lies to the king or the pope.

The extent of Bohemia, and also its population, have been variously estimated. Its length is about 162 miles, and its breath 125. Some centuries ago, the inhabitants were estimated at three millions; but in later times they have been very much diminished. It is said, that in the year 1622, and the three or four following years, no fewer than 35,000 families, and many other individuals quitte the country, among whom were many of the nobility, on account of the intestine religious wars, and the succeeding irruptions of the Swedes. In M. Hoeck's "Statistical View of the States of Germany," &c., 1801, the kingdom of Bohemia is stated to contain 962½ square miles, 250 cities, 308 market towns, 11,455 villages, 430,000 houses, 1,340,510 men, 1,356,433 women, and the total of the population 2,856,943. The number of Lutherans has been estimated at 299,500, of the reformed at 25,110, and of Jews at 36,000. Some writers have stated the number of Protestants at 35,000, and that of the Jews at 30,000, of whom 8,000 are settled at Prague. In their dispositions, habits, and manners, the Bohemians resemble the Germans; being indeed a mixture of Slavonians and Germans, the former of whom live in villages and are slaves. They have no middle rank of people; for every lord is a petty sovereign, and every tenant a slave. The Bohemian peasants, on the imperial demesies, have been lately relieved from the flate of villânage, in which they had been so long and so unjustly retained; and it is hoped, that the example of the emperor will be followed by that of the Bohemian nobility in general, so that their vassals may recover those rights of which they have been long deprived. The natives of this country are singularly robust and strong-built, hand- some, except that their heads are somewhat too large, and active, fiery, courageous, and sincere. The gentry are ingenious, brave, and more inclined to arms than arts. Learning in Bohemia is in a low state; though the kingdom possesses one university, 12 gymnasii, 2,219 German schools, 200 schools of industry, and 33 ladies' schools.

The Bohemian language is a dialect of the Slavonic, but somewhat harsher than that of their neighbours, who speak the same language, and who change the consonants, and particularly the e, into vowels. The Bohemians formerly used the same letters with the Ruffians; but in the time of Bohemus the Pious, the Latin was introduced among them. Upon the first introduction of Christianity in this reign, the religious service was performed in the Latin tongue, a language unknown to the people; but in consequence of the representation of Methodius to pope Nicholas the Great, he also vesp'd the prayers to be rehearsed in the vulgar tongue. But some years after, when a bishop was sent into Bohemia, the Latin tongue was again ordered to be introduced in all their churches. Perform of a superior class, from their intercourse with the court of Vienna, speak high Dutch or German, with which the language of the common people is also intermixed.

Bohemia is, upon the whole, one of the highest countries in Europe, and forms a large extended plain, surrounded, as we have observed, by high hills covered with wood. The vale in the middle, which is watered by the Elbe, the Moldau, and the Egra, is protected from the wind, and it has neither lakes nor morasses which taint the air, which is dry and clear, with unwobbleome vapours. The climate is therefore favorable, and not liable to those sudden changes, which are so fatal to health in other places. The heat of summer, and the cold of winter, are alike moderate. The soil is in general rich, though in some places it is sandy. It is fertile in corn, wine, fruits, paille, flax, ginger, hops, wool, flax, and timber. The Bohemian hops, which are medly used, are carried as far as the Rhine in great quantities. Bohemia produces a strong large breed of horses, many of which are purchased for the sale of the French cavalry. Its mountains are the richest in Europe, in gold, silver, precious flores, copper, quicksilver, iron, lead, tin, sulphur, and sulphate. The Bohemian tin is reckoned the best of any except the English. All kinds of marble are also found in this country, together with pit-coal, alum, mucovy-glass, excellent mineral waters, and hot baths. It also furnishes numerous herds of cattle, and abundance of game and wild fowl, and also bears, lynxes, wolves, foxes, badgers, martens, beavers, and otters. Its rivers and ponds afford a plentiful supply of fish, and such as are of the best quality and flavour.
BOH

According to the statement of M. Hoenck (ubi supra), Bohemia had, in 1787,

Total 7,785,655 8738

The territorial produce of grain, forage, vines, woods, and rivers, amounted, in 1789, to 30,057,039 florins. Of cattle there were, in 1771, 9739 oxen, 2,333 bulls, 9688 cows, 2723 calves, 8153 sheep, 16,778 hogs, 584 he-goats, 1785 fly-goats, and 553 ales. The produce of grain amounted to two millions of minots (a minot being equal to three bushels) of wheat, ten millions of minots of grain, four millions of minots of barley, and eight millions of minots of oats. In the lift of natural productions are also to be reckoned fruit-trees, hops, principally in the circle of Saaz, flax, tobacco, farron, poultry, bees (of which, in 1791, there were 20,257 hives), tin (chiefly at Schlackenwalde, and there are ten mines of tin in the circle of Saaz, and in two of that of Luttenzitz), coal, 10,000 quintals in the circle of Saaz, silver, alum, at Commothan, in 1788, 1539 quintals. This author also states, that Bohemia had, in 1782, 95 manufactories, which employed 395,615 workmen. These manufactures are of linen, wool, cotton, flax, paper, glass, leather, &c. amounting in the whole to 35,645,477 florins, of which strangers take to the value of 11,940,737 florins. The articles of export, according to his enumeration, are alum, Epsom-salt, butter and grefae, flax, flax, poultry, grain, mineral waters, lace-skins, wood, hops, cobalt, hides and skins, fruit, hores, pork, brimstone, vitriol, game, flax, tin, dimity, articles in iron, articles in glass, carvets, hats, linens, bras, paper, pet-as, aqua fortis, lace, cloth, and thread. The articles of import are cotton, lead, white lead, books, iron, and iron articles, colours, flax, jewellery, spicery, horned cattle from Hungary, coffee, cotton, flax, galls, mercurides of Lyons, liqueurs, flax, Hungarian cattle to the value of 80,000 florins, and wine to the value of 500,000 florins. The balance of trade is said to be in favour of the country. M. Hoenck also informs us, that the revenues of the state are fifteen or sixteen millions; but that the expenses are enormous, that out of this sum the surplus amounts to 6,60,000 florins; that the contribution in 1789 was 3,64,607 florins, and the tax on the Jews 216,006 florins; and that the annual revenue from the domains of the crown was, during the life of Maria Terefa, 333,720 florins; these domains are now estimated at 177,774 acres. The number of soldiers to be furnished by Bohemia, in time of peace, is 51,664; and, in time of war, 76,596. The capital city of Bohemia is Prague; which see.

Bohemia, a broad navigable river of North America, 10 miles long, which runs W.N.W. into Elk river, in Maryland, 11 miles below Elkon. Bohemian, or Moravian, Brethren, in Ecclesiastical History, is an appellation given to the Protestantists in Bohemia. By their adherents they were called Picards, i.e. Bohards. They were defended from the better fort of Husflite, and were distinguished by several religious institutions of a singular nature, and well adapted to guard their community against the reigning vices and corruptions of the times; and as soon as they heard of Luther's design of reforming the church, they sent deputies, in the year 1522, to recommend themselves to his friendship and good offices. In succeeding times, they continued to manifest the same zealous attachment to the Lutheran churches in Saxony, and also to those that were founded in other countries. Upon this their religious principles were examined, and nothing was found, either by Luther or his disciples, in their doctrine or discipline, that was liable to confute. Their confession of faith, though not altogether approved by this reformer, was regarded as an object of toleration and indulgence. Nevertheless, the death of Luther, and the expulsion of the brethren from their country, in 1547, changed their religious connections; and many of them, more especially those who retired into Poland, embraced the religious sentiments and discipline of the reformed. Their attachment to the Lutherans seemed, however, to be revived by the convention of Sendomir in 1790; but as the articles of union, that were drawn up in that assembly, soon lost their authority, the Bohemians by degrees entered universally into the communion of the Swifs church. This union was at first formed on the express condition, that the two churches should continue to be governed by their respective laws and institutions, and should have separate places of public worship; but, in the following century, all remains of diffusion were removed in the synods held at Altrog, in 1620 and 1627, and the two congregations were formed into one, under the title of 'The Church of the United Brethren.' In this coalition the reconciled parties flaved to each other reciprocal marks of toleration and indulgence: for the external form of the church was modelled after the discipline of the Bohemian Brethren, and the articles of faith were taken from the creed of the Calvinists. See Unitas Fratrum.

Laflitis has a treatise De Gratia Fratrum Bohemicorum. Camerarius has also given the history of the Bohemian brethren, from whom ecclesiastical historians have derived a large train of facts, as the Husflites, Adamants, Taborites, Calnitans, &c., which see respectively.

Bohemian chaffater, in Ornithology, a bird of the Puffenn order, common in many parts of Europe, in Northern Asia, and America. It sometimes visits the feathered parts of Britain in the winter. The common English name of Bohemian chaffater was imposed upon this bird by old writers, under the idea that it was peculiar to Bohemia. Later authors call it the Water chaffater, from the hony appendages at the extremity of the secondary quill-feathers, which are of a scarlet colour, and in appearance bear some resemblance to sealing-wax. This is called Ampelis garulus by Linnaeus. Donov. Brit. Birds, &c.

Bohemicus, the name of a species of Falco that inhabits the mountains of Bohemia. The legs of this kind are yellowish; body above cinereous, beneath hoary white; five exterior quill-feathers black on the outside; orbits of the eyes white. Gmel. Falco Bohemicus. Mantuje-halibich, misfauze, Mayer.

This bird is scarcely a foot in length; bill near the angles of the mouth yellowish; irides yellow; tail acute and long; legs thickish, and feathered below the knees; claws black and roundish. Feeds on mice.

Bohkat, in Ethnology, is the Arabic name of a sort of Ray that inhabits the Red sea, and is described by Forskal under the appellation of Raja dissembler.

Bohme, in Geography, a river of Germany, which runs into the Aller, 4 miles S. E. of Bethem, in the principality of Luneburg-zell.
BOHMISCHKRUTT, a town of Germany, in the archduchy of Austria, 5 miles S.S.W. of Feldsburg.

BOHN, John, in Biography, was born at Leipzic the 20th of July 1649, where he received the remains of his education. At a proper age his father sent him to Jena, to be initiated into the study of medicine. In 1659, he returned to Leipzic, continuing his studies there, until 1663, when deeming it advisable to participate in the knowledge of the improvements making in his profession, in different parts of Europe, he went to Copenhagen, Holland, England, France, and Switzerland, every where attending the lectures of the most celebrated matters, but particularly attaching himself to Malpighi. Returning, at the end of two years, to Leipzic, he took his degree of doctor in medicine, and was in succession advanced to the rank of professor in anatomy, and in therapeutics. In 1661 he was appointed public physician to the city of Leipzic, and, in 1700, dean of the faculty of medicine, which offices he continued to hold with credit to the time of his death, in 1718.

Besides numerous dissertations on the different branches of medicine, which had great merit, he published, in 1668, "Exercitationes phylologicae xxvi." 40. This work was afterwards considerably enlarged, and republished in 1682, under the title of "Circulus anatomico-philologicus, sive economia corporis animalis," 40. In this he examines, with accuracy and judgment, the different hypotheses then prevailing in medicine. He here first shewed the difference between the cyphic and the hepatic bile. Finding the liquor arsini coagulable, he supposed it contributed to the nourishment of the focus; which, however, later experience contradicts, as features born without heads, or where the passage through the oesophagus into the stomach has been closed, are found to attain, in utero, equal bulk and firmness, as those that are perfect. He supposed the heart to be excited to contraction by the stimulus of the blood; and shews the offa pubis are not separated in parturition, to allow a free passage to the focus; which was in his time the prevailing doctrine. In this "De variolis, haematus in patria graffatis," published in 1679, he advises giving purgatives with calomel, on the first attack of the complaint, with the view of rendering the disease more mild; a practice of which later experience has proved the utility. In his "De Renunciatione vulnerum," 1689, 490. Amsterdam, he shews what wounds are necfarily fatal. His treatise "De Officio medici dupliciti, clinico, et forensi," 490. 1704, gives rules for the conduct of physicians, in attending their patients, and in giving evidence before a court of judicature. This is a work of great merit, and has scarcely been exceeded by any later production on the subject. These have all been frequently reprinted. Haller. Bib. Med. Eloy. Blumenbach.

BOHOL, in Geography, one of the Philippine islands between Mindanao and Mindoro, about 16 leagues long from north to south, and 8 or 10 broad. The south coast towards Mindanao is the most populous; that is, from Lobag, the metropolis, to the little island or peninsula of Panglao. The soil does not produce rice, but is laid to be rich in gold mines, and to yield, in great abundance, cocoas, batatas, and several sorts of roots which serve instead of rice. In the mountains there are multitudes of cattle, and fish in the sea, which the natives exchange with those of the neighbouring islands for cotton. N. lat. 10°. E. long. 122° 5'.

BOHONIZ, a town of Bohemia, in the circle of Bechin, 2 miles S.S.W. of Teia.

BOHRAN, a town of Silefia, in the principality of Breslaw, 16 miles south of Breslaw.

BOHRLITZ, a town of Moravia, in the circle of Brunn, 9 miles W.N.W. of Aupfitz.

BOHUS, or BAHUS, a fortified island of Sweden, in Gothland, encircled by two branches of the Gotha, about 9 miles north of Gothenborg. The fort is Scandia, a place of considerable strength, and forming the frontier fortresses during the confed war between the Danes and Swedens. It was erected in 1359 by Haquin IV. king of Norway, and, before the invention of gun-powder, it was a wooden fortress; but in 1448 was built with stone by Christian I. The situation is strong, and it is garrisoned by 150 men. The summit affords a pleasing view of the Gotha, winding at the feet of barren rocks. Bohus gives name to a jurisdiction of which it is the capital. It formerly belonged to Denmark, but by the treaty of Rosedahl, in 1658, it was ceded to Sweden.

BOHUSLAW, a town of Poland, in the patrimony of Kow, near the river Ros. N. lat. 49° 37'. E. long. 31° 11'.

BOJA, in Antiquity, a collar or chain fastened about the necks of criminals to prevent their escape. The word is also written boga, boda, and boga.

BOJAR, in Ancient Geography, an island in the Jefean sea, of Anton. itin.

BOJADOR, Cape, or BAJADORE (which means), in Geography, lies on the western coast of North Africa, placed in the Tables of the Commissioners of Longitude, in N. lat. 26° 12' 35", W. long. 14° 27'; and, in Rennell's map, in N. lat. 26° 26', W. long. 14° 17'.—W. long. 14° 49', by M. Hervier, and 14° 28' Conn.-de-Temps. This cape was doubled by Galiano and the Portuguese navigators, under the direction of prince Henry, and embellished by their voyages to Madeira, which required their quitting the coast and venturing into the open sea, in the year 1433. For 20 years before this time, this cape had been the boundary of their navigation, and it had been deemed impassable. But this successful voyage, placed by the ignorance of the age on a level with the most famous exploits recorded in history, opened a new sphere to navigation, as it discovered the vast continent of Africa, still washed by the Atlantic ocean, and stretching towards the south. Of such consequence was the doubling of this cape, that the Portuguese soon after advanced within the tropics, and in the space of a few years discovered the river Senegal, and the whole coast extending from cape Blanco to cape de Verde.

BOIANO, a town of Naples, in the county of Molife, the fee of a bishop, suffragan of Benevento, who resides at Campo Basso; 9 miles south of Molife. See BOVIANUM.

BOIARDO, Matteo-Maria, in Biography, count of Scandiano, a person eminent for literature, was born at Fratta near Ferrara, about the year 1359, and educated at the university of that city, where he principally resided. Being highly esteemed by the dukes Borso and Hercules I., he was appointed by the latter governor of Reggio in the Marches, where he died in 1404. He was well acquainted with the Greek and Latin languages; and translated into Italian, from the former, the history of Herodotus, and from the latter, the golden age of Apuleius, and the chronicle of Ricobaldo. His elegies in Latin verse are reckoned among the most elegant productions of that age. He also wrote in Italian verse a comedy, entitled "Timon," taken from a dialogue by Lucian, and other pieces. But his greatest fame was derived from his "Orlando Innamorato," which combines with the ancient epic the extravagance of modern romance. His style was rude, and his verification stiff and harsh; but the fervor of his fancy and the liveliness of his imagery rendered this work, which he left unfinished, captivating and popular. It was continued by Niccolo Agolino, and
and recomposed and polished, about half a century afterwards, by Lud. Domenico and Fr. Berni. The work of the latter is so well executed, that it has almost superceded the original. The best edition of Boiard's own performance is that of Venice in 1544. This work served as the model and groundwork of Ariosto's "Orlando Furioso;" which is properly a continuation of it, with new adventures. Boiard's fomets bear the character of a much purer style than his Orlando. Meroni.

BOIARI, in Geography, a town of Poland, in the pala-

tinate of Kiev, 29 miles S.S.E. of Bilacercikew.

BOICINGA, or, more properly, Boicingua, in Zoology, the Brazilian name of the most common kind of rattlesnake that is found in South America — Crotale Boicingua of Beale.

BOICUAIBA, a kind of Peruvian serpent, supposed to belong to the Boa genus. It is described as being twenty feet long black on the anterior part. The rest yellow.

BOIGA, the name of an American snake, called by Lin- mius Celubir abatelta.

BOIGUACU, the name of a sort of reptile, called also libia, and by the Portuguese Cobra de voador. The relations of those writers who speak of this extraordinary creature par-
take rather of the marvellous, insomuch that we cannot but entertain considerable doubt as to the identity of the species; that it is of the boa tribe there can be no dispute. Perhaps it is no other than the libiboca and boiguan of Seba, which Dr. Shaw describes under the name of Boa regia; a species somewhat allied to constrictor, and of which the history has probably been confounded with that of the latter kind. The boiguanu is represented as the largest of all the serpent tribe, in which it agrees with constrictor. It grows, we are told, to the length of four and twenty feet, and more. The mid- dle of the body very thick, but becoming smaller at the head and tail. Down the middle of the back runs a chain of black spots, a band's breadth distant from one another, each having a spot of white in its middle; and below these are two other rows of smaller black spots, towards the belly. Each jaw is said to be furnished with two rows of sharp teeth white as pearl. The head very broad, with two protruberances over the eyes, and, in some of this species, two claws, like those of birds, behind the anus, towards the tail. The last particular of which must evidently be an absurd mistake, arising from the inattention of the describer.

We are further told, that the boiguanu is a terrible crea-
ture, one that preys upon the larger animals, and will seize upon a man. That it either lies in ambush in the thickets, or on the branches of large trees, from which it throws itself upon its prey. It has no venom in its bite; and its flesh is eaten, and esteemed a delicacy. This fort is common in the Breals. The size to which it attains sometines is astonishing. Borritus preferred the skin of one (supposed to be the same) which had been killed by himself, that was twelve yards long; and he relates, that there was a serpent of this kind destroyed in Java, that measured thirteen yards and a half in length, and had, when killed, a boar in its belly. And de Lact re-
lates, that in Rio de le Plata there are some of this kind of serpents so large, that they will swallow a whole flag, the horns not excdded. This is probably exaggerated. It is affirmed of the boa constrictor, by others, that when the enormous creature has gorged an animal of this kind, the horns remain sticking out of the mouth of the serpent, till the digestion of the flesh takes place, and the horns drop off. The boiguanu is eaten by the natives of Brazil.

BOIL, in Ancient Geography, a people, who, according to Cæsar (lib. vi. c. 25.), were a Gauliih nation, but from Gaul paffed into Germany; and, settling in the preffent Bohemia, continued there till they were expelled by the Marcomanni. Strabo calls them at different times Celtes and Gauls; and M. Pelloutier is of opinion, that they were a tribe of the Celte, who inhabited Thrace and Illyria. Some of these, he says, occupied the Hercanian forest on the other side of the Danube, and migrated into Bolesia; others were mixed among the inhabitants of Thrace; and others remained in Illyria, between the Danube and the Drave. Of these Boi there were, therefore, several distinct tribes. After Bella-
vapus had made an irruption into Italy through the country of the Taurini, the Boi and Lingiones entered it by the Pen- nine Alps. These Boi occupied the more southern part of Gallia Cipadana, or Clysanne Gaul, and were separated from Etruria by the Apennines, and from the Senones by the Rus- tici. Their principal city was Bona. In the year of Rome 565, they advanced in Italy as far as the plain of Pannonia, and were defeated there by the dictator C. Sul-
picio. Pursued by the Romans, they retired over the Da-

nube, and inhabited the confines of Pannonia and Illyria, along with the Taurini and Scordisci. In this country they contended with Doerebifas, king of the Getae, and were de-
stroyed by his troops. Their country afterwards remained defect and uncultivated, and was called the "defect of the Boi." The Romans in process of time built here the towns of Scabartania and Sabaria. Caesar is supposed to have re-
ted to these Boi, when he says, that the Boi who had remained on the other side of the Rhine, and who had de-
scended from Noricia, where they laid siege to the town of Noricia, were summoned by the Helvetii to unite with them in an irruption into Gaul. Another body of the Boi hav-
ing entered into Germany, settled on the north of the Da-

nube, in an extensive country, almost wholly surrounded by mountains, and having on the western part the Herceynian mountains. This country was afterwards occupied by the Marcomanni, and is now called Bohemia. These Boi were blended by degrees with other nations; but retaining some kind of importance, they preferred an imperfect trace of their name in that of Boierii, whence proceeded Bavaria. The Boi, who joined the Helvetii on their attack of the Gauls, were overpowered by Caesar; but after their defeat, the Ædui prevailed with Caesar to allow them a settlement, on account of their distinguish'd valour, in a small district of their terri-

ory. It is said that he built for them a small town called "Gergovia," of which no trace now remains. M. d'Anville places these Boi in a kind of peninsula, formed by the rivers Liger and Elaver, before their re-union. Another body of the Boi, denominated by Aufonius "Pieboi," occupied the western part of Gaul, comprehended in Novem-Populana, south-west of the Biturgis Vixifii, upon the sea-coast.

BOIL, or FURUNCLE, in Surgery, is a painful, circum-
scribed, and inflammatory tumor, seldom larger than a pigeon's egg, generally of a conical figure, seated in the subcutaneous adipofe membrane, and proceeding from an inter- nal caufe. Its apex or central point is but slightly raised above the skin, and commonly tends to suppuration. No part of the surface of the body is exempt from the attacks of this disorder, but those parts are more liable to boils which abound with cellular substance. The purulent fluid they contain is usually incofled in one or more eyes or fasciuli, and is very flow in coming to a state of fermentation; so that it is re-
quite to aid the formation of matter by warm stimulat- ing applications, and at the same time to support the constitution by strenthening remedies, nutritious diet, and salubrious air.

Several boils will often appear at the same time, and after they have healed, new ones may arise; in which case, we may sufpcct the patient to be of an ill habit of body, and re-

quire
quire particular medical attention. But it is a very bad pra-_tice, though by no means uncommon, to administer frequent purges in such cases, which tend still more to diminish the tone of the patient, already too much exhausted. The state of the fæces must be remedied by such means as are indicated by the peculiar circumstances of the patient; for no general plan can be preferred, which is proper in all cases.

Before a considerable boil breaks, the patient sometimes feels himself indisposed, rather feverish, and is troubled with a number of slight complaints, which all disappear as soon as the tumor is formed; so that in this case it seems to have some similarity with a critical metafasis. Otherwise, boils, on account of the sense of tension and pain which they occasion, are more troublesome than dangerous.

The best common method of treating these tumors locally, is to bring them as soon as possible to suppuration, as this seems to be their natural tendency; and as the attempt to diffuse them generally succeeds either very imperfectly or not at all, some few cases excepted. For diffusing them are recommended the external applications of spirit of vitriol mixed with honey, strong vine-vinegar, camphorated oil, &c. In most cases, however, it is necessary that we should immediately endeavour to promote suppuration, which may be done by means of simple emollients; such as bread and milk poultices, linseed cataplasms, or a mixture of oatmeal and honey. If the pain be extremely great, we may add a small quantity of the extract of hemlock or poppies, and give a grain or two of opium internally. When the inflammation is moderate, but the hardnesfs con- siderable, inflammatant and caudescent remedies, such as roasted onions, white-lily roots, gum ammoniac, &c. must be combined with the emollients. Mr. Fletch affirms that no remedy brings boils to a speedy and quick, to suppuration, as the leaves of the vicinus communis boiled in milk, and applied in the form of a poultice.

When the tumor does not burst spontaneously, which it generally does at its point, it is to be opened with a lancet. Besides the general rules, according to which such an abcess must be treated, it is necessary also that the core or membranous part of the boil should be extracted in due time, and that all the remaining hardnesfs about the circumference of the sore should be diffused. For as long as this core remains in the cavity, the sore will not heal perfectly, neither can it be brought to heal unless the hardnesfs be diffused, but either an ulcer or a fistula is produced, or the sore flins over, whilst an induration still remains behind, which gives rise, according to the part in which it is situated, to various troublesome symptoms, and after some time becomes again inflamed, nor does it disappear entirely till it is diffused by a complete suppuration.

We may indeed attempt to diffuse such indurations by means of the usual debilitants, such as the external applications of mercury, hemlock, lox, belladonna, &c. but they will generally fail of their effect, and we shall be obliged to wait till a new inflammation is produced. It is therefore best to support and promote the suppuration from the very commencement, and not to suffer the abscess to heal up till all remains of induration have disappeared; and when the suppuration does not proceed with sufficient vigour, it ought to be promoted by means of warm turpentine, and digestive oint-ment. If this do not produce the requisite effect, it should be mixed with red precipitate; and to the indurated parts we ought to apply externally hot fomentations, with other emollient and stimulant remedies, according to the general rules laid down under the article Abscess.

Boils, gum. See Gum.

Boileau, Nicholas, named Defrées, in Biogrophy, an eminent satirical poet and critic, was born either at Paris, or at Crewe near that city, in 1654. Boileau himself, after having been truly emulated by his writings, had the silly vanity to praise himself in the high antiquity of his lineage. He pretended that John Boileau, the ancestor of his family, was created in 1333 by Charles V. King of France: and he boasted, in consequence of a suit instituted against his family, and occasioned by a severe petition into the validity of titles assumed by the noblesse of the kingdom, under a commission of inquiry established by Lewis XIV. in 1695, that he had gained his cane with flying colours, and that he had a patent in his possession which allowed him a nobility of 400 years' antiquity. It is said, however, that the sentence passed in favour of Boileau's nobility was the result of his reputation as a poet, honoured with the protection of the king; that the titles produced had been fabricated; and that a writ had been found among the papers of the poet for 20 louis d'ors, paid by him for his share in the titles which had been forged by an obscure person of the name of Haudiquier. However this be, his own writings were unquestionably his best "lettres de noblesse." As a younger brother, he was hardly treated in his youth, more especially because his father regarded him as a heavy and stupid lad, deficient of that vivacity of temper and understanding for which his elder brothers were distinguished. We are informed also, that he underwent an operation for the stone at eight years of age. These circumstances probably induced him to declare, that if he could be restored to infancy, on the hard conditions he had experienced, he would not have accepted the grant; and hence he always disputed the common opinion, that infancy is the happiest period of our lives. Boileau, indeed, seems not to have thought the other parts of his life more happy than his infancy; to him all appeared equally miserable; youth, tormented with passions, vanity with cares, and old age with infirmities; and he seemed to have adopted in some measure that philosopher's opinion, who, when he was asked "what was the happiest period of a man's life?" answered, "that which is past." "It would be difficult," says Defrées, "to determine this question; we are sure, however, that it is hardly ever the present time." Boileau was intended by his father for the profession of an advocate; but his taste for polite literature, to the culture and gratification of which he devoted his leisure hours, dis-qualified him for this mode of life; and his repugnance to it was strongly indicated by his dropping asleep, while his brother-in-law, M. Dongois, a clerk of parliament, was reading an arrest, which he had taken great pains to compose. Upon this, he was sent home to his father as an invincible dunces, who would be nothing else but a simpleton during his life. Relived from the embarrassment of pursuing a profession which he detested, his attention was next directed to scholafic divinity, from which he was equally averse. When his father found, that his views respecting him were altogether frustrated, he allowed him to indulge his own inclination, and to devote himself wholly to literature. At the age of 30 years, Boi- leau's true character, which had long been unknown to any but his intimate and confidential friends, was developed; and he appeared before the public as a writer of fables. He began with ridiculing the numerous tribe of bad writers, and he thus excited a host of enemies. Among others the duke de Montaufler reproached him on account of the sever-ity of his personal fables as injurious to society; but he contrived to disarm his enmity by a single stroke of sat-tery, which verified, says D'Alembert, the lines of La Fontaine:

"Amuse the great with adulation,
Your praise to all their faults extend,

Whatever
BOI

Whate'er their former indignation,
The bait goes down, and you're their friend."

Twelve of his satires were published; one of these was his satire against women, the most bitter and outrageous of all, which is said to have been occasioned by his having been in early life jilted by a young perfon to whom he was going to be married, and who ran away with a mosquetaire. Racine the younger, one of his particular friends, however, says, that he never had a mistress, nor ever thought of marrying. On the publication of this satire he was attacked from all quarters; but his friend Racine confided him as well as he could: "Courage," says he, "you have attacked a numerous corps, which is all tongue; but the storm will blow over." The belly of his satires was that entitled "A Fanc Efpert ?" a piece of irony, abounding with the most keen and polished ridicule. Whatever reproach Boileau incurred for the personality of his satires, it is mentioned to his honour, that he always disdained falling between folly and vice; and that he never attacked bad taste and dunci with any other arms than ridicule, while vice and profligacy were treated by him with just indignation.

The satires of Boileau were followed by his Art of Poetry, which is reckoned the bell of all the poetical works of criticism existing, equally admirable for the good sense of its maxims, and the appropriate beauties of language by which its precepts are exemplified. This was succeeded by his Epitres, formed after the model of Horace, and rendered peculiarly pleasing by the union of morality with criticism, and description with sentiment; interfered with characteristic traits and anecdotes of himself. In one of these, addressed to the king, he artfully, at the instigation of Colbert, endeavoured to divert the sovereign's mind from the schemes of conquest to the glory of promoting the welfare of his subjects by plans of utility and beneficence. Lewis was gratified by the delicate praise with which this advice was accompanied, and applauded the epitres; but went to war with Holland. In 1674, he published his Lutrin, a mock-heroic kind of composition, founded on a trifling dispute between the treasurer and chanter of the holy chapel, and ranking among the first productions of this class. Boileau had now acquired a degree of reputation which recommended him to favour and patronage at court; and the king honoured him with a pension, an exclusive privilege for printing his own works, and the office, conjointly with his friend Racine, of royal historian. In this latter capacity neither he nor his associate had an opportunity of appearing before the public. Boileau, indeed, published his Ode on the taking of Namur, which is more an historical than a poetical effort. At this time he attended frequently at court; and yet he maintained a freedom and frankness of speech, more especially on topics of literature, which are not common among courtiers. When Lewis asked his opinion of some verses which he had written, he replied: "Nothing, sir, is impossible to your majesty; you wished to make bad verses, and you have succeeded." He also took part with the persecuted members of the Port-royal; and when one of the courtiers declared, that the king was making diligent search after the celebrated Arnauld, in order to put him in the Bastille, Boileau interposed, "His majesty is too fortunate; he will not find him!!" and when the king asked him, what was the reason why the whole world was running after a preacher, named le Tourneux, a disciple of Arnauld, "Your majesty," he replied, "knows how fond people are of novelty: —this is a minifter who preaches the gospel." Boileau appears, from various circumstances, to have been no great friend to the Jesuits, whom he offended by his Epitres on the Love of God, and by many free speeches. By royal favour, he was admitted unanimously, in 1684, into the French academy, with which he had made very free in his epigrams; and he was also associated to the new Academy of Inscriptions and Belles Lettres, of which he appeared to be a fit member by his "Translation of Longinus on the Sublime." To science, with which he had little acquaintance, he rendered, however, important service by his burlesque "Arret in favour of the University, against an unknown perfonage called Reaon," which was the means of preventing the establishment of a plan of intolerance in matters of philosophy. His attachment to the ancients, as the true models of literary taste and excellence, occasioned a controversy between him and Perrault concerning the comparative merit of the ancients and moderns, which was prosecuted for some time by epigrams and mutual reproaches, till at length the public began to be tired with their disputes, and a reconciliation was effected by the good offices of their common friends. This controversy laid the foundation of a lasting enmity between Boileau and Fontenelle, who inclined to the party of Perrault. Boileau, however, did not maintain his opinion with the pedantic extravagance of the Dacier; but he happily exerted his wit on the misrepresentations of the noted characters of antiquity, by the fashionable romances of the time, in his dialogue entitled "The Heroes of Romance," composed in the manner of Lucian. In opposition to the abjured opinion of father Hardouin, that most of the classical productions of ancient Rome had been written by the monks of the 13th century, Boileau piously remarks, "I know nothing of all that; but though I am not very partial to the monks, I should not have forry to have lived with friar Tibullus, friar Juvalen, Dom Virgil, Dom Cicero, and such kind of folk." After the death of Racine, Boileau very much retired from court; induced partly by his love of liberty and independence, and partly by his diffidence of this adulation which was expected, and for which the clove of Lewis's reign afforded more beauty materials than its commencement. Separated in a great degree from society, he indulged that austerit and misanthropical disposition, from which he was never wholly exempt. His conversation, however, was more mild and genial than his writings; and, as he used to say of himself, without "nails or claws," it was enlivened by occasional fables of pleasantry, and rendered instructive by judicious opinions of authors and their works. He was religious without bigotry; and had abhorred fanaticism and hypocrisy. His circumstances were easy; and his prudent economy has been charged by some with degenerating into avarice. However, however, occur of his liberality and beneficence. At the death of Colbert, the pension which he had given to the poet Corneille was suppressed, though he was poor, old, infirm, and dying. Boileau interceded with the king for the restoration of it, and offered to transfer his own to Corneille, telling the monarch, that he should be ashamed to receive his bounty while such a man was in want of it. He also bought, at an advanced price, the library of Patrou, reduced in his circumstances, and left him in the possession of it till his death. He gave to the poor all the revenues he had received for eight years from a bench he had enjoyed, without performing the duties of it. To indigent men of letters his purse was always open; and at his death he bequeathed almost all his possessions to the poor. Upon the whole, his temper, though naturally austere, was, on many occasions, kind and benevolent, so that it has been said of him, that he was "crude only in verse;" and his general character was distinguished by worth and integrity, with some allies of literary jealousy and injustice.
judice. He died of a dropsey in the breast in 1711, at the age of 75, and bequeathed the greater part of his property to charitable uses. His funeral was attended by a very considerable number of persons of rank and literature. How came this man (exclaimed a woman in the street) to have so many friends? They say he never spoke well of any body in his life.

As a poetical writer, he has been denounced the "poet of good fate," correct in his verification, choice and pure in his language, just and rational in his sentiments, always guided by judgment and taste, observing the limits of decorum, and never betrayed by wit or fancy into extravagancies. Few, if any writer, ever composed so much, with so little occasion for enamef or alteration. Voltaire, who often denied the equity of his decisions in matters of criticism, fays of him, in a letter to Helvetius: "I agree with you that Boileau is not a sublime poet; but he executed admirably whatever he undertook. He is clear, easy, happy in his expreffion; he seldom rifes very high, but he never finks. Besides, the fulcuses of which he treats are not of a kind to require great elevation. — I shall, therefore, always warmly recommend that kind of writing which he has so well taught, that respect for language, that quick fecucion of ideas, the art and facility with which he conducts his reader from one obfjcut to another; and above all, his simplicitie, which is the true fruit of genius." Boileau was the first writer who formed the national taffe of France, and by his translations and imitations gave his countrymen a true reh for the epiftles and fatures of Horace, which before his time were not made fensible to the public taste. His greatest work, according to D'Alembert, is want of fenfibility; and if he fhould be defigned, which is incompatible with that coldnefs of heart that distinguished his character, is effential to a true poet, his claim to this honourable appellation musl be difallowed. Nevertheless, his works may be juftly regarded as master-pieces of their kind, and can never die, as long as the language in which they are written exisles. Hapving taken great pains in the compofition of them, he was not infensible of their peculiar and charaftcriftic excellence; accordingly, in some lines written by himself, and intended to be placed under his portrait, he makes no heflation in affirming that he had united the merits of Perius, Juvenal, and Horace. Boileau and Pope have been thought much to reftemb one another, as to both the kind and discriminating character of their writings; but, fays a very competent judge, Boileau, with a nearly equal portion of wit, has much more delicacy and correctness; while Pope as much surpasses him in force and fancy. Both abound in good fentiments; and each hath enriched his language with nervous lines that have passed into proverbial fentences. In another place the fame writer observes, that after we have rendered to Boileau D'effraux all due homage as a great poet, and as the legiflator of taffe, his faults as a faturif indicate an acriommous and unfeeling character, a great conceit of his own powers and confrence, and an unparagonable difregard of the happiness and reputation of others. "If the Englifh poet had as much efficiency as the French, and more peevif irritability, he feems to have had a more feeling heart, and a more fente of judgment," We may remark, that perfonal fate foon kifs its falt and poifonancy; and that the fatures of Boileau, as well as the Dunciad of Pope, are left read now than any of their other works.

Besides the works of Boileau, already mentioned, there are several smaller pieces both in prose and verfe. Of the whole there have been various editions, with explanatory notes; and of thefe the principal are that of Gigon, 2 vols. 4to. 1716, with illustrations, by Brolette; that of the Hague, with Picart's figures and notes, 2 vols. fol. 1718, and 4 vols. 12mo. 1722; that by Alix, with Cochin's figures, 2 vols. 4to. 1740; and that of Durand with illustrations, by St. Marc, 5 vols. 8vo. 1747.

Boileau had several brothers of very fingular characters. One of them, doctor of the Sorbonne, was born in 1635, studied in the university of Paris, took his degree of doctor in theology in 1662, was appointed dean of Sens, and vicar of the archbishop Gondoin, in 1667; and in 1694, was prefented by the king with a canonry in the holy chapel of Paris. He died dean of the faculty of theology in 1716. He is well known by a number of works in a peculiar fyle, fome of which were not remarkable for decency; but he fucceeded in Latin, "left the bishops," he faid "to condemn them." He was not more a friend to the Jesuits than his brother; and he defcribed them as "Men who confined the creed, and fhortened the commandments." As dean of the chapter of Sens, he was appointed to harangue the celebrated prince of Condé, when he paffe through the city. This great commander took particular pleafure on these occafions in deconcing his panegyrics; but the doctor, perceiving his intention, counterfeited great confufion, and addreffed him in the following manner: "Your highnefs will not be surprized, I truft, at feeing me tremble in your prence, at the head of a company of peaceful priests; I fhould tremble ftronger, if I was at the head of 30,000 foldiers." He manifefted a contempt of fanaticism, as well as of decorum, by his "Hiftoria Flagellantium, &c." or, an account of the extravagant, and often indecent, pra- tice of discipline by flagellation, in the Christian church. It was translated into French; and not many years ago (viz. 1777, 4to. and again in 1782, 8vo.) by M. de Lomme, into English. In his treatife "De antiquo jure reformati- rum in regimen ecceflalifico," he discovers the greatfieft freedom of fenfiment, endeavouring to shew, that in the primitive times the prelates participated with the bishops in the government of the church. He was also the author of several other publications, difplying much curious learning and a fatical turn, which are now configned to oblivion.

Gilles, the eldeft brother of Boileau Delfpreux, was born in 1631, and had a place in the king's houfehold. He was a man of wit and learning, and published a tranflation of Arrian's "Epitomes," with a life of the philofopher, Paris, 1675, 8vo. He also published a tranflation of Diogenes Lartaus, in 2 vols. 12mo. 1668; and two diatribes againft Menage and Coltar. His "Pothumous Works" were published in 1670. He also wrote verfe, in no high effimation; and his poetical pretentions exited a jealousy of his brother's riling fame, which produced an open variance between them. He was a member of the French academy; and died in 1669. Gen. Dic. Nouv. Dic. Hift. D'Alembert's Hift. des Membres de l'Acad. Franc. 1787, and Eloge, &c. 1779, — tranflated by Aikin in 2 vols. 8vo. 1799.

Boileau, or Boileau fils, thofe which have been put, while in the balls, into hot water, to make them wind the better.

In which fenate, boiled filk flands oppofed to raw.

Boileau, or Bowle, a large copper vefel, wherein things are expo'd over the fire to be boiled.

The boiler in the alum-works is a vefel, in which the liquor is evaporated to a deftuffe and is made of lead. The general size is about eight feet fquare, and they contain about twelve tons each.

They make them in this manner: firft, they lay long pieces of call-iron, twelve inches fquare, as long as the breadth
breadth of the boiler, and at about twelve inches distance from one another. These are placed twenty-four inches above the surface of the fire. On these flabby bars of iron they lay, cross-wise, the common flat bars of iron, as close as they can lie together, and then make up the sides with brick-work. In the middle of the bottom of this boiler is laid a trough of lead, wherein they put at first about a hundred pound weight of the rock. They use Newcasle coals in the boiling, and if they find the liquor not strong enough, they add more of the rock at times, as it boils. Phil. Trans. No. 142.

The boiler for making colours, &c. must be made of pewter; because iron and copper will be corroded by the fatty substances used in the manufacture of them.

Count Rumford (See his Essays, vol. i. p. 220.) recommends double bottoms to boilers, and also to saucepans and kettles of all kinds, used for culinary purposes; which contrivance, he says, will, in all cases, most effectually prevent what is called by the cooks, "burning-to." The heat is so much obstructed in its passage through the thin sheet of air which, notwithstanding all the care that is taken to bring the two bottoms into actual contact, will still remain between them, that the second has time to give its heat as fast as it receives it to the fluid in the boiler; and consequently it never requires a degree of heat sufficient for burning any thing that may be upon it. He suggests that it will probably be best to double copper saucepans and small kettles throughout; and as this may and ought to be done with a very thin sheet of metal, it would not cost much, even if the lining were to be made of silver. When the two sheets of metal that form the double bottoms of boilers are made to touch each other throughout, by hammering them together after the false bottom has been fixed in its place, they may be tacked together by a few small rivets placed here and there, at considerable distances from each other; and when this is done, the boiler may be tinned. In this operation, if proper care be taken, the edge of the false bottom may be folded by the tin to the sides of the boiler, and thus the water or other liquids, put into the boiler, will be prevented from getting between the two bottoms. The Count adds, that this invention of double bottoms might be used with great success by distillers, to prevent their liquor, when it is thick, from burning to the bottom of their stills. (See Still.)

Having found in the course of his experiments, (See Phil. Trans. 1753, Part I.) that confined air is the best barrier that can be opposed to heat for the purpose of confining it, he proposed to confine the heat in the boilers of his construction, and to prevent its escape into the atmosphere, by means of double covers. These covers were made of tin, or rather of thin iron plates tinned, in the form of a hollow cone; the height of the cone being equal to about one-third of its diameter; and thus the air which it contained was entirely shut up, the bottom of the cone being closed by a circular plate or thin sheet of tinned iron. The bottom of the cone was accurately fitted to the top of the boiler, which it completely closed by means of a rim about two inches wide, which entered the boiler, which rim was soldered to the flat sheet of tinned iron that formed the bottom of the cover. The steam, generated by the boiling liquid, was carried off by a tube about half an inch in diameter, which passed through the hollow conical cover, and which was attached to the cover, both above and below, with solder, in such a manner that the air with which the hollow cone was filled remained completely confined, and cut off from all communication with the external air of the atmosphere, as well as with the steam it generated in the boiler. For his various contrivances in the most advantageous construction of boilers for the faying of fuel, and for producing the desired effect, we refer to his Essays, vol. ii. p. 18, &c.

BOILERY, or Boilary, in the Salt Works, denotes a salt-house, pit, or other place, where salt is made.

BOILING of MEAT, in Cookery, is the exposing of meat to the heat of boiling water, while it is immersed in it for a certain time. By this joint application of heat and moisture, the texture is rendered more tender and more soluble in the stomach; and it is only in this way, that the firmer parts, as the tendinous, ligamentous, and membranous parts can be duly softened, and their gelatinous substance duly extracted. A moderate boiling renders the texture of animal flesh more tender, without much diminution of its nutritious quality; but if the boiling is extended to extract every thing soluble, the substance remaining becomes less soluble in the stomach, and at the same time much less nutritious. But as boiling extracts in the first place the more soluble, and therefore the fatty parts; so the remainder, after boiling, is in proportion to the continuance of the operation less alkalifeet, and less heating to the stomach.

Boiling is commonly practiced in open vessel, or in vessels not closely covered; but it may be performed in diggers, or vessels accurately and tightly coiled; and in such vessels the effects are very different from those that take place in open vessels. As we can hardly employ any other degree of heat than that of boiling water, the water in the digester is never made to boil, so there is no exhalation of volatile parts; and, although the solution is made with great success, and may be to any degree required, yet if it be not carried very far, the meat may be rendered very tender, while it still retains its most rapid parts; and this kind of cookery will always give the most desirable state of boiled meat.

Boiling, in the ordinary way, is different, according to the proportion of water that is applied. If a small quantity be applied, and the heat in a moderate degree is continued for a long time, this is called "fluming," and has the effect of rendering the texture more tender, without extracting much of the soluble parts; and of course it leaves the meat more rapid, and sufficiently nourishing. Cullen's Med. vol. i. p. 400, &c.

BOILING, ebullition, in Physics, is the internal commotion excited in a mass of water or other liquefied substance, by the successive conversion of the lower portions of the fluid into vapour, and their violent effort under this expansive and elastic form to make their escape. It is usualliy, though not necessarily, produced by the application of heat. The circumstances which precede or accompany the phenomenon of boiling, are best observed in a thin transparent flask nearly filled with water, and suspended over a lamp or a charcoal fire. Numerous minute globules are seen collecting from all points towards the sides and rising in a stream to the surface; occasioned evidently by the discharge of air, which is always in some proportion combined with water. As the heat increases, the liquid particles near the bottom of the flask suddenly burst into steam, and shoot upwards; but in ascending through the colder mass, they again collapse, drop their progres, and seem lost. Such alternate expansions and contractions, by throwing the fluid into a gentle tremor, frequently causes a peculiar sort of winging noise, which is rightly supposed to be the cause of the approach of actual boiling. This inging is more likely to happen in the cale where heat is applied partially; for instance, if a tea-kettle be placed at the side of the fire, since the heat is then more equally and unequally diffused through the body of the water. But after the whole contents being fully penetrated, are warmed up to the requisite degree of intensity, the steam, as fall as it is formed,
formed, ascends continually and escapes unimpaired through the fluid, which it therefore heaves with violent agitation.

The same appearance almost is produced by removing or even diminishing the atmospheric preasure. Thus, if a tumbler holding warm water be introduced under the receiver of an air-pump, as the exhaustion proceeds, or the incumbent weight is gradually withdrawn, the latent portion of air is discharged in a rapid flow of expanded bubbles. But this process, at some certain point of rarefaction, is succeeded by the vehement commotion which constitutes boiling; and the water, assuming its invisible form, fills the imperfect void with vapour, which betrays its existence by condensing against the sides of the receiver in copious drops. Nor is heat positively necessary towards vaporization, for it only confipires in accomplishing that effect, and supplies the want or the imperfection of our means of producing exhaustion. By the help of an air-pump of the bell construction, the coldest water may be made to boil, nay, ice itself could be changed into invisible steam. Hence the utter impossibility of ever obtaining a perfect vacuum, because the restraining influence of preasure being entirely removed, the liquid matter unavoidably presented would always diffuse a thin vapour.

The opposite influence of heat and preasure on the constituent of fluids is well exhibited by a very simple yet striking experiment. Take a large thin phial, and having warmed it gradually to avoid the risk of cracking the glass, fill it completely with boiling water, cork it tight, and expose it to a current of cold air. As the water cools, it necessarily contracts its volume, and leaving an imperfect vacuity below the neck of the phial, it hence becomes to a considerable degree relieved from the load of atmospheric preasure. It therefore soon begins again to boil, nay, it will boil more briskly the fatter it cools; and this singular appearance, so contrary to our usual notions, may continue perhaps for the space of half an hour, till the water has grown as cold almost as the temperature of the human body.

On the same principle depends the construction of what is called the pulse glass: this consists of two balls connected by a pretty long tube; one of these balls is filled with coloured water or spirits of wine, which having been made to boil and expel the air by its vapour, at the same instant the part projecting from the other ball is hermetically sealed. As that vapour condenses with cold, it will leave the included liquid then in a fort of vacuum, and the heat of the hand is then sufficient to caufe it to boil and to flow from one ball into the other.

If a vessel containing water be placed over a steady fire, the water will grow continually hotter till it reaches the limit of boiling, after which the regular accelliions of heat are wholly spent in converting it into steam. The water therefore remains at the same pitch of temperature, however fiercely it boils. The only difference is that, with a strong fire, it sooner comes to boil, and more quickly boils away. Hence the reason why a vessel full of water, and plunged into the centre of a larger one, which is likewise filled with that fluid, barely acquires the boiling heat, but will never actually boil.

The formation of steam occasions a prodigious consumption of heat: for if the time be noted in which water, by the action of a strong fire, is raised from the limit of freezing to that of boiling, it will be found to require more than five times longer a space to boil entirely away. Thus, a portion of heat corresponding to above 900 degrees by Fahrenheit's scale, is always consumed in the act of boiling, or rather it is transferred and enters into the composition of steam, the gaseous product. This absorbed heat is as constantly evolved when steam condenses and returns to its liquid form. Hence in distillation a very large refrigeratory is required for condensing a comparatively small quantity of aqueous or spirituous vapour. Hence too the explication of the following remark that steam scalds more cruelly than boiling water.

The heat of boiling water, being subject to the influence of the atmospheric preasure, is thus not absolutely fixed. It varies with the variation of the barometer, and decreases as the mercury descends. The extent of this fluctuation may in our changeable climate amount to five degrees by Fahrenheit's scale, the successive difference of a degree corresponding nearly to each twentieth part of the remaining incumbent weight. On the tops of lofty mountains water will boil much sooner than in the plains below. This curious fact has been noticed by several travellers, and was particularly observed by Sauvage on the summit of Mont Blanc. A still greater variation would be experienced on the peak of Chimborasco, the highest point of the Andes, where water would boil with a heat fearfully superior to that which is commonly assigned for the boiling of spirits of wine.

It is therefore evident that, under an augmented preasure, all liquids will more slowly reach the crisis of ebullition and will then have acquired a more intense heat. Thus water may be heated up many degrees above the mean point of boiling, if it be subjected to the action either of condensed air or of confined steam. Such is the principle of Papin's Digestor; which, being nearly filled with water, is kept perfectly close, and let on a good fire. As the steam formed is prevented from escaping, it necessarily concentrates, and extracting accumulated energy, it by its prodigious compression enables the water continually to receive additional heat. Nor would this progress at all stop, till the elasticity of the imprisoned vapour comes to surmount every obstacle, and bursts the vessel with terrible expulsion. Accidents of that fort are extremely dangerous, and the experiment has consequently never been pushed to its utmost practicable limits. When the fracture takes place, not only the confined steam is liberated, but the preasure being now removed, the excess of heat instantaneously converts a part or the whole of the water likewise into steam, which augments the general effect. This we may perceive in the bursting of a glafs cracker; for the little base is shivered into atoms, and the water which it contained is entirely difpered, beating down flat the wick of the candle by the violence of the sudden expansive blift.

Hence the boiling heat of a deep cauldron is always rather greater than that of a shallow pan. This excess we might estimate at nearly one degree of Fahrenheit, for each foot of depth. The heat of ebullition must also rise somewhat higher, if the steam be not allowed to escape as fast as it is generated; for which reason there may be a slight difference of energy between rapid and slow boiling. Hence by the combined operation of both these causes, water deeply lodged in the bowels of the earth or concealed under the dark bed of the ocean, is capable of acquiring the most intense heat from the action of subterranean fires; a principle of which Dr. Flutton has ingeniously availed himself in framing his Theory of the Earth.

But the position of the boiling point is likewise modified by the influence of chemical attraction. Thus sugar, common salt, and other false substances, have all of them a tendency to fix water and retard the crisis of its conversion into effuse vapour. Strong brine will not boil until it is heated up several degrees above the ordinary limit. Hence a vessel containing fresh water, and immerfed in another which is filled with brine, will gently boil, while the surrounding fluid only simmers. On the other hand, the addition
tion of alcohol renders water more volatile. In the distillation of spirits, the fermented liquor in the copper boils always at a lower temperature, or at some intermediate point between the ebullition of water and that of alcohol. The spirituous fumes which rise carry along with them a portion of evaporated water. Hence the necessity of rectification, or repeated distillations, to procure alcohol in its purest state; for the boiling heat is lowered, and consequently the proportion of aqueous admixture is diminished, at each successive process. See Digest, Ebullition, Fire, Fluid, Heat, Pressure, Steam, Vapour.

Boiling of silk with soap, is the first preparation in order to dyeing it. Thread is also boiled in a strong lye of ashes, to prepare it for dyeing. Boiling is also a part of the process for bleaching warp linen.

Boiling to death, caldarii decurent, in the Middle Age, a kind of punishment inflicted on false coiners, thieves, and some other criminals. This punishment was inflicted on those who were guilty of murder by poison, 22 Hen. VIII. cap. 19. but this act was repealed by 1 Edw. VI. cap. 12.

Boiling is also a method of trying or assaying the goods or fallacies of a colour of a dye, by boiling the stuff in water with certain drugs, different according to the kind or quality of the colour, to try whether or not it will discharge, and give a tincture to the water.

With this intention, red crimson filks are boiled with alum, and scarlets with soap, in quantity equal to the weight of the silk.

Boiling waters, in Natural History. See Spring, and Water.

BoiNitz, in Geography, a town of Hungary, eleven miles W. N. W. of Kremnitz.

BoJOBl, in Zoology, the Brazilian name of the Linnaean boa caninus. See Canina.

BoiODURUM, in Ancient Geography, a town of Vin- delicia, situate on the Danube, according to Ptolemy; the Itinerary of Antonine places it on the route from Oulabis to Augufina Vindelicium, between Stanacum and Quintians.

BowieHUM, or BoiHUM, the country of the Boii, answering to the present Bohemia, which fee. On the south of it lay the "Gabreta Sylva," and to the south, west, and north, the "Hercynii montes." The interior of it was penetrated with difficulty, and was little known.

BoJOWKA, in Geography, a town of Poland, in the palatinate of Brachaw, forty-eight miles east of Brachaw.

BoIOQIURA, in Zoology, a name by which the natives, in some parts of America, call the rattle snake. Supposed to be the Crotalus borridus, of Naturalists.

BoireL, Anthony, in Biography, born at Argentan, in Normandy, about the year 1625, applied himself to the practice of surgery, in which he acquired considerable reputation. In 1677 he published, "Traité de plaies de tête," 8vo. extracted principally from the works of Hippocrates, Galen, and of Ambrof Paré, which he appears to have studied diligently. He has added some improvements to their practice.

BoiS, Cardinal du. See Dupois.

BoiS, Gerard du, a member of the congregation of the Oratory, and a Latin professor in it, was born at Orleans, Vol. IV. in 1620. Having succeeded father Le Comte, in his place of librarian to St. Honoré, and having possession of his books, he finished for the press his eighth and last volume of the "Ecclcsialis Annals of France," which was printed in 1653; and in consequence of it he obtained a pension from the French clergy. He afterwards undertook to write the history of the Papal church; and, in 1650, published the first volume in folio. The second, which he did not live to finish, appeared after his death, which happened in 1656. This work is written in pure elegant Latin, and contains a variety of interesting facts relating to civil as well as ecclesiastical history. Nov. Dict. Hist.

Bois, Boys, or Boyse, John, an eminent divine, and one of the translators of the bible, in the reign of James I. was born at Nettlestead in Suffolk, in 1562, and made such early proficiency under the instructions of his father, that at the age of five years he read the Bible in Hebrew; and at six, wrote that language in a fair and elegant character. At the age of 14 he was admitted into St. John's college, Cambridge, and by his great skill in the Greek language obtained a scholarship before he had been half a year at college, and afterwards a fellowship. Declining the profession of physic, for which he was intended, he devoted himself to the study of divinity, and was ordained in 1583. He officiated for 10 years in his college as principal Greek lecturer; and, as an instance of his industrious application, and of the early hours of study at that period, it is mentioned, that he voluntarily read a Greek lexicreat four in the morning, which was attended by most of the fellows. On the death of his father, he succeeded him in the rectory of Well-Stowe, near Bury, in Suffolk; but in 1596, he married the daughter of Mr. Hole, rector of Boxworth, in Cambridgeshire, and having before resigned Well-Stowe, took possession of this living. In this situation the neglect of domestic economy involved him so much in debt, that he was under a necessity of selling his choice collection of books. Afterwards, however, he retrieved his affairs by keeping a boarding-school; and was appointed one of the Cambridge translators of the bible. (See Bible.) The part that fell to the lot of that class of divines, with whom he was connected, was the Apocrypha; and this he completed in four years, without deriving any advantage from it besides his own. He was afterwards appointed one of the five delegates who met at Stationer's-hall in London, for the purpose of revising the translation, and who were employed for nine months in this business, with an allowance from the Stationers' company of 30s. a-week each: [For the allowance which he gave to H. Savile, in the publication of St. Chrysolom's works, to which he devoted the labour of many years, he received the very inadequate recompence of a single copy of the work. However, such was his reputation, that he obtained, without solicitation, from Dr. Andrews, bishop of Ely, a prebend in his cathedral, in 1615; and he was thus enabled to spend the last 25 years of his life in tranquill retirement. Although he was always hard frudent, he published nothing; but kept behind him many MSS., particularly a commentary on the greater part of the N.T. A work of which few copies were printed, and, therefore, little known, appeared after his death, under the following title: "Johannis Boisi veteris Interpretis eum Beza aulique recentioribus collatio in IV Evangelia, et Actis Apollinarum." London, 1655, 8vo. He furnished the character of an excellent Latin writer, a profound scholar, a loyal subject, a strict churchman, and a plain practical preacher. It was his practice to attend the public service of the church twice, if not thrice a day; and his charity was as extensive as his devotion was regular and constant. Although he devoted eight hours a day to study even in his old age, he preferred his health by the exercise of walking.
to which he had accustomed himself from his youth, by con-
fining himself to two meals a day, dinner and supper, by
fitting or walking an hour after dinner before he went into
his study, by occasional fasting, sometimes twice in a week,
and sometimes once in three weeks, and by not fasting
after supper, particularly towards the close of life, but di-
verting himself with cheerful conversation for two hours
among his friends. When he was a young student at Cam-
bridge, he received from the learned Dr. Whitaker these
three rules for avoiding those delinquencies which usually attend
a sedentary life, to which he adhered with equal constancy
and success. The first was to study always standing; the
second never to study in a window; and the third never to
go to bed with his feet cold. Accordingly he attained the
age of 84 years, and died in 1643. Biog. Brit.

Bois, Du, Lake, in Geography, lies in North America,
to the north-west of Lake Superior, and receives the river
de la Plue, in N. lat. 49°. It was formerly famous for the
richness of its banks and waters, which abounded with all
the necessaries of a savage life. The French had formerly
several settlements in and about it; but it has since declined,
though it is now recovering its pristine state. The few In-
dians who inhabit it might live very comfortably, if they
were not so immoderately fond of spirituous liquors. This
lake is rendered remarkable by its having been named on
the part of the Americans, as the spot from which a line of
boundary between them and British America was to run
west till it struck the Mississipi, which, however, as Mr.
Mackenzie observes, can never happen, because the N. W.
part of the lake du Bois is in N. lat. 49° 37' and W. long.
62° 31'. and the northernmost branch of the source of the
Mississipi is in N. lat. 47° 38' and W. long. 95° 5', ascertained
by Mr. Thomson, astronomer to the North-west Company,
who was sent expressly for that purpose in the spring of
1798. He, in the same year, determined the northern bend
of the Millourny to be in N. lat. 47° 32' and W. long.
101° 25', and according to the Indian accounts, it runs to
the south of west, so that if the Millourny were even to be con-
dered as the Mississipi, no western line could strike it. It
does not appear, says Mackenzie, to be clearly determined
what course the line is to take, or from what part of lake
Superior it strikes through the country to the lake du Bois;
it if were to follow the principal waters to their source, it
ought to keep through lake Superior to the river St.
Louis, and follow that river to its source; close to which
is the source of the waters falling into the river of lake
de Plue, which is a common route of the Indians to the lake
du Bois; the St. Louis passes within a short distance of a
branch of the Mississipi, where it becomes navigable for
canoes; and if the navigation of the Mississipi is considered
as of any consequence by this country, from that part of the
globe, such is the nearest way to get at it. The lake du
Bois is nearly round, and the canoe course lies through the
centre of it among a cluster of islands, some of which are so
extensive that they may be taken for the main land. The
reduced course would be nearly north and south. But, ac-
cording to the navigating course, the distance is 75 miles,
though in a direct line it would not be so long. About
two-thirds of it there is a small carrying place where the
water is low. The carrying place out of the lake is on an
island, and named Portage du Rat, in N. lat. 49° 37' and
W. long 94° 25', and is about 50 paces long. The lake
discharges itself at both ends of this island, and forms the
river Winipig, which fec. Mackenzie's voyage, &c. through the

Bois-belle, or Henriechomont, a small sovereignty of France
before the revolution, situate in Berry, between Bourges
and Sancerre, about 10 leagues in circuit, containing about
6,000 inhabitants; its principal towns are Bois-belle and
Henrichemont, which see.

Bois-belle, a town of France, in the department of the
Cher, 15 miles N. E. of Bourges.

Bois-commun, a town of France, and principal place of a
district in the department of the Loiret, containing about
1,600 inhabitants; 7 leagues N. E. of Orleans, and 7 W. of
Montargis.

Bois, Glacier der, one of the lower Glaciers of the Alp-
ines mountains adjoining to Mont Blanc, and the valley of
Chamouny in Switzerland, from the thawed ice of which
flows the river Arvon. This glacier is more than 15 miles
long, and above three in its greatest breadth. The general
thickness of the ice was found by M. Saussure to be from 50
to 100 feet.

Bois-le-dieu, or the Duke's wood, a city of Dutch Brabant,
seated on the river Dommel, where it receives the waters of
the Aa; so called from its situation in a wooly country, to
which the dukes of Brabant were accustomed to resort for the
purpose of hunting. The woods were cut down by order of
Godfrey III. duke of Brabant; and he laid the foundation of
a city in 1184, which was confirmed in 1196, by his son duke
Henry I. and much enlarged in 1332, 1475, and 1559.
The city is encompassed by the Dommel and Aa, by the
waters of which it may be easily inundated; and it is some-
times inaccessible except by boats. The principal forts that
defend it are those of Crevecoeur, near the Meule; another
called Fisbalbe; and a small fort called St. Antoine, towards
Brabant. It has also a castle, built by order of the States
General, in the 17th century, as a check on the Roman cat-
tholics then more numerous than the reformed. It has four
gates; and its walls are flanked with bastions; the approach
to it by land is on causeways, and by water at three gates
or avenues. The cathedral, erected in 1666, and dedicated
to St. John the Evangelist, is one of the most beautiful
structures in the Low Countries. Its wooden tower which
was very lofty and supported by four stone pillars, was de-
broyed by lightning in 1584. It has had several other
churches and monasteries. This city suffered very much in
the 16th century, during the religious wars; but at length
the Dutch made themselves masters of it in 1639. Pope
Paul IV. founded a bispohip at Bois-le-dieu in 1559, having
jurisdiction over ten cities and 189 villages; the chief re-
venue of which arose from the abbey of Tongerlo. The di-
ocrit of Bois-le-dieu, called "Mayvey," is situated between
Holland and Guelderland, having Holland to the N., Upper
Guelderland and the duchy of Cleves to the E., the quarter
of Antwerp to the W., and the bispohip of Liege to the S.
It is divided into five small districts, and comprehends 102
villages, and three cities, Bois-le-dieu, Helmont, and Eynd-
hoven. On the 14th of September 1794, an engagement
took place near this town between the British army and the
French, in which the latter were victorious; and on the 9th
of October, in the same year, the town was taken by the
French.

Bois, St. Marie, is a town of France, in the department of
the Saone and Loire, and chief place of a canton, in the
district of Charolles, 7 miles S. E. of Charolles.

Bois d'Oingt, a town of France, in the department of the
Rhone, and chief place of a canton, in the district of Ville-
franche, 4 ½ leagues N. W. of Lyons. The place contains
900, and the canton 13,501 inhabitants; the territory com-
prehends 192 ¾ kilometres, and 18 communes.

BOISEAU, in Commerce, a measure of two buffels and
half of a peck at Bourdeaux in France.
BOISMONT, Nicholas Theinel de, in Biography, abbot of Grouin, preacher in ordinary to the king, doctor in theology, and member of the French academy, was born in 1715, and obtained great reputation for eloquence, particularly in the composition of funeral orations. His principal works are, a panegyric of St. Lewis, and funeral orations on the Dauphin, on the queen of Lewis XV. and on that king himself. These pieces are distinguished by great fertility of ideas, a rapid and animated style, lively and noble imagery, and philosophical reflection. On, for instance, the orator exercises too much skill in decoration, and is too fond of antiteles. He is reckoned, however, the most eloquent of French orators in this department, and M. D'Alembert has alluded to him in a strain of high applause in his eulogy of Flechier. Nouv. Dict. Hilt.

BOISROBERT, Francis le Metel de, a man of wit and pleasantry, much favoured by cardinal Richelieu, was born at Caen in 1592, and contributed much to the establishment of the French academy, of which he was a member. He wrote poems, comedies, tragedies, tales, letters, romances, &c. which succeeded for a time, but are now almost forgotten. He was the amiable companion of Richelieu, and gained by his buffooneries the abbacy of Chattillon-sur-Seine, though his habits were far from being clerical. He was generous and beneficent, and took pleasure in serving men of letters. He died in 1661. Nouv. Dict. Hilt.

BOISSARD, John-James, an eminent antiquary, was born at Belfaing in 1528, and travelled, for the purpose of collecting antiquities, into Italy, the isles of Corfu, Cephalonia, and Zante, and the Morea. After his return home, he was made governor to the sons of the baron de Clervac, and travelled with them into France, Germany, and Italy. Having lost a great part of his valuable collection at Montbelliard, when the Lorrainers ravaged Franche Comté, he took pains in repairing his loss, and published his great work, much valued by antiquaries, and now scarce, entitled "De Romane urbis topographia et antiquitate," in 4 vols. fol. 1597—1602, enriched with many engravings by Theodore de Bry, and his sons. He also published a work, entitled "Theatrum vitae humanae," 1597—1599, 4to. containing the lives of 198 illustrious personages, with their portraits. His "Book of Emblems" was published, with figures, by Theodore de Bry, in 1593, 4to. His Latin verses were infected by Gruter in the "Deliciae Poetarum Gallorum," and after his death was printed his work "De Divinatione et magicae praefiguratione." Fol. He finally settled at Metz, and died there in 1602. Gen. Dict. Nouv. Dict. Hilt.

BOISSEAUX, in Geography, a town of France, in the department of the Seine-et-Oise, and principal place of a canton, in the district of Corbeil; the place contains 479, and the canton 14,724 inhabitants; the territory comprehends 1774 kilometres, and 26 communes.

BOISZKY, a town of Poland, in the palatinate of Bielek, 12 miles S.W. of Bielek.

BOITTAPO, in Zoology, a sort of serpent that inhabits Brail, and is called by the Portuguese cóbra de épo. This is an ambiguous species, it is described as being from eight feet long, as thick as a man's arm, round, and pointed towards the tail, like a shoe-maker's awl. The body covered with fine sub-triangular scales, the colour olive and yellowish. It lives on frogs, and must be of the poisonous kinds, since its bite is represented dangerous.

BOITMANNZDORF, or BOEDENDORF, in Geography, a town of Silevia, in the principality of Nefyż, 5 miles N.E. of Nefyż.

BOITZENBURG, a town of Germany, in the circle of Upper Saxony, and Ucker Marc of Brandenburg, 8 miles S.W. of Prenzlow.

BOITZENBURG, or BOETZENBURG, a town of Germany, in the circle of Lower Saxony, and duchy of Mecklenburg, at the confluence of the Boitzee and the Elbe. It was surrounded with walls in the 14th century; at this town, vessels that pass the river pay a toll, producing annually 40,000 dollars, of which the duke of Mecklenburg-Strelitz is entitled to 6000; 3 leagues E. of Lauenburg.

BOIVIN, Louis, in Biography, a distinguished scholar and penman of the academy of belles letters, was born at Men- treuil l'Argilé in Upper Normandy, and educated, first, under the Jesuits at Rouen, and afterwards at Paris, where he settled. His acquirements in literature were various and extensive; but his temper, according to his own account, was intractable and unocial, enterprising, vain, and versatile. He was employed by several eminent magistrates as the associate and director of their private studies; but the labours of his disposition involved him in great trouble and expense. He published some learned dissertations on historical subjects, in the "Memoirs of the Academy of Belles Letters;" and made great progress towards a new edition of Josephus. He died in 1724, aged 75 years.

BOIVIN,
BOIVIN, John, a younger brother of the preceding, was born in 1662, and instructed by his brother, established his reputation as a man of letters at Paris, at the age of 18 years. His disposition was a counterpart to that of his brother, and he was much esteemed for his amiable temper and manners. The abbé de Louvain assigned him a considerable pension, and in 1714 procured for him the place of under-keeper of the king's library. In 1721, he was admitted member of the French Academy, and became penurious of that of belles lettres in 1734, on the death of his brother. He excelled in the Greek language, of which he was professor in the royal college. His printed works are "An apology for Homer, and the shield of Achilles," 12mo; a French translation of "Homer's Iliad," 12mo; a French translation of the "Odipus of Sophocles, and the Birds of Aristophanes;" "Greek Poems," much admired for their accurate delicacy; an edition of the "Mathematici Veteres," 1603, fol.; a Latin "Life of Claude Pelletier;" a Latin translation of the "Byzantine History of Nicephorus Gregoras, with notes," 1702, which is esteemed faithful, learned, and elegant. He also published several dissertations on historical and literary topics in the "Memoirs of the Academy of Belles Lettres." He died in 1726. Nouv. Dict. Hist.

BOLUM, in Ancient Geography, one of the four principal cities of the Doride country in Greece. It was seated on the river Pindus, to the east of Eretria.

Species. B. procarpica. A tree sixty feet high, three feet and a half in diameter. Trump with a greyish, smooth bark, throwing at its summit a great number of branches, some upright, others inclining, and almost horizontal, which spread in all directions. Leaves alternate, oval-lanceolate, entire, terminated by a long, tender point, smooth, firm, green, on short petioles; two caduceous filaments at the base of each petiole; the exterior part of the wood is white, the interior brown, intermixed with yellowish green. The latter is very firm and compact. It is a native of Guiana. See La Marek, Encyc. Method.

BOKELMAN, John Frederic, in Biography, published the beginning of the last century at Leyden, "Medicus Romanus fenus, fexaginta solidis remittimus." On this subject, a most interesting controversy was carried on some years after, between Drs. Mead and Middleton, in which many of the literary took part; and this dissertation, originally written to convey a cenure on Drelincourt, was republished. The subject will be noticed again in the life of Dr. Mead. Haller Bib. Med.

BOKENEM, in Geography, a town of Germany, in the circle of Lower Saxony, and bishopric of Hildesheim, 16 miles S.S.E. of Hildesheim.

BOKEY, a town of Germany, in the circle of Franconia, and bishopric of Wurzburg, 4 miles N. of Kirfingen.

BOKHARA, Bucharia, or Bogor, a famous city of Great Bucharia (see Bucharia), situated on the river Sogd, in that district, lying N. E. of the river Jhon, or Oxus, called Ogudiana, or Al Sogd. It is fentled very advantageous for trade, in a delightful and fertile country, and has repeatedly contended the metropolitan dignity with Samarcand. Besides its own wall, which was very strong, it had an outward inclosure, comprehending not only the suburbs, but a district about four leagues in extent on each side, which contained several villages and farms, watered by the river Sogd. The Sogd, which is the valley or plain of Samarcand on the eait, and the mountain called Vorka on the north, were the boundaries of this territory; although its jurisdiction extended to several towns which were situated beyond its great wall. Mirkhond, in his history of the polity of Japhet, affirms, that Bokhara was the capital of Turquellen, in the time of Oguz Khan, one of the most ancient kings of the Moguls, or Tartars, and reckoned by the Mahomedan Tartar: the eighth in descent from Japhet; and enumerates several towns which were dependent upon it. Bokhara afterwards became the capital of the state of the Samanides founded by Ismail, the great grand-son of Saman, in the year of the Hegira 575, or of Chrifi 989, under the caliph Motadhid. After the fall of the empire of the Samanides, the Moguls of Cathai made themselves masters of this city; but it was retaken by Mohammed, king of Karafin, in the year of the Hegira 594, or A. D. 1197. This conquest of the Karafmians alarmed the nations of the north, and drew towards Jihon very powerful armies of Moguls and Tartars, who detached some of the finest provinces of Asia. In the year of the Hegira 617, or A. D. 1220, Jenghiz Khan, after a siege of some continuance, took this city, and ordered it to be set on fire; so that nothing of it remained, except the talan's palace, called "Ark," constructed of stone, and some few private houses built of stone, all the rest having been wooden edifices. He then caused a search to be made in the palace and houses, and commanded all the soldiers, who had concealed themselves, to be put to death. Bokhara continued for some years in this desolate state; but at length the Khan ordered it to be rebuilt, not long before his death. In the year of the Hegira 727, or A. D. 1329, Tamerlane took this city from Sultan Hafian, who was the last prince of the house of Jenghiz Khan; and the Timurides, or descendents of Tamerlane, retained possession of it till about the year of the Hegira 924, A. D. 1498; when Babur was depopulated of all his territories in Transoxiana and Khosrow, by Shahu and Khan, who obliged him to fly to India; and from that time Bokhara has always belonged to the Ubecks, who have maintained it by frequent wars with the Persians. Herbelot Bib. Or. p. 190.

Bokhara was eminently distinguished in former times by the arts and sciences which flourished in it, and by its famous university, to which students resorted from all parts, and in which the celebrated Avicenna was educated. As an emporium of commerce, it was also no less famous. To this place merchants repaired from all parts of India, from the different countries inhabited by the Tartars, from Persia, and even from the dominions of the grand signor on one side, and from Russia and Poland on the other; so that in the warehouses and markets of this city might be seen a great variety of oriental and European merchandise. About the middle of the 16th century it was visited by Anthony Jenkins, an Englishman, whose curious and interesting account of the mart of this city has been translated into several languages, and copied by the best writers. See Hacklau's Collection, p. 335. At that period, indeed, it sustained some injury from the vicinity of Samarcand; but since it became the seat of the Khan of the Ubeck Tartars, who is master also of Samarcand, which he visits only in the summer season, its commerce has revived, to which the convenience of its situation in no small degree contributes. When it was visited by the English agents in 1741, (see Hanway's Travels, i. 242.) it was large and populous, full of its Khan; standing on a rocky ground, with a flinty wall of earth; the houses of clay, but the numerous mosques of brick. The citizens manufactured soap and calicoes, and the chief products were cotton, rice, and cattle. From the Kalmucks they received flax and musk; and from the Bakschians, they used to receive lapis lazuli, and other precious stones; that city being computed at 16 days' journey from Bokhara.
BOKHARA. There was gold and copper coin; and after Nadir took this city, the Persian and Indian silver became common. The inhabitants were civilized, but perishing. In the 10th century it was distinguished by the manufacture of fine linen. N. lat. 29° 34'. E. long. 62°.

BOLI, a river of Africa, which rises in the country called Jellabonder, between the heads of the Senegal and Jella, and joins the Banning, or an arm of the Senegal, in the 47° of Brooko, in N. lat. 13° 11'. W. long. 59° 31'.

BOKIRA, a river of India, which runs into the sea, 50 miles W. of Junagur.

BOKSAJ, a town of Hungary, 10 miles south of Lugos.

BOL, FERDINAND, in Biography, a painter of history and portrait, was born at Dort in 1611, educated at Amsterdam, and placed as a disciple in the school of Rembrandt. He was chiefly distinguished by his portraits, which he painted in a free, bold manner, but not with that clearness of flesh, and remarkable relief, for which his master was famous. His colouring was too much tinged with brown in the caricature; but with this exception, his portraits had a great appearance of life and nature. As a painter of history, he manifested a good taste of composition, as well as a tolerable expression in some of his figures; but he was deficient in grace and elegance. His "Appointment of the 70 elders in the camp of the Israelites," and "Moses breaking the tables of stone," in the council chamber of Dort, are well designed and executed. In the chamber of the burgomaster there is an historical picture of "Fabricius in the camp of Pyrrhus," which is exceedingly admired. The etchings of this artist are bold and fine. The following, from his own compositions, are generally much esteemed; viz. "Abraham's Sacrifice," "St. Jerome, seated in a cave," "Holding the crucifix," and "Philosopher, holding a book." BOL died in 1681. Pilkington and Strutt.

BOL, JOHN, a painter of landscapes, history, and animals, was born at Mechlin in 1534, and completed his studies at Heidelberg. His subjects were views of several cities and towns in the Low Countries, and different prospects of Amsterdam; and in his pictures the vessels, with the reflections of them from the water, are admirably executed. His invention and composition were very pleasing; his colouring poetical great harmony and union; and his manner of sketching and pencilling is broad and fine. Van Mander highly commends one of the paintings of Bol, in diluter, the flory of which is "Dedalus and Icarus." This artist etched a set of landscapes, which are "views in Holland," in the style of a matter. He died in 1593. Pilkington and Strutt.

BOLA, in Ancient Geography, a town of Italy, the capital of the country of the Aequi, situated, according to Plutarch, 50 miles from Rome. Pliny places it in Latium. See Aequi.

BOLABA, A, more usually pronounced Borabora, in Geography, one of the Society islands in the southern Pacific ocean, situate four leagues N. W. of Otaha, and inferior to it in extent, being about seven leagues in circumference. The reef that surrounds it is nearly full of islets, much larger than those that are scattered among the rocks, enclosing Otaha and Uluta. It differs from those islands, and from Huahine, in having only one harbour on its coast, whereas the shores of the others, being strongly indented, form, like the coasts of Eimeo, numerous places of shelter for shipping. It is also distinguished by a very lofty, double-peaked mountain in its centre, and is more rude and craggy than the other Society isles. Its eastern side appears barren; the western more fertile; a low border, which surrounds the whole, and also the islands on the reef, are productive and populous. Its earliest inhabitants are said to have been malefactors banished from the neighbouring islands. As their number rapidly increased, and their military prowess gained reputation, they established their authority in Uluta and Otaha, and also in Maunova and Toohoo. Their conquests acquired to such a high state, that the supposed tutelary divinity of Bolabola, named Ooau, or Ooa, had been adopted by the people of Tiararaboo, in preference to two imaginary deities whom they formerly worshipped. The Bolabolan warriors are punctured in a different manner from those of the more eastern islands. Bolabola was discovered by captain Cook, together with the group called by him the "Society Islands," in July 1769; but though he took possession of it in the king's name, he did not land upon it either in his first or second voyage. But in 1777, he landed on this island, notwithstanding the account which he had received of its inhabitants, and was introduced to Ooau, who had been represented as a very formidable chief, but whom he found old and feeble, though still much esteemed and feared. Ooau was succeeded in his government of this and the neighbouring islands by his daughter, who, in 1774, at the age of 12 years, had been betrothed to a chief named Bobs, who governed Otaha under Ooau, and was designed to succeed him in the sovereignty. In 1791, when captain Edwards visited Bolabola, a man named Tsthahoe, had the chief authority. S. lat. 12° 32' 59'. W. long. 151° 54'. Missionary Voyage, Intro. p. 41.

BOLACA, in Ancient Geography, a town of Pelopennesus, in Tripillya, a country of Elis. Polybius.

BOLAVONASANDA, in Geography, a town of Siberia, in the government of Irkutsk, 30 miles N. W. of Ugha.

BOLBACH, a river of Germany, in the duchy of Stiria, which rises in a lake, 10 miles S. W. of Voitsberg, and runs into the Sulm, near Wippelsbach.

BOLBE, in Ancient Geography, a town of Afa Minor, in Caria, called also Heraclea.

BOLBE, a march of Macedonia, near the Ionian sea, before Apollonia, according to Scylax.

BOLDEC, or BOLLEVEC, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Havre; the place contains 4921, and the canton 14,717 inhabitants; the territory comprehends 105 kilometres, and 18 communes.

BOLBENA, in Ancient Geography, the name of a country in Afa, in the Greater Armenia. Ptolemy.

BOLBITINA, a town of Egypt, situate near the second mouth of the Nile, adjoining to the spot where Rosetta now stands.

BOLBITINUM OTIUM, a name given by Ptolemy and Pliny to the second mouth of the Nile, from that of the town, Bolbitina, seated near the canal called "Tell." The Bolbitine branch is now called that of Rosetta, Kofleta, or Rachid, which fed. Strabo informs us (I. 17. tom. ii. p. 1153) that, under the reign of Piamitchius, the Macedonians, with 50 vessels, landed at the Bolbitine, or Bolbetic branch, and there fortified themselves.

BOLBONACH, in Botany. See LUNARIA.

BOLBULLA, in Ancient Geography, a name given by Pliny to an island of Afa Minor, situate on the coast of Ionia.

BOLCA, in Geography, a branch of the Tyrolese Alps, situate 50 miles N. W. of Venice, and noted for foilli fish, in argillacous felsitus.
BOL

BOLCHERETSKOI, a town of Kamtschatka. N. lat. 52° 54' 30". E. long. 156° 37" 30'.

BOLCHOF, or Bolchof, a town and district of Russia, in the government of Orel, seated on the river Nagra, falling into the Oaca; 32 miles N. N. W. of Orel.

BOLD SHORE, in Sea Languages, a reef coast or shore, so that ships may approach close to it.

BOLDSON, an island of Sweden, in the province of Hallingland, having a good harbour.

BOLE, in Mineralogy, Bol, Germ. Bol, Fr. Argilla boles, Werner. The colour of bole is generally an obscure Flabella yellow, or reddish, or whithit brown; it is also sometimes, though rarely, met with of a greyish yellow, or fliehred; its surface is often marked with black spots and dendritic figures. It occurs generally massive, seldom diffimmated. Internally it exhibits a slight glimmering lufrte. Its fracture is perfectly conchoial. It flies, when broken, into irregular, sharp-edged fragments. The dark coloured varieties are opaque, the lighter coloured are more or less translucent. It has a greasy feel; adheres strongly to the tongue; gives a thinning ilreek; is very soft, and easily frangible. Sp. gr. 1.4 to 2.

When put into water it absorbs a portion with great eagerness, and then breaks down into small fragments, with a very sensitive cracking noise; but is not reduced to an impalpable powder. When finely pulverized, and diffused through boiling water, it remains tufpended in this fluid a much less time than any of the plastic clays, and is entirely separable by the filter.

Before the blow-pipe it turns black, and melts without addition, though with some difficulty, into a porous, greenish, grey fag.

According to a somewhat inaccurate analysis of Bergman, the Lemnian bole contains:

- Siliceous powder - - 47.
- Carbonated lime - - 5-4
- Carbonated magnesia - - 6-2
- Alumine - - 21
- Oxv of iron - - 5-4
- Moisture and volatile matter 17.

Bolc occurs in beds of wakke at Strigau in Sileia, and in basalt at Schelenberg in Saxonia; it is found also in Tuscany and Sienna in Italy, and in the island Lemnos in the Archipelago.

The only use of bole, at present, is as a coare red pigment; for which purpose it is calcined and leivated, and is vended in Germany under the names of Berlin and English red. Anciently, however, a very high rank was assigned to bole among the articles of the Materia Medica; it was considered as a powerful alltrigent, sudorific, and alexiphatic, that from Armenia and Lemnos being particularly esteemed. The Lemnian bole, in the time of Dioscorides, was dug up in the presence of the priests of Venus, and after being mixed with them with goats' blood, was moulded into cakes, which were impredded with the figure of a goat, in order to authenticate them; hence it was called Sapor Figillum Capritinum. It still continued to be a conccracted remedy even in the 16th century; according to Belon, the vein was opened annually on the 6th of August, and, after prayers paid by the priests, as much of the earth was taken out as was thought sufficient for the ensuing year; the entrance to the vein was then closed, and the severest punishments were denounced against any one who should open it without permission. Part of the earth was sent to Constantinople, where it was made up into small cakes, and received the feel of the emperor; the remainder was prepared in the island itself, and was impressed with the feel of the governor. The profits of this manufacture were too considerable not to be encouraged upon, and the bolar earths, and even the clayey marls of Italy, France, and Germany, obtained a place in the Materia Medica, under the general name of Bole. From which, however, they, together with the Lemnian earth, have been at length deferedly excluded.

Bolc is also used for the body or trunk of a tree; and hence boling trees are those whose heads and branches are cut off.

BOLEMOV, in Geography, a small town of Poland, in the palealtine of Rava.

BOLENA, a town of the Morea, in the duchy of Clarence, 5 leagues from the gulf of Lepanto; the see of a bishop, suffragan of the archbishop of Patras.

BOLENBERG, a small town of the duchy of Mecklenburg, on the Baltic.

BOLENE, or BOLLENE, a town of France, in the department of Vaucloie, and chief place of a canton in the district of Orange; 3 leagues north of Orange. The town contains 4064, and the canton 10352, inhabitants; the territory comprehends 1324 kilometres, and 7 communes.

BOLENIÆ, or BOLENE, in Natural History, a name given by ancient writers to a sort of stone of a roundish figure, and marked with several ridges and lines. They are supposed to be the same with those called Brotica and Ombrica, bothberg imagined to fall from the clouds in time of thunderstorms; but they are really no other than a common species of Echinus.

BOLENA, in Geography, a town of Spain in Arragou, 4 leagues from Huéca.

BÖLERAZ, a small town of Lower Hungary, in the upper outward district of the county of Preßburg.

BÖLESKO, a town of Hungary, 28 miles north of Topolzent.

BÖLESLAW, or BUNTZLAW, a circle of Bohemia, on the confines of Lutatia and Sileia, from which it is separated by mountains. The capital is Buntzlaw.

BÖLESLAWIEC, a town of Poland, in the palealtine of Siradâ, 24 miles S.S.W. of Siradia.

BOLETUS, in Botany (Gr. Boletos, from its globular form), a genus of the class cryptogamia, and of the order fungi, formed by Linnaeus, and disfigunised from the agarics by having what is generally the lower surface composod of tubes instead of gills. The name was given by the Romans to a species of eludent fungus, esteemed by them a great delicacy, and celebrated by their historians and poets for being the vehicle of the poison administered to Claudius Casar, by his wife the younger Agrippina. This has been generally supposed by modern botanists to be the Agaricus csernalisinus, thence called by Scheffer Cserenaus; but Withering thinks it was the deliciosus of Linnaeus. See agaric.

Among the moderns it was first adopted as a generic name by Tournefort, who applied it to the common morel, the fungus fagininosus of some of the older botanists, afterwards referred by Linnaeus to his genus phallos. La March, displeased with Linnaeus for altering Tournefort's names, has restored the name boletus to the morel, and has separated it from phallos on account of its not being perforated at its summit. He has, in consequence, divided Linnaeus's genus boletus into two; calling those that are shelfie and woody, agaricus, and those that are pedicellate and soft, faulis. The Linnaean agaricus he has named amanita, as Dillerius and Haller had done before him. Juflieu and Poirier concur with him in these alterations. But this, as Bosc well observes (Novveau Dictionnaire,
BOL

Dictionnaire, sub voce Boletus), is to increase a confusion already too great, and to overturn a nomenclature which has been generally adopted in Europe since the publication of the sexual system. For, however Linnaeus may have capriciously changed ancient names, and however it may be wished that, in the present instance, he had called his bole-
tus, agaricus, which would have preferred to the official agaric its customary generic denomination, it is better to let things remain as they are, than again to unsettle the language of the science, and thereby to impede its further advance-
ment. We shall, therefore, go on as we have begun, in
adhering strictly to the Linnaean nomenclature, where we are not induced to depart from it by weighty scientific
reasons.

Linnaeus has enumerated only fourteen species, and
Richard has made no addition to the number. Gmelin
has extended them to a hundred and seven; but there is
reason to suspect, that he has sometimes given the same
species more than once under a different name. The setting
of synonyms is in every part of botany an intricate and often
unsatisfactory business, but peculiarly so in the class crypto-
gamia. Withering, in the third edition of his Arrangement of
British plants, has described fifty-one species, many of
which have several varieties. In this number are included
eight of the Linnaean species. He disposes them under
three grand divisions, as they have central, lateral, or no
stems; and subdivides them according to the colour of their
stems.

None of them being cultivated, we shall confine our-
sew to those which are of British growth.

Stem Central.

* Tubas rubic. 1. B. pellucida. "Tubes decurrent, very
short; pores minute, angular; pileus concave, rich
brown, scaly; stem whitish, thick, short." 2. B. fabrianae.
"Tubes very short; pileus light brown, smooth, clothly
to the touch, regularly convex; flesh very white; stem pale
brown, covered with a beautiful white net-work on its
whole surface; root conical; resembles the elapholium in
habit." 3. B. cyanescent. "Tubes brownish with age, not
decurrent; pileus brown, convex, very fleecy; flesh white,
changing to a fine blue when exposed to the air; stem brown,
rounded at the base." 4. B. polyporus. "Tubes very short;
pores circular, extremely minute; pileus brown, irregular;
flesh very thin; stem brown, varying from perfectly central
to perfectly lateral, tough, thickening upwards." 5. B.
leptochepilus. "Tubes very short; pileus tawny brown, flat,
thin, leatherlike; stem brownish, thick as a crow-quill."
First observed in Britain by Mr. Dickson, growing on rotten
fitches. 6. B. aurantiac. "Tubes not decurrent, readily
parting from the pileus; pileus convex, full orange-red,
vivid, thin at the edge, and without tubes for about one-
teenth of an inch; stem whitis, rough, with coloured pimples,
spiny, lichen. It is eaten in France when young.

* Tubas feronii. 7. B. bovinus, Linn. "Tubes not touch-
ing the stem, unequal in length; pileus thin at the edge,
brown or olive, clammy, large; flesh spongy, white; stem
dirty white, with reddish stains, from three to seven inches
high, and about an inch in diameter." It varies in the co-
ours of its tubes and pileus, and in the smoothness of its
bristles.

* Tubas rubic. 8. B. fuliginous. "Tubes decurrent, ob-
long; pileus yellowish brown, with red brown, scurfy,
scars, the centre hollowed; flesh solid, pure white; stem
brownish, tapering downwards." 9. B. perennis, Linn.
"Tubes decurrent, not separating from the pileus, very
short; pileus flatish, hollow in the centre, fringed with hairs,
marked with alternate circles of brown and tawny, leatherly;
stem red brown, often excrescent, short, wiry, frequently com-
ing up so thick that the piles run into one another." There

is a variety of a cinnamon colour, within and without, the
B. cinereus of Jacquin, first found in this kingdom by
Mr. Dickson. 10. B. subfomentarius, Linn. "Tubes rather
Angular, of different shapes; pileus yellow, convex, fl relaxing,
smooth, somewhat woolly; stem yellow." 11. B. rubic. "Tubes
olive-colour, fixed to the stem; pileus rich red,
moistly oval; pileus red cinnamon, convex, to the
touch, rather clammy; flesh thick, spongy, buff-colour,
infantly turning blue when wounded; stem red cinnamon,
spongy within, and rich yellow, but infantly changing to
a blue." 12. B. piperatus. "Tubes decurrent, deep orange,
or earthy red; pileus brown, open, irregular; pileus yellow,
smooth, nearly flat, thin at the edge; stem greenish yellow."
Its pungency on the tongue and throat is like that of a cap-
fiem. First found in England by Mr. Soverby, in Hainant
loose from the stem, very short; pores angular; pileus co-

lor of brown horn, with a black circle at the edge, convex,
dimples, leathery, smooth, very thin, about an inch in di-
diameter; stem colour of brown horn, black at the base,
smooth." Chiefly found on rotten branches of hazel. 14.
B. nigripes. "Tubes decurrent, very short; pileus whitish,
the size of a pin's point; stem black at the bottom." * Tubas
color. 15. B. elapholium. "Tubes short, adhering firmly
to the pileus; pileus dead white, convex, but very irregular;
stem yellow, thick and short." 16. B. cudus. "Tubes not
fixed to the stem, readily parting from the pileus; pores cir-
cular, small; pileus brown, with ruff-coloured patches, nearly
globular, seven or eight inches across when fully expanded;
flesh white, greenerish when wounded; stem light brownish
yellow, tapering upwards." Buller reckons it a variety of
bovinus. 17. B. gregarius. "Tubes without, pores bluish-
unequal; pileus chefnut, smooth, thin, latitudinal; flesh white,
about three inches over; stem pale chefnut, pinky below, in-
separable swelling into the pileus. 18. B. tuteus. "Tubes
readily separable from the pileus; pores round, frail; pileus
dee brown, rather conical, frilled, vivid; flesh white, not
changing; stem dirty white, cylindrical, widening at the
weight, in proportion. 10. B. obovatus. "Tubes infantly
turning blue when wounded; pores bright yellow, round or oval;
pileus olive-brown; flesh bright yellow, turning blue when ex-
posed to the air; stem brown below, yellow or crimson
above." 20. B. fuscus. "Tubes a little decurrent, un-
equal in length, changing to deep blue; pores lemon-yellow,
angular; pileus crimson, changing to rich red brown, semi-
globular; flesh white, changing yellow to a buffish colour
when wounded; stem yellow, with broad crimson streaks, ap-
parently twisted." Found by Mr. Withering, near Birming-
ham, but only in one place. 21. B. ebraxyferent. "Tubes
decurrent; pileus gently convex, pinky-red; stem yellow
below, pinky upwards, swelling in the middle." 22. B.
flavus. "Tubes a little decurrent; pores irregular in shape
and size; pileus convex, deep orange; when young, shining
with a vivid varnish; stem yellow, cylindrical; curtain white,
leaving a ring." 23. B. ebraxyferent. "Tubes in contact with
the stem; pores very minute; pileus red-dish-buff, very con-

vex, vivid; stem bright yellow." The plant abounds with
a mild milky juice. Its flavour is like that of the agarius
campestris. 24. B. subrubrius. "Tubes short; pores min-
ute; pileus yellow, brown, olive, convex, thin, leathery;
flesh thin, white; stem dirty yellow, hard, tough, at
sometimes excrescent.

Stem lateral.

* Tubas rubic. 25. B. albicus. "Tubes decurrent, not
perpendicular to the pileus; pores angular, very irregular in
shape; pileus white, lobed; stem solid, sometimes only a
knob." The whole plant white, with a cottony substance,
which
which is easily rubbed off. 26. B. rugosus (Lucidus, Curtis).  

Pores very small; pileus chestnut coloured, thinning, flat, marked with concentric grooves; edge thick, wrinkled; item chestnut coloured, hard, uneven, thinning. 27. B. frondosus.  

Tubes decurrent; pores very small, sometimes confluent; pileus brown, lobed, tinged, leathery; item black at the base, very irregular and mitched; sometimes nearly two feet across. 28. B. lacteus.  

Tubes very short; pileus pinky-brown, smooth, oblong, convex, thin, curled in at the edge; flesh white; item black; whole plant leathery. 29. B. crinatus.  

Tubes short, not separating; pores irregular; pileus golden yellow, variously shaped, jagged, curled; item brown, woody, dilated, thick, porous. 30. B. fuscosus.  

Tubes short, flaming; pores large, angular; pileus pale buff, lined with feather-like scales; flesh firm, white, glutine; item dark coloured, white within. *Tubes yellow.* 31. B. rangiferinus.  

Tubes decurrent, ragged at the extremity; pileus an expansion of the item, dirty yellow; item dark brown, with one or more lateral branches, splitting at the end into several horn-shaped branches, either expanding into the pileus, or barren with yellow tops. The whole plant resembles the palmed branches of one of the larger species of deer. 32. B. calceolus.  

Tubes decurrent; pores small, unequal; pileus deep buff to chestnut, of a substance like cork, hollowed in the middle, thin, and waved at the edge; item tough, white, conical. 33. B. laterifolus.  

Tubes very short; pores very minute; pileus yellow, smooth, flat, very thin, leathery; item yellow, spreading out at the top to form the pileus.  

*Stemmata.* 34. B. tuberosus.  

Tubes pointed; pores irregular; pileus white, convex, thin, downy when young, smooth when old, perfectly resembling cork. 35. B. medullatus. "Wholly white, crystallous, spreading; pores small, on the upper surface only." On decayed wood and branches of trees. 36. B. sphyllum.  

Tubes very short; pileus semi-circular, whitish, smooth, thin, soft, leathery. 37. B. fuscovulvus (fllinillus, Dickson).  

Tubes very long, changing first to straw-colour, then to tawny; pores irregular; pileus smooth, semi-circular, white or tawny; flesh yellow brown. 38. B. sphylopinus.  

Pores fringed, angular; pileus often large, brown, woolly, turning quite black when old. 39. B. lachrymatus.  

Pileus orange-coloured, wrinkled, reticulated, with a broad, white, arched border; pores chiefly on the upper surface of the white border. Frequent in damp cellars. 40. B. vericolor.  

Tubes short, minute; pileus thin, velvety, striped with concentric circles of various colours. *Tubes brown.* 41. B. ceticarius.  

Tubes long; pores minute, rich yellow brown; pileus rich dark red, semi-circular, very uneven, with concentric ridges. 42. B. cryptarum.  

Tubes very long; pores minute; pileus leathery, thin, supine, becoming wooly when old. 43. B. hypriphoratus.  

Tubes long; pores finious; pileus rugged, zoned, woody; lobes many from one root. 44. B. alternus.  

Tubes short; pores labyrinthine; pileus leathery, woolly, with different shades of the same colour. *Tubes red.* 45. B. lactinius.  

Tubes very short; pileus brownish, arched, warty, thin, fringed at the edge. 46. B. abcinus.  

Pores angular; pileus thin, gently convex, wrinkled, woolly, greyish, whiter at the edge. 47. B. bipusius.  

Tubes short; pores minute, irregular; pileus bright aurora, streaked. 49. B. velatinus.  

Pores angular, irregular; pileus large, very irregular in shape, covered with a dense pyle of a silvery grey colour. *Tubes green.* 50. B. ignarius. "Tubes very slender; pores very fine, yellow, changing to red brown; pileus shaped like a horse's hoof, smooth, red brown to blackish." It is the official agaric, the agaricus amandus of La Maree. For the domestic and surgical uses to which it is applied, in different parts of the continent of Europe, and the manner in which it is prepared, see the article Agaricus, in Pharmacy. 51. B. fuscocrurus. "Pores circular, equal; pileus white, convex, thick at the edge, uneven."  

To the La Maree adds the agaricus quercinus of Linnæus, and observes, that it properly belongs to this species; for though it has the appearance of gills, they are really tubes with large mishapen pores, which near the edge of the pileus have a more regular form. Bulliard and Woodward incline to the same opinion; and we ourselves have already suggested that it seems to connect the agarici with the boleti. See Agaricus.  

*Boletus* (Haller). See Helvella Mitrata.  

*Boletus* (Tournefort). See Clathrus Cancelatus.  

*Boletus* (Tourn. Michel. and Haller). See Phallus Esculentus.  

*Boletus*. (Gled.). See Hydnium Refundum and Auriscalpium.  

BOLI, or BOLLI, in Geography, a town of Ablatic Turkey, in the province of Natolia, 140 miles, east of Constantinople, and 74 N.W. of Angora. This town is situated on a small river, which discharges itself into the Black Sea. It is the capital of a maritime canton, called by the Turks "Boli viatiflă, and in the interior part of its extent very mountainous. N.lat. 40°45'. E.long. 31°26'."  

BOLIDES, in Meteorology. See Fire-Balls.  

BOLINA, in Ancient Geography, a sea-port town of the Peloponnese, in Achaea, near Argysa.  

BOLINÆ, a river of the Peloponnese, which watered the towns of Argysa and Bolina, according to Pausanius. It discharged itself into the small gulf of Panormus.  

BOLINAO, in Geography, a sea-port town on the island of Loçan, or Manilla.  

BOLINBROKE, a town of America, in Talbot county, on the eastern shore of Maryland, 5 miles E. of Oxford. It lies on the N.W. point of Choptank river.  

BOLINGEA, in Ancient Geography, a people of India, near the Indus, mentioned by Pliny, Ptolomy, and Steph. Byz.  

BOLINGBROKE, in Geography, a small town of Lincolnshire, England, is seated in a valley between the river Witham and the sea-coast. Here was formerly a very considerable castle, which was nearly demolished by Oliver Cromwell and his partizans, who also laid other parts of the town, with the church, in ruins. In the times of feudal vassalage, the castle at Bolingbroke was distinguished among the pompous mansions of the nobles. Here the celebrated John of Gaunt, duke of Lancaster, occasionally held his court, and it was the birth-place of his fourth son, who was afterwards crowned king of England. He was the fourth Henry who sat on the English throne, and from the place of his birth was known by the name of Henry of Bolingbroke. The St. John family also derive the title of viscount from this place. The only manufacture of the place is earthen-ware, and that is very inconsiderable. In the parish are 73 houses, and 283 inhabitants.  

BOLINTHOS, in Natural History, a name given by Aristotle, and some of the other ancient Greeks, to the mouse of Abian, that is, the Bonaesus.
BOLPLEIKA, in Geography, a town of Ruffia, in the government of Saratof, on the west side of the Volga; 24 miles from Saratof.

BOLISSUS, in Ancient Geography, a town of Asia, in Asia, near Chio, according to Herodotus. Thucydes (I. 86) mentions a victory gained by the Athenians over the inhabitants of Chio near this town.

BOLKOF, in Geography. See Bolchor.

BOLKOWITZ, a town of Silecia, 30 miles south of Glogow.

BOLLANDISTS, in Literary History, a denomination given to certain Jesuits of Antwerp, who were a considerable time employed in collecting the lives and acts of the saints. — Thus called from J. Bollandus, one of the first and chief of the association.

BOLLANDUS, John, in Biography, a famous ecclesiastical historian, was born at Tilmount in the Low Countries, in 1596, and educated among the Jesuits, by whom he was employed in collecting memorials of the church-saints, under the title of "Acta Sanctorum." The plan of the work was formed by father Rofvede, and it was to be arranged according to the order of celebrating their memorials in the calendar. Bollandus, in 1643, published "The Lives of the Saints of the Month of January," in 2 vols. fol.; followed in 1648, by those of February, in 3 vols. fol. He had begun those of March, when he died in 1665. This work was continued by Hendechsins, Paprock, and others, on a scale of such extent, that the commencement of October reaches the 47th volume folio. Nouv. Dict. Hist.

BOLLARDS, large poles set in the ground on each side of a dock. On docking or undocking ships, large blocks are hauled to them; and through these blocks are reeled the transporting hawsers to be brought to the capstans.

BOLLEN, in Geography, a town of Germany, in the circle of Aulria, and duchy of Carinthia, 7 miles east of Millstatt.

BOLLENZ. See Bregrano.

BOLLIN, a river of England, which runs into the Mersey, 2 miles E.N.E. of Warrington.

BOLLITO, in the Glafs. Works, a name by which the Italians called a sea-green colour, or artificial crystal.

To prepare this colour you must have in the furnace a pot filled with forty pounds of good crystal, first carefully skimmed, boiled, and purified, without any manganese; you must then have twelve ounces of the powder of small leaves of copper, thence calcined, and half an ounce of zaffre in powder; mix them together; and put them at four times into the pot, that they may the better mix with the glass; stirring them well at each time of putting in the powder, lest they should swell too much and run over.

BOLLOS, in the mines of Peru, a denomination given to the ingots or bars of silver procured there from the ore by the operation of the fire, and the use of aqua fortis.

BOLM, in Geography. See Bulam.

BOLNEST, Edward, in Biography, practised medicine in London in the seventeenth century. He published, in 1653, "Chemia Medecina illustrata," or the true grounds and principles of the art of physic, 8vo. London, and the following year a translation of it into Latin "De lineamenti fundamento et principi. art. med."

BOLNKI, in Geography, a town of Lithuania, in the province of Wilna, 14 miles E.S.E. of Wilcovenitz.

BOLOGNA, or Bologna, a city of Italy, the capital of the Bolognese duchy, is, next to Rome, the largest, richest, and richest city in the Ecclesiastical State. Its ancient name was Felina, derived from Felinus, a Tufcan king, who is supposed to have built it 25 years before the foundation of Rome. The name of Bologna is traced by some to a fanciful Bltius, called Bonus; but others deduce it from the Bolli. Its circuit is between five and six Italian miles, and the number of its inhabitants is estimated at 80,000; but the whole district, which includes 535 cities, towns, and villages, is said to contain 76,500 persons. Its figure is oblong, the length of it much exceeding the breadth; and viewed at a distance, it bears some resemblance of a ship, the tower of Asinelli, which is 171 feet high, being the mast. It is surrounded by a solid and lofty brick wall, well built, and adorned with piazzas, which extend through the streets, and under which passengers may walk without being incommoded by the sun or rain. The houses in general have lofty porticoes, which would have a better effect if the streets were not so narrow; but in this particular, magnificence is sacrificed to convenience. For, in Italy, shade is considered as a luxury. This city is seated at the foot of the Apennines, in an extensive, fertile plain, which liberally supplies the inhabitants with its rich produce. The river Savona washes its walls, and the rivulet Reno passes through it, parting into several small streams; and the latter, by means of a canal, communicates with the Po, and affords great advantage to the city.

The public edifices of various kinds are numerous and magnificent. In the centre of the city stands a high tower, called degli Asinelli, from Gerardo Asinelli, who built it at his own charge in 1108; near it is the leaning tower, called Carriedo, which by a fall of part of it is now reduced to the height of 156 feet, and which inclines, so that a plumb-line let down from the top deviates seven feet from the wall at the bottom. Of the palaces in Bologna, that which is denominated the Public Palace is much the most spacious, though not the most elegant. In this the cardinal legate is lodged; and it has also apartments for the Gonfalonier, as well as halls, or chambers, for some of the courts of justice. This edifice contains some very magnificent apartments, and a few good pictures, of which the most esteemed are, a large one, by Guido, of the Virgin, and the infant Jesus, seated on a rainbow; a Sampson, also by Guido, refreshing himself with the water which issues from the jaw-bone, with which he has just defeated the Philistines; and a St. John the Baptist, by Raphael. The first object which strikes the eye of a stranger on his arrival at this town, is a noble marble fountain in the area before the Palazzo Publico. The principal figure is a statue of Neptune, 11 feet high, with one hand stretched out, and the other holding the trident. The body and limbs are finely proportioned, the anatomy perfect, and the character of the countenance severe and majestic. This figure of Neptune, as well as all the others of boys, dolphins, and seafarers, which surround it, are in bronze. The whole is the workmanship of Giovanni di Bologna, and is highly esteemed; and yet there seems to be an impropriety in making water flow from the breasts of the sea-nymphs or seafarers. Over the entrance of this palace is a bronze statue of pope Gregory XIII, weighing 11,200 pounds, and executed by Minganti. Near it is another statue of pope Boniface VIII. The interview between the emperor Charles V. and pope Clement VII. in 1529, when that prince submitted to be crowned by the pope, is recorded by an inscription on a copper-plate. In the Sampieri palace
are several pieces by the three Caracci; one of the best ever done by Albano, representing Cupid kissting his mother Venus, and, with an air of triumph, pointing at the rape of Proserpine by Pluto; and another, more admired than all the rest, and condemned by the judges as the master-piece of Guido, the subject of which is the "Repentance of St. Peter," and consisting of two figures, that of the saint who weeps, and a young apostle who endeavours to comfort him. Although the nobility of Bologna are not now very rich, many of their palaces are furnished in a magnificent taste, and contain paintings, particularly those of the celebrated masters which this city had the honour of producing, that are their chief ornaments, and are held in high estimation. The palaces were built, and ornamented, when the proprietors were richer, and when the finest works of architecture, sculpture, and painting, could be procured on easier terms than at present. The galleries and apartments are spacious and magnificent; and yet there are circumstances in the most splendid, that must hurt the eyes of those who are accustomed to that perfect exactness in finishing, which prevails in English houses. The glasses of the windows of some palaces is divided into little square panels, which are joined together by lead; and the floors of all are so indifferently laid, that you often feel a loose brick flaking under your feet, as you walk through the finest apartments.

Bologna is also emblazoned with a great number of churches and convents, which are enriched with a variety of paintings, sculptures, &c. Of the churches, of which there are said to be 2200, that of St. Petronius is the largest. In this church the emperor Charles V. was crowned in 1530; and on the pavement of it, in the form of a meridian line, confining of pieces of red and white marble inlaid, of a hand's breadth; those in which the signs of the zodiac are cut, are a foot square. This line is half the length of the church, which is 360 feet; and at its commencement is a Latin inscription, expressing that "the whole length of this meridian line, distinguished by the signs, &c. is the fix hundred thousand parts of the circumference of the terrestrial globe." On the pavement, at the end of the line, is an inscription in white marble, denoting the "meridian line from the zenith to the tropic of Capricorn." Opposite to the vertical point, is the date MDCLIII. A small round aperture has been made in the roof of the church, towards the south, through which the rays of the sun form a circular luminous spot, about eight inches in diameter, on the pavement, which shows the proper meridional point on the line every day. The church of the Dominicans is one of the most magnificent in Bologna. The chapel, dedicated to the honour of St. Dominico, who is said to have died at Bologna in 1221, is much admired. It consists of a curious dome, in which the glittering of gold appears throughout, adorned with the most capital paintings, representing the history of his life. His monument is of white marble, ornamented with beautiful baso-relievs, by Michael Angelo; and the altar, together with the large candlesticks that stand upon it, are of silver. The pavement and the walls are inlaid with marble of different colons. In the vestry is deposited, amidst jewels and various treasures, a manuscript of the Old Testament, or at least of the Pentateuch, pretended to have been written by Ezra himself. See B. E. It is a large folio, carefully preserved in a glass case, and was presented to the convent by the Jews, when they removed either from Rome, and were allowed to erect a noble synagogue about the close of the 14th century. The other principal churches are the Franciacon, in which are paintings by Faccin, Luigi, Caracci, Brizio, Guido, and Tiarini; that of St. Agnes, containing, ever the high altar, the martyrdom of the saint, 

by Domenichino; St. Bartholomew, before which stands a marble statue of St. Petronius, by Brunelli, and in which are an annunciation, the nativity, and the flight into Egypt, by Albano; the church of the Capuchins, in the vestry of which is a crucifixion, by Guido; that of S. Giovanni in Monte, famous for an admirable picture of St. Cecilia, by Raphael, which is much extolled by Addison, and reckoned one of Raphael's capital pieces, &c. &c. The churches also are enriched with valuable paintings and other ornaments, as well as the palaces and churches. A Dominican convent, seated on the top of a hill, about three miles from the city, is in possession of a portrait of the virgin Mary, said to have been painted by St. Luke. Sigoni says, that it was brought from the church of Santa Sophia at Constantinople in 1665, and it is thought to have brought many miracles in favour of the inhabitants of Bologna. A curious gallery, open to the south, and closed by a wall to the north, is built all the way from the city to the convent; on the open side it is supported by a long row of pillars; and was erected by voluntary contribution, in honour of the virgin, and for the convenience of pilgrims. This long colonade is about twelve feet in breadth, from the pillars to the wall, and about fifteen feet high; all the communities of the town walk, once a year, in solemn procession, to the convent, and bring the holy picture to visit the city. It is carried through the principal streets, attended by every inhabitant who can afford to purchase a wax taper. During this procession, the bells continue ringing, the cannon are fired, and the troops under arms practice the same ceremonies when the picture passes, as if it were commander in chief of the forces. In the library of the convent, belonging to the church of S. Salvatore, are many curious MSS.; particularly one of the history of queen Elifier, written on yellow coarse leather in large Hebrew characters, and done up in a roll or volume, according to the original signification of the word. The canons pretend that this was written by Ezra. Here is also shown a Hebrew MS. of the O. T. written on vellum, in 3 vols. fol. said to have been written in 953; it has, however, points or vowels. Among other MSS. amounting to about 500 in number, are the N. T. called the "Codex Bononiensis," said to be of the 11th century, containing the whole N. T. except the apocalypse, abounding with abbreviations; and a Greek version of the minor prophets and Daniel, supposed to be of the 10th century; and among the printed books are Manutius's edition of Cicero's works, 4 vols. fol. published at Milan in 1498, and a Latin bible in folio, which, by a printed advertisement annexed to it, appears to have been completed at Mentz by John Fulk and Peter Schoffier in 1402.

The university of Bologna is one of the most ancient and most celebrated seats of literature in Europe; it was founded, as Ione say, by the emperor Theodosius in 438, but others, with greater probability, attribute it to Charis the Great. For an account of the academy of sciences, see Academy. Over the gate of the magnificent edifice appropriated to that academy, is the following liberal inscription: "Bononieniec Scientiarum atque artium institutum ad publicum totius orbis usum." Here are an observatory, with the necessary instruments for astronomical observations; a very valuable library, in three spacious rooms, where any person may study and have the use of the books four hours every day; also, apartments for the students of sculpture, painting, architecture, chemistry, anatomy, astronomy, and every branch of natural philosophy. They are all ornamented with designs, models, instruments, and every kind of apparatus requisite for illustrating those sciences. There are also professors who regularly read lectures. There is a hall full of 

models
The anatomical theatre is adorned with statues of celebrated physicians; and the museum belonging to it supplies an abundance of anatomical preparations, and a complete suite of anatomical figures in wax: a man and woman are exhibited in the natural state, the same with the skin and cellular membrane removed, so that the external muscles of the whole body and limbs appear. In the subfequent figures the more external muscles are gradually removed, till nothing but the simple skeleton remains. These figures are very well formed, preferring the natural appearance and situation of the muscles and blood-vessels with all great exactness as could be expected in a work of this nature. There are also models in wax, of particular parts, and of several of the members of the human body separately.

The inhabitants of Bologna carry on a very considerable trade in silks and velvets, and leather bottles, which are manufactured here in great perfection. The country produces immense quantities of oil, wine, honey, wax, flax, and hemp; and furnishes all Europe with hams, dried tongues, farfages, macaroni, sweetmeat, olive, perfumes, wafh-balls, liqueurs, and effences. The people are industrious, and allowed to enjoy the fruits of their labour; the nuns are very ingenious in making artificial flowers, and imitating fruits of various kinds; and very beautiful works are also made of walnut-tree and rock-crystal. The markets are plentifully supplied with provisions; fruit is had in great variety, and of excellent quality; and the common wine of the country is a light white wine of an agreeable taste, which is preferred by strangers to any of the French or German wines that may be had there. The inhabitants, in general, are facetious and polite to strangers, who may receive at Bologna every kind of accommodation that may suit their taste.

Bologna long retained the name of a republic, sent an ambassadress to the pope's court, and the word "Libertas" was inscribed on the arms and coin of the late, with the flattering capitals S. P. Q. R. The civil government and police of the town were allowed to remain in the hands of the magistrates, who were chosen by the senate, which formerly consisted of 40 members; but since this republic came under the protection, as it is called, of the pope, he thought proper to add ten more; but the whole 50 still retain the name of the "Quaranta." One of the senators precluded in the senate, and was called the "Guelfonier," from his carrying the standard (Guelfonial) of the republic. He was the chief magistrate, was attended by guards, and was constantly at the palace, or near it, to be ready on any emergency; but he remained only two months in office, and the senators took it by turns. In the midst of all this appearance of independence, a cardinal legate from Rome governed this republic; he was appointed by the pope, with a vicc-legate, and other attendants. The orders which the legate inflicted, were supposed to be with the approbation of the senate; or at least, they never disputed the office, which was of higher dignity than any other in the gift of the court of Rome, and continued for three years; at the expiration of that time, his holiness either appointed a new legate, or confirmed the old one in the office for three years longer. This ecclesiastical viceroy lived in great magnificence, and had a numerous suite of pages, equerries, and halberdiers, who attended him in the city. When he went into the country, he was accompanied by guards on horseback. The gonfalonier and magistrates regulated all the usual matters which regarded the police, and decided, in common causes, according to the laws and ancient forms of the republic; but in affairs of great importance, and, indeed, as often as he chose to interfere, the cardinal legate without doubt influenced all decisions. This must be mortifying to the senators and noble families; but was left felt by the people in general, who exhibited every appearance of living under a mild and beneficent government. Bologna was the fee of an archbishop, who had for his suffragans the bishops of Crema, Borgo, St. Domino, Modena, Parma, Piacenza, and Reggio. Bologna is 23 miles S.W. of Modena, and 145 N.W. of Rome. N. lat. 44° 29' 36", E. long. 11° 24' 15". Keyser's Travels, vol. iii. p. 247. Moore's View of Society, &c. in Italy, vol. i. p. 252. See Bolognesi.

Bologna Stone. See Donjonian Stone, and Porcelain.

BOLOGNE, in Geography, a town of France, in the department of the Upper Marne, and chief place of a canto in the district of Chaumont, 6 miles north of Chaumont on the Moselle.

BOLOGNESE, Francisco, in Biography, an eminent painter of landscape and historiography, whose original name was Francisco Grimaldi, was born at Bologna, in 1606, and educated in the school of Annibal Caracci. He completed his studies at Rome; and his improvement was such, as to attract the attention of Pope Innocent X., by whom he was employed both in the gallery of his palace at Monte Cavallo, and in the Vatican. Among his numerous admirers and friends were the prince Pamphilj, the pope's nephew, and many of the principal nobility at Rome; Lewis XIV., and cardinal Mazarin at Paris, who procured for him a large pension, and employed him in decorating the Louvre; and after his return to Italy, the popes Alexander VII., and Clement IX. He was peculiarly happy in his execution of landscape; and was distinguished by his fresh and bold colouring, light and fine touch, and an elegant mode of composition. His landscapes in the manner of Caracci are models of the style of that school, though the colouring of them is thought to be somewhat too green. He understood architecture, and also etched, with great freedom, taste, and spirit, a great number of landscapes, partly from his own designs, and live after Titian. His agreeable manners and amiable disposition attached universal esteem. His benevolence was singularly manifested towards a Sicilian gentleman and his daughter, who had retired to Rome from the troubles of his country. They lodged near him, and were known to be so poor as to want bread. As from Bologna he was apprized of their situation, he repeatedly knocked at their door in the morning, threw in some money, and withdrew undiscovered. The Sicilian artist detected him in one of his acts of benevolence, and in token of gratitude fell at his feet. The painter raised and embraced him, and they continued mutual friends through life. Bologna died at Rome in 1658, and bequeathed considerable property to his six children. His principal works are at Rome, and consist of large landscapes, and historical pieces in fresco. The pictures of his best time are very rare, and afford large prices. His son Alexander was a good painter in the style and taste of his father, though much inferior. Among his engravings are the "Bronze Serpent," from a composition of his own, which, though slight, is a spirited, free etching, in the style of a painter. Pilkington and Strutt.

Bolognese, or the duchy of Bologna, in Geography, a territory
ritory of Italy, in the ecclesiastical state, bounded on the north by the Ferrarese, on the east by Romagna, on the south by Tuscany, and on the west by Modena; anciently inhabited by the Boii and Ligures. It was formerly a republic, under the protection of the emperor of Germany; but in 1278, it became subject to pope Nicholas III. After many vicissitudes, pope Julius II. in 1513, annexed the city of Bologna, and all its dependencies, to the papal dominions; and in consequence of its voluntary submission to the see of Rome, it was indulged in several privileges, which it continued long to enjoy without molestation. But after the city of Bologna was taken by the French in the campaign of 1796, the Legations of Bologna, Ferrara, Modena, and Reggio, entered into a treaty to form a republic, under the name of the "Republica Cispadana," or "Citalpine Republic," which was confirmed by the eighth article of the treaty of Campo Formio, October 17, 1797.

The soil of this territory is rich and fertile, and in the vicinity of Bologna it is so much improved by cultivation, that it appears like one continued garden. The vineyards are not divided by hedges, but by rows of elms and mulberry-trees; and the vines lying in a very beautiful picturesque manner, in fition from one tree to another. The country is not only fertile in vine, but likewise in corn, olives, and parrune, and has, not without reason, acquired the name of "Bologna la Grafia." The Bolognese affirm, that their cheese is not inferior to that of Parma, and they sell a great quantity of it under the name of Parmesan cheese. See Bologna.

BOLOGNETTI, Pompeo, in Geography, was born at Bologna in Italy, about the year 1616, where he received his education, and attaching himself to the practice of physic, was admitted doctor, and then professor in medicine, at the university there, in which capacity he was much admired, his lectures being unusually attended. His works are "Conflium de precautione occulente medicum, ab insulbibus iminentis contagii," Bono, 1610, folio; which perhaps gave birth to Dr. Mead's work on that subject, or suggested the idea of it. "Remors femens," 1650, 4to. Haller. Bib. Med. Eolv. Dict. Hist.

BOLOGNINI, Angelo, a celebrated professor of medicine and surgeon, who flourished in the beginning of the 16th century, was born in the neighbourhood of Padua, but practiced and taught medicine at Bologna. At thearnell in the treat of his pupils, he says, he published, in 1568, "De cura ulcerum interiorum, et de angustias communibus in solutum continuas," 4to. which has been frequently reprinted. He was of the school of Avicenna, on whose works he commented in his lectures. He gives forms for preparing ointments with mercury, which he highly extols, and says, they cure thules, though the salivary glands should not be affected, which, however, he admits to be defirable. The latter part of his life was spent in retirement at Padua. Alfrue. de Morb. Gal. Hall. Bib. Med.

BOLOTOVA, in Geography, a town of Siberia, 24 miles N.E. of Nertchink.

BOLSCHAJA, a town of Siberia, on the Irtil, 240 miles E.S.E. of Tobolik.

BOLSCHAKINA, a town of Siberia, 68 miles south of Orelenga.

BOLSEC, Jerom, in Biography, a carmelite of Paris in the 16th century, who defeterd his order on account of some free opinions, and became a refugee at Ferrara. There he commenced the practice of physic, and being acquainted with Calvin, removed to Geneva. In this city he divulged some opinions concerning predetermination, which excited the resentment of the Genevan reformer, and which induced the magistrates of Geneva, probably at his instigation, first to imprison him, and finally to banish him, as one convicted of sedition and Pelagianism. He was afterwards expelled from the canton of Bern, whither he had retired; and failing in his endeavors to ingratiate himself with the Protestants of Paris and Orleans, he returned to the bosom of the Catholic church. He then avenged himself by writing a very florid account of the life of Calvin in 1577, and another of that of Beza in 1582, the falsities of which faber Catholics are afloat to quote. He also wrote against Calvin's constitutions, and his arguments were afterwards made use of by Cardinal de Richelieu. Bolese practiced physic at Autun, and in Lyons, in which latter city he died, a few years after he had written Beza's life. Gen. Dict.

BOLSENA, in Geography, a town of Italy, in the Ecclesiastical state, and patrimony of St. Peter, delightfully situated on a lake that is of the same name, which is about 55 Italian miles in circumference. In this lake are two islands, namely, Bifentina and Martana, with a church in each island; in the former the unfortunate Amalasunta, daughter of Theodorie, king of the Ostrogoths, is said to have been put to death in 534, by order of the ungrateful Theodeutus, his cousin, whom the pope had admitted to a share in the government. We learn from Pliny, Hist. Nat. i. 95, that in his time these two islands were floating. He calls this lake Tarquinian, a name which it derived from Tarquinium, one of the principal 12 Etrurian cities, whose territories anciently extended to this lake; but it has been doubted, whether Pliny refers to the islands of this lake. Bolsena is adorned with mountains, covered with trees, forming a kind of august amphitheatre. On an eminence near it may be seen the ruins of the ancient "Volturnum." It is 7 miles S. of Orvieto.

BOLSOVER, a considerable market town of Derbyshire, England, has been noted for its manufactories of buckles, spurs, bridle-bits, ferrap-iron, and other similar articles; but the greater part of them is now made in Birmingham, and its vicinity. The town is governed by a constable, and two headboroughs; and a copyhold court is held here every three weeks. Here was formerly a castle, which, according to the Doornicz-book, was pillaged, at the Norman conquest of England, by William Pevere. It was of considerable extent, and from its remaining fortifications was evidently of great strength. Its fortress is mentioned by Leland, as being in ruins when he visited this part of England, in the time of Henry the Eighth. A modern mansion, still called the castle, occupies the site of the ancient buildings, and was erected by Sir Charles Cavendish in 1613. It is of square shape, and assumes the casemate character by towers at the four corners, and an embattled parapet. In this mansion, a superb entertainment was given by William Duke of Newcastle, to Charles the First and his queen in the year 1635. Upon this occasion, all the neighbouring gentry were invited to partake of the festival, which was conducted upon so magnificent a scale, that the expenses were estimated as amounting to 15,000l. Grand pageants, &c. were represented before the royal guesrs, and the fancy and tale of Ben Jonson were employed in preparing speeches and fecence upon the occasion. It now belongs to the Duke of Portland, whose family obtained it by marriage with a daughter of the Earl of Oxford. In the parish church is a magnificent monument to the memory of the above-named Sir Charles Cavendish, many of whose family are interred here. Bolsover has a weekly market on Fridays, one annual fair, and a fair fair for hiring servants, &c. It is 8 miles from Mansfield, and 135 N. W. from London. In the parish are 435 houses, and 1057 inhabitants.

2
At Elton, a small village three miles N. E. of Bolsover, was born Fedediah Burton, a man who, though only a poor labourer, acquired extraordinary celebrity, for his retentive memory, and recondite powers of calculation.

Three miles north of Bolsover are the great coal works, called Norbzig's Colliery. These belong to the Duke of Portland, and are let out to a company of persons who lend great quantities by the canal to Workop, Redford, Stockwith, &c. Bibliotheca Topographica, No. 32.

BOLSTER, among Surgeons, a de fult yielding substance either hid under the head or a broken limb.

Bolster is also used for a flaffing, intending to fill out or raise a flat, finking, or hollow part. In which leave bolsters are contrived for crooked, punched, and other diisorted backs, shoulders, &c.

Bolsters of a faddle, in the Mingage, those parts which are raised on the bows, both before and behind, to reft the rider's thighs, and keep him in a posture of withflanding the disorders which the horse may occasion. Common faddles have no bolsters behind, or even before.

Bolsters, in Sea Language, small cushions or bags, filled with tarred canvas or rope yarn, &c. and placed under the shrouds and stays, to prevent their chafing against the treffe-trees, by the motion of the maff, when the ship rocks at sea.

Bolsters are also pieces of fir fayed upon the upper side of the treffe-trees, and againft the thwart-flip fides of the maff-head. They muft be sufficiently long to clear the fid-hole and after cross-tree, and broad enough to project one inch and a half, or more, without the treffe-trees, and the fame in depth, and rounded from the upper to the lower edge on the outsife, and nailed to the treffe-trees at each end. Their ufe is to prevent the shrouds chafing by the motion of the maff.

Bolsters of an anchor are cylindrical pieces of iron, with a hole through the middle, used when holes are to be punched, or opened with pins.

BOLSWAERT, BOLSIVERD, or BOLSIVERT, in Geography, a town of Friesland, in the United Netherlands, faid to have been built in 713 by Bolfwine, fon of Radbode, king of Friesland, from whom it took its name. It was almoft burnt down in 1495, and again in 1515, when it was rebuilt and encompaffed with a rampart of earth. About a league from this town is a port, which, though much obftructed by fun, is very useful to the inhabitants.

Bolswvert is about two miles in circumference, and was formerly one of the Hanfe towns; and a great part of the Friesland baize, which formed a confiderable article of exportation, was won in this place. It is distant 13 miles S. W. of Leeuwarden, and 7 S. E. of Haringen. N. lat. 53° 2'. E. long. 5° 24'.

BOLSVERDE, or BOLSIVERD, BOUTIUS ADAM A., in Biography, an engraver and printseller of Antwerp, derived his name from Bolfwert in Friesland, where his family resided, and flouriffhed about the year 1620. He worked only with the graver, and successfully imitated the free, open style of the Bloemarts, in whose school he probably perfected himself in his art. When he worked from Rubens, he altered that style, and his plates are neater, fuller of colour, and more highly finifhed. His plates from Bloemart are a fet of "Twenty landfipes," "The forest of the hermits and hermitfes of Egypt and Palestine," and "The Nativity of Christ," and those from Rubens, in a more finifhed style, are the "Resurrection of Lazarus," and its companion "The Last Supper," which is a very beautiful engraving. Strutt.

Strutt, of BOLSVERDE, SCHELTIUS A., brother of the preceding, flourifhed about 1626, and worked entirely with the graver. His general character, as an artist, is thus described by Bofan: "We have a large number of prints, which are held in great esteem, by this artist, from various masters, but especially from Rubens, whose pictures he has copied with all possible knowledge, taste, and great effect. The freedom with which this excellent artist handled the graver, the picturifque roughness of etching, which he could imitate without any other affifting instrument; and the ability he possessed of diftinguifhing the different minds of colours, have always been admired by the connoiffleurs, and give him a place in the number of thefe celebrated engravers, who are declaimed of rendering their works as useful as they are agreeable, and of acquiring a reputation, as lafiting as it is juftly merited." His prints are the exact tranfcripts of the pictures from which he engraved them; and his laft works, though not equally neat or finifhed, are always beautiful and indicate the hand of a master. His bolifled engravings are from Rubens; and his neats from Vandyck and Jordans. Some of this master's works have been carefuily copied, so as easily to deceive the uninformed. Among the elabo rate engravings of this artist the following are mentioned: viz. the "Erazen Serpent," from Rubens; "Abraham offering his Son Isaac," from Theodore Rombout; the "Education of the Virgin, by St. Anne," the "Marriage of the Virgin," the "Nativity of Christ," the "Adoration of the Wise Men," the "Feast of Herod," in which the daughter of Heraldis is exhibited, prefenting the head of John the Baptist to his mother, and the "Miraculous Draught of Fishes," all from Rubens; "Christ crowned with thorns," Vandyck, and a "Crucifixion," from the fame, in which a figure appears prefenting the sponge to Chrift; St. John and the Virgin are seen flanding at the foot of the crosses, and Mary Magdalene reeling towards it. This is one of his most beautiful engravings. The firft impressions, in which the left hand of St. John is not feen, are very scarce; in the second, the hand appears upon the shoulder of the Virgin; but in subsequent impresfions, the hand was again erased. Strutt.

BOLT, in Building, an iron falling for a door, moved with the hand, and catching in a flaple or notch made to receive it. Bolts are chiefly of three kinds: plate, round, and spring-bolts.

Bolt of a lock is the piece of iron which, entering the flape, falls the door; being the part which is moved backwards and forwards by turning the key. Of these there are two forts; one fluits of itself by only putting to the door, and is called a spring-bolt; the other, which only moves when the key open'd or shuts it, is called a dormant-bolt.

Bolt is also used for a large iron pin, having a round head at one end, and at the other a key-hole or slit, wherein to put a pin or falling, serving to make fast the bar of a door, window-shutter, or the like.

This is more particularly called a round-bolt, or window-bolt.

Bolts, in the Artillery, are of several forts; thofe which go between the cheeks of a carriage to strengthen the tranfoms are called transom-bolts. The large iron bolts or knobs on the cheeks of a carriage, keep the handspike from fiding, when it is poising up the breech of the piece. The two short bolts that being put one in each end of an English mortar-carriage, serve to traverse her, are called traverse-bolts. The bolts that go through the cheeks of a mortar, and, by the help of quoins, keep her fixed at the elevation given her, are called bracket-bolts. And the four bolts that fallen the bracket or cheeks of a mortar to the bed, are called...
BOL

BOL

called bolt-bolts. Besides these there are boltier, eye, breech-
ing, garnish, joint, floor-bed, and axle-tree bolts. See Car-
rige.

Bolts, in Carpenter, denote pieces of wood cleft with
wedges, in order to be split into laths.

Bolts, or iron pins, in a Ship, are of several sorts, of
which the most common have small round heads, and are
used to unite two or more pieces together. Some have
round flat heads, called flauzer-heads, with a mortise in
the other end, or point, and are used to fallen moveable
pieces to those that are fixed; others have an eye at one end,
for lashing or hooking blocks, &c. and are driven in maft-heads,
yards, caps, &c. Some have a square part left at the back
of the eye, that they may not be driven on the eye, and
danger splitting. Bolts are frequently distinguished accord-
ing to the places where they are used; as, chain-bolts, bolts
for carriages, &c.; ring-bolts, serving for the bringing-to of
the planks, &c. driver-bolts, used to drive out others; set-bolts,
employed for forcing the planks, and other works, and
bringing them close to one another; ring-bolts, on each side
full of jags or bars, to keep them from flying out of their
holes; cleflb-bolts, those which are clenched or fatallcd at
the ends where they come through; fore-lock-bolts, made
like locks with an eye at each end, whereunto a fore-lock of
iron is driven to prevent flarting out; finder, or finder-bolts,
made with long and thick heads, flack into the untermoft
bends or wales of a ship, to fave her fides from bruises and
hurts. The following machine for drawing bolts in and out
of ships was invented by Captain Bolton of the Navy, and
obtained from the Society of Arts their prize of the gold
medal. A model of it is preserved in the repository of the
society for the use of the public. The description of
it (See Transactions of the Society, vol. xvi.) is as
follows:

AAAAAA (Plate of Ships) is the frame of the machine.
B, a cylindrical tube, having a female screw in the inside.
C, a wheel with teeth attached to the cylinder B. D, an
endless screw adapted to the wheel C. E, handle of the
winch. F, the bolt drawing out. G, blocks to support
the frame. H, a hollow piece of fléce, having on its out-
side a male screw, whose threads work within the female
screw in the cylinder B. To this piece of fléce the bolt is
to be rivetted. I, a semicircular piece of fléce, which is to
be introduced into the notches on H, when a similar notch
has been cut in the head of the copper bolt, which by this
means is prevented from turning in H, while drawing. K,
the bolt, as prepared to receive the machine. L, a fléce bar,
whom smaller than the bolt to be drawn, having at one
end a male screw, A, and at the other end another male
screw that fits into the female screw in B. M, a female
end of a male screw, having a square hole larger than the
bolt. N, a bolt with a male screw at one end ready to be
drawn in.

The machine, of which a plate is annexed, consists of a
frame supporting a cylindrical female screw tube. On this
tube is mounted a wheel with teeth adapted to an endless
screw fitted to the frame, and worked by a handle.

To draw the bolt out.

The head of the bolt must be cut off, and a hole made
in the timber big enough to receive the male screw H, which
is put over the bolt: a split is then to be made, either by a
faw or cold chisel, in the head of the bolt, to receive the
key I, and which corresponds to the split in H; the bolt
head is then to be rivetted as firmly as possible upon H: the
cylindrical tube, D, is then to be screwed on, turning the
whole machine round till it can be done longer, when
the endless screw is to be used. If the machine is of a pro-

per strength, and the rivetting well done, the power is sufh-
c as to extract the bolt or break it, but generally it will be
drawn out uninjured.

To draw bolts into ships.

It will be necessary to have a bar, L, which is recommended
to be made of steel, long enough to pass from the outside
to the opposite of the ship, and somewhat thinner than the
copper bolt intended to be drawn in. This may be called a
conductor. On one end should be a male screw, a; the
bolt to be drawn in should be tapped at one end to receive
the male screw, a, on the conductor, and at the other end
should be another male screw that fits into the female screw
in B; after which the operation is the same as drawing a
bolt out, and the machine should be applied accordingly.
When the bolt arrives at its destined place, it may be secured
on the inside by a nut, which is as good a way of fastening
as clinching, and much more expedients.

This machine, though only of the height of eighteen
inches, will draw bolts in or out of any length; for, after
the bolt has riven to the top of the tube, it will only be
necessary to screw the machine back, and follow up the work
with blocks of timber, as represented in the drawing.

Note. If the upper part of the hole in H be made square,
larger than the round hole as shown at M, and the head of
the bolt rivetted into it, it will do away the necessity of the
key, I, render the machine kfs complicated, and save much
time and trouble.

Bolts of an Anchor, are cylindrical iron pins for fasten-
ing the two parts of the flock together.

Bolts for shibors, in Rope-making, are large iron pins
with round heads, driven in the board or the crank-wheel
for the whirr to run on.

Bolt is also used for a measure or certain quantity of can-
avs, amounting to twenty-eight ells.

Bolt of silk or fluit denotes a long narrow piece, of in-
definite measure.

Bolt, peake, in Essex, denotes the peaf-draw, when the
grain is threfhcd out of it.

Bolt, thunder. See Thunder-bolt.

Bolt-ropc, in Saxon Language, is a rope sewed to the edges
of a fail, to prevent it from rending by the force of the
wind, or any other cause.

A bolt rope should be made of fine yarn spun from the
bolts hemp, and sewed neatly on with good twine. To avoid
stretching, the rope must be kept well twistcd while sewing
on, and care taken that neither too much nor too little
slack is taken in: that part of the rope at the lecc of the
fail is to be crofsed at every foot in length, at every
seam, and in the middle of every cloth at the foot, with
crofs stitches: four crofs stitches should be taken at all
the beginnings and fastenings off; the firdt stitch given twice,
and the last three times. Small fails have two crofs stitches
at every seam, and three at every fastening off.

Bolted flour, that which has passed through the
bolter.

Bolter, in Building, any prominence or jutting out,
as of a piece of timber, end of a beam, or the like, advancing
beyond the naked of the wall.

Bolters, or Bolters, a kind of sieves for meal,
being the buttons made of woolen, hair, or even wire.
The word seems to be preferred by the Germans, deelal, a fieve;
whence also beetlen, to bolt. The bakers use bolters,
which are worked by the hand; millers have a large fort,
worsoht by the motion of the mill.

Bolt-head, a vessel used by the chemists, the fame
as metrafs; which see.

Bolt-head, in Geography, a promontory of England, on
the
the south-coast of the county of Devon, 19 miles S. E. of Plymouth. N. lat. 50° 9'. W. long. 30° 47'. The promontory 44 miles W. N. W. of this is called Belt-tail.

BOLT and TON, in Harlesey, is a bird bolt in pale piercing through a ton.

BOLTING, or Boulting, the act of separating the flour from the bran, by means of a sieve or bolter.

Bolting-cloth, or Boulter-cloth, sometimes also called bulling-cloth, denotes a linen or hair-cloth for fitting of meal or flour.

That kind of bolting-cloth which is used for fitting of meal, and also for a variety of needle-work, for young ladies' Samplers, and for filling up the frames of window-pane, &c. is waved after the manner of gauze of fine-spun woollen yarn. The wool necessary for making this cloth must be long, well-coated, and spun to a fine equal thread, which, before it is powdered, must be scalded in hot water, to prevent it from shrinking. The web must be stiffened; and in the manufacture of it the English have the advantage of the Germans, whose cloth of this kind is much cheaper, but much inferior in value to that of England. The bolting-cloth of this country is stiffer, as well as smoother, and the flour passes through it much better than through that of the Germans, which is either very little or not at all stiffened. A manufactory of this cloth was established at Otla, near Dresden, by one Daniel Kraft, about the end of the 17th century; and at Hartau near Zittau, it was introduced by one Plewsky, who learned the art of making it in Hungary. The cloth, which is sent from hence for sale, not only everywhere round the country, but also to Bohemia, Moravia, and Silesia, is woven in pieces, containing each from 65 to 65 Leipzick ells; the narrowest being 15, and the widest 14 inches in breadth. Large quantities of it are also made by a company in the duchy of Wurttemberg. Bolting-cloth is also made at Gera, as well as at Potsdam and Berlin; at the latter of which places there is a manufactory of it carried on by the Jews.

Bolting-mill, a veritable engine for fitting with more ease and expedition. The cloth round this is called the bolter.

The method of applying a sieve in the form of an extended bag to the works of the mill, that the meal might fall into it as it came from the stones, and of causing it to be turned and shaken by the machinery, was first made known in the beginning of the 16th century, as we are expressly told in several ancient chronicles.

Bolting, or Boulting, among Sportsmen, signifies rounding or dilating a fox, rabbit, or badger, from its retreating place.

Bolting, in Law, a method of pleading, or arguing, formerly in use in the courts of law; inferior to mounting. The cause is argued first by three students, then by two barristers; an ancient, and two barristers sitting as judges.

The word comes from the Saxon bolt, a hovel; because done privately within doors, for instruction.

BOLTON, Edmund, in Biography, an English antiquarian writer of the 17th century. By religious protestion he was a Roman Catholic, and probably enjoyed some office under Villiers duke of Buckingham. He was diligent in his researches into subjects of history and antiquities, and was the author of several works, of which the principal are the following; viz. "A Life of Henry II.;" "Elements of Armories," Lond. 1610; "A translation of Florus;" "Nero Cæsar, or Monarchy deprraved," Lond. fol. 1624, in which he attempts to establish the improbable opinion, that Stonehenge was a monument to the memory of queen Boadicea. His "Vindiciae Britannicae," left in MS., was designed to prove the great antiquity and early importance of London. From all his performances, Bolton appears to have possessed the credit, national, and love of trifles, often attendant on antiquarian studies, when they are not directed by taste and judgment. The time of his death is not known. Biog. Brit.

Bolton, in Geography, a village of Yorkshire, in England, had a very considerable monastery of canons regular, of the order of St. Austin, founded in 1120 by Robert de Romel, and this had afterwards other benefactors, and at the dissolution its annual revenues were valued at 212l. Part of the religious house still remains, and one room is appropriated to a free school, which was founded by Robert Boyle, &c. This village is rendered remarkable from the birth-place and residence of Henry Jenkins, who was born in the year 1500, and lived to the age of 169 years. He enjoyed a constant state of good health, and polished his faculties to the last year of his life. See LONGEVTY.

Bolton-le-Moors, is an ancient manufacturing town of considerable consequence in Lancashire, in England. It may be considered as the original seat of the cotton trade in this country, and for the manufacture of ornamental and fancy goods is still particularly celebrated. Leland, in his Itinerary, notices the cottons (then a species of woolen) and coarse yarns which were brought to this town in his time, and observes, that many villages in the vicinity were engaged in this manufacture. Coal-pits were also worked at that time, and coals are still obtained in abundance from pits in the neighbourhood. The making of fustians was introduced into this town, at a very early period, and still continues a prominent object of trade. During the civil wars in the reign of Charles I., Bolton was besieged by prince Rupert in 1644, and many of the inhabitants were killed. The town is well built, and has rapidly increased in size and population. It is seated in a flat district, as its name partly implies. The advantage of canal conveyance to Manchester and Bury, has proved highly important to the town, whose manufactories are thereby greatly promoted. Bolton has a free school, of which Ainsworth, the author of the Latin dictionary, was once a master. The prosperity of Bolton may be partly estimated from the following comparative state of its population. In the year 1773, there were 5539 inhabitants in this town and Little Bolton. These were augmented to 11,739 persons in 1789; and in 1821, when the population of the country was estimated by order of the house of Commons, there were found to be 3476 houses, and 17,413 inhabitants in the township and chapelry of Great and Little Bolton. The principal mart for the sale of goods made at this place is Manchester, where the manufacturers resort on Tuesdays, Thursdays, and Saturdays. "The neighbourhood of Bolton," observes the judicious Dr. Aikin, "has been distinguished for producing men of great talents in mechanical invention, who have generally been wholly undoubted, and indebted only to native powers, and the habit of observation. The most celebrated of these was Sir Richard Arkwright, of whom false pride and prejudice alone can think it derogatory to say, that he puffed a great part of his life in the humble station of a barber in the town of Bolton. His mind was so ardently engaged in the improvement of the mechanism used in the manufactures, that he could scarcely keep above want by the exercise of his proper profession; but his perseverance and ingenuity were at length rewarded with a measure of opulence, which nothing but the tide of prosperity in a commercial nation could bestow." See ARKWRIGHT.

At Smithells, an old hall, or mansion, north of Bolton, formerly belonging to the Fauconberg family, is a curious old
old wainscotted room, the panels of which are adorned with upwards of 53 heads, cut in wood. This hall is shown and visited as a curiosity, from a superficially prevalent opinion that an impression of a foot may be felt in the floor made by one Martin Martyr, in the reign of Queen Mary.

Bolton, in the parish of Bolton, is a conical hill, crowned with a building called Rivington-pike. Some relics of lead and calamine have been worked in this neighbourhood, but have not hitherto proved very fortunate to the adventurers.

Bolton is 11 miles from Mancheister, and 197 miles N. W. of London. It has a market on Mondays, and two fairs annually. Aikin's Description of the Country round Manchester, 4to. 1795.

Bolton, a township of America, in Chittendens county, Vermont, seated on Osion river, about 104 miles N. E. from Bennington, containing 85 inhabitants.—Alfo, a township in Tolland county, Connecticut, incorporated in 1726, and settled from Westfelfeld, Hartford, and Windsor, 14 miles E. from Hartford.—Alfo, a township in Worcefter county, Massachusetts, 18 miles N. E. from Worcefter, and 34 W. of Bolton; containing 861 inhabitants, and a good bed of lime-estone.

Gen. Char. Cal. commo-n; imbricate, with nearly equal linear, acute scales. Cor. compound, radiate; florets of the disk tubular, funnel-shaped, five-leaf, numerous; of the ray many, linear, entire, pelluviferous. (Schreb.) three-toothed. (Bofc.) Pil. gern ollong; style filiform; stigma two, thole of the ray ollulate. Primarc. none; calyx unchanged. Seed solitary, imbricapped, slightly toothed, two-horned; receptacle naked, honey-combed, hemispheric.

Species. 1. B. afterfides, (marticaria all. Linn. Munt. 110.) "Leaves quite entire." Stem upright, two feet high, even, scarcely angular, slightly streaked; leaves alternate, remote, felifle, lanceolate, even, bent down at the base, ragged about the edge; panicle thin, filiform, with one- or two-flowered peduncles; disk yellow; ray pale fleil-coloured. 2. B. gigliifolia. "Lower leaves ferrate." Five or six feet high. Both species are natives of South America, flower late in the autumn, and were cultivated by Mr. Miller in 1758.

Boltsacken, or Boltsack, in Geography, rocks at the N. entrance of the Great Belt, 5 miles S. E. from the island of Samoc. N. lat. 55° 40'. E. long. 10° 40'.

Bolty, in Ichthyology, a fish of the Labrus genus, (Lobrus niloticus of Linnæus), that is found in the Nile. It is figured and described by Sonini, in his "Voyage en Egypte." This, it is observed, is one among the small number of fishes that inhabit the river Nile, the flesh of which is delicate, and of a good flavour. Daubenton, in the French Encyclopedia, calls the species Nebuloxus, on account of the obscure spots with which the fins are marked.

Boltznitz, in Geography, a river of Germany, which runs into the Elfler near Elflerwaards, in the margraviate of Meifen.

Bolus, a mountain of Asia, in Armenia, 144 miles S. E. of Erivan.

Boluadin, a town of Atfatic Turkey, in the province of Natolia, 28 miles N. of Kara-huffar.

Boluc biffi, in the Turkish Affairs, denotes the chief of a company, or a captain who has the command of an hundred janizaries.

Bolukus, in Ancient Geography, a town of Greece, in Thebpratia.—Alfo, a town of Illyria, which belonged to the Trojans. Steph. Byz.

Bolus, in Pharmacy, is a very useful form of extemporeous prescription adapted to a variety of cases in which a more solid or a more liquid form would not answer the purpose. The consistence of a bolus is the same as that of an electuary, that is, about as soft as dough, so easily to flood down the throat without falling to pieces. As it must in some degree be taffed while swallowed, it generally conlicts of the medicine in powder, worked up to the proper tenacity by means of some grateful syrup, soft extract of liquorice, or a palatable conserve; or, if the medicine be an oil, balsam, or other liquid, dry sugar, with flour, almond-pales, and the like, are added to bring it to the due consistence. It is intended to be only a single dose.

The substances most proper to be exhibited in this form are those that are very heavy, and scarcely to be suspended in any liquid so as to be drank off, such as coloſem, tin-powder, ftele-shings, nitribof mineral, or those that are too bulky to be made into a convenient number of pills, and are nauseated by the patient in a liquid form, such as cinchona, chamomile, burnt-ponce, Deaver's powder, valearian root; or some of the stronger acids and aromatics, as guaiacum, camphor, mufk, ealto, ammonia; or those that are little soluble in the fomach, unlefs previously mixed with some easily foltile matter, and yet do not readily combine with liquid fufficient to be drank off, as oil of turpentine, the balfams and the like, mixed with sugar and flour. Bolufes differ from troches in this, that the latter are made firmer, though equally foltile, and being intended for slow folution in the mouth; they confift only of infipid, or not unpalatable ingredients. Substances that readily become very moif, such as the kali preparatum, fould not be used in this form, unlefs the bolus is intended to be taken immediately; but on this head lps caution is required in compounding electuates.

This form of medicine should be avoided where the patient is in a flate in which the power of swallowing is with difficulty exercifed, as in apoplectic, and other conmute disorders; in fome fplanitic and painful affections of the throat; or where the œphagus is naturally very narrow. Alarming accidents have sometimes arisen from a neglect of these precautions. It is likewise difficult to get very young children to swallow them, unless made extremely thin. These minutiae will not appear trifling to thoée who are in the habit of personally witnessing the trouble and difficulty which daily attend the exhibition of medicines, and are fo liable to defeat the most judicious plans of the prescrifer.

In hospitals and dispensaries this form is very commonly adopted, as it is prepared with little trouble, and is economical in the more expenfive drugs, no more of them being employed than the immediate wants of the patient require.

Bolus-head, in Geography, a cape of Ireland, on the south-west coast of the county of Kerry, 38 miles S. W. of Killarney. N. lat. 51° 44'. W. long. 12° 12'.
BOLYWICK, a town of Norway, 40 miles W. of

Tønsberg.

BOILZANI, Urbano Valeriano, in Biography, one of
the revivers of literature in the 15th century, was born at
Belluno about the year 1440. Having entered, when young,
to the order of the Minories, he travelled through Egypt,
Palestine, Syria, Arabia, Greece, and Thrace, observing
whatever was curious either in nature or art. In the course
of his perambulations, he twice ascended the summit of
Ætna, and surveyed its crater. As a strict observer of his
vows, he declined accepting the honours and dignities
which were offered him. His fixed abode was at Venice,
where he taught the Greek language, and, among other
scholars, instructed the learned Gian-Antonio Flaminius,
and John d'Medici, afterwards pope Leo X. He was the first
who facilitated the attainment of the Greek, by composing
a grammar in that language; of which the first edition was
printed in 1497, and a second, much enlarged, in 1512. He
died in 1524.

BOILZANO, or Boilzen, in Geography, a town of Ger-
many, in the Tyrol, seated on the river Eysac, near its con-
fluence with the Adige, famous for its four annual fairs, each
of which continues a fortnight, which are much reterted to
by Italian and German merchants; 6 leagues S. W. of
Brixen, and 9 N. of Trent. It was taken by the French in
March, 1597. N. lat. 46° 28'. E. long. 11° 14'.

BOILZANO, a town of Italy, in the Vicentin, belonging to
the State of Venice, 2 leagues E. of Vicenza.

BOIL, in Zoology, the name of an American serpent of the
Boa genus, called Likiefe bone, and boma. It is said
to grow to a vail size, and to be perfectly harmless; but the
latter affirmation is improbable; it is not certainly of the
poisonous race of serpents. This is called the boma, because
it emits a remarkable noise resembling the sound of that
word, when pronounced with a deep hollown voice.

BOMAL, or Bomel, in Geography, a town of Ger-
many, in the duchy of Luxembourg, seated on the Ourte,
7 miles S. W. of Spa, and 53 N. W. of Luxembourg.

BOMANGOY, a town of Africa, in the kingdom of
A Augoy, or Goy (which fce), situate on the north bank of
the river Zaire. S. lat. 5° 36'. W. long. 13°.

BOMARZO, a town of Italy, in the ecclesiastical fiate,
and patrimony of St. Peter, once episcopal; 14 miles from
Civita Castellana.

BOMB, in the Military Art, a hollow iron-ball, or shell,
urnished with a vent, by which it is filled with gun-powder,
and which is fitted with a fusee, or hollow plug, by which
it gives fire, when thrown out of a mortar.

In the English artillery, bombs are now commonly called
shells.

The word bomb comes from the Latin bombus, crepitus,
or fricasus: by reason of the noise it makes.

The method of preparing a bomb is as follows: a hol-
low iron globe A B (Plate Gunny), is called pretty
thick, having a round aperture A, by which it may be
filled and lighted; and circular anfe B C, D, of hammered
iron fixed in the mould when they are cold, for the com-
modious putting it into the mortar, as well as for carrying it
from one place to another. In France, the handles are call
iron: but they are thus rendered more clumsy, and liable to
break sooner than the others.

It has been usual to make the lower part of the bomb the
thickest, that it may fall on that side, and never on the fusee,
and that it may also better resist the shocks, or impression
of the powder by which it is discharged from the mortar:
but Mr. Muller thinks that neither of these considerations is
of any great importance, and recommends rather to make
them every where equally thick, because they would thus
burst into a greater number of pieces. Artillery. p. 151. in
his Sytem, &c. vol. v.

After the shells have been gauged and examined as to
their dimensions and weight, they must be well searched
within and without by means of a copper grater, to ascertain
whether there be any holes or cavities in them; and the
iron pin or spike at the bottom of the inlise, which supports
the corp when they are cast, should be best done or broken
off. They are then to be hammered all oyer, to knock off
the scales, and discover flaws; and no hole, in the large
shells, is allowed, of more than 3 of an inch deep. An
empty fusee is then driven into the fusee hole; and the
shell is suspended in a tub of water, so that the water may
cover it, without running into the fusee; in this situation
the nose of a pair of hollows is introduced into the fusee
hole, and several strong pulls given with the hollows; and
if no bubbles rise in the water, it is concluded that there
are no holes in the shell, but that it is found and fit for
service.

When the shell has been thus proved, and is found to be
dry within, gun-powder is introduced into its cavity, by
means of a funnel; but it is not quite filled. Artillerists,
though they agree that shells should not be quite full, have
ever ascertained the precise quantity which would serve for
their bursting into the greatest number of pieces. Captain
Defaguilier, after having made several experiments,
apprehends, that the most proper quantity of powder is two
thirds of the weight which would fill the cavity. A little
space or liberty is left, that when a fusee or wooden tube a,
of the figure of a truncated cone, is driven through the
aperture, the powder may not be bruised. This fusee is
prefcled in at fire by the hand as far as it will go, and then
drove with a mallet as hard as possible, taking care, however,
not to split it; for if the leaf crack were in it, the com-
position would give fire to the powder, and the shell would
burst either in the mortar, or in the air, and thus do no
execution. For the method of preparing and filling the
fusee, see fusees.

This fusee is set on fire, and burns slowly till it reaches the
gun-powder, which goes off at once, bursting the shell to
pieces with incredible violence: whence the use of bombs in
besieging towns. Special care, however, must be taken,
that the fusee be so proportioned, as that the gun-powder
do not take fire before the shell arrives at the defined place;
to prevent which, the fusee is frequently wound round with a
wet clammy thread.

The fusees are driven into the shell, so that only about
an inch and a half come out beyond the fusee-hole; and
then the shell is said to be fixed. They are charged long
before there is occasion to use them; and in order to secure
the composition with which they are filled, the two ends are
covered with a mixture of two parts of pitch, one of
robin, and three of bees-wax, which will guard the com-
position within from the access of air; and it will thus
keep as long as you please. When the fusee is to be put
into the shell, the little end is opened or cut off; but the
great end is never opened till the mortar is to be fired.

Bombs or shells are made of different magnitudes, from that
of 17 or 18 inches diameter downwards; the very large ones
are not used by the English, that of 13 inches diameter
being the largest size now employed by them. The follow-
ing table shews the weight, dimensions, &c. of English and
French shells.

Mr. Muller gives the following proportions, from the 13 inch bombs, now commonly used, and observes that they may be easily adapted to any other calibre, by making the diameter of the shell to 30, as any part expressed in inches, to the same part expressed in parts of the diameter divided into 30 equal parts.

- Diameter of the bore
- Diameter of the shell
- Diameter of the hollow sphere
- Thickness of the metal at the fuze hole
- Thickness at the opposite part
- Diameter of the fuze-hole

Weight of the shell unloaded, 11.7 tons.

Weight of the powder contained in the shell, 230.5 lbs.

**N.B.** The letter d denotes the cube of the diameter of the bore.

But shells have also been lately made with the metal every where of the same thickness, and are found to burst into a greater number of pieces by this construction. The Germans do not name their shells from the diameter of the bore which receives them, but from the weight of a stone-ball that fits the same bore as the shell. This a 7lb. howitzer admits a stone-ball of that weight: the shell for this weighs 15lbs. and corresponds to the English 5½ inch. The 30lbs. howitzer shell weighs 60lbs., and is rather more than 8 inches in diameter. At the siege of Gibraltar, small shells, as 4½ inches, and hand-granades, were quitted into grape for 13-inch mortars. The fusees were turned inwards next the iron-tampon, and leaders of quick-match for communicating fire to the fusees were introduced through holes made in the wood-bottom, and placed as near the fusees as possible in the centre of the grape. These answered very well for short ranges. In general, the winage, or difference between the diameter of the shell and mortar, is 3, 5 of the latter; and the diameter of the hollow part of the shell is 7, 1 of the fame. For finding the weight of an iron-shell, the following rule has been given. Take 5/7 of the difference of the cubes of the external and internal diameters, and this will be its weight.

In order to find how much powder will fill a shell; divide the cube of the internal diameter of the shell in inches by 57.3, which will be the number of pounds of powder. To find the size of a shell for containing a given weight of powder; multiply the number of pounds of powder by 57.3, and the cube root of the product will be the diameter in inches.

Bombs only differ from granades, in that the latter are much less; and instead of mortars are thrown out of the hand. Bombs are thrown not only out of mortars and howitzers, but out of cannon. The following shells may be fired from guns; viz. hand-granades from 6-pounders; 4½ shells from 12-pounders; 5½ shells from 24-pounders; and 8-inch shells from 68-pr.carronades. Shells may be also thrown from guns to short distances, in case of necessity, though the bore be not of a diameter sufficient to admit the shell. For this purpose the gun may be elevated to any degree that will retain the shell upon its muzzle, which may be affixed by a small line passing from the lugs of the shell round the neck of the gun. To produce a greater effect, the space between the shell and the charge may be filled with wads, or some other substance.

Bombs may be used without mortar-pieces, in the manner practised by the Venetians at Candia, when the Turks had posted themselves of the ditch, rolling down bombs upon them, along a plank let flopping towards their works, with ledges on the sides to keep the bomb right forwards. They are sometimes also buried under ground to blow up. See CAISSE.

M. Blondel, who has written on the art of throwing bombs, observes that the first bombs were those thrown into the city of Watchtendonch, in Guelderland, in 1588, though others pretend they were in use a century before, viz. at the siege of Naples by Charles VIII. in 1495. Stowe says (p. 584), that mortars and bombs were invented in 1544 by foreigners, whom Henry VIII. employed. But they came not into common ufe before the year 1634, and then only in the Dutch and Spanish armies. One Malthus, an English engineer, is said to have first carried them into France, where they were put in use at the siege of Colliour, in 1642.

The art of throwing bombs makes a branch of gunnery, founded on the theory of projectiles, and the laws and quantities of gun-powder.
BOM

Meff. Blondel, Guinée, de Reffons, de la Hiere, and others, have written expressly on the art of throwing bombs.

Bom-battery. See Battery.

Bom-chef, is a kind of chef filled usually with bombs, sometimes only with gun-powder, placed under ground, to tear and blow it up in the air, with those who stand on it.

Bom-chefs were formerly much used to drive enemies from a poll they had seized, or were about to take possession of: they were set on fire by means of a fusiff fire, at one end, but they are now much disused.

Bom-water. See Water-bomb.

Bom-vessell, which are small ships formed for throwing bombs into a fortress, are said to be the invention of M. Reyncen, or Renard, and to have been first used at the bombardment of Algiers, in 1681. Till then, it had been judged impracticable to bombard a place from the sea.

The bomb-ketches on the old establishment carry one 13-inch, and one 10-inch mortar; with eight 6-pounders, besides swivels, for their own immediate defence. The modern bomb-vessels have four 13-inch mortars, four 68-pounders, and 16 and 18-pounders carronades, and the mortars may be fired at and angle of 20 degrees; though these mortars are not intended to be used at sea, but on very particular occasions, their principal use, at these low angles, being to cover the landings of troops, and to protect our coasts and harbours.

A bomb-ketch is generally from 60 to 70 feet long from stem to stern, and draws eight or nine feet water. The tender is generally a brig, on board of which the party of artillery remain, till their services are required on board the bomb-vessels. The following instructions serve for their management and security in action.

1. A Dutch pump, filled with water, must be placed in each round-top, one upon the for'o-castle, one on the maindeck, and one on the quarter-deck; and furnished with leather buckets, for a fresh supply of water.

2. The bomb-muzzles must be wetted by the pumps before the tarpaulins and mortar-hatches are taken off; and a wooden screen, 5 feet square, is to be hung under the booms, over each mortar, to receive the fire from the vents.

3. The embrasures being fixed and properly secured, the port must be let down low enough to be covered by the face of the embrasure. Previous to its being let down, a spar must be laid across it, to which the tacles for raising it again must be fixed: this spar serves to project the tackles clear of the explosion.

4. The mortars must not be fired through the embrasure at a lower angle than 20 degrees, nor with a greater charge than 50 lbs. of powder.

5. Before firing, the doors of the bulk-head, under the quarter-deck, must be shut, to prevent the cabin being injured by the explosion.

6. The bed must be wedge the circular curb, as soon as the mortar is pointed, to prevent re-action; the first wedge being driven tight before the rear ones are fixed, in order to give the full bearing on the table, as well as the rear of the bed. The holes for dog-bolts must be corked up, to prevent the sparks falling into them.

7. When any fireballs are to be used on board the bomb, they must be fixed on board the tender, and brought from thence, in boxes in her long-boat; and kept along-side the bomb-ship till wanted, carefully covered up.

8. In the old constructed bomb-vessels it is necessary to hoist out the booms; and raft them along-side previous to firing; but in these new ones, with embrasures, only the boats need be hoisted out; after which the mortars may be prepared for action in 10 minutes. See Ketch.

BOMBA, in Zoology, a species of TRICHOA, one of the genera of Animalculae or Vermes infusoria. This kind is briefly described as being of a changeable form, with a few hairs on the anterior part. This is found abundant in stagnant water: the body is thick, somewhat pelliculid, of a yellowish colour, and filled with paler molecules. Müll. Gmel. &c.

BOMBARDE, BOMBARDE, a piece of artillery, an ancient in use, exceedingly short and thick, and with a very large mouth, by some also called basiffy, by the Dutch donderbuys. Some derive the word, by corruption, from Bombard, as supposing this piece first used in Lombardy. Du-Cange, after Volius, derives it from bombus and ardeo; Menage, from the German bombarden, the plural of bomber, ballif. But we doubt whether the Germans knew any such word. It is no unusual thing with Menage, and many other etymologists, to give derivations from words of their own making.

There were some of these pieces said to have carried balls of 300 pounds weight; Froisart mentions one of fifty feet long. To load them, they made use of cranes, &c. The bombard is supposed to have been in use before the invention of cannon.

Bombards can hardly be supposed to have been of metal, nor charged with gun-powder. They were rather a fort of baliste for throwing stones, and were played with ropes.

BOMBARDIER, an engineer, or person, whose business is to take care of the firing and throwing bombs out of mortars. He first drives the fusee, then fixes the shell, points, loads, and fires.

BOMBARDIER, in Entomology. See CARABUS.

BOMBARDING, the art or act of attacking a city or fortresses, by throwing bombs into it, in order to ruin or set on fire the houses and magazines, and do other mischief.

Bombarding is not reckoned the most honourable method of making war, as it rather tends to do mischief to the inhabitants than to the works.

BOMBARIN, in Zoology, the name used by some old writers for the Hippopotamus.

BOMBSINE, in Commerce, a kind of silk stuff manufactured at Milan, and thence sent into France and other countries. The French also use the word bombeine for stuff made of cotton, more properly called dimity.

BOMAST, in Rhetoric, denotes a style too high and pompous for the subject and occasion; or a certain manner of elocution and action, which is grand when supported by dignity in the sentiment, and force in the expression, but never fails to appear ridiculous where the sentiment is mean, and the expression flat. See Style.

Gen. Char. Cal. permanent, either of one leaf, tubular-campanulate, three, four, or five cleft; or of five unequal leaves. Cor. either five petals, or one petal five-cleft. Stam. filaments five or more, connate at the base, sometimes slightly, sometimes tubular. Fil. germ superior, turbinate oblong. Stigma capitate, with five teeth more or less developed. Pericarp. large ovate-oblong, membranous and almost woody, five-celled, five-valved. Seeds numerous, round, woolly. Receipt. columnar five cleft, forming the partitions.
BOM

Species, 1. B. pentandrum. (Linn. Tab. 1795.) *Flowers pentandrous.* Linn. „Anthers bent; leaves in fevens." Willden. A tree sixty or eighty feet high. Bark greenish, smooth, easily separated from the wood; often sprinkled, especially when young, with large, conic, spinose tubercles; branches, near the summit, pendant; leaves on long petioles, digitate, foliodes from five to nine, either entire or serrate, lanceolate, ending in a point; flowers in a simple umbel; partial peduncles about an inch long, with several alternate bracts; petals five, white and velvety without, smooth, concave, and of a purple or delicate rose colour within; anthers two or three, on a filament, twisted together; fruit half a foot long, shaped like a cucumber, very fleshy at its base; seeds oval with a sharp point, enveloped with a great quantity of short dark cotton which is not fpun, but used for filling pillows, mattrasses, &c. Rumphius says that the valves open at the base. Plummer affirms the contrary. Jacquin, who saw the living plant in fruit, gives no information on the subject. A native of both Indies. Cultivated by Mr. Miller in 1739. 2. B. erianthos. (Cavan. Tab. 152.) "Flowers pentandrous; anthers simple, erect; leaves in fevens." Wild. Trunk very spinous; leaves terminated by a filament, very smooth, calyx short and very large; petals three inches long; whitish, covered without with a short thick down, smooth within, concave, and round at their extremity; tube formed by the lower part of the filaments, bottle shaped; anther linear, longitudinally fixed to the upper part of the filament. Found by Commerson in Brazil. 3. B. pyramidalis. "Stem without thorns; leaves cordate, angular; flower pentandrous; anthers united; fruit very long, pyramidal." Cavan. A large tree with very spreading branches; wood white and fio light that fishers use it instead of cork; bark thick, fibrous, cinereous, marked with whitish spots, and reddish wrinkles; leaves a foot in diameter, strongly curved, green on the upper, yellowish and downy on the lower surface, on long and thick petioles; flowers numerous on long peduncles; cornoll large, monopetalous, campanulate, deeply divided into five segments; calyx large, reddish, green, campanulate, with five blunt divisions; filaments five, thick, supporting as many large nearly arrow-shaped anthers which are spirally united and enclose the summit of the style; style reddish, club-shaped, marked at the end with five spiral furrows; capsule furrowed, from eight to ten inches long; seeds very small, somewhat egg-shaped, enveloped with fine, short, reddish cotton. A native of the Antilles. 4. B. grandiflora. "Leaves in fevens; flowers pentapetalous, large, polyandrous; stamens united into a tube at the base." Cavan. Calyx large, expanding with four blunt divisions; coroll superbf. of five petals, each five inches long, but narrow in proportion to their length, whitish, fleshy at their base, velvety without, smooth within, and rounded at their extremities, infected at the base of the tube of the filaments, which is naked, entire in its whole length, and terminated by a prodigious number of red filaments a little shorter than the coroll; anthers kidney-shaped, small and loosely attached to the filaments; style filiform, thick, longer than the stamens, with five small teeth; fruit unknown. Described by Cavanilles from a specimen in the Herbarium of Thouin. It grows about Rio-Janeiro. 5. B. Cebia. "Flowers polyandrous; leaves in fives." Linn. "Trunk closely armed with short, strong spines, so large as to be hollowed out into canoes of twenty-five tons burden; calyx small, campanulate, with five small teeth; coroll monopetalous; tube straight, twice as long as the calyx; border divided into five long, concave obtrufs segments; filaments numerous, proceeding from five distinct bodies, which are united at the base and form a conic tube adhering to the base of the coroll; anthers oblong, fleshy, somewhat evolute, with five angles; capsule oblong, small at the base; seeds nearly round, covered with down, which is used by the lower ranks to stuff pillows and chairs. A native of South America, near Carthage. Cultivated at Hampton Court in 1692. 6. B. kephibyllum. "Flowers polyandrous; leaves in fevens." Linn. "Stamens in five bodies." Cavan. A tree fifty feet high, six feet diameter at its base; wood soft, light, and brittle; bark thick, cinereous, spinous when young; leaves digitate; calyx four cleft; flowers numerous, large, odorous; coroll of five petals, downy without, attached by its base to the bottom of the tube of the filaments; filaments very numerous, kidney-shaped, shorter than the coroll, loosely attached; fruit elongated. 7. B. globosum. "Leaves in fives or fevens, obovate, emarginate; fruit globular." Wild. (Aub. Guian. Tab. 251.) A tree thirty feet high; trunk a foot and a half in diameter; leaves palmate, green, smooth, oval, obtuse, finely crenulated at the summit, the middle one the largest, on long petioles, with two long, pointed, caducous stipules at their base; flowers unknown; fruit in axillary and terminating racemes. A native of Cayenne. 8. B. gossypium. "Leaves five-lobed, acuminate, tomentose beneath." Linn. A large tree with green, nearly smooth bark; leaves alternate on long, fleshy, pubescent petioles; flowers large, in fimple panicles on downy peduncles; calyx of five unequal leaves; petals five, as long again as the calyx, expanding, yellow; filaments numerous, slightly united at their base; anthers oblong, curved; capsule oval-obtusif; feeds kidney-shaped. A native of the coast of Coromandel.

The species known to Linneus were at first placed by him with the common cotton and its congeners, under the old Greek name Xylon; but afterwards separated on account of the simple calyx. Thoie with the double calyx he then called gossypium; those with the simple one bombax. The species of the genus bombax, as it now stands, differ so much from each other in most of the parts of fructification, as almost to justify the division of them into distinct genera. The calyx, the coroll, the number and support of the stamens, the form and insertion of the anthers, all vary: nothing is constant but the simple calyx; the five-celled, five-valved capsule, and the woody seeds. We have altered the natural and essential generic characters, and so formed them as not to exclude any of the species.

Propagation and Culture. Silk cotton is propagated by seeds sown in a hot-bed in the spring. In about two months it should be transplanted into a small pot filled with fresh loamy earth, and plunged into a moderate hot-bed of tanners' bark. At first it should be shaded from the sun; but afterwards, when the weather is warm, should be allowed fresh air, and frequent fumplings of water in small quantities, with a uniform degree of heat. In autumn it must be removed into the bark-love and sparingly suppled with moisture. It makes a pleasing variety in a large bed, but is not likely to produce flowers in England. See Miller, Gardener's Dictionary.

BOMBAY, in Geography, a small island in the Indian Sea, near the western coast of Hindostan, about 7 miles in length and very narrow, containing a very strong and capacious fortres, a large city, a dock-yard, and marine arsenal. It is separated on the N.E. by a narrow strait from Saffette, another island, and these two, together with the neighboring shores of the continent, form a large found, in which are several other islands, particularly Caranjah and Elephahta;
Elephant, the latter (which see) being famous for its subterraneous temple, and both of them acquisitions from the Mahattas. It was first taken possession of by the Portuguese, soon after their arrival in India, and called by them Brazil or Good Bay, from the excellence of its harbour, which is so spacious as to accommodate, as it is affirmed, a thousand ships at anchor, and well sheltered from all winds. The Portuguese ceded it to the English in 1662, as part of the dower of the Infanta, Queen of Charles II. After the king's marriage, a fleet under the command of Lord Marlborough was sent to take possession of it; and Sir Abraham Shipman was appointed Governor. But upon their arrival in September 1663, the Vicerey, actuated by the Pophis clergy, who objected to the cession of the island to heretics, refused to surrender it. At length, however, in 1664, he was terrorized, and a treaty was established, by which Mr. Cook, upon the death of Shipman, was invested with the possession of the island, in quality of Governor. By this treaty the inhabitants were to be continued in the free exercise of their religion, and in the undisturbed possession of their estates under the crown of England. Although the trade of Bombay was at this time very prosperous, it was soon found, that the royal revenues were not sufficient for defraying the charge of the establishment, and that the trade itself was subject to very considerable obstructions; so that the king found it expedient to make a full grant in fee-tail of the port and territory to the East India Company, which was done by charter, dated 26th March 1668, and thus they have continued to hold it to the present time.

The city of Bombay, the principal port and settlement of the English in this part of India, is situated on the northern part of the island, N. lat. 18° 58', E. long. 72° 38'. It is about a mile in length, but narrow; and defended both towards the sea and land with various fortifications, which have been constructed at a great expense, and which have rendered it the most considerable fortress in India. On the island also there are small forts sufficient for protecting it from any irruption of the Indians; and in the harbour there are barracks hewn out in the rock, for the purpose of caring ships. The houses of Bombay are in general neither splendid nor commodious; but there are several handsome buildings, among which are the governor's palace, and a large, elegant church near it; the houses are not flat-roofed, as they are in other parts of the East, but they are covered with tiles in the European fashion. The English have glass windows. The other inhabitants of the island have their windows of small pieces of transparent shells framed in wood, which render the apartments very dark. The soil of the island is fertile, and incapable of any great improvement; its chief produce consists of cocoa and rice, bides mangoes and some Indian fruits. It draws a considerable supply of provisions from the continent, and from the fertile island of Salfette. Large quantities of salt are manufactured on the shore, from the sea-water that flows into pits adapted to this purpose. The sea-breezes and frequent rains cool the atmosphere, and render the climate of this island temperate; and though the air is not so pure as at Madras, yet it is much more wholesome than at Bengal; the coast of Malabar being pretty healthy, though less so than the coast of Coromandel. The island of Bombay has been rendered much more healthy than it was formerly, by a wall, which has been built to prevent the encroachment of the sea, where it formed a salt marsh, by draining the marshes in its environs, and by an order that none of the natives should manure their cocoa-nut trees with putrid filth. Nevertheless, many Europeans, especially on their first arrival, are seized with fevers, fluxes, and other disorders, which prove fatal; and others shorten their stays by not adhering to a mode of life suitable to the climate. The natives, however, and others, who abstain from excess of animal food and strong liquors, enjoy a good state of health, and live to a considerate age. The want of fresh water is an inconvenience to which the inhabitants are subject; the best being that which they prefer in eifiers after rain; whereas that which is supplied by their wells has a brackish taste.

This island is become very populous, in consequence of the toleration which is granted by the English to persons of every religious profession. The number of inhabitants is estimated by Niebuhr at 140,000, and of these the Europeans form the most considerable class. The other inhabitants are Portuguese, or Indian Catholics; Hindoos, the original possessors of the country; Persians from Kerman; Mahometans of different sects; and some Oriental Christians. The English have a handsome church at Bombay, but they are disadvantageously circumstanced with regard to officiating clergy. The Catholics are much more numerous than the Protestants, and have many priests, as well Europeans as Indians, who attend their studies at Goa. The pope, many years ago, appointed for their superintendence a bishop of Bombay, but he was dismissed by the governor of the island. The Catholic churches are decent buildings, and are within sumptuously ornamented. The Jews had once a college and a synagogue in the middle of this island; but the college was converted into a country-house for the English governor, and the synagogue into a suite of assembly rooms.

Bombay is the seat of the English government for the coast of Malabar; as Madras is for the Coromandel coast, Calcutta for Bengal, and Bencoolen was for Sumatra. These four governments, of which that of Bengal has the superiority and control, are obliged, by an act of the British parliament passed in 1773, (1 Geo. III. c. 63.) to afford mutual assistance in cases of extraordinary exigence. The different establishments are under similar administration, and all proceed to subjects of the company are determined by the law of England. The council or regency of Bombay (as well as that of Bengal) consists of a governor and three members of council. The other servants of the company are factors and writers of different ranks, and are sometimes transferred from one department to another. The governor and members of council of the other presidencies are to be under the control of the government-general of Bengal, with respect to treaties with the native powers of India, levying war, making peace, collecting and applying revenues, levying and employing forces, or other matters of civil and military government; and they are required in all cases to obey the orders of the said government-general, unless the directors of the company shall have sent to the president any contrary orders not known to the government-general, of which, in that case, they are to give this government immediate advice. The Court of Directors are to appoint to these several governments, and likewise the commander in chief of all the forces, and the three provincial commanders in chief. All governors and councils are prohibited from trading, except from the company. 24 Geo. III. c. 25. 33 Geo. III. c. 52. See Board of Control and East India Company.

Bombay Hook, an island of America at the mouth of Delaware river, about 8 miles long and 2 broad, formed by the Delaware on the eastern side, and Duck Creek and Little Duck Creek on the Maryland side; these are united together by a natural canal. The N.W. end of Bombay Hook is about 47 miles from Cape Henlopen and May; from the Hook to Reedy Island is 9 miles. BOMBAZINE,
BOMBAZINE RAPIDS, lie on a river in Lincoln county, and district of Maine in America, and are navigable for boats with some lading, at a middling pitch of water. They took their name from Bombazine, an Indian warrior, who was slain by the English in attempting to cross them.

Bombazine, a lake, seven or eight miles long, in the township of Colleton, county of Rutland, and state of Vermont.

BOMBELLA, in Entomology, a species of Bombyx, of a middle size, that inhabits Aulria, the wings of which are cinereous, sprinkled with fuscous. Fabr. Mant. This is Fontana Bombecella of the Vienna catalogue. (Wien. Schmutz.)

BOMBERG, Daniel, in Biography, one of the early printers, was a native of Antwerp, and settled at Venice, where, in 1718, he printed a folio edition of the Hebrew Bible. See BIBLE. He also began an edition of the Tan- mud, in 1520, and completed it three years afterwards in eleven volumes folio. Each of the three impressions of this immense work is said to have cost him 100,000 crowns. His whole property was devoted to the impressions of valuable editions of Hebrew Bibles and rabbinical works, for which purpose he employed a great number, as some say, more than 100 of learned Jews. Bomberg was himself a Hebrew scholar. He died about the middle of the 16th century.

BOMBIC ACID. The silk worm has a small reflexor near the anus, from which, when full grown, or even when in the chrysalis state, a minute quantity of an acid liquor is seen to ooze out. If the entire animal is bruised, it gives a liquid containing the usual solid animal matters, together with a native acid. Alcohol separates the former, and leaves the latter in solution, which, by evaporation, furnishes a very pure pungent yellow fluid, which dyes all the marks of an acid by reddening blue vegetables, and uniting with alkalis and some earths. The discoverer, Chemist, considers it as peculiar, and hence it has obtained a separate place in the list of animal acids; but from analogy with the experiments on the formic acid, and other circumstances, the separate existence of the bombic acid is very questionable. No other chemist has yet undertaken to confirm or dispute the original statement. Mem. de l'Acad. de Dijon. 1783.

BOMBICHIUS, in Geography, a town of Asia in Syria, 44 miles N. E. of Aleppo.

BOMBINA, in Entomology, a large species of Curculio, defribed by Fabricius as a native of Cayanne. The colour of this insect is ferruginous brown, and the wing-cases fritated, with black elevated tubercles.

BOMBINA, in Zoology, a species of Rana, or frog, the belly of which is orange, spotted with sky-blue, and the pupil of the eye triangular. Blumen. This kind appears to be extremely variable in point of colour and markings.

In the tenth edition of the Linnaeus. Syst. Nat. it is described as the Rana virgata. Rees, in his "History of Frogs and Toads," calls it Bufo igneus, (Bufo vulgo igneus dictus.) It is likewise Le somnane, and the couleur de feu, of Lacpède, and Rana ignea, or fire-frog, of Dr. Shaw.

The permanent更换ites, if they may be so expressed, of this particular species, do not seem to be very correctly ascertained. Gmelin, upon the authority of preceding writers, constitutes the following varieties: a has the belly black, with clear white spots and speckles; b is of a fulvous colour; and c is distinguished by its loud honorous voice.

This is the smallest of the European kinds of either the frog or toad. The general habit resembles that of a toad, but it is fast to keep and swim with as much or even greater facility than the common frog. Dr. Shaw observes, that he places it among the frogs instead of toads, on account of its depositing its ova in clustered heaps; not in strings like the latter animals. In Germany, Italy, and other European countries, which this creature inhabits, it is known to delight in marshy places. The found of the male, which alone is vocal, is clear and sharp, and is thought by some to resemble, in a very peculiar manner, that of a man giggling with laughter.

This, indeed, is not the universal opinion; some authors compare it to the tone of a bell, or the noise of a cuckow, for which reason it has obtained the name of bombicina.

This animal, according to Dr. Shaw, may be considered rather as an aquatic than terrestrial species; being rarely found on land, but chiefly inhabiting turbid stagnant waters, in which, in the month of June, it deposits its spawn, the ova being much larger in proportion than in most others of the genus. The tadpoles are hatched towards the end of June, and are of a pale yellowish brown colour; and, when young, are often observed to hang from the surface of leaves, &c., by a glutinous thread proceeding from the small tube or tuber beneath the lower lip. They arrive at their full size towards the close of September, and at that period are remarkable for the feby or muscular appearance of the tail, which is stronger in proportion than in most other tadpoles.

About the beginning of October they assume their complete or ultimate form; and when the tail has so far decreased as to be still a quarter of an inch in length, that remaining portion becomes entirely obliterated in the space of about twelve hours.

The fire-frog is a lively active animal; leaping and swimming admirably well. When surprized on land, or unable to escape, it inflated itself to a globule; at the same time turning back its head and hiding in a singular manner, and if farther seized and irritated, evacuates from the hinder part of the thighs, a kind of foamy serous frothy fluid, of no bad scent, but which, in some circumstances, has been found to excite a slight sensation of acrimony in the eyes and nostrils.

This species is observed to breed at the age of three years, and may be supposed to live about ten; but this is not entirely ascertained.

It ought not to escape remark, that the triangular form of the pupil of the eye, which Gmelin and others consider as the most striking criterion of this species, can only be observed in a full light, for when examined in the shade its shape is circular.

BOMBOESKJE, in Zoology, the Sciusrus Asiaticus in Le Bruyn's it. p. 434, t. 1734.

BOMBUS, in Medicine. See Flatulency.

BOMCUS, in Majo, an artificial motion with the hands, imitating, in cadence and harmony, the buzzing of bees. The word is originally Greek, and signifies the buzz or noise of bees, gnats, and the like. In this sense, bombus made one of the species of aphana used by the ancient auditors.

BOMBICILLA BOMBEICA, in Ornithology, the name under which Birson defers the Bohemian character, Am- pelis Garrulus. The same author likewise calls an American variety of this bird Bombicilla Carolinenss.

BOMBYCINUM, in Ancient Writers, properly denoted a species of silk, brought from Affyria and the island of Cos. In which sense it stood distinguished from Sericum, another sort of silk brought from the Indies.

BOMBYCINUM velamentum. See Velamentum.

BOMBYLIUS, in Entomology, a genus of Ditterous insects, distinguished by the following character: beak or fucer very long, fateria, slanting, and consisting of two unequal valves, within which three fatacte bristles are contained; feelers two, short and hairy; antennae fubulate, and connected at the base. Linnaeus. Syst. &c.

The antennae of the insects in this genus are short, and contain three articulations, the frill of which is long, the second short, and the third or last conical, and terminating
in a kind of appendage, almost forming a fourth joint, as is to be observed with the affinities of gallies. Those who have carefully examined the structure of the trunk with the microscope affirm, that the number of valves or bristles concealed within the external bivalve sheath are four instead of three, as Gmelin describes them. The antennae are infected at the base of the trunk.

Insects of this genus have the head comparatively of a small size, of a form somewhat round, and almost wholly occupied by the eyes. The thorax large, the abdomen bulky, and rounded at the extremity as in the bee. Both the thorax and abdomen are hairy, or covered with down. The wings longer than the body, and extended horizontally. Legs long and slender.

The size and rotundity of the body afford an excellent natural character, by which this tribe of insects may be distinguished from those of the genera emmis and alisus, with which some naturalists have confounded them. The Fabrician species of volucella, cytherean, and anthrax, have been referred to the bombylus genus with very little propriety.

The true bombylus is a lively active tribe of insects, that subsist entirely on the nectarous juices they extract from flowers, with the assistance of their long proboscis or trunk. They fly with much rapidity, making all the time a sort humming noise similar to that of the bee. In England the largest species (major) has acquired the name of the humble bee fly. The insects of this tribe are found in the winged state in the summer, but their metamorphose is utterly unknown.

Only a small number of species in this genus are at present known, namely major, medius, minor, minimus, ater, fulceus, griseus, virceus, and albifrons: these are natives of Europe. The extra-European kinds are equilis, capenis, cupreus, maculatus, pygmeus, and vericolor.

BOMBYX, a genus of LEPIDOPTEROUS insects, or rather one of the subdivisions of the PHALAEN, an extensive genus, in which all the insects of the moth tribe are comprised by Linnaeus. Fabricius, in his "Entomologia Systematica," admits the bombyx as a genus, applying the term phalæna, which Linnaeus gave indiscriminately to all the species of the moth tribe, as a general name to that particular description of moths which have the palpi cylindrical, the tongue advanced and membranaceous, and the antennæ dilated.

The true definition of the bombyces, whether considered as a subdivision of the phalæna, or as constituting a genus of themselves, is not sufficiently explicit. A great number of the species may be readily referred to their proper station in the genus, by observing with attention the characters laid down by Linnaeus; but there are others which cannot be so accurately distinguished from the noctua as we could wish, by the assistance of these characters. If, for instance, we advert to the earlier editions of the Linnaean System nature, we shall find even in the final number of species which that naturalist describes, that the greatest confusion prevails in this respect. Had Linnaeus been himself correct in his ideas of the natural character of the bombyces, we are almost persuaded he would not have considered phalaena bucephala as a noctua, any more than dominula, fuliginosa, Jacobae, and some others, which he includes as such in his arrangement of the lepidoptera.

Linnaeus thought at first the pectinated antennae of the lepidoptera a sufficient criterion of the bombyces, provided the wings were incumbent and deprived, while the insect remained in a resting position, because the geometrical, though often furnished with pectinated antennae, have the wings expanded, horizontally when at rest. But later observations of other naturalists have determined this character of the bombyx to be insufficient to distinguish it.

In the Systema naturæ, Linnaeus divides the bombyces into sections in the following order; the elingites, or those without a manifest spiral tongue, and the spirilligenes, having an involuted spiral tongue. These two principal sections are subdivided again; the elingites, into those with the back smooth or not crested,—with expanded wings,—with reversed wings,—with deflected wings,—with erect crests, or tufts on the back; and the spirilligenes, those smooth, with expanded wings,—with deflected wings,—and with the back crested. This mode of arrangement is entirely superceded by the Entomologia Systematica of Fabricius. The latter writer takes his characters, as usual, chiefly from the tongue and palpi. His bombyx is thus generally described; feelers two, compressed, reflected; tongue short, and membranaceous; antenna dilated. By this many of the Linnaean bombyces are excluded, for the reception of which he establishes two other genera, those of Collyps and Hepialus, both of which most strictly appertain to the Linnaean bombyces.

The bombyx coffus gave Fabricius the idea of forming a distinct genus of the species analogous to this insect. The characters by which it is described are these; the tongue is continued to the costus; the palpi or feelers two, compressed, cylindrical; with no tongue; and the antenna short and dilated. His hepialus has two hairy feelers, between which is the rudiment of a bilabiate tongue; and the antenna are moniliform. Gmelin, in the last edition of the Syll. nat. endeavours to reconcile the Fabrician genera as subdivisions to the principal Linnaean genus phalæna. His bombyces consist of the attacæ, which have the wings expanded, and the bombyces (strictly so) which have not the wings expanded, and these latter are again arranged in subdivisions in the following order: first, those with reversed wings, as in quercifolia; second, those with deflected wings, as in buprestis and belis; third, those with incumbent wings, as in antiqua; and fourth, those with convoluted wings, as in bela. The four families, into which Olivier separates the bombyces, scarcely differ from the preceding; they consist of those with expanded wings, with wings reversed, with wings bent down (deflected), and with wings recovered (incumbent).

The bombyces are to be considered as a true natural family of the moth tribe, which for the most part may be distinguished by the natural observer, who will attend to the structure of the antennæ, the form of the body, the position of the wings, and some few other particulars to be mentioned hereafter. The antennæ, which are dilated, and either pectinated or ciliated, differ greatly in the two sexes of the same species; the male being generally distinguishable by having the antennæ much broader, or longer, than in the females. The thorax of the bombylus is rather more bulky, and the body thicker than in the noctua, especially in the females. Thus far consistent with the Linnaean character; but a strict attention to the feelers and structure of the tongue, as Fabricius observes, will be also necessary to determine many of the bombyces, which approach so closely to the noctua as not to be accurately distinguished by any other means. For this reason Fabricius is commendable in having endeavoured to define the precise limits between the bombyces and their analogous tribes: his character is more definite than that which Linnaeus had previously assigned to this family. The discrimination of Fabricius is obvious in separating the two tribes or genera of coelius and hepialus from the bombyces, under which head Linnaeus comprehends them; for those insects certainly form distinct natural families, both in their general appearance, their metamorphoses, their habits of life, and other peculiarities, from which
BOM

which ought to be considered as the natural family of bom-
byces. The insects of the bombyx tribe never fly except in the
evening. During the day time they secrete themselves un-
der the leaves, or beneath the branches, in the clefts of trees,
where they may remain secure till about sunset, at which time
they appear to be on the alert, at first crawling about the
branches, then fluttering their wings, and becoming brisker
in all their motions as the evening comes on. The larger
fort of moths, which we see first fluttering from the woods or
hedges after some of the geometries, are the *fœfis*, the
Fabrician hepialis, which fly twirly as their trivial name im-
plies, but low or near the surface of the ground; these at
twilight are succeeded by the bombyces and noctule, whose
flight is more elevated. They continue to sport about till
it becomes quite dark. The males of the bombyces are
commonly first upon the wing in search of the females, which
latter are in some few species entirely destitute of
wings, or at least have only the rudiments of them close to
the thorax; in which case the female waits upon the trees or
herbage for the arrival of the male; the female of bombyx
antiqua, the vapourer moth, is a striking proof of this, for
it has so little the appearance of a moth that any one, except
an entomologist, would mistake it for an apterous or wing-
less insect. Thoese females which have wings are commonly
larger even than the males.

The bombyces are produced from a larva, or as it is more
usually termed by common observers, a caterpillar. This
is of a long cylindrical form, having in some species a smooth
skin, or in others more or less tuberculated; sometimes the
skin is covered with a fine silky down, or with hairs; and
some of the larger kinds are armed with spines and
bristles. All the larve of the bombyces subsist on vegetables.
Their jaws are strong, and of a horny texture, and below
them is a small opening, through which the creature draws
the silky thread of so much utility in its general economy.
Most of these larve have sixteen feet, some have only fourteen
feet, and others no more than twelve, six of which are hooked,
and situated on the three first annulations near the head, the
others towards the lower extremity of the body are short,
broad, and very different in structure.

The greater number of species in the bombyx tribe, when
in the larve state, lead a solitary life, in which case they
separate as soon as they are hatched from the eggs, and
crawl about to provide for themselves, the smallest of these
even being able to obtain its own subsistence; they can eat
as readily, and spin, or throw out the silky thread with as
much facility as when grown bigger. The latter is of con-
siderable utility to the larva, for when it wishes to defend
from one branch of the tree or built to another, instead of
being obliged to pursue a circuitous course, by crawling or
walking, it need only take one end of the silk thread to
any particular spot and lower itself by itssilence to the branch
defined; or when suspended mid-way between the branches,
it can pass side with a swinging to any other point
within a convenient distance. In like manner, when observed
by birds or other enemies, it can drop in an infant and
elude the enemy, waiting concealed below among the leaves
or on the ground till the danger is over, and then remount-
ing to the former spot by the aid of this thread. This is
a provision of nature for the security of the larve of the bom-
byces, in common with that of other lepidopterous insects.
Some species of the bombyces live in societies, as may be
observed, for instance, in *bombyx neustria* of entomologists,
(the leeky-moth of English collectors). The larve of this
species, by their united labours, spin a capacious habitation,
in which the infant brood is hatched from the eggs and after
undergoing their several transformations finally become
moths.

Like other larve of the moth tribe, thoese of the bom-
byces cast their skin several times. When full grown, and
approaching the pupa state, thoese of the bombyx kind spin
a fort of web, in which we find the most valuable kind
produced by these creatures at any time of their lives. The
silk spun by the hairy larve is observed to be of little value,
because the creature interweaves it with the hairs it plucks
off its skin for this purpose. The common silk worm (*bom-
byx mori*), whose cocoon contains the most valuable kind
of silk, as is well known, has the skin perfectly smooth, or
free from hair. There are certain species of the larger bom-
byces, the larve of which have smooth skins, but full brest
without any of the spines or bristles, that produce very
strong silk, and are reared with the view of obtaining the
cocoons for the manufacture of silk in the East Indies.
The breed of these useful insects has long been cultivated in
India, although the silk produced from them is very little,
if at all, known in Europe. See Silk. The bombyces
remain in the pupa state for a certain time, varying according
to the species, some only a few days or weeks, others six or
twelve months, two years, or even three. The same day
that the creatures emerge from the pupa state they are in
a condition to perpetuate their race. Almost immediately after
coupling the males die; the females live long enough to de-
posit the eggs in a proper place for their security, and where
the infant brood may find subsistence, after which they
perish likewise.

The species of the bombyx tribe are numerous. Thoese
already described by naturalists amount to a large number;
and there are, in the cabinets of the curious, many more,
especially of the extra-European species, that have never
been described; even in the collections of this country, thoese
of the latter description are numerous. The following are
described by Linnaeus and Fabricius, and enumerated by
Gmelin: atlas, helpeus, auratus, cceropia, paphis, poly-
phemus, cypria, cytherea, multia, promothea, erythrina,
laun, megaera, podium, mistias, femirias, bores, luna,
epiathes, argus, pavonia, minor, media, major,
achelus, angulata, licipia, tau, jo, abas, falomce, profer-

anthe compta, fuliginosa, ornatrix, privena, francia, fese-
ftina, viciella, yeftinella, bomble, pedelllina, an-
nula, grisca, jacobae, rubricillis, pulchella, bella, hi-
trio, and ember. To which are to be added bombbyx figura
Donov. Ind. Inf.; heiplus mappa Donov. Brit. Inf.;
collus labyrinthis, argenteus, lituratus, and nebuloisus,
Donov. Ind. New Holland.

In adhering to the Fabrician system, in preference to that
of LINNEUS, we are to exclude from the foregoing list of
bombbyces the following species: lagenus, rofrata, fagitta,
gemina, deforata, and faga, all of which are to be referred
to the Fabrician genus byblus: humuli, jodutta, lupulina,
hefta, obliqua, canna, crux teuldno, afella, buto, and mappa.

The word seems also to have been used for a key, or con-
trivance for flushing and opening the holes of wind in-
struments.

BOMABX, in the Ancient Naturalis, signifies indifferently
either filk or cotton.

BOMENE, in Geography, a port town of Zeeland, one
of the provinces of Holland, on the north shore of Schouwin
island, one league east of Bruylsweven.

BOMING, an island of Asia, in the mouth of the
Ganges. N. lat. 28° 45'. E. long. 91° 25'.

BOMIO, in Ancient Geography, a station near Axbridge,
according to Antonine's itinerary; but placed by Camden
and Gale at Boverton, in Glamorganshire.

BOMMEL, in Geography, a town of Holland, in the
island of Over-Flashe, 7 miles W. of Willemstad.

BOMMEL, a strong town of the duchy of Gueldres,
ested on the Wali, in the island of Bommel-Waert, first sur-
rounded with a wall by Otho III. count of Gueldres, in
1229; 60 miles N.E. of Antwerp, and 7 N. of Bois-le-Duc.
Bommel was taken by the republican troops of France,
October 4, 1794.

BOMMEL-WAERT, a kind of island, in the province
of Gueldres, about five leagues in length from Louveleen N.W.
to Fort St. Andrew S.E., and two in its greatest breadth,
formed by the rivers Maes and Waah. It is defended by
three forts, viz. St. Andrew, Voor, and Crevecoeur.
The first has five bastions, and was built in 1599 by the ad-
imal of Arragon, and the cardinal Andrew of Aultria,
lieutenant general of the Spanish forces; the second is situ-
ated at a small island, called Voreen, at the end east of Bomm-
el-Waer, and was constructed by the prince of Orange,
and on that account is sometimes called Fort Naafan; and
the third is at the south side of the island towards Bois-le-
Duc. These three forts were contrived to surrender to
prince Maurice in the year 1600. In 1672, the French
took the island under marshall Turenne, who, after destroy-
ning the fortifications, abandoned it in the following year.
At the commencement of the religious disputes, count
Charles de Manfvelt, passing this island with some Spanish
troops, was encompassed by several Dutch ships under the
command of count Hohenlo, who ordered the dykes to be
opened, and thus totally inundated the island, so that the
Spaniards were obliged to retire to the citadel, and would
have miserably perished, if a sudden frost had not constricted
the count to abandon the siege, and to allow them liberty
to retire. In commemoration of this deliverance a chapel
was built at Bruxels, in honour of the immaculate concep-
tion of the Virgin, next the Dominican church, which, being
destroyed in 1697, was afterwards re-built with greater mag-
ificence. In 1794, the republican troops of France, hav-
ing compelled the Dutch to abandon Bommel, overtook
them in their retreat, and compelled a great part of them to
surrender. They afterwards availed themselves of the frozen
state of the Waal, and were making progress towards Gork-
cum and Calemburg; but they were attacked by the British
troops in conjunction with the Hessians, and driven across
the river, with the loss of a considerable number of men and
four pieces of artillery. But this temporary success was of
no permanent avail for restraining the progress of the French
army.

This island belonged to the province of Gueldersland,
except the town of Louveleen, which, with a very small dis-
firict at the western end of the island, belonged to Hol-
land.

BOMO, in Ancient Geography, a name given to the island
of Euboea, from the cattle with which it was florid; the
ancient Arabic word bomo, or bombo, signifying, according
to Hefchylus, cattle, or herds of cattle. This is, probably,
the most ancient appellation; the island having been first
peopled, as Strabo informs us, by the inhabitants of Arabia
and Phrynie.

BOMOL, in Geography, a town of New America, in
New-Yorke, 10 miles S. of Cinaula.

BOMONICA, in Antiquity, an appellation given at
Sparta to the children, who, in the sacrifices of Diana,
should receive the greatest share of stripes with rods, which
they sometimes continued to do the whole day, and
even, as Plutarch relates, to death itself.

The word is formed from bauos, altar, and nain, victary;
importing as much as victor ad areat, or conqueror at
the altar.

BOMPART, MARCELLUS, in Biography, praftified me-
dicine at Clermont Ferrand the early part of the fourteenth
century, and was aulic counsellor to the king. No memo-
rial of his life are here; but his work "Misr Homo," in
which he gives a succinct account of all the principal
diseases afflicting the human frame, was much efteemed.
It was dedicated to Pietre, Riulan, and Guy Patais; and to
be patronized by them was highly creditable: also "Nouveau
Chaffe Pelle," Paris, 1630, 8vo.; and "Lettres d'Hippope-
tracates traduites et commentées," 1632, 8vo. Haller, Bib.

BOMPEN, in Geography, a town of Hindoostan, in the
Panjab, 15 coffes eait of Seba, and 3 miles S.E. of Dnado,
a town on the Beyah. N. lat. 31° 55'. E. long. 75°
57'.

BOMRAUSE, a town of Hindoostan, in the Carnatic,
55 miles W.N.W. of Madras, and 36 N. of Arcot. N. lat.
13° 24'. E. long. 79° 38'.

BOMY, a town of France, in the department of the
fruits of Caias, and chief place of a canton in the district
of St. Omer, 8 miles S.W. of Aire.

BON, JOHN, in Biography, a native of Antervile,
in Champagne, and eminent in his time for his knowledge
in medicine, physician to the king of France, and to the
cardinal de Guife, published, in 1571, "Therapeutia Phur-
rurn," 1670. Paris, "induced to it," he says, "by the igno-
rance of the surgeons, midwives, and tonfors, who at-
tended women in child-birth. By their blunders and in-
expertness in their art, many women lost their lives, and many
children
The accented part of a bar that a discord regularly prepared is struck, and resolved on the unaccented part.

BONA, John, Cardinal, in Biography, was born at Modoni, in Piedmont, in 1659, and entered at an early age in a reformed congregation of Cistercians. After having studied philosophy and theology at Rome, he returned to his own country, and became, in 1651, general of the congregation; and he was, at length, viz. in 1669, nominated a cardinal by pope Clement IX. Upon the death of this pontiff, he was thought of as a fit person to succeed him; but another was elected. The cardinal spent the remainder of his days in study and pious exercises, and died at Rome in 1674. He was the author of several works, chiefly of a devotional kind; such as, "De Divina Philmodia, deque variis ritibus omnium ecclesiasticorum in paulendas divinæ officias," 4to. containing an historical account of the practice of psalmody in the Christian church; and "Remis Liturgicarum libri duo," 4to. giving a similar account of the celebration of the mass. Both these works have been often reprinted; and of the latter an edition much enlarged was published at Turin, in 1747, by father Salles, in 4 vols. fol. Gen. Dict.

BONA, John de, professor of medicine at Padua, published, 1758, "Historiae aliquot curationum, mercis sublimato correodente, perfectorum," Verona, 4to. This medicine was much commended by Baron Van Swieten, and forms probably the basis of most of our nostrums celebrated for their power of removing pimples, blotsches, &c. from the face and other parts of the skin. It was intended by the author to supersed the salivation in the cure of les venera, and in some cases it has been used with complete success; but it too often disappoints the expectation of the prescriber, to be entirely depended on. "Tractatus de Scorbuto," 4to. 1761. The author shews that this disease, though most frequent in cold marshy places, is not unfrequent in warm countries. "Dell ufo e dell abuso dell café," Venet. 1761. Coffee, which is hot and drying, should only be used, he says, by persons of cold phlegmatic constitutions. In the quantity it is usually taken in this country, it will scarce be hurtful to any habit or constitution. "Observationes medicæ ad proximam in nofoconio anno," 1765, 8vo. Patav. 1766. Haller Bib. Anat.

BON, John, in Geography, called by the Moors Rau-Adzar, and the promontory of Mercurius, or Hermes, of the ancients, is a cape of Africa, in the kingdom of Tunis, in the Mediterranean sea, distant 11 leagues E.S.E. from that of Zibec, and forming the eastern point, as Zibec does the western, of the gulf of Tunis. It is so high, that from its summit the mountains of Sicily, distant more than 20 leagues, may be discovered in fair weather. See AEGL, MURUS, and DAKHUL. Cape Bon is situated about N.N.E. from Tunis. N. lat. 36° 50′. E. long. 11° 15′.

BON, in Modern History, the name of a feast celebrated annually by the Japonese in honour of the dead. On this occasion they use a great number of lights, and run with eagerness to the tombs of their departed relations with such choice meats as they conceive to be suited to the taste and nourishment of the dead.

BON, Fr.; Buono, Ital.; as tems bon, and tempo buono, used, in Majic, to express the accented parts of a bar. It is the first note of binary measure of two minims or two crotchets in a bar; the first note of the ternary measure of 3 or 4; and the first and third notes of common time. It is opposed to tems mauvair and tempo catarrco, the unaccented part of a bar. The French, at present, distinguish these portions of a bar by the terms temps fort and temps faible, strong and weak, and almoos loud and soft parts of a bar. It is on the accented part of a bar that a discord regularly prepared is struck, and resolved on the unaccented part.
adjacent country produces corn and fruit, and great numbers of small and large cattle, but is much exposed to the incursions of the plundering Arabs. The French have a factory at Bona, where they purchase corn, oil, leather, wax, and wool, and constantly keep a resident agent, who has charge of the correspondence between Bona, Algiers, La Calle, and Marfellles. N. lat. 37°. W. long. 7° 50'.

Bona Fortuna, Cape, is a cape of Raffia, in the White Sea. N. lat. 65° 25'. E. long. 35° 25'.

Bona Sohlus. See Bassaws.

Bona Dea, the good goddess, in Mythology, a mysterious kind of divinity, whose name was unknown to men, and whose sacred rites, performed by the Veiltal virgins for the safety of the Roman people, were attended only by women. Some have supposed that this name belonged to Cybele, or the earth, as the source of all good things. Pintarch confounds her with Flora. Varro pretends that she was the wife of Faunus; and that she maintained her character for chastity to such a degree, as never to allow herself to look upon any man besides her husband. Lactantius, on the contrary, says, that this wife of Faunus, having drunk wine in violation of the prevailing custom of the period in which she lived, was whipped to death by her husband with rods of myrtle; and that he, afterwards repenting of the deed, and lamenting the loss of his wife, placed her in the rank of divinities. The feasts of the Bona Dea were annually celebrated, with peculiar solemnity, on the first day of May. The house, in which the rites of the festival were performed, was adorned at a great expense; and as the night was the season appropriate to this purpose, the apartments were illuminated with a great number of lights. The veils were conveyed into the house of the sovereign pontiff, or one of the chief magistrates; and care was taken to exclude all males, and all animals of this species; and every thing masculine was so scrupulously excluded, that even pictures of that fort were covered during the ceremony. To this purpose, Juvenal (vi. 339.) says:

"Quaeque nullus alterius deum xenos imitata figuram ed." It was supposed, that if a man by chance, and without any deliberate intention, became the witness of these mysteries, he would be struck blind. Clodius, however, was guilty of polluting these mysteries. Whilst Pompeia, the wife of Cæsar, with whom he was in love, was, according to annual custom, celebrating in her house the awful and mystic sacrifices of the "Bona Dea," Clodius determined to gain access to his mistresses, even in the seclusion of her holy ministry. Accordingly, he dressed himself in a woman's habit, and by the benefit of his smooth face, and the introduction of one of the female servants who was in the secret, hoped to pass without discovery. But by some mistake between him and his guide, he lost his way when he came into the house, and unluckily fell in among the other female servants, who, detecting him by his voice, alarmed the whole company by their shrieks, to the great amazement of the matrons, who presently threw a veil over the sacred mysteries, while Clodius found an opportunity of making his escape by the favour of some of the damoels. This story was presently spread abroad, and raised a general scandal and horror through the whole city. Cæsar put away his wife upon it; and persons of all ranks were deuced of availing themselves of this circumstance to get rid of a citizen, who, by this, as well as other specimes of his auda- ciouset, seem born to create much disturbance to the state. It had been the constant belief of the populace, that if a man should ever pry into these mysteries, he would be instantly deprived of sight; but it was not possible, as Ciceron says, to know the truth of it before, till Clodius ventured upon the experiment; though it was now found, as he tells him, that the blindness of the eye was converted to that of the mind. The affair was soon brought before the senate, and by them referred to the college of priests, who declared it to be an abominable impiety; upon which the confuless were ordered to provide a law for bringing Clodius to a trial for it before the people. Clodius's faction, however, ultimately prevailed; and when the trial came to the fилус, 25 condemned, and 31 abdicated him. When Cæsar, on this occasion, was summoned to give evidence, he declared, that he knew nothing at all of the matter, though his mother Aurelia, and Siler Julus, who were examined before him, had given a punctual relation of the whole fact; and being interrogated, how he came then to part with his wife? he replied, "that all who belonged to him ought to be free from suspicion as well as guilt." Cicero, in his oration for Milo against Clodius, often refers to this sacrilege, with a view of rendering his adversary odious to the people. Many Roman writers have expressed against the licentiousness and inanity of these mysteries, called by way of eminence the Roman mysteries, and celebrated on the 4th of December, though those of the goddesses Cybele were celebrated on the first of May. Nevertheless, this goddess is called holy in an inscription recorded by Gruter, "Bona Dea Sancti sacrum, &c." Lucretius (i. 598.) depicts the good goddesses as bearing a mural crown, and drawn in a chariot by lions. She is also thus represented on the medals of the emperor Philip. The Greeks also had their good goddesses, whom they denominated the goddesses of women; and the Carthaginians paid divine honours to a goddess under this appellation, whom they believed to be Juno.

Bona Fides, or Bona Fide, is usd in speaking of things done with an honest intention, in opposition to those done with a design of fraud and deceit, said to be mala fide. In this sense, we say, a grant, a conveyance, bona fide.

In many cases, in the civil law, the bona fide of an action excludes the want of some of the customary forms.

Contracts bona fide, among Cæstrians, stand contradistinguished from those ficti juici, the former being gained by plain honesty and confidence, which sometimes include several things not expressly mentioned; whereas the latter are restrained to the express terms of the deed. A buyer bona fide, is he who really believed the thing to belong to the seller at the time when he purchased it. A possessor bona fide, is he who is in possession of a thing belonging to another, but which he truly believes his own. To be entitled to the benefits of next accession, it is requisite the persons have possessed the thing bona fide, or really thought themselves the proprietors.

Prescription cannot arise from acts done mala fide; since what was unjust in its origin, can never be made just by time and continuance. See Prescription.

Bonæ Fideæ Actiones, those wherein for farther light, the judge might take cognizance of things not mentioned between the parties.

Bona Fide Judgment, that wherein the parties are obliged to pay each other what is due bona fide, i.e. justly and equitably; and the judge has a power of electrom what is thus due to the actor or plaintiff; a power given him by the formulo of the praetor, viz. ex fide bona, vel quantum quidam militia.

Bona Cæsara. See Good A-bearing.

Bona Gratia, a phrase anciently used in speaking of divorces, which were brought amicably about for some just reason, with the consent of both parties, and without any crime
crime on the part of either, as in case of old age, difcape, barreftrens, monachism, captivity, or the like.

Bona defunti ad colligendum. See Colligendum.

Bona Mobilia. See Mobilia.

Bona Notabilia, in Law. Where a perfon dying has goods, or good debts, in another diocefe, but within the fame province, besides his goods in the diocefe where he dies, amounting to the value of five pounds at least, he is said to have bona notabilia: in which cafe, the probate of his will, &c. belongs not to the bishop of the diocefe where he dies, whole jurisdiction cannot extend beyond the bounds of his own diocefe, but to the archbishop of the province.

Though if a perfon happens to die in another diocefe than that wherein he lives, on a journey; what he hath about him above the value of five pounds, &c. shall not be bona notabilia.

Bona Patria, a jury or afmey of countrymen, or good neighbours. See Assize and Jury.

Bona peritura, perishable goods. By lat. 13 Ed. I. cap. 4, the cargo of a ship that hath been cast away shall be kept for a year and a day, and reftored to the rightful owner; but if the goods be fuch as will not endure fo long, they are bona peritura, which the sheriff is allowed to fell, and to account in money for the value.

Bona vacantia, goods, fuch as roat fift, shipwrecks, treafure-trove, wafis, and effrays, in which no one can claim a property. Thes goods, by the law of nature, and by the imperial law, belonged to the first occupant or finder; but in the modern confitutions of European governments, they are annexed to the supreme power by the positive laws of the fate.

Bonacciolus, Lewis, in Biography, a phyfician of great eminence and authority, pradtice medicine at Fer-

rar, in the early part of the 16th century. His great work "Annæas mallebris, five de fettus formatione," was first published in 1503, in fol. "qua, prater alia, plurima quo-
quæ ad coitum, et ad rem veneram facientia, dictione liber-

rima deferuntur." It was neverthelefs dedicated to Lu-
cretia, daughter to pope Alexaner VI. But the dedica-
tion, Blomenbach observes, is only to be found to the folio edition, princip, which is extremely rare. A copy of this edition was fold by Paternon, in 1791, with the fplendid Paris library.

This writer, Douglas fays, was the firft who diftinguifhed the citoriis from the uymphæ, and fowed them to be diftinct parts. The Ænæas was again printed in 1587. It was alfo inferted by Cafpar Wolfius in his Collection of Treatises, called "Gynecia, five de mulierum morbis," 4to. 1586, re-edited by If. Spachius, fol. 1597; and with Pi-
næus's phyfiological treatifes. Though of little value now, the work was for a long time held in great efteme; the au-

Bonachi, in Geography, a town of North America, in New Navarre, 180 miles S. of Cafia-grand.

Bonacopus, Hercules, in Biography, of Ferrara, and for some years professor in medicine at Bologna, pub-

lished, in 1552. "De affectu quem Latini tamina appel-
lant, 4to. " De humorum exuperantiam fignis ac ferapfs, de compositions Thoricus, de modo preparandi aquam ligni fancti, &c." 4to. 1557; the latter medicine was now in the zenith of its reputation for its powers in curing the fites ve-
neres; "De curatione pleuridis, ad Hippocratis, Galeni, &c. monumentis depremptas," 4to. 1552. He died in 1558.

Bonacopus had much learning, and contributed by his works to revive among his compatriots a taste for literature, partic-

ularly for the works of the ancient Greek fathers in medi-

ine. His brother, or near relative, James Bonacopus, was also in much efteme. He was phyfician to pope Paul III. He died in 1553; aged 69 years. Altrac. de Morb. Gall. Haller. Bib. Med.

Bonafides, Francis, professor in the practice of medicine at Padua, published, in 1533, "Quello de cura

pulmionidis per veneficonem, adversus Curtum," 4to. Ve-

net. He defends the practice of the Arabian phyficians, who recommended bleeding by the vena faphena, on the fide opposite to the part affected, in plethoric habits; in dedication confifions, by the bafifca in the arm of the fide where the pain was felt; a different not attended to in modern practice. Haller. Bib. Med.

Bonaire, in Geography, an ifland almost uninhabited, near the coaft of South America, about 20 leagues from the continent, and 14 S.E. of Curaçoa, belonging to the Dutch. It is about 50 miles in compafs, and has on the S.W. fide, near the middle of the ifland, a good bay and road. Here were formerly a few houfes, with a fort guarded by a small num-

ber of soldiers; and five or fix Indian families refided here, and cultivated maize, yams, potatoes, &c. The ifland has plenty of cattle and goats, which are annually falted and fent to Curaçoa. On the south fide is a good falt pond, from whence the Dutch procure falt. N. lat. 12° 16'. W. long. 68° 18'.

Bonames, a town of Germany, in the circle of the Upper Rhine, 3 miles N.N.W. of Frankfort on the Mayne.

Bonamy, Peter-Nicholas, in Biography, was born at Louvres, in the district of Paris, in 1694, and educated for the ecclefiatical profeflion. But, devoting himself en-
tirely to literature, he became under-librarian of St. Victor, and diftinguifhed both by the politenes of his manners, and the variety as well as affufity of his studies. In 1727, he was admitted a member of the Academy of Infpictions and Belles Letters, and made many valuable contributions to its Memoirs. His papers are characterized by fimple but correct language, variety of erudition, clearfnes of argument, and folidity of criticism. At the infligation of M. Turgot, a place was created of hifloriographer of Paris, and Bonamy was appointed to occupy it. He was thus led to write va-
rious memoirs relative to the hiftory and antiquities of the city; and on occasion of a bequeft of a curious library to the city, he was made librarian. From the year 1747, he con-
ducted the "Journal de Verdun" with the ftrictefl propriety and decorum. In univerfal efteme for candour and probity, as well as learning, he died at Paris, in 1770, aged 76. Gen. Bib.

Bonamy's Point, in Geography, lies on the southern fide of Chaleur bay, at the N.W. extremity of Eel river cove, and forms the S. limit of Riffigouche river.

Bonana, in Ornithology, a species of Oriolus, of a fulorous colour, with the head and broad cheflnut; back, quill, and tail feathers black. Gmel.

This is called by Brillon santhornmus, and le carouge. It is fuppofed to xochitlan of Hern. Mex. and xochital altera of Ray. Brown names it the bonana bird.

The length of this bird is seven inches; bill black; bafe of the lower mandible grey; head, neck, and broad che-

fut; upper part of the back velvet black; lower part, with the lump, belly, thighs, and under the wings, a deep orange red; vent the fame, tipped with cheflnut; greater wing-feeters, quills and tail, black; legs and claws grey. The female differs in having the colours less vivid than in the male.

The bonana bird is a native of Martinico, Jamaica, and the other iflands in the Welf Indies, where it chiefly inha-

bits
bits woods. The neck of this species is of a curious structure, being composed of leaves and fibres of vegetable, sewed with the greatest ingenuity to the leaf of a banana plant, in such a manner that the leaf itself forms one of the sides to the neck; when completed, it is said to be exactly in shape of the fourth part of a globe.

Another bird, of a species very analogous to the above, is described by Ray and Sloane under the names of watchy picket, Spanish nightingale, American hang-neck, and iterus minor nidian suspansus. This appears to have been confounded with the former kind. Briffon, deeming them both the same, included the synonyms of the two species together, which led later observers into an error. Dr. Latham separates them; and, upon the authority of this able ornithologist, Gmelin gives the watchy picket as a distinct species under the name of variolus nidianus. This specific name is chosen, in allusion to the manner in which the neck is fastened to the extremity of the further twigs of the trees in which it lives. The neck of the banana bird is before referred; that of the watchy picket is very different, being of a long cylindrical form, composed of stalks, fibres, and the inward hairs of the "old man's beard," which latter bears a strong resemblance to horse-hair. The two opposite methods of constructing, as well as placing the neck, as Dr. Latham judiciously observes, cannot surely belong to one bird. See NIDIPENDULUS.

Obf. Gmelin places the watchy picket, with a note of scepticism, as a synonym to motacilla calidris. This might possibly mislead, without observing that Sloane, Ray, &c. describe more than one bird under that name; the latter is the American nightingale of Edwards, and the hang-neck warbler of Latham, the bird called the watchy picket by Sloane, Hist. Jan. 2. p. 290.

BONANNI, Padre Filippo, in Biography, a Jesuit, who published at Rome, in 1722, in 4to. drawings of a curious collection of musical instruments, represented in the hands of the performers; entitled "Gabinetto Armonico Pieno d'Istrumenti Sonori indicati e spiegati—ed offerto al S.tno Re David." The collection is curious, and the instruments are not ill executed; but we are not sure that the drawings are always correct.

BONARATTE, in Geography, a small island of the Indian ocean, south-east of Saleyer, ceded by the Macassars to a raja of Boni, in Celebes, who used it as a place of education for his dancing girls, and appropriated to the same purpose by the kings of Boni. It is chiefly inhabited by Bougogene.

BONARELLI, Guidubaldo, Count, in Biography, an Italian poet, was born in 1563, in the palace of the duke of Urbino, to whom his father was favourite minister; and, after previous instruction at home, was sent to study theology at Pont à Mousson, in France, where he made such proficiency, that he was invited, in the age of 19, to take the chair of philosophy at the Sorbonne. He returned, however, into Italy, and was employed by Cesar, duke of Modena, in some important negotiations at the courts of Rome and France; but incurring disgrace by his marriage, he withdrew to Ferrara, and, in 1607, published the pastoral drama by which he acquired celebrity. This drama was acted by the academy of "Entrepids" at this place, of which Bonarelli had been one of the founders. In his way to Rome, for the purpose of assuming the office of major-domo to cardinal Este, he was seised at Fano with a disorder, which terminated his life, Jan. 8, 1608. The drama of Bonarelli, entitled "Filii di Sciro," was much applauded both in Italy and other countries at its first appearance, and was ranked by common opinion next to the Aminta of Tasso, and the Paftor Fido of Guarini. Although this pastoral has many poetical beauties, it strongly indicates the corrupt taste which then prevailed: nevertheless it maintains its place among Italian pastorals. Many editions of it have been printed; and it has been translated into the French and English languages. Gen. Biog.

BONARES, in Geography, a town of Spain, in Andalusia; one league from Lucena.

BONARIENSIS, in Ornithology, that species of Loxia, or grosbeak, described by Buffon under the name of noir-fouré. The head and back of the neck are blue; body above blackish, beneath yellow; belly and vent sulphur colour; wings and tail blackish, edged with blue. This bird is about seven inches long, and is observed generally to fly in pairs; they haunt gardens, where they do much mischief, as they feed on seeds. The bill is blackish; legs reddish; claws acute, curved, and grooved; the hind claw largest. This is the marginell grosbeak of Latham.

BONARIENSIS, a species of Tanagra, that inhabits Bonana. This is eight inches long; the colour black, glossed with violet, and with greenish on the wings and tail. Gmelin, &c. Bonon calls this bird tanganus. The beak is black, the legs blackish, with large claws. The female is of a brown colour, with the head black, and glossed with blue.

BONARIENSIS, a species of Motacilla, of a black colour; throat and sides fuscous; face, chin, middle of the belly, and exterior tail feathers, white. This bird is of the size of a linnet; bill blackish; hind-claw large. Buffon calls this demi-fain noir et roux. It is the white-chinned warbler of Latham.

BONAROTA, in Botany, Michel, and Scopoli. See Pederota.

BONASCOLA, in Geography, a town of Italy, in the state of Genoa, near the sea-coast, 4² miles S.S.W. of Brugnetto.

BONASIA, in Entomology, a species of Cicada (membracis, cruciata) found in America. Fabricius describes it as having the thorax bicornuted, produced behind, and edged with white; at the base of the wings is a white spot.

BONASIA, is also the name of a species of Ptilio (Heronius), the wings of which are fuscous, with a common fulvous band; the lower pair spotted at the base with black.

BONASIA, in Ornithology. Under this name Buffon describes several species of the Tetrao genus; as for instance, tetrao Canadenis he calls bonafia fruti Hudsonis; tetrao Canace, bonafia Canadensis; tetrao lagopus, bonafia fœcata; and tetrao togatus, bonafia major Canadensis.

BONASUS, in Zoology, one of the synonyms of the wild ox. See Bos Taurus.

By some the bonafus is underfoot to be that particular kind of wild ox which has the horns bent back, and the mane very long, Bonafus of Tinny, &c. boninis in fætus, juba longissima. Linn. Syll. Nat. The bison is thought by Gmelin to be the bonafus of Aristotle.

BONAT, in Geography, a town of France, in the department of the Creufe, and chief place of a canton, in the district of Gueret, 3² leagues N. of Gueret.

BONAVENTURA, St., in Biography, a cardinal of Rome, and entitled the "Seraphic doctor," was born at Bagnarea, in Tuscany, in 1221; and having entered into the order of Minorites, in 1243, studied at Paris under Alexander de Hales, and there taught theology with great applause. He received his doctor's degree in 1255, and in the following year was made general of his order. He declined accepting the archbishopric of York, to which he
was nominated by pope Clement IV. in 1265; and, after his death, the choice of a successor was referred to the cardinals to Bonaventura, who fixed on Gregory X. by whom he was made cardinal, and whom he attended to the second council of Lyons, in 1274, where he died in the same year. He was canonized by Sixtus IV. in 1492, and declared a doctor of the church by Sixtus V. in 1588. His works have been collected in 8 vols. fol. and were printed at Rome in 1588; and an edition of them in 14 vols. 4to. has also been published. Among these are his "Life of St. Francis," the founder of his order, and "A Commentary on the Matter of the Sentences," in which he appears to be a complete master of the theology of the 13th century. To him has been ascribed the institution of the religious confraternities; and though his private character, and literary talents, are commended both by protestants and catholics, he has incurred some reproach for zeal with which he promoted the worship of the virgin Mary, as the mother of God. Morel. Encycl. Mohilem. vol. iii.

Bonaventura, Frederic, an eminent scholar and physician of Urbino, in Italy, who flourished in the early part of the 17th century, published, in 1601, "De natura partus oesometritis, aduersus vulgarem opinionem, libri decem," Francof. folio; an enormous volume, containing upwards of one thousand pages, on this uninteresting subject, in which he has introduced the opinions of different writers, and accounts of all the controversies that have been held on the legitimate period of uto-gellation in women. The author had published a dissertation on the subject, in the preceding year, which he incorporated in the great work, but with which a modern reader would probably have been fully contented. Haller. Bib. Med.

Bonaventura, Cape, in Geography, is situated on the coast of New Guinea, in S. lat. 6° 15', and about 65 leagues N.E. from port St. Auguline. The land is low and luxuriant, and produces the cocoa-nut, bread-fruit, plantain, &c.

Bonaventura, the name of an island, north-east of the bay of Chaleur, off the coast of New Brunswick, in the gulf of St. Lawrence, and a little to the south-west of the point which forms the south-west entrance into that river; about a league from Cape pé bay. — Allo, an island on the south-west side of the entrance into Porto-Bello harbour, opposite to the mouth of Guanache river. See Porto-Bello.

Bonaventure, of Buenaventura, a river, bay, harbour, and fort, on the coast of Papayan, in South America, nearly south from Panama bay. N. lat. 4° 20'. W. long. 77°. Barks and sloops of 40 or 70 tons may go up to a village a league beyond the fort. Bonaventure is the staple port of Cali, Papayan, Sta. Fé, &c.

Bonaventure, Cape and Port, are situated on the east coast of Newfoundland, about south-west of Bonavista cape, and form the north entrance into Smith's found, from whence the coast runs S. by W. into Trinity bay. — Allo, a bay on the east side of the island of St. Vincent. N. lat. 13° 9'. W. long. 61° 18'.

Bonavista, so called in reference to its beautiful appearance at sea, the most easterly of the Cape de Verde islands, about 20 miles long, and 12 broad, and distant about 70 leagues west from the coast of Africa. Its surface is low towards the sea, but within hilly, particularly towards the north-east extremity, where is a hill, which, from its conical and truncated shape, appears to have been a volcano; and there is another hill, much higher, towards the south-west end, with high land to the northward of it. The southeasterly winds are strong and sandy, barren, and uncultivated; milk, goats, flocks, and turtle, are the principal food of the inhabitants. It affords some salt; and if the culture of it were not neglected, it would yield cotton and indigo. It is known at a distance by several white banks on its north side, where the shore is bold, and where a rapid river discharges itself into the sea. This island has a good harbour on its west side, where vessels may lie in 15 or 16 fathoms water. At the distance of a league or a league and a half from the south-east point of the island is a reef of rocks; and over this point, says Capt. Cripe, there is a pretty high round mountain, rising not far from the shore. This point, by his observations, is in N. lat. 16° 9', and longitude from London, by account, 21° 51' W. The latitude of the north end of the island is 16° 12' N., and of the south end 15° 57' N. but that at the east end was not ascertained. Mr. Wales, in the second voyage, determined the latitudes of these three points as follows: north point 16° 13' 34" N., east point 16° 33' 57" N. and latitude of the south point 15° 57' N. Stavenius says, that this island has two eminences of a middling height, that appear distinctly upon it; and that there are two reefs, one at the north side, and one at the south side, which stretch out to the eastward, and which are both very dangerous. According to the account in lord Macartney's embassy to China, the sea-coast on the south-east side was guarded by rocks; but towards the south-east end the shore was much covered with white sand. On that side there seemed to be neither cultivation nor inhabitants. The latitude of Bonavista was 16° 10' N. and the longitude 22° 47' W. The variation 12° 36' to the westward of the pole. This island belongs to the Portuguese.

Bonavista, Cape, the extreme N.W. point of the island of Cuba in the West Indies, opening into the gulf of Mexico, from whence the land falls off southerly to cape St. Antonio.

Bonavista, Cape and Bay of, lie on the east side of Newfoundland island, the cape lies in N. lat. 46° 54', and W. long. 52° 34', and was discovered by John Cabot and his son Sebastian, in 1497, under a commission for exploring unknown lands, obtained from Henry VII. The bay is formed by this cape and cape Freels, 15 leagues apart.

Bonaye, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Nantes. The place contains 834, and the canton 9,530, inhabitants; its territory comprehends 135 kilometres and 7 communes.

Boncat, a town of France, in the department of the Lower Pyrenees, 6 leagues N. of Bayonne.

Bonchamps, a town of France, in the department of the Mayenne, 2 miles S.W. of Craon.

Bonconica, Oppenheim, in Ancient Geography, a town of Gaul, placed between Mogontia to the north, and Borbotomagus to the south, seated on the river Rhenus, in Germany prima.

Bonconvento, or Bon-convento, in Geography, a town of Italy, in the territory of Sienna, where the emperor Henry VII. died; 12 miles S. of Sienna.

Boncore, Thomas, doctor in philosophy, medicine, and law, in Biography, has left a memoir of a destructive pestilence, which raged at Naples, where he was in high credit, as a practitioner in medicine, in the year 1622. "De populi, horniih, ac perlinent guttulis affectione, nobilissimam urbem Neapolim vexante, coniilium," 4to. 1622, Neap. An early account of the scarlatina anginosus; or malignant sore throat, which has of late years made such frequent appearance, and proved so destructive, among children particularly, in this country. Elov. Bib. Hill.

Bonk, John, an English grammarian of the 16th century, was a native of Somersetshire, and after finishing 6
his grammatical education at Winch Gibraltar, was entered, in 1569, at the age of 19 years, a student in the University of Oxford, where he was distinguished by his proficiency in academic learning. Having taken his degree of bachelor and master of arts, the former in 1573, and the latter in 1579, he was promoted by the master and wardens of New College to the mastership of the free-school at Taunton, in Somersetshire, which office he occupied with reputation for several years. At length he quitted the laborious station of school-master, and directed his attention to physic, which he practised more for amelioration than profit. He died in 1612, and was buried in the chancel of the church at Taunton. He wrote "Commentaries on Horace and on Persius."

Bond, or Obligation, in Law, is a deed whereby the obligor, or person bound, obliges himself, his heirs, executors, and administrators, to pay a certain sum of money to another called the obligee, at a day appointed. If this be all, the bond is called a simple one, "Simplex obligation;" but there is generally a condition added, that if the obligor does some particular act, the obligation shall be void, or else shall remain in full force; as payment of rent, performances of covenants in a deed, or repayment of a principal sum of money borrowed of the obligee, with interest, which principal sum is usually one half of the penal sum specified in the bond. In case this condition is not performed, the bond becomes forfeited, or absolute at law, and charges the obligor while living; and after his death the obligation depends upon his heirs, who, on defect of personal affets, is bound to discharge it, provided he has real affets by descent as a recompence. So that it may be called, though not a direct, yet a collateral, charge upon the lands.

This security is called a "specialty;" the debt being therein particularly specified in writing, and the party's seal, acknowledging the debt or duty, and confirming the contract, rendering it a security of a higher nature than those entered into without the solemnity of a seal. In order to make a good obligation, it has been held that three things are necessary, viz., writing in paper or parchment, sealing, and delivery; but it hath been adjudged not to be necessary, that the obligor should sign or subscribe his name, sealing being deemed sufficient, and subscribing being no essential part of the deed. And though the seal be necessary, yet if the word sealed be wanting, it is remedied by verdict and pleading over, for all necessary circumstances shall be intended; and if it were not sealed, it could not be the deed or obligation of the party. Moreover, though sealing and delivery be essential in an obligation, it is not necessary to mention in the bond, that it was sealed and delivered, because, according to Lord Coke, "2 Co. 54 a." these are things which are done afterwards. The name of the obligor subscribed is sufficient, though there is a blank for his Christian name in the bond; and where the obligor's name is omitted to be inserted in the bond, if he signifies and seal is, the court of Chancery may make good such an accident. An obligation is good, though it has no date, or a false or impossible date; the date not being of the substance of the deed; but the day of the delivery is the day of date, though no day be set forth. Every deed is supposed to be delivered and made on the day of its date; and if the plaintiff declare on a date, he cannot afterwards reply, that it was first delivered at another day. A plaintiff may suggest a date in a bond which has none, or one that is impossible, &c. provided that the parties and sum are sufficiently expressed. A person shall not be charged by a bond, though signed and sealed, without delivery, or words, or other act, amounting to a delivery. But it may be delivered by mere words; and an actual delivery, without speaking any word, is sufficient. If a bond be altered by interlineation in a material part, it becomes void; and it may be made void by rasure, &c. or by raising the date, &c. after delivery. If the words at the end of the condition, "that then this obligation to be void," are omitted, the condition will be void, but not the obligation. If the condition of a bond be impossible at the time of making it, or be to do a thing contrary to some rule of law that is merely positive, or he uncertain or indefinite, the condition alone is void, and the bond shall stand fingle and unconditional; for it is the folly of the obligor to enter into such an obligation, from which he can never be released. If it be to do a thing that is malum in se, the obligation itself is void; for the whole is an unlawful contract, and the obligor shall take no advantage from such a transact.ion. And if the condition be possible at the time of making it, and afterwards becomes impossible by the act of God, the act of law, or the act of the obligee himself, there the penalty of the obligation is saved; for no prudence or foresight of the obligor could guard against such a contingency. Co. Litt. 266. When a condition is doubtful, it is always made most favourably for the obligor, and against the obligee; but so that a reasonable construction may be made as nearly as possible according to the intention of the parties. If no time be limited in a bond for payment of the money, it is due presently and payable on demand. 1 Brown. 52; and if a condition be impossible in respect of time, it shall be paid presently. Jones 146. 1 Leon. 101. If the party, who is bound to perform the condition, disfables himself, this is a breach. A bond made with condition not to give evidence against a felon, &c. is void; but the defendant must plead the special matter. 2 Wilk. 341, &c. Condition of a bond to indemnify a person from any legal prosecution is against law, and void. 1 Latw. 667. And if a sheriff takes a bond as a reward for doing of a thing, it is void. 3 Salk. 75. See Condition.

On the forfeiture of a bond, or its becoming fingle, the whole penalty was formerly recoverable at law; but here the courts of equity interposed, and would not permit a man to take more than in conscience he ought, viz. his principal, interest, and expenses, in case the forfeiture accrued by non-payment of money borrowed; the damages sustained, upon non-performance of covenants; and the like. And a similar practice having gained some footing in the courts of law, (see 2 Keb. 553, 555. Salk. 550, 597. 6 Mod. 11. 60. 101,) the statute 4 and 5 Ann. c. 16. at length enlarged, in the same spirit of equity, that, in case of a bond, conditioned for the payment of money, the payment or tender of the principal sum due, with interest and costs, even though the bond be forfeited, and a suit commenced thereon, shall be a full satisfaction and discharge. The court of Chancery will not generally carry the debt beyond the penalty of a bond; yet in a case, where a plaintiff sought relief against such penalty, though it was decreed, it was on the payment of the principal money, interest, and costs; and notwithstanding they exceeded the penalty, this was affirmed, 1 Vern. 350. 1 Eq. Ab. 92. 6 Vin. tit. Penalty. 3 Comm. 435. And where the condition of a bond is to perform a collateral act, damages may be recovered beyond the penalty, and the court of K. B. will not stay the proceedings on payment of the money into court. 2 Term Rep. 388.

All persons who are enabled to contract, and who are supplied in law to have sufficient freedom and understanding for that purpose, may bind themselves by bonds and obligations. 5 Co. 119. 4 Co. 124. 1 Roll. Abr. 340. If a person, illegally imprisoned, enters into a bond, during such restraint, to the person who causes it, the same may be avoided.
avoided for dures of imprisonment. Co. Litt. 253. 2 Infr. 482. The bond of a femce covert is mov. fato void, and shall bind neither her nor her husband. The bond of an infant, even for necessaries, with a penalty for payment, is void. But if an infant, femce covert, &c. enter with a stranger, who is not subject to their disabilities, into an obligation, the stranger shall be bound by it. However, infants, idiots, femce coverts, and alients, may be obligees. Sole corporations, such as bishops, prebends, parsonys, vicars, &c. cannot be obligees; but a corporation aggregate may take any chattel, as bonds, leases, &c. in its political capacity, which shall pass in succession, because it is always in being. Cro. Eliz. 461. Dyer. 481. 2 Salk. 64. 2 T. Abr. 147. If a drunken man gives his bond, it binds him; and a bond without consideration is obligatory, and no relief shall be had against it, for it is voluntary, and as a gift. Jenk. Cent. 169. But on the general issue, the defendant may give in evidence that they made him sign the bond when he was so drunk that he knew not what he did; and though a voluntary bond cannot be relieved against in equity, it may not be paid in a course of administration, so as to take place of real debts, even by simple contract; yet it shall be paid before legacies. 1 Chan. Cas. 157. An heir is not bound, unless he be expressly named in the bond, though the executors and administrators are. Dyer 13. Two or more persons may bind themselves jointly in an obligation, or they may bind themselves jointly and severally; in which latter case, the obligee may free them jointly, or he may free any one of them at his election; but if they are jointly and not separately bound, they must be freed jointly; and in such case, if one of them dies, his executor is totally discharged, and the survivor or survivors only chargeable.

With regard to discharge of bonds, if a lesser sum be paid before it is due, and the payment is accepted, it shall be good in satisfaction of a greater sum; but after the money is due, a lesser sum, though accepted, shall not be a satisfaction for a greater sum. Moor. 677. 3 Bulst. 301. 1 Salk. 593. 1 Lutw. 696. If a bond is voided, the money cannot be recovered in a subsequent action. Cro. Cas. 85. Moore. 872. Cro. Eliz. 716. 727. 2 cro. 579. A bond, on which neither principal nor interest has been demanded for 20 years, will be presumed in equity to be satisfied, and be decreed to be cancelled; and a perpetual injunction granted to stay proceedings thereon. 1 Ch. Rep. 779. Finch. Rep. 78. Satisfaction, moreover, may be presumed within a certain period, if any evidence can be adduced in aid of the presumption, such as the settlement of an account in the intermediate time, without any demand. Yet length of time is no legal bar; and is only a ground for the jury to presume satisfaction. 1 Term. Rep. 270. As to the pleading of performance of a condition, the defendant must set forth in what manner he has performed it. By flat, 8 and 9 Will. Ill. c. 11. § 5. in actions on bonds for performance of covenants, the plaintiff may assign as many breaches as he pleases, and the jury may assess damages. In debt on a bond, the defendant may have several pleas in bar. 1 Salk. 180. But a defendant in an action on a bond cannot plead, "Non exit factum," and a tender as to part. 5 Term Rep. 97. In debt on an obligation the defendant cannot plead, "Nil debet," but must deny the deed by pleading "Non existat factum," for the fee of the party continuing it, it must be disputed. 4 Coke. Lig. 458. The defendant being prosecuted, is to plead "Non damnificatus, &c." The selling of any bond, bill, &c. for money, being the property of any one, is made felony, as if offenders had taken other goods of like value. Stat. 2 Geo. II. c. 25.

Form of a bond or obligation, with condition for the payment of money. "Know all men by these presents, that I David Edwards, of Lincoln's Inn, in the county of Middlesex, esquire, am held and firmly bound to Abraham Barker, of Dale-hall, in the county of Norfolk, esquire, in ten thousand pounds of lawful money of Great Britain, to be paid to the said Abraham Barker, or his certain attorney, executors, administrators, or assigns; for which payment well and truly to be made, I bind myself, my heirs, executors, and administrators, firmly by these presents, sealed with my seal. Dated the fourth day of September, in the twenty-first year of the reign of our sovereign lord George the third, by the grace of God king of Great Britain, France, and Ireland, defender of the faith, and so forth, and in the year of our Lord one thousand seven hundred and—"

The condition of this obligation is such, that if the above bounden David Edwards, his heirs, executors, or administrators, do and shall, well and truly pay, or cause to be paid, unto the above named Abraham Barker, his executors, administrators, or assigns, the full sum of five thousand pounds of lawful money of Great Britain, with lawful interest for the same, on the fourth day of March next ensuing the date of the above written obligation, then this obligation shall be void and of none effect, or else shall be and remain in full force and virtue.

David Edwards, (L. S.)

Sealed and delivered, being first duly

limped, in the presence of

George Carter,
William Browne.

Blackstone's Com. ii. 340. Jacob's Law Dict. by Tome-

lins, vol. i. tit. Bond.

Bond of Arbitration. See Arbitration.

Bond of resignation. See Resignation.

Bond-tenants, are the fame, in respect to the nature of their tenure, with copy-holders, and customary-tenants. Blackstone's Com. vol. ii. p. 148.

Bond, in Masonry and Brick-laying, is when bricks or stones are, as it were, knit and interwoven; and when they fix, make good bond, they mean that the joints are not made over, or upon other joints; but reach at least six inches, both within the wall and on the surface, as the art of building requires.

Bondage properly denotes a state of servitude or slavery.

Bondage, bondageum, in English Law Writers, the fame

with villenage.

'Tenants in bondage paid heritors, and did fealty; they were not to fell trees in their own garden, without licence of the lord.

The widow of a tenant in bondage held her husband's estate, quamdiu vivserit fine marito.

Bondage, by the forelock, or bondageum per anteriores crimina capitati, was when a Freeman renounced his liberty, and became slave to some great man; which was done by the ceremony of cutting off a lock of hair on the forehead, and delivering it to his lord; denoting, that he was to be maintained for the future.

Such a bondman, if he reclaimed his liberty, or were fugitive from his master, might be drawn again to his servitude by

BON

BON
by the nose; whence the origin of the popular menace, to pull a man by the nose.

BONDELIA, in Ancient Geography, a town of Italy, in Etruria. Ptolemy.

BONDENO, or BUONDENO, in Geography, a town of Italy, in the duchy of Ferrara, at the conflux of the Panaro and Po, 9 miles W. of Ferrara.

BONDMAN, BONDO, formed from the Saxon bond, signifying a fetter, in the English Law, is used for a villain, or tenant in villenage. See Villain.

The Romans had two kinds of bondmen; one called servi, who were those either bought for money, taken in war, left by succession, or purchased by some either lawful acquisition; or else born of their bondwomen, and called serva. Both are called in our law villains in gros, as being immediately bound to the person and his heirs. We may add a third kind of bondmen mentioned by Jullian, called adferpittii glebe, or agrigeniti; who were not bound to the person, but to the ground or place, and followed him who had the land. Thence, in our law, are called villains regardants, as belonging to the man or place.

In the English as well as Scottish laws, those called by the Romans serva, are sometimes also denominated nativi, as being born on the land. See NATIVUS.

BONDORF, in Geography, a country of Germany, in the circle of Swabia, about five leagues long, and between one and three broad, lying between the Brigaw and the landgraviates of Baar and Stuhlingen. It had formerly lords of its own, but in 1013 was purchased by the abbey of St. Blaise. It is supplied in the imperial matrices, at 25 florins, 30 kruizers; and its contiguous to the chamber, at Wetzlar, is 12 rixdollars, 15 1/2 kruizers. This territory comprehends the town of Bondorf, 23 miles N. N. W. of Zuric, and several villages.

BONDOU, a kingdom of Western Africa (formerly a part of the kingdom of Bambouk), the capital of which is Fatteconda, near the eastern bank of the river Falme. This kingdom is bounded on the north by Kajaga, on the east by Bambouk, on the south-east, and south and the Simbani wildernesses, on the south-west by Woluli, and on the west by Foota Torra. It lies between N. lat. 15°32' and 15°35', and between W. long. 10°8' and 11°18'. Mr. Park, in his journey through this kingdom towards the east, found that the country, though covered with woods, like that of Woluli, rose into hills, especially towards the Falme river, and that the soil varied to a considerable degree; but wherever the land was cleared, great natural fertility was observable. Bondou, in particular, may literally be pronounced a "land flowing with milk and honey." Both these articles, together with rice, and Indian corn of two or three species, were to be obtained at a small expense. Of their honey, the unconverted or pagan natives make an intoxicating liquor, much the same as the mead, or metheglin, of Europe; and this, and the wine of the palm-tree, constitute their principal liquors. The price of a fowl in Bondou was a button, or a small bit of amber; goat's flesh and mutton were proportionably cheap; and for six or eight amber beads Mr. Park might at any time have purchased a bullock. The domestic animals are nearly the same as in Europe. Swine are found in the woods, but their flesh is not esteemed. Probably the marked abhorrence with which this animal is held by the natives of Mahomet, has spread itself among the Pajus. Poultry of all kinds, the turkey excepted, may be had everywhere. The Guinea fowl and red partridge abound in the fields; and the woods furnish a small species of antelope, of which the venison is highly and deservedly prized. Of the other wild animals in the Man-
dingo countries, the most common are the hyena, the pan- thcr, and the elephant. But of the method of taming the latter animal, and applying his services to the use of man, the natives of Africa are totally ignorant; and when they were told by Mr. Park, that this was done in the east, they treated the information with contempt, and exclaimed "Tobuboo fonnio," i. e. the white man's lie. They find means, however, to destroy the wild elephants by fire-arms for the sake of their teeth, which they transfer in barter to those who fed them again to the Europeans. They eat the flesh, and deem it a great delicacy. The pastures of Bondou furnish an excellent breed of horses; but the usual beast of burden in all the negro territories is the ass. The application of animal labour to the purposes of agriculture is no where adopted, and the plough is an instrument altogether unknown. The chief implement used in husbandry is the hoe, which in different districts is of various forms; and labour is universally performed by slaves. The Mandingoes cultivate, besides the grains proper to tropical climates, ground-nuts, yams, and pompiions. They likewise raise cotton and indigo, and they produce of these materials a tolerably fine cloth, of a rich blue colour; and they make good soap from a mixture of ground-nuts and a ley of wood- ashes. Their trade with the whites is composed of slaves, gold-dust, ivory, and bees-wax. Their inland traffic confits chiefly of salt, which is procured from the Moors, in barter for corn and blue cloth, and of warlike stores, which are obtained from the European traders on the Gambia river. These are sold again to itinerant merchants, called "Slaves," who come down annually from distant countries, with slaves, and a commodity called "Shea-toulou," which is an excellent sort of butter, produced from the kernels of a nut boiled in water. They also bring tin, a fine of iron, which is manufactured in the interior districts; and these articles of this metal which are in use among the natives of the coast, are made of iron from Europe. The natives of the Gambia countries are also supplied, in considerable quantities, with sweet smelling gums and frankincense, which are the produce of Bondou.

Bondou is chiefly inhabited by Foulahs; a race of negroes, who lead a wandering life, and employ themselves chiefly in the purlieus of cattle, and the cultivation of corn. Among these, however, are a great number of Mandingoes, by whom the trade of the country is chiefly conducted. The government in Bondou, and in all the adjacent petty states, is monarchical, but no where absolute. The persons, who are called chief-men, constitute a sort of aristocracy, which serves much to repress the powers of the sovereign. The king cannot declare war, nor conclude a peace, without their advice. When Mr. Park visited Bondou, the king was a "Sonikee," or Pagan, like the king of Woluli; but he had adopted the Moorish name of Almani, and with the name he seemed to have imbibed somewhat of the Moorish disposition; for although the traveller had prefixed to him his umbrella, and some other articles, he compelled him, as he had before compelled major Houghton, to sit in his presence, and surrender his coat, which, he said, he should reserve for his own wearing, on great and public festivals. In return, however, he gave Mr. Park five minkallies (drams) of gold-dust, and loaded him with presents. Every considerable town is under the immediate government of a magistrate, called the "Alkaid," by whom the duties and customs on itinerant traders, which are paid in kind (the only system of taxation), are levied. The office is hereditary. The people of the lower classes are reduced, by fiefs, or vassalage, to individual proprietors; but the power of the matter is far from being unlimited. He may punish his

5 C. slave
flavo corporally; but cannot deprive him of life for any offence, nor ever tell him to a stranger, without first bringing him to a public trial, called a "Palaver," before the chief
men of the town; and on such occasions the cause of the
flava is pleaded by the native Mahometans, who are a sort of
professional advocates. These indulgences indeed extend
only to native or domestic flava; for captives taken in war,
and those who are obtained in traffic, may be sold at pleasure,
and treated as the owner thinks proper. Park's Travels

BONDUR, a town of Attic Turkey, in the province of
Natolia, 21 miles west of Ishbarth.

BONDREE, in Ornithology, the honey buzzard (Falco
apeustus), stands under this name in Buffon's History of
Birds. The French writers of the present day also call it
bonducée.

BONDUC, and bonducella, in Botany (Plumier).
See Guillaudina.

BONDUC, in the Materia Medica, a name by which
many authors have called the Mollucca, Marcho, or Descour
nuts.

BONE, in Anatomy. The bones are the molt solid parts
of animals, and may be regarded as the walls of a building
supporting and containing the other parts. The human
body is composed of a pile of bones, the extremities of
which are variously shaped, and adapted to each other, and
calculated to admit of a variety of motions. Bones appear
to be composed of a vascular substance, not differing ma-
terially in structure from that of the rest of the body, ex-
cept that there is deposited in it the intercellular phosphat
of lime, which gives to the whole mass rigidity, strength,
and a permanent figure. That flate of the vessels in which
they secrete, and deposit, earthly matter, occurs in diseases of
other parts of the body. The nutrient vessels of arteries, mem-
branes, and ligaments, occasionally deposit lime, and cause
the ossification of those parts. The earth of bone is also
deposited in some species of tumours, and often in consider-
able quantity, and in an irregular manner in the cellular sub-
stance of a limb, when the bone of it is diseased. After this
general view of the subject, we proceed to give an account
of the structure of a bone, both with respect to the arrange-
ment of its earthly particles, and with relation to its vascular
tissue.

It is customary, however, in giving an account of the
structure of bones, first to describe their original formation
in the foetus; and this is useful, because it demonstrates the
simplicity of the proofs, and tends to refute old and erro-
neous ideas respecting it. The parts of the young foetus
which are afterwards to become bones, are merely a vascular,
gelatinous substance, scarcely distinguishable from the other
parts; afterwards the outline of the bone becomes evident,
and its substance is rendered white and firm, in proportion
to the quantity of lime deposited in it. The quantity depo-
sited in it, even at the time of birth, is only sufficient to give
form and to the whole mass, but not to prevent its flexibility.
The extremities of all the long bones consist of large portions
of cartilage, and these, by degrees, become bone. This
change is effected by an alteration, first, in the organization
of the part; the cartilage is absorbed, the vessels enlarge, so
as to admit of injection, and then they appear to have the
power of depositing earthly matter, or forming bone. The
formation of bone begins in the centre of a cartilage, and
gradually extends from thence to the remote parts, so that
the separate piece of bone, formed at the extremity, remains
to nearly the period of puberty, joined to the body of the
bone, by a crust of cartilage. In this stage it is techni-
cally termed an epiphysis. The observation of these facts
led formerly to the erroneous notion, that it was necessa-
ary that cartilage should exist, prior to the formation of bone;
and that it was converted by pressure, or in some inexplicable
manner, into bone. It were a waste of argument to refute
this opinion. We can perceive a striking advantage that
results from the bones of the foetus being formed as they are.
Their flexibility admits of the form of limbs becoming
adapted to the varying figure of the pelvis, through
which they must pass, and their elasticity, which is powerful,
restores them afterwards to their natural shape.

The subject which first engages our attention, in examin-
ing the structure of bone, is the arrangement of the earthly
parts. The phloiplat of lime is deposited by the arteries
in minute points or particles, and these being placed length-
wise, with respect to each other, form fibres; again, these
fibres being placed parallel to one another, form bony plates,
scapes, or laminae. That bones are fibrous and laminae, is
evident from a mere inspection of them in the foetal state;
that they are fo in the adult subject may be demonstrated by
calcination, or long exposure to weather; in which cases the
connecting vascular substance is more suddenly or slowly dif-
fused, and thus the arrangement of the earthly matter is
rendered visible. The earthly fibres of long bones extend
themselves in a direction parallel to the axis of the bone; in
broad bones they shoot out in every direction, like rays
from a centre. In long bones the earthly matter is conisolated
in the circumference and sides, so as to form thick and strong
walls; whilst a tube or more spongy bony structure is found
in their centre. In broad bones a similar structure is ob-
served; the earthly matter is consolidated exteriorly, so as to
form dense plates or tables; whilst interiorly the fabric of
the bones is spongy or cancellous. In the internal spongy
part of bones the marrow is deposited. In the middle part
of long bones the walls are very thick, being composed of a
great number of bony lamellae, and these walls gradually be-
come extenuated as they approach to the extremities of the
bone, where they are proportionally very thin. Long bones
are also slender in the middle, but at the same time strong,
on account of the great quantity of earthly matter thus conisolated
to form their walls; whilst there is but little cavity or
medullary structure. These bones expand greatly at their
extremities, in order to afford an extent of surface for the
formation of joints, and for the support of the weight of
the body. In the extremities of long bones, though the
walls are thin, there yet exists a great deal of bony matter,
which is deposited so as to leave interfaces between its
fibres, forming what is termed the cancellous structure, or
lattice-work of bones. It has been therefore concluded,
that the quantity of earthly matter may be nearly equal in
each part of a bone, and give to it an equal degree of
strength; but that it has this distinction of arrangement,
that in the middle it is compacted so as to form very thick
and dense walls, occupying but little space, and leaving but
little internal cavity, whilst in the extremities it occupies a
greater space, and forms a less solid kind of fabric. It
would be describable to ascertain, with some precision, where
similar circumstances are to be met with in broad bones; and
though no precise rules can be given, yet this may be ad-
mitted as a general truth, that where a broad bone dwells out
into a protuberance, there we shall find the walls or tables
thin, and the cancellous structure abundant; and, on the
contrary, where a broad bone is condened so as to occupy
but little space, there we shall find the tables proportionately
thicker, and the cancellous structure less in quantity.

Having thus described the arrangement of the earthy
of bones, we may next inquire into the advantages which re-

8

in

BON

BON
in the middle, to allow of the convenient arrangement of large muscles round them; they become expanded at their extremities to afford an extent of surface for the formation of joints, and the support of the weight of the body. A cavity is left in the middle; for if all the earthy matter had been compacted into the smallest possible space, the bones would have been such slender items, as to be very unsuitable to their offices; and if they had been of their present dimensions and solid throughout, they would have been unnecessarily strong and weighty. Besides, it can be proved by mathematical demonstration, that the strength of the bone becomes augmented, in proportion as its fibres are placed at a greater distance from its centre.

With regard to the vascular structure of bones, there can be no doubt but that it exactly refembles that of the rest of the body. That bones possesses numerous arteries, is proved by the injection of young bones from the general arterial system of the subject; for they are made very red by the injection conveyed into them by numerous, though minute arteries, which enter them by pores evident on their surface. The effect of feeding animals with madder is an additional and striking proof of the same fact; for the bone becomes deeply tinged with the red colour of the madder. The cause of this phenomenon has of late been explained by Dr. Rutherford: he has shewn that it arises from a chemical attraction that exists between earth and certain colouring materials, which causes them to combine so intimately as to form pigments which are called lakes by painters. Dr. Rutherford diffused madder in distilled water, and added to it muriate of lime, which produced no change of appearance in the solution; on the further addition of phosphat of soda, a double decomposition took place; the muriatic acid combined with the soda, and the phosphoric acid with the lime. The phosphat of lime also combined with the madder, and they were together precipitated, forming a beautiful red powder. If blood be constantly conveyed into bones by numerous arteries, it must be returned from them again by veins, or otherwise it must accumulate in them in considerable quantities. That bones possesses absorbers in common with other parts is equally clear, and is proved by their mode of growth, and also by their diseases. The growth of the tube of a bone is a proof of the mutation of its parts by absorption; for if bones grew merely by new matter deposited on the surface, the tube of the bone should be of the same dimensions in the adult as in the foetus. On the contrary, however, the tube enlarges, and bears the same proportion to the whole bone in either state. If any number of lamina of the sides of a bone, or if a portion of its whole substance perishes, the mortified part is detached in the same manner that it is in soft parts; and this detachment is manifestly the effect, in the first instance, of the agency of the absorbing vesseis. Though a portion of animal substance has perished, it still possesses the same powers of cohesive attraction that it did while living; it still tenaciously adheres to the living parts; but a space takes place all round the dead portion, and the production of that space can only rationally be attributed to the removal of parts by the absorbers. In diseases of bones their form becomes entirely altered, if an increased deposition of matter takes place in their internal parts; and this alteration of form could not happen unless the walls were removed by absorption, and deposited anew in conformity to the augmented bulk and figure, which the diseased deposition had occasioned. Not to cite lesser instances, one may be mentioned, which Mr. Hunter used to shew in his lectures, of a very large and globular bony tumour, which had formed in the extremity of one of the bones of the leg in an ox. The tumour was so solid, that the section of it admitted of being polished, and the walls of the bone had become thin, and of a spherical form, so as to make a neat kind of case containing this bony tumour. That bones possesises nerves as well as arteries, veins, and absorbers, cannot be doubted; for though they have not naturally but little sensibility, they become extremely painful when diseased; and again a fungus sometimes grows out of a bone, which is sensible, though it may have no connection whatever with the surrounding soft parts; of course it must have derived its nerves, by means of which it possesses its sensation, from the bone out of which it arose. That the vesseils and nerves of a bone are connected together by common cellular substances, as in other parts of the body, is demonstrated by pricking a bone in dilute muriatic acid, which diffolves all the lime, and leaves the vascular matter a little thickened, but perfectly flexible. We then see that this vascular and cellular matter has a laminated arrangement corresponding to that of the earthy, which has been described, so that between each layer of earthy matter, there is a laye of soft substance, and of course the different layers of soft substance are connected by vesseils and cellular membrane, which intervene between the bony fibres, and connect the different stratas together. Bones are covered by a strong, firm, fibrous substance, termed perioleum, on which the vesseils are first distributed; from this they proceed, connected by cellular substance, between the fibres of the bone. The vesseils and nerves of the bone enter it through holes which are evident on the surface, and which are larger and more numerous in the extremities of the long bones than in the middle. The vesseils do not penetrate the bone in a transverse direction, but obliquely, running transversely through a certain number of lamelia, and then taking a perpendicular course between others, which prevents the bone from being weakened, particularly at any one part, by that want of earthy matter which is necessary to leave room for the admission and distribution of vesseils.

The marrow that is contained in bones is of an unctuous nature, and in herbaceous animals, hardens when it becomes cold; but it remains fluid in those which are carnivorous. Some of the red parts of the blood is deposited with it in young animals, but in those that are adult it is no longer tinged with blood. The marrow is contained in fine cells, which do not communicate with one another, like those of the common cellular substance. This is proved by fawing a bone through, and keeping it in a temperature which will preserve the marrow fluid, with the part which is sawn downwards. Under these circumstances, if the cells communicate, the gravitation of the liquid marrow would cause it quickly to drop out, and leave the cells empty; but this does not happen. The cells which contain the marrow are lodged in the cancelli of the bone, at the extremities of the long bones; but in the middle they are unsupported by this kind of offeces structure. The cellular substance which contains the marrow, being condensed upon the inside of the walls of the bone, and adhering to them, has been termed the peri-oleum internum. In the principal bones we perceive arteries, much larger than those for the nutrition of the bone, which penetrate the walls obliquely, and spread their branches upon the medullary cells, for the nourishment of these parts. That these are the chief nutrient arteries of the marrow cannot be doubted; and it has been contended, that they have exclusively this power, and that they do not analo-

C 2

ifered
BON

BON

firmed as a very strange peculiarity, were not the minute
contiguous nutrient arteries to involute with one another.
The writer of this article is of opinion, that they do in this,
as in other instances, for it is common in amputation to cut
off the trunks of the medullary arteries, and yet the marrow
of the remaining bone does not perish; and, again, the bone
may be injected from the medullary artery alone. We may
next inquire into the uses of the marrow. Havers thought
that it transfused through the bone, and by this means pre-
vented it from becoming brittle: may, he even declared the
pores through which such transfusion was supposed to take
place. The cells, however, which contain the marrow are
perfect vessels; and we know that no transfusion of con-
tained fluids takes place through the membranes which con-
tain them during life, though in consequence of putrefaction
it does after death. If a bone be deprived of its periosteum
in a living body, no transfusion of oil from its surface takes
place; and even after death a recent bone may be deprived of
its periosteum, and put in warm water for a considerable
time, and yet no sudden transfusion of oil from the surface
will take place, as might be expected if there were natural
channels for this purpose. The canals which Havers de-
scribed, are probably the passages through which the ve
sfalso are transmitted. If then this opinion of the use of the
marrow be unfounded, we have still to inquire, for what purpoe
is it designed? The utility of the bones being formed as
they are, in parts and tubular in their middle, expanded and
spongy at their extremities, has been already explained. If
then spaces are necessarily left in their interior parts, thos
spaces must be filled with something, for they cannot be left
void, or the immense pressure of the atmosphere would crush
their parietes, and abolish the vacuum. There is no matter
in the animal body more suitable to fill their spaces than the
marrow; and it is to be regarded as a part of the adipose
system of the animal. In corroborate of this remark, it has
been observed, that in impoverished and drooping subjects,
where there is no fat in other parts, there is likewise none
even in the bones: and if a bone be fawn, and the medullary
cells broken down, so that the fluid which they contain may
drop out upon paper, that it will not penetrate it, and render
it transparent like oil; but, on the contrary, that it will en-
crust upon it, from its being of a gelatinous nature, like that
fluid which is found in the interstices of the common reticu-
lar or cellular substane. From the circumstances which have
been detailed in the foregoing account, viz. the great and
general vacuolarity of bones—the quantity of soft substance
existing in every part of them—their growth and mutation
of form in dcifie, &c.; it is natural to conclude, that there
exist in the composition of every bony fibre, arteries for its
formation, absorbents for its removal, cellular substance for
the connection of its parts, and nerves to give animation to
the whole. In this view of the subject, we perceive no
essential difference of structure between bones and other parts
of the body; nor do we expect any material difference in the
functions of their nutrient, and other ve
sfalso. We nati-
urally conclude that bony fibres are formed and repaired, and that
they undergo mutation or removal in the same manner, and
from the same causes, that soft parts do. Mr. Hunter, how-
ever, from observing the flattered appearance of the bones
of animals, who have been at one time fed with madder, and
at another with common food, and observing that the exterior
frià was red if the animal was killed after having been for
some time fed with madder, and white if it had only taken
its ordinary food, concluded that bones grew by a deposition
on their surface, and a correspondent removal of the internal
part of the walls of the bone. Mr. Hunter also, to investi-
gate the truth of Du Hamel's opinion respecting the growth
of bones, bored two holes in the tibia of a pig, one near the
upper end, and the other near the lower; the space between
the holes was exactly two inches; a small leaden shot was in-
serted into each hole; when the bone had been increased in its
length by the growth of the animal the pig was killed, and the
space between the two holes was exactly two inches. Mr. Hun-
ter's experiments and opinions are published by Mr. Home in
the second volume of Transactions of a Society for the impro-
vement of Medical and Chirurgical Knowledge. We forbear
to give a more detailed account of them, or enter into
any diffusion of the subject, but refer the reader to the origi-
nal paper, because we believe that no theory will be found,
on consideration, to be adequate to account for the pheno-
mena of the growth and diftees of bones, except that
which admits the bony fibres to be of the same structure as
the soft fibres of the body, and consequently concludes that
both are formed, removed, and renovated in the same manner.

BONE, in Chemistry and the Arts. The analysis of bone,
and the products obtained from it by various chemical pro-
cesses, deserve considerable attention, as this great class of
animal substances ranks among the most important to the
chemist.
So great a similarity is found in the composition of the
bones of different animals, that their properties may first be
described generally.
Bone, when first taken from the animal, is moilt and
greasy on its surface; and if cylindrical, it contains a quan-
tity of the peculiar fat called marrow. When this is sepa-
rated, and the bone exposed to the air, it gradually dries,
becomes brittle and whiter; but the articulating heads long
remain moilt, greasy, and yellow. When once dry, and
kept in a dry and airy place, they are scarcely susceptible of
further spontaneous alteration.
The effect of mere heat on bone has long been known to
chemist and the arts, as furnishing some very important arti-
cles of chemical manufacture. Heated in the open air, bone
first becoms oily and yellow, gives out a Watery vapour, to
which succeeds a thick, dense, fetid smoke, which readily
takes fire, and when once kindled, affords heat enough, when
the bones are in sufficient quantity, to complete the entire
celeration, which lasts for many hours, during which they
become incessively black and carbonaceous, brittle, and at
last, when everything combustible is consumed, they remain
neatly white, friable, light, and extremely porous or cellular
in texture, and retaining their original shape and bulk. This
process of burning bones in the open air, in large heaps, is
performed near great towns for the sake of the earthly salt
bone-off, which is left behind, and forms on an average about
half the weight of the fresh bone. It is composed chiefly of
phosphat of lime, and is used by the assayers as the material
for cupels, and for a few other purposes.
But the volatile products which are wafted in the above
proceeds, are highly valuable when the bones are distilled in
close ve
sfalso, without addition as before, but with a proper
apparatus to receive and condene the volatile products. In
these circumstances, with a heat at first gentle, but gradually
increase,
increasing, bone yields, at first, a limpid water, with a peculiar animal oily smell, which soon becomes impregnated with carbonated ammonia, together with an oil, at first of a clear yellow, pungent, and not ungrateful to the smell, but afterwards rendered brown, and even black, by the increasing heat, strongly fetid and ammoniacal. With the empyreumatic oil, a large quantity of sulphurated hydrogen, of carbonated hydrogen, and of carboenic acid gas escapes. The products of this distillation, when condensed, are the ammoniacal water, and the empyreumatic oil; the former contains, besides carbonat of ammonia, a portion of ferbic and prussic acid united with the alkali; the oil may be separated into the fats and more empyreumatic, by changing the receiver occasionally, and keeping apart the first portions of the oil as the purest. If this oil is again repeatedly distilled by itself from clean vessels with gentle heat, it becomes at last as colourless as water, pungent, and not very unpleasant to the smell, so volatile at a common temperature as only to be kept by inverting under water the mouths of the vessels that contain it, and acting in medicine as a powerful sedative. It is called from the name of the inventor, Dippel’s oil, which fee.

The only valuable part of the products of the distillation of bone is the ammonia, or volatile alkali, which is mixed with every part of the distilled liquid, and is afterwards purified by subsequent processes, afflicting in the formation of the Muriait of ammonia, or forming the pure Carbonat of ammonia of the bones, the fat volatile, spirit of hartshorn, &c. When the distillation is discontinued, the bones remain in the retort of a brown colour, and swimming in a black, thick, extremely fetid, tenacious oil. If they are then gradually heated to redness in close iron vessels, every thing volatile is distilled, and the earthy part remains dry and friable, still retaining the original form of the bones, but thoroughly impregnated with the charcoal of the oil, so as to become a fine glossy black. This is afterwards ground to a fine powder, mixed with fire into cakes of a convenient weight, and forms one of the species of lamp-black, used very largely as a pigment.

The harder and compact bones, such as ivory, furnish a similar and more valuable black pigment, simply by heating to redness in close vessels.

But the analysis by heat, though it furnishes some valuable articles of commerce, is not well calculated to exhibit the constituent parts of bone in their proper characters.

In fact, the ammonia, probably much of the oil, and all the gasses, are formed by the action of heat out of the real constitutents of bone, as they exist in the animal.

Water and acids are the chief re-agents to be used by the chemist.

Cold water has scarcely any action on bone, but by long maceration its texture becomes more loose and open, and the gelatious part becomes gradually changed, as by flow animal putrefaction.

Hot water acts with great ease upon bone, when reduced to small pieces by rafping or bruising; the first effect is to separate most of the natural oil of bone which rises to the top, and when cool concretes to a foamy fat. The water then diffuses the gelatin, which is found to compose a very considerable part of the sublimate, even of the driest and most compact bone; and in this method a clear inipid pure jelly is extracted, rendering the water, even when in large proportions of a fluid, tremulous consistence when cold, which, by evaporation, leaves at last a strong, hard glue.

The experiments of M. Pelletier on this subject are important. This accurate practical chemist took six pounds of dry bone filings, procured from the button-mould makers, macerated them for two days in cold water, and then boiled them for nine hours with 24 quarts of water. The product was a very strong clear jelly, and at the bottom of the vessel the marc, or earthy residue, which was pressed in order to separate the portion of somewhat turbid jelly, with which it was entangled. By subsequent boiling down, the jelly became so stiff when cold, as to bear to be cut into firm slices, which were hung up on strings in a place under cover from the weather, (as in the common manufacture of glue), and in a fortnight became hard, brittle glue of good quality. The produce was 15¼ ounces of clear glue, half in ounce more from the marc, and somewhat foul, and the marc itself weighed 4½ lb. 3 oz. The loss in the operation amounted to 15 oz. In like manner 50 lb. of ivory shavings, exhausted by repeated boiling, gave 9½ lb. of clear glue, and 30 lb. of the marc remained.

These facts are important to the manufacturer; nor is the use of bone less interesting as an article capable of supplying much good and wholesome nutriment to man and other animals. In the m. king of soup is a matter of common observation, that bones contribute, when boiled with the meat, to the richness of the liquor; but it is not commonly known how much they may be made to add to the nutritious quality; nor is it generally known that the hardest and driest bones, even those that have been kept for years, retain their gelatious part unchanged.

The exact proportion of jelly cannot easily be ascertained by extraction with water, for even when converted into the hardell glue, it has become intimately united with a portion of this fluid; and it is by no means certain that the utmost dedication of glue equals the degree of dryness of natural gelatin, as it exists in the more fold bones.

The quantity of jelly is also much increased, either by giving the water by which it is extracted a higher heat than the boiling point, or by reducing the bones to a fine powder, and using repeated coction and pulverization.

The former method was used by Papin, who, in his valuable experiments on the solubility of animal sublunates, when confined with highly heated water in his Diggiler, found that he was able to extract every thing from powdered bone, but the more earthy part. The latter mode has been brought into notice by M. Proft, in an important economic-chemical memoir on the “Method of ameliorating the sublunates of the Soldier,” published at Madrid, in 1791.

Though there is a great general similarity between the bones taken from different parts of the body, they differ much in the relative portion of fat, of gelatin, and of earth. The younger the animal, the less earthy is, ceygetis parillus, is contained in its bones. The large, round, joint-heads of the thigh, and other large bones, contain much more oil than the ribs or blade bones, as is seen when they are exposed to the air; the latter soon becoming dry and clean, but the former remaining long foul and greasy.

No method of extracting all the soluble part of bone answers the purpose so completely, as long boiling in Papin’s diggiler with a very great heat; the earthy residue then remains quite friable in the fingers, and gives little, if any, volatile, oily, or ammoniacal product on burning. But the jelly which remains in the water, and the oil which swims at the top, are found to have acquired a burnt unpleasant taste; and in the process, a considerable quantity of gas is generated, doubtless from the decomposition of the soluble part. On the other hand, even when repeated boiling and laborious pulverization, unaided by a higher heat than that of boiling water, the earthy residue still feels clammy and cohesive between the fingers, and retains some of the oil.

M. Proft affirms, that the knuckle and joint bones simply chopped into small pieces, and boiled for a quarter of an hour in a common copper, yielded no less than one fourth of their weight of fine inipid fat, which rose to the top of
the water, and on coolingconcreted into the confidence of
fats. The haunch bones yielded about one eighth of fat.
The utmost economy of bones, therefore, when used as
human food, may be obtained in the following method.
First chop the fresh bones into small pieces, and extract the
fat in the way just mentioned; then dry the bones, and
powder, or reduce them to a fine palls, by some pretty
strong mechanical power; and boil them with about ten
times their weight of water, for some hours, till half the
water is wafted, more or less according to the kind of bone;
the joint and thick bones making a richer jelly than the thin
bones, and therefore requiring somewhat less boiling down
 to make a jelly of a determinate confidence.
M. Prouit finds that this proportion of water is sufficient
to leave a jelly of about the fame richness as would be pro-
duced by dissolving one ounce of bone jelly, dried to the
confidence of portable soup, in thirty-one ounces of water,
and makes a jelly of a very agreeable degree of richness.
The extraction is much assisted by using an iron vessel with
a close lid, to give a heat somewhat greater than that of
boiling water, though not to the degree of a Papin's
digester.
In all the above experiments on the extraction of jelly and
fat from bones, the uncooked bone is understood to be used.
The bones of boiled meat, though deprived of some of their
extractive matter, are still rich in nutritious; but roasting
renders them entirely unfit for this purpose.
The earthy part, which comprises on an average about
half the weight of the larger bones of animals, was disco-
vored first by Gahn, a Swedish chemist, to consist of the
phosphoric acid united with a large proportion of lime. It
will be more minutely described under the article POSTHOSP.
HAPP OF LIME; and it is the most convenient substance from
which PHOSPHORS is prepared. It may here be men-
tioned, that the stronger acids, such as the sulphuric or ni-
tric separate a part of the lime from this earthy part, but
only a part, for when sulphuric acid is added to bone ash,
phosphat of lime is formed in great quantity, most of which
remains at the bottom of a supernatant liquor, consisting of
a great excess of phosphoric acid united with a small portion
of lime, and also some soluble lime diffused therein. It
should be remarked in the analysis of this ash, that this acid
phosphat of lime, is not decomposed by any fingle acid,
nor even by the pure or carbonated alkalies; for, on adding
the latter, the precipitate is not carbonated lime, but still
the phosphat.
This earthy salt, when in solution, is, however, entirely
decomposed by the nitric or acetate of lead; the lime re-
maining diffused in the liquor by the nitric or acetic acid,
and the phosphat of lead forming an insoluble precipitate.
Phosphat of lead is dissolusible from sulphat of the same
metal by being readily soluble in nitric acid. If the phos-
phat is sprinkled on hot charcoal, the lead is reduced, and
the lunulose meal and peculiar smell of phosphorus are per-
ceivable. The phosphat of lime is equally dissolusible from
the sulphat of lime by being very soluble in most acids, even
when diluted.
Much light has been thrown on the analysis, and with it
the physical structure of bone, and of almost all other of the hard
substances or protecting parts of the body, by the accurate
and numerous experiments of Mr. Hatchett, whose re-
searches into these subjects are admirably calculated to flame
the extreme advantage which physiology derives from the
labours of the chemist, when assisted by accurate knowledge,
and guided by a philosophical spirit.
When bones, boiled or fresh, are steeped in any acid, a
flight effervescence is perceived, and they presently are ren-
ered soft and flexible by the gradual abstraction of the
earthly basis (chiefly phosphat of lime), which becomes dis-
soved in the acid. If the bone be previously boiled for a long
 time in water, its gelatin is removed by this liquid; but
if the bone is in its natural state, the gelatin also is gradually
dissolved in the acid, rendering it yellow and somewhat ten-
acious. The insoluble residue, (except in a few kinds of bone,
such as the enamel of the teeth) is either a membrane or a
pugy cartilage, retaining the form of the original bone;
for, in the prints of osification, membrane or cartilage
forms the fibril basis or rudiments of bone, which is after-
wards completed by the gradual deposition of the earthy
fats. Though phosphat of lime forms the chief ingredient
in the earth of bones of all animals, a small portion of sul-
phat of lime is mixed with it; and Mr. Hatchett has detected
also a little carbonate of lime. The carbonic acid of this is
that which occasions the slight effervescence during the actions
of the acid: the lime remains dissolved in the acid after the
precipitation of the phosphat of lime by pure ammonia. A
carbonated alkalii then precipitates it together with the now
decomposed earth of the calcareous sulphat.
We have thus shown the great constituent parts of bone to be gelatin, soluble by boiling in water, and giving a
fine clear jelly; oil, separable, during the boiling, by rising
to the top of the water, and when cold concreted into a
fats: phosphat of lime, soluble in dilute nitrous muriatic or
acetous acid, and precipitable thence by pure ammonia;
some sulphat of lime; a little carbonate of lime; and a mem-
braneous or cartilaginous substance, retaining the form of
the bone after every thing else has been extracted by water and
an acid.
For a highly probable opinion on the nature and origin of
this membrane or cartilage, we are indebted to Mr. Hatchett,
who has shown a number of characteristical marks, in which
it still strongly resembles unspilled albumen, and by which
it differs from gelatin. The chief of these are the follow-
ing:
When dry, it is semi-transparent, like horn, and more or
less brittle. In this state it refolds the action of water very
powerfully; for when boiled for many days with this fluid,
a scarcely perceptible precipitate is given by nitro-muriat
of tin; a tell of dissolved albumen. In this it distinctly
refunds coagulated albumen, and as pointedly differs from
gelatin, which, as we have seen, is readily extracted by
water even from the dryest and hardest bones.
This bony membrane, as well as albumen, is scarcely
acted on by cold muriatic and sulphuric and dilute nitric
acids, which last readily extracts gelatin from bone. How-
ever, after an immersion in these acids of some weeks, the
bony cartilage, when taken out and steeped in ammonia,
gradually dissolves into a blood-red liquor. But if the nitric
acid is heated, the albuminous membrane is rapidly dissolved
with the copious discharge of nitrous gas.
With caustic fixed alkalii, the bony membrane or cartilage
is readily dissolved into a perfect animal soap (a strong mark
of resemblance to albumen, and difference from gelatin),
during the proceeds much ammonia is given out. Acids
again separate the albumen from the soap, unaltered in chem-
ical properties.
Lastly, the bony cartilage is extremely slow to enter into
a state of purification, though kept moist and warm for
many weeks; and in this too it resembles coagulated
albumen.
Therefore, in addition to the above-mentioned constituent
parts of bone, we may add albumen, in a condensed state,
forming the substance of the original cartilaginous mem-
brane or cartilage, both of all the organized bones, and, as
Mr. Hatchett has also shown, of most of the hard parts,
which serve for the covering, protection, and arming of
almost
almost every part of the animal creation. See the articles Shell, Horn, 

The enamel of the tooth is a singular variety of the bone, being entirely deliquescent of the albuminous membrane. When an entire tooth is immerred in dilute nitrous acid, the enamel totally dissolves without residue; but the core of the tooth is acted on like other bone, leaving a cartilage of the same shape. The solution of enamel is found to be almost entirely phosphat of lime, by the tests already mentioned, being precipitable by pure ammonia, giving phosphat of lead, by adding the acetate of this metal, &c.

Fifth-bones Mr. Hatchett found to contain rather a larger quantity of cartilage, in proportion to the phosphat of lime, than the bones of quadrupeds. Of the different kinds of horn and defensive weapons, the stag's horn, elephant's-tusk, and the horned and heavy defences, entirely resilient bone; but the horns of cattle, rams, and the fatter species, contain but little earthy residue, that they owe their solidity entirely to the extreme condenfation of the other constituents, the gelatine and albumen.

Bones may be softened by a short immersion in a weak acid. This arises from the partial abstraction of the earthy bases; and advantage may be taken of this property in the working of bone, for the various purposes of manufacture to which this article is applied by the turner, comb-maker, cutter, &c. Bone, thus softened, is again made hard, by being steeped in alum-water. Alkalies also soften bone, as they do every other animal matter, by beginning to act upon the softer parts. See Ivory.

Bones readily take various colours, which, if dissolved in an acid, sink deep into the substance of the bone, and produce a pleasing effect. The metallic solutions are generally preferred for this purpose. To give a green, dissolve verdigris in distilled vinegar, immerse the bones in the solution, put the whole in a vellum, very well closed, and bury it in a dung-hill, or give it a flow and uniform warmth in any other way for about ten or twelve days. The bones are then found very deeply and permanently dyed green, and capable of a good polish. The once prized Turquoise stone is a jollic bone of various animals, accidentally impregnated with phosphat of copper whilst buried in the earth. To give the artificially dyed bones a finer colour, boil them in nut-oil, and they will then take a very high polish.

A permanent black is given to bone, either by nitrated silver, or in the following manner: boil equal parts of Li-tharge and quick-lime in water, and the bones along with them for some hours, illuring them frequently. Other metallic solutions may be used for different colours.

Or the dye may be given by preparing the vegetable coloured lakes, or concentrated dyes; and by rubbing the bone, first with dilute nitrous acid to open its texture, and then rubbing in the dye for some time. This may be applied in various ways, first softening the bone by a weak acid, whereby it is made fit to receive the colour.

Bones are whitened by simple exposure to sun, wind, and weather, being first thoroughly cleaned, and particularly by occasional immersion in brine: thus the bones of sea-birds and fih, left for some time on the shore, are found beautifullv white and clean. The same effect is produced much more speedily, but perhaps less permanently, by the oxyuratic acid, the bone being exposed for some hours to this acid gas in clofe vessels, as Mr. Smith of Bristol has observed. The acid first makes the bone yellow, which, by exposure to air, goes off, and leaves the bone beautifully white. This colour a little fades, when the bone is kept in clofe cafes excluded from the light. See Skeleton.

From all that has preceded, it will appear obvious that, to the chemist and manufacturer, bone is one of the most curious and valuable of the animal substances, though considerately vulgarly as little better than refuse, and scattered about without care. Besides its use as a hard and good material for turnery and workmanship of various kinds, it gives, by chemical decomposition, a large quantity of useful, nutritive jelly, fit for human food, or the same, in the form of glue, for the arts. When subjected to fire, it yields a vast quantity of ammonia, and is actually the material used in very many manufactures of the ammoniacal salts; and the refuse, strongly calcined in clofe vessels, (and therefore retaining its carbonaceous ingredient,) produces useful and fine black pigments; or, burned with access of air, leaves an earthy salt, necessary to some important chemical processes.

Some of the preparations from bone are only used in medicine. Of these, are Dippel's oil, and the lefs rectified alburn cornu cervi, (oil of hart horn,) both powerful suditories, and supposed antispasmodics; the spiritus cornu cervi, (spirits of hart horn,) so universally known as a stimulant and cordial; and the carbonat of ammonia, often called salt of hart horn. The white calcined earth of bones, cornu cervi calcination, enters into the composition of one or two pharmaceutical preparations, but without exhibiting any obvious properties. In dyes of the bones, where the softening and spontaneous deformity shews an evident want of their earthy bases, this calcareous phosphat has been given with apparent advantage. Of the unprepared bones, the elk's tooth, rhinoceros's horn, and thongs of the dried human skull, &c. are medicines entirely explided only within a few years from the European pharmacopoeia, and iflill maintaining high credit in the countries whose characteristic credulity and superstitition in medicine first brought them into repute. The only real utility of unprepared bone in medicines is found in furnishing, when boiled in water, a light and nutritious jelly for the invalid; and for this purpose, hart horn thongs are employed with advantage. Johnson's Animal Chemistry. Encyc. Method. Arts and Metiers, (Artile Ecaille), &c. &c.

Bones, Diseases of the, in Surgery. As bones are organized parts of the animal body, they are liable to most of the diseases with which the softer organs are afflicted. These are either spontaneous, or accidental; but, from the hardness of their composition, and the small degree of vascularity and tendibility they possess, there must necessarily be a considerable difference between the phenomena and symptoms of diseased bones, compared with those of the soft parts. They are naturally endowed with little or no feation; but are extremely painful in an inflamed state, when the blood-veils, which enter their substance, are dilated, and the nervous filaments are kept upon the stretch, as in the case of veneral nodes, &c.

Bones may be wounded with a sharp instrument or con- tused with a blunt one, in the same manner as the muscles, or integuments; and they will re-unite again, if the injury they suffer be not so extensive as to intercept the circulation, or destroy their vitality. But, if a bone be so injured as to perish, its substance will either be gradually conaminated and dissolofed, or call off in a larger portion, by the process we denominate exfoliation. If any two ulcerated surfaces of flesh (suppose two contiguous fingers) be applied together, and allowed to heal, they will coalesce, and the veils from one part will shoot into the other: in like manner, if the articulating surfaces of two contiguous bones (luppole
BON

(suppose of the tibia and femur), be directed of their cartilage by ulceration, their extremities may coalesce, and form one continuous bone, which is named enchysiphis. A stiff joint, from this cause, is irremediable, and in general it may be considered as the most favourable termination of diseased joints; for they too commonly are attended with such disabling symptoms as to require amputation, in order to preserve the patient's life. See White Swelling; and Distortions of the Joints.

The consideration of Fractures and Dislocations is referred for their proper places in the Cyclopaedia; where will be likewise described the manner of reducing bones, vulgarly called bone-setting. This art, (which requires a very correct acquaintance with the anatomy of the joints and muscles), has, most unaccountably, been often left to ignorantbarriers and mechanics, who are totally destitute of knowledge on these subjects! We might, with as much reason, entrust the repairing of a watch, or a mill, to persons who never had an opportunity of examining their mechanisms! By accident, it is barely possible, bone good might be done; but the greater chance is, that the instrument would be damaged rather than rectified, in the hands of such unskilful operators.

Bones will, in ricketty and scrofulous constitutions, pass into a state of spontaneous enlargement, or decay, or flexibility, &c. The spongy parts of bones, e. g., the extremities of cylindrical bones, are more liable to become diseased in such subjects, especially during the early period of life; but in general, patients, who are also very susceptible of morbid changes in the bones, they are their hard parts chiefly which become affected, as in the middle of the tibia, or ulna, or upon the central portions of the frontal and parietal bones. See Rickets, Scrofula, and Lupus Venereal.

Some observations on the surgical treatment of diseased bones will also be made under the heads of Caries, Necrosis, Sina Bifida, Distortion, Curvature, Mollities, and Exostosis.

The structure of bones may be altered from several causes; but principally, from either a deficiency, or a redundancy of the phosphat of lime, which enters into their composition, and gives them solidity. When there is too little phosphat of lime, the gelatinous part of the bones being unable to sustain much weight or resistance, they will become pretternaturally flexible; and, on the contrary, when there is too much phosphat of lime, in proportion to the gelatinous part, the bones will be very fragile, and perhaps, may even break from the mere action of the muscles. The flexible state is most common in young persons, and the superabundance of offensive matter is chiefly predominant in old age; but either condition of the bones may occur at any period of life, from peculiar morbid dispositions. The popular notion of our bones being more fragile in cold weather than in hot, is erroneous, and without foundation; since the difference of season make no difference in the texture of the living bones: and the only natural cause to be assigned for the fracture of our limbs more frequently in the winter than in the summer, is that of an increased slipperiness and hardness in the ground from frost, &c., which must necessarily occasion more physical violence and frequency in our falls.

Bones, in the funeral solemnities of the ancients.—Divers usages and ceremonies relating to the bones of the dead, have obtained in different ages; as gathering them from the funeral pile, washing, anointing, and depositing them in urns, and thence into tombs; translating them, which was not to be done without the authority of the pontiffs; not to say worshipping them, still practised to the bones of the saints in the Roman church. Among the ancients, the bones of travellers and soldiers, dying in foreign countries, were brought home to be buried, till, by an express S. C. made during the italic war it was forbid, and the soldiers bones ordered to be burned where they die; the reason was, left the melancholy sight should discourage the people from venturing their lives. Antiquaries are divided as to the manner of distinguishing the bones of the deceased, from those of the heads and flaves, who were sacrificed at his funeral, and thrown into the same fire: probably it was done by dipping the body of the dead in the middle of the pile, and the others towards the sides. Potter's Archæol. tom. ii. lib. iv. cap. 6.

The Romans had a peculiar deity, under the denomination of Offalga, to whom the care of the induration and knitting of the human bones was committed: and who, on that account, was the object of the adoration of all breeding women. Pufle. Ant. tom. ii. p. 341.

Bones, fossil, or petrified, are those found in the earth, frequently at great depths in all the strata, even in the bodies of bones and rocks.

There are divers forts of fossil bone; some of a huge size, usually supposed to be the bones of giants, but more truly of elephants, or hippopotami; others smaller, as vertebrae, teeth, and the like.

It has been disputed whether these be really animal substances, or mineral, that is, bones thus figured. Modern naturalists generally allow them to be animal, not merely on account of their figure and resemblance, but of their chemical principles, which are found to be wholly of the animal kind. It is supposed they were repopulated in those strata at a time when all things were in a state of solution, and that they incorporated and petrified with the bodies where they happened to be lodged.

In the Philosophical Transactions (vol. lxxiv. p. 407, &c.) we have some observations on fossil bones by the late Mr. John Hunter. They were occasioned by an examination of bones of this kind, found in the caves of Gallonruth and Klausstein, two small villages in the principality of Bayruth, (or Bareth,) and presented to the Royal Society by the margrave of Anspach. These bones are considered more as incrusted bodies than extraneous fossils, since their external surface has only acquired a covering of crystallized earth, with little or no change in their internal structure. The principal earth with which bones are most commonly incrusted is the calcareous; and this happens either by the bones being immersed in water, in which this earth is suspended, or by water's passing through maides of this earth, which it diffuses, and afterwards deposits upon bones which lie underneath. Bones which are incrusted seem never to undergo this change in the earth, or under the water, where the fossil parts were destroyed: while bones that are fossilized become to in the medium, in which they were deposite at the animal's death. The incrusted bones have been previously exposed to the air; which is evidently the case with these bones, and also with those of the rock at Gibraltar, those found in Dalmatia, and those of the island of Utirio. They are thus distingished from fossilized bones: but as they are found in different situations, it is more difficult to account for their present state. Those in Germany are found in caves; the coast of Dalmatia is laid to be wholly formed of them; and this is the case with a large portion of the rock of Gibraltar. With respect to the first class of bones, as they are those of carnivorous animals, resembling, in some respects, those of the white bear, and yet differing, in some circumstances, from the present animal of that species, Mr. Hunter suggests, that the animals to which they
they belong resort to different periods to those caves, as
places of retreat, and perished in them. In Gibraltar, they
are mostly the bones of animals of the ruminating tribe, of
the rare kind, and of birds, with some of a small dog, or
fox, and likewise shells. Those in Dalmatia appear to be
mostly of the ruminating tribe. From these facts, it may
be presumed, that their accumulation did not arise from any
inductive mode of living, as the same mode could not suit
both carnivorous and herbivorous animals. As to the local
distribution of these bones, it is necessary to recur to successive
shifts of the situation of the sea, in consequence of which
we may have a flinty and marine extraneous fossils, one of
earth, mixed probably with vegetables and bones of land
animals, a stratum of terrestrial extraneous fossils, then one
of marine productions; but as the sea carries its inhabitants
along with it, wherever there are those of land animals,
there will also be a mixture of marine ones; and from the sea
commonly remaining thousands of years nearly in the same
situation, we have marine fossils unmixed with any others.
As all operations respecting the decomposition, as well as
the growth, of animal and vegetable substan ces, proceed more
rapidly on the surface of the earth, to which the air has
access, than within it, we shall find fewer changes as we
descend into the earth, and at last probably arrive at a cer-
tain depth, where no change takes place. Substances,
therefore, that are fossilized at a great depth, and deposited
in flINT, clay, &c. are preferred for a very long time from
putrefaction; as much so as if they were in a vacuum; the
heat also in such situations being uniform, commonly about
53° or 55°; and in the colder regions they are still longer
preferred. It has been generally understood, that in ex-
traneous fossils the animal part is destroyed; but Mr. Hun-
ter has not found this to be the case. Shells, and bones of
fish, must probably have the leaf in quantity, having been
longed in that flake, otherwise they should have the moll;
for the harder and the more compact the earth, the better is
the animal part preferred; and this is an argument in
proof of their having been longed in a fossil flake. In the
fossil bones of sea-animals, as the term in the whale, the
animal part is in large quantity, and exists in two flates;
the one having some tenacity, but the other like wet dust;
in some of the harder bones it is more firm. In the fossil bones
of land animals, and those which inhabit the waters, as the
sea-horse, otter, crocodile, and turtle, the animal part is in
great quantity. In the horns of flags dug up in Great
Britain and Ireland, when the earth is disloved, the animal
part is in considerable quantity, and very firm. The same
observations apply to the fossil bones of the elephant found
in England, Siberia, and other parts of the globe; also
those of the ox kind; and more particularly to their teeth,
especially those from the lakes in America, in which the
animal part has suffered very little; the inhabitants finding
little difference in the ivory of such tusks from the recent,
except its having a yellow flain; the cold may probably
affect their preservation. In incurved bones, the quanti-
ty of animal substance is very different in different bones:
in those of Gibraltar, there is very little; it partly retains
its tenacity, and is transparent, but the superficial part dis-
olves into mucous. Those from Dalmatia furnish similar
results. Those from Germany, especially the harder bones
and teeth, seem to contain all the animal substance natural
to them, though in this respect they differ among themselves.
The bones of land animals have their calcareous earth united
with the phophoric acid of the aerial, and retain it, when
fossilized, as Mr. Hunter thin in proportion to the cangu-
tration of animal matter they contain. This he infers from the
quantity of effervescence. In some bones of the whale, put in
to the muriatic acid, the effervescence is very great; in the
Dalmatia and Gibraltar bones it is less; and in those of the
Germ an caves, it is very little, since they contain by much
the largest proportion of animal substance. From the ex-
periments and observations of the ingenious Mr. Hatchett,
(see Phil. Trans. vol. lxxxix. p. 335,) we learn that the bones
of the Gibraltar rock contain principally of phophat of lime;
and that the cavities have been partly filled by the carbon-
ate of lime, which cement them together. Fossil bones, he
says, remarkable bones which, by combustion, have been de-
prived of their cartilaginous parts; for they retain the figure
of the original bone, without being bone in reality, as one
of the most essential parts has been taken away. Such
fossil, or burned bones, can no more be regarded as bone,
than charcoal can be considered as the vegetable of which it
retains the figure and fibrous texture. Bones which keep
their figure after combustion, resemble charcoal made from
vegetables replete with fibre; and cartilaginous bones, which
lose their shape by the same cause, may be compared to fus-
culent plants which are reduced in bulk and shape in a sim-
ilar manner. Hence he is led to question if bodies, con-
sisting of phophat of lime, like bones, have concurred ma-
terially to form lirate of lime, or chalk; as it appears to
be impossible, that phophat is converted into carbonat of
lime, after these bodies have become extraneous fossils.
The destruction, or decomposition of the cartilaginous parts
of teeth and bones in a fossil flate, must have been the work
of a very long period of time, unless accelerated by the action
of some mineral principle; for, after having, in the usual
manner, steeped in muriatic acid the os homeri of a man,
brought from Hythe in Kent, and said to have been taken
from a Saxon tomb, Mr. Hatchett found the remaining cartilage
nearly as complete as that of a recent bone.

M. Cuvier communicated to the Societe d'Histoire Na-
turale at Paris, a curious memoir upon the fossil bones of
animals. The following abridgment has been taken from
the Societe Philomatique, No. 18, Year VI. In order to
determine the relations and differences that subsist between
the several species of animals that do exist, or have existed
on the surface of the globe, he directed his attention to
the following. 1. The animal which afforded the bones
and teeth, called the bones and horns of the mammal,
by the Russians and Siberians, and of which remains
are found in Europe, is a species of elephant, resembling
the elephant of Asia; but differing from it in the alveolus of
its teeth, its tusks being longer, the angle of its lower jaw
more obtuse, and the laminæ of which its grinders are com-
posed thinner. The true analogous living animal is not known,
thought it has been hitherto considered as the ordinary
elephant. 2. The animal, of which the remains are found
on the banks of the Ohio in North America, which the Amer-
icans and English have also named mammal, though it
differs much from the former. Remains of it are found
in Europe and Asia. It must have been nearly as high as
the elephant, but more bulky; its tusks are smaller; its
grinders are armed with large cutting points, of which the
fection by wear presents double transversal lozenges. There
are three molar teeth on each side, one of four, one having
six, and one eight points. 3. The animal of which the
three teeth tinged by copper afford the turquois flate, and of
which there was a mine at Simore, in Languedoc. The
remains of this species are found in the department of Ain,
in Peru, and elsewhere. It must have considerably resembled
the former; but the points of its molar teeth are round, and
when worn, their division presents a circle, then a semi-
oval, and afterwards a figure of a trefoil, which has caused
them to be confounded with the teeth of the rhinoceroses;

Vol. IV.
some of these teeth have 12 points, others 6, others 4.

4. The rhinoceros. The feet and fragments of the jaws of this animal are found in France, and elsewhere, in which the author has hitherto observed nothing which differs from the common rhinoceros; but, as he has not yet seen an entire bone, he cannot positively affirm that they are identical. 5. The species of rhinoceros, with an oblong cranium, which is found in Siberia, Germany, and other countries. This animal has been teeth, and parts of the jaw-bones, found in France, which appeared to him likewise to belong to this animal; the principal character of this species consists in the long closure of the nose, the living analogous animal is unknown. 6. A molar tooth with two transverse cervices, which is in the possession of Citizen Gillet; and of which the National Museum possesses a young tooth that resembles neither the teeth nor the gums of any animal yet known, whether living or fossil: the only tooth which this slightly resembles is the last molar tooth of the rhinoceros. This tooth, therefore, indicates the existence of a fifth fossil species, of which the living analogous animal is unknown. 7. The animal, twelve feet in length, and fix in height, of which the skeleton was found under ground at Paraguay, and is preferred in the royal cabinet of Spain, at Madrid. The author proves by a detailed comparison of the bones, with those of all the known quadrupeds, that it is a proper and distinct species, more nearly approaching the flesh than any other genus, and that it may be called the giant flesh. Citizen Cuvier, in this place, communicates the interesting discovery he has made, that the flesh (brachyops tridactyla, Linn.) has naturally and constantly nine cerebral vertebrae. It is the first known exception, established by Citizen Daubenton, that all quadrupeds have neither more nor less than seven cerebral vertebrae. 8. The animal, of which the remains are found in the caverns near Gaylenreuth and Mugendorf, in the margravate of Baysuth, in Franconia. Various authors have considered it as a white bear; but it differs from this animal, as well as from all the known bears, in the form of its head, which is particularly characterized by the projection of the front, by the absence of the small tooth, which all the known bears have behind each canine tooth, by the oblique channel of the humerus, in which the brachial artery paves, and by several other circumstances in the figure and proportion of the bones. This animal, however, resembles the bear more particularly than any other kind. 9. The carnivorous animal of which the bones are found in the plainer-tones of Montemartre: the form of its jaws, the number of its molar teeth, and the points with which they are armed, indicate that this species is referable to the genus canis; but it does not completely resemble any species of this genus. The most striking distinctive mark is, that the seventh molar tooth is the greatest in the animal of Montemartre, whereas the first is the largest in dogs, wolves, foxes, &c. 10. The animal of which the lower jaw was found near Verona, has been considered by Joseph Monti as a portion of the cranium of the fow-cow; a notion which all the geologists have adopted, though it be the contrary to the most simple notions of comparative anatomy. This jaw, according to Cuvier, has belonged to an animal resembling, though specifically different from, the mammoth, the animal of the Ohio, and that of Simon. Its most particular character consists in the curve which forms its symphys. 11. The animal of the flag kind of which the bones and the antlers are found in Ireland, in England, at Macnicht, &c. It is sufficiently different from all the flags, and even the elk, to which it has been referred, by the enormous magnitude of its antlers, the flattening of their superior part, and the branches which spring from their base. Several figures of these are given in the Philosophical Transactions. 12. The genus of the ox or beave alone affords several fossil species: the craniums of two were found in Siberia, which have been described by Pallas, who referred one of them to the ordinary buffalo; but he has since attributed them to a peculiar species, natives of Thibet, named arni. Citizen Cuvier proves, by osteologic comparison, that those craniums have not belonged to the buffalo. The other appeared to Pallas to have belonged to the buffalo of the Cape, or the musk ox of Canada. Citizen Cuvier shows that they cannot have belonged to the former; but not being in possession of the cranium of the arni, nor the musk ox, he makes no decision respecting their identity with the fossil craniums.

The author likewise describes two kinds of craniums which have been found in the turf-pits of the department of La Somme, which greatly resemble our common ox, and that of L'Aurouches, but are more than one fourth longer.

From this inquiry the Citizen Cuvier concludes, 1. That it is not true to affirm that the animals of the tooth have formerly lived in the north, their species not being perfectly identical. 2. That in every country there have lived animals which do not at present exist, either on the same spot, or elsewhere in any known country. Hence he leaves to geologists, the task of making, in their lists, such changes or additions as they may think best suited to explain the facts which he has thus established.

Bone is also applied abusively in speaking of other matters which bear some analogy, either in respect of structure or office, to the bones of animals.

In this same rock are sometimes called the bones of the earth. Divers species of figured bones, as the cephalites, enolithes, &c. are denominated mineral bones, enoliths, oolites, &c. Some naturalists consider shells as a species of bones. The lobster, according to Fontenelle, is an animal which carries its bones on its outside.

Bones, Giants. See Giants' bones.

Bones, Mammoth. See Mammoth.

Bone-fire. See Bon-Fire.

Bone-lace. See Lace.

Bone, burle, Nuper's, quitter, ring, subale. See the several articles.

Bonef, in Geography, a town and abbey of the Netherlands, in the county of Namur, 3 leagues north of Namur.

BONENCONP, a town of France in the department of the Cote d'Or, and chief place of a canton, 5 miles S.W. of St. Jean.

BONETTA, Sleah, lies about N. E. by E. from Bonnivillle island, one of the Cape de Verd islands, distant from it about 12 or 14 leagues.

BONEZIDA, a town of Transylvania, on the Samos, 12 miles N. of Claufenburg.

BONFARIO, James, in Biography, an eminent Italian scholar of the 16th century, was born at Gorziano, in the Brescian territory, and studied in the university of Padua. From thence he went to Rome, where, for some time, he served the cardinals Merino and Gimbacchi, as secretary; and after wandering from place to place, he refuted his studies at Padua, where he was probably employed in the instruction of youth. Deriving from none of his employments more than a precarious subsistence, he was, in 1545, invited to the chair of philosophy, in the city of Genoa, to which he united the office of historiographer, with a considerable pension. Whilist he was busily prosecuting his studies, he was charged and convicted of an unnatural crime; beheaded in prison; and his body was publicly burnt in July 1555. As a writer in the Latin and Italian languages, both in prose and verse,
he excelled; and his translation of Cicero's oration for Milo, is reckoned one of the most elegant pieces of Italian prose which the century affords. His capital work is the "Annals of the republic of Genoa," written in Latin, and comprising the history from 1528, where Giulianini left off, to February 1550. It was first published at Padua, in 1586, 4to., and translated into Italian by Patichetti. The style is elegantly simple, the narrative lively, and the sentiments elevated. His Italian letters and poems were printed at Brescia in 1746-47. Gen. Dict. Nouv. Dict. Hill.

BONFATTI, in Geography, a town of Italy, in the kingdom of Naples, and province of Calabria citra 3 leagues W. of St. Marco.

BONFINI, Anthony, in Biography, was born at Al- eoloi, and after being some years professor of belles-lettres, at Recanati, was invited by Matthias Corvinus king of Hungary, in 1484, to his court, where he was employed in writing the history of the Huns. Here he enjoyed the office of tutor to the queen, Beatrice of Arragon, and received many honours from Matthias, and his successor Ladislaus. He died in 1502, aged 75. Of the history of Hungary he left 4½ decades, brought down to 1495; of which 3, or 50 books were printed, by Martin Brenner, in 1543, and the remaining 15 books were added to a new edition by Sambucus, in 1568. This work is written with elegance, and is clasped among the best modern histories in Latin. He also wrote an account of the capture of Belgrade by Malomet II.; and a work entitled "Symphonia Beatricis, seu dialogorum de fide conjugalit et virginitate, lib. iii." He likewise translated, from the Greek into Latin, the works of Philostratus, Hermogenes, and Herodian. Gen. Dict.

BONGARS, James, a polite scholar and able negotiator, was born of protestant parents at Orleans in 1553. Having studied first at Strasburg, and attended a course of law under Cajucius, he entered into the service of the king of Navarre, afterwards Henry IV., by whom he was employed for 30 years in various negotiations, particularly with the German princes. Being at Rome in 1585, he wrote a severe reply to the violent bull fulminated by pope Sixtus V. against Henry IV.; and he also published a spirited answer to a German piece, imputing the bad successes of the joint expedition in 1587, to the misconduct of the French. He was distinguished by his knowledge of books, and had collected a large library, a great part of which was at length annexed to the public library of Bern. As a critic he became known by a valuable edition of "Iustin," Paris, 1581, 8vo. He also edited a collection of the Hungarian writers, and the "Gefta Dei per Francos." But his reputation was principally owing to his Latin letters, written during his negotiations, and published after his death, at Leyden, in 1647, and afterwards translated into French. The style is clear, easy, and polished, and they seem to have been dictated by an honest heart. A collection of his French letters, "Le Secretaire fans fard," has also been published. Although a Calvinist, Bongars, disapproved of the religious wars of that party. He died at Paris in 1612. Gen. Dict.

BONGO, or Bungo, in Geography, one of the islands of Japan. The principal town, seated on the east side of the island, is called by the same name. This is a port opposite to Tonfi, and separated from it only by a narrow channel. N. lat. 32° 41'. E. long. 131° 57'.

BONGOPAL, in Botany, Pito. See MYSTICRA AROMATICA.

BONGUATRORA, Serpens ornatus festivus convivens bon-guatrao of Serba, in Zoology, the name the coluber abestula bears among the natives of the island of Ambonya. See AHELUTA.

BONHAMPTON, in Geography, a town of America, in Middlesex county, and state of New Jersey; about 6 miles N. E. from New Brunswick.

BONI, a kingdom of the island of Celebes, which lies on the western side of a bay, called on that account the bay of Boni, is the second kingdom, in point of importance, in the island. Its extent from the river Chinarra to the river Salenico is about 30 leagues; and within land it is bounded upon Soping, Lamoer, Macaess, and Boeleboele. In ancient times this kingdom was independent of, and unconnected with any other. It is still in close alliance with the two small kingdoms of Soping and Loeboe, or Lochoe. The natives of Boni, that they may not appear inferior to the Macaess, deduce their origin in like manner from the gods. The first king, they say, descended from heaven, and was known by the name "Matta Salombo," that is, the all-ceiling. This sovereign, their first monarch, instituted the laws of the country, which are still observed; made the royal island, called "Worning Porong;" and appointed seven electors, under the denomination of "Matana petoes." The prince or sovereign is called "pajong;" and he is elected for life by seven nobles, which number is kept up by the pajong, and they are appointed by him from certain freeholders. The pajong is often restrained by a sort of parliament, elected by the freeholders; it consists of 400 members, of which are called "mattons," 100 are called "pabon nan," and 100 are called "galarag." The first sovereign, after reigning 40 years, resigned the kingdom to his son, and, with his wife, ascended again to heaven; and from him all the succeeding kings of Boni are descended, none others, besides his polterity, born of marriages with royal princes, being entitled to the crown. Notwithstanding the common descent of the rulers of Boni and Macafer from the gods, these two nations are avowed enemies. About the beginning of the 17th century the Bouginfe, or people of Boni, and their queen, were compelled to confide to the mahometan religion; and the condition imposed upon them was, that the enemies of Macafer should likewise be the enemies of Boni, but not the enemies of Boni those of Macafer. At this time Boni was able to bring 70,000 fighting men into the field. The hatred which was thus excited among the Bouginfe against the Macaess, and their incessant quarrels, enabled the Dutch, who, as their interest required, favoured sometimes the one party, and sometimes the other, to make themselves masters of the island. The princes of Boni, Soping, &c., united themselves to the Dutch by the Boni contract, which was concluded November 18th, 1657; and to this the Macaefers were afterwards compelled to accede. At present the Bouginfe are the most powerful, as the Macaessers were about a century ago.

The Bouginfe, or Buggees as they are usually called by the English, are of a middle size, and have a brown, but not dark, complexion. Among the female sex in particular, some are found almost entirely fair. Their features in general are agreeable, only that their nose is a little flattened. They are left open and more treacherous in their dispositions than the Macaessers; and never attack their enemies openly, but endeavour to fall upon them by surprise. Those who never did them an injury are not secure from being murdered by them, when they can do it with privacy; and they often commit such actions for no other reason, as they fly, than to try the goodnature of their knifes, or daggers. Many Macaessers, as well as Europeans, have fallen sacrifices to this thirst for blood. Their daggers and allagays are commonly poisoned, as well as their small darts, which they can shoot at their enemies to a considerable distance by blowing them through a tube. Their clothing consists of a piece of red or blue cotton cloth wrapped round the body, and drawn between
between the legs. The upper part of the body is quite naked. On the head they wear a piece of cotton cloth in the form of a handkerchief, with which they cover their hair, which is as black as pitch, and very long. On the other parts of the body, neither the men nor women suffer any hair to grow; they pull it out by the roots, in the same manner as the Mahometans and Indians do, as soon as it appears. Their food is chiefly rice, fish, and piangas; and their beverage is water, though they are not deficient of "faquers," or palm wine. The Bugnese women are in general much handsomer than those of the other Indian tribes; some of them, if their complexion had the same mixture of red and white as our females, would be accounted beauties in Europe. They are naturally of an amorous disposition, and are capable of undertaking anything to gratify their inclinations. The Bugnese, who have in general adopted the mahometan religion, may have four wives, provided the husband can maintain them; but if they are not satisfied with each other, they may separate with as little trouble as they were united. They are a high spirited people, fond of adventures and emigration, and capable of undertaking the most dangerous enterprises. The appellation "Bugnese," has become, among Europeans in the east of India, synonymous with soldier, just as feapoy is in the west. The people of Celebes are very industrious, and they are very adventurous merchants; and the Bugnese, in particular, often find their way to the spice islands, in spite of the vigilance of the Dutch. They write their language from left to right, in a character peculiar to themselves; on the sea-coast they universally speak the Malay tongue, and have many Malay phrases in their own language. Their funerals are attended with very little ceremony. The body is wrapped up in a piece of white cotton cloth, and deposited in the grave, over which some sweet scented flowers are strewn, and two roses are crested, one at the head and another at the feet. Stavorinus's Voyage to the East Indies, vol. ii.

Boni, lay of, a bay in the kingdom of Boni, in the southern part of the island of Celebes. It is called Sewa by the natives, and Bugnese, or long bay, by the English. Of this bay we have the following account by captain Forrest. Having passed the strait between Celebes and Selayor, called the "Budgerooms," keep on in a direction N.E. by N. about 130 miles, and you will find, near the west coast of the Sewa, a small islet called "Bakoornoo," visible 5 or 10 leagues off, and having some rocky islets at its ebb end. Farther on, about a day's sail, or about 60 miles, is the mouth of the river Chinrama, which takes its rise in the Warjoo country, the capital of which is Tofferoo, lying a day's journey by water from the mouth of the river; it afterwards passes through Boni; it has a good muddy bar, passable by large ships, and is navigable a good way up; it has several mouths, and on its banks are many towns, which carry on a great trade in gold, rice, fago, edulis, tortoise-shell, pearls, &c. The anchorage is good off the river's mouth. Half a day's sail farther north, along the west coast of the Sewa, is the river Penecreeke, which is not very considerable. Farther on are two places called Akologan and Telladopin, which are pretty well inhabited. Continuing still north, you come to the river Sewa, not very considerable; then to the river Loo, famous for boat-building; then you come to Mankakou, where are gold and plenty of fago, very cheap, and also caffia and seed-pearl. Being now come to the bottom of "Bugnese-bay," the fago-tree abounds very much; and in many parts of the Sewa, there are spots of foul ground, on which they fish for swallow, which they generally carry to Macaifer, to sell to the China

junk. On the east side of the Sewa the country is not so well inhabited as on the west side. The south-west point of the Sewa is called "Perungo," where is a cluster of islands, rather small, among which is good anchorage. Stavorinus's Voyage, vol. ii. p. 213.

BONJEUX, a town of France, in the department of the Varinche, and chief place of a canton, in the district of the Apt. The place contains 2450, and the canton 6178 inhabitants; the territory comprehends 130 kilometres, and 6 communes; 8 leagues E. of Avignon.

BONIFACE, in Biography. There are nine popes of this name. Boniface I. succeeded Zosimus in the year 418; and when the Ischii, occasioned by a party that favoured Eulalius, was terminated, he was fully established in possession of the papal fee in 419. Before his election he was a presbyter of irreproachable character, and after his advancement he was a lover of peace; and though he maintained what he called the just rights of the Roman See, in the jurisdiction which his predecessors had exercised over the bishops of Illyricum, he made no attempt to extend his authority and claims. He revoked the privileges granted by Zosimus to the fee of Arles, and restored them to the fees of Narbonne and Vinci, which had been unjustly deprived of them; and with a moderate that redounds much to his honour, he refused to interfere in a dispute which took place between the clergy of Valence and Maximus, their bishop. He died at a very advanced age, November 4, 422; was canonized as a saint in the church of Rome; and his festival was kept on the 25th of October. Bede gives credit to the relation of miracles wrought by this pope, and Baronius (ad ann. 423) says, that he relieved Rome in the time of a famine.

Boniface II., a Roman by birth, and a Goth by descent, supplied the vacancy occasioned by the death of Felix III. in 520; and upon the death of a competitor, named Dicoricius, obtained quiet possession of the papal chair. This pope confirmed the decrees of some Gallican bishops, who condemned the semipelagian doctrine; and in 521 he proposed to alter the mode of electing a pope, and to assume the prerogative of appointing his successor. He obtained a decree for this purpose, and actually nominated a deacon, whose name was Vigilius. But at a second council the Roman senate, in concurrence with the bishops and clergy, obliged the pope to revoke his former decree, and to acknowledge himself guilty of high treason. Boniface died in October, 532.

Boniface III., a native of Rome, succeeded Sabastian, after a vacancy of almost a year, in 607; and having ingratiated himself with the emperor Phocas, to whom he was deputed as a nuncio by pope Gregory, in 603, he obtained from this tyrant the title of "universal bishop," and "head of the church," which was taken from the bishop of Constantinople, and transferred to Boniface and his successors in the see of Rome. Thus, says Bower, was the power of the pope, as universal bishop and head of the church, or in other words, the papal "superemacy," first introduced. It owed its original to the word of men; it was procured by the bafeli means, or by flattering a tyrant in his wickedness and tyranny; and according to the previously declared judgment of Gregory the great, it was in itself "anti-christian, heathen, basphemous, and diabolical." Boniface afterwards assembled a council for settling the election of bishops, in which they were forbidden to nominate their own successors, and the content of the people, clergy, and sovereign, and the confirmation of the pope, were made necessary. Boniface died in November, 607.

Boniface IV., a native of Valeria, in the country of the Marsi,
BON

Boniface V., a native of Campania, and a prebendary of the Roman church, succeeded Dunedidit in December 619. In 624 he sent the pall to Julius, the successor of Mellitus in the see of Canterbury, and interested himself in the propagation of Christianity in Britain, by sending letters and presents to Edwin the king of Northumberland, and allo to his queen Edelberg, sister of Eadbald king of Kent, who, having assumed the Christian profession, was allowed by her marriage articles the free exercise of it. He died in October 625. Some decretal epistles, relating to matters of small importance, are ascribed to him. According to Molein (Ecc. Hist. vol. ii. p. 185), this Boniface enacted that infamous law, by which the churches became places of refuge to all who fled thither for protection; a law which procured a fort of impunity to the most enormous crimes, and gave a loose rein to the licentiousness of the most abandoned profiteers.

Boniface VI., was a Roman of infamous character, and succeeded Formosus in 896. Baronis (ad Ann. 897.) will not allow him a place among the popes. He died soon after his election.

Boniface VII., denominated "Anti-pope," was a deacon of the Roman church, of the name of Franco, and advanced to the papal chair in 975, upon the death of Benedict VI. to whose murder he is said to have contributed. Soon after his election he was constrained by an adverse party to leave Rome, and to fly to Constaninople; but he carried with him the treasures of St. Peter. Gerbert styles him "of all monsters of wickedness the most wicked." Upon the death of the emperor Otto II. in 984, he returned to Rome, and occupied the see in the room of John XIV. whom he displaced, imprisoned, and put to death. Franco died in 985; and he had rendered himself so odious by his tyrannical conduct, that his corpse was treated with the utmost indignity, and dragged naked through the streets.

Boniface VIII., a native of Anagni, and a descendant of the noble family of Cætani, was employed by popes Martin IV. and Nicholas IV. in several important legations, and succeeded pope Celestine V. whom he artfully persuaded to resign, in December 1294. The beginning of the following year he was enthroned at Rome with great solemnity and parade; in the procession from St. Peter's, where he was consecrated and crowned, to the Lateran, for the purpose of being intronized, he was mounted on a white horse, richly caparisoned, with the crown on his head, whilst the king of Arragon held the bridle in his right hand, and the king of Hungary in the left, both on foot. His subsequent conduct corresponded to the haughty grandeur of his installation. In order to secure himself against any future trouble from Celestine, he confined him in prison at Anagni, where he died. Failing to mediate a peace between James king of Arragon, and Charles II. king of Sicily, he formed an alliance against Frederic of Arragon, whom the Sicilians had made their king, and proceeded to excommunicate him and all his adherents; but he was at length obliged to confirm him in his dominions. His next measure was that of humbling the family of Colonna, two cardinals of which had opposed his election; for this purpose, after having declared the whole family infamous by a public decree, confiscating their estates, and excommunicating all who countenanced or protected them, he ordered a crusade to be preached against them and their friends, demolished their houses and castles, and obliged them to seek shelter in foreign countries; and he moreover punished with utter demolition the city of Praetet, for its attachment to them. To Boniface is commonly ascribed the institution of the jubilee in 1290. See JUBLIS. In his attempt to mediate a peace between Philip the Fair king of France, and Edward I. king of England, he was charged with partiality to the latter, so that Philip could be prevailed on merely to agree upon a truce; and his enmity against Boniface, which was smothered for some time, at length broke out into a flame. Philip, with a view of supporting the war against England, prohibited the exportation of any gold or silver from the kingdom without his permission; and Boniface, apprized that this order was levelled against the see of Rome, cried a bull, forbidding secular princes to exact, and the clergy to pay, any sums from the ecclesiastical revenues, without his approbation. The animosity between the pope and the French potentate was increased by the arrogance with which a legate from Rome delivered the pope's missal, enjoining the king of France, in common with other Christian princes, to aid the king of Tartary in a war against the Saracens, and by the frequent arrest of the legate. Boniface, much enraged, dispatched a nuncio to demand his release; and in cal of reful, threatened to declare the kingdom devoted to the holy see, to absolve his subjects from their allegiance, and to summon all the Gallican bishops to Rome. The king resented this violent proceeding, renewed the prohibition against carrying money out of the kingdom, and forbade his ecclesiastics on any pretence to visit Rome. In these hostile measures the king was supported by the fates of the nation, which appealed to a general council, and Boniface prepared to formulate decrees of excommunication and forfeiture of his crown against Philip. Nogaret and Sciarra Colonna were sent, on this occasion, into Italy to excite the perfecuted Ghibellines against the pope, who was then at his palace in Anagni. They secretly approached it with a body of troops, and made themselves masters of the perfon of Boniface and all his treasures. During the three days of his confinement the pope was treated with great indignity, particularly by Colonna. At length the people of Anagni, recovering from their consternation, rescued the pope from his captivity; who returned to Rome, where he was feized with a fever, which terminated his life in October 1303. He was buried at St. Peter's in a grand mausoleum, which he had erected for himself. Although Boniface has been justly extolled for his learning, intrepidity, and experience in public affairs, and for his patronage of literature; he was arrogant and overbearing, ambitious, crafty, and violent, and aversive to such a degree, that he was intent upon accumulating riches to exalt the church and aggrandize his own relations. He was the author of several works, such as epistles and decrees, two discourses on the canonization of Lewis IX. of France, called St. Lewis, two famous prayers, one to our Saviour, and the other to the Virgin. He also caused to be published the sixth book of the decretals, and wrote a treatise entitled "De regulis juris."

Boniface IX., a native of Naples, descended from a noble family in reduced circumstances, whose name was Peter Thomacelli, was more distinguished by his prudence and address than for his profound and extensive learning, and was elected pope at Rome upon the death of Urban VI. in 1389. The greatest part of his pontificate was devoted to negotiations with his rivals at Avignon, Clement VII. and Benedict XIII., in
in which were displayed on both sides much cunning and artifice, and at the same time an inflexible resolution of retaining the tara. Boniface was arbitrary in the exercise of power, and towards the end of the year 1439 he would have been maltreated by the people, if he had not been feasonably recalled from the enraged multitude by the interposition of Ladislaus, king of Naples, who happened to be then at Rome. He afterwards retired to Perugia, and from thence he removed to Assisi; but on the approach of the jubilee year, 1440, the Roman people, apprehending, that in the absence of the pope it would not be celebrated with the usual solemnity, and the papal interdicts affected, deputed an embassy to invite his holiness to Rome. Upon his arrival he was received with joy and invited in extraordinary powers, in the exercise of which he repaired and fortified the walls and towers of the city, and the castle of Angelo, and also placed garrisons in them, so that he made himself absolute master of the city. Some ascribe to Boniface the institution of Annates (see Annates); but though the origin of these is of more ancient date, it is allowed to have been in a very high degree aversive and rapacious, to have foil church preferences to the bell bidder, without regard to merit or learning, and to have made it his constant study to enrich his family and relations. He died a martyr of the stone in 1434. Bower’s History of the Popes.

Boniface, called the “Apostle of the Germans,” was a native of England, whose original name was “Winfrid,” born in Devonshire, A.D. 676, and was educated in a Benedictine monastery at Exeter. This famous ecclesiastic, who was ordained a priest A.D. 700, with two companions, passed over into Frisia in 709, in order to preach the gospel among the heathens; but failing in his first attempt, on account of a war which broke out between Rabod the king of that country, and Charles Martel, he returned to England. However, he renewed his pious undertaking in 718; and at Rome he was solemnly empowered by the Roman pontiff, Gregory II. to preach the gospel not only in Frisia, but throughout Germany; a commission he executed with considerable success. In the year 723, he was consecrated bishop by Gregory II., who changed his name of Winfrid into that of Boniface; and he is said to have been the first who took a solemn oath of obedience to the pope, which he did at this time. Upon his return to Germany, with the instructions of the pope, and the peculiar protection of Charles Martel, he preached in Thuringia, Helfia, and Bavaria, and erected a great number of Christian churches. As these were too numerous to be governed by one bishop, this prelate was advanced to the dignity of archbishop, in 732, by Gregory III., under whose authority, and the auspicious protection of Carobon and R. in, the son of Charles Martel, he founded in Germany the bishoprics of Wurtzbourg, Pari- bourg, Erfurt, and Aichlade; to which he added, in 744, the famous monastery of Fulda. His last promotion, and the last recompense of his industrious labours in the propagation of the truth, was his advancement to the archiepiscopal see of Mentz, A.D. 746, by pope Zachary, by whom he was at the same time created prince of Germany and Belgium. In his old age he returned again to Frisia, where, he might finish his ministry in the scene of its commence- ment; but his pietty and zeal were ill rewarded by that barbarous people, by whom he was murdered in 754, together with fifty ecclesiastics, who accompanied him, and who shared the same fate. He was interred in the abbey of Fulda, and canonized by the church of Rome, to which he was ardently devoted. His zeal for the glory and authority of the Roman pontiff equalled, if it did not surpass, his solicitude for the service of Christ, and the propagation of his religion; and in combating the heathen superstitions, he recurred to other weapons than those which Christianity recommended, employing violence and terror, and sometimes artifice and fraud, in order to multiply the number of Christians. His epistles, and those of his coadjutors, first published with notes by Serrarius, in 1605, and re-published in 1629, are written in a barbarous style, and discover an imperious arrogant temper, a cunning and insidious turn of mind, an excessive zeal for increasing the honours and preten- tions of the fonsalternal order, and a profound ignorance of many things, the knowledge of which was indispensably necessary in an apostle, and particularly of the true nature and genius of the Christian religion. The Benedictines have published his statutes, and some of his sermons. Bower’s History of the Popes, vol. iii. Moheim’s Ecc. Hist. vol. ii. p. 205, &c. Cave’s Hist. Lit. t. i. p. 612. Dupin, Ecc. Hist. cent. 3.

Boniface, count of the Roman empire, one of the two generals of Placidia, the mother of Valentinian III., Actius being the other (see Aetius), who have been erroneously named as the last of the Romans; was the intimate friend of St. Anguline, bishop of Hippo, but incurred his displeasure by marrying a wife of the Asian race, after a solemn vow of chastity, and a resolution of retiring from the world, and by other infamous licentious conduct with which he was charged. However, the people applauded his ipotels integrity, and the army declared his impartial and inexorable justice. Of his justice, the following singular fact is recorded. A penant, who complained of the criminal intimacy between his wife and a Gothic soldier, was directed to attend his tribunal the following day: in the evening, the count, who had diligently informed himself of the time and place of the affiquation, mounted his horse, rode ten miles into the country, surprised the guilty couple, punished the soldier with infant death, and silenced the complaints of the husband by presenting him, next morning, with the head of the adulterer. Boniface, having defended Marselles, when attacked by Ataulphus, was rewarded by the emperor Honorius with the command of the troops in Africa, which province he rescued from the repeated attempts of John, who usurped the empire. Placidia, who assumed the government of the empire during the minority of her son, highly pleased with his bravery and loyalty, called him to court upon the death of that usurper, preferred him to the poll of “comes domelticorum,” and sent him into Africa with unlimited power. These marks of favour excited the jealousy of Actius (see Aetius), who artfully contrived, under the mask of friendship, to engage Boniface in a revolt, which took place in 427. Accordingly, Placidia declared him a public enemy, and sent troops against him. Having defended himself for some time, he found at length that he was likely to be overpowered; and therefore, after some hesititation, the last struggle of prudence and loyalty, he dispatched a trusty friend to the camp of Gondelric, king of the Vandals, with the proposal of a strict alliance, and the offer of an advantageous and perpetual settlement. The Vandals accepted the proposal, and Gondelric, who succeeded his brother, and whose ambition had neither bounds nor fetters, transported his troops from Spain into Africa in 429, and obtained, by the concurrency of several favourable circumstances, an easy conquest. Placidia discovered, when it was too late, the artifice that had been practised by Actius; and Boniface, who also perceived and lamented his error, returned to his allegiance. But his efforts to recover Africa were unavailing; and he was under a necessity of abandoning the country, and of returning to Ravenna, where
Boniface, Natalis, an engraver of great merit, who flourished in Italy, towards the conclusion of the 16th century. His works are chiefly etchings, performed in a fine, fine style; and his small figures he executed with great spirit. His chief work was the plates composed by D. Fontana, architect to pope Sixtus V. concerning the removal of the Vatican obelisks. Strutt.

Bonifacio, or Bonfaccio, in Geography, a sea-port town of the island of Corfu, department of Liamone, and chief place of a canton, in the district of Sartene, on the south coast, and in the strait between the islands of Sardinia and Corfue. The town is small and fortified, and the canton contains 3172 inhabitants; 28 leagues south of Balia. N. lat. 41° 34'. E. long. 9° 20'.

Bonifacio Point. See Baldivia.

Bonifacio Strait, commences near the town of the same name, on the S.E. of the island of Corfue; and its length to point Tico, the most northerly point of Sardinia, is 24 leagues.

Boning, in Surveying and Leveling, &c. is the placing of three or more rods or poles, all of the same length, in or upon the ground, in such a manner, that the tops of them all may be in one continued straight line, whether it be horizontal or inclined, so that the eye may look along the tops of them all, from one end of the line to the other.

Bonjour, William, in Biography, a learned Augustinian, was born at Toulouse in 1670; and at Rome, whither he was sent for by cardinal Norris in 1695, he became distinguished by his learning and piety. He was employed by pope Clement XI. in several matters of importance, and particularly in the examination of the Gregorian calendar. Bonjour had also the superintendence of the feminary established by cardinal Barbarigo at Montefiaccione, and deannounced the Academy of Sacred Letters. He was acquainted with almost all the oriental tongues, and more especially with the Coptic, or ancient Egyptian. Actuated by a zeal for acquiring knowledge, and for propagating the gospel, he visited China, where he died in 1714, whilst he was employed in forming a map of that empire. His works are, 

Bonis arrestandis ne dispensetur. See Arrestandi.

Bonis non amandis, a writ directed to the sheriffs of London, &c. where a writ of error is brought, to charge them that the person against whom judgment is obtained be not suffered to remove his goods, till the error is tried and determined.

Bonis, terris, et catallis rehambondis poff purgationem. See Terris.

Arresto fullo super Bonis mercatorum. See Arresto.

Bonito, in Ichthyology, synonymous with the French bonite. This appears to be a name assigned indiscriminately to more than one or two kinds of fishes, although it seems to be confined in some degree to those of the Scophem genus. The Scophem pelamis of Lochi. is the fish mentioned under the name of bonito by Obheck, who also calls it Scophem pelamis. The bonito is vaguely described as a large sea-fish, with a long, broad, and thick body; eyes, and likewise the gills, large; and the greater part of the body free from scales. It is observed still further to be a fish of great beauty, and very common in some seas; our East India ships usually falling in with immense schools of them. It is impossible to say whether this may be the Scophem pelamis, or not; but as a matter of opinion, we think it to be the same, because the latter is found in immense schools between the tropics, and in the Atlantic ocean. The bonito of Bloch is the Latin name of Scophem horrida.

Boniton, the common. French name of Scophem amia of Linnaeus.

Bonizo, in Geography, a town of Italy, in the duchy of Mantua, on the south side of the Po, opposite to Olligno.

Bonkose, in Ichthyology, the Scophem nebulae, a fish discovered by Forskal in the Red Sea. Bonkose is the name it bears in Arabia.

Bonlieu, in Geography, a town of France, in the department of the Ardeche; 5 leagues N.N.W. of Tournon.

Bonn, in Latin Bonam, a small but populous and fortified city of Germany, in the circle of the Lower Rhine, and electorate of Cologne, or, according to the French arrangement, the chief place of a district, in the departments of the Rhine and Mofelle. The place contains 8537, and the canton 18,951 inhabitants; and its number of communies is 31. The number of houses is said not to exceed a thousand; and as it has little foreign trade, most of the inhabitants are attracted thither by its being the residence of the elector of Cologne. The streets are narrow, crooked, dirty, and badly paved, and in winter badly lighted. The public walks are few, and not very agreeable. The churches are flately; and the town-house is adorned with fine paintings. The Jews at Bonn have a street to themselves, consisting of a few houses; and their number is estimated at 250. Bonn was taken from Louis XIV. into whose hands it was surrendered by the elector, in 1675, by William prince of Orange; in 1685, by the marquis of Brandenburgh; in 1703, by a detachment of the duke of Marlborough's army, after a siege of three weeks, and the loss on both sides of 2000 men; and on the 6th of October, 1794, by the troops of the French republic. It is situated 14 miles N.S.E. of Cologne, 30 E. of Aix-la-Chapelle, and 28 N.N.W. of Coblenz. N. lat. 50° 40'. E. long. 7'.

Bonna, in Zoology, synonymous with Bonnus; which see.

Bonnacht, or Bonnach, an old term, which occurs frequently in Irish history, and was the same with coin and livery; being a certain proportion of meat, drink, and money for the maintenance of a soldier, and sometimems free quarter. Hollinghead speaks of it as an Irish impostion, which beggar the farmers; and Sir John Davis, the eminent attorney general of Ireland in the reign of James I. in his judiciously adressed tract, entitled "A Discovery of the Caufes, why Ireland was never subdued," has these words: "But the most wicked and mischiefous custom of all others, was that of coin and livery, which consisted in taking of man's meat, horse meat, and money, of all the inhabitants of
of the country, at the will and pleasure of the soldier, who, as the phrase of the Scripture is, "did eat up the people, as it were bread," for this he had no other entertainment. This extortion was originally Irish, for they used to lay bonnages upon their people, and never gave their soldiery any other pay. But when the English had learned it, they used it with more influence, and made it more intolerable; for this oppression was not temporary, nor limited either to place or time, but because there was every where a continual war, either offensive or defensive, and every lord of a country, and every marcher, made war and peace at his pleasure, it became universal and perpetual, and was indeed the most heavy oppression that ever was used in any Christian or Heathen kingdom. The curious reader will do well to consult the whole pamphlet in Sir J. Davis's Historical Tracts, p. 132, at f. q. of the edition printed in Svo. Dublin, 1757. This practice was forbidden by the statute of Kilkenny passed in 1450, and by several succeeding acts, in one of which (under Henry VIII.) it is called a damnable custom. Spenser, in his "View of the state of Ireland," seems, however, to think the statute unnecessarily severe in making it treason. Hollinghead, Irish Statutes. Spenser's State of Ireland.

BONNAT, in Geography, a town of France, and chief place of a canton, in the department of the Creuse, and district of Gueret; the place contains 20,32, and the canton 10,804 inhabitants; the territory comprehends 2571 kilometres, and 12 communes.

BONNAUD, in Biography, published, in 1770, "De- gradation de l'espece humaine par l'affage des corps de baleine," 12mo. Paris. In this very fertile and ingenious little work, the author forcibly represents the various evils consequent on using flays diffened with whalebone: these are indignation, and other disorders of the stomach, ruptures, and difficult respiration, often terminating in consumptions; besides, they not unfrequently occasion deformity of the body, which they are supposed by their admirers to contribute in preventing. Haller Bib. Med.

BONNAV, in Geography, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Befançon, 2 leagues N. of Befançon.

BONNE, a town of Savoy, in the Lower Faucigny, 10 miles E. S. E. of Geneva. "N. lat. 46° 11', E. long. 6° 7'.

BONNE, a bay on the west coast of Newfoundland. N. lat. 49° 35', W. long. 53°.—Also, a bay on the coast of Spain in the Mediterranean, nearly east from Malaga. N. lat. 36° 42', W. long. 2° 40'.

BONNEBOIS, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Pont l'Evêque, 2 leagues S.W. of Pont l'Evêque.

BONNEFONS, John, or BONNEFOS, in Biography, was born, in 1554, at Clermont in Auvergne, became an ad- vocate in Paris, and, in 1584, lieutenant-general at Bar- sur-Seine, and died in 1614. He was distinguished as a Latin poet, and particularly by that kind of poetry, which is the short verse of Catullus, abounding with diminutives and tender expressions. Of this kind is the piece entitled "Pancharis," which is reckoned the most elegant performance of any modern writer. It seems to have been the aim of Bonnefons to imitate Joannes Secundus, the celebrated author of the Bafia; and his resemblance, with regard to softnesses and sweetness, has approached the extreme of lasciviousness and effeminacy. His poems in heroic verse have also been esteemed. The Pancharis was published at Paris in 1588, and translated into French by La Bergerie; and all the poems of Bonnefons are printed after those of Béza, in Barbon's edition of the latter, Paris, 1577. There are London editions in 1720 and 1727. A son of Bonnefons distinguished himself by Latin poetry, chiefly written on public characters and events. Not. Dict. Hist.

BONNER, Edmund, an English prelate of detectable memory as a persecutor of Protestants, was born, as it is generally believed, of poor parents at Hanley, in Worcestershire; but some have affirmed that he was the natural son of George Savage, rector of Davenham, in Cheshire. About the year 1512, he was admitted a student of Broadgate hall (now Pembroke college) in the university of Oxford, famous at that time for the education of civilians and canons. In 1519, he took his degrees of bachelor of the canon, and bachelor of the civil law; and about the same time entered into holy orders. In 1525, he was created doctor of the canon law. More distinguished by his talents for business than for his learning, he was appointed commissary of the faculties by cardinal Wolsey, who conferred upon him a plurality of ecclesiastical benefices. After the cardinal's death, he contrived to incommode himself into the favour of king Henry VIII., and became a zealous supporter of the reformation, as well as an advocate for the king's divorce from Queen Catharine, and a frequent supporter of the measures that were adopted for abolishing the pope's supremacy in this kingdom. He was also patronized by Crom- well, secretary of state, and employed as ambassador at several courts. In 1532, he was deputed on an embassy to Rome, to excape the king's appearance to a citation at that court; and in 1533, he was sent to pope Clement VII. then at Marcellis, to deliver the king's appeal from the pope to the next general council against his excommunication; and on this occasion he expounded himself by his boldness and inden- tate warmth to personal danger. He was likewise em- ployed in other embassies to the kings of Denmarck and France, and to the emperor of Germany. Being recalled from France in 1538, on account of the boldness with which he remonstrated against the protection afforded to an English traitor, he was nominated to the bishopric of Hereford, and, before his consecration, translated to the see of London in 1539. At the time of the king's death in 1547, he was ambassador at the court of Charles V. Till this time he appears to have concurred in promoting the reformation; and by the subervency of his principles to his interest, as well as by his capacity for public business, he secured the favour and confidence of his tyrannical master. But from his subsequent conduct it is evident that he was secretly attached to the Romish religion; for soon after the accession of Edward VI., he feplied to take the oath that was required for renouncing the pope's authority, and he professed against the king's in- junctions and homilies, which, however, he had never read. But being committed to prison for disobedience, he afterwards recanted, and was released. Whilst he outwardly professed zeal for the reformation, he privately used all the means in his power for obstructing its progress and establish- ment. His conduct warranted the suspicions that were ent- tained of his sincerity; and in order to bring it to a tell, he
he was ordered by the privy council to preach at St. Paul's

c roofs on certain articles, connected with the principles of
the reformation, and given to him in writing. But he per-
formed this service in a manner so unsatisfactory, that, upon
the complaints of Hooper and Latimer, commissioners
were appointed to proceed summarily against him; the refult
of which was, that he was committed to prison, and deprived
of his bishopric. These proceedings, allowed even by his
enemies to be arbitrary and severe, routed his remonstrations;
nor was he long obliged to wait for an opportunity of ample
retaliation. Upon the accession of Mary to the throne, he
was restored to his bishopric, by a commission dated August
1553; and in the convocation of the following year, he was
appointed president in the room of Cranmer, who was com-
mittled to the tower. In this year he visited his diocese,
and indulgently rooted up all the seeds of the reformation.
In the four succeeding years he was an active and savage per-
culator; and he is said to have committed to the flames
200 persons, who avowed their firm adherence to the
protestant religion, and who refused to embrace the gross errors of
papacy, besides imprisoning and torturing many more.
Bonner's disposition was in the highest degree cruel and
ferocious; and religious bigotry, grafted on a temper natu-
 rally savage, rendered him a fit instrument to be employed by
the artful Gardiner in the condemnation and execution of
heretics. But though his nature did not seem to recoil at
this savage employment, he dreaded the increased odium
that attended it, and refused any longer to be the execu-
tioner of the laws. However in 1556, he concurred in
the degradation of Cranmer, and enjoyed the malignant pleasure
of triumphing over him with his utmost insolence. In
the following year his name was infected in a kind of inquisitorial
commission for searching after, and punishing all heretics, as
all persons who were of the protestant religion were then
denominated. Upon the accession of Elizabeth, he had
the early opportunity to accompany the other bishops in their progress
for meeting her at Highgate; but she looked upon him
with feelings of just indignation and horror, as a man pol-
uted with blood. He remained for some months un-
 molested; but in May 1559, he was summoned before the
privy council; and refusing to take the oath of allegiance
 and supremacy that were tendered to him, he was deprived
of his bishopric, and committed to prison. In this state of
confainment he remained for some years, bearing his reverse of
condition with a degree of cheerfulnes which might have
become a better man, and occasionally rousing off, by keen
and humorous repartees, the popular insults that were offered
him. He died in prison, September 5 1560; and was
buried at midnight in St. George's church-yard, Southwark,
left any indignities should be offered to his remains by the
incensed populace. Bonner was singularly savage in his
natural temper, blustering and profane in his conversation
and manners, furious and violent in his conduct, gross
and corrupt in his person, and in every respect fitted for the
part he acted, as an unrelenting and brutal persecutor. He
was generally regarded as the best of any fixed principles;
and he has been charged even with Atheism. As a cano-
nist and politician he was allowed to excel; but his knowledge
of divinity was very imperfect, and he had no reputation for
learning. However, several pieces, theological, contro-
versial, and pastoral, were published under his name. By
his intercile with queen Mary, he obtained several advantages for
the see of London, which his successors have enjoyed. Biog.

BONNET, CHARLES, an eminent natural philosopher,
was born at Geneva in 1720, and educated under a domestic
tutor, whom his father provided for him, as affording in-

ior advantages to those which he enjoyed in any of the public

schools. At the early age of 16, he discovered that pecu-
iliar inclination of his mind, which led him to those studies
that laid the foundation of his future fame and excellence.
From the perusal of the Spectacle de la Nature, he was in-
duced to direct his particular attention to the structure and
manner of the ant-hill, and added many curious observations
relating to it, to the facts that had been previously
collected by Meff. Poupart and Reaumur; and he was fur-
ther led by the Memoirs on Insects, published by the latter,
to repeat many of his experiments, and to discover new
facts, which indicated in a youth of 18 a degree of sagaci-
ity and research that surprised and gratified this eminent
naturalist, by whom he was encouraged and procured.
The interesting observations which he made on different species of
caterpillars, and other insects, in the years 1758 and 1759,
were communicated by him to Reaumur. His father had
dedicated to the profession of the law; but the study
of natural history was his chosen and favourite employment.
Having, in 1740, decided a question that had been left
unsettled by Reaumur, respecting the multiplication of trea-
ses, or aphides, without actual conjunction, he communi-
cated a paper on this subject to the Academy of Sciences
at Paris, and, in consequence of it, had the honour of be-
coming a correspondent of this illustrious body. His eye-
light was irreparably injured by the minutest of his re-
searches on the generation of these animals. In 1741,
he found that many species of worms pollce, in a degree, the
reproductive power of the polype; and in 1742, he dis-
covered that the respiration of caterpillars and but-
terflies, was effected by means of their pores, called "Stigmata.
" The "tæna, or tape-worm, was also a subject of his succe-
sful investigation. In 1743, he was advanced to the rank of
doctor of laws, and on this occasion he totally abandoned
the profession of the law. A paper on insects, which was
this year communicated to the Royal Society of London, ob-
tained for him the honour of being elected a member. His ob-
servations on aphides and worms, under the title of "Infe-
tology," were published in 1744; and this work was intro-
duced with a preface, in which he gave a brief sketch of his
ideas concerning the development of germs, and the scale of
organised beings. This work was very favourably received
by the public; but few had been the nature of his re-
searches and the affinity of his application, that his eyes
and his health failed him; and he was reduced to the dis-
tressing necessity of laying aside his microscope, and of
deferring from reading and writing. This self-denial, pecu-

liarily afflicting to his ardent mind, he bore, however, with
philosophical resignation; and by a total intermission of his
studies he had the satisfaction of regaining a considerable
degree of health and ease, though he was never able to
employ his eyes as he had been accustomed to do. In 1746,
he commenced a course of experiments on the vegetation of
plants in moist and other singular substances; and in
the following year he examined with minute attention the leaves
of plants, with a view of ascertaining the appropriate action
of their upper and under surfaces. He also employed
coloured injections for the purpose of determining whether
the sap ascends by the bark or wood; and he made various
observations on vegetable moulds, and other circumstances
of vegetation, which were communicated to the public in
one of the most curious and original of his works, entitled,
"Inquiries into the nfe of the leaves of plants;" first pub-
lished at Leyden, in 1734, 4to; to which supplements
have been added as late as the year 1779.

Bonnet, probably constrained to remit his attention to
experiments by the circumstances already mentioned, directed

his speculative researches to the faculties of the human mind; and having collected a mass of materials on this subject, he published a kind of abridgment of them, under the title of an "Essay on Physiology," in 1755, at London. This work, which appeared without his name, and which he did not acknowledge for 30 years, contains a concise statement of the fundamental principles of his philosophy. "It traces the origin and progress of the human mind, from the first germ of life, to the development of all its faculties, the mutual dependence of which it points out, as deduced from actual observation. It enters into the different subjects of human liberty, and endeavors to reconcile it with the divine preexistence, and with the philosophical principle, that every effect must have an adequate cause. From the essential properties of the activity of the soul, and the effects of habit upon it, the whole art of education and government is deduced; and a system of the former is laid down, materially different from the usually established methods." Our author's metaphysical ideas were evidently founded on the principles of Malebranche and Leibnitz; but as he had freely discussed some points of a delicate nature, and which were likely to involve him in personal controversy, he chose to conceal his name. His next work, the fruit of five years' labour, was an "Analytical Essay on the faculties of the Soul," first printed at Copenhagen in 1760, 4to, at the expense of the king of Denmark. In this work he assumes the hypothesis of a statute organized like the human body, which he animates by degrees, and shows how its ideas would arise from impressions on the organs of sense. Although this performance was well received by some philosophers, it soon subjected the author to the charge of materialism and fatalism; but to this charge he made no reply. Accustomed to retirement, to which mode of life he was obliged to recur, on account of his deafness and other bodily infirmities, he fought the comforts of a domestic life; and in 1755, he married a lady of respectable family, the aunt of the celebrated Sauffure, with whom he passed 37 years of congenial felicity. In the prosecution of his physical system, Bonnet published at Amsterdam in 1762, his "Considerations on organized bodies," 2 vols. 8vo. The principal objects of this work were, to detail, in an abridged form, all the most interesting and well ascertained facts, respecting the origin, development, and reproduction of organized bodies; to refute the different systems founded upon the "epigenesis," and to explain and defend the systém of germs. His "Contemplation of Nature," which appeared in 1764, Amst. 2 vols. 8vo., was a popular work, displaying the principal facts relating to the different orders of created beings, in an instructive and entertaining manner, and recommended by the charms of an eloquent style, with a constant reference to final causes, and the proofs of wisdom and benevolence in the creator. This was translated into several European languages, and enriched with notes by the author himself, and also by others, in a new edition. His concluding work was his "Paléontologie," printed at Geneva in 1769, 2 vols. 8vo. This treatise on the origin and future state of living beings, and supports the idea of the revival of all animals, and the perfecting of their faculties in a future state. To this work he annexed "An inquiry into the evidences of the Christian revelation, and the doctrines of Christianity, which, with a piece "On the existence of God," was published separately at Geneva in 1770.

Towards the year 1773 he resumed his attention to natural history, and published, in Rozier's journal, a memoir on the method of preserving insects and fish in cabinets. In the following year he sent to the name journal a memoir on the loves of plants, originating in the discovery of a kind of eel or mouth in the pith of a lily. Other memoirs contained a detail of his experiments on the reproduction of the heads of flies, and of the limbs and organs of the water salamander. He also made observations on the pipe or Bub- rimian toad, on bees, on the blue colour acquired by muff rooms from exposure to the sun, and on various other subjects in natural history. His reputation introduced him as an associate into most of the literary societies of Europe; and in 1783 he was elected into the select number of foreign associates of the academy of sciences in Paris. His correspondence was extensive, and his attention to public duties exemplary. In the great council of the republic into which he entered in 1752, and in which he had a seat till 1768, he distinguished himself by his manly eloquence in the support of wife and moderate measures, and his constant zeal in the cause of morals and religion, with which, in his opinion, the prosperity of the state was essentially connected. The last 25 years of his life were spent altogether in the country, where he enjoyed, with a competence, the intercourse of chosen friends. Some part of his time was employed in the education of youth, for which office he was admirably qualified. The revival of his works occupied near eight years of his life, and required a degree of application which was injurious to his health. This collection appeared at Neuchâtel, in 9 vols. 4to, or 18 vols. 8vo. and contains, besides the works already mentioned, several smaller pieces in natural history and metaphysics. They are all written in French. Towards the year 1788 he manifested alarming symptoms of a dropsey in the breast; and these became more aggravated in process of time, and occasioned a variety of sufferings which he endured with patience and ferenity, till at length he was reliev ed by death, May 20, 1793, at the age of 75 years. Public honours were rendered to his remains by his fellow citizens; and his funeral oration was pronounced by his illustrious friend and kinman, M. de Sauffure. Mem. pour servir a l'Hist. de la Vie et des ouvrages de M. Charles Bonnet; Berne 1794. Gen. Biog.

DONNET, Jacques, published, in 1726, at Amsterdam, "Histoire de la musique," the history of music and of its effects from its origin to the present time, explaining, in what its beauty consists, 4 vols. 12mo. This history was at first undertaken by the abbe Bourdelot, uncle to the editor of this work, and distinguished by his erudition. Donnet Bourdelot, brother of Bonnet, the first physician to the duchess of Burgundy, continued it after the death of his uncle, and at length arranged and digested the materials which he found among the MS. papers of his uncle and his brother. Indeed the first volume only was written by Donnet; the three last were compiled in a patriotic fury by Fren cce, a physician, in 1705, who died in 1707, in the flower of his age, having only arrived at his 33d year. He seems to have been wholly stimulated to this undertaking by the abbé Raguenet's parallel between the music of the Italians and the French; which, though written with the utmost circumspection and civility to France, M. Fren cce thought too favourable to Italy; and instead of a continuation of the history of music, has given us nothing but a violent philippic against the abbé Raguenet, for daring to draw a parallel between the music of France and Italy, and a cenuse of the most illustrious Italians of the 17th century, such as Carissimi, Luigi Reffi, Scarlatti, and Corelli; and setting up Lulli against them all, has formed his imitation of the abbé into three dialogues, in which two of the interlocutors are champions for Lulli, and only one, and that a lady, neither a deep logician, nor a powerful advocate for the Italians, is the heroine that undertakes their defence. But the poor Italians have no quar-
ter given them; not only their mimic and fingering, but even their language is confounded for its elisions, its metaphors, its similes, construction, and inverted phrases. The execution of the Italians he compares to the dexterity of the folder who was brought to Alexander, to exhibit a trick which he had acquired by infinite pains and practice, of checking a pea into a distant hole which just fitted it. When all the reward which the great conqueror bestowed upon the folder for his ufeless application of time was, to order him a peck of peas.

Indeed all the praise that is due to Bonnet for the first part of what he calls a history of mimic, is, the having collected materials towards a history of the art; but his being a musician, and equally unable to explain the theory of the ancients as the practice of the moderns: so that his work is totally devoid of taste, order, and useful information.

Bonnet, of Bonet, Theophilus, an eminent and respectable practicing physician, and voluminous writer in medicine, of Geneva, where he was born, March 5th, 1620. Following in the steps of his father and grandfather, he early attached himself to the practice of physic. After visiting several foreign academies, he was admitted doctor in medicine at Bologna, in 1643, and was soon after made physician to the duke de Longueville. Though he soon attained to high credit in his profession, and had a large share of practice, he dedicated a considerable portion of his time to reading, and to dissecting such subjects as the hospital afforded him, with a view of discovering the seats of the diseases, under which the patient had laboured; minutely observing every deviation he observed from the natural structure of the viscera, or other parts of the body, and thus opening a new road for improving the science he cultivated. He also appears to have made extracts of every thing he deemed worthy of notice, from the various works he read. His hearing from some accident becoming defective, he withdrew from practice, and employed the last ten or twelve years of his life in arranging the materials he had collected. The first fruit of his labour, which he gave to the public, in 1668, was "Pharos medicorum," 2 vols. 12mo. This was printed again, much improved and enlarged, in 1679, in 4to. under the title of "Labyrinthes medic.," &c.; &c. compiled principally from Bellonius and Septarius. In 1675, "Pro- dorum anatomia practica, five de spectabilis morborum causis," fol. the precurser of his principal work, "Sepsichremum, seu anatome practica, ex edentibus morbo denutum," was published. The work was enlarged by two folios. vol. 1679, which far exceeded the expectation raised by the prodromus. It was enlarged by nearly a third part, and republished by Manget, 2 vols. fol. 1700, and was afterwards taken by Morgagni, as the basis of his work, "De sedibus, et causis morborum," by which the sphenichremum is in a great measure superceded. "The author begins with observations on the appearances of the brain and other parts of the head; then of the contents of the thorax, abdomen, and pelvis; and lastly, of the extremities; forming an immense body of dissections, which he has illustrated by many pertinent and ingenious observations. "Courses de medicine, et de chirurgie," 2 vols. 4to. 1679. An epitome of the art of surgery, with some fictions relating to the practice of medicine, selected from the most accredited authors of the age. Medicina postero-renalica, collecettia," 2 vols. fol. 1684, shewing how largely the practitioners of the northern parts of Europe, Sweden, Denmark, Germany, Holland, and England, have contributed to the improvement of anatomy, surgery, and medicine, by extracts and accounts of the works of the principal writers of those countries. "Mercurius complauitias, seu index medicopraenicis, decimones, cautiones, observationes in singulis aedificibus, &c. infendens tutam medendi viam," fol. 1682. A most useful work, shewing under the name of every disease or affection where cases or observations may be found, and what authors have written upon them. Such an index continued to the present time, though very voluminous, would be highly useful. Bonet also published "Epitome operum Sennerti," fol. 1683, and "J. D. Turqueti de Muyern, de Arthritide," 1717, 12mo. and "Rohault tocatus phyricus, e Gallico in Latinam traditus," 1675, 8vo. He died of a dropy, March 5th, 1689. Hall, Bib. Med.

Bonnet, in a general sense. See Cap, Hat, Mitre, &c.

Bonnet, in fortification, a kind of little ravelin, without a ditch, having a parapet three feet high; anciently placed before the points of the salient angles of the places; being palisaded round; of late also used before the angles of bastions, and the points of ravelins, and faulchblayes. See Plate Fortis.

The bonnet has two faces, from ten to fifteen, or more rods long; the parapet is made of earth, from thirty to thirty-six feet thick, and from nine to twelve feet high: it is environed with a double row of palisadoes ten or twelve paces distant from each other; hath a parapet three feet high, and is like a little advanced corps du guard.

Bonnet à prêtre, or prêtre's cap, is an outwork, having at the head three salient angles, and two inwards. It differs from the double tenaille only in this, that its sides, instead of being parallel, grow narrower, or closer at the gorge, and open wider at the front; on which account it is also denominated queue d'aronde, or swallow's tail.

Bonnet, in Geography, a river of the county of Leitrim, in Ireland, which passes within four miles of Lough Clean, from which the Shannon issues, and carries boats into Lough Gilly, and thence into Sligo bay. Dr. Beaufort observes, that the day may come, when the spirit of enterprise and commerce will open itself a paffage by this channel also. Beaufort.

Bonnet, St. a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap, 25 leagues N. of Gap. The place contains 1509, and the canton 10,284 inhabitants; the territory comprehends 245,000 hectares, and 20 communes.

Bonnet le Château, St. a town of France, in the department of the Loire, and chief place of a canton, in the district of Montbrison, 4 leagues S. of Montbrison. The town contains 1566, and the canton 12,945 inhabitants. The extent of the territory includes 192¾ square miles, and 10 communes.

Bonnet le Castel, St. a town of France, in the department of the Puy de Dôme; 3 leagues E. of Brioude.

Bonnet de Broëgères, St. a town of France, in the department of the Rhône and Loire, and chief place of a canton, in the district of Villefranche, 6 leagues N. of Villefranche.

Bonnet de Charray, St. a town of France, in the department of the Isère, and chief place of a canton, in the district of St. Marcellin, 14 leagues S. W. of St. Marcellin.

Bonnet de Joux, St. a town of France, in the department of the Saône and Loire, and chief place of a canton, in the district of Charolles, 2¼ leagues E. of Charolles. The town contains 1321, and the canton 6140 inhabitants; the territory comprehends 160 kilometres, and 7 communes.

Bonnet, in Heraldry, a cap of velvet worn within a coronet.

Bonnet pepper, in Botany. See Capsicum Annuum.

Bonnet, in Sea-Language, an additional part of a sail, laced
laced at the bottom or foot of the fore-fail, try-fail, and from main-fails, of some vessels with one maff, in moderate winds. It is made like the foot of the fail for which it is intended, and has lashings in the upper part, to correspond with and fall through holes in the foot of the fail, by which it is fastened.

The words in reference to it are, *lace on the bonnet, that is, fallen to the course; shake off the bonnet, that is, take it off the course.*

**Bonneck chinitis**, in *Conchology*, is the common or trivial name applied by French collectors to the *Patella Chinitis*, in the same manner as we should call it in English the *Chinde bonnet*, or limpet shell; thus also the French *Boumet de Pologne*, for the Limnean *Buccinum fictilis*, &c.

**Bonneck chinitis**, in *Zoology*, the French name of *Sinica*, Gmel. or Chinese ape of Pocock's *synopsis, a species that inhabits the country of Bengul. See Sinica. Obs. The same animal is called *Guerea coromand*, by late French writers.

**BONNETABLE, in Geography, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Manners. The place contains 3,457, and the canton 11,551 inhabitants; the territory comprehends 105 kilometres, and 10 communes.**

**BONNETELLA, in Entomology, an European species of *Tinea, described by Linneus*, in *Pot. Suec. Fabricius and others. The wings are white, with two little silvery lines, the posterior one of which is waved.**

**BONNETIA, in Botany, in honour of Charles Bonnet of Geneva, Schreb. 915, Wilden 1350. Maria Auhlet 222. Jaff. 343. Linnce. method. Chails, *polyandra monogynia*. Nat. ord. uncertain. Jaff. Gen. Char. Cal. of one leaf deeply divided into five ovate, acute, concave segments, two larger than the others. Cor. petals five, ovate, somewhat obtuse, concave, longer than the calyx, the three superior smaller, upright; two lower larger, inclined, at a distance from each other. Stam. filaments very numerous, inserted into the receptacle, shorter than the corolla, dilated at the top. Anthers yellow, oblong, tetagonal. Poll. germ inferior small, oblong. Style incurved. Stigma hollow, the two-shaped. Icarg. capsule at the top, membranous, oblong, three-celled, three-valved, valves sharp pointed. Seeds many, small, black, oblong, involved in a coloured membrane, affixed to the three-sided receptacle.**

**Eff. Char. Cal. five-parted, two parts larger. Cor. five-petalled, three smaller upright, two larger inclining. Cor. oblong, three-celled, three-valved, many seeded. Species. B. patyfris, Lamark. Illust. tab. 454. A tree fifteen feet high, seven or eight inches in diameter; branches upright, chiefly towards the top of the trunk; leaves alternate, petiolate, ovate, entire; smooth; petioles channelled, with two small stipules at their base; flowers purple, spiket, one, two, or three together, furnished with three scaly bracteae, one larger at the base of the peduncle, the two others lateral. A native of Cayenne and Guiana.**

**BONNEVAL, Claude-Alexander, Count of; in Biography, a descendant of an ancient family of Limousin, was born in 1672, and having entered betwixt him into the army, served with distinction in Italy under Catlin and Vendome. Abandoning his country in 1706, and entering into the service of the emperor, a sentence was pronounced against him by the minister Chamillart, which subjected him to decapitation. Notwithstanding this pronouncement, he ventured to Paris, and publicly married a lady of the family of Biron. In 1716 he served against the Turks under prince Eugene, and was a major at the battle of Peter-Warradin, where he behaved with singular valour; but in 1726 he had a dispute with prince Eugene, and challenged him, for which offence he was deprived of his employment, and condemned to a year's imprisonment. Upon regaining his liberty he meditated revenge, went over into Turkey, became a military man, and was created a hafhaw of three tails, general of artillery, and at hail, master of the ordinance. In this situation he introduced European improvements among the Turks, and lived much esteem to the age of 75 years. He left a son, who succeeded him in the office. He was a man of quick parts, courage, and ability; but singular in his conduct, quarrelsome in his disposition, and addicted to fatigues. Upon changing his religion, he said, "It was only changing his night-cap for a turban." With all his eccentricities he preserved a calm temper; and said, "In all my perfections I never lost my appetite or good humour. Happy those who have philosophy in their blood!" His "True Memoirs," and his *New Romantic Memoirs,* were published in London, in 1755. Nouv. Dict. Fil.**

**BONNEVAIL, in Geography, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Chateaudun, seated on the Loire. The place contains 1,531, and the canton 12,618 inhabitants; the territory comprehends 337 1/2 kilometres, and 27 communes.**

**BONNEVILLE, a town of Savoy, the chief place of a district in the department of Leman, and before the French revolution, the capital of Turin, seated on the banks of the Arve, at the bottom of a chain of rocks, which from this place diminish into hills. The adjacent country is a rich plain, producing plenty of wine and corn, but neither populous nor well cultivated. The place contains 3,900, and the canton 9,286 inhabitants; the territory comprehends 165 kilometres, and 15 communes. N. lat. 46° 11' E. long. 6° 15'.**

**BONNEVILLE-de-Bouchoux. See Bouchoux.**

**BONNIFRES, a town of France, in the department of the Seine and Oise, and chief place of a canton in the district of Mantes; the place contains 769, and the canton 11,954 inhabitants; the territory comprehends 207 1/2 kilometres and 27 communes.**

**BONNY, a town of France, in the department of the Loiret, and chief place of a canton in the district of Gien; containing about 1,700 inhabitants; 3 leagues S.S.E. of Gien.**

**BONNY, a river of North Africa, which forms the delta of New Calabar, in the kingdom of Benin, discharging itself into the bay of Biafra. N. lat. 4° 40'. E. long. 6° 15'.**

**BONNY, in Mineralogy, a name given by our miners to a bed of ore found in many places in hills, not forming a vein, nor communicating with any other vein, nor terminating in stringers, as the true veins do; it is a bed of ore of five or six fathom deep, and two, or somewhat less than that, in thickness, in the larger part; but there are smaller, to the depth of a foot long. They have their trains of flood-flows from them, and often deceive the miners from the expectation of a rich lead vein. They differ from the squatts only in being round beds of ore, whereas these are flat. Phil. Trans. N° 69. p. 2598.**

**BONO et mulo, Writs, de; in Law, a special writ of gaol-delivery was anciently used for each particular prisoner under this title; but these being found inconvenient and oppressive, a general commission for all the prisoners has long since been established in their stead. 2 Inst. 43.**

**BONONCINI, Gio. Maria, in Biography, Modanece Accademia Filarmonica di Bologna, and father of the celebrated John and Anthony Bononcini, published in 1673; a work
work entitled "Il Musico Pratico," or the Pratical Musician, dedicated to the emperor Leopold, in thin quarto. This treatise contains many useful precepts, and examples of composition; but is neither so accurate as to be implicitly followed, nor so ample as to supply all the wants of a musical student of the present times. Page 18, he speaks of a canon, in his opera terza, for fifteen hundred and ninety-two voices, or fix hundred and forty-eight choirs; which, on account of the difficulty of finding such a number ofingers assembled together, he has reduced to twenty-two. In the historical part of this treat, his knowledge is not very profound, or reading extensive; and the authors he cites, in support of his information, give it no additional weight. The examples he has given of the life of the second, page 64, are, in many instances, erroneous, and such as can be found in the works of no good contrapuntist of the last century. The second is not only confounded with the ninth by this author, page 64, but improperly prepared and resolved.

This discord of the second seems to require one of the parts to remain stationary, till the suspended harmony is completed; but Bononcini often puts both parts in motion. In his example of counterpoint upon a plain song, page 76, there are other disallowances.

Much explanation and instruction are given for the ecclesiastical modes, but none of the keys, used in secular music, are defined or ascertained.

Bononcini, John, the celebrated opera composer, and rival of Handel, was the son of Gio. Maria Bononcini, of Bologna, the subject of the preceding article. He first arrived in England in 1720, on the establishment of our famous "Corporation of the Royal Academy of Music," under the auspices of King George I. and the principal nobility and gentry in the kingdom; for the support of which 50,000l. were subcribed. We have now before us the original deed and covenant, with the seal and sign manual of all the subscribers, who became academicians, and bound themselves and their respective executors, administrators, and assigns, to pay all such respective sums or sums as shall from time to time be demanded out of their subscription, &c. The king subscribed 1000l. and the rest, to the number of 73, in this original lift, 200l. each.

It is a curious record to be in possession of the autography of such a number of the heads of our most ancient and illustrious families thus preferred. It is not, indeed, equally important or honourable with the lift of the barons who signed the Magna Charta; but it is such a memorial of our prosperity, good-humour, patronage of a polite art, and happiness, that we would give a facsimile of each signature on a copper-plate, if we had room.

In order to render this academy as complete as possible, it was determined by the directors not only to engage a lyric poet in their service, but the best vocal performers that could be found in the several parts of Europe where there was a musical theatre, and the three most eminent composers then living who could be prevailed upon to visit this country. For this purpose Bononcini was invited from Rome, whom, he tells us himself, in the dedication of his Cantatas and Duets to George I. (Qui 92 trova, chiamato a Roma per servigio della real Academia di Musica). Attilio Ariosti, from Berlin, was likewise engaged as a composer on this occasion: and Handel, who resided at this time with the duke of Chandos, at Cannons, was not only included in the triumvirate, but commissioned to engage the singers.

During the first year of this establishment, these three composers furnished new operas alternately, till January 1721, when, for dispatch, an act of the opera of Muzio Scacchiola was assigned to each of these masters; the first act to Ariosti, probably from senility, as he was far from young when he came hither; the second act to Bononcini, at that time about 50; and the third to Handel, the youngest of the three.

As this division of the drama seemed to imply a contention and trial of skill, the public took sides, perhaps less from feeling than the spirit of party; for party whets our appetites for pleasurable as well as politics. Many of the nobility and gentry, who had been in Italy, and had witnessed the applause which Bononcini had received there as a composer, were partial to him here. While others who had visited the court of Hanover before the decease of queen Anne, and knew the favour in which Handel had found with the elector, as a great performer on the organ and harpsichord, before his compositions were much known, and afterwards had heard his productions performed in London, were unwilling to be pleased with the compositions of his principal rival. Ariosti, though a good musician, seems to have been out of the question; neither his name nor talents being equally splendid with those of the other two, by whom, and for whom, the contest continued with as great a rage as between the houses of York and Lancaster, till the year 1727, when Bononcini, after the run of the last and best opera which he had composed in England, "Alcynax," quitted the contest with Handel, and ceased to write for the stage. But the feuds among the friends of these great musicians, which Swift's epigram had rendered so ridiculous, did not end here, but continued as long as Bononcini remained in this country.

Here, as his biographer, it seems our duty to give his real character as a composer. He was seldom heard on the violoncello in this country, though as a performer on that instrument he was extremely admired in Italy; and his melody was, perhaps, more polished and vocal, though not so new as that of his powerful Saxon rival. Having been born and brought up in Italy, where singing was so highly cultivated, he was reported by all his countrymen to sing in a most exquisite taste. His recitative too, both in writing and utterance, was universally allowed to be the best of the time, and in the true genius of the Italian language; but as a correct, powerful, and inventive composer, he was an infant compared with Handel.

Of all the works which this celebrated composer published in England, his book of "Cantate E Duetti," dedicated to his
his majesty George I. in 1721, the year after his arrival here, seems the belt. In 1722, his "Diversimenti da Camera, tradotti (transfigured or accommodated) pel Cembalo da quelli compositi pel Violino e Flauto," were published by Lulmeid, and sold at his lodgings in Suffolk-street. In these we meet with pleasuring and mazurka passages, but they are too inferior in force, contrivance, and invention, to the lefsons of Handel, that even his admirers, on a comparative view, must have regarded them as frivolous and trivial. The adagioz are the bell movements in them, and have notes of taste and passages of expression, which must have been then new to English ears. Bononcini, however, like other composors of his time, is very sparing of his passages, and indulges idlenefs and want of invention by frequent repetita, or repetitions, which Handel seems always to avoid more than any composor of this period, except the Scarlatti's, father and Ion. In several of these lefsons the subject is heard in one part or other throughout a whole movement; as in the minutes, page 35, the first bar is perpetual.

His funeral anthem for the duke of Marlborough, was fet and performed the same year, 1722. The short symphony, and whose first movement are grand, and of a melancholy caf. The second movement has not much to recommend it. The third is more languid, than passionate or pathetic. The fourth is plaintive, but was not new at the time it was written. The fifth and fift movement has musical merit, but none of true feeling, or genius; nor "heart-rendering sighs," or fuch exclamations of sorrow and affliction as would naturally be expected from a man of great abilities, who either felt the words or the fobs of his patron.

Bononcini was a celebrated and voluminous composor long before he arrived in England: his eightieth work, confiding of "Duetti da Camera," was dedicated to the emperor Leopold, and published at Bologna in 1691. The seven operas he composed during his residence in England, made but a fmall part of his dramatic productions. He produced two operas at Rome in 1694; after this he went to Vienna, where he composod many operas and oratories for the imperial court and chapel. In 1720, he was again in high reputation as a dramatic composor at Rome, whence he was invited to London by the directors of the Royal Academy of Music. In 1722, he published "Twelve Sonatas for two Violins and a Bafe." It was about this time that he was accused of arrogating to himself a madrigal composed by Lotti of Venice, and published in that city in 1705, in a work entitled "Due lirii, o Madrigali del pit Vocif," dedicated to the emperor Joseph. The title of this madrigal is "La vita caduca," and has for initial line "In mia fiepe embroja." We are in poftition in the book in which this composition was printed, and, upon examination, are extremely astonished that Bononcini would rilk the great reputation of which he was already in poftition, for a production which could increase it little. The counterfeit of this madrigal is certainly correct, but it is dry, and all the subjects of fugue are fuch as had been used by thofe hundreds before Lotti was born. There are many madrigals by much older masters, particularly Luca Marenzio, Stradella, and the elder Scarlatti, that are learned and pleafing in modilation, and more familiar and agreeable in the traits of melody that are used as subjects of imitation. Indeed, Bononcini's plagiarism was as work as wicked. We urb to doubt the truth of the charge, from an idea that his reputation was fo well effablifhed, and his genius fo fertile, that he had not the leaft occasion to have recourse to fuch illicit means of extending it. The crime of theft is very much aggravated when the theft is not impelled to it by want. Rich men and milers have, however, been often detected in illegal appropriation. Yet upon a careful and critical examination of the works of John Bononcini, we think his wealth did not confift in rich and deep mines of fcience, nor were his resources in learned and elaborate composition, either in the ecclesialical or madrigal style, very great. His performance on the violoncello, his cantatas, and his operas, had been admired in every part of Europe; but not content with partial fame, he aimed at universality. In his anthem for the funeral of the duke of Marlborough, he attempted to rival Handel in his grand church style; and finding in how much veneration well written madrigals were held at the Academy of Ancient Music in London, where Handel at this time was regardod as a modern, and an innovator, he was tempted to risk the reputation he had fairly acquired, by trying to augment it in an ill-faf manner. Tradition had filled our minds with ideas of his abilities, which the examination of his works has diminished; while a brief fentiny into the productions of Handel has greatly augmented our veneration for that composor. We have now before us, in a printed pamphlet, all the letters that paffed between the secretary of the Academy of Ancient Music and fignor Ant. Lotti on this occasion, with fuch testimonies and certificates, from the most respectable professors at Venice and Vienna, in proof of the madrigal in dispute, having been composod by that master and not by Bononcini, that not the leaft doubt remains of the fact.

Soon after the funeral of the duke of Marlborough, the countefs of Godolphin, who, upon the deceaf of her father, became duchefs of Marlborough, as fettled in his patent of creation, received Bononcini into her houfe, in the Stable-yard, St. James's, and fetted on him a penfion of 500l. a year. Here he lived in cafe and affluence, enjoying as an artifl the "istum cum dignitate in its full extent; the duchefs having concerts twice a week, in which no other music was performed to the first people in the kingdom than the compositions of her favourite master, executed by the principal fingers of the opera. It is fuppofed that he gained a 1000l., by the book of cantatas which he published by a two-guinea subscription; many of the nobility subscribing for five or ten copies; the duke and duchefs of Queenbury for twenty-five books each, and the countefs of Sunderland alone for fifty. After the difpute concerning this madrigal, his importance and reputation diminished considerably; and about the year 1735, he quitted the kingdom. After which he refided at Paris for several years, where he composod masses and motets for the chapel royal. At the conclusion of the peace of Aix la Chapelle in 1748, he was invited to Vienna by the emperor of Germany to compose the music for that occasion, and, is faid to have been prefented with eight hundred ducats for his trouble. After the celebration of the peace was over, quitting Vienna in company with Monticelli, he fet off in the fame post-chaise with this celebrated finger for Venice, where they were both engaged, Bononcini as composor, and Monticelli as first man, in the operas for the ensuing Carnival in that city. Here we lost fight of this renowned composor, who if we fuppofe him to have been no more than thirty years of age in 1691, when his eightieth work was printed at Bologna, and dedicated to the emperor Leopold, he must at this time have attained his eighty-seventh year; which will give weight to the general opinion, that his life was extended to near a century!
BON

Italy, with but to found the town follows at the particular and It over, Ferrara, when but town few and dufted earth lerio, Ptolemy carried terting. They cyhndric, Not. Auguftus. carries gathered the maffers or some brothers in England, logna, gina all records were gathered in letters. Bologna, or Bologna, Italy, requires renewing of the time, it was performed at Venice, 1698; Bologna, 1703; Ferrara, and Padua, 1707; Bologna again, 1709; Udine, 1715; and a third time at Bologna, 1719; and seems to have been the opera that was performed in England, during 1706, fifteen times: 1707, twenty; 1708, ten; and 1709, eighteen; in all sixty-four times!

BONONCINI, in Ancient Geography, a town of Gallia Cifpadana, called Fellina, at the time when the Etruscans were masters of the northern part of Italy, and then their capital; supposing by some to have been founded by an Etruscan prince, denominatad Fellinus. But when these first poftellers were driven away by the Boans, it acquired the name of Bononia. In the year of Rome 506, the Romans conducted a colony to this place, with a view of fortifying this side of the country. It afterwards became a municipal city, and owed much of its magnificence to Augustus. See Bologna.—Alfo, a town of Upper Pannonia, placed by Ptolemy at the Drave.—Alfo, a town of Daucia Ripensis. Not. Imp.—Alfo, a town of Upper Moefia, in the route from Viminicum to Nicomedea, between Dorticon and Ratetia. It. Antonin.—Alfo, a town of Lower Pannonia, in the route along the Danube, between Cufi and Cucci, 19 miles from Sirmium, according to Annianus Marcellinus.

BONONIAN STONE, a small, grey, soft, glofy, fibrous, ponderous, sulphureous stone, about the bigness of a large walnut, or even of an orange; when broken, having a kind of cryfial, or fparry talce within; found in the neighbourhood of Bologna, or Bononia, in Italy; and, when duly prepared, making a species of phosphorus. It is of no certain figure; but it is sometimes round, sometimes oblong and cylindric, and sometimes denticular, which latter kind is said to be the most shining and transparent. Its colours are various; some being ash-coloured, others of a sky-blue, some of a ferruginous colour, others yellow, others greyfih white, and some almost perfectly white. The belf for ufe arefaid to be the fky-coloured and the white. This stone is found in several parts of Italy, but especially in the district of Bologna, towards the Apennine mountains, and on mount Palerno, or Paterno, about five Italian miles from Bologna. They are fomt commonly found after heavy rains, among the earth washed off from the neighbouring mountains. In this cafe the feveral masses of it appear, when the earth is washed away, as bright as burnifhed silver, or with the glittering of talle refembling the glofs of a looking-glass. This ftone is the ponderous fpar, or combination of vitrific acid with ponderous earth. See Spar.

A chemifl, whose name was Vincenzo Cafelarolo, having gathered fome pieces in a river at the foot of mount Paterno, carried them home, in hopes by the fire to draw filver out of them; but instead of what he expected, found that admirable phenomenon they exhibit, which consists in this, that having been exposed to the light, they retain it, and glint in the dark. This difcovery was made about the year 1630.

The property of this ftone is, that though it has no lucid appearance in the dark, until it undergoes a particular calculation, it becomes capable, by previous preparation, of imbuing, when exposed for a few minutes to the light of day, or even to the flame of a candle, a fuch a quantity of light, that it afterwards shines in the dark for an interval from eight to fifteen minutes, like a glowing coal, but without any fenfible heat. The light it emits is fufficient to read by, if the letters be placed near it. It does not retain its light long, but requires often renewing; and when well prepared, its virtue will laft five or fix years, but feldom longer. The method of ufing it to the greatest advantage, is to remain for some time in a dark room, and to introduce the calcined fublifance immediately after its being exposed to the light.

M. Homberg is paid to be the first perfon who taught us the true manner of preparing and calcining the Bononian ftone, having made a journey to Italy on purpose to learn it. Though others allege, that the true art of preparing and calcining the ftone is lost; there having been but one, an ecclefiafitl, who had the true fecret, and who is fince dead, without communicating it to any perfon. See Phil. Trans. N° 21.

M. Homberg, on his return from his travels in Italy, brought with him a great number of thofe ftones, and calcined 200 of them in fo many different ways, that he at laft found out the fecret. His method was as follows: He firft scraped the ftone all over, till it appeared like tale; then, having fhook it thoroughly in brandy, and inclosed it in a paife or crufh made of other ftones of the fame kind pulverized, he calcined it in the fire, or a fmall furnace. After this operation, he took off all the powder of the crufh in which the ftone was incufed. Both the powder and the ftone, when brought into the dark from the open air, make a luminous appearance; and the former, if kept in a strong and well-stopped phial, when expofed to the air, imbibles the light, and if sprinkled on pictures and letters, illuminates them in the dark. In preparing the paife, the ftone muft be pulverized in a brafs mortar. This circumstance is mentioned by Lemery, who, in his "Cour de Chymie," describes at large the whole procfs of preparing this ftone, which he acknowledges to have learnt from Homberg himfelf.

The whole art of preparing this ftone, fo as to make it shine in the dark, is defcribed at large in Hook's "Philofophical Collections," by sir Marc Antonio Celio; and in a book of the fame author, published at Rome in 1680, on this fubject: and the fublifance has hence been called "Il Fosforo de Marc Anton. Celio."
The following has been flated as an approved method of calcining this stone. Make a cylindrical furnace of iron or copper plates, 7 inches in diameter, and as many in height. Line the inside of it with a strong forte, fo that the infide may be 6 inches wide in the clear hollows; at the top of this make four nofhores, 6 inches deep, and 14 inch wide; to this annex a cylindrical part of the fame diameter, but a little higher; and at the bottom make two air-holes, or air-holes, big enough to admit the hand. Line this, like the other, with good fute, and give it a bottom of late, that it may more powerfully reftect the heat; and line the cover for the top with late. Into this furnace introduce an iron-wire grate near the bottom, for fufhaining the coals, and fo as to admit of free accefs of air. On this grate lay fome pieces of lighted charcoal, and over thofe fome pieces not lighted, all bruifhed to the size of about a walnut. Some of the ftones muft be powdered, and thofe which are to be calcined muft be dipped in strong aqua vitae, and while wet rolled in the powder, or the powder itfelf may be made up into thin cakes with mucilage of gum tragacanth. The ftones, thus covered, or the cakes, muft be laid upon the bed of charcoal clofe to one another, and another bed of fmal pieces of charcoal laid over them to the top of the furnace; the cover of the furnace is then to be put on, and the fire lighted. When the charcoal is entirely consumed, and the whole is cold, take out the ftones, and, feparating the crufh from them, wrap them up in filk or cotton, and keep them clofe in a box for ufe. Preferve the crufh taken off the ftones;
for this shines as well as the stone; and being pulverized, may be rubbed over any surface for emitting light, the surface being first dabbed over with the white of an egg in order to make it adhere; and this will shine like the stone. This kind of furnace is not absolutely necessary to the operation; but it is convenient to know the quantity of charcoal requisite for giving the shining quality to the stone; since an excess of heat destroys it, and too small a degree is not sufficient to produce it. The greatest degree of phosphoreous fumes seems to depend on a due application of the heat. An extreme degree of heat fuses this stone. For other methods of preparing this kind of phosphorus, see PHOSPHORUS. See also LIGHT.

This property of affording a phosphorus by calcination, is common to the other gypseous, when pure from metallic or other heterogeneous mixtures; the artificial gypseums succeed equally with the natural, and it is found to belong to a variety of other substances. M. Margraf observes, that all sublimes which have this property, contain a vitriolic acid, united to an alkaline or calcareous earth.

M. Elpigi observes, that one Zangarini had a method of making figures and pictures of the Bononiac stone, which would shine variably in the dark; but he adds, the perfons died without discovering his secret. See Phil. Trans. No. 134.

BONONIENSIS, in Ornithology, the specific name of the greater lapwing, tringa boenusis of Gmelin, and cannot boenusis major of Brillon. The legs of this kind are ochraceous; head and upper part of the neck chestnut; body above black, beneath white; throat and breast spotted with ferruginous. Gmel. Obs. This is larger than the common lapwing (tringa vanellus); the bill is yellowish and black at the tip.

BONONIENSIS, passerula boenusis of Brillon. This is fringilla brevicauda of Gmelin, or short-tailed sparrow.

BONUSAI, or BONONIACI, in Ecclesiastical History, an ancient branch of ADOPHONI, in the fourth century, denominated from their leader Bononius, a bishop of Malacton.

Gen. Char. Col. tubular, five-toothed. Cor. monopetalous, almost labiate; tube longer than the calyx; border with fine emarginate divisions; the two superior long and straight, the three inferior pendunt. Stam. five, incising. PiJ, germ superior; style capillary; stigma bifid; Pericarp, capsule ovate, three fided; cells three; seeds three.

Species, B. gennimflora, an annual plant; leaves alternate, smooth, lanceolate, toothed; flowers violet, large, axillary, growing in pairs. A native of New Spain.

BONPOURCEL, a denomination given to a coarse kind of bread used in Welfphalia. See BREAD.

BONS-HUMIES, or BON-HUMIES, in Ecclesiastical History, a fort of hermits of St. Augustin, founded by F. de Paula. They were brought over into England in 1230. by Edmund, earl of Cornwall, and settled at Athurig, in Bucks, beside which they had only one house more at Edington in Wiltshire. They followed the rule of St. Austin, and wore a blue habit.

The name is said to have arisen from Louis XI. of France, who used to call F. de Paula, prior of the order, le bon honnaire. Till then they had been called the Mininis, or order of Grammont. See ALBIGENSES.

BONSDORFII, in Entomology, a species of Curculio, of an oblong form. Colour white, with a black band and spots; faunt ticated and brown. Bonfd. Cure. Suec. Inhabits Sweden, and is half the size of curculio sylvaticus.

BONTAIN, in Geography, a kingdom of the island of Celebes, situate on the south coast, and on the east shore of the bay of Boni. It is bounded on the west by the river Tino, which divides it from the kingdom of Tourette; on the north, by the mountains which bear its own name; on the east, by the river Kakekongang; and on the south by the sea. It was anciently enclosed among the dependent allies of Maccafer, and governed by their kings; but it has been twice conquered by the arms of the Dutch East India company and their allies, and was ceded to them, in property, by the treaty of Boni. The country is pleasant, and fertile in rice. It has a large bay, where ships may lie in perfect safety during both the monsoons. The foundings are good and regular, and the bottom soft mud; nor is there any danger in coming in, except from a ridge of rocks, which are above water, and are a good mark for anchoring. The highest land in sight is called "Bontain-hill," S. lat. 5° 30'; and when a ship is in the offing, at the distance of 2 or 3 miles from the land, she should bring this hill N. or N.W., and then run in with it and anchor. In this bay there are several small towns; that which is called "Bontai," lies in the N.E. part of it (S. lat. 5° 10'. E. long. 17° 28'); and here is a small palisaded fort, on which are mounted eight guns, that carry a ball of about eight pounds weight; it is just sufficient to keep the country people in subjection, and is intended for no other purpose; it lies on the south side of a small river, and there is water for a ship to come close to it. Weed and water are to be procured here in great plenty; likewise plenty of fresh provisions, at a reasonable rate: the beef is excellent, but it would not be easy to procure enough of it for a squadron. Rice may be had in any quantity, and also fowls and fruit; in the woods there are herds of wild hogs, which may be purchased at a low price, as the natives, who are Mahometans, never eat them; and fish may be caught with the finest. The tides are very irregular; it is commonly but once high and once low water in 24 hours, and there is seldom a difference of fix feet between them. The inhabitants of Bontain, and those of Boele-Comba and Bern, are the best-humoured, most peaceful, and most tractable of all the subjects belonging to the Dutch company, in the whole island of Celebes.

BONTENII, Angeli, in Biography, a native of Perugia, and author of the first history of music in the Italian language with which we are acquainted. He was an able professor, of considerable learning, who flourished about the middle of the 15th century. His work, which has for title "Historia Musica di Gio. And. Angelini Bontenii," was published at Perugia, in small folio, 1495. It is become somewhat scarce, which enhances its value with collectors of books; and having been long unable to procure a copy, we imagined when once was found, from Brodard's character of the work, that we were in possession of a greater treasure than on examination it proved to be. For with great parade of his learning, science, and acquaintance with the Greek theorists, that are come down to us, he leaves us in utter darkness concerning the practice of ancient music as ever; and, to say the truth, he has furnished us with but little information concerning the modern of his own time, with which, however, as a contrapunctist, he seems to have been perfectly well acquainted. Indeed, by the frequent use he makes of scientific terms, his book, when casually opened, has more the appearance of a dry mathematical treatise, than the history of an elegant art.

The most curious and interesting part of his work, is the account which he gives of the discipline of the college of singers in the service of the pontifical chapel, and of the great masters who then flourished at Rome, who had disfrunished
guished themselves in writing "Alla Palestrina" for the church; leucar music was then but little cultivated, and less respected there, till operas and oratorios had made some progress in polishing melody, and in the just accentuation and explication of words.

Gen. Char. Pet. calyx one-leaved, five-parted; segments obtuse, erect, permanent. Cor. one-petalled, fogenic; tube long, erect; border gaping; upper lip erect, rounded near the end, margined; lower lateral, A of the size of the fomentum. Stam. filaments fuscate, bunting to the upper lip, the length of the corolla; anthers fimple. Pet. germ ovate; style fimple; stigma bifid, obtuse. Pericarp, drupe ovate, with an oblique apex. Seed, nut oval, one-celled, germinating.

Species, B. dapphinx, Barbadoes wild olive. (La Maree Illust. Tab. 516.) "Leaves alternate; peduncles one-flowered." Linn. A shrub four or five feet high; leaves rather fluff, lanceolate, smooth, green on both sides, lower ones serrate, upper ones entire. Flowers yellowish, with a line of dusky purple across the lower lip; axillary single, or in pairs; tube and lower lip hairy. It was cultivated by Mr. Bentick in 1696, and flowered with Dr. Sherard in June 1725.

Propagation and Culture. It is cultivated in Barbadoes for making hedges, and may be raised in England from seeds from a hot-bed early in the spring. It must afterwards be transplanted into a small pot filled with light earth, and plunged into a moderate tanker's bark hot-bed, with a large allowance of air and water in hot weather, but should always remain in the fove. It may also be propagated by cuttings in the summer. Being evergreen, and growing in a pyramidal form, it makes a pretty variety in the fove. Bontia, (Brown Jamaica). See Aviceena geminata.

BONTIA, (Pet.) See Epidendrum coronatum.

BONTIA, in Conchology, a species of Helix, of which several varieties are descried by Cemmimt. This shell is somewhat conic, ventricose, perforated, and pelliculc, with the tip black; on the first whorl three yellowish bands; aperture ovate. Helix bontia is a native of Bengal; the shell is extremely fragile.

BONTIUS, JAMES, in Biography, a native of Leyden, was educated in philosophy and medicine, under his father Gerard; and being sent to the East Indies, practised physic at Batavia about the middle of the seventeenth century. On his return to Europe he wrote several valuable works on the drugs and practice of medicine of India. These are, "De conservanda valetudine, ac dieta fani in India observandis;" "Methodus medendi, qua aoptaret in India orientali uti;" "Obervationes selectae ex diffinitione cadaverum ac autopatia decrepitae." He also published curious observations relating to the botany and natural history of those regions, more especially the vegetables used in medicine and diet in his work entitled "De Medicina Tardorun," in 1623, and afterwards, with Alpinus's work "De Medicina Egyptianur," 171. In 1718. He also published "Hiftoria Nat. et Med. India orientalis," fol. in 1638. His brother Regnier was many years professor of medicine at Leyden, and rector of the university. He died in 1623. Haller. Bibl. Med. Pract. et Botan. Vol. IV.

BONTORY, in Geography, a town of Poland, in the palatinate of Bracaw, 20 miles east of Bracaw.

BONVINCI, ALESSANDRO, called "Le Moreto," in Biography, an eminent painter of history and portrait, was born at Rovato in 1574, and studied for some years under Titian; but he was enamoured with the designs of Raphael, which he accidentally saw; and devoting himself to the illustrative study of these master-pieces of art and genius, he became an exceeding good painter. His works are eagerly bought, and much admired for the tendernees of the penelings, the correctness and spirited explication of the figures, the neatness of the finishing, and the rich variety of the draperies, consisting of velvets, damasks, or satins, copied after nature, and wonderfully imitated. He was equally excellent in portrait, and placed by some critics in competition with Titian. He died in 1664. Piltgton.

BONUS HENRICUS, in Botany, (Baub. &c.) See Cheirymphidium.

BONZES, or BONZUS, a name given to the priests and religious of China, Japan, and Tonquin. This is the appellation under which the priests, who are attached to the worship of Foo (see Fo), are generally known among Europeans. They are called "Talahpiets" by the Siamese, "Las" by the Tartars, "Ho-shang" in China, and "Bonzes" in Japan. They generally live in a fort of community, in places apart, or configned wholly to them. The island Pout-oa, near Chufan, is a famous feat of bonzes, being wholly inhabited by them, to the number of 3000, all of the sect of Ho-shang, or unmarried bonzes.

They live a kind of Pythagorean life, and have not less than four hundred pagodas, or temples, in this little island. They have also females, called bonzesses, a fort of nuns, who dedicate themselves to the worship and service of some temples or idols. They are obliged to abate from all converse with men, and on that account are cloistered in large monasteries, like those of the Romish and Greek church. For incontinency these bonzes are condemned by the mandarins to a kind of pillory called Rauhby, which fee.

These bonzes, or Chinese priests of Foo, worship him under the forms of several animals, through which they pretend that he had transmigratate before he was defined; and ingrudging the worship of this imaginary deity to themselves, in the Chinese temples, they support and propagate it, with a view to their own personal emolument and influence, by the most unwarrantable impostures. They admit, however, the distinction between good and evil; and they declare, that, after death, rewards will be bestowed on the good, and punishments inflicted on the wicked, in places destined for the souls of each. They teach, that the god Foo appeared on earth for the purpose of saving mankind, and of restoring to the paths of salvation those who have sinned; that it is by them their sins are expiated; and that he alone can procure for them a happy regeneration in a future life. They enjoy the first observance of five precepts; of which the first forbids the killing of any living creature, of whatever nature it may be; the second, the taking away of the goods of another; the third forbids men to pollute themselves by uncarnal; the fourth, to lye; and the fifth to drink wine. They, above all, recommend the practice of certain acts of mercy; such as, treating their bonzes well, building monasteries and temples for them, and supplying them with every thing necessary for their maintenance, as the most effectual means of participating the benefit of their prayers, mortifications, penances, and other meritorious actions, towards the atonement of their own sins, and for obtaining a happy transmigration in another life. On the other hand, they terrify those who withhold their benefactions from them with menace, accusing them that they...
shall hereafter revive in the form of dogs, rats, serpents, horses, and mules; and that they shall be for ever exposed to the most degrading and wretched transmigrations. These measures seldom fail of making a deep impression on the minds of the credulous vulgar, insomuch that they often persuade them to burn, at the funerals of their deceased relatives, paper gilt, or washed with silver, silk, cloth, and other garments, which, they pretend, will be converted into substantial gold and silver, and superb vestments, for the use of their parents and friends. Le Compte relates a story of an old man, who was led to believe, by the representations of these bonzes, that his soul should pass into the body of one of the emperor's post-horses. The poor man was so deluded, that he could neither eat nor sleep, and his grief was such as to threaten the speedy termination of his life. He learned, however, that the souls of the Christians were exempted from these dreadful metamorphoses; upon which, he applied to one of the Jesuits for Christian baptism, affuring him, that he would rather be of that, or any religion, than transmigrate into a post-horse. The Jesuit complied with his request, and, to satisfy the bonzes more effectually acquainted with all the arts of hypocrisy and deceit; and destructively practise them as occasions occur. They addict themselves to rigorous fasting, frequent watchings, and long prayers before the altar of Fo. When they cannot obtain gifts by cunning and address, they endeavour to procure them by exciting compassion, and by submitting to the severest penances, and practising the most rigorous austerities. With this view they often appear in public places, as frightful spectacles of mortification. They often drag along the streets heavy chains fastened round their necks, arms, and legs: they beat their heads against the stones and polls, and mangle their bodies, so that they are smeared with blood; they carry burning coals upon the tops of their naked heads; and some of them are carried about in a kind of sedan, the inside of which is filled full of nails and spikes, so that they cannot sit without wounding themselves; and these nails they sell to the populace for a few pence, as amulets and preservatives against all harm, and as efficacious means of bringing down blessings on the purchaser and his family. By pretending to know the present state of the dead, and the future condition of the living, they contrive to extort money from the surviving friends, in order to procure for the deceased a speedy release and passage into a better state. Many other instances of their knavery are related by Du Halde, Le Coquart, and other writers. We are informed, that these are so atrocious in their nature, that the relation of them cannot be read without horror; and we are led to hope, that they are recited by the Jesuit missionaries, to whom the bonzes have been great enemies, and against whom they have excited various persecutions, with some exaggeration.

We read of their privately seizing men and women, and hurrying them away in a close sedan, where nothing is to be seen but the tops of their heads, and their eyes moving in a terrifying manner, to the next river or canal, and drowning them without mercy, before crowds of spectators, who are harangued by one of the fraternity into a firm belief that the persons so treated had earnestly requested to be thus dispatched out of the world, in order to obtain immortality in a future state. With all the external appearances of fanaticism and authority, these bonzes unite voluptuous manners and secret profissg, of which various instances are recited. Notwithstanding the abomination which induces the vulgar to support the popular superstition of the country, the condition and character of a bonze are generally depicted in China. Men and women of every rank and station, imbodiments from the drags of the people. Thoie of Pegu, however, are said to be generally gentlemen of the highest extraction. See Pegu. To recruit and perpetuate their sect, they purchase young children, whom they betimes initiate in all their mysteries, and whom they instruct in every trick and deception which may render their profession profitable: these afterwards succeed them, and transmit their arts to other young bonzes, who are educated in the same manner. They are, in general, very ignorant, and unable to give an exact account even of the true doctrine of their sect. Although they have no regular hierarchy, they acknowledge superiors, and when they call "ta-ho-fang," or grand bonzes. This rank fecures to those who have attained it particular distinction, and the first place in all religious assemblies at which they may be present. There are bonzes of all conditions; some defined only for collecting, others; better filled in the art of speaking, and who have acquired some knowledge of the Chinese literature, are commissioned to visit the literati, and to intimate themselves into the houses of the great; old men, rendered venerable by age, and by a grave deportment, are employed to exercise their talents among the female sex; these reside in all their assemblies, which, though not common, are held, however, in several provinces. These religious clubs are very lucrative to the bonzes. One of these priests enters the chapel, where the female devotees are assembled, and sings some anthems to the god Fo. At length, after having for some time repeated "Omito FoO," (Omito being the name of another deity more ancient than Fo, and worshipped by the Japanese under the name of Amida, which see), and after being intoned with the tinkling noise of several small kettles, upon which they heat, they place themselves at table, and the noisy devotion terminates with mirth and a good repast. On days of greater solemnity, the bonzes adorn their places of worship with fearful idols, and numerous paintings, exhibiting under various forms the different punishments inflicted on the wicked in hell. The prayers and feasting continue seven days, during which their chief business is to prepare and consecrate treasures for the other world. In every province of China there are temples, to which numerous votaries repair; some of them making pilgrimages thither from very remote places. The pilgrims climb these sacred mountains with great difficulty, and are sometimes dragged up on their bented knees. These, whole age or immunities, or urgent business, will not allow of their joining these devout caravans, commission some of their friends to bring them a large leaf, filled with characters, and stamped by the bonzes in a particular corner. The centre of this leaf is occupied by the image of the god Fo. On the weirdments of the god, and around his figure, are traced out a multitude of circles, intended for the following purpase.—The devotees of the god, whether male or female, wearing hanging from their necks, or around their arms, a kind of chaplet, composed of 100 beads of moderate size, divided by three which are much larger; and a bead, still bigger, in form of a small gourd, ornaments the top of the chaplet. These beads they roll between their fingers, pronouncing the mysterious words "Omi-to Fo" and each of these invocations is accompanied by a genuine. When they have completed the number of 100, equal to that of the beads, they mark with a red stroke one of the circles which surround the figure of the god Fo, on the leaf. This leaf becomes the register of all the prayers which they have repeated in the course of their lives. To verify its authenticity, the bonzes are, from time to time, invited to their houses, where they must attest the number of circles marked with red strokes, and imprint their seals on the leaf. When any of them dies, this valuable memorial is carried at the funeral with the greatest solemnity, and deposited in a small box closely sealed and fastened: they call it "luo-in," or a passport for the other world; and it cools
BOO

Ornithology, has India, their monasteries, denotes 120 town farid from small flatte the variety of St. Cotton, the old and a new league.

Alfo, liaif ancient by this which fiantina, and coarfe p. Catefby's Mary, the worfhip and fanctified. It is about this counterfeiting is been calculated, and againll the ornithology, is calculated, as they pretend, to procure followers, and a number of partifians, fufficient to fecound their efforts, when European troops and fleets shall be ready to attack them; and sometimes they allege, that the missionaries perfole people to embrace their doctrine merely by the aid of forcery, and that they gain converts, and fix their attachment by lavishing gold and flour among them, of which they have great abundance, because they poiffe the fecret of imitating and counterfeiting these precious metals. By fuch and fimilar representations, they have checked the zeal, and counterfefted the efforts of Christian missionaries. Le Compte, State of China. Du Halde's China, vol. i. Groffiere's China, vol. ii.

It has been observed (see Embaffy to China, vol. ii. p. 100.), that the likeness is fo frong between the apparent worship of many of the priests of 9o, and that which is exhibited in churches of the Roman faith, that a Chinefe, conveyed into one of the latter, might imagine the votaries he faw were then adoring the deities of his own country. On the altar of a Chinefe temple, behind a fercen, is frequently a repreffentation which might serve for that of the Virgin Mary, in the perfon of "Shin-moo," or the facred mother, fitting in an alcove with a child in her arms, and rays procceding from a circle, which are called a glory, round her head, with tapers burning confantly before her. The long clothe gowns of the Ho-hangs, or priests of 9o, bound with cords round the waist, would about equally fuit the frians of the order of St. Francis. The former live, like the latter, in a state of celibacy, refe he together in monaftries, and impofe occasionally upon themselves voluntary penance and rigorous abifline.

BOO-HIADJAR, in Geography. See AGAR.

Boo-jemab, a river of Africa, in the province of Confantina, which runs along the western fide of the marth which separates betwixt Bofa and the ancient Hfippo. Over this river is a bridge of Roman bricke.

Boo-Blanter, a town of Africa, in the kingdom of Tunis, laid by Shaw (Trav. p. 79.) to be built on the ruins of the ancient Utica, which fe.

BOBBERAK, a river of Africa, in the kingdom of Algiers, formed by the junction of the Nilab and Bagdourah. Its mouth, which is made up of a number of branches, is the eaftern boundary of the province of Tiferit.

BOOBY, a word of uncertain etymology, derived by Skinner from the Spanifh lubo, foolish; but deduced by Junius from beadorb, an old Scottifh word for a coward or contemptible fellow; denotes a dull, heavy, stupid perfon.

Booby island, in Geography, a small ifland in the Weft Indies, lying directly oppofite to Mosquito bay, at the S.E. extremity of the ifland of St. Christopher's, and more than half a league from it, off the north end of Nevis ifland. — Also, a small ifland, fuppofed to be one of the iflands called Prince of Wales's iflands, extending from thence and Wales's ifland, as far as New Guinea.

Booby, in Ornithology, the name of pelecanus fufus in Catefby's Natural History of Carolina. The great booby of Catefby is a variety of pelecanus bollanis. Brown booby of Latham, pelecanus afer; leffer booby, pelecanus parvus; spotted booby, pelecanus maculatus.

BOODGE-BOODGE, or BOOGE-BOOGE, in Geography, a town of Hindoftan, the prefent capital of the territory of Cutch, and refidence of its rajah. It is alfo called Booz, and placed in a map, to which Mr. Rennell refers, about 34 geographical miles to the E. or E.S.E. of the eaftern branch of the Indus: 120 miles S.E. of Tatta, and about 200 W. of Ahmedabad.

BOODH, Boudhba, Buddha, or Buddha, in Mythology, a deity very anciently and very generally worshipped in India. The name of this deity is variously exprefled by different writers. In the Pali language, and among the Cingalefe, his common name is Boudhba. Mr. Chambers, in the Aflatic Researches, writes Buddou; and Paulinus (Muf. Borg.), Buddha; and from these two appellations we may eafily deduce the Buddy or Buttta of Beaufofre and Bochart, the Bod of the Arabians, Bouda of Edrif, Boudo of Clemens Alexandrinus, and Bouuth of M. Gentil. The name is faid to be an appellation, synonymous with fage or philofopher, and expreffive of wisdom. By Buddha, says the learned Bryant, (Anal. Ane. Mythol. vol. iii. p. 573.) we are certainiy to understand the idolatrous fymbol, called by some nations Buddo; the fame as Argus and Theban. In the mythology transmitted concerning it we may fee a reference both to the machine itself, and to the perfon preferred in it. In consequence of which we find this perfon alfo fyled Bod, Budhu, and Buddo; and in the west Butus, Battus, and Bezotus. He was faid by the Indians not to have been born in the ordinary way; but to have come to light indirectly through the fide of his mother. By Clemens of Alexandria, he is called Bonta; and in the iftory of this perfon, however varied, we may perceive a relation to the Arkite deity of the fie, called Pofeifdon; alfo to' Arcalus and Dionifus; fyled Beotus and Thermisus. Different learned men have fuppofed Bouddha to have been the fame with Noah, Mofes, or Siphoos the 39th king of Egypt; and Sir William Jones fuppozed Boudhba to have been the fame with Sefac or Seftoltris, king of Egypt, who by conquest fpread a new fystem of religion and philofophy from the Nile to the Ganges, about 1000 years before Chrifi. In order to reconcile fome differences of opinion among the Hindoos, with regard to the time of Buddha's appearance, this learned writer agrees with Giorgi in fuppoeding, that they have confounded two Buddha's; the younger of whom eftablifhed the new religion, which gave great offence to the brahins in India, and was introduced into China in the firft century of our aera; whereas the more ancient Boudhba preceded him by many centuries, and is referred by Sir W. Jones, after a variety of computations, to the year 1029 before Chrifi.

For want of adverting to this circumstance, he confounded the latter Buddha with the Woden of the Goths. Mr. Chambers alfo remarked, that Pood or Poden, which is the Sinnefe mode of pronouncing the Boodh of the Indians and Birmans, bears a striking refeemblance to the Gotham Woden; and it is further fuggereed, that Bohd is the deus Mercurii, the Wednesday, or Woden's day, of all Hindoos. But etymological reafoning, more efpicially when it inter- feres with chronology, is not fufficient to eftablih the identity of Boodh and Woden. According to the chronology of the Hindoos, which Sir W. Jones has minutely inveftigated and detailed, Boudha was the ninth "Avatar," or defcent of the deity, in his capacity of preferver, or the ninth incarnation of Vifahun, which was long antecedent to the exiftence of the defired hero of Scandinavia, who, according to fome writers, was a contemporary of Pompey and Julius Cefar, and who is placed by the author of the Northern Antiquities,
Boodhides — c.
As that part, reverence and honor was the pillar and chief of his
He revered the sacrifice of cattle, or depriving any being of life, and is
denominated the author of happiness. His place of residence
is said to have been discovered at Boudha Gaya in Bengal, by the illustrious
Arama, renowned amongst men; and according to an inscription in Sanscrit, found on a stone
in this place, and translated by Mr. Wilkins, (Asiatic Researches, vol. i. p. 284) he caused an image of the supreme
spirit Boodh-dha to be made, and worshipped it according to the
law, with perfumes, incense, and the like; and he thus
qualified the name of that supreme being, the incarnation of a
portion of Vefhnoo: "Reverence be unto thee in the form of Boodh-dha! reverence be unto the lord of the earth! reverence be unto thee, an incarnation of the deity and the eternal one! reverence be unto thee, O God, in the form of the God of mercy, the dispeller of pain and trouble, the lord of all things, the deity who overcometh the fins of the
Kale Yoog, the guardian of the universe, the emblem of mercy toward those who serve thee!" &c. As the doctrines of Boodh and Woden are different, and their deities are very
remote, they must of course be different persons. The
Buddha of the Hindus is unquestionably, says Sir W. Jones,
the Toce or Fo of China; and M. de Guignes, on the
authority of four Chinese historians, affirms, that Fo was born
about the year before Christ 1027, in the kingdom of Catha-
Mr. Chambers, following M. Gentili, and followed
by Paulinus, conceives, by a very forced train of etymology, the
Fo or Fohu of the Chinefe is the corruption of Boodh-
Nor is the derivation of Taautos, Toth, or Touth, the
Egyptian name for Hermes from Boudha, less fanciful;
and yet Fo-hi, the progenitor of the Chinefe, a military
tribe, whom the Hindus call the Chandranerva, or children
of the moon, was, according to their Puranas or legends,
Buddha, or the genius of the planet Mercury.

Among the various appellations by which the deity Buddha is
known in several parts of the East, that of Godama is very
common. This Godama, Gaudama, or Gotama, &c. as his
name is differently esprefled, is said to have been a philo-
osopher, and is believed by the Buddhists to have flourished about
2500 years ago; he is said to have taught in the Indian schools the
heterodox religion and philosophy of Boodh. See Goda-

The image that represents Boodh is called Gaudama or
Goutum, which is now a commonly received appellation of
Bhood himself; this image is the primary object of worship
in all countries situated between Bengal and China. The
seeraries of Boodh contend with those of Brahma for the
honours of antiquity, and are certainly far more numerous.
The Cingalee in Ceylon are Boodhists of the purest fource, and
the Brahmins acknowledge to have received their religion
from that ifland, which they call Zehoo. From thence it was
brought, as the Rahaans say, to Arracan, and it was then
introduced into Ava, and probably into China; for the
Birmans confidently affirn, that the Chinefe are Boodhists.
Kempfer, speaking of the Buzd, or Seaka, (Shaka, Sha-
kya, Sjaka, or Saxya, denoting, according to Paulinus, the
cunning, or the god of good and bad fortune,) says,
(Hill. Japan. b. iv. c. 6.) "I have strong reasons to believe,
both from the affinity of the name, and the very nature of this
religion, that its author and founder is the very fame
person whom the Brahmins call Buddha, and believe to be the
essential spirit of their Wiftana (Vifhtou) or their deity, who
made his ninth appearance in the world under this name: the
Pegus call him Samana Khutama." Where he treats concern-
ing the introduction of Boodh into China, he says, (id. ibid.) "about the year of Christ 516, one Darma, a great
faint, and twenty-third successor in the holy line of Seaka
(Buddha,) came over into China from Tibet, as the Japanec writers explain it, that is, from that part of the
world, which lies westward with regard to Japan, and laid,
properly speaking, the first firm foundation of the Boddhism
in that mighty empire." Others say, that the sect of Boudha
was introduced into China in the year of our era 619, and
that from China it extended itself to Japan, Tonquin, Co-
china, and the most remote parts of Tartary.

Whatever may be the antiquity of the worship of Boodh or
Buddha, we can entertain no doubt of the wide extent of its
reception and prevalence. In the island of Ceylon, in the
extensive Birmian empire, in the kingdoms of Siam and
Cambodia, the prevailing religion is that of Boudhia or
Godama, and Mr. Chambers (Asiatic Researches, vol. i.
p. 162, &c.) has given very good reasons for believing that
the worship of Boudhia extended all over India, and
was not rooted out by the Brahmans in the Deccan, fo late
as the 9th, or even the 12th century of the Christian era.
From the history of Cashmir, presented to the sultan Aca-
bar, on his first entrance into that kingdom, we learn, that
Jelowk, one of its most powerful princes, tolerated the
decine of Boodh; and that it was not till the reign of Nerkh
the 59th prince, A. D. 312, that the Brahmans acquired
the ascendency over the followers of Boodh, and burned
down their temples. In Nepal the most ancient religion is
that professed by a sect who call themselves "Baryeftu,
and who seem to be worshippers of Boudha.

In Narhoara or Nehrwaleh, the capital of the kingdom of Guzerat, we
find that even after the Mahomectan invasion, in the 11th
century of our era, Edriu, who wrote in the 12th century,
informs us, that the people continued in the worship of the
idol Boddha or Bud. This Arabian geographer adds, that
the worship of the prince of this country, who reigned on the
Mahabar coast, with the title of Balbara, and whose
dominions extended over Guzerat, and the greatest part, if
not the whole of Viipapur, was addressed to Budha, who,
according to St. Jerome and Clemens Alexandrius, was
the founder of the sect of the Gymnosophists, in like manner,
says M. d'Anville, as the Brahmins were used to attribute
their institution to Braham. If the conjectures of Sir William
Jones, relating to the inscriptions found at Mongheer, and
on the pillar of Baddal, be well founded, the governing power
on the banks of the Ganges, as late as about the time of the
birth of Christ, were of the sect of Boudhia; and however
idle and ridiculous the legends and notions of the wor-
shippers of Boudhia may be, they have been in a great mea-
ure adopted by the Brahmins; but with all their defects
and extravagances much aggravated, rajahs and heroes being
converted into gods, and impossibilities accumulated on im-
probabilities. From various authorities, to which we might
refer, it sufficiently appears, that the worship of Boudhia,
or Buddon, has prevailed in several parts of India at a period
prior to that of the Brahmins; and that this sect forms the basis of
that religion which the Brahmins have brought with them into
the southern parts of the peninsula of Hindoostan, into Ma-
dura, Tanjore, and Myloore. In those parts of India, and
chiefly on the coast of Coromandel, and in Ceylon, the god
Bouath, says M. Gentili, of whom, at present, they know
no more in India than the name, was the object of worship; but
but it is now totally abolished; except that there may be
found some families of Indians, who have remained faithful
to Boasuth, and do not acknowledge the religion of the
Brahmins; and on that account separated from and de-
spised by the other castes. It is generally allowed, that
about the time of Christ the Brahmins gained a superi-
ority over the worshippers of Boudha; and about 900 years
afterwards, we find them totally overthrowing his doc-
trine in its native country, and perfecting his followers.
The Vedas, which are commonly supposed to be the
oldest books of the Brahmins, are of later date than that of
the Boasuth, as is evident from the mention which they
make of that periphrase. Asiatic Researches, vols. i. ii.
For a further account of the votaries of Boudha, as well as the
principles and rites of his worship; see Brachmans, Go-
doma, Ramans, Samaranans, and Tirinanans. See also
Birmian empire, Ceylon, China, Cochinchina, Siam, &c.

BOODICOTA, in Geography, a town of the peninsula
of India, in the Myroor country; 87 miles E. N. E. of Se-
ringapatam, and 35 E. S. E. of Bangalore. N. lat. 12° 30'.
E. long. 76° 20'.

BOOG, or Bogoe, a small island of Denmark, between
the islands of Moen and Falitter.

BOOGGOO, in Zoology, the species of Babburan called
Simia marmot, by Linnaeus. See Malson.

BOOK, a writing composed on some point of know-
ledge by a person intelligent therein, for the instruction or
amusement of the reader.
The word is formed from the Saxon boc, which comes from
the Northern buoch, of buechas, a beech or service-tree,
on the bark of which our ancestors used to write.

Book may be defined more precisely, a composition of
some man of wit or learning, designed to communicate,
to prove, or illustrate some science, art, truth, or invention.

Book is distinguished from pamphlet, or single paper, by
its great length; and from tome or volume, by its containing
the whole writing on the subject. Tidore makes this distinction
between liber and codex; that the former denotes a single
book, the latter a collection of several; though, according to
Scipio Malfé, codex signifies a book in the square form; liber,
the book in the roll form. The primary distinction between
liber and codex seems to have been derived, as Dr. Heylin has
observed, from the different materials used for writing, among
the ancients. From the inner side of the bark of a tree, used
for this purpose, and called in Latin liber, the name of liber
applied to a book was deduced; and from tablet, formed from
the main body of a tree, called taulos, was derived the
appellation of codex.

We say an old book, a new book; a Latin, a Greek
book; to read, to write, to publish a book; the preface,
the title, the dedication, the index of a book. To collate a
book, is to see that it be perfect, and that none of the sheets
be either wanting or transposed. Book-binders speak of
folding, felting, beating, profiling, covering, gilding, and
lettering of books. See Bookbinding.

A large collection of books is called a library. An inves-
tory of a library, in order to the reader’s finding any book,
is called a catalogue.

The history of notitia of books makes the first part, ac-
cording to some the whole, of the literary science.—The
principal points of the notitia of a book are, its author, date,
printer, edition, versions, comments, epitomes, fuscce, cule-
gories, cenures, condemnation, suppression, adversaries, vin-
dicatar, continuators, and the like.

The history of a book is either of its contents, which is
given by analysing it, as is done by journalists and reviewers;
or of its appendages, and accidents, which is the more imme-
rate province of those called literaturs, and bibliothecarians.

The contents of a book are the matters delivered in it;
which make the province of the author. Of these there
is one principal matter, called the subject; in respect of
which the rest are only incidents.

The appendages of a book are, the title, preface, epite-
dedatory, summaries, table of contents, index, and the
like, which are the proper province of the editor, unless per-
haps the title page, which is frequently usurped by the
book-seller.

In the composition of a book, there occur sentiments,
which are also the materials of it; method, the order where-
in these are disposed; and style, or expression, which is the
language in which they are clothed.

The giving of histories, catalogues, and bibliotheces
books, is said to have been first introduced by the Germans:
we may add, that they have been succeeded in them;
and to them the chief works of this kind are owing. 1. Alb.
Fabriicus has given us the history of the Greek and Latin
books; Wolfius, that of the Hebrew books; Boecler, of
the principal books in each science and faculty; Struvius,
of the books of history, law, and philosophy; the abbot
Fabriicus, of the books of his own library; Lambecius, of those
in the Vienna library; Le Long, of the books of Scripture;
Matrinus, of the books printed before the year 1550; and
Morhoff, a general literary history of this kind, under the
title of Polyhiflor. The various catalogues of choice lib-
raries are useful and necessary for the same purposes; fo are
likewise the relations, &c. and the reviews which have been
periodically published. See Bibliotheca.

Books, as to the materials of, they were first written on
bones, witnesses the Decalogue given to Moses (which is the
oldest book we have any warranted account of); then, on
the parts of plants, e. g. the leaves, chiefly of the palm-tree;
the rinds and barks especially of the tília or phylara, and the
Egyptian papyrus. By degrees, wax, then leather, were introduced,
especially the skins of goats and sheep, of which, at length,
parchment was prepared; then lead came in use: also linen,
alk, horn, and, lately, paper itself. See Paper.

The parts of vegetables continued long the common mat-
ter of books; infomuch that most of the names and terms
belonging to books, in most languages, are taken thence;
as the Greek biblios, the Latin libro, codex, folium, tabula,
and the English book itself. We may add, that vegetable barks
appear fill in some measure retained for books in certain of
the Northern countries, as among the Calmic Tartars, where
a library was discovered by the Russians, of an unusual form
as well as matter: the books were exceedingly long, but of
no breadth: the leaves very thick, and made of barks of
trees, incased over with a double vamish; the ink, or writ-
ing, being white on a black ground. Hilt. Acad. R. Infem.
t. iii. p. 6.

Whatever were the materials used by the ancients for
their books, they were liable to be easily destroyed by the
damp, when hidden in the earth; and in times of war, de-
vastation, and rapacity, it was necessary to bury in the earth
whatever they wished to preserve from the attacks of fraud
and violence. Accordingly, it is well known, that perfons,
whose property was thus expoed, concealed in this manner,
not only silver and gold, but wheat, barley, oil, and honey;
and also their garments, and their writings. With this
view, Jeremiah ordered the writings, which he delivered to
Baruch, to be put in an earthen vessel. See chap. xxxii.
In the same manner the ancient Egyptians made use of
earthen urns, or pots of a proper shape, for containing
what-
whatever they wanted to inter in the earth, and which, without such care, would have been soon destroyed. We need not wonder then, that the prophet Jeremiah should think it necessary to exclude those writings in an earthen pot, which were to be buried in Judaea, in some place where they might be found without much difficulty on the return of the Jews from captivity. Accordingly two different writings, or small rolls of writing, called books in the original Hebrew, were designed to be enclosed in such an earthen vessel; but commentators have been much embarrassed in giving any probable account of the necessity of two writings, one sealed, the other open; or, as the papyrus has been commonly understood, the one sealed up, the other left open for any one to read: more especially, as both were to be alike buried in the earth and concealed from every eye, and both were to be examined at the return from the captivity. In order to solve this difficulty, the ingenious Mr. Harmer (Obs. on Script. vol. iv. p. 4.) remarks, that though one of them is said to be sealed, it doth not follow that it was sealed in such a manner as not to be opened. Like modern deeds for the conveyance of land, it might have been sealed, though not with wax, yet concealed to the present easen manner, with ink, so as to be valid. Moreover, the word translated open, in reference to the evidence, or book which was open, is not the same that is twice used by Nehemiah, ch. viii. 5.; but it is a word, which signifies (1 Sam. iii. 7, 21. Dan. ii. 19. 32. x. 1.) the revealing of future events to the minds of men by a divine agency; and it is particularly used in the book of Elisha, (ch. viii. 13.) to express a book's making known the decree of an earthly king. Consequently the open book of Jeremiah seems to signify, not its being then lying open or unrolled before them, while the other was sealed up; but the book that had revealed the will of God, to bring back Israel into their own country, and to cause buying and selling of houses and lands again to take place among them. This was a book of prophecy, opening and revealing the future return of Israel; and the other little book, which was ordered to be buried along with it, was the purchase-deed. By adhering to the different modes of writing in the East, we obtain a satisfactory interpretation of a passage in the book of Job, (ch. xix. 23, 24.) and a distinct view of the beautiful gradation which is lost in our translation: "O that my words were now written! O that they were printed (written) in a book! that they were graven — in the rock for ever!" In the East there is a mode of writing, which is designed to fix words in the memory, but the writing is not intended for posterity. Accordingly, we are informed by Dr. Shaw, (Trav. p. 194.) that children learn to write in Barbary by means of a smooth, thin board, slightly covered with whiting, which may be wiped off, or renewed at pleasure. As many occurrences were effaced from the memory of the Arabs in the time of Job, as well as from their writing-tables, as it now often happens in Barbary; Job expresses his wish not only that his words were written, and written in a book, from which they should not be blotted out, and graven in a rock, the most permanent mode of recording them, and much more effectual for perpetuating them than a book.

We find in Signor Caltaggutta's account of the aellbas, a scheme for the making of a book, which from its imperishable nature, is for calling the book of eternity. The leaves of this book were to be of the aellbas paper, the covers of a thicker sort of work of the same matter, and the whole fewed together with thread spun from the same substance. The things to be commemorated in this book were to be written in letters of gold, so that the whole matter of the book being incommensurable and everlastingly permanent against the force of all the elements, and subject to no changes from fire, water, or air, must remain for ever, and always preserve the writing committed to it. See Paper.

Books, form of. The first books were in the form of blocks and tables, of which we find frequent mention in Scripture, under the appellation fapher, which the Septuagint renders σημεία, q. d. "signs" or "tablets"; of which form the book of the covenant, book of the law, or book of divorce, book of curies, &c. appear to have been. As flexible matters came to be written on, they found it more convenient to make their books in form of rolls, called by the Greeks κωδικία, by the Latins volumina, which appear to have been in use among the ancient Jews as well as Greeks, Romans, Persians, and even Indians. And of such did the libraries chiefly consist, till some centuries after Christ. The form which obtains among us is the square, composed of separate leaves; which was also known, though little used, among the ancients; having been invented by Attalus, king of Pergamus, the name also who invented parchment; but it has now been so long in possession, that the oldest manuscripts are found in it. Montfauneau affirms, that of all the ancient Greek manuscripts he has seen, there are but two in the roll form; the rest being made up much more after the manner of the modern books. See Book-binding.

The rolls, or volumes, were composed of several sheets, fastened to each other, and rolled upon a stick, or umbilicus; the whole making a kind of column, or cylinder, which was to be managed by the umbilicus, as a handle; it being reputed a kind of crime to take hold of the roll itself. The outside of the volume was called front; the ends of the umbilicus, were called cornua, horn; which were usually carved and adorned likewise with bits of silver, ivory, or even gold and precious stones. The title κωδικιας was stuck on the outside. The whole volume, when extended, might make a yard and a half wide, and fifty long. Fabric. Bibl. Antiq. c. 19. § 6. 67.

Sir John Chardin informs us, in a note on II. viii. 1. that the eastern people roll their papers, and do not fold them, because their paper is apt to fret. Whilst the Egyptian papyrus was in common use, its brittle nature made it proper to roll up what they wrote: and as this had been a customary practice, many continued it when they used other materials, which might very hastily have been treated in a different manner. This method of rolling up their books is referred to in the New Testament; and that they were of the same form much more anciently, we learn from Jer.xxxvi. 2. P. xl. 7. &c. &c.

It is customary not only to wrap up Oriental books and letters, which are rolled up, in an elegant and costly covering; but to inscribe words on these coverings, which give a general notion of their contents. This practice of writing on the outside of the case of a letter, or book rolled up, seems to be at East as ancient as the time of Chrysofom, as we learn from a note of Lambert Bos on P. xxxix. 7. as it occurs in the LXX. v. 40. in our version. Chrysofom remarks, that they call a wrapper (παντοκράτιον) the κυκλη, which is the word the Septuagint translators make use of to express the Hebrew word we translate volume: "In the volume of the book it is written of me." The learned father seems to suppose, that there was written in or on the covering of the sacred volume, a word or words which signified the "coming of the Messiah." But Chrysofom would hardly have thought of such an interpretation, if it had not been frequently done at Constantinople in his time, or by the more eastern princes that had begun to transact with the Greek emperors, or been known to have been practiced
practised before those times among the Jews. Chrysostom lived in the 4th century. Aquila, who is thought to have lived about 100 years former, and is allowed to be a most close translator of the Hebrew, used, according to Bois, "the same word ἔρως, or wrapper, to express the Hebrew word which we translate volume." He therefore supposed that what was written to which this passage refers, was written on the covering or wrapper of the sacred books. This explanation suggests a much more agreeable mode of rendering the word that our English term "volume;" since every ancient Hebrew book was a volume, or roll, and consequently the passage merely expresses: "In the book it is written of me." But if we understand it of the case in which their books were wrapped up, the thought is not only clear and distinct, but very energetic, and amounts to this: that the firm and substance of the sacred books is, that the Messiah comes, and that those words accordingly might be wrote or embalmed, with great propriety, on the wrapper, or cafe in in which they were kept.

Another translation renders the word Τόμος, which intimates that the motto was inscribed on the cylinder, round which books of this form were wound to be rolled. In this case, it was probably written in that part of the cylinder which reached beyond the parchment, linen, or whatever material was used, and which was convenient enough for exhibiting, in brief, what the purport of the volume was. Mr. Harper (Observation script. vol. iv. p. 11.) suggests, that the circle of gold, with the name of one of our Saxon princes upon it, and ornamented after the manner of those times, might be designed to case the end of the cylinder, or one of the cylinders, on which some book belonging to that monarch, or relating to him, was rolled; of which ancient piece of gold an engraving is given in the seventh volume of the Archaeologian, or Transactons of the Antiquarian Society. This sort of capping to those cylinders used to be called the "Aedel."

To the form of books belongs also the economy of the inside, or the order and arrangement of points and letters into lines and pages, with margins, and other appurtenances. This has undergone many varieties: at first, the letters were only divided into lines, then into separate words; which, by degrees, were noted with accents, and distributed, by points and slants into periods, paragraphs, chapters, and other divisions. In some countries, as among the Orientals, the lines began from the right, and ran to the left; in others, as in Northern and Western nations, from the left to right; others, as the Greeks, followed both directions alternately, going in the one, and returning in the other, called basiphraphioid. In the Chinese books, the lines ran from top to bottom. Again, the page in form is entire, and uniform; in others, divided into columns; in others, distinguished into text and notes, either marginal, or at the bottom; usually it is furnished with signatures and catch-words; also with a register to discover whether the book be complete. To these are occasionally added the apparatus of summaries, or side notes; the embellishments of red, gold, or figured initial letters, head-pieces, tail-pieces, ligatures, schemes, maps, and the like. The end of the book, now denoted by finis, was anciently marked with a Δ, called coronis, and the whole frequently wafted with an oil drawn from cedar, or citron chips, fixed between the leaves to preserve it from rotting. There also occur certain formule at the beginning and end of books; as among the Jews, the word הָרְסֵין, or corus, which we find at the end of the books of Exodus, Leviticus, Numbers, Ezekiel, &c. To exhort the reader to be courageous, and proceed on to the following book. The conclusions were

also often guarded with imprecations against such as should falsify them; of which we have an instance in the Apocalypse. The Mahometans, for the like reason, place the name of God at the beginning of all their books, which cannot fail to procure them protection, on account of the infinite regard had among them to that name, wherever found. For the like reason it is, that divers of the laws of the ancient emperors begin with the formula, In nomine Dei.

At the end of each book the Jews also added the number of verses contained in it, and at the end of the Pentateuch the number of sections; that it might be transmitted to posterity entire. The Maforetos and Mahometan doctors have gone farther; so as to number the several words and letters in each book, chapter, verse, &c. of the Old Testament, and the Alcoran. See Alcoran, Bible, Massora, &c.

The kinds and denominations of books are various. Books, with regard to their use and authority, may be divided into human and divine, also called sacred and inspired books.

Books, Sibylline, those composed by certain pretended prophets, deposited in the Capitol, under the care of divinat. See Sibylls.

Books, Canonical, those received and allowed by the church as parts of holy scripture. Such are the books of the Old and New Testament, as commonly bound up together. See Canon, and Bible.

Books, Apocryphal, those excluded out of the canon, yet received and read in some churches. See Apocryphal.

Books, Authentic, those which are decisive, and of authority: such, in the civil law, are the Code, Digest, &c. in our law, the Statutes, &c. Bacon de Augm. Sc. i. 8. c. 3.

Books, Auxiliary, those left essential, yet of use, as subservient to the others: as in the study of the law, books of Institutes, Formula, Maxims, Reports, &c.

Books, Elementary, those which deliver the first principles of sciences: such are those under the titles of Rudi- ments, Methods, Grammars, &c. by which they stand contradistinguished from books of a superior order, which aim at making further advances in the sciences.

Books, Library, such as are not ordinarily read over, but turned to, and consulted occasionally; such are dictionaries, &c.

Books, Exoteric, those intended for the use of popular and ordinary readers.

Books, Aeromatic, those containing more secret and sublime matters, calculated for adepts and proficients in the subject.

Books, Public, the records of past times and transactions kept by public authority.

Books, Church, or Ecclesiastical, those used in the public offices of religion.

Books, again, with regard to their scope and subject, may be divided into historial, those which relate facts, either by nature or mankind; dogmatical, those which lay down doctrines, or general truths; mystific anomalous, those of a neutral kind, containing both facts and doctrines; historico- dogmatical, those which only relate to divine matters, or at most, indicate the arguments by which they are proved, as Mallet's Geometry; scientifico-dogmatical, those which not only relate the doctrines, but demonstrate them, as Athel's Elements. Wolf. Phil. Rat. § 3. c. 1. § 74, 75, 76, &c.

Books, Pontifical, among the Romans, were those appointed by Numa to be kept by the pontificius maximus: describing
scribing all the ceremonies, sacrifices, feasts, prayers, and other religious matters, with the manner, and circumstances, wherewith each was to be celebrated; these were also called indigentamenta, as containing the names of all the gods, and the occasions, and formule of invoking each. Liv. 1. p. 23.

Books, *Ritual*, those which directed the order and manner of founding, building, and consecrating cities, temples, and altars; the ceremonies belonging to walls, gates, tribes, curia, camps, and the like. Book, *Augural*, called by Cicero *recurrent*, were those wherein the science of foretelling futurity, from the flight and chattering of birds, was contained. Cic. *Orat. pro domo sua ad pontif. Serv. ad Æn. l. 5. v. 738. Lomei, de Bibl. c. 6.

*Aruspice*, those wherein the mysteries of divining from the entrails of victims are preferred.

*Acherontic*, those wherein the ceremonies and discipline of Acheron were contained; sometimes also called *Libri Etrusci*, as being supposed to have been composed by Tages the Etrurian; though others pretend, that he: had received them from Jupiter himself: some suppose these to have been the same with the *Libri fatales*; others, with the *libri aruspicini*. Serv. ad Æn. l. 3. v. 358. *Lomei, ubi supra.*

*Fulgelral*, those written touching thunder and lightning, and their interpretation. As that composed by the Tucheus nymph Bigois, preferred in the temple of Apollo. Serv. ad Æn. l. 6. v. 72.

*Fatal*, those wherein the ages, or terms of the life of men were written, according to the Etrurian discipline. These were consulted by the Romans in all public calamities; and inscriptions taken from them, how to expiate the offended deities. *Cenfer. de Dict. Natal. c. 14.*

*Black*, those which treat of necromancy and witchcraft; or those which are printed in the old black letter, the Celtic character, now only retained by the Germans. The same denomination is also given to some other books, on account of the colour of their backs, or the diminutives of their contents; whence also *Red book*, and *Domesley-book.*

*Good*, in the common usafe, are those of devotion and piety, as soliloquies, meditations, prayers, &c. Vide *Shaftesb.* Charact. tom. i. p. 165. *Idem. tom. iii. p. 327.* A *good book*, in the bookfeiler’s language, is a fable one; in the language of the curious, a fcare one; in that of men of fentif, an ufulful and instructive one.

Among five principal things which Rabbi Akiba recommended to his son, one was, that if he studied the law, he should take care to do it in a *good book*, lest he should be obliged to unlearn all again. Vide *Cren. de Fuirib. Librar. See also farther, on the head of judging and choosing of Books.*

*Spiritual*, those which treat more expressly on the spiritual or Christian life, and their exercises, as to contemplation, &c. *Books, Prophane*, such as do not treat of matters of religion.

*Books, with regard to their authors*, may be divided into *anonymous*, those without any author’s name; *cryptonymous*, those whose authors’ names are concealed in some anagram, or the like; *pseudonymous*, those which bear false names of authors; *pseudonymous*, those published after the author’s death; *generous*, those really written by the persons whom they pretend for their authors, and still remaining in the same wherein they were left by them; *spurious, or supposititious*, those pretended to be written by others than their real authors; *interpolated*, those which since their composition have been corrupted by spurious additions or insertions.

*Books, with regard to their qualities*, may be divided into *clear* or *perplicuous*, which, in the dogmatical kind, are those where the authors define all their terms accurately, and keep strictly to those definitions in the course of their works; *obscure*, those where words are used vaguely, and without defining: *prolix*, those which contain more things than were necessary to the author’s design; as if in a book of surveying, a man should give all Euclid; *useful*, those which deliver things necessary to be known, either in other sciences, or in the businesse of life: *complete*, those which contain all that is known concerning the subject: *relatively complete*, those which contain all that was known concerning the subject, at a certain time; or, if a book were written with any particular design, or view, it may be said to be *complete*, if it contain neither more nor less than is necessary for the accomplishing of that end; in contrary cases, books are said to be *incomplete.*

*Books, with regard to the matter of which they consist*, may be divided into *paper-books*, those written either on linen and cotton paper, or on the papyrus, of which last kind few are now remaining. Montfavon Pal. Græc. l. i. c. 2. p. 13. *Parchement-books*, *libri in membrana*, those written on skins, or peltis, chiefly of sheep. *Leather-books*, *libri linteis*, among the Romans, were those written on skins, or tables, covered with a linen cloth. Such were the Sibylline books, and divers ancient laws, epistles of princes, leagues, annals, &c. Plin. Hift. Nat. l. xiii. c. 2. *Lettwr books*, *libri in ceris*, mentioned by Ulpian, are by Guiliandinus taken for such as were written on boards, different from that usually written on; which was the *libri*: by Scaliger, with more probability, for such as were written on certain skins, or certain parts of skins, different from those commonly used, which were the pelts, or back parts of sheep. *Ulp. l. 52.*

*Guiliand. Papyr. Membr. 3. n. 50.* Scaliger, and Guiliand. *Biblo-books*, *libri in schedis*, those written on wooden planks, or tablets, smoothed for that purpose with an *africa*, and a plane. Such were the ordinary books among the Romans. *Wassen-books*, *libri in ceris*, mentioned by Pliny, have occasioned some dispute. *Herm. Barbarus* supposes the term to be a corruption, and inclines to read in *schedes*, instead of in *ceris*, on the authority of some ancient MSS. Others see no need of the emendation, since it is known the Romans sometimes covered their planks or *schedes*, with a thin skin of wax, to make them susceptible of erasements and amendments, which the *libri in schedis* were not, and consequently were less fit for works that required elegance and accuracy than the waxen ones, which are also called *cera* or *libri ceraei.* *Elephantine books*, according to Turnebus, were those written on thin slices, or leaves of ivory; according to Scaliger, those made of the guts of elephants; according to others, those wherein the acts of the senate, relating to the emperors, were written; according to others, certain huge or bulky books, consisting of 35 volumes, containing all the names of the 35 tribes. *Salmanuth. ad Panirol. n. ii. p. 255.* Guiliand. Pap. Mem. n. 2. p. 48. *Scal. ad Guili. p. 10.* Calv. Lex. Jur. p. 534. Fabr. Decrip. Urb. c. 6.

*Books, with regard to their manufacture and commerce*, may be divided into *manuscript*, those written with the hand, whether Originally by the authors, called *autographi*, or at second hand by *librarii*, or *copyists*, printed, those wrought off from the press: *books in quires, or folios*, those not bound or stitched; *books in folio*, these wherein a fluet is folded but once, or makes two leaves, or four pages; *books in 4°*, where
where it makes four leaves; in 8°, where eight; in duodecimo, where twelve; in 16°, where sixteen; in 24°, where twenty-four.

Books, with regard to circumstances and accidents, may be divided into left, those which have perished by the injuries of time, or the malice or zeal of enemies. Such are divers even of the ancient books of Scripture, written by Solomon, and others of the prophets. Fabr. Cod. Pfeud. Vetus. Tert. tom. ii. p. 171. p. 247. Books promised, those which authors have given expectations of, which they have never accomplished. Jan. ab Almoleven has given a Bibliotheca of books promised, but still latent, or not published. Books fictitious, those which never existed: to which may be added divers feigned titles of books. Loefcher has published a great number of plans, or projects of books, many of them good and useful enough, if there were but books written corresponding to them. M. Dugono has a whole volume of schemes, or projects of books, containing no less than 3000.

Books in Ant. Anti, &c. See Anti, Anti, &c.

Books, the scope, or design of; is various; that of force is to trace the origin of things di¢overed; of others, to fix and establish force truth, or rafle some doctrine to a higher pitch or subility; of others, to remove some currence, or prejudice, which had before obtained, or fix more accurate and precise ideas of: of others, to explain the names and words used in different nations, ages, and sects; of others, to improve our knowledge of facts, and events, and show the order and ways of Providence; lastly, others aim at divers, or all of these ends.

Books, the use of, are numerous; they make one of the chief lustrums, or means of acquiring knowledge: they are the repositories of laws, and the vehicles of learning of every kind: our religion itself is founded on books: “Without them,” says Bartholin, "God is silent, justice dormant, phyfic at a stand, philosophy lame, letters dumb, and all things involved in Camillian darkness." De Libr. Legend. Diff. i p. 5.

The eulogiums which have been bestowed on books are infinite: they are represented as the refuge of truth, which is banished out of conversation; as standing counsellors, and preachers, always at hand, and always disinterested; having this advantage over oral instructors, that they are ready to repeat their lesson, as oft as we please.

Books supply the want of masters, and even, in some measure, the want of genius and invention: and can rafle the dullest persons, who have memory, above the level of the brighteft without them. An author who wrote not inde¢anly, though in a barbarous age, sums up all their praise. Vide Lucas de Penne ap. Morhoff. Polyb. lib. i. cap. 3. p. 27.

"Liber est lumen coris, speculum corporis, virtutum magifter, vitiorum depulor, corona prudentiam, comes initii, domelitice amicus, congresso talentis, collegia & confiliarius praefidentis, mythotheum eloquentia, horus plenus fructibus, pratum floribis diffinuens, memoriae penus, vita recordationis; vocatur properat, juitus felicitat, temper praefita elo, nonquam non morigeros, rogatos confelitum respondet; arcanæ revelat, obvocir illudrat, ambiguæ certiorat, perplexa revolvit, contra adversam fortunam defendit, fideiüe moderatorem, opes adagerat, fæcurnum propulsit," &c.

Perhaps their greatest glory is, the affection borne them by many of the greatest men in all ages: M. Cato, the elder Pliny, the emperor Julian, and others, are on record for a very extraordinary devotion to books. This has perpetuated his passion by some Greek epigrams in their praise. Richard Bury, bishop of Durham, and lord chancellor of England, has a treatise on the love of books. Philobiblon, five de Amore Librorum. Vide Plin. Epist. vii. lib. iii. Vol. IV.

Cato’s attachment to books may be observed in the following paragraph.

"M. Catonem vidi in bibliotheca sedentem multis circuminfatum Stoicorum libris. Erat enim, ut seis in exo inhaustis avitus legendi, nec fatiari poterat; quippe qui, ne reprehensionem vulgi inanem reformidans, in ipfa cura soleret leggere, sepe dum fenatus cogperet, nihil opere reipublicæ detraxens." Vide Cic. de Divin. lib. iii. n. 111. See also Cic. Orat. pro Arch. tom. iv. p. 2182.

Books, the ill effects objected to, are, that they employ too much of our time and attention; engage us in pursuits of no use to the commonwealth, and indipose us for the functions of civil life; that they render men lazy, and prevent their exerting their own talents, by furnishing them, on every occasion, with things that are the productions of others; and that our natural lights become weakened and extinguished, by inuring ourselves to see only with foreign lights: besides, that ill men are hereby furnished with means of poisoning the people, and propagating superstition, immorality, enthusiasm, or irreligion, which will always spread faster, and be received more greedily, than lefions of truth and virtue. Many other things are added concerning the emptiness of books, and the errors, fables, and follies they are fraught with: which, together with the multitude and perplexity of them, are such, that it may seem easier to discover truth in this nature and renown: things. than in the uncertainty and confusion of books. Add, that books have turned all the other instruments of knowledge out of doors, as experiments, observations, furnaces, and the like, without which the natural sciences cannot be cultivated to purpose; and that, in mathematics, books have so far superseded the exercise of invention, that the generality of mathematicians are now contented to learn the solution of problems from others; which is to relinquish the chief end of their science; since what is contained in mathematical books is properly the history only of mathematics, not the science, art, or talent of solving questions; which is hardly to be had from books, but only from nature and meditation.

Books, for the art of writing, or compounding, we have much fewer helps and instructions than for the art of speaking; though the former be the more difficult of the two; as a reader is not so easy to be imposed upon, but has better opportunities of detecting faults than a hearer. A great cardinal, indeed, reduces an author’s business to a few heads; were they but as easily practifed as preferred: “Let him consider who it is writes, what, how, why, and to whom.” Augull. Valer. de Cunt. in end. lib. The conditions required in a book are, according to Selden, “solidity, perspicuity, and brevity;” the first will be well attained, by keeping the piece long by us, often reviewing and correcting it by the advice of friends: the second, by disposing the sentiments in a due order, and delivering them under proper and useful expressions: the third, by throwing every thing aside that does not immediately concern the subject. Were these rules observed, it would fearfully be possible for any, except an angel from heaven, to write many books. "Vix totidem quot Thebarum parte vel divitis olia Nili." The custom is much altered since the times of the ancients, who carried their scrupulousness into what relates to the composition of books beyond all that has been above expressed; so august was the idea they formed of a book, that nothing would suffice less than its being a treasure: “the fawus operet ecc, non librus;” no labour, no afdudity and exactitudes, were thought enough to fit a work for the public view: every sentiment and expression were to be maturely weighed, and turned on all sides; and not suffered to pass, unless every word were a pearl, and every page beft with 5G gems.
gems. So that they put the reader in possession in a single hour, of what had cost them perhaps ten years' intense thought and application. Such were those books, which were reputed "cedro digni," fit to be annotated with cedar-juice, and thus rendered incorruptible, for the instruction of all future ages.

Books, for the origin of, we have nothing that is clear: the books of Moses are doubtless the oldest of all that are extant; but there were books before them, for Moses cites several. A book of Enoch is cited in the epistle of Jude, v. 14. and 15, from which some endeavour to prove the reality of antediluvian writings; but the book cited by that apostle is generally allowed both by ancient and modern writers to be spurious. See Bible.

Of prophetic books, the oldest extant are Homer's poems, which were even fo in the time of Sextus Empiricus; though we find mention in Greek writers, of about seventy others prior to Homer; as Hermes, Orpheus, Daphnis, Horus, Linus, Musaeus, Palamedes, Zoroaster, &c. of the greater part of these, there is not the least fragment remaining; and of the others, the pieces which go under their names are generally held by the learned supposititious. F. Hardman goes farther; charging all the apocryphal books, the Greek and Latin, except Cicero, Pliny, Virgil's Georgics, Horace's Satires and Epistles, Herodotus, and Homer, as spurious, and forged in the thirteenth century, by a club of persons under the direction of one Severus Arcintius. Fab. Bib. Græc. lib. i. cap. 1. § 1. 6. tom. i. Hardouin de Num. Herod. in Proluf. Act. Erud. Lipp. an. 1710. p. 70.

Among the Greeks, it is to be observed, the oldest books were in verse, which was prior to prose; Herodotus's history is the oldest book extant of the prose kind. Strabo. Geog. lib. i. Heuman. Via ad Hift. Liter. § 20. p. 50. § 21. p. 52.

Books, the multitude of, has been long complained of: the complaint is as old as Solomon, who lived three thousand years ago; they are grown too numerous, not only to procure and read, but to see, to learn the names of, or even to number. England has more to fear on this score, than other countries; since, besides our own produce, we have, for some years past, drained our neighbours. However, as bij shop Caramuel's scheme miscarried, which was, to write about a hundred volumes in folio, and then prevail on the civil and military powers to oblige all their subjects to read them, we need not much regret the multitude of books.

In reality, there are few of the immense number of books which deserve seriously to be studied: for the rest, part of them, like this, are only to be occasionally consulted, and the rest read for amusement. A mathematician, for instance, ought not to be entirely ignorant of what is contained in the mathematical books; but then a general knowledge is sufficient, which may easily be had by running over the chief authors; out of whom references may be made, directing to the places where they may be found, when wanted. For there are many things which are much better preferred in books than in the memory; as astronomical observations, tables, rules, theorems, proportions, and in fine, whatever does not spontaneously adhere to the memory, when once known. For the leis we croud that facility, the reader and freer will the genius remain for inventing.

Other books may be valuable in themselves, for some special purpose, or in some peculiar science, but are not fit to be perused except by those who are engaged in that particular science, or business. To what use is it for a divine, or a physician, or a tradesman, to read over the huge volumes of reports of adjudged cases in the law? Or for a lawyer to learn Hebrew and read the Rabbins, unless his inclination leads him, and his leisure allows him to employ himself in this way? For improvement of knowledge and saving of time, it is of great importance for young persons to have the most proper books for his reading, recommended by a judicious friend.

Books of importance of any kind, and especially complete treatises on any subject, should be first read in a more general and curiously manner, to learn in some degree what the treatise promises, and what you may expect from the writer's manner and skill. For this purpose let the preface be read, and the table of contents, if there be any, before this first survey of the book. By this means you will not only be better fitted to give the book a first reading, but be much allayed in a second perusal of it, which should be done with greater attention and deliberation, and you will learn with more ease and readiness what the author professes to teach. In reading it will be useful to mark what is new or unknown to you before, and to review those chapters, pages, or paragraphs. Unless a reader has an uncommon and most retentive memory, we may venture to affirm, that there is scarcely any book or chapter worth reading once, that is not worthy of a second perusal. At least it will be proper carefully to review all the lines or paragraphs which were previously marked, and to recollect the facts which were thought truly valuable. There is another reason why it will be useful to take a superficial and cursory survey of a book, before we sit down to read it, and to dwell upon it with studious attention; and that is, that there may be several difficulties in it, which we cannot easily understand and resolve at the first reading, for want of a fuller comprehension of the author's whole scheme. Many such difficulties would be unravelled when we have proceeded farther in such books, or would vanish themselves upon a second reading. What we cannot thoroughly understand at first may be noted down as matter of subsequent consideration and inquiry, if the pages that follow do not happen to strike a complete light on those which went before. In perusing books that treat of subjects of natural, moral, or divine science, it should be considered that it is our business, not merely to know the opinion of the author, for this is but the mere knowledge of history; but truly to reflect, whether his opinions are just or not, and to improve our own knowledge of the subject by a careful investigation of it. With this view we should deal freely with every author whose works we read, and yield our assent only to evidence and just reasoning. If a writer on any particular subject, to which your attention is directed, maintains sentiments similar to your own, but does not explain his ideas, or prove his politics to your satisfaction, mark his defects, or faults, and endeavour to do it better, either in the margin of your book, or rather on some papers of your own. e. g. When the author is obscure, enlighten him; where he is imperfect, supply his deficiencies; where he is too concise, amplify, and set his notion in a fairer view; where he is redundant, mark the paragraphs that ought to be retrenched; where he trifles and indulges in impertinence, abandon those passages, or pages; where he argues, observe whether his reasons be conclusive; if the conclusion be true, but the argument weak, endeavour to confirm it by better proofs; where he deduces any propositions obscurely, or doubtfully, make the justifs of the inference to appear, and add further inferences or corollaries, if such occur to your mind; where you sup-pose he is mistaken, propose your objections, and correct his errors; what he writes so well as to approve itself to your judgment, as both just and useful, treasure up in your memory, and count it a part of your intellectual gains.

If the method of a book be irregular, reduce it into form, by
by an analysis of your own, or by hints in the margin; if those things are heaped together, which should be separated, digested and divide them. If several things relating to the same subject are scattered through various parts of the same treatise, let them be brought together into one view, by suitable references; or if the matter of a book be really valuable and deserving the labour, you may arrange it in a better method, reduce it to a more logical scheme, or abridge it into a letter form. All these practices will have a tendency to advance your own skill in logic and method, to improve your judgment in general, and to give you a more comprehensive survey of that subject in particular. When you have finished the treatise, with all your observations upon it, recollect and determine what real improvements you have made by reading that author. If a book have no index, or good table of contents, it is useful to make such as you are reading it; taking notice merely of those parts which are new and well written, and well worthy of remembrance, or review. If the writer be remarkable for any peculiar excellencies, or defects in his style, or manner of writing, attentively observe them, and whatever ornaments or blemishes occur in the language, or manner of the writer, you may make just remarks upon them. One book perused in the manner now proposed, will tend more to enrich the understanding, than skimming over the surface of 20 authors.

"There are many who read," says the excellent author of whole useful observations we are now availing ourselves, (see Watts's Improvement of the Mind) "with conflagration, and yet make no advances in true knowledge by it. They are delighted with the notions which they read, or hear, as they would be with stories that are told, but they do not weigh them in their minds as in a full balance, in order to determine their truth, or falsity; they make no observations upon them, or inference from them. Perhaps their eye slides over the pages, or the words slide over their ears, and vanish like a Rhapsody of evening tales, or the shadows of a cloud flying over a green field in a summer's day; or, if they review them sufficiently to fix them in their remembrance, it is merely with a delgin to tell the tale over again, and to shew what men of learning are. Thus they dream out their days in a course of reading without real advantage. As a man may be eating all day, and for want of digestion is never nourished; so these endless readers may cram themselves in vain with intellectual food, and without real improvement of their minds, for want of digelling it by proper reflection.

"Never apply yourself," says the famous writer, "to read any human author with a determination, before-hand, either for or against him, or with a settled resolution to believe, or disbelieve, to confirm, or oppose whatsoever he faith; but always read with a deliberate to lay your mind open to truth, and to embrace it wherever you find it, as well as to reject every falsity, though it appear under never so fair a disguise. How unhappy are those men, who seldom take an author in their hands, but they have determined before they begin, whether they will like or dislike him! They have got some notion of his name, his character, his party, or his principles, by general conversation, or perhaps by some flight view of a few pages; and having all their own opinions adjusted before-hand, they read all that he writes with a prepossession either for or against him; unhappy those who hunt and pursue for a party, and scrape together out of every author, all those things, and those only which favour their own tenets, while they despise and neglect all the rest!"

The author subjoins an useful caution; and wishes not to be underlaid, as perusing a person to live without any settled principles, by which to judge of books, men, and things, or to be always doubting about his foundations. But having settled, upon good grounds, the most necessary and important principles of science, prudence, and religion, we should read, with a just freedom of thought, all those books which treat of such subjects as may admit of doubt, or reasonable dispute. When we peruse those authors who defend our own settled sentiments, we should not hastily conclude that all their reasonings are just and solid; nor eagerly embrace all their lefser opinions, because we agree with them in the greater. When we read those authors who oppose our most certain and established principles, we should be ready to receive any information from them in other points, and not abandon every thing they say, though we are well fixed in opposition to their main object:

"Seize upon truth where'er it is found, Amongst your friends, amongst your foes, On Christian, or on heathen ground; The flower's divine where'er it grows; Neglect the prickles, and assume the role."

Upon the plan of reading above stated and recommended, a few books well chosen, and thoroughly studied, may suffice. It may be added, that as knowledge is naturally advantageous, and as every man ought to be in the way of information, even a superfluity of books is not without its use, since hereby they are brought to obtrude themselves on us, and engage us when we had laff design. This advantage, an ancient father observes, we owe to the multiplicity of books on the same subject, that one falls in the way of one man, and another best suits the level, or the apprehension, of another. "Every thing that is written," says it does not come into the hands of all persons: perhaps some may meet with my books, who may hear nothing of others which have treated better of the same subject. It is of service, therefore, that the same questions be handled by several persons, and after different methods, though all on the same principles, that the explications of difficulties, and arguments for the truth, may come to the knowledge of every one, by one way or other. Add, that the multitude is the only security against the total loss or destruction of books: it is this that has preferred them against the injuries of time, the rage of tyrants, the zeal of persecutors, and the ravages of barbarians; and handed them down, through long intervals of darkness and ignorance, safe to our days.

Books, the scarcity of, is an evil much more to be lamented, in the Survey of palest ages, than their multitude at any later period. Before the art of printing was invented, the trouble and expense of procuring copies very much retarded the progress of literature. The universal ignorance that prevailed in Europe, from the seventh to the eleventh century, may be ascribed to the scarcity of books during that period, and the difficulty of rendering them more common, conversing with other caueth arising from the state of government and manners. The Romans wrote their books either on parchment, or on paper made of the Egyptian papyrus. The latter, being cheaper, was of course the most commonly used. But after the Saracens conquered Egypt, in the seventh century, the communication between that country and the people settled in Italy, in or other parts of Europe, was almost entirely broken off, and the papyrus was no longer in use among them. They were obliged on that account to write all their books upon parchment, and as the price of that was high, books became extremely rare and of great value. We may judge of the scarcity of materials for writing them from one circumstance.
There still remain several manuscripts of the 8th, 9th, and following centuries, written on parchment, from which finer former writing had been erased, in order to substitute a new composition in its place. Thus, it is probable, several of these works of the ancients perished. A book of Livy or of Tacitus might be erased, to make room for the legendary tale of a saint, or the superstitious prayers of a missal. As the want of materials for writing accounts for the loss of many of the works of the ancients, and for the small number of MSS. previous to the 11th century, many facts prove the scarcity of books at this period. Private persons seldom possessed any books whatever; and even monasteries of note had but one missal. Towards the end of the seventh century, even in the papal library at Rome, the number of books was so inconsiderable, that pope St. Martin requested Sanctamand, bishop of Maeftricht, if possible, to supply this defect from the remoteft parts of Germany. In the year 875, Lupus, abbot of Ferriere in France, sent two of his monks to pope Benedict III. to beg a copy of Cicero de Oratore and Quintilian's Institutes; "for," says the abbot, "although we have part of these books, there is no complete copy of them in all France." At the beginning of the tenth century books were so rare in Spain, that one and the same copy of the bible, Jerome's epistles, and some volumes of ecclesiastical offices and martyrologies, often served several different monasteries. Among the constitutions given to the monks of England by archbishop Lanfranc, in 1072, the following injunction occurs: At the beginning of Lent, the librarian is ordered to deliver a book to each, of the religious, for the perusal of which a whole year was allowed; and at the returning Lent, those monks who had neglected to read the books they had respectively received, are commanded to prostrate themselves before the abbot, and supplicate his forgiveness. In 1299, John de Pontiffara, bishop of Winchester, borrow of his cathedral conveit of St. Swithin, at Winchester, "bibliam bene glossatam," that is, the bible, with marginal annotations, in two folio volumes; but gives a bond for the return of it, drawn up with great solemnity. For the bequest of this bible to the convent, and 100 marks, the monks founded a daily mass for the soul of the donor. If any person gave a book to a religious house, he believed, that it would be a donation merited eternal salvation, and he offered it on the altar with great ceremony. The prior and convent of Rochester declare, that they will every year pronounce the irrevocable sentence of damnation on him, who shall purloin or conceal a Latin translation of Aristotle's Poetics, or even obliterate the title. Sometimes a book was given to a monastery, on condition that the donor should have the use of it for his life; and sometimes to a private person, with the reservation that he who receives it shall pray for the soul of his benefactor. In the year 1225, Roger de Infula, dean of York, gave several Latin bibles to the university of Oxford, on condition that the students who perused them, should deposit a cautionary pledge. The library of that university, before the year 1300, consisted only of a few tracts, chained or kept in chests, in the choir of St. Mary's church. Among the statutes of St. Mary's college at Oxford, in 1446, one is, that no scholar should occupy a book in the library above one hour, or two hours at most, so that others shall be hindered from the use of the same. The famous library established in the university of Oxford by Humphrey duke of Gloucester, a munificent patron of literature, contained only 600 volumes. About the beginning of the 15th century, there were only two churches in the university of Paris, which were single copies of Cicero, Ovid, Lucan, and Boethius.

The price of books became so high, that persons of a moderate fortune could not afford to purchase them. In the year 1174, Walter, prior of St. Swithin's at Winchester, purchased of the monks of Dorchester, in Oxfordshire, Bede's homilies and St. Aulkin's psalter for twelve measures of barley and a palf, on which was embroidered in silver the history of St. Birinus converting a Saxon king. About the year 1400, a copy of John of Meun's "Roman de la Rose" was sold before the palace-gate at Paris for 40 crowns, or 33 l. 6s. 6d. The counts of Anjou paid, for a copy of the homilies of Haimon, bishop of Halberstadt, 200 facep, five quarters of wheat, and the fame quantity of rye and millet. Even so late as the year 1471, when Louis XI. of France borrowed the works of Rhyas, the Arabian philosopher, from the faculty of medicine at Paris, he not only deposited by way of pledge a considerable quantity of plate, but he was obliged to procure a nobleman to join with him as surety in a deed, binding himself under a great forfeiture to restore it. Many other instances might be cited, in order to shew how scarce books were at the period to which we now refer, and with what difficulty, and at what extravagant prices, copies of them were procured; and therefore we can be at no loss in accounting for the extreme ignorance that prevailed. But when, in the 17th century, the art of making paper was invented, and more especially after the manufacture became general, the number of MSS. increased, and the study of the sciences was wonderfully facilitated. Indeed, the invention of the art of making paper, and the invention of the art of printing, are two very memorable events in the history of literature and of human civilization. It is remarkable, that the former preceded the first dawning of letters and improvement in knowledge, towards the close of the eleventh century; and the latter ushered in the light which spread over Europe at the era of the reformation. Murat. Antiqu. Ital. vol. iii. vol. ix. Mem. de L'Acad. des Inscript. tom. ix. Hist. Lit. de France, par des Religieux Benedettiis, tom. vii. Naudé Addit. a l'Histoire de Louis XI. par Comines, ed. Frennoy, tom. iv. Robertson's Hist. Ch. v. vol. i. Whatton's Eng. Poetry, vol. i. diff. 2.

Books, to form a judgment of. Those who have treated of the subject, direct us to observe the title, the author's or editor's name, the number of the edition, the place where, and the year when it is printed (which in old books is frequently marked at the end), and the printer's name, especially if it be a celebrated one; proceed then to the preface; and index of contents, and look for the author's design, and the occasion of his writing; consider also his country (each nation having its peculiar genius), which may sometimes be learned from the dedication; if his life be annexed, run it over, and note his profession, what rank he was of, and any thing remarkable that attended his education, studies, conversation, or correspondences with learned men; not forgetting the elogies which have been given to the author, which often occur at the beginning, or even any critique or censure, especially if made by a man of judgment. If the preface does not give an account of the method of the work, run briefly over the order and disposition of it, and note what points the author has handled; observe whether the things and sentiments he produces be trite and vulgar, or solid, and fetched from greater depths. Note, whether he go in the common road, or make any innovation, and introduce any new principle.

But it is a small number of books we have opportunity of thus judging of by perusing them; besides, when we have read a book over, the judgment comes too late for many purposes. Life is too short, and time is too precious, to read every new book quite over, in order to find that it is
not worth reading. It seems necessary, therefore, to have other indications, whereby to prevent our being at the charge of procuring, or the pains of perusing a worthless book. Divers rules of this kind are given by Baillet, Struvius, Stollius, and others; which, though in reality no more than prefaces, and frequently liable to be falsified, are not without their use. The journalists de Trevoux objected to them all: "The shortest way," say they, "to judge of a book is to read it, if you be qualified in the subject; otherwise, to refer yourself to those who are so." Heuman is somewhat more explicit; making it a mark that "a book is good, when it is esteemed by persons intelligent in the subject it treats of; and when those who commend it receive no advantage from the applause they bestow on it, nor are leagued with the author in any cabal, for espousing any particular principle, system, or party, in religion or learning," Baillet, Jugem. des Scv. tom. i. b. ii. p. 121. Struv. Introduct. ad Not. Rcl. Liter. cap. 5. § 3. p. 390. Stoll. Introduct. Hist. Liter. p. i. § 11. p. 9. Budd. de Criteriis boni libri, paem. Mem. de Trev. an. 1712. Art. 17. Heuman. Confp. Republ. Liter. cap. vi. § 11. p. 280.

But more particularly, it is indicated that a book is good: 1. If the author be known to excel in that talent more immediately necessary for such a subject; or have already published anything on the fame that is esteemed. Thus we may conclude, that Julius Caesar will teach us the art of war better than Peter Ramus; Cato, Palladius, and Columella, agriculture better than Aristote; and Cicero, oratory better than M. Varro: add, that it is not enough the author be skilful in the faculty, but that he be so in the particular branches of it, concerning which he treats; some, for instance, excel in the civil law, yet not in the public law; Salmusius proved himself an excellent critic in his Exercit. Plinius, but was much inferior to Milton in his Defenio Regia. 2. If the book be on a subject that requires great reading, it may be presumed good, if the author had a copious library, or could have access to one; or if he lived in a place where books were not wanting; though here is danger too of running into excesses of quotations; especially, says Struvius, if the author be a lawyer. 3. A book which took up a long time in compounding, cannot often fail of being good. 4. Books on points of doctrine by ecclesiastic writers, are to be presumed better than those writ by the retainers to particular sects. 5. The age of a writer may also give us some indication: books, which require labour, are usually better performed by younger persons than those who are far advanced in years. 6. Another indication may be taken from the author's state and condition; thus, history written by a person who was an eye-witness to what he relates, or is concerned in public affairs, or has access to the public records, or other monuments, from whence intelligence may be drawn; who is not biased by party, or any other indirect or sinister motive, will be supposed to be good. Thus Sallust and Cicero were well able to write the history of the Roman Empire. D'Avila, de Comines, Guicciardini, Clarendon, &c. were preeminent in the civil wars they describe; Xenophon, having an employment in the Spartan state, has treated excellently of that commonwealth; and Amielot de la Houssaye, by living long at Venice, was enabled to explain the secrets of their policy. Camden wrote annals of the affairs of his own time; Thuanus had correspondence with the best writers in every country; and Puffendorf had access to the public archives. So, in literary matters, we give credit to those who have the direction of libraries. 7. The time or age wherein the author lived may give some light; every age having, according to Barclay, its peculiar genius and excellency. See Bartholin. Struv. Budd. Heuman. Baili. lib. cit.

Some judge by the bulk or size of books; following the grammarians Callimachus's rule, that every great book is of course an ill one, μηδενες μεγας και μεγας καινος; a single leaf of the Sybil was doubtless preferable to the vast annals of Volusius; yet Pliny's observations will nevertheless hold true, that "a good book is so much the better by how much it is bigger." Plin. Epil. 20. lib. 1. Martial prescribes a remedy against the largeness of a book, when that is the only complaint, read but a little of it:

"Si nimius videaris, Ferique coronide longus
Elle liber, legito pauca, libellus ero."

Yet is the smallness of a book a real presumption in its favour: he must be a poor author, who cannot furnish a pamphlet, or loose sheet, with things curious, and written with spirit; but to support the fame through a volume in folio, requires very extraordinary abilities indeed. Add. in Spec. No. 124.

There are some general maxims, which persons are frequently guilty of in passing judgment on the books which they read. One is, when a treatise is written but tolerably well, we are ready to pronounce a favourable judgment of it, and sometimes to exalt its character far beyond its merit, if it agree with our own principles and support the opinions of our party. On the other hand, if the author be of different sentiments, and espouse contrary principles, we can find neither wit nor reason, good sense, nor good language in it. For avoiding or correcting this error, it should be considered, that books are never to be judged of merely by their subject, or the opinion they represent, but by the justness of their sentiments, the beauty of their manner, the force of their expression, or the strength of reason, and the weight of just and proper argument, which appear in them. Another mistake, which some persons fall into, is this: When they read a treatise on any subject, with which they have but little acquaintance, they find almost every thing new and strange to them, their understandings are much gratified and improved by many things unknown to them before; and hence they are led to admire the treatise, and commend the author; whereas, if they had previously attained a considerable degree of skill in that science, perhaps they would have found that the author had written very indifferently, that neither his sense nor his method was just and proper, and that he delivered nothing that was not very common or very trivial, in his discourse on that subject. On the other hand, if we have made ourselves masters of any particular theme of knowledge, and surveyed it long on all sides, there is scarcely any writer who much pleases us afterwards, because we find little or nothing new in him; and yet in a true judgment perhaps his sentiments are unexceptionably just, his Illustrations clear, and his reasons forcible, and all the parts of the discourse are well connected and set in a happy light; but we knew most of these things before, and therefore they do not strike us, and we are in danger of discrediting them. There are some other follies into which persons are apt to be betrayed in forming their judgment of books. Some persons, who are of a forward and lively temper, and who are fond of intermeddling with all appearances of knowledge, will give their judgment of a book as soon as the title of it is mentioned, for they would not seem ignorant of any thing that others know; and especially, if they happen to have any superior character or possessions, they fancy they have a right to talk freely and to pronounce magisterially on every thing, even of a literary kind, that occurs. Thus, blind men will talk of the beauty.
beauty of colours, and of the harmony or disproportion of figures in painting; the deaf will prate of discords in music; and those who have no pretenions to literature, will pronounce, with an unpardonable prepossession, on books of science; and those who have little or no acquaintance with either the speculative or practical principles of religion, will arrange the best treatise on divine subjects, though they do not understand the very language of the Scripture, nor the common terms or phrases used in Christianity. Judges of another description set themselves up to decide in favour of an author, or against him, according to the company they have kept, and the judgment pronounced concerning a book by others of their own limb or size, though they have no knowledge of or taste for the subject themselves. These, with a fluent and voluble tongue, become mere echoes of the praises or censures of other men. Others, again, pass judgment from the secret stimulations of vanity, pride, or envy, and in order to justify an unwarrantable and severe censure, they will allege a mistake or two, which they have discovered, or a few sentiments and expressions not suited to their capricious taste and humour. It is, however, an indication of perverences and prejudice, to rail at any human performance because it is not absolutely perfect. Horace has given us a better example:

"Sunt delicia tamen, quibus ignovisse vienis: Namque chorsa forum reddid, quem vult manus, et mens.

Poeptique graevum perfeque remittit acutum; Nce temper feriet quedoque minusari arcus Verum, uti phara notitc in carmine, non ego panes Offendac mala, quas aut incerta fudit,

"Be not too rigidly censorious:
A thing may jar in the best master's hand,
And the most skillful archer mis his aim;
So in a poem elegantly writ,
I will not quarrel with a small mistake,
Such as our nature's frailty may excuse." Roscommon.

Another, and very frequent fault in passing judgment upon books, is this, that persons spread the fame praises, or the fame reproaches, over a whole treatise, which are justly applicable only to some detached parts of it. After all, when any person pretends to give his judgment of a book, we should consider whether he be a capable judge, or whether he may not lie under some unhappy bias or prejudice, for or against it, or whether he has made a sufficient inquiry to enable him for forming a just opinion. Watts's Improvement of the Mind and Witty, vol. v. ch. 4—5.

The importation or sale of mafs-books, or other popish books, is only prohibited by the Statutes and the Statute of the 5th of queen Anne, c. 19. empowering the chancellor and some other great officers of state, to fet the price of books; but this is now repeated by 2 Geo. ii. c. 36. § 1.

The sole right of printing books bequeathed to the two universities of England, the four universities of Scotland, and the colleges of Eton, Westminster, and Wincheller, are secured to them by Stat. 15 Geo. iii. c. 53. See Literature Property.

Books, burning of, was a kind of punishment functioned, both among the Greeks and Romans, by legal sentence. At Athens, the works of Protagoras were prohibited; and all the copies of them which could be collected, were burnt by the public cryer. Diogenes Laert. i. ix. 52. At Rome, the writings of Numa, which had been found in his grave, were, by order of the senate, condemned to the fire, because they were contrary to the religion which he had introduced. Liv. i. xl. c. 29. Phil. xiii. 19. Plutarch, in vit. Numa. As the populace of Rome were, in times of public calamity, more addicted to superstition than seemed proper to the government, an order was issued that all superstitious and astrological books should be delivered into the hands of the praetor. This order was often repeated; and the emperor Augustus caused more than 20,000 of these books to be burnt at one time. Liv. i. xxv. c. 1. l. xxxix. 16. Tacit. Annal. vi. 12. Sueton. lii. c. 31.

Sometimes the care of the execution of the sentence for burning books was committed to triumviri appointed on purpose; sometimes to the praetors; and sometimes to the ediles. Labienus, whom from his factual spirit some have called Rabienus, is said to have been the first who undertook the severity of it, under the emperor Augustus. His enemies procured a fenatusconsultum, whereby all his books, published during several years, were ordered to be collected and burnt. The thing, says Seneca, (in the introduction to the 5th, or, as others reckon, the 10th book of his "Controversie," then appeared new and strange to take revenge on learning! "Res nova et infleta, supplicia de studiis fami!" Cassius Severus, a friend of Labienus, hearing the sentence pronounced, cried aloud, that they must burn him too, since he had got all the books by heart; "Nunc me vivum uti oportet, qui illos edicit!" Labienus could not survive his books; but shutting himself up in the tomb of his ancestor, pined away, and was buried alive. It is related as somewhat singular, that a few years after, the writings of the person, who had been the cause of the order for burning Labienus's books, shared the like fate, and were also publicly burnt. In a manner somewhat similar, the works of Ben-Arias Montanus, who affixed to make the first catalogue of prohibited books, in the Netherlands,
thiethand, were afterwards inserted in a catalogue of the fame kind. The expreffion of Caius above cited gave oc-
casion to a law of Augustus against abusive writings. Ta-
cit. Annul. i. i. c. 72. When Cremutius Cordus, in his
History, called C. Caius the last of the Romans, the fe-
rate, in order to gather Truth, caused the book to be
burned; but a number of copies were conciliated and pre-
ferred from the flames. Tacit. Annul. iv. c. 37. An-
tiochus Epiphanes caused the books of the Jews to be burned;
and in the first centuries of our era, the books of the
Chriftians were treated with equal severity, of which Arno-
bius (Adv. Gentes, i. iii. &c.) bitterly complains. Efue-
bius informs us (Hist. Eel. i. viii. c. 2), that Diocleian
caused the sacred Scriptures to be burned. After the spre-
ding of the Chriftian religion, the clergy exerted against
books that were either unfavourable or disagreeable to them,
the fame severity which they had cenfurcd in the heathen
as foolish and prejudicial to their own cause. Thus, were
the writings of Arians condemned to the flames at the con-
cil of Nice; and Conflantine threatened with the puni-
ishment of death those who should conceal them. Socrates,
i. i. c. 6. The clergy assembled at the council of Ephesus,
requested the emperor Theodosius II. to caufe the works of
Nelidius to be burned, and their request was complied
with. Cod. l. i. tit. 5, 6. The writings of Eutyches
shared the like fate at the council of Chalcedon; and the
fame practice of burning books thought to be heretical
with regard to religion, or injurious to the state in a political
view, has been imitated in fubfquent ages, and in various
nations even of the Christian world.

Divers other ancient testimonies concerning the burning

Books, Privilege of. See Privilege.
Books, whitening of. The following process for whitening
prints, printed books, and paper, has been announced and
described by M. Chaptal. Simple immersion in oxygenated
muriatic acid, for a longer or shorter space of time, ac-
cordirig to the strength of the liquid, will effedce an
engraving. But in whitening the paper of a bound book, it
is neceffary that all the leaves should be maffontered by the acid,
and therefore the book must be well opened, the leaves
separated; and the boards must be made to reft on the edge of
the vellum containing the whitening liquor. This liquor
in the process attains a yellow tint, and the paper becomes
properly white. At the end of two or three hours,
the book may be taken from the acid liquor and plunged
into pure water; and the water should be renewed every
hour to extrad the remaining acid, and to disfipate the
disagreeable smell. In order to render this procifce more
effectual, the book-binders detroy the binding, unfew the
book, and separate its leaves; they then place the in cafes
formed in a leaden tub, with very thin flips of wood or glass,
of that the leaves may lie flat and separate from one another
at very small intervals. The acid is then gently poured into
the tub, without deranging the leaves. When the paper is
become sufficiently white, the acid liquor is drawn off by a
cock at the bottom of the tub; and its place is supplied by
clear, fresh water. The leaves are then dried, and, after
being prelled, re-bound. The leaves may with greater
advantage be placed vertically in the tub. With this view,
M. Chaptal contrufled a wooden frame, adjusted to the
proper height, according to the size of the leaves proposed
to be whitened. This frame supported very thin flips of
wood, at the distance from one another of half a line.
In each of these intervals it placed two leaves, and kept them
fixed in their place by two small wooden wedges, pushed in
between the flips. When the paper was whitened, he lifted
up the frame with the leaves, and plunged them into cold
water, to take off the remaining acid, as well as the smell.

By this operation books are not only cleaned, but the paper
acquires a degree of whitenefs superior to what it poftced
when firft made. This acid will also serve to destroy ink spots;
but it has no action upon spots of oil, or animal greafe;
however, a weak solution of pot-ash will effecufully
remove flains of that kind. To oxygenate the muriatic
acids, it is only neceffary to dilute it, and mix it in a very
strong glass vessel with mangleafe, in fuch a manner that the
mixture may not occupy the whole content of the glafs. Air-
bubbles are formed upon the surface of the liquor; the
empty space is filled with a greenih vapour; and, at the
end of four hours, the acid may be further diluted
with water, and then used. In order to remove spots of greafe
from book and pigtis, M. Defchamps, member of the Phi-
llofophical Society at Lyons, recommends to take out as
much as poftible of it by means of blotting paper; and then
to dip a small brush in the effential oil of well rectified spirit
of turpentine, heated almost to ebullition, and draw it gently
over both fides of the paper, which must be carefally kept
warm. This operation must be repeated as often as the
quantity of greafe imbibed by the paper, or the thicknefs
of the paper, may render neceffary. When the greafe is entirely
removed, the paper may be restored to its former whitenefs,
by dipping another brush in highly rectified spirit of wine,
and drawing it, in like manner, over the place which was
ftained, and particularly round the edges, to remove the
border that would fhil prefent a ftrain. Bibilofhico Eco-
nomique, vol. i. See Blemiching.

Books, common place. See Common-Place.
Books, text. See Text.
Books, is also used for a part or division of a volume, or
large work.
In this knife we lay the book of Genesis, the first book of
Kings, the five books of Moses, &c.—The Digest is con-
tained in fifty books, the Code in twelve books.

Books are usually subdivided into chapters, fometimes in
fecciones, or paragraphs; accurate writers quote chapter
and book.

Books is also used for a list or catalogue of persons' names.
—Such among the ancients were the cenforial books, being
tables or regifters containing the names of all those who
were cenfured or taxed under Augustus. Tertullian affeurs
us, that our Saviant's name was found in the cenforial book

Books, in Matters of Commerce, denote the several regifters
wherein merchants and other dealers keep their ac-
counts. Hence to book, is to regifter in a book.

We lay, such a perfon's books are in good order; mer-
cants cannot possibly do without books; they are even
obliged by the laws to keep books. But more or fewer are
required, according to the nature or extent of their dealings,
or the precision and exactness they defire therein.

The ancients had also their books of accounts; witness
the codex accessi & expensi, fo often mentioned in Roman
writers; and the patrimonial books, which were rentals,
containing an account of the lands, goods, and chattels, and
other effects belonging to each perfon.

Among the defects to which the trial by jury is subject,
one is the want of a compulive power for the production
of books and papers belonging to the parties. In the hands of
third perfons, they can generally be obtained by rule of
court, or by adding a clause of requisition to the writ of
"subpoena," which is then called a "subpoena duces tecum."

But,
BOO

But, in mercantile transactions especially, the sight of the party's own books is frequently decisive; as the day-book of a trader, when the transaction was recently entered, is really understood at the time; though subsequent events may tempt him to give it a different colour. And, as this evidence may finally be obtained, and produced on a trial at law, by the circuitous course of filing a bill in equity, the want of an original power for the same purposes in the courts of law is a material defect.

Book-binding, the art of sewing together the sheets of a book, and securing them with a back, and strong paste-board fides, covered with leather, &c.

Binding is distinguished from stitching, as in the latter the leaves are only fewed, without bands or backs.

We say, French binding, law-binding, marble-binding, binding in parchment, in sheep, in calves leather, &c. also half-binding, wherein the leaves are generally left uncut, and only the back covered with leather, the pasteboard sides being covered with marbled, or blue paper. Dutch-binding is where the backs are of vellum. The Italians are still contented to bind in a coarse, thick paper, called binding alla ruftica, the inconvenience of which is its being liable to wear out without careful use. Without doubt, the art of binding is almost as ancient as the science of composing books; and both the one and the other followed immediately the first invention of letters. Whatever the matter might be, on which men first wrote, there was a necessity of uniting the several parts together; as well for the making them of one piece, as for the better preserving them; hence the origin of book-binding.

According to Olympiodorus (apud Phot.) it was one Phyllinus, a learned man at Athens, who first taught the use of a kind of glue, to fasten the several leaves together; on which account a statue was erected to him.

Books, the manner of binding in volume, i.e. of gluing the leaves together; that of rolling them on round pieces, or cylinders of wood, appears the most ancient; though that of binding them square, and of sewing several quires one over another, lays claim to considerable antiquity. The first of the two, which we call Egyptian binding, held a long time after the age of Augustus; but it is now disused, excepting in the Jewish synagogues, where they continue to write the books of the law on vellum sewed together; making, as it were, only one long page, with two rollers and their clasps of gold and silver, at each extremity.

The form now in use is the square-binding, which is said to have been invented by one of the Attali, kings of Pergamus; to whom we likewise owe the manner of preparing parchment, called in Latin, from the name of his capital, Pergamaena, or Charta Pergamaena.

Books, manner of binding. The first operation is to fold the sheets according to the form, viz. into two leaves for folios, four for quartes, eight for octavos, &c. which the workmen do with a flop of ivory or box, called a folding-flick; in this they are directed by the catch-words and signatures, which are the letters with the numbers annexed to them, at the bottom of the pages. The leaves thus folded, and laid over each other in the order of the signatures, are beaten on a block with a heavy hammer to make them fold and smooth, and then prepped. Being thus prepared, they are sewed in a sewing-prefs, upon pack-threads or cords, which are called bands, at a proper distance from each other, and in a convenient number. And, as the bands are done by drawing a thread through the middle of each sheet, and giving it a turn round each band, beginning with the first, and proceeding to the last. The common number of bands is fix in folios, and five in quarto, octavo, &c. Sometimes they use a law to make places for the bands, which are sunk into the paper, so that the back of the book, when bound, is smooth, without any appearance of bands. After this the backs are glazed, the ends of the bands being opened, and scraped with a knife, for the more convenient fixing of the paste-boards; then the back is turned with a hammer, the book being fixed in a prefs between boards, called backing-boards, in order to make a groove for admitting the paste-boards. The boards being then applied, holes are made for drawing the bands through, the superfluous ends being cut off, and the parts hammered smooth. Then the book is preffed in order for cutting; which is performed by a particular machine called a plongy, to which is fixed a knife. After this the book is put into a prefs called the cutting-pres, betwixt two boards, the one lying even with the prefs, for the knife to run upon; the other above it, for the knife to cut against.

The book being cut, the paste-boards are squared with a proper pair of iron shears; and it is then ready for sprinkling, gilding, blacking, or marbling the leaves. The colours with which is is sprinkled, are usually vermilion, or fat-green; which is done with a brush made with hog's bristles, holding the brush in one hand, and moving the hair with the other.

In the French-binding a book is put in parchment, i.e. a flip of parchment is applied over the back between each band, and the ends pasted on the inside of each paste-board. This preparation, called indufion, seems peculiar to the French binders; who are enjoined by ordinance to back their books with parchment on the penalty of 50 livres, and the re-binding of the book; it is done in the prefs, where the back being grated to make the paste take hold; the parchment is applied; and they afterwards add glue to fortify it.

In 1799 a patent was granted to Mr. John Williams and Mr. Joseph Williams, stationers, London, for an improved method of binding all sorts of books. By the specificaion it appears, that this invention consists of a back, of a semi-circular, semi-oval, or any other curved form, turned a little at the edges, made of iron, steel, copper, brass, tin, or any other metal, ivory, bone, wood, vellum, paper, leather, or any material capable of retaining a firm situation. This back, being put on the book before bound, so as just to cover but not to press the edges of the paper, will, when the book is opened, prevent its spreading on either side, and cause it to rise in any part which is opened to nearly a level surface. This firm back, turned at the edges, so as to cause all sorts of books to open freely, is the object of this patent.

The method of binding, practised by the inventors, is as follows: they forward the paper in the usual manner; few on vellum slips, glue, cut, clothe, and board, or half-board; and put on the firm back by fastening it at the sides, through holes, by vellum, or securing it by inclining it in vellum or velvet wrappers, or other matters, pasted down upon, or drawn through the boards. Mr. Ebenezer Palmer, stationer of London, obtained a patent in 1800 for an improvement in the mode of binding books, particularly account books of merchants. This consists in the addition of a certain metallic chain, which is made and applied in the following manner: first, provide several small bars of metal, about the thickness of a halfpenny, or more, according to the size and thickness of the book; the length of each bar being from half an inch to several inches long, in proportion to the strength required in the back of the book; at each end of every bar is made a pivot of different lengths, in proportion to the thickness of two links, which they are to receive. Each link is made in an oval form, and contains two holes, proportioned
portioned to the sizes of the pivots; and these links are of the same metal as the hinge; each of them being nearly equal in length of the width of two bars. The links are then riveted on the pivots, each pivot receiving two of them, and thus holding the hinge together, on the principle of a link-chain or hinge. There are further two holes or more of different sizes, as required in each bar of the hinge or chain, by means of which each section of the book is strongly fastened to the same; which hinge, so fastened, operates with the back of the book, when bound, in such manner as to occasion the several sections to open fo as to bring them on a parallel with each other, and consequently admit the ruled lines being written into, without any inconvenience, close to the back.

Manner of gilding books on the edges. The book, being put tight into the press, between two boards, is scraped with a knife called a scraper; and after that with another called a smoother, in order to take out all scratches. Being thus made smooth, they scrape a little yellow ochre upon the book, wet it with a little size-water, and rub it off with some clean shavings. The gilding size is made with the white of an egg, mixed with water, and beat well together. The leaves being wetted with the size-water, with a brush, the gold is then laid upon it, and afterwards dried before the fire. When dried, it is burnished off with a dog’s tooth fet in a handle. See Gilding on paper, &c. Blacking the leaves is done by fine antimony, the leaves being wet, and the antimony rubbed upon them until quite dry, when it is burnished like the gold.

The head-band is now added, which is an ornament of thread or silk, of two or three colours, placed at each extreme of the book, across the leaves, and woven or twisted, sometimes about a single, and sometimes a double piece of rolled paper, or, what is more laffing, of glued paper-thread.

For the covers; the skins used undergo several preparations, which we shall explain in calf, as being the leather most used; and as being that to which all the rest with a little variation may be referred. The calf-skin, being moistened in water, is cut to the size of the book, and the thickness of the edges pared off on a marble stone kept for that purpose. The cover is next smeared over with paste, made of wheat-flour; then stretched over the paste-board on the out-side, and doubled over the edges withinside. They then cord the book, or bind it firmly between two boards, to make the cover stick to the paste-boards and the back; on the exact performance of which depends a great part of the truth and neatness of the book. The back is then warmed at the fire to soften the glue, and the leather of the back is rubbed down, with a folding-flick or bodkin, to let and fix it close to the back of the book. It is now set to dry, and when dry, uncorded: the book is then washed over with a little paste and water, the edges and squares blacked with ink, and then sprinkled fine with a brush, by striking it against the hand, or a flick; or with larger spots mixed with vitriol, which is called marking. Two blank leaves, on each side, are then to be pasted down to the cover, and, when dry, the leaves are turn’d in the press, and the cover rolled on the edges.

The cover is now glazed twice with the white of an egg: it is then filled plain, or with gold; and at last polished with a polishing iron, polished hot over the glazed colour. If the book be required to be lettered, they paste a piece of red Morocco on the back, between the first and second band to receive the title in gold letters; and sometimes a second between the next bands underneath, to receive the number of the volume.

The plain binding, properly so called, is now complete; the gilding on the back and cover, as it makes a part of the book-binder’s business among us (though, with the French, &c. it is a distinct profession), we shall here subjoin.

Manner of gilding books on the back and covers. In ordinary binding, they gild little else but the back, and the outward edges of the cover. On the backs are gilt the title of the book, &c. with flowers, rosettes, knots, fioris, &c. between the bands; on the covers are sometimes added compartments, arms, &c. All these ornaments are made with each its several gilding tool, engraved in relief; either on the points of puncheons, as those of letters, rosettes, &c., or around little cylinders of brafs, as the lines, embroideries, &c. The puncheons make their impression, by being preffed flat down; and the cylinders by being rolled along by a handle, to which they are fitted on an iron flay, or axis.

To apply the gold, they glaze those parts of the leather, whereon the tools are to be applied, three or four times with a liquor made of the whites of eggs diluted with water by means of a sponge; and, when nearly dry, they slightly oil them, and then lay on pieces of leaf-gold, and on these apply the tools, with a careful even pressure of the hand, or roll the cylinders, both the one and the other, reasonably hot. If the figures be large, and require a great relief, as arms, &c. they are beat or preffed down. The gilding thus finished, they rub off the superfluous gold, and polish the whole; the glos of which is greatly aflied by a final preffing between horns peculiar for the purpose.

Our book-binders, for gilding on rough leather, make use of re-in dried and powdered, instead of whites of eggs; and the gold leaf, first cut to a proper size, is laid hot somewhat oiled flamp, and preffed down: and thus the re-in melts only in those parts where the hot flamp is applied, and the gold fixes on it, whilft the other parts of the leather remain rough as at first. Dr. Lewis’s Com. Phil. Tech. p. 615. See Gilding.

Ahat. Fritich, chancellor of the university of Jena, has a dissertation expresses concerning book-binders, Dr. Biplogitis; wherein he treats of the laws prescribed by those artificers, and the tax or price settled by the magistrate for binding books, of every sort in sheep-skin, vellum, &c.
