VOL. VII.
CASTRAMETATION.

Castrametation is, in its strict and limited sense, the art of tracing out and disposing of, advantageously and regularly, the different parts of a camp on the ground. But taken in its more indefinite and unlimited acceptation, it extends to and is connected with all the ordinary operations of the campaign, as well as the conducting and management of sieges. Under the spirit of these considerations, an able officer, in choosing situations for the encampment of his troops, will endeavour to derive advantages from every situation, of which the variety is almost endless and indefinite, that nature presents to his view, as plains, mountains, passes, hollow ways, ponds, marshes, rivers, particularly such as are navigable and commodious for the transportation of forage and provisions, rivulets fit for forming inundations, woods convenient for making abattes and furnishing abundance of palisades and fire-wood; positions advantageously situated for works, for commanding and keeping open his communications with those tracts or districts of country from which he draws his supplies of forage and provisions; for covering and protecting his convoys; for securing a sufficiency of ground commodious for drawing up his troops on in order of battle, if necessary, and for their facile and expeditious performance of all the requisite movements without disorder or confusion even in the face of the enemy; and posts well calculated for bridding the enemy's operations, and checking his inroads into his country, whilst they facilitate his incursions into the enemy's. He should not only be capable of discerning these advantages, but should also be able to turn them immediately to account without suffering the opportunity of profiting by them to escape him. And under the lead of these considerations, when the besieging army is unavoidably encamped, as is indeed often the case than otherwise, that the different parts of it are separated from one another by rivers, great or small, ravines, or other obstacles and obstructions, he should know how to open and establish such communications between them, in the most expedient manner, as will render their co-operations, in either covering, forwarding, and protecting the different branches of the approaches, or in checking and curbing the assailers of the besieged, as convenient, easy, and efficient as possible. He should not only be able to discern, almost immediately, the positions in the environs of the place most advantageously situated for facilitating these purposes, but ought to occupy them whether they be a little too near to or too far from the enemy's works, taking care to keep the rear of his camp (the form or figure of which he must change or vary from what is customary, but, at the same time, secondum artum to make it suit his situation and circumstances) out of the reach of their cannon. He should know how to determine without loss of time the precise distance from the works of the place he invests, necessary for the safety and security of his camp against annoyance from them, that he may avoid the unnecessary labour, delay, and trouble of throwing up too extensive lines of circumvallation. He should carefully guard against his camp's being looked into by commanding ground near any part of it in front, on either flank, or in the rear. For it is better to occupy such eminences with good redoubts or to make the lines themselves communicate with them, than to leave the camp exposed to danger or molestation. And in the disposition or arrangement of the line of circumvallation for its defence, he ought to avoid himself of heights, riviers, ravines, steep banks, and slopes, dikes, ditches, pits, walls, buildings, fences, abattes, thicketts, &c. and, in short, every thing that can be embraced by it, and from which any additional strength or advantage can be derived to it.

In every country its quarter-master general ought to be a man of the most extensive military knowledge and information, as ruinous consequences may result from his being a peron of a different description. And the officers under him ought also to be men of the first intelligence. They ought
ought not only to understand how to trace out ground for troops to encamp in the usual or customary manner, but they ought also to be so far conversant in geometry and in the doctrine of ratios or relation, as to be able without confessing themselves to the rules prescribed by any writer on castration, which are applicable to every situation, with such prudence and readiness to vary the form of an encampment in such a manner as to make it suit the circumstances they are placed in, preferring, at the same time, in the different parts of it order, regularity, and due proportion. They should possess knowledge enough to enable them to discern immediately which of two positions, apparently in other respects alike advantageous for an encampment is capable of being secured and defended with the least trouble and difficulty. They ought to understand the principles of fortification, and particularly of irregular construction, without which the camp itself cannot be carried to much perfection. And they should, in short, be well acquainted with the doctrine of politics and the combinations of attack and defence, which unit, if, form the sublime part of war.

In a nation, or tribe of people, even the most savage and uncivilized, has had a particular mode of encamping. By which a regular method of forming an encampment was first introduced, cannot with certainty be determined. A home knowledge, however, of geometry, was necessary for taking out a camping site; but it is more than probable, that regular encampment was not made use of in Egypt. The great numbers of people all crowded together, and exposed to the inroads of canes and other produce, was much worked in that country, must have been encamped, as they could not return home daily. But the first, before they left Egypt, must have been often and long encamped, and, of course, after the manner of the Egyptians. Mofes gives us no account of the way in which they encamped, either in Etham, or near Pelusium, in front of Bad-sephon, before he carried them into the Red Sea. But in the regular chapter of the book of Numbers he delivers a general view of what he was commanded to observe in regard both to their castration and order of march. They were ordered to pitch their tents, every man by his own camp, and by his own standard, throughout their several hosts.

Those, who were under the standard of Judah, viz. the tribes of Judah, Thadoc, and Zebulan, to the amount of 185,000 fighting men, formed the east line of the camp, to the right side of the sun. They, on descending, were the first, or lead the van, and were commanded by Nahum, Nelson, and Libah.

Those under the standard of Reuben, viz. the tribes of Reuben, Simeon, and Gud, amounting to 151,500 warriors, formed the north side of the camp. They were commanded by Liban, Swhat, and Ezemp.

Those under the standard of Ephraim, viz. the tribes of Ephraim, Manasse, and Benjamin, amounting to 187,500 warriors, formed the west side, and were commanded by Liban, Gudrei, and Abdon.

Those, however, on a march, did not follow immediately those that formed the north side of the camp, but the Levites, who with the tabernacle followed the warriors under the standard of Reuben.

Those under the standard of Dan, viz. the tribes of Dan, Asher, and Naftah, to the number of 177,000 fighting men, formed the north side, and were commanded by Annez, Paged, and Ahira. Those, on a march, brought up the rear.

In the middle of that immense encampment, the Levites, to the number of 21,000, encamped with the tabernacle of the congregation afar off from the sides of the camp, with Mozes and Aaron and his sons in front of it, towards the east.

It is probable, may be said evident, that this huge camp was a square, as nearly 600. For although the number of fighting men that pitched their tents under the standard of Judah, on the east side of the camp, amounted to 185,450, exceeding the number of those who encamped toward the west, or on the opposite side of the camp, under the standard of Ephraim, by 72,050, yet the number of warriors encamped on the north side of it, under the standard of Dan, amounting to 157,050, exceeded the number of those encamped on the south side, under the standard of Reuben, by 6,150 only. Now had they encamped in the latter manner as we must now suppose they did, and with the same depth in each front or side of the camp, we would have been a trapezium, having it sides to one another as the numbers 185,450, 157,050, 157,050, 138,550, 21,000. This however, would have been a very awkward and inconvenient figure for it; by making the depth of the encampment on the east side to that on the north side, as 170 to 157; and the depth of it on the west side and south side respective as 157 to 157, they might easily have made their camp a square. And it is more than probable, that it was a perfect square when the ground adapted for it. For Mofes was made in all the knowledge and learning of the Egyptians, and they were sufficiently acquainted with geometry to know that all rectilinear figures with the same perimeter, the square contains the greatest area.

Mofes neither ordered nor how their tents were arranged, nor whether they formed their camp with an unbroken front. That fanciful French writer, however, M de l'Ecluse, in his "Traite de l'Attaque et de la Defense des Places des Autres," article third, modestly affirms, that Mofes always interchanged his camps. In speaking of lines of circum-vallation and counter-vallation, he uses the following words: "On ignore que des Egyptiens, des Juifs, des Almogins, ils en ont servi premier. Je penfe heros plus pour les premiers que pour les autres, parce que je les crois plus anciens. Mofes le ret a nous toujours dans les campements, l'escarre ne doit pas qu'il eût le premier, qui ne fût le ro des forces de precuation, et lorsqu'il parle de l'escarre des villes ou ne voit rien, que puifle marquer ou faire un effet que c'est plus par la premiere fois."

Mofes tells us, that the Israelites, on quitting their camp, moved in four large bodies, of three tribes each, with the Levites and the Tabernacle of the congregation between the second and third of these divisions.

The Romans also, on quitting their camp, marched in four principal bodies or divisions, but the extraordinary led the van; next to them marched the allies of the right wing, who were followed by the baggage of both; after them marched the first of the two Roman legions, with its own baggage behind it; then followed the second legion with both its own baggage behind it, and that of the allies of the left wing, who closed the rear. The cavalry marched in files in the rear of the respective bodies to whom they belonged, and sometimes on the flanks of the bundles of burden lined with the baggage, keeping them together, and covering them from shot. When any attack was expected to be made upon the rear, the extraordinaries of the allies were placed there, instead of leading the van.

The two legions and the two wings of the allies changed their places daily on a march, which the four principal bodies of the Israelites do not appear to have done, that they might
CASTRAMETATION.

might enjoy by turns the advantage of arriving first at water and forage. When they were threatened with any immediate danger, and were marching through an open country, they advanced in three parallel lines behind one another, with the baggage of each line in its front.

Before the end of a march, and the approach of the army to the place of encampment, a tribune, accompanied by some centurions, advanced to examine and survey the ground, to determine the situation of the camp, and on which side of it the legions could be most conveniently encamped.

As to the castrametation of the Romans, according to Polybius, and during the commonwealth, see the article Camp. The French Encyclopædia, following Justin Lycurgus, chiefly make it nearly an equilateral quadrangle or square; but Polybius makes it a perfect square.

As to the castrametation of the Greeks, we understand from Polybius that they had no invariable, fixed, or determinate method of encamping. Xenophon, in treating of the Lacedæmonian republic, delivers Lycurgus’s sentiments respecting castrametation, and informs us, that that lawgiver regarding the four angles of a quadrangle, or square, as inferior, enjoined the circular form for a camp, unless it were secured by a mountain, or had its rear covered by a wall or river.

His words are these: "Εννοεῖ δε καὶ ἐπηρετηθῆσθαι τριερότερα τριερότερα τριερότερα τριερότερα, χρείας Λυκοργῷ δὲ καὶ μὲν γέγορο τὰ τὰ γενεάτα, τὰ τετραγωνίων ἀρχήτων υπώκωται, καὶ δύο ἐπιστάξις ἔχει, τὸ τετράγωνον ὑποτάσσεται τοιούτῳ ἐπιστάσιμ διότι τοιούτῳ ἂν ὑποτάσσονται αὐτότως, καὶ οὐλόμενον ἁπατήν τοιούτῳ." Even this mode of castrametation, delivered by Lycurgus, was not fixed or determinate, but might vary with the circumstances of ground and situations; and we have the authority of Polybius for asserting, that the Greeks in general, when they encamped, considered chiefly the natural strength of the position they chose for that purpose, and accommodated to it the admeasurement and disposition of the different parts of their camp, partly from anxiety to avoid the labour of throwing up an intrenchment round it, and partly from the persuasion that works raised by art are less secure than those that are made by nature. In compliance with what the nature of the ground demanded, they were accordingly obliged not only to give their camp occasionally every kind of figure, but also to vary the positions and dimensions of its several parts, as the place for each was favourable or otherwise. Hence, this judicious historian tells us, arose that great inaccuracy, namely, that the Grecian soldiers never knew either his own place in the camp, or that of the body to which he belonged. On the other hand, he says, the Romans willingly submitted to the task of throwing up an intrenchment, and to other painful labours, for the sake of the advantage they found in employing a method of castrametation that was never changed, and which rendered all the parts of the camp familiar to the army.

The Romans, on their marches, cheerfully underwent much greater fatigue for the security of their camps than the Greeks were willing to submit to, each folder frequently carrying three or four palisades for the intrenchment. This was a labour, Polybius tells us, which in the discipline of the Grecian armies was regarded as impracticable; whereas the Romans performed it without much difficulty. The Greeks, he says, on their marches, were hardly able to support the toil of moving along their own bodies. But the Romans, after flinging their shields with the leather braces behind their shoulders, took their javelins in their hands, and were at the same time able to carry the palisades. They also discovered more judgment both in the choice and shape of their palisades than the Greeks, whose aversion from labour and fatigue must have frequently left their camps in a state of great insecurity.

Besides the account given by Polybius of the Roman method of encamping, there is a description of their castrametation, given on a mutilated scroll or label by Hyginus, who observes to have been a camp and land measure in the time of Trajan and Hadrian, when the empire was in its highest pitch of glory, as Trajan had extended it beyond the Tigris on one side, and beyond the Danube on the other. Hyginus’s fragment was first published in 1605, but in a form so defective and mutilated, as to be hardly intelligible. In 1665, it was published at Amsterdam, with a very curious, learned, and elaborate commentary on it by Rhabdus Hermannus Schadenius.

In the time of Marius, the military affairs of the Romans without doubt underwent a considerable change, which probably affected their ancient system of castrametation, but to what extent it is impossible to determine. But the alterations then introduced gradually occasioned a great departure from their former rules and regulations. It is no wonder then that their castrametation, according to Hyginus, differs so materially as it does from that of Polybius. Though the empire of the Romans was at its utmost extent, and exulted in full force and vigour, their language was on the decline, and its purity in a great measure lost. The legions, by refiling long in the conquered countries, adopted by degrees the barbarisms of the natives, and became familiar to their manners and customs. The attacking of large bodies of mercenaries to them gave rise to a different establishment, both for their national and auxiliary troops; in the latter of whom they could not always place so much confidence as formerly, and occasioned the creation of many new officers and appointments, which rendered a new method of castrametation necessary. Hence, this writer makes use of terms that are not to be found in any other author, and seem to have been unknown in the time of Polybius. The scroll or label containing his rules of castrametation is entitled "Hygin Gromatici de Castrametatione Liber."

He informs us, that a complete army consisted of three legions, with their supplementa, or auxiliaries, making use of this number for the purpose of exemplifying or illustrating his castrametation, and observing at the same time that the largest army was composed of no more than five or six such legions. He tells us, that every camp, as often as circumstances will permit, should be one half longer than it is broad, or have its length to its breadth in the ratio of three to two. Such a camp he calls castra tertio. He accurately makes the length of a camp for three legions equal to 2,400 Roman feet, and its breadth equal to 1,600 feet. General Roy, however, says that the particular measure is given by him do not correspond exactly with these general dimensions, and makes the fun of them, as he has collected them from the original, give the length of the camp equal to 2,270 feet only, and the breadth equal to 1,600 feet, the one falling short of 2,400 feet by 50, and the other exceeding 1,600 by 20.

When the camp was longer in proportion to its breadth, than in the ratio of three to two, it was called castra clausa, because a general founding of all the martial instruments together became necessary, as the buccinum or bugle horn founded in front of the praetorium could not then be distinctly heard at the distant parts of the camp.

Hyginus divides the length of his camp into three unequal parts, by streets extending across the whole breadth of it. The first of these, lying in front of the praetorium, he calls the praetorium. The second, lying between the principal street
street and the quintan street, and in the middle of which stands the praetorium, he calls the latera prætorii; and to the third, situated beyond the quintan street and behind the praetorium, he gives the name of reventura.

The principal street, according to him, was 60 feet broad, and had the middle of it before the centre of the praetorium distinguished by the name of gruma, from the crux-ruffed, or some similar instrument, which was used for tracing out the right angles of the camp. And those employed in this business, or in making allotments of lands in the conquered countries for the veterans, were probably called grumacei. The praetorium street, leading from the gruma perpendicularly to the principal street, is also 60 feet wide. The breadth of the quintan street is 30 feet as well as that of the singular street, which runs quite along the four sides of the camp, dividing the interior part of it from the exterior, or that which lies between the said street and the intrenchment. But when an army consisted of five or six legions, the breadth of each of these streets was equal to 10 feet. The interval between the tents on the outside of the singular street, and the intrenchment making part of the exterior division of the camp, is every where 60 feet wide. This camp commonly had only four gates, viz., the right and left principal gates, the decuman gate, and the praetorium gate. Hyginus says, that the decuman gate received its name from the tenth cohort of the legion's being encamped near it. General Roy, however, places this gate differently from Hyginus, and differs also from Schelius in several particulars in regard to the interior divisions and arrangement of the camp.

It was the practice of the Romans during the commonwealth to place their own legions in the centre, both in the camp and when drawn up in order of battle. Hyginus, however, places the most of the legionary troops in the exterior part of the camp without the singular street, and nearest to the rampart, for the defence of which they were more to be depended on than the mercenaries, in whom they did not confide so much as they formerly used to do in their socii or allies. He alleges that the foreign troops, by being kept thus within, or surrounded by the Roman legions, were more easily rendered obedient and attentive to their duty. They certainly had it left in their power to defect, or carry intelligence to the enemy, than they would had they been encamped next to the intrenchment. The form of his camp must in a great measure have depended on the proportion which the number of the legionary troops bore to that of the mercenaries, or auxiliaries, since when the last was but small, the Roman cohorts could encamp with a greater depth and left extended front, leaving more space between the singular street and the rampart; and when it was great, with a smaller depth and a more extended front, leaving less space between the said street and the rampart.

Hyginus tells us, that a complete century of foot consisted of eighty men, and that one tent held eight men. When all the men of a century then were off duty, they would have required ten tents. But as part of each century was always on duty, they pitched only eight tents, leaving thereby sufficient room for that of the centurion. For every tent a space of 12 feet in length was allowed. The length of the ground then occupied by the men of the century and the centurion was equal to 120 feet. The breadth of the space allowed for each tent was equal to 10 feet. Five feet more were allotted for the arms, and nine for the bat-horses, or beasts of burden. The whole breadth therefore of the hemistrigium, or half-striga, amounted to 21 feet; and the length of it was what Hyginus terms intalulina. Another hemistrigium lying contiguous to this, but in an order reversed, that the horses might stand those in the other, and feed at the same manger, made a breadth of 48 feet for one striga, to which, if a width of 12 feet along the whole length of the space occupied by it for a striga, between it and the next striga be added, we get 60 feet. The whole space then, including the said street of 12 feet wide, allotted for one striga, or two hemistrigia, consisting of two centuries or 160 men, contained 120 multiplied by 60 feet, or 7200 square feet. And a cohort, which consisted of six centuries, occupied of course 21,600 square feet. For the Hygian camp of a Roman army, composed of three legions, with their supplementa or auxiliaries, consisting of 47,626 men, see Plate of Cæstremetation, figs. 1, 2, 3.

It is evident that in the Hygian camp the fame number of troops occupied a much smaller space than they did in the Polybian camp. The Roman armies under their emperors were more impatient of labour and fatigue than they were under the commonwealth, which led to the shortening of the length of the intrenchment and the crowding of as many men as possible into a given space. They also got into the practice of employing a much greater proportion of cavalry to their number of infantry than they did before their government became imperial. And the cavalry were commonly exempted from working on the intrenchments. Thise and other caules made them depart gradually from their ancient systenm of castramentation, as described by Polybius, and make their camps sometimes rectangular, sometimes triangular, sometimes circular, and, to avoid labour, give it different forms to suit the circumstances of advantageous ground, and the necessity of their situation.

Distribution
## Castrametation

Distribution of the troops in the Hyginian camp, containing three legions, with their supplements, or auxiliaries.

N.B. Hygines does not give the number of the emines imperatoris, or chief attendants on the emperor; neither are we told how many camps there were with the regular (fri-
date or drivers), when they were to go out against the enemy, used to encamp in the phalanx or the phalan-
men; but when defeated, a heavy battle, were placed in the retentura, or in some other part of the camp.

Through general Hygines's principle of proportion or diff-
tinction between the different cohorts, He does not mention

Hygines places 12 ft of the camp, without the regular street, or the exterior part of the camp.

General Roy thinks that Hygines be the fana meant the front of the cohort, and by his depth, it is
regard to the fight of tents he came from Schloss, who
knew them turn parallel to the regular street, whereas he
places them perpendicular to it. He says that the width
of the camp with the regular street was every where equal
to 1260 feet; that the length of the prestentura within
the same street was equal to 720 feet; that the distance
across the pretentura, from the principal to the quintus dec.,
was also equal to 720 feet; but that the distance across the
pretentura was only equal to 450 feet, or two thirds of the
distance of either of the other two parts. See figs. 1, 2, and 3.

Of modern Castrametation.

The invention of gumps wider and the application of it to
military purposes, have necarily rendered modern castramet-
tation very different from that of any nation among the an-
cients. The principal object of Europeans in forming their
encampments is the convenience or facility of drawing up
their troops at the heads of them. Hence it follows that
we should necessarily in such a manner as to be able with
expedience and without confusion, to assemble and parade
them in the way division which is regarded as the best
for fighting in the situation we happen to be in. The order
of battle therefore should determine and regulate the order
of enencampment. Consequently, the place of each regiment
in the line of battle should be at the head of its own encamp-
ment, and the extent of the battle from the right to the
left of the camp should be equal. The front of the troops
formed in line of battle, with the same intervals in the one
as in the other. The front of principal line of the
camp, commonly directed or laid out in such a manner as
the commandant may direct, the other.

It being once admitted that the army should be enencamp-
med in the order in which they ought to fight, it was
much matter to deliver general rules for the adaiinencamp-
ment and the tracing of camps.

A camp does not always supply a politics, though a
position occupied usefully supposes a camp.

The dispositions and the order of battle unavoidably vary
with the nature of the ground and situations. The arrange-
ment of the troops in their camp vary as circumstance
demands. The order of battle all frequenly depends on the
views and intentions, genius and capacity of the General,
and on his facility in executing and relative powers. That
wonderful man and extraordinary general. Amidst the loss
of the no less celebrated Amorcan Baraer, made a differ-
ent order of battle and arrangement of his troops in almost
every engagement with the Romans. Whenever the ground
and weather admitted of his employing fagagets and his
enemies, he was sure to pierce it as at Treba and the
Thasymene lake. And when he found no circumstances of
ground, situation, or weather, that he could convert to his
advantage, he changed the disposition of his troops and his
order of battle, as at Cannae.

Were there but one fixed and determine order of battle,
or method of arranging troops for action, there need be
but one invariable mode of encamping, or method of
castrametation. But nature delights in variety. Ground is
admirably various and diversified, and fire arms are by no
means foated to all this diversity, or to the effect of con-
sequent accidents. The Roman army, order of battle, or
manner of fighting, were adapted to all times and in all sorts
of ground, and were calculated for combating equally well
in every district, and for preventing a front in the enemy by a
side or rear movement, from whatever quarter they might be
foully attacked. The Macedonian phalanx, on the other
hand, from which our manner of forming troops in files is
manfully derived, was adapted to only one time and place,
and to see fixed or determine manner of action. It was
fitted and tardy in its movements, and its whole strength,
like that of our infantry, confined in its remaining an un-
broken and entire body, or in the conjoint action of those
who composed it. Whenever they were obliged to en-
gage the Romans individually, they were sure to be de-
feated and destroyed. The phalanx could neither move
forward nor backward, nor to the right or left. It could
not break, and having engaged, it was certain to be
out breaking and leaving intervals or openings. If troops
engaged with it in close action, surrounded with arms and
armour, alike calculated for either resistance or encoun-
ter, to rush in and attack these separated and broken parts,
both on their flanks and in the rear. The phalanx, there-
fore, never engaged the Romans on ground uneven and ir-
regular, without being defeated, and meeting its destruc-
ction. Of this, the battle of Cynocephale was a remark-
able instance. The phalanx also, like our infantry, was not
well adapted either to defensive or offensive operations in
the dark, or during the time of night; whereas, the Ro-
man arms and mode of fighting were alike fitted both to
day and night. The Macedonian phalanx, like a modern
army in close action, when its fire becomes useless, required
ground that was level, plain, naked, and free from every
obstacle, such as fences, ditches, walls, woods, thick-
ness, breaks, chasms, and rivers, &c. The troops in it left
all their strength and capacity of doing when they engaged either in separate
companies, or man with man. A Roman soldier, on the
other hand, when once armed and ready for service, was
equally fit for moving in any time and in any place, or
upon any emergency of an army. However sudden or un-
expected, and however grave its issues, he and his com-
pany were able to engage in the same manner and the
same spirit as Gallic foot troops, or even in the very
heat, or with great part of it; whether in a separate
company or a small unit of his own. Magnificyn
in attempting to present itself as an army and attempt
a country as this would be directly breaking and getting
into disorder whenever it met with the level or bare ex-
posure, or exposed. A few hundred active men, armed
each with the Roman shield and a light hick' would be
very few against any almost equal numbers of closing
around with the phalanx; but one part of such
a phaenant, body or an army, and of course using
a dreadful carnage among them with very little loss or injury
to themselves. Were the magnificy to fire on their closing
with them, the flame would only increase their confusion
and facilitate their defeat. If they attempted to de-
 fend themselves either immediately or in separate and small
bodies they would certainly perish. They would therefore
be reduced to the alternative of either surrendering them-
sefes prisoners without resistance, or of throwing away
their arms, and running as fast as their legs could carry
them;
them; for they could not carry their musquets along with them and retire with half the celerity that troops armed in the other way could follow them. Were there any reason for apprehending an invasion of this country, ten thousand active men armed in this manner would be of more use for the purposes of defense than sixty thousand of either sharpshooters, or common infantry. But custom and prejudice, and perhaps ignorance too of the proper mode of defending it, may possibly prevent the adoption of such a measure. As to cavalry, it is manifest that they can be of but little use in either attacking or defending it, since there are but few situations in it where they could be brought to act with advantage and effect.

As to the men in the phalanx had shields, or bucklers, as well as spears, the width or breadth of a file in it was equal to three feet. A Roman soldier standing under arms also occupied three feet, but in order of battle he necessarily occupied six feet, in order to have the free use of his large shield on his left arm, and the gladion in his right hand in action.

Though the arrangement of troops in a camp must vary with the nature of the ground, it is customary to suppose for each corps of an army such a fixed or determinate order of battle as can be made use of on a plain or level ground. Such an order serves for forming the tableau, delineation, picture, or description of the force of the army, and for regulating the order of service in regard both to the superior officers, and the troops that they command.

The number of men that forms a battalion varies in different countries of Europe, and has varied at different times. The space necessary for constituting the breadth of a file also varies: some make it equal only to 22 inches, but others, perhaps with better reason, allow two feet for it, as the three ranks are thereby left confined in their fringes.

Troops are divided not only by battalions and squadrons, but also by regiments and brigades.

An army generally consists of infantry, cavalry, and artillery, and may be called or denominated the union or junction of the battalions, squadrons, and artillery. The formation or arrangement of these three corps constitutes the order of battle. And this name or appellation for the said arrangement comes from the principal design or intention of making it, which is always to give battle.

The number of lines, on which an army ought to engage, is not at all fixed or determined; for the ground, the disposition of the enemy, the number of troops, &c. may render material changes or alterations necessary. It is a point, indeed, that no determination can be come to, which will suit every circumstance of ground or situation.

An army, however, when drawn up in order of battle, is generally ranged in two lines with a corps of reserve behind them, and confining like them of battalions and squadrons, to succour those parts that may be hard pressed and in danger of yielding or giving way. This corps is stronger or weaker as occasion requires. For the most part the infantry is posted in the centre of these lines, and the cavalry on the wings. The ground, however, makes it necessary sometimes to place the cavalry in the centre and the infantry on the wings, and sometimes part of the infantry on the flanks of the position, and the greater part of the cavalry on one wing with the remainder of it behind the infantry.

The common practice of posting the cavalry on the wings of the infantry, and in a line with it, seems to be in various respects improper and injudicious. It cannot advance quicker than the infantry without leaving its flanks of both uncovered and exposed. It cannot in such a position either protect the infantry or receive protection from it. Disposed of in this manner it therefore renders the movements of the whole slow and tardy. It is usually alleged that the cavalry is posted on the wings of the infantry in order to cover its flanks. This, however, is a very bad reason, for cavalry cannot form a flank for itself, but infantry may. The arrangement of our different species of troops, and the forming of them in files after the manner of the phalanx, excludes every idea of quickness or celerity, which is the very life and soul of military manoeuvres, and alone can render them successful.

It is generally a maxim in the order of battle to place the second line 900 feet at least, or 1000 feet behind the first, to prevent the enemy’s balls or shot from reaching it. This distance may, and most probably will change during the course and progress of an engagement. Attention, however, should be paid to it in placing the troops in order of battle.

It is customary to place fewer battalions and squadrons in the second line than in the first, when the first is full, in order that the first, if routed or thrown into confusion, may have sufficient intervals to pass through for the purpose of recovering from their disorder, and regaining regularity and order.

All the infantry of Europe commonly fight en ligne plaine, or in continuous lines, without any intervals between the battalions, but such as are necessary for the guns, for each of which about 20 feet is usually allowed. When intervals are admitted between regiments that consist each of more than one battalion, or between brigades, an additional allowance of 40 feet is generally made.

Sometimes hussars and dragoons are placed out of the line to cover the flanks of the cavalry. This, however, is for the most part a bad and injudicious disposition; for cavalry never can be so disposed of as to afford an efficient cover and protection to the flanks of cavalry, though infantry may. They are laid to be out of the line, because they ought to be posted a little behind the lines. All troops indeed, or bodies detached for any service, are laid to be hors de ligne, or out of the line.

In the camp, the same distance or interval of 20 feet for each piece of artillery is allowed between the battalions, or ought to be, as in order of battle; and when the divisions are admitted between regiments, or brigades, 40 feet more are allowed.

The situation of the park of artillery is not precisely fixed or ascertained. It is customary, however, to place it for the most part either behind the centre of the second line of infantry at the distance of about 1000 feet from the same, and in a line with the reserve; or behind the reserve, at the same distance of about 1000 feet. On other occasions, as circumstances make it advisable, or necessary, it is placed towards the centre at a greater or less distance from the first line of infantry. For the form of a park of artillery, see Plate, Castreametation, fig. 4.

When an army then encamps in three lines, and the park of artillery is in a line with the reserve, the depth of the camp cannot well be less than from 2500 to 2750 feet; and when the park of artillery is about 1000 feet behind the reserve, the depth of the camp must be from about 3500 to 3750 feet.

The depth of the tents of a battalion depends on the manner in which the companies composing it are encamped, whether by a whole company, a half-company, or a quarter-company, in each row of tents perpendicular to the front of the encampment. But, including the tents of the officers, futters, and servants, the depth is usually about 200 feet, and that of a squadron is about 400 feet.
The front or auxiliary houses of the first line, are of any length < 20 feet; beyond the front each house is continued in front of the house which determines the extent or length of the camp, and on which are placed the colours and standards of the troops that occupy it: and those of the second line are commonly about 150 feet behind the officers' tents. There ought to be nothing, however, in front of the camp that can in the smallest respect interfere with the movements and re-formation of the troops in order of battle.

The intervals between files of cavalry are different in different countries. And their depth, when encamped, will, of course, be influenced by that of the camp, which, itself, is not regulated by certain rules and arrangements founded on custom or usage.

If \( n \) be supposed to represent the number of men in a battalion, \( d \), the number of men in a file, and \( b \), the breadth or width of the file, the front of the battalion will be generally expressed by \( \frac{n \times b}{d} \). Thus, if \( b = 2 \) feet, and \( d = 3 \), the front of the battalion in feet will be equal to \( \frac{2n}{3} \), which, when \( n = 600 \), gives 400 feet for the front of the battalion; when \( n = 800 \), or the battalion is 800 strong, gives 533.33 feet for its front; and when \( n = 900 \), or the battalion is 900 strong, gives 600 feet for its front; and so on.

If the width of the file be supposed equal to 12 inches, or \( 1 \) foot, and \( d \) be equal to 3, the front of the battalion will be expressed by \( \frac{11 \times n}{18} \) feet. And if, in this case, \( n \) be 600, or the battalion 600 strong, its front will be equal to \( \frac{11 \times 600}{18} \) feet = \( \frac{6600}{18} \) feet = 366.66 feet 8 inches. If the battalion be 800 strong, its front, in this case, will be equal to \( \frac{11 \times 800}{18} \) feet = 488.88 feet; and if it be 900 strong, its front will be \( \frac{11 \times 900}{18} \) feet = 550 feet; and so on. And whatever is the length of its front in order of battle, the same ought to be the front of its encampment, when the ground and circumstances will permit.

If \( d \) be supposed equal to 2, or the files to be only two men deep, which is as deep, perhaps, as they ever should be, when it is intended that all the men shall fire without hurting or wounding another, one another, the length of the front of a battalion in each of the foregoing supposed cases will be but one-third greater. When the number of men in it is given, the length of its front will be as the breadth of the file directly, and the depth of the file in number of men inversely. When the number of men in it and the breadth of the file are given, the length of its front will be inversely as \( d \), the depth of the file. And when both the breadth of the file, and its depth in men are given, the length of the front of the battalion will be directly as the number of men in it.

The breadth or width of a file of cavalry is generally equal to three feet. The Macedonians allowed three feet of their measure for the width of a file in their phalanx, when drawn up in order of battle; and the Romans allowed also three feet of their measure to a folder when standing under arms, but its feet to him when in order of battle. If \( n \) then be supposed to denote the number of men in a squadron of cavalry, and \( d \), as before, the depth of the file in men, its front will be expressed generally in feet, by \( \frac{3n}{d} \), which, when \( d = 3 \), is simply equal to \( n \). Hence, then, it appears, that the front of a squadron, drawn up three deep, is equal to as many feet as there are men in it, and that its front, when it is drawn up only two deep, is equal to half as many more feet as there are men in it.

The width of the large squares in a camp depends also, in a great measure, on the number or encamping the companies. For, if \( f \) denote the front, \( h \) the length of a tent, \( n \), the number of the rows of tents, \( r \), the width of each of the small squares, \( m \), their number, \( q \), the number of the large squares, and \( v \), the variable width of one of them, we shall have \( v = \frac{f - 2q - m}{3} \).

The camp maxim most commonly delivered are the following:

To give the camp the same length of front that the troops occupy, when drawn up in order of battle, whatever be the width or depth of the file.

To make the troops encamp by battalions and squadrons, except the royal artillery, who usually encamp on the right and left of their parts, wherever it is placed, with the train horses in the rear of the same.

To place the bread-waggons in the rear of the camp, and as near as possible, for the convenience of distributing the bread easily.

That the commander in chief should encamp in the centre of his army, or, at least, at such a convenient distance from it, that a speedy and easy communication may be kept up at all times between head-quarters and every part of the camp.

To pay particular attention to the convenience of winter fuel and storage, and to cleanliness, for the preservation of health among the troops.

The highest and most important branch of castremetation, however, consists in the choice of situations proper for encampments and for engagements. The doctrine of positions, indeed, and the combinations of attack and defence, form the sublime part of war. And in illustrating this subject, we conceive we cannot do better than adopt the concise observations of marshall Saxe, who, in point of natural endowments, genius, and talents as a commander, as well as of military information, acquired by experience, study, and reflection, was certainly inferior to no general that has appeared in modern times.

Of situations proper for the encampment of armies, and for engagements.

It is the part of an able general, to derive advantages from every different situation which nature presents to him; from plains, mountains, hollow ways, ponds, rivers, woods, and an infinite number of other particulars, all which are capable of rendering great services, when they are converted to proper purposes: but although they make to material an alteration, both in situation and circumstance, wherever they happen to be, yet, as such advantages are frequently overlooked, till the opportunity of profiting by them is lost, it may not be unaccountable to enter into some detail upon the subject.

Let us then, in the first place, suppose a piece of ground divided by a rivulet, and a chain of ponds. See Plate, Castremet. tab. fig. 5 and 6. A represents the army marching up to attack BB, whose infantry is at first drawn up in one line to cover the ponds; but, as soon as the enemy arrives within reach, my infantry in the front of thee ponds, (fays the marshall,) marches back by the intervals or banks between them, to form a second line; and my cavalry is at the same time advanced upon the right, to keep in awe the enemy’s left wing, which movement alone is sufficient to disconcert him; if he attempts to attack this cavalry, it is to repel the intervals between the ponds, which are guarded by bodies of infantry, that are posted immediately behind them.
This manœuvre will have so long engaged the enemy's attention upon his left, that he will not have sufficient time to change his disposition, or to reinforce his right; because the moment my cavalry is arrived upon my right, I attack all that part of the enemy's line that lies between me and the rivulet, which very probably I shall throw into confusion. His right wing being thus defeated, the rest of his army will be assailed in front and rear by my two wings of cavalry, and in flank by all my infantry. If he inclines in the left to the right, in order to prevent a front to my infantry, he will thereby expose his left flank to the troops which I have polled upon my right, and upon the intervals between the ponds: under these circumstances, therefore, it will be impossible for him to make any movement, without being thrown into confusion.

According to this disposition, I suppose the enemy's army to consist of double the strength of mine: and although it may be imagined, that the cavalry upon my right is in danger of being cut to pieces, yet the more the attention of the enemy is taken up with an object in his front, the more he will be entangled in the snare that is laid before him; for I shall thereby be furnished with a better opportunity of falling upon his rear; after which my cavalry must be more than commonly unfortunate, if it be not able to make good its retreat by the intervals between the ponds, where the enemy will certainly not dare to pursue it.

Fig. 7, represents the two armies in another situation, where AA is to attack BB: C, C, C, are three strong redoubts thrown up at the distance of three hundred paces in the front of BB, furnished each with two battalions, and every thing else that may be necessary for their defence: D represents some detached cavalry: E, E, are two flanking batteries: F, F, two battalions posted in two redouls to cover the batteries. I suppose the enemy's army AA to be twice as powerful in numbers as BB; nevertheless, in what manner is he to attack me in this disposition? It is impofible for him to march up in line of battle, without being broken and disordered, till he has first rendered himself master of my redoubts; in attempting to do which, he will be exposed to a severe flanking fire from my two battalions; and to pass the redoubts, and leave them in his rear, will be impracticable: if then he resolves to attack them by detachments, I shall in like manner make others to maintain them; in which I must have considerably the advantage, on account of the damage that he will unavoidablely sustain from my cannon: if he advances with his whole army against them, I give the signal for my cavalry, which is concealed behind the wood, to move up at full speed, and fall upon his rear; at which time I also march up, and charge him in front; being, therefore, at once embarrassed by the redoubts, thrown into some disorder, and attacked in rear, there is all the appearance of my obtaining an easy victory.

This is an excellent disposition, where you can be certain that the enemy is either inclined, or obliged to attack you; for one cannot possibly be too careful in avoiding every step that may correspond with any hopes or expectations of his. This is a maxim in war never to be departed from, but in extraordinary cases, where no fixed rules can be given. A good opportunity for engaging should never be neglected, merely because the situation may happen not to be slightly agreeable to your fancy; for you must form your disposition according as you find it, and decline the attack altogether, unless you can make it with advantage; by which I mean, unless your flanks are well covered; unless you engage a small part of his army with a large part of yours; can amuse, or keep a check upon him, by the means of any small river, marsh, or other obstacle that may lie between you; supported by circumstances of which nature, you can attack him with confidence, although considerably inferior in numbers, because you will risk nothing, and may obtain a great deal.

Suppose, for instance, his army, BB, to be divided by a river, in the manner represented in fig. 8, and that I am to attack him with AA in that situation: I shall, therefore, make the following disposition for it. With my right wing I shall keep in awe his left, and with my left try all efforts to defeat his right: according to appearances, I shall be able to pierce him in the part marked C, upon the back of the river; for it is but reasonable to suppose, that the strong must overpower the weak; in consequence of which advantage, as the communication between the two divisions of his army will be thereby cut off, and the left, in which his principal strength confided, be no longer able to sustain the right, he will be rendered incapable of maintaining his ground; and, finding himself exposed both in front and flank, will undoubtedly retire.—Let us proceed to another example.

A is the enemy's army which I am to attack with B: the rivulet between us is supposed to be every where fordable; and the encampment of A to be made upon its banks, as is usually the custom in such situations, as well on account of the protection which it naturally affords, as for the convenience of the water: the enemy being in this disposition, I arrive towards the evening, and encamp with B on the opposite side. As he will not be inclined to trust to the uncertain event of an immediate engagement, he will undoubtedly, therefore, not pass the rivulet, or quit the advantage of his poll, to attack me in the night-time; on the other hand, I rather imagine that he will be altogether taken up in providing for the defence of it: on my side, I shall only leave one week line opposite to him, and marching all night with the remainder, gain the position, C. I have nothing to fear from the enemy, in making this movement; for he will certainly not venture to pass the rivulet, or to leave his poll unguarded, on bare furnaces or conjecture only. The day arriving I discoveries me upon his left flank, as well as in front; after which it will be impossible for him to make any disposition, or to form any order of battle, without being thrown into confusion; for I shall fall upon him before he can have sufficient time to finish it; but his attention will principally be taken up, in sustaining his poll upon the rivulet, which I shall attack at the same time, with the troops that were left on the opposite side for that purpose: he will detach some brigades to oppose me upon the left, which, arriving en detail, and having to engage with a large body, drawn up in good order, will easily be repulsed; innumeth that he will be in a manner totally defeated, before he can be even able to persuade himself, that the real attack was made on this side; and, after having thus at length discovered his mistake, he will scarce to be in any kind of capacity to remedy it.

Fig. 9, represents another situation, in which the enemy's army, AAA, is supposed to be formed in separate bodies, and extended to a considerable distance all along a large river, in order to cover a province, as is frequently the case. AAA is, therefore, to defend the river, and BBB is the offensive army, endeavouring to pass it; and extended in like manner upon the opposite borders. These large rivers have generally plains on both sides, bounded by mountains, out of which issue small ones, or rivulets, that are sometimes of a considerable size, and that discharge themselves into the greater: by the means, therefore, of such a rivulet, one must endeavour to build a bridge, unknown to the enemy; for
in this he the great difficulty of passing all rivers after having then prepared your bridge all along the rivulet, you are at this time near that part of the river marked C, where you are to force your passage; in which case, I take it for granted, you will be able to succeed, especially if you make at the first time two light attacks at the places marked D and E: the enemy will not dare to vacate any of his posts, neither will the general offices, planted in different quarters, execute any orders they may receive to that effect; for as, at this time, they will be engaged themselves, and as each will fear, of his to be the real attack, they will then have time to be induced, not unadvisedly, to sally, that their commander in chief had not been informed of it; during all this time the grand effect is making at the place between the rivulet and the mountain marked F. The first step to be taken after the passage, is to posts yourself of the enemies; by which means you divide the enemy, and, having cut off his communications, he can hardly hope to time his arrival afterwards so well, as to be able to attack you on both sides at once; and although he even does, he will, nevertheless, be easily demolished: the circumstance of your being posted of these advantages, without having suffered any loss in the obtaining of it, will add to his confusion: for, notwithstanding your passage should be disputed, yet the opposition you meet with can never be considerable enough to prevent it; especially when you have used proper precautions, and made your disposition with judgment. After you have once taken post, and erected your bridge, for which four hours are a sufficient space of time, and as much more will be required for the passage of 5,000 men, you may allow the enemy twenty-four hours to prepare into your real defense, and twenty-four more to allisable either half of his army, at the place in which he has attacked you; but even this will be rendered impracticable, because I suppose you to be effectually covered, after you have passed, by the rivulet on the one side, and by the mountain on the other.

All the large rivers that I have been produce a great variety of situations where passages of this kind may be executed; and smaller ones afford likewise the same; but they are seldom quite to commissioons, because the pangs and mountains which surround them are usually not so advantageous, nor the rivulets so considerable. In short, by discernment one may reap advantages from a thousand different sorts of situations; and a commander void of that cannot possibly be expected to do any great things, even with the most numerous armies.

The marshal concludes these remarks on the choice of situations for encampments and engagements with the following observations upon the battle of Malplaquet. If, instead of polling the French troops in bad entrenchments, the three woods over-against the hollow ground had been only cut down, and three or four redoubts thrown up in it, supported by a few bridges, I am of opinion (he says) that things would have taken a different turn; for, had the allies attacked them, they must have lost an infinite number of men, without ever having able to carry them. It is the property of the French nation to attack; but when a general is unwilling to depend altogether upon the exact discipline of troops, and upon that great order which, according to the present system, is always necessary to be observed in actions, he ought, by throwing up redoubts, to introduce the method of engaging in detail, and of attacking by brigades; in which he might certainly have succeeded very well. The first shock of the French is scarcely to be resisted; nevertheless it is the part of a general to be able, by the prudence of his disposition, to renew it: and no means can facilitate this so much as redoubts; for you can always

C A S

CASTRATION. a book, among Boodkellers, is the taking out of some lefs, Iheft, or the like, which renders it imperfect, and unfit for sale. The word is also applied to the taking away of particular passages, on account of their objection, too great freedom with respect to government, &c.

CASTRATION is also used among Gardiners, in speaking of melons and cucumbers; where it signifies the same with pruning or removing of other plants.

CASTRATION, in Surgery, from 

CASTRATION, in Surgery, from caphra, "quia castrum facit," the operation of rendering any animal incapable of generating, by the excision of the testicles in male subjects, and of the ovarics in females. This operation is commonly named GELIDING and SEPULRING among farriers, who are in the constant practice of thus stimulating various brutes for domestic use, &c. Even several of the watery tribe of animals have sometimes been castrated, for the purpose of rendering them more fat and juicy for the table of epicures! This operation has been performed by the Turks, Persians, Egyptians, and Hebrews, time immemorial, espiously upon their slaves, from motives of jealousy: nor was it unknown to the Greeks and Romans, as appears from the writings of certain ancient medical and liturgical authors; and, even in the present day, the Italians are so barbarous as to calibrate great numbers of male children, with a view to preserve their infant voice for singing! See Eunuch. The effect on the physical constitution of a man is the same; whether the testicles be injured by contusion, so as to break down their natural texture; whether the spermatic vesicles be oblitered, still leaving the testes entire; or, whether
C A S

ther those organs be wholly removed by excision. In any of these cases, the offence was regarded as so atrocious, by the old laws of England, as to amount to felony: "et fe-
quirit aliquando pena capitis, aliquando perpetuum exi-
hum, cum omnium honorum ademptione," (Blaekst. fol. 1344); and this, says Judge Blackstone, although the crime of mayhem was committed upon the highest provocation: (Comment. vol. iv. b. iv. c. 15.). See Mayhem. But, in our pre- 

cence, the has cannot affect regular-bred Surgeons who per-
formance the operation, only with a view to the good of their pa-
tients; notwithstanding, a different opinion has been held by 
certain writers, who affirm, "that it is penal in Physicians and 

C A S

Surgeons to excise even with consent of the party:" (See Encyclop. Brit. vol. v. p. 250, edit. ult.) It becomes, however, a doubtful and nice point, on some occasions, to decide upon the necessity and probable advantages of castrat-
ing a man.

We shall here say nothing of the corresponding more cruel mutilation in women, as it is very properly exploded 

from surgical practice; and although we are told by Anthe-
numen, Helychius, Sindus, Galen, Arbistote, and others, 

that the female ovaries (formerly called testicles) have 

actually been atrochemed by some barbarians, it is doubtful whe-
ether most of the cases alluded to did not rather consist in 
padlocking, or infestation; which Cornelles Cellius de-

scribes, as having been exercised also on boys. But, for 
a more detailed history of the origin and extension of this 

practice, as an act of policy or refinement, we refer to vol. 

i. of M. Dutard's Hist. de la Chirurgie, Introd. pp. 36-44. 

Paris, 1774; and to M. Mahon's pothumous work, entitled "Medecine 

Legale et Police Medicale," 5to. vol. 11. Paris, 1801. We shall now offer a few 

remarks on this operation, as it concerns the practical 

surgeon.

Castration is advisable in any case, where the life of a 

person is considerably endangered by a change of structure 

and loss of function in the testicle; as well as in many other 
cases, where the removal of an indurated and greatly enlarged 
testis would materially contribute to the relief or accommo-
dation of a patient. It can very rarely be requisite to ex-
tirpate a testicle for the existence merely of an abscess, or 

for varicocele veins of the spermatic cord; though this 

operation has been sometimes resorted to, under such cir-

cumstances. But when it has been resolved on as proper 

to be done, the following are the most approved modes of 

operating:

After having shaved the hair from the affected side of the 

scrotum and pubes, the patient is placed upon a table of a 

proper height, with his head and shoulders somewhat ele-

vated, his legs and thighs at some distance from each other, 

and his knees a little bent; and in this posture he must be 

secured by two attendants. Or, as Mr. Minnina observes, 

the patient may be placed upon a high and strong chair, 

while the operator sits upon a low one, or kneels down be-

fore him. The skin of the anterior surface of the scrotum 

is then drawn into a fold, in such a manner, that the inci-

sion by which this fold is to be separated, shall reach from 

the top to the bottom of the scrotum. The operator holds 

this fold at one end with the fingers of his left hand, while 

an assistant holds it at the other, and cuts it at once com-
pletely through with a bistoury. Mr. Theden draws the 

fold of the scrotum, with the aid of an assistant, as tight as 

the skin will admit; after which he thrusts his bistoury through 

this fold, with its edge turned upwards and the back direct-

ed towards the diseased testicle; he then raises the knife up-

wards, and thus cuts through the whole fold of the skin in 

the quickest manner, whereby he thinks the patient is spared 

a great deal of pain.

This incision may be so long, that its upper extremity 

shall reach above the abdominal ring, whilst the lower 

extremity terminates an inch higher than the base of the 

scrotum. Should the incision be found too small, it must 

immediately be enlarged either at its upper or lower ex-

tremity, as it ought to extend over the whole tumour, in order 

that the tumica vaginalis may also be cut through in the same 

direction. Although it is desirable that this incision should 

be made precisely in the middle of the fold, this is in some 

rare cases impracticable, on account of the dilated blood 

vessels being situated there, the division of which would 

produce a violent hemorrhage, when another place must 

be chosen for making the incision. But should these vessels 

occupy a very large extent, we are obliged to cut them 

through, in which case the bleeding arteries must be secured 
or compressed by an assistant, whilst the operator is making 

his second incision.

The lips of the wound are now drawn asunder at both 

sides, to the distance of some inches from each other; or, the 

operator directs them away from the tumica vaginalis, in 

order that he may gain more room. When there is any 

fluid contained in the tumica vaginalis, this must be divided 

from top to bottom, with the same knife, as in the hydro-
coccyx. If we now find the diseased testicle for the greater 

part detached, we lay hold of it with the left hand, separate 

it here wherever it is attached, and divide its stronger pos-
terior adhesion, with the scissors, in such manner as at the 

same time to separate all the diseased substance that may be 

found there; after which the spermatic cord is separated 

above from all its adhesions, and the whole of the cellular 

substance diseased away from it. The spermatic cord being 

thus laid bare, the operator accurately examines it, and if it 

be in its natural condition, he immediately ties it very 

firmly, (with many fringing waxed threads, twitted together), 

an inch above the diseased part, and then cuts off the testicle 

half an inch below the ligature. After this, the spermatic 

cord will be immediately retracted towards the abdominal 

ring, in which situation it must be kept without stretching it, 

and consequently the ligature, the end of which is fastened 

over the old pubes by means of adhesive plaster, must not be 

drawn any tighter, but held loose. By this means, and by 

the application of a little lint under the end of the spermatic 

cord that has been cut, it is prevented from having too much 

fluids laid upon it, as well as from forming its adhesion too 

low.

In most cases, however, it might be advisable to detach 

the spermatic cord from above down to the place where it 

is intended to divide it, and not to disengage the testicle till 

after the cord has been tied. For the excision of the testi-
ice is always combined with some degree of pain and spasm 

of the spermatic cord, which may be avoided by tying and 

dividing the spermatic cord, before we cut out the testicle.

Mr. Theden having (he says) observed various nervous 

affections, such as spasms and epileptic symptoms, to super-
vene upon the tight application of ligatures, adopted the 

Tamponade, the advantage of which he maintains upon the 

following grounds: After some hours the artery contracts 

so strongly that no hemorrhage is any longer to be appreh-
ended; the pain and irritation of the spermatic cord is 

avoided; a swelling of the spermatic cord, and a conglomera-
tion of fluids in the cellular substance situated on the outside 
of the peritoneum, and at the back, which may frequently 
give rise to fatal consequences, never take place when this 
method is adopted, as they do when ligatures are employed.

He performs the operation in the following manner: he first 

lays a piece of agaric, equal in size to the circumference of the 

spermatic cord, upon its divided extremity, and over 

that
that a larger, which he prefixes chiefly upon that part where the spermatic artery lies, and then pulls them, with a very gentle prehrief, towards the abdominal ring, so as not to excite the slightest pain to the patient. He then applies close to the divided spermatic cord several bunches of seraped lint, covers all the wounded parts with the same substanctie, wets the whole with his arquebuse diluted with water, and again directs the attendant to place his finger upon the spermatic cord. Finally, he covers the whole of the disclings with comprefles, which are also wetted with the arquebuse. For security's sake, he directs the spermatic cord to be kept constantly gently con prufed, for the space of twenty-four hours, by attendants who relieve each other.

Mr. Le Blanc also believes, that the fatal conquequences, which so frequently follow cafonation, generally depend upon the too great tightness with which the spermatic cord is tied. On this account, he directs that the ligatures should be drawn only moderately tight, and indeed of drawing them tight, to apply again, and secure it upon the part for several hours, by a gentle prehrief with the hand.

Mr. Warner stops the haemorrhage after cafonation, by applying gentle prehrief to the vessels, by means of his thumb and fore-finger, with which he lays hold of the vessel for the space of several minutes; he has also found the application of a small piece of linen to the orifice of the vessels, to answer his purpose without occasioning the slightest degree of pain.

But though the tamponade has been also used by other practitioners with success, it is, however, judiciously considered by the greater part as not perfectly safe. For reasons, which, though well known, are however very important, Mr. Marshall condemns it in the strongest terms, and recommends tying as the safest remedy; but the method, according to which he performs this operation, has something peculiar to itself, which will scarcely come into general use. He considers the prevention of the retraction of the spermatic cord into the abdominal ring, as the principal cause of all the troublesome symptoms. He therefore always separates the spermatic cord as high as the abdominal ring, loosening both it and the tefticle from all its adheions with the neighbouring parts, by means of his finger or a sharp instrument. He then divides the spermatic cord, an inch below the abdominal ring, and ties it, applying under the string, which conufts of four waxed threads, two small comprefles, in order to prevent its cutting the parts; besides which, he considers it to be very useful, to pull the spermatic cord into the abdominal ring, which consequently cannot be done without making an incision into the ring.

Mr. Lader concludes from his experience, that the spermatic cord may be tied, without there being reason to apprehend dangerous conquequences, provided we use the precaution first to separate it from the neighbouring parts to which it adheres, and tie it, with a broad ligature, gradually, and not tighter than is necessary. For this purpose, he uses a ligature, conuisting of five or six strong threads, which he applies loose round the spermatic cord, after having separated both that and the testicle completely from all the surrounding cellular substance; he then draws the spermatic cord gently forwards, cuts it through with a pair of scissors, and gradually tightens the ligature till the haemorrhage ceases, upon which he makes a second knot, and cuts off the ends of the ligature so as to leave some inches of the threads hanging out of the wound. For the sake of greater security, he applies, besides this ligature, sometimes and then narrower ones in a similar manner.

Mr. Morfinna, however, is of a contrary opinion. The ligature, which with him is formed of three strong waxed threads, he introduces at the proper place under the exposed spermatic cord, and fastens it anteriorly, with a double knot, in such a manner, as to draw the whole string as tight as possible, in order that all the parts included in the ligature may be, in a manner, crushed. The double knot he further secures by a single one, in order that it may not get loose. This violent method of tying, he says, at first produces exquisite pain; but that is only momentary, and afterwards nothing of it is felt. By this means almost all the violent symptoms, which generally succeed the operation, may be avoided, and the cure will be greatly acceleratod. Only when the ligature has not been drawn sufficiently tight, or when, in consequence of the spermatic cord being much loaded with fat, or not sufficiently detached from the cellular substance, it again becomes loose before the nerve has been destroyed, the pain, and sometimes also the hemorrhage, returns, which is frequently followed by nervous affections.

In order to prevent such accidents, he always applies a second similar ligature loose round the string, fastening the ends of the string, with a paff, upon the patient's belly, in order that in case of necessity, particularly if a haemorrhage should occur, they may be immediately nufed. When the patient, after the application of the ligatures, still feels pain in the spermatic cord, extending to the abdominal ring, the surgeon may conclude, that the ligatures have been applied too loose, or at least that the nerve has not been completely destroyed. In this case, he must renew the ligature, by applying a second string at the same place, and in order to prevent haemorrhage and all the other symptoms, he should continue to tighten it, till the pain entirely remits. Mr. Richter entirely concurs in this opinion, and appeals to experience in proof of the assertion, that a ligature drawn perfectly tight produces far less violent symptoms, than one which is only moderately tight, and merely irritates, instead of altogether suppressing the vital actions. Mr. Pearson, of the Lock hospital, whose instructions will be hereafter a-duded, is of the same opinion.

The method of stopping the haemorrhage employed by Mr. Sibold, is done without including the nerve in the ligature, whereby he thinks all the dangerous symptoms may be obviated; as the stopping of the haemorrhage is the only purpose for which the ligature is applied. He draws the spermatic artery forwards, with Bromfield's tenacleum, and ties it, without including any other part of the spermatic cord in the ligature, and without giving the least pain to the patient by the operation. Applying the ligature round the whole spermatic cord, he entirely condemns, and expresses his surprise that surgeons, notwithstanding all the dangerous conquequences that have been found to arise from it, still fasten to tie the spermatic artery quite separate from all the surrounding parts; an operation, which has not only always succeeded with him, but has likewise been always performed with great facility.

But after the excision of the testicle and the application of the ligature, should some other artery, besides the spermatic, either in the internal or external coats of the scrotum, bleed profusely, it is proper either to draw it forward with a needle and tie it also, or when this cannot be done, to apply pressure and styptic remedies.

When the scrotum is perfectly found, or when we are sure that all the indurated parts have been entirely removed from it, we ought, as Mr. Fearon advises, to endeavour to effect the healing of the wound by the first intention; for which purpose the divided parts must be gently drawn together, in order to bring the lips of the wound in as accurate contact as possible, in which situation they must be secured
C A S

C A S.

fenced by means of adhesive plaster; or, as Mr. Lodier ad
dvices, two futures may be applied, and between these long
flips of adhesive plaster.

In other cases the wound is to be filled up with dry lint,
and the lips of the wound drawn somewhat nearer together
by means of long slips of adhesive plaster, which are covered
with a pledge spread with ointment; over this is laid, a
thick, lint and dry compress, and the whole is secured with
the T bandage. After the dressings have been applied, the
patient is put in bed, where he should lie with his feet con-
fstantly stretched out. Mr.Schumacker directs us to lay the
patient, after the operation, in a horizontal posture upon
mattresses stuffed with horse hair, in order that the divided
portion of the spermatic cord may always keep the same
position, and not contract when the knees have been
drawn upwards, and are afterwards extended. This hori-
zontal position which is adopted by most practitioners, Mr.
Murinna conceives to be inconvenient, and therefore places
the patient on his back, with his head and shoulders some-
what elevated, and his thighs moderately bent.

The lint, that has been introduced into the wound, must
be suffered to remain there, till it spontaneously separates
in consequence of suppuration, which generally happens on
the fourth or fifth day; till which period the renewal of the
dressings must also be deferred.

After every thing that can easily be separated has been
extracted out of the wound, it must be carefully cleansed
of the blood and matter, again hoarsly filled up with dry lint,
and we must continue to draw the lips of the wound gently
together, by means of adhesive plaster, without however
exciting pain. Afterwards the dressings are to be renewed
daily, or, if the suppuration be very copious, twice a
day, till a complete cure is obtained. The upper part of the
wound, in which the spermatic cord is situated, must
not be suffered entirely to close till the ligature has been
drawn out; however, we must here also endeavour to pre-
vent too violent a suppuration. After the ligature has been
drawn out, the small wound must be cicatrizied by the
application of dry dressings and gentle preasure.

Upon this subject Mr. Pearson has offered some judicious
observations. He says, "1. It is seldom necessary to re-
move any part of the serotum when the diseace has not ar-
ived at the ulcerated state. I have never seen the mere
bulk of the part form a valid objection against leaving the
whole of the intestaments; for the serotum will generally
contract within very moderate dimensions. But where the
skin adheres to the tellbe; where it has undergone a mor-
bild alteration; or when the person has formerly been punctu-
ted several times for a hydrocele; the intestaments will be
found in such an indurated state, that it will be generally
prudent to remove the altered and callous parts. However,
the removal even of a considerable portion of the diseased
serotum will not necessarily prevent us from healing the
wound by the fifth intention; for the skin of this part dilates
so readily, that the lips of the wound can be easily detained
in contact by employing a few ligatures.

"2. Of all the methods that have been devised for the
suppression of hemorrhage, the application of a ligature
round the bleeding vesell is the least painful, and the most
certain; and in the operation of which we are now speak-
ing, it is the safest and most expeditious method, to tie
the whole spermatic cord. It has frequently been delivered
as the opinion of very respectable surgeons, that the most
dangerous consequences are to be apprehended, from in-
cluding the spermatic cord in the ligature. Some have for-
bidden us to include the cremaster muscle; others have ad-
viced the separation of the nerve; and some have only di-
rected us to avoid the vas deferens. Heister and other
eminent surgeons, have declared the separation of the nerve
from the blood vessels, to be both unnecessary and imprac-
ticable; and they who advise such a practice, are charged
with being ignorant of anatomy. It is however probable;
that in Mr. Bronnfeld's method of securing the spermatic
artery, the nerve may be generally avoided. I think this
mode of proceeding is not entirely free from objection; for
as the cord is divided at the beginning of the operation,
it must be truited to the fingers of an assistant till the divided
tellbe be removed from the serotum; but it has more than
once happened, that the cord has retracted, so as to escape
from the fingers of the assistant; and the operator has con-
sequently found great difficulty in securing the vessels under
such unfavourable circumstances. Mr. Pott has directed us
to tie the spermatic cord, after the operator has separated
the vas deferens from the blood vessels with his finger and
thumb. When the spermatic cord is in a natural state, there
will be little difficulty, or loss of time, in complying with
this direction; but where it has been for some time diseased,
the cellular membrane loses its mobility, so that the several
parts are not easily separable; in such cases, it is of con-
sequence to know whether the separation of the vas deferens
be a part of the operation, which cannot be omitted with-
out danger to the patient. It is the result of my experience
hitherto, that no danger nor inconvenience whatever will
ensue from including the vas deferens in the ligature: I am
farther of opinion, that by following a contrary rule, the
operation is made more complex, without being rendered
either less painful or hazardous: and in this opinion I am
supported by the authority of the most respectable writers
on surgery.

"Some practitioners have thought it advisable to interpose
a piece of lint, or some other soft substance between the li-
gature and the spermatic cord; and this was probably ad-
viced, either to prevent the waxed silk from cutting the ves-
sels; or by thus increasing the lateral preasure, to render it
unnecessary to draw the ligature so tight as to give much
pain. When the spermatic artery is perfectly free from
disease, and the cord is small and flexible, a very small de-
gree of preasure, thus applied, will no doubt be sufficient
to prevent a haemorrhage. But where the spermatic artery
is much enlarged, and the cord has become unnaturally dense
and elastic, a very gentle preasure will be insufficient to close
the bleeding vessels; and if the ligature be drawn very tight,
we shall in a great measure forego the advantages that were
proposed. Among the reasuns that have been offered
against including the whole spermatic cord in the ligature,
it has been urged: 1st. That the patient always suffers ex-
quise pain when the cord is tied; and 2dly. That severe
inflammation, great disorder of the contents of the abdomen,
and even alarming convulsion, are among the symptoms
that supervene to this mode of treatment. I do not pretend
to deny, that violent pain, and sometimes dangerous con-
sequences have attended the usual way of tying the spermatic
cord; but I would beg leave to suggest, that these con-
sequences may probably depend less upon including the whole
cord in the ligature, than upon tying it too gently. If we
were proposed to refrain the haemorrhage from the divided
spermatic artery, a very moderate degree of preasure would
be sufficient; but as a nerve, a muscle, &c. are also to be
included, there ought to be the farther intension of inter-
cepting all communication between the brain and the part
below the ligature: if a sufficient force be exerted to pro-
duce this effect, the vitality, and consequent the sensibility
of that portion of the cord will be quickly destroyed. I
therefore always draw the knot as tight as possible; and al-
though
though the patient may complain at the moment, yet the
pain very soon goes off; so that in no one instance where
this method was followed, have I ever known the least sub-
sequent inconvenience. All imperfect and partial pressure
must necessarily be followed by the alarming symptoms which
different practitioners have recorded. It would therefore
be much better not to tie the cord at all, than to fail of
drawing the ligature to such a degree of tightness, as im-
mediately to kill the included part; and this additional rea-
son for the operation may likewise be subjoined, that when
the knot is left comparatively loose, the separation will not
be completed as soon, a when the life of the parts that are
compromised by it is instantly destroyed. When the cord is
found at any time to denote an escape, that the ligature ap-
plied in the usual way, proves insufficient to restrain the
hemorrhage, we are advised to carry a needle with a double
ligature through the middle of the cord, and tie it on both
sides; this method will certainly be effectual, but the op-
erator ought to be careful lest he puncture the artery, when
he passes the needle into the spermatic cord." See Pearson
on Cancerous Complaints. p. 71. &c.

In most cases that require castration, the testicle is not
only entirely detached, but also so large as to fill the whole
tunica vaginalis, which is itself either partly, or entirely
detached, or has only formed flat adhesions with the testicle
in various parts. This may generally be discovered before
the operation, both by the eye and the touch, from the
size, the weight, and especially the hardness of this part.
When the testis has besides a rugged surface, and occas-
sions pain, we are enabled to distinguish the nature of the
disease with still greater certainty; namely, that there is
little or no water contained in the tunica vaginalis, and that
this is for the greater part adhering to the testicle, and dif-
cased. In this case, after having divided the external inte-
guments, and sufficiently laid bare the tumor, an incision
several inches in length, should be made into the tunica va-
ginalis, below the abdominal ring and over the spermatic
cord, the fluid that may be contained in it discharged, the
spermatic cord detached as much as possible from all its con-
nexion with the surrounding parts, and if it be free from
diseased, tied in the manner above-mentioned. The whole
tunica vaginalis, with the detached testicle, is then to be cut
out of the cellular substance of the femur, after which the
whole mass under the ligature is cut away with the
scapel.

Only it is necessary, in performing this operation, that
we should not care not injure either the spermatic ferot
or the spermatic cord itself. In order that this accident may
be avoided, we must draw the tunica vaginalis tight, by means
of a double tenaculum, and direct the assistant to draw tight
the external skin, in order that we may be able to cut as
much as possible within the cellular substance. When, as
happens in some rare cases, the tumor has formed adhesions
with the serotum, we must separate it with the scissors, but
cut not through the testis, as the incised parts of the
skin may be healed, and preferred during the suppuration.
In the still rarer case, when the tunica vaginalis adheres not
only to the testicle, but also to the external skin, on its
whole anterior side, in such a manner as to render it impos-
ible to draw the skin into a fold; we must divide the exter-
nal skin, by a perpendicular incision, lay bare the tunica
vaginalis, and then perform its excision, as well as that of
the testicle, after the manner above described.

Should the spermatic cord be indurated or diseased, which
may readily be discovered by the sight and touch, it must
be tied an inch above the diseased part. But should the
cord be diseased as high up as the abdominal ring, it must
also be laid bare higher, the abdominal ring itself enlarged,
the spermatic cord drawn tight, separated from all its con-
nexion with the parts in the abdominal ring, and tied as
tight as possible above the diseased part in order to pre-
vent the subsequent renewal of the disease, and effect a radical
cure. As it is not to be expected that the disease will ex-
tend higher than the abdominal ring, we may also tie the
cord, with hopes of a successful event, even though it should
be diseased as high up as the abdominal ring.

This indurated and diseased state of the spermatic cord
cannot be discovered before we undertake the operation
as the larger size of the tumor, the manner in which it has been produced, and the length of time during
which it has continued, will direct our attention to it.
When therefore we find the tumor to extend into the
abdominal ring, and that it is preternaturally hard and painful
to the touch, without the patient having previously been
affected either with an one of or internal hernia, the
spermatic cord is in all probability diseased. As even in
this case the operation has sometimes been successfully per-
formed, and the patient's life preserved, by widening the
abdominal ring, separating the spermatic cord, and then
vrying it; the surgeon ought also in such a case, provided
the other circumstances be favourable, to perform that
operation.

CASTRATION, in Rural Economy. See GIVING AND
SPARING.

Castration is a term which has sometimes used by
the older physicians to signify the cutting of violent med-
icines, especially purgatives. See Correction and Cor-
rectors.

Castration also denotes the art of retrenching, or cut-
ging away any part of a thing from its whole.

Castrato. A male singer, with a soprano or female voice, occasioned by a cruel act, which needs no
further explanation than what is given under the article
Castration, which see. It is a delicate and difficult
subject to discuss. The custom in the East has pre-
valed from the highest antiquity. The chambers of the
Egyptian kings, in the time of the Pharaohs, were enu-
neches, and in the East the practice of emasculation has long been
general on the guardians of the sexes in the harems of the
great. Italy is the only country, perhaps, on the globe
where the abominable custom has prevailed of gratifying the
peculiar fane at the expense of humanity. The Italics pretend to have very severe laws against this inhuman prac-
tice, but even these laws have been employed in the pontifical
chapel to sing the soprano, or treble parts, ever since the
establishment of the See in the beginning of the 17th cen-
tury; till which period the treble parts were sung by
Spaniards in falset, which see. The favour and fortune
which some of the castrati have obtained by their voice,
taste, and talents in singing, have stimulated for idol and un-
natural parents to have their children mutilated in expecta-
tion of their advancement, though the horrid operation does not give or improve a voice, but only preserves it from
change at the time of puberty; and as not one boy in a
100 has a fine voice, though all boys have a shrill and
cavernous voice previous to manhood; yet of all the un-
happy children thus mangled, the number is very small of
those who have voices fit for the theatre. And even when
there is a voice, the want of genius, diligence, figure, and
intelligence, will prevent their ever acquiring the favour or
the pity of the public; and though they merit the utmost
commination for the inhumanity of their barbarous parents,
they are always treated with scorn and derision by the gros
and vulgar part of society. See Eunuch; where we
shall
nearly resume the subject, and detail the history and use of

econocks from the most remote antiquity to the establishment

of the musical drama in Italy.

CASTRODE D'Alora, in Geography, a town of Portugal, in

the province of Tras los Montes, on the Douro; 4 leagues S.E. of Elvas.

CASTREL, or rather Kerstrel, in Ornithology, faldo

timidissimi, a Linnaeus, which fer.

CASTRENSIAN, or Castrensia, in Antiquity, an order of

servants in the Greek emperor's household, to whom belonged the care and service of what related to his table and

cooking. They were thus called either on account of their

attending the emperor, when in camp, or because they observed a sort of camp-discipline in the court; or rather because they were considered as folders, were paid as such, and had the privileges belonging to the military body.

The castrensi were also called "caufenos minorit," and

"ministerianit;" to this order belonged the bakers, butlers, waiters, fuller, tailors, &c. They had a head, or superior, who was called "comes castrensi," which was a palatine dignity under the chamberlain.

CASTRES, in Geography, a city of France, and principal

place of a district, in the department of the Tarn; before the revolution, the see of a bishop, suffragan of Alby.

In the reign of Louis XIII. the inhabitants were chiefly

Protestants, and formed within themselves a kind of repub-

lic, but since that time the walls have been demolished, and the place laid open. It is a town of good trade, containing

15,380 inhabitants; those of the canton amount to 17,260:

the territory comprehends 14,285 kilometres, and 75 communes. Turpentine fumes have been found in its neighbourhood. It is distant 32 miles from Toulouse. N. lat. 43° 40'. E. long. 2°. Also, a town of France, in the department of the Girond, and district of Cadillac; 12 miles S.E. of Boucaux.

CASTREZZATO, a town of Italy, in the Brfian; 11 miles W. of Brescia.

CASTRI, a town of European Turkey, in Livadia, built on the site of the ancient Delphos, but has little remains of its former splendour. It contains about 200 houses, and the inhabitants are miserably poor; 14 miles N.W. of Livadia.

CASTRIES, a town in the department of the Hérault, and chief place of a canton, in the district of Montpellier; 2 leagues N.E. of Montpellier. The place contains 550, and the canton 4534 inhabitants: the territory includes 1050 kilometres, and 20 communes.

CASTRIES, Bay of, so called by Perouse, is situated in

the North Pacific ocean, at the top of a gulf about 200 leagues from the Strait of Sangaar, on the coast of Tartary; it affords deep water, and a safe commodious anchorage. N. lat. 51° 32'. E. long. 145° 26'. In this bay the furthest winds are more leesy, more constant, and more Lizable than in the seas of China, from which they proceed; because, being confined between two lands, their greatest variation cannot exceed two points to the eastward or westward. With a fresh breath the sea rife to an alarming and dangerous height. The bay of Callcras alone, says Perouse, of all those we visited on the coast of Tartary, deserves that name. It affords a secure asylum against bad weather, and it would even be possible to winter there. The bottom is muddy, and shoals gradually from 12 to 3 fathoms, in approaching the shore, from which the breakers extend to three cables' length, so that it is very difficult to land, even in a boat, when the tide is low. No sea abounds more with weeds and different species of fish; and among the winds
call quantities of salmon are caught, to the number of 2000

in a day, which are found in a rivulet that discharges itself at the top of the bay. The inhabitants of this coast are described as a very worthy and hospitable people. Their chief subsistence is salmon, prepared on the fire with a small grain, which is their most valued food. This grain is brought to them from the country of the Mantchous, who dwell several or eight days' journey from them, up the river Segæne, and who have a direct communication with the Chinese.

Besides this grain they also bring from their country man-

korns, both which they probably receive in exchange for oil, dried fish, and perhaps for some flocks of lambs or eels, which, together with dogs and squirrels, were the only quadrupeds whose exuviae were observed. The Tartar village of the Orotchys, for to a nation of this name they belong, was composed of four huts, strongly built of the trunks of fir-trees throughout their length, and properly notched to fit each other at the corners. A frame supported the roof, which was composed of the bark of trees, and the fire was situated in the middle, under an aperture sufficiently large to give vent to the smoke. These four huts were inhabited by four different families, who seemed to live in the closest union, and the most perfect mutual confidence. Such were the inviolable fidelity of these people and their respect for property, that the French navigators left in the middle of their huts, and under the seal of their probity, their bags full of manufactures, beads, iron utensils, and, in short, all the articles exchanged with them; nor was their confidence in any instance abused. Each hut was surrounded by a piece for drying salmon, which was exposed by the women, to whom the operation is committed, on poles to the heat of the sun, after having been smacked two or three days round the fire in the middle of their houses. The people of this bay, as well as those of Segaleen, wear on their thumbs a thick ring of lead or bone, against which they cut in flitting the salmon with a sharp knife, worn by each of them at his waist. Their village stood on a neck of low and marshy land, exposed to the north, and appeared uninhabitable during the winter. But on the opposite side of the gulf, on a more elevated spot open to the south, and near a wood, was another village, consisting of eight huts, larger and better con-

structed than the former. Above thee, and near them, were subterraneous huts, like those of Kamitschata, described in the 3d volume of Cook's late voyage. They were large enough to contain, during the rigour of winter, the inhab-

itants of eight huts. At one extremity of this village were several tombs, better constructed, and equally extensive with the houses; each of which contained four or five biers, properly framed and adorned with Chinese manufactures. Bows, arrows, nets, and, in general, the most valuable articles, were deposited within these monuments, of which the wooden doors were secured by a bar supported at each extreme. Their houses were also filled with their effects in the same manner. Their clothes, furrs, snow-floes, bows and arrows, and pikes, remained in this deserted village, which they inhabit only during the winter. They pass the summer on the other side of the gulf. In their interment of the dead, they proportion the expense of their maufoles to their respective wealth. Whil"st a relative kind of magniti-

dence is manifested in the monuments of the more affluent, those of the poorer classes are exposed on a bar, which is placed on a flage supported by laces four feet high. All have their bows, their arrows, their nets, and 6 me pieces of cloth round their tombs, and we may well conceive, from the veneration which these people pay to their ancestors, that it would be deemed sacrilege to rob their tombs. Thefe
These people, like the inhabitants of Segalien, seem to acknowledge no chief, and to submit to no government. Nevertheless, the gentleness of their manners, and their respect for old age, may give this apparent anarchy a character of mildness. We never witnessed, say the French navigators, the slightest quarrel; and their mutual affection and parental tenderness afforded an interesting spectacle. However, these people are filthy and offensive to a disgusting degree; and there is not, perhaps, a race of perfons more heedfully constituted, and whose constenance is more in-confident with all our ideas of beauty. Their average height is under 4 feet 15 inches, French measure; their form is slender, and their voice weak and shrill, like that of children. They have prominent cheek-bones, and small blue eyes in diagonal directions. Their mouth is large, nose flat, short chin, almost without beard, and skin olive, varnished, as it were, with oil and smoke. They let their hair grow, and braid it in tresses, somewhat in the European manner. That of the women falls loose upon their shoulders, and they have the same call of countenance with the men. It would not be easy to distinguish them, if they were not for a flint or difference in their drefs, and in their leaving their necks entirely open. All the ears of the female sex are limited to cutting and sewing their clothes, disposing the fish for drying, and nursing their children, whom they fuckle till they are three or four years old. Females seem to be much respected in this part of the globe. The men never conclude any bargain without the consent of their wives. The silver ear-rings and copper jewels which adorned their drefs, are entirely reserved for women and little girls. The men and little boys are drest in jackets of nankeen, dog's skin, and fish skin, in the form of carters' frocks. If these extend below the knees, they wear no drawers; otherwife they have such as are used by the Chinese, and which extend to the calf of the leg. They have all boots of seal skin, which they reserve for winter; and they wear at all times, and at all ages, a leathern girdle, to which are fuppended a knife and flint, a flint, fcel, a little bag for tobacco, and a pipe. The women are covered with a large nankeen gown, or one of salmon-fkin, which they have the art of taming, and of rendering extremely flexible. This drefs extends to the ankle, and is sometimes adorned with a fringe of small copper ornaments, which make a noife like little balls. As to their religion, they feem to have neither temple nor priests; but they appear to have fome idols—a rough sculpture, fuppended from the roots of their cocoanuts. These images, however, may only serve as memorials of fome child devoured by the bears, or fome hunter whom these animals may have wounded. They are represented as a people whose delicacy and refinement of manners indicate a degree of civilization, not exceeded by any who have neither flocks nor agriculture. Dogs are their most valuable property. These they harness to fmall flegdes, very light, and extremely well made, and exactly similar to thofe of Kamtchatka. These dogs are of the wolf kind; and though small in size, are very strong, docile, and gentle, and seem to possess the character of their masters; while thofe of Port des Franfois, which are much smaller and of the fame breed, are wild and ferocious. The bay of Caftrions abounds with iflands; the fould of which confifts of lava and other volcanic fubfances. Among the latter, the eruption of which appeared more ancient, were discovered various cryffallisations; but no craters of volcanoes could be perceived. Vegetation in the month of July was nearly fuch as it is in the environs of Paris in the middle of May. Strawberrics and raspberries were still in bloom; gooseberries began to redden, and celery and water-creffes were very scarce. Several fine foliated oyster-shells of a vinous and black colour, were found strongly attached to the rock, and separated from it with difficulty; and their valves were so thin that it was very difficult to preserve them entire. With the drefs were taken up some wifles of a fine colour, some piffes, fimall muscles of the common kind, and fome varieties of the cockle. Several species of birds, such as palfets, wild ducks, cormorants, plover, white and black wag-tails, and a small blue fly-catcher, were thinly scattered. The beach and the woods echo with the croaking of frogs, and afford refuge to bold eagles and other birds of prey. The martin and land-martin alone appeared to be in their natural cliff. The earth feems to continue in a frozen state throughout the fummer, as the water taken into the ship was only 1 3/4 above the freezing point, and that of the dreams never above four degrees. The mercers, however, was confantly at 5°, even in the open air. The momentary heat penetrates but a little way; it only quickens vegetation, which begins and ends in the short interval of three months, and infinitely multiplies grats, mixl-toes, and other troublesome insects. No plants are cultivated by the natives; and yet they are fond of vegetable fubfances. The grain of the Mantinou, which is probably a small fheeted millet, is their greatest luxury. They gather with great care some fonipontaneous roots, which they dry for their winter provifion; among others the yellow lily, or faranana, which is a species of onion. They are unaccustomed to the use of the fhillte, and are only drest in the moft ordinary of the Chinese manufactorys, or the exuviae of some teretifal animals and fcafs. Voyage of La Pérouse, vol. 11 Engl. Tranl.

CASTRIMONIUM, in Ancient Geography, a fmall town of Italy, in Campania, rendered municipal by a law of Sylla.

CASTRIOT, George, in Biography, Sec SCANDERBEG.

CASTRO, Pietro di, an eminent painter of those subjcets that are comprehended under the denomination of still life, fuch as vases, vefles, musical instruments, gems, vesfels of gold, silver, and cryflal, books, and rich bemarkc. He was well acquainted with all the true principles of perspective, and the chiaro-fcreto; and none of his contemporaries were inferior to him in transparency and truth. His colouring was peculiarly excellent, and he manifefled peculiar judgment in grouping a variety of objects, fo as to give union and harmony to the whole. This artist died in 1603. Pilkington.

CASTRO, Alphonso de, a Francifcan friar, was a native of Zamora, in Spain, celebrated as a preacher, and much esteemed by the emperor Charles V. and his fon, Philip II. He accompanied the latter into England, when he came hither to marry queen Mary. His principal refidence was in the Low Countries; and though nominated to the archbifhopric of Compofella, he never took posifion of it, but died at Brussels in 1558, at the age of 63 years. As a writer he is principally known by his work "Against Heretics," containing 14 books, partly historical and partly polemical. An enlarged edition of this work by Feuardent, a Francifcan, was published at Paris, in 1570. Castro was also the author of a commentary on the 12 minor prophet and of several homilies. Du Pin's Eccl. Hist.

CASTRO, John de, an eminent Portuguese commander, was born at Lisbon, in 1500, and ferved at Tangier. He then accompanied Stephen de Gama to the iftrails of the Red Sea, which he accurately decribed. On his return to Portugal, he was appointed to the command of a squadron for guarding the coast; and he soon afterwards attended Charles
Charles V. in his expedition to Tunisia. He strengthened the fortifications of Durr, the siege of which the Turks, after great loss, had been obliged to abandon; and then took a number of towns: but in 1548, he expired in the arms of St. Francis Xavier, after having been very recently advanced to the viceregency of the Indies. His description of all the coasts from Goa to Durr is preserved in the Jesuits' college, at Evora. His life was written in Portuguese by Hyacinth Freyre d'Andrade, and has been translated into Latin.

Castro Paulus, a celebrated lawyer of the 15th century, was born at the place from which he took his name, in the kingdom of Naples, and received his education in part from Christopher da Cagiglione. From an obscure origin, he rose, by indefatigable application, to several stations of eminence, and distinguished himself as a professor of jurisprudence at Avignon. Florence, Sienna, Bologna, and Padua. At the latter place, where he was teacher of the law for 45 years, he died about the year 1456. His reputation was such, that it was proverbially said, "If there had been no Bartolus, Paul would have held his place;" and Cujacius said, "He who has not Paul de Castro, let him tell his cost, and buy him." His works are principally commentaries on the code and digest, and have been printed at Venice, Francefort, and other places. Gen. Biev.

Castro in Geographia, a town of Spain in Aragon; 70 miles N.E. of Balbaitro.

Castro, a strong town of South America, in the island of Cufi, near the coast of Cufi, in the South Pacific ocean; 180 miles S. of Baldivia, and subject to Spain. S. lat. 43° 14'. E. long. 82°.

Castro, anciently called Mitilene, a sea-port town of the island of Metelin, and the capital, situated on the north-east coast, facing the Gulf of Adriatic, with two harbours; one of which is capable of receiving large vessels. It was formerly a place distinguished by its grandeur and magnificence, of which some vestiges still remain. It has two castles, one ancient and another modern, each of which is furnished with a Turkish garrison and commander. The inhabitants are chiefly Greeks, among whom are some Armenians: the former have four churches and a metropolis. The chief trade is ship-building. It is 30 miles S.W. of Adriatic N. lat. 39° 14'. E. long. 66° 26'.

Castro, a duchy of Italy, in the state of the church, bounded on the north by the Orvietan, on the east by the Patrimonio, on the south by the sea, and on the west by the Sienefe; 25 miles long, and from 8 to 13 wide. The duchy of Castro, together with the earldom of Rome, was conferred by Pope Paul III. on his natural son, Peter Alofino Farne, who afterwards became duke of Parma and Placentia: it was mortgaged by one of his descendants to the Monte di Pieta at Rome; but upon his paying neither principal nor interest, it was forfeited by Pope Urban VIII. and in the year 1661 was annexed to the papal dominions. The town of Castro, from which it derives its name, which was formerly a bishop's see, was demobilised by Pope Innocent X. and the see removed to Aquapendente, because the inhabitants had murdered a bishop whom he had sent to them.

Castro, a town of Naples, in the province of Otranto, the see of a bishop, suffragan of Otranto; which has been frequently plundered by theCorsairs; four miles S.S.W. of Otranto.

Castro de Calduzio, a town of Spain, in the province of Galicia; 9 leagues N.E. of Orense.

Castro de Dayro, a town of Portugal, in the province of Beira; 5 leagues S.S.W. of Lamego.
hand, was superceded for Corelli, who was appointed leader. In 1731, a concert was advertised at Hickford's room, for the benefit of Signor Corelli, first violin of the opera, who was to play the first and eighth concertos of his mother, the famous Corelli, and several pieces of his own composition, particularly a solo, in which he engaged to execute "twenty-four notes with one bow." This advertisement was burlesqued, the next day, and a solo promised by the first violin of Goodman's Fields' playhouse, in which he would perform "twenty-four notes with one bow."

In 1732 Handel composed, in his opera of Sforzas, an Aira parlante, 'cor di madre, on purpose to display the talents of Castrucci in the accompaniment; and from this period to the year 1777, he seems to have led at all concerts, giving way only to the two boys, Cleg and Dubourg, in the solo, in which, from their youth as well as talents, they were highly favoured by the public. This year Castrucci, in advertising a benefit concert, wrote himself first violin of the opera; promising a particular concerto, with an echo, adding, that "as he has for the space of so many years had the honour to serve the English nobility, he hopes they will favour him this last time, being to return the ensuing summer to Rome, his native city."

About the year 1777, poor Castrucci, Hogarth's caricured musician, was superceded at the opera, in favour of Pletting, for whom he had such an antipathy, that in his most lucid intervals, he infantly lost his temper, if not his reason, on hearing it pronounced. It was a common and irritating practice with some of his young waggish acquaintance, who had no respect for age and talents, to adduce him in conversation by the name of Mr. Pletting, as if he were a fool. I beg your pardon,—Mr. Castrucci I mean," which put him in as great a rage as Hogarth's street musicians could do on May-day.

After his dismissed from the opera, oppressed with years, infirmities, and poverty, he was obliged to supplicate for a benefit at the opera-houses, which on the merit of his past services was, with due benevolence, granted him at the age of 83, when he performed a solo for the last time, and died soon after.

He was a voluminous composer for his own instrument. Two books of solos, and 12 concertos for violins, though never much known, seem to have more fire and variety than most violin music of his time, till Veracini, still more inflamed, surpased him in genius, hand, knowledge, and capacity.

He had a brother, Prospero Castrucci, who for several years led at the Cattle concert, and played concertos with his brother, a parti eguali; but though inferior to Pietro, he was not devoid of merit.

Castrum, in Ancient Geography, a term which, in combination with others, gives name to several fortified places; of which some were towns, and others mere forts. They are too numerous, and of little importance, to be here recited.

Castrum Dolora, in Middle Ages Writers, denotes a castella, or lofty tomb of flate, erected in honour of some person of eminence, usually in the church where his body is interred; and decorated with arms, emblems, lights, and the like.

Ecclesiastical writers speak of a ceremony of consecrating a castellum dolora; the edifice was to be made to represent the body of the deposed, and the priest an angel was to give them off, and say the prayers after the same manner as if the corpse were actually present.

Castrum, in Geography, a town of Germany, in the circle of Welfphalia, and bishopric of Munster; 5 miles S.S.E. of Cleopinburg.

CASTS. See Cast, Casting, and Impressions from Medals.

Castulo, or Castulum, in Ancient Geography, Castalia, a considerable town of Spain, towards the eastern part of Batia, belonging to the Carthaginian. It had the title of "Conventus" when the Romans made themselves masters of the country, but before this time the Carthagians had contended for the possession of it with the Romans to whom it naturally belonged. It was the native place of Invidia, the wife of Hannibal. This town was situated in a mountainous country; and some have derived its name from "Castulo," an orontial term, signifying the noise of a fall of water; and we learn from Strabo, that there were rocks near the place which gave rise to the river that passed to Castulo. The town itself, placed on a mountain, at least very vear it, seems to have some relation, by its name and situation, to Castalo, famous for its fountain "Castalia;" and hence some have been led to imagine that it was founded by the Phocaean, to whom belonged, in Greece, the fountains of Callalica and Parthenius. Silvia Rubens has not omitted this allusion. Julius Cesar, having purchased the lands in the territory of Castulo, established a college in it. There were defiles in the vicinity of Castulo, mentioned by Livy, and called "Saltus Castalensium."

Casul Consistory, in Laze, a writ of entry, where a tenant by courtesy, for life, or for life in fee or in tail, or for another's life it takes its name hence, that authority being given by that. Writ 2. 13 Edw. I. c. 24, to the clarks in chancery to make new forms, as often as any new case should arise, not under any of the old forms; they framed this writ to the likeness of the other called Casulo pro vincia.

Casul Preces, a writ of entry, given by the statute of Gledscott, 6 Edw. I. c. 7, in case where a tenant in dower aliens in fee, or for term of life, in tail, and lies for him in reversion against the alien.

Causal, something that happens fortuitously, or without any design, or measures taken to bring it to pass.

Casual death. See Deedband.

Casual remission, those which arise from foritures, absolutions, deaths, attainders, &c.

Case of 27, a denomination given by some to what is more frequently called cadaver. See Caseist.

At m Quincher, chancellor of the university of Tubingen, has published a system of casuistic theology, containing the solution of dubious questions, and caules of conscience. Theologia Casuistica, 6 vols. 1to. Tubingen. 1802.

Casualty, in the Biblia, a word used to denote the earth and clay matter which is by washing in the flattering-meals, &c. separated from the timber, before it is dried and goes to the crazing mill.

Causali, in Ancient Geography, a people of Upper Germany, according to Thucydides, who dwelt near the Naix.

Causaria, a place of Gaul, in the division called the "Greek Alps" which was situated at a small distance to the north of Naix.

Le père, preceptor of Lewis XIII. called the books of the catusiis the art of quilling with God; which does not seem far from the truth; by reason of the multitudes of distinctions and subtilities with which they abound.

CASULAE CARIANENSIS, in Ancient Geography, an episcopal see of Africa, in the Byzacene territory.

CASURGIS, a town placed by Ptolemy in Germania Major, supposed to be the present Caruzim, in Bohemia.

CASUS AMISSIONIS, in Status Law. In actions proving the tenor of obligations inseparable from the debtor’s retiring or canceling them, it is necessary for the purveyor, before he is allowed a proof of the tenor, to condescend upon such a “Catus amissiones,” or accident by which the writing was destroyed, as shews it was left while in the writer’s possession.

CASWELL, in Geography, a county of America, in the district of Hillborough and state of North Carolina, containing 1,006 inhabitants, of whom 2,736 are slaves. The chief town is Leeburg.

CASYRUS, or CHASIRUS, in Ancient Geography, a mountain of Asia, in Safiana; near which Pliny places the town of Sofrates.

CASYSTES, a port of Asia Minor, in Ionia, placed by Strabo at the foot of mount Corica.

CAT, Claude Nicholas le, in Biography, was born at Blerancourt, in Picardy, September 6, 1700. His father, Claude Le Cat, who was a surgeon of eminence, would have educated him to his business, but finding him disposed to theological studies, he encouraged him in that pursuit, and he performed the duties of an ecclesiastic several years. Being well versed in geometry, he, for a time, employed himself in acquiring a knowledge of military architecture, and made some drawings in that line which gained him credit; but his friends not approving that project, and requiring him to fix on the object he now purposed following, he determined on studying medicine, some knowledge in which he had acquired early, under the tuition of his father. He was now sent to Paris, and as he was of an ardent disposition, he soon, by his intense application to his studies, attracted the notice of the professors. Though anatomy was the part to which he seemed particularly attached, yet he soon showed himself to be of meaner proficiency in surgery and medicine, infomuch, that in the year 1729, M. Trelain, archbishop of Rouen, appointed him his physician and surgeon, though he did not take his degree of doctor in medicine, until the year 1732, when that honour was conferred upon him at Rheims. He had the preceding year been chosen surgeon major to the Hotel Dieu, at Rouen. For this honour, and for the attachment his countrymen constantly showed him, he was not ungrateful. In the year 1733, having now completed his studies, he went and resided among them, and in the same year he began his course of lectures in anatomy and surgery, which soon became so numerous that, the rooms in which they had been accustomed to be given would not contain the course of pupils, who required admission. He therefore proposed building a theatre for the lectures, and founding a college, or school for the study of anatomy and surgery,
CAT

which he had the pleasure of seeing carried into execution. He also formed a literary society, which was afterwards erected into a royal academy, to which, as one of the most zealous and active members, he was appointed secretary, which post he held to the time of his death. In 1759, an addition of 200 livres was made to his salary as principal surgeon to the Hotel Dieu, and in January, 1762, the king gave him letters of nobility. In the mean while he had made himself known to most of the philosophical, and medical societies in Europe, by his communications on the subjects of anatomy and surgery; he was also a frequent correspondent with the editors of the Journal des Savans, Mercure de France, and other literary and medical journals. The subjects of his communications were sometimes such as rather showed his ingenuity than his judgment, and tended more to amuse than to improve the mind; as, of the nature and properties of the serum fluid, on the causes of the colour of the skin in negroes, &c. Many of them, however, were of a higher kind, and in the opinion of Haller, whom he occasionally opposed, and who was therefore, perhaps, no just appreciator of his merits, he made some improvements both in anatomy, and surgery. But the same veracity of observation, which made it difficult for him to fix on a profession, might prevent his being a correct experimenter, to which an almost unerring attention is necessary. He died in full possession of the esteem and estimation of his fellow citizens, August 22, 1765.

Of his works, which are numerous, Haller has given complete lists, with occasional remarks, in his Bib. Anat. & Chirurg. The following are the titles of some of the principal of them. "Traité des Sens, Rouen, 1740. Éve avec figures." It has been several times reprinted. Haller finds some of the figures faulty. "Recueil de Pieces concernant l'Opération de la Taille," Rouen, 1752. 80. Some of the plates in this work are also corrected by Haller. He also wrote on silvants of the bone, on the causes of the menes. "La Théorie de l'Oeuf, Supplement à cette Article du Traité des Sens." Paris 1767. 80. The most finished, Haller says, of his works. Éloq. D. Hist.

CAT, in Geography, a like of North America. N. lat. 52° 30'. W. long. 91° 49'.

CAT Island, or Guanabani, one of the Bahama islands. It was the first land discovered by Columbus, to which he gave the name of St. Salvador, Oct. 11, 1492. It lies on a particular bank to the east of the great Bahama Bank, from which it is parted by a narrow channel called Exuma Sound. N. lat. 24° 50'. W. long. 74° 30'.—Also, an island near the gulf of Mexico, and the coast of West Florida. N. lat. 29° 56'. W. long. 89°.

CAT, in Geo. language, denotes a ship formed on the Norwegian model, used by the northern nations of Europe, and sometimes employed in the English coal trade. It has three masts and a bowsprit, rigged like an English ship; having, however, pole-masts, and to top yellow ware. The mizen is with a gaff. These vessels usually carry from four to six hundred tns.

CAT, in a ship. See CAT-blocks.

CAT as a horse. See Anchor and Catching.

CAT HEAD, or CAT-scythe, in Ornithology, MUSCIPULA CAROLINENSIS, which it.

CAT's eye, in Mineralogy, a silicious gem, called by the Latin, occlusa, and sometimes onyxopus, as having white zones or rings like the onyx, and belonging to the division of chatoyant stones, or such as vary their colour according to the position of the light and the eye of the observer, which M. Chapital considers as varieties of the opal. Near the middle it has a point, from which proceed, in a circle, greenish traces of a very lovely colour. Its colour is generally of a greenish or yellowish grey, or light, or dark-yellowish brown, or reddish brown, or striped with these colours; and in certain positions, particularly when polished, emitting a silvery or yellowish moveable effulgence. Klaproth mentions two varieties of this mineral; the one whitish or yellow, from Ceylon, which, says Kirwan, is found in bunt or rounded fragments; its lustre 2, and tranparency, 3; 2; its fracture imperfectly conchoidal, sometimes approaching to the pimienty; fragments, 3; hardness, 10; sp. gr. from 2 50 to 2 60. Klaproth says, that the species from Ceylon had 1 50% of specific gravity; and was found to contain of alinum 95 per cent. of alumina 1 3, of lime 1 25, and of oxyd of iron 4. The other species is reddisht, and is procured from the Malabar coast. This, or others, says Klaproth, was composed of 54 4 per cent. of alinum, 14 of lime, and 3 of oxyd of iron. Its specific gravity was 2 52. This is the sandstone of the Turks, called gneis. The belt of these stones are very scarce. One of them, an inch in thickness, was in the cabinet of the dukes of Tuscany. See Asteria and Chalcedony.

CAT-fish, in Ichthyology; one of the shark tribe are known by this title. The leather cat-fish, Catulus minor, and Squana cachette of Linnaeus, is called also the leather dog-fish. —Great cat-fish of Edward, Catulus maximus of Willughby and Ray, is the Linnaeum Squana essaria See Squalus.

CAT-gut, a denomination given to small strings for fiddles, and other instruments, made of the intestines of sheep or hogs dried and twisted, either singly or several together. These are sometimes coloured red, some times blue, but are commonly left whitish or brownish; the natural colour of the gut. They are used also by watch-makers, cutlers, turners, and other artificers. Great quantities are imported into England, and other northern countries, from Lyons and Italy.

CAT-harings, in Sea Language, are small ropes running in little blocks from one side of the ship's bows, on each side of the bowspirt, being like two radii which extend from a centre, taken in the direction of the bow spirit. That part of the cat-head, which rests upon the fore-cable, is securely bolted to the beams; the other part projects like a crane, as above described, and carries in its extremity two or three small wheels, or sheaves of brass, or strong wood, about which a rope, called the cat-fall paffes, and communi cales with the cat-block, which also contains three sheaves. The machine formed by this combination of pulleys is called the cat, which serves to pull the anchor up to the cat-head, without tearing the ship's side with its chains. The cat-head serves also to suspend the anchor clear of the bow, when it is necessary to let it go; it is supported by a foot of knee which is generally ornamented with sculpture. The cat-block is hitted with a large and strong hook, which catches
catches the ring of the anchor when it is to be drawn up.

Cat's head, in Mineralogy, a denomination given to a fort of white flinty humps, not inflammable, found in coal-mines. In these there are frequently impressions of ferns. Phil. Trans. No 366. p. 970.

Cat-holes, two small holes above the gun-room ports, to bring in a cable or hauller through to them the capitan, when it becomes necessary to heave the ship a-tern.

Cat-mint, in Botany. See Catmint.

Cat of Mountain, in Zoology. See Catbus purdis.

Cat's paw, a light air of wind perceived at a distance in a calm, by the impression made on the surface of the sea, which it sweeps very lightly and then decays.

Cat-salt, a name given by our salt-workers to a very beautifully granulated kind of common salt. It is formed out of the brine or leach brine, which runs from the salt when taken out of the pan. When they draw out the common salt from the boiling-pan they put it into long wooden troughs, with holes bored at the bottom for the brine to drain out; under the troughs are placed veflets to receive this brine, and across them are placed certain small flicks, to which the cat-salt affixes itself in very large and beautiful crytals. This salt contains some portion of the bitter purging salt, and is very sharp and pungent, and is white when powdered, though pellicled in the mafs. It is used by some for the table, but the greatest part of what is made is used by the manufacturers of hard soap.

Cat-silver, and Cat gold, names given to certain soluble substances, usually called also glimmer, and in Latin, micas. They are various species of the bractearia, or folioaceous talcs, in finall spangles. The fragments of mica, denominated as above, according to their colour, are employed as a fund for drying ink up a paper. See Mica.

Cat's-tail-grafs, in Botany, different species of Phleum; which ic.

Catabanes, in Ancient Geography, a people of Arabia Dicerta, who inhabited the parts between the town of Pelusium and the Red Sea, according to Pliny.

Catabani, a people placed by Pliny in Arabia Felix, towards the frant of the Arabian gulf.

Catabapti, a perfon averse from baptism; particularly from that of infants.

The word is compounded of the preposition κατα, which, in composition, signifies again, and βάπτω, I wafh. See ABASTISTS and Baptiists.

Catabasion, in the Greek Church, a place under the altar, wherein the relics are kept. The word is formed from καταβαςω, I defend; because they went down into it.

Catabathmos, or Catabathmus, in Ancient Geography, a valley below the steep declivity of a mountain, whence its name, from καταβαςω, to defend, on account of the precipitation of its descent; extending to Egypt, over-against the spot where stood the temple of Jupiter Ammon, and repelling Egypt from Cyrenaica. It is also called "Carto Sappiras;" and the Arab pilgrims, who pass through it in their way to Mecca, denominate it in their language, "Hafachiri," or the ruined places. Steph. Byz. makes it a place of Libya, between Ammon and Patara; and Pliny reckons 86 miles from this last place to Catabathmos. Trolency mentions two places under this appellation; one the greater Catabathmos, which he makes a sea-port of Libya; and the other, the lesser Catabathmos, which he says was a mountain.

Catabaw, in Geography, a river of North Ameri-
CAT

268) in describing the angel Raphael's descent from heaven, says: he

"Sails between worlds and worlds!"

where the novelty of the word enlivens the image more than if he had said, this. This trope, however, is sometimes found in the graved authors, and even in the sacred writings. Thus, we read of the "blood of the grape," and Solomon, (Prov. xxx. 15.) says, "the horned-bee hath two daughters." In all these instances the trope is a metaphor: but when St. John says in the Revelation, ch. 12, "I turned to see the voice that spake to me," it is here a metonymy of the adjunct; the word voice being put for the person who uttered it. St. Matthew, (ch. xxvi. 6,) mentions "Simon the leper," not that he was then a leper, but had been so, and was cured; which is a synecdoche of the part. And when a criminal is said "to have had his reward," that is, his punishment, it is an irony. Ward's Oratory, vol. ii. p. 23.

CATACLASIS, from καταλλαζω, I diffurt, in Surgery, denotes a disorder of the eye, wherein the eye-lid is inverted by a convulsion of the muscles that clothe it; called also campylyon.

CATACLYSMUS, from καταλισμος, I diluge, a Greek name for a deluge, or inundation of waters.

CATACOMBS, in Antiquity. This word, derived from the Greek καταλω, κατω, a hollow or cavity, is used to denote grottoes or subterraneous excavations for the burial of the dead.

There are monuments of great curiosity, and considerable both in size and number. Of the remarkable excavations existing, there are various kinds. Some are temples, like those of India, in the mountains of Ellora; some have been originally executed for the purposes of sculpture; others have owed their origin to the operations of quarrying for building materials, and have been subsequently converted to other purposes: of this nature are the catacombs of Rome, and the quarries, or Latomiae of Syracuse, which served for public prisons.

The religious ideas of various nations led them to honour the dead with extraordinary solicitude, and tombs and mausoleums are among the most eminent remains of antiquity; where rocks afforded a convenient opportunity, it was an idea at once natural, and of peculiar propriety, to excavate in these silent retreats the habitations of the dead.

In Egypt the honours paid to the dead partook of the nature of a religious homage. By the process of embalming they endeavoured to preserve the body from the common laws of nature, by which every fabulace is decomposed, and returns to its original elements. They also provided magnificent and durable habitations for the dead, proud tombs, the astonishment of all succeeding nations, which have not preferred but buried the memory of their founders. But by a singular facility, the well adapted punishment of pride, the extraordinary precautions by which it seems in a manner to triumph over death, have only led to a more humiliating disappointment. The splendour of the tomb has but attracted the violence of rapine; the sarcophagus has been violated; and while other bodies have quickly returned to their native dust in the bosom of their mother earth, the Egyptian, converted to a mummy, has been preferred only to the infults of curiosity, or avance, or barbarism.

The date of the construction of not one of these monuments is known; indeed, most of them must have been executed progressively during a considerable time; it is, therefore, impossible to follow any chronological order in describing them: we shall, however, begin with those of Egypt, which, while they are in many respects the finest and most remarkable, are, in all probability, more ancient than any European influences.

The catacombs of Alexandria begin at the place where the ruins of the old city terminate, and extend along the sea-shore for a considerable distance. They consist in general of long galleries, with apartments on each side, excavated in the rock: in the side of these rooms there are three tiers of holes, or niches, in which the bodies were deposited; but they have been all violated, and nothing is found in them at present. The galleries sometimes run parallel to one another, and sometimes crofs at right angles; others are carried one above the other, according to the situation of the ground. Many have been washed away by the sea, and others are rendered inaccessible by the drifting sand. The apartments in general but little exceed the length of a man, but some which were probably the tombs of considerable persons, may, according to Dr. Pococke, "be reckoned among the finest that have been discovered, being beautiful rooms cut out of the rock, and niches in many of them, so as to deposit the bodies in, adorned with a sort of Doric pilasters on each side." Norden gives a fection of the front of these, vol. i. page 16, which is an apartment of a circular form, and terminated by a dome. There are four doors opposite one another, ornamented with pillars and an entablature, and pediments terminated with a crescent. One of these doorways serves as the entrance to the apartment, the other three lead to large square receptacles, each of which contains a kind of chest or sarcophagus of the fabulance of the rock, and sufficiently large to contain a body. From the style of the decorations observed in this subterranean chamber, one would be led to date its construction much later than the antiquity of the catacombs.

Near the pyramids of Secara, which are at a short distance from Cairo on the opposite side of the Nile, there is a difject to a circular plain which has a rising in the middle. Domes and skulls are scattered over this spot; under which are the catacombs of the mummies, extending about half a mile, the whole country being a rocky foil, covered over with sand five or six feet deep. At some distance from these are the catacombs of the birds.

The catacombs of the mummies are entered by various wells about four feet wide, and 20 or 30 feet deep, cut through the rock, the upper part being sand, which is often moved by the wind and fills up the cavity. Some of these wells Dr. Pococke observed to be eaved with unburnt bricks at the top as far as the depth of the sand, which from the size he imagined to be very ancient. The wells have holes on each side to descend by, but too much worn away to be of any use. Having descended the well, a passage succeeds, about 50 feet long, and five feet wide, which leads to another gallery of the same size, and about six feet high. On one side of this gallery there are apartments with platforms about two feet high, on which it is probable the mummies were laid during part of the process of preparation, and on the other side there are narrow cells just big enough to receive a large coffin. To this gallery there succeed one much narrower, with niches on each side, which seem designed to let coffins in upright. From these passages there are cut oblong square apartments, which are full of the remains of mummies, and probably here the inferior person of a family were deposited, piled up one another, as we may suppose the heads of the family were let upright in the niches, which appear to have been walled up as well as all the other apartments.

This is the description given by Pococke of the catacomb which he examined; and it seems likely that the sepulchre referred
The catacombs of the birds are similar to those last described, but more magnificent. These sepulchres were opened while the French were in possession of Egypt, and more than five hundred mummies of the ibis discovered.

Sint is a large well-peopled town, apparently built on the site of the ancient Lycopolis, or the city of the wolf. No antiquities are found in this town; but the Lybian chain of mountains at the foot of which it stands, exhibits proofs of the ancient proximity of some grand and flourishing city. These rocks are about half a league from Sint, and are excavated by a vast number of tombs of various dimensions, and decorated with more or less magnificence. Denon has given a view and plan of one of the largest of these catacombs. The outer porch is a large vaulted excavation, with a doorway leading into the interior of the tomb, which confids of several chambers one within the other, of various sizes and perfect regularity. All the inner porches are covered with a profusion of hieroglyphics, and the most delicate and elegant ornaments. M. Denon observes, that "if one of these excavations was a single operation, as the uniform regularity of the plan of each would seem to indicate, it must be an immense labour to construct a tomb; but we may suppose that such a one when once finished, would serve for ever for the sepulture of a whole family, or even race, and that some religious worship was regularly paid to the dead; else where would have been the use of such finished ornaments, of inscriptions never read, and of a ruinous, secret, and buried splendour? At different periods, or annual festivals, or when some new inhabitant was added to the tomb, funeral rites were doubtless performed, in which the pomp of ceremony might vie with the magnificence of the place; which is the more probable, as the richness of decoration in the interior part forms a most striking contrast with the outer walls, which are only the rough native rock. I found one of these caves with a single tallow, in which were an innumerable quantity of graves cut in the rock in regular order; they had been ransacked in order to procure the mummies, and I found several fragments of their contents, such as linen, hands, feet, and looe bones."

Besides these principal grottoes, there is such a countless number of smaller excavations, that the whole rock is cavernous, and riddled under the foot.

At Gebel Silsils, on the banks of the Nile, between Edfu and Ombos, the site of the principal quarries of Egypt, there are various chapels consisting of porics with columns and entablatures, covered with hieroglyphics, all cut out of the solid rock, and likewise a large number of tombs also hollowed out of the mountain. These tombs are very curious, though they are disfigured with trenches and rubbish.

In several of these tombs small private chambers are found, many of which contain large festoon figures; these chambers are adorned with hieroglyphics traced on the rock, and terminated with coloured tawo representing constantly offerings of bread, fruit, liquors, fowls, &c. The ceilings, also tawo, are ornamented with painted scrolls in an exquisite taste; the floor is inlaid with a number of tombs of the same dimensions and forms as are given to the cases of mummies, and equal in number to the sculptured figures; those that represent men have small square boards with a head-dress hanging behind on the shoulders; the women have the same draperies, but falling down in front over their naked necks. These latter are commonly represented with one arm falling within the arm of the figure beside them, and the other holding a lotus flower, a plant of Acheron, the emblem of death. Some of these sepulchral chambers contain but a single figure, and may probably be the tombs of men who have died in celibacy. Others contain three or more figures, and seem to be family monuments.

At Montosalte there are also quarries, the grottoes of which still remain: they resemble those of Sint, and seem to have served as tombs to the ancient Egyptians, and as places of retreat to the first solitaries.

The catacombs of Thebes are, among all these monuments, the most extraordinary and magnificent; these consist of the Necropolis or city of the dead, on the west bank of the Nile, which was the common burial place of the inhabitants, and the tomb of the kings.

The Necropolis of Thebes is situated on the north-west of this city, on a slope of the lower part of the Lybian chain, an arid and declivitous spot, which seems to be devoted by nature to silence and death. The rock cut down on an inclined plane presents three sides of a square, in which double galleries have been excavated, and behind them specular coves. These excavations are almost innumerable, and occupy a space of nearly a mile and a half square. At present they afford a lodging to the inhabitants of Kurru and their numerous flocks, who, strong in these retreats, maintained themselves against the French in their late invasion of Egypt with singular obstinacy, and were only reduced by a regular siege. M. Denon, who accompanied this expedition, has given a lively and interesting description, which we shall transcribe.

"I now began my researches accompanied by some volunteers. I examined the grottoes which we had taken by assault: they were constructed without magnificence, consisting of a regular double gallery supported by pillars, behind which was a row of chambers often double, and tolerably regular. If we had not observed tombs, and even some remains of mummies, we might be tempted to believe that there were the dwellings of the primitive inhabitants of Egypt, or rather that after having first served for this purpose, these subterranean caves had become the abode of the dead, and had at last been restored by the people of Kurru to their original definition.

In proportion as the height of these grottoes increases, they become more richly decorated, and I was soon convinced by the magnificence both of the paintings and sculptures, and of the subjects which they represented, that I was among the tombs of great men or heroes. The sculpture in all is incomparably more laboured, and higher finished than any that I had seen in the temples; and I found in astonishment at the high perfection of the art, and its singular delicacy to be fixed in places devoted to silence and obscurity. In the working of these galleries, beds of a very fine grained calcareous clay have occasionally been crossed, and here the lines of the hieroglyphics have been cut with a firmness of touch, and a precision, of which marble offers but few examples; the figures have an elegance and correctness of contour, of which I never thought Egyptian sculpture susceptible. Here too I could judge of the style of this people in subjects which were neither hieroglyphic nor historical, nor scientific; for there were representations of small scenes taken from nature, in which the stiff profile outlines, so common with the Egyptian artists, were exchanged for supple and natural attitudes; groups of persons were given in perspective, and cut in deeper relief than I should have supposed any thing but metal could have been worked. One cannot help being struck with the little analogy which the greater number of these subjects have with the feet wherein they are immersed; it requires the presence of
of mummies to perish, one's first that these excavations are
tombs. I have found here bas-reliefs representing games, such as
rope dancing; and after taught to play tricks and to
rear on their hind legs, which are sculptured with all the na-
ture and simplicity which B. Smith has shown in representing
the four animals on the can Auschwitz.
The plan of these excavations is not less singular; there
are some which are fronted and complicated, that one would
have taken them for labyrinths or subterranean temples. After
passing the apartments described in the account that I have
first described, we entered long and gloomy galleries, which
wind backwards and forwards in numerous angles, and seem to
occupy a great extent of ground; they are melancholy, repul-i
tive, and without any decoration; but from time to time open in other chambers covered with hieroglyphics, and branch out into narrow paths that lead to deep perpendicu-
larly; which we defended by erecting our arms against the
side and fixing our feet into steps that are cut in the
rock. At the bottom of these pits we found other adorned
chambers, and lower still are vaults of perpendicular pits and horizontal chambers, and at half ascending a long flight
of steps, we arrived at an upper space which we found be-
on a level with the chambers that we first entered."

M. Denon made many references among these tombs, in
hopes of finding one that had not been rifaced, that he
might light upon a perfect mummy and find out the man-
ner in which they were laid within the tombs, a secret which
the inhabitants obstinately concealed, as the situation of
their village had given them almost an exclusive trade in this
singular article of commerce. During their search, M. De-
non and his companions arrived at a narrow hole, before
which were scattered numerous fragments of mummies. After
some hesitation, they proceeded, and having crawled along near a hundred paces over a heap of dead and half
decayed bodies, the vault became looser, more spacious, and
decorated with a considerable degree of care. They now
found that this tomb had already been searched, that those
who first entered it not having torches, had used bushes to
give them light, and that these had set fire to the linen and
rein of the mummies which had caused such a combustion as to
split some of the bones, melt the gums and reins, and
blacken all the sides of the cave. They could observe how-
er, that this vault had been intended for the burial-place of
two could noble persons, whose figures were sculptured
in relief seven feet in height, holding each other by the
hand. Above their heads was a bas-relief representing two
dogs in a leash lying on the altar; and two figures kneeling,
had the appearance of worshipping, which makes it prob-
able that two friends were buried here who were unwilling
to part even in death. Besides this, there were lateral chambers ornamented and filled with cupids that had been
enraged with more or less care, showing that through the
years had been conducted and decorated by persons of con-
sequence, they received not only the cupids of the founders, but of their children, friends, relations, and perhaps
all the servants of their house. M. Denon found se-
veral bodies lying on the ground covered up, and besides
without any coffin, and others that were not tattooed; and observed
various particulars concerning these.
The sepulchres of the kings of Thebes are mentioned by
Diodorus Siculus as a wonderful works, and such as could
never be excelled by any thing afterwards executed in this
kind. He says that 47 of them were mentioned in their
history, that only 17 remained to the time of Ptolemy La-
gus, and adds, that most of them were destroyed in his
time. It seems probable that most of these sepulchres were
built and not excavated in the rock, as it is not easy to de-
fer such fort of monuments. Strabo, however, says, that
above the Memnonium were the sepulchres of the kings of
Thebes, in grotttes cut out of the rock, being about 40 in
number, wonderfully executed and worthy to be seen. In
these, he says, were obelisks with inscriptions on them set-
ing forth the riches, power, and empire of these kings as
far as Syene, Babia, India, and India, their great re-
tainer, and the army consisting of a million of men.
The magnificent catacombs, called the tombs of the
kings, lie to the north-west of Thebes, at some distance in
the desert. Having passed the Necropolis, the traveller
enters a narrow and rugged valley flanked with perpendicu-
lar rocks, and ascending a narrow steep passage about 12
feet high, which seems to have been broken down through
the rock, the ancient passage being probably from the
Memnonium under the hills, he comes to a kind of em-
pyramide about 150 yards wide, which is called Elab-
thin. This is, the gate or court of the kings, being the
sepulchres of the kings of Thebes. In this court there are
four of about 15 excavations, but only nine can be entered;
the hills on each side are high steep rocks, and the whole
plain is covered with rough stones that seem to have rolled
from them.
The grottoes present externally no other ornaments than
a door in a square frame, with an oval in the centre of the
upper part, on which are inscribed the hieroglyphic figures
of a beehive, a man with a hawk's head, and beyond the
circle two figures on their knees in the act of adoration.
Having passed the first gate, long arched galleries are disco-
veryed of about 12 feet wide, and 20 in height, caved with
hieroglyphics and painted; the vaults, of an elegant ellipti-
qual figure, are covered with innumerable hieroglyphics, dis-
posed with so much taste, that notwithstanding the singular
grotesques of the forms and the total absence of dem-tint
or aerial perspective, the ceilings make an agreeable whole,
rich and harmonious association of colours. Four or five of
these galleries, one within the other, generally lead to a
spacious room containing the sarcophagus of the king, com-
pofed of a single block of granite about 14 feet long by 4
in breadth, ornamented with hieroglyphics both within and
without; they are square at one end, and round at the
other, like the splendid sarcophagus deposited in the British
Museum, and supposed by Dr. Clarke, to have contained
the body of Alexander. They are covered by a lid of
the same material, and of enormous thickness, shitting with a
groove; but neither this precaution, nor these vast blocks of
stone, brought from such a distance with such immense la-
bour, have been able to preserve the relics of the sovereigns
from the attempts of vassals; all the tombs are violated.
The figure of the king appears to have been sculptured and
painted at full length on the lid of each sarcophagus.
The paintings and in these sepulchres are among the
most curious and interesting remain of Egyptian art, and
in wonderful preservation, the colours being as fresh as when
first executed. Some of these figures were copied by Bruce;
and Denon who in a short time observed every thing with
the eye of an artist, has published a most valuable collection
which have all the appearance of spirited and characteristic
reminiscences. We shall extract part of his relation. "I
discovered some little chambers, on the walls of which were
represented all kinds of arms, such as panoplies, coats of
mail, tigers' flanks, bows, arrows, quivers, pikes, jacks, sab-
fers, helmets, and whips; in another was a collection of
household utensils, such as cauldrons, chairs of drawers, clairs,
solas, and beds, all of exquisite forms, and such as might
well grace the apartments of modern luxury. As these
were probably accurate representations of the objects them-
seves,
CATACOMBS.

fellows, it is almost a proof that the ancient Egyptians employed for their furniture Indian woods carved and girt, which they covered with embroidery. Besides these, were represented various smaller articles, as vases, coffee-pots, ewers with their basins, a tea-pot, and basket. Another chamber was consecrated to agriculture, in which were represented all its various instruments, a fledge similar to that in life and present; a man hoeing grain by the side of a canal, from the borders of which the inundation is beginning to retire, a field of corn reaped with a sickle, fields of rice with men watching them. ‘In a fourth chamber was a figure clothed in white playing on a richly ornamented harp with eleven strings.’ — M. Denon. Also observed figures with the heads cut off, which represented black men while their executioners were coloured red. (Pococke and Denon.)

Quitting Egypt, the European examples of catacombs come next to be described, and we shall begin with those of Rome, which though by no means the most considerable for size or beauty, are, however, the most generally known.

The catacombs of Rome are a vast collection of subterranean labyrinths, excavated sometimes in stone or tufa, but more commonly in beds of pizzollana, which run sometimes to 80 feet below the surface of the earth. Thus it seems probable, that these excavations were originally dug for the purpose of procuring this useful sublance, and afterwards appropriated as a burial place. In many places the sinking of the earth has suddenly afforded an access similar to those caves which have been filled up others, so that the extent of it is subterranean city is unknown. The principal entrances are those of San Sebastiano, San Lorenzo, and Porta Porfcre. These galleries are in general three or four feet wide, and fix or even in height. Some, however, are so low that it is necessary to floup greatly to pass along them. There is no mastony or vault, the earth supports itself. In the two sides of these alleys, the sarcophagi containing dead bodies were placed lengthways, in recesses three or four tiers over one another, and closed with very thick tiles, or sometimes slabs of marble, cemented in a manner which would be very difficult to imitate at present. Some tombs are placed on the floor. There are also found a large number of urns containing bones, which, upon access of air, are reduced to powder. Sometimes, though rarely, the name of the deceased is found on the tile or urn, and frequently a palm is seen painted or engraved, with the cypher X. P. These are supposed to be the graves of the early Christians, and their contents are regarded by the Romans as sacred relics. The sarcophagi are for the most part quite plain, and the small sculpture, painting, or ornament, that has been found in the catacombs, is of the lower ages of the empire, and very indifferent. Almost all the galleries and chambers which have been discovered are of a size enough for a human being to pass through. The catacombs of Naples are much larger and finer than those last described. These caverns do not extend under the city like those of Rome; they are situated in a mountain to the north of Naples, and dug one over the other partly in a stone used for building, and partly in beds of compacted pizzollana. There are three tiers of galleries, but earthquakes have closed the greater part.

From the entrance of the catacombs a straight street, 16 feet wide, and about 14 in height to the top of the vault, continues to a considerable length. It then becomes irregular, and seems to have been pierced at random in the mountain, as well as several other slots of various dimensions, with which it communicates on all sides. These ca-

vernous cellars, in their distribution, the excavations of a fome quarry with various large chambers, in which pillars have been left to support the ceiling. Among these subterranean halls, there are some which may have served as chapels, with altars of rough stone, and some fresco paintings, representing the virgin and saints, which seem to be of the 10th century.

The walls on both sides, through their whole length, are pierced with an infinite number of recesses; there are in some places five, six, and even seven rows one above the other. These recesses are large enough to receive a human body horizontally, but not a sarcophagus: they are of various sizes, and seem to have been calculated for the individual tenant. When the body was deposited in these recesses, they were closed with a long, flat stone, or with brickwork well cemented. In some places there were niches in which the bodies were placed upright; these perhaps are the sepulchres of particular families. Some of the tombs are ornamented with Mosaic paintings of the lower ages; and there were found marble monuments with Greek and Latin inscriptions, but these have been faved to form the pavement of the church della Sanita. All the niches have been opened and the remains removed.

There are also considerable catacombs at Civita Turchino, near Carneo.

Sicily possesses many monuments of this kind; for that the ancient gentiles of Catana, Palermo, Agrigentum, and Syracuse, are satisfied by extraordinary excavations. The catacombs of Syracuse are the most ample and magnificent of any in Europe. These form a kind of subterranean town, with its greater and smaller streets, squares, and places, all cut in the rock on several levels, and evidently originally designed for a place of sepulture, differing in that respect from the other remarkable excavations of that town, the Latomie and Dionysius’s cave, which were at first stone quarries, while the catacombs are not at all adapted for that purpose, their entrances being neither spacious nor convenient.

The catacombs are entered from the church of St. John, one of the oldest Christian churches in Sicily. They consist of various streets crossing one another in many directions, and are hewn with great care and regularity. The principal street continues to a very great distance, but its whole length cannot be estimated, as the sinking of the ground has filled it up in one part. On each side the walls are occupied by large tombs inclosed in the rock. At flatted distances large excavations branch off, which sometimes contain near 60 coffins hollowed out of the rock. In other places there are private sepulchral chambers with doors which appear formerly to have been fastened with locks; in the middle of these chambers there are large inhabited tombs, doubtless intended for the heads of families. The intersec-

tions of the streets form large openings, and there are various considerable circular halls with domes, and pierced at top with an opening to the outer air; these halls are fluced, and there are tombs placed symmetrically in them of the same kind as those in the streets.

In exploring these caverns the traveller is surprized to find himself returned to the same spot whence he set out, but upon a lower story. Though it is only possible to visit a part of these vast excavations, the extent of what is seen excites the utmost admiration of the energetic industry of the nation that could construct such noble sepulchres. They are undoubtedly the greatest monument of the ancient Syracusans. The only ornaments found in these catacombs, have been added at a later period, and consist of some indifferent Greek paintings of the last age of the empire, executed upon a stucco applied to the rock. Among the coffins of all ages which are excavated in the floors of the sepulchral
pulchral chambers, there are some so small as to be fit for nothing but the reception of a cat or lap-dog.

The entrances of Syracuse have not the salutary appearance of those of Naples and Rome, but a curious tranquillity pervades in them perfectly. Aptok, the sanctuary of Apollo, was a magnificent building with two temples dedicated to Apollo, and a columned portico. The temples were adorned with columns and statues. The entrance to the temple was through a large court, which was surrounded by colonnades. The court was paved with marble slabs, and the steps leading up to the temple were flanked by a colonnade. The temple was dedicated to Apollo, and was considered a place of pilgrimage.

CATADUPI, in Ancient Geography, an appellation given by the ancients to the inhabitants about the cataracts of the Nile. The cataracts are represented as all deat; being made to by the continual drip of the falling waters.

CATALCA, on the coast of the Persian gulf, was a city of Carmania, according to the chronicle of Nepos, and was inhabited by the Persians. It was a city of great importance, and was the seat of a viceroy of Persia. The city was fortified with walls and towers, and was a place of refuge for the Persians in time of war.

CATALONIUM, a promontory of Africa, placed by Ptolemy in Marrrum.

CATAFALCO, an Italian term literally signifying fest. It is chiefly used for a decoration of architecture, sculpture, and painting; raised on a timber scaffold, to show a coffin, or tomb, in a funeral service.

CATAGOGION, in Ancient Geography, a town of Sicily, according to the scholiast of Aristophanes.

CATAGRAMATICA, in the Materia Medica, medicines proper to unite broken bones; by promoting the formation of a callus. The term comes from κατα, against, and γραμμα, to record. But as this is a power which is not certainly known to exist in any medicine whatever, the term, says Dr. Cullen, is falsely employed. See Consolidation.

CATAGOGION, a heathen festival at Ephesus, celebrated on the twenty-second of January, in which the devotees ran about the streets decked in divers attire and unbecoming manner, with huge cudgels in their hands, and carrying with them the images of their gods; in which case they ravished the women they met with, abused, and often killed the men, and committed many other disorders, to which the religion of the day gave a sanction. Dura-Cage.

CATAGPHIA, in Ancient Geography, denote ohique figures, or views of men's faces; answering to what the moderns call profiles. Cataphraga are said to be the invention of Simon Clorus, who first taught painters to vary the looks of their figures, and sometimes direct them upwards, sometimes downwards, and sometimes sideways, or backwards. Pin. Hist. Nat. lib. xxxv. cap. 8. cum Nat. Hardouin.

CATALONIUM, in Ancient Geography, now Calatonia, a town of Gaul, in Belgica Secunda; called also “Duro Cataluni,” in the Itinerary of Antonine. It was before this place that the emperor Aurelian vanquished Tetricus, the president of Aquitania, who had been proclaimed emperor by the troops, according to Vopieus and Eutropius.

CATALECTIC, a term in poetry, derived from καταλεκται, to pass over, or to pass over the head, wherein the Roman knights used to expel themselves in running and fighting on horse-back.

But the most natural meaning is that of a rope, fastened at one end to the top of the theatre, and at the other to the bottom, to walk or run down, which was the highest glory of the ancient scholabontes, or funambuli. Elephants were also taught to run down the catadromus. Socrates speaks of the exploit of a Roman knight, who passed down the catadromus mounted on an elephant's back, in Ner. cap. xi. p. 5.

CATADUPA, in Hydrography, a cataract, or water-fall. See Cataract.

The term comes from κατα, downwards, and di, to make a move by falling.

The appellation catadupa seems to have been peculiarly given to a place in Ethiopia joining on Egypt, where the Nile, which here first assumes that name, rushed down a steep rock into the subjacent plain, with a noise so impetuons, that the inhabitants are said to have lost all sense of hearing. Plin. Hist. Nat. lib. v. cap. 9. Ammian. Marc. lib. xxii. cap. 34. &c. Socra. Nat. Quod. lib. iv. cap. 49

CATACLYSM, in Scripture, a term applied to any sudden alteration in the state of things, or to any extraordinary event which has had a powerful effect on the human race. It is often used in the Bible to denote the destruction of the world by a flood, and the submersion of the whole earth by a universal conflagration.

CATARACT, in Antiquity, an appellation given by the ancients to the inhabitants about the cataracts of the Nile. The cataracts are represented as all deat; being made to by the continual drip of the falling waters.

With respect to the nature of this singular disease, which is aptly enough compared by Van Swieten to that condition of the body, which was produced, according to the

2
CATALEPSY.

The symptoms of the poet, by the sight of Medusa's head, much difference of opinion has existed among physicians, and various denominations have been given to it. By the ancient writers it does not appear to have been accurately distinguished from other febroile discharges. According to Galen, those affected with it were originally called *stupor*, and the disease itself *estoebe* or *catathexis*; but the catachex of Galen bears a greater resemblance to apoplexy or tetanus, and the term, perhaps, included the cataplectic, together with their discharges. Celsius Aurelianus, who confiders the cataplectic as bearing an affinity chiefly to lathargy and apoplexy, has enumerated the symptoms, which his predecessors had employed to distinguish it. By Praxagoras and others it was included, he says, with the coma toto affections, under the general terms, coma, lethargy, &c. By others some prominent symptom was alluded as a name for the disease, implying that its nature or affinity with other diseases was not understood; thus it was called *anaolia* by Antigenes, from the loss of hearing which accompanied it, and *aphonia* by Diocles, from the loss of voice; circumstances by which, however, it is obvious, it could not be distinguished from *seizures*, epilepsy, and many disimilar disorders. Aplegeades itself denominated it catalepsia; but he has not left any distinct description of the disease, such as it is now considered. (See Cels. Aurelian. de Tar. Paffion. lib. ii. cap. 5.) It is not quite clear whether Celsius was acquainted with the catalepsy, or not. The learned Van Swieten is of opinion, and in this he is followed by Morgagni, that this disease is meant by Celsius, when he speaks of pernomia, as it were, thunderdruck, *atonii*; (De Medicin. lib. iii. cap. 26.) for although he confounds the disorder of the *atonii* with the apoplexy of the Greeks, yet he describes it as a rare disease; while in the subsequent chapter he speaks of apoplexy again, as a palsy of the whole body, and a common disease; meaning the complaint commonly understood by that term. (See Van Swieten. Com. 51067.) In short, the accounts to be collected from the ancient writers respecting the catalepsy are confused and imperfect, and appear to refer to various lethargic or coma toto affections; and even to some epispasic discharges, such as tetanus. Nor do we find all difference of opinion done away, if we defer to the modern records of medicine; in which several histories are related under the title of cataleptic affections, which obviously belong to other genera of disease. This confusion, together with the extreme rarity of the true disease, and the wonderful histories of cataleptics, which have been detailed by authors, have induced some physicians of eminence, (and among these Dr. Cullen must be particularly mentioned,) to doubt of the existence of such a disease. In his Synopsis de Nofology, Dr. Cullen has mentioned this complaint as a species of apoplexy, under the title of *Apoplexia Cataleptica*; having believed that the cases of catalepsy described by authors were either varieties of apoplexy, or altogether feigned. He had seen no instance of cataleptic symptoms, but what was obviously a deception. The number of well authenticated examples on record, however, in which no cause of an attempt to deceive appears, and which are related by physicians of character and fagacity, render the existence of catalepsy inadmissible. Its symptoms are the following:

The patient is suddenly seized, sometimes after feeling a head ache, or stiffness of the neck, or exhibiting obvious signs of torpor of the mind or body, but generally without any previous symptom, with a rigidity of all the limbs; or in other words, the senses and the power of voluntary motion are suddenly suspended, so that the patient remains fixed in the attitude peculiar to his work, and the countenance retains the expression characteristic of the mental condition. "Sec manus erecta non delabitur; faciei musculi ad ritem, ad horum continuamen, ritem vel exitum conflatans exprimunt." Yet such is the state of equal, though involuntary action in the antagonistic muscles, that the limbs are laid common to retain any position into which they are put by exterior force. During the paroxysm the sensations are in general suspended; the patient neither receives any impression from external objects, nor retains any recollection of what happened during the fit. The vital functions continue to be performed, but more feebly; the pulse and respiration are regular, but the former is smaller than in health; the colour of the countenance usually undergoing little or no change. After a duration, which is various in different inclinations, commonly after a few minutes, sometimes after the lapse of a few hours, and occasionally, though rarely, after a continuance of three or four days, the paroxysm suddenly declines. The patient awakes as it were from sleep, generally with deep sighing, and all the functions of the body are restored.

The congeries of symptoms just enumerated constitute what has been called by systematic writers, the perfect paroxysm, *catalepsia vera*, in which the abolition of the senses, both internal and external, is complete. But more frequently the lout of sense is only partial; and in some instances the senses all remain undiminished, while the voluntary motions are altogether suspended; so that, although the patient is conscious of every thing that is passing around him, he is unable to speak or move, or in any way to make known his feelings or wishes. An interesting example of this kind is on record, (see Duncan's Med. Comment. vol. x. p. 242.) in which a female lay in complete possession of her mental faculties, but deprived of the power of moving a muscle of the body. She was in the diffurbing condition of finding herself given up by the attendants as dead, of being laid out, with her toes tied together, and her chin tied up, and of hearing certain arrangements for her funeral talked of, yet she was unable to make the slightest sign of her possession of senses, feeling, and life. In other cases there is a certain degree of sense and consciousness during the fit, and of recollection of the circumstances of it afterwards; and the limbs, if bent, do not retain firmly the position into which they are moved, but return gradually to their original position. Some patients are able to move one hand or limb, while the others remain rigid; and some, though apparently lifeless in all other respects, yet retain the power of swallowing whatever is put into their mouths. These are said to be examples of imperfect paroxysmatic catalepsy. See Sauvages's Nofol. Method. cl. vi. ord. 5. Vogel, de Morb. Cognosc., et Curand. § 572. Burlet. Inflit. Med. Pract. tom. iii. cap. 5.

There is also another variety of the furious catalepsy, which is described by the title of *Euphias,* by some writers, in the paroxysm of which the imagination of the patient has pictured dreams of an extraordinary nature, which left a vivid impression upon the memory; and after the termination of the fit, (for it appears to have happened generally with females,) has related accounts of surprising celestial visions, with which she had been favoured during the trance. Many of the histories of trances which are on record, are, however, beyond a doubt, altogether fabulous; and in many instances they have been pure deceptions, feigned with a
view of furthering some political or religious design, or of serving some private purpose—deceptions such as were practiced by diviners of old, and as have been resorted to by fanatics in all ages. Sometimes these 

  ephelias have been among the extravagancies of maniacs.

The particular condition of the body, or of the nervous system, which constitutes the cataleptic state, has been attempted to be explained in various ways. Dr. Cullen considered it as depending upon the same condition of the brain, by which the modification of palsy and apoplexy are produced, and there are some cases on record, which accord with this opinion. Such are two cases related by Henry ab Heera, (Observ. med. Obf. 3.) which are obviously of an apoplectic nature. One of the patients was a Capuchin friar, who was attacked with the fit, when fasting, and remained in an upright posture. The fit went slowly off, but he was fezied a second time, and died. Vogel believes that the source of the cataleptic symptoms is rather to be traced to the phrenic or abdomen than to the head, which seems to imply a notion that they were of an hyllerical nature. The speculation of Boerhaave, Home, and others, respecting the interrupition, superabundance, or deficiency of the nervous fluid in the voluntary muscles of the patient, merit little attention: they are either altogether gratuitous, or consist of a mere consideration of the facts in other and more ambiguous terms. We know very little in regard to the connection of many of the irregular actions of the nervous system, with the physical condition of the nerves, or of their common source, the brain; and we must content ourselves, for practical purposes, with endeavouring to trace, in the case of uncommon diseases, some analogy with those more common affections, with the treatment of which we are already acquainted.

  Epilepsy appears to assume occasionally a cataleptic form; i.e. the paroxysms, which were in the beginning epileptic, become ultimately cataleptic; or vice versa; or the two forms alternate with each other. In these cases in which the patients have died apoletic, the apoplexy must be considered as partaking of the nature of epilepsy, or, perhaps, enlogging to the epileptic state; for the symptoms of catate, as they generally appear, are incompatible with the condition of pure apoplexy. In the latter, the nervous communication from the brain to the muscles is lost, and the limbs are consequently deprived of all power of action; in the catalepsy, on the contrary, a considerable degree of action exists in all the antagonist muscles, at the same time, and in an equal degree, so as to retain the limbs in any position, in which they may be placed. The pulse, it may be also added, continues its usual beats, and is smaller than in health; and the complexity of the countenance is unaltered; nor do any of the ill effects of apoplexy remain after the termination of the paroxysm. In by far the most numerous well-authenticated instances on record, catalepsy obviously bears the closest analogy to, or rather appears to be a modification of, hylleria. This conclusion will be drawn, whether we consider the nature of the symptoms, the fey and constitution of the patient, the accidental complication and conversion of the disease, or the remedies which have been successfully employed in its cure.

As a proof of the intimate connection of the cataleptic with the hyllerical paroxysm, we shall relate an account of one defended by Dr. Jebb, which is similar to several others that have been recorded. The young lady, who was the subject of the disorder, was fezied with the fit, when Dr. Jebb was announced on his visit. "She was employed," he says, "in netting, and was piling the needle through the mesh; in which position she immediately became rigid, exhibiting, in a very pleasing form, a figure of death-like sleep, beyond the power of art to imitate, or the imagination to conceive. Her forehead was serene, her features perfectly composed. The paleness of her colour, her breathing at a distance being also scarcely perceptible, operated in rendering the similitude to marble more exact and striking. The position of her fingers, hands, and arms, was altered with difficulty; but preferred every form of flexure they acquired; nor were the muscles of the neck exempted from this law; her head maintaining every position in which the hand could place it, as firmly as her limbs."

"Upon gently raising the eye-lids, they immediately closed with a degree of spasm. The iris contracted upon the approach of a candle, as in a state of vigilance; the eye-ball itself was slightly agitated with a tremulous motion, not discernible when the eye-lid had defended itself."

"About half an hour after my arrival, the rigidity of her limbs and flute-like appearance being yet unaltered, she sang three plaintive songs, in a tone of voice so elegantly expressive, and with such affecting modulation, as evidently pointed out how much the most powerful passion of the mind was concerned in the production of her disorder, as indeed her history confirmed. In a few minutes afterwards she sighed deeply, and the spasm in her limbs was immediately relaxed. She complained that she could not open her ears, her hands grew cold, a general tremor followed; but in a few seconds, recovering entirely her recollection and powers of motion, she entered into a detail of her symptoms, and the history of her complaints. After she had discoursed for some time with apparent calmness, the universal spasm suddenly returned. Her features now assumed a different form, denoting a mind strongly impressed with anxiety and apprehension. At times she uttered short and vehement exclamations, in a piercing tone of voice, expressive of the passions that agitated her mind; her hands being strongly locked in each other, and all her muscles, those subjacent to speech excepted, being affected with the same rigidity as before." (See Select Cases of Paralysis of the Lower Extrem. by Dr. Jebb, Appendix.) These paroxysms obviously participate of the character of hylleria. The appearances, indeed, are not common; but the varying forms of hyllerie diseases are a subject of general observation. Sydenham long ago remarked, that "a day would scarce suffice to enumerate all the symptoms of hylleric complaints, so various they are, and so contrary to one another, that Proteus did not assume more shapes, nor the chameleon a greater variety of colours." A very large proportion of the decided cases of catalepsy, which have been distinctly recorded, occurred in the female sex, or in hypochondriacal constitutions. Sauvages has related the histories of several cataleptic patients, all of whom were females, and of hypochondriacal habits; and several modern and well-authenticated examples are of the same nature. (Sauv. loc. cit. Jebb, loc. cit. Hil. Acad. Roy. de Sciences, Paris, 1738, &c. British Magazine, 1800. Edin. Med. & Surger Journ. vol. i. p. 61, 185. Mem. Roy. Acad. Scien. of Sweden, 1778.) The last reference is to the case of a melancholic or hypochondriacal man, in whom the catalepsy was accompanied with tremors, or locked jaw. Incidences are related by other authors in which the catalepsy was joined, or alternated, as well with melancholy, fromambulim, convulsions, &c. as with proper hylleric symptoms; or readily passed into these maladies.

The remote or occasional \emph{causes} of catalepsy are various. In the majority of instances they appear to have been the same which, in constitutions naturally predisposed to diseases of mobility, excite all the varieties of hylleric and other nervous symptoms; such are all circumstances which powerfully...
powerfully influence the mind, or debilitate the body, and thus induce a degree of morbid sensibility and irritability throughout the system. Hence, among the more frequent causes of catalepsy enumerated by authors, are grief, terror, anxiety, love, intense studies, indigestion, cold, strong liquors, acute fevers, &c. Where the disease has been a modification of epilepsy or of apoplexy, if this ever happen, the causes were such as produce other forms of those complaints. See Epilepsy, &c.

If we consider the nature of the cataleptic disease, in its more common form of catalepsy hystericus, it will be obvious by what means the cure is to be attempted. In the various cases which are recorded, it has been often successfully treated by the same remedies to which other nervous and somnambolic diseases commonly yield. Where it occurs in florid and plethoric habits, as in the same with that solely following from the apoplexy of the jugular vein has been practiced with advantage, especially during the paroxysm; this, however, is very rarely requisite. Gentle laxatives have been found useful; and in this, probably, as in other nervous complaints, the regular evacuation of the bowels is of the utmost importance. The whole tribe of stimulants and tonics have been resorted to, especially in the modern infinances, the former with a view of counteracting the inordinate actions of the nervous system, and the latter in order to restore the strength, and obviate the morbid irritability of the patient. In the fit, opium, ether, volatile alkali, and various fixed antipathodics, have been administered; erethines have been applied to the nostrils; narcotic or acrid and stimulating gyfflers injected into the bowels; and friction with mustard, or strong spirits, also employed on the limbs, and surface of the body. In the intervals between the paroxysms, bitter medicines have been given, the cold bath has been preferred, and exercise in various ways resorted to successfully in different infinances. The principle, in short, upon which the disease has been treated, appears to be this; that upon which all other diseases of nervous mobility have been successfully combated. If the lethargic, apoplectic, or epileptic disorders assume the cataleptic form, which must be determined by the concomitant circumstances, the remedies adapted to the cure of these disorders respectively will of course be indicated.

Before we conclude this article, we cannot forbear to mention an extraordinary account of a woman, labouring under catalepsy hystericus, which has been lately published by an old and most respectable physician, Dr. Petetin, of Lyons, president of the Medical Society of that place. The title of his work is "Electricité Animale, pronouee par la découverte des phénomènes physiques et moraux de la catalepie hystérique, &c." The cafe which is here related occurred some years ago, and another similar one now exists at Lyons. The history, we must acknowledge, excites our scepticism, but, on the other hand, the respectability of Dr. Petetin, supported by a letter, which we have perused, from a young physician of character at Lyons, who went to see the patient, doubtless of a healthy mind, but, notwithstanding, the truth of its truth, is entitled to attention. In these cases, it is affirmed, that the fingers were transferred to the pit of the stomach, and to the ends of the fingers and toes; i.e., that the patients, in a state of insensibility to all external impressions upon the proper organs of sense, were, nevertheless, capable of hearing, feeling, smelling, and tasting whatever was approached to the pit of the stomach, or to the ends of the fingers and toes. Dr. Petetin attributes these extraordinary phenomena to the influence of animal electricity or galvanism; and affirms, that if the objects were not applied to the pit of the stomach, but made to communicate with it by an electric conductor, the sensations were still excited; but that if the communication was interrupted, as by a piece of silk, or other non-conductor, the effect was altogether prevented. The patients are said to have answered questions propted to the pit of the stomach, to have told the hour by a watch placed there, to have tasted food, and smelt the fragrance of apricots touching the part, &c. &c. Dr. Petetin concludes that hystericat catalepsy should be thus defined: "Abolition reile des sens, et apparente de la connaissance et du mouvement, avec transport, des premiers ou de quelques-uns d'entre eux dans l'egyptage, à l'extremité des doigts et des orteils; et pour l'ordinaire disposition de la part des membres à recevoir et à conférer les attitudes qu'on leur donne," p. 140.

The physician whole letter on the subject we have perused, observes, that Dr. Petetin's pamphlet has been and is still confounded by many "comme une fable comme le rêve d'une imagination exaltée," but he avers, that it is nevertheless true. "I can assure you," he concludes, "that I have observed this cataleptic patient with the most scrupulous attention; that my experiments have been made with every caution, not for the purpose of publication, but solely with a view of satisfying myself as to the reality of a disease of which I had long doubted; and that the result has been a perfect conviction that all I have seen is true. If it be not, my fenes have strangely deceived me." Until we obtain further evidence upon the subject, we leave our readers to balance these authorities against the extraordinary nature of the facts which they promulgate.

Catalina harbour, in geography, a bay on the east coast of Newfoundland. N. lat. 45° 38'. W. long. 53° 45'.

CataliStis capis nemine distriptionis, in Lavo, an ancient writ that lay where a house was within a borough, for rent aufling out of the name; and which warranted the taking of doors, windows, &c. by way of dillets for rent. Old Nat. Br., p. 66. This writer says of the house.

Catalis redendus, an ancient writ which lay, where goods, being delivered to persons to keep till a certain day, are not, upon demand, delivered on that day. It may be otherwise called a "writ of detinue," and corresponds to "actio depositis" in the civil law. Reg. Orig. 139. Old Nat. Brev. 63.

Catalogue, a lift or enumeration of the names of several books, men, or other things; disposed according to a certain order.

George Willer, sometimes improperly called Viller, and Waier, a bookseller at Augsburg, who frequented the Frackfort fairs, first adopted the plan of caufing to be printed for every fair a catalogue of all the new books, in which the fize and the names of the printers were marked. Le Mire, better known under the name of Mirus, a catholi c clergyman, who was born 1798, and died in 1830, in his work "De Scrip toribus Ecclesiasticis fecundi xvi," printed in the "Bibliotheca Ecclesiastica" of Fabricius, Hamb. 1682, fol., informs us, that catalogues were first printed in the year 1554; but Labbe (Bibliotheca Bibliothecarum, Lipt. 1682, 12mo, p. 119.), Reimann (Einleitung in die Historiam Literarum, l. p. 203.), and Hunmann (Confectus Reip. Liter. c. vi. § 5. p. 315.), who took their information from Le Mire, erroneously make the year to be 1564, which error is copied by Fabricius. Willer's catalogues were printed till the year 1592 by Nicol. Baffius, printer at Frackfort. Other booksellers, however, must soon have published catalogues of the like kind, though that of Willer continued a long time to be the principal. Among the many curious and rare articles in the library of professor Baldinger, three
A collection of old catalogues, the earliest of which are the following: Catalogus novus mundinarum autumnalium, Francof. ad Morn. anno 1586, celebratatur. Plerique apud Joan. Georg. Portenbachium et Th. Lutz. bibliopolam Aug- guitanam venales habentur; A catalogue of all the new books — printed at Franckfort, by Peter Schmid. This catalogue was published by book-sellers of Augsburg; but not by Wilier, of whom we have, Catalogus novus mundinarum autum- nalium, Francof. ad Morn. anno 1585.—Plerique in zedibus Georgii Willeri, bibilopolae Auggutan, venales habentur. A catalogue of almost all the books which have been published be- tween last Easter and the present September fair. Franckfort on the Main, printed by Nicolas Ballens. To all these cata- logues, printed in 300. and not pagod, the following order is offered. The Latin books occupy the first place, begin- ning with the Protestant theological works, probably because Willer was a Lutheran; then the Catholic; and after these the books of jurisprudence, medicine, philosophy, poetry, and music. The second place is assigned to German books, which are arranged in the same manner. The last Euler catalogue of Wilier, that is found in Balding's library, is dated 1603, with the following title: "Plerique libri in zedibus Elis et Georgii Willeri, fratrum bibliopolarum Aug- guitanorum, habentur;" printed by Baffleus at Franckfort. In 1604, the general Euler catalogue was printed with a permision from government, as appears by the following title: "Catalogus universalis pro mundinis Francof. de anno 1604;" Francof. permiltu superiorior exudebat Joh. Saur. After this the Leipic book-sellers began not only to reprint the Franckfort catalogues, but to enlarge them with many books which had not been brought to the fairs in that city. Accordingly Balding's library has "Catalogus universalis pro mundinis Frandofurtenhibus vernalbus de anno 1601," printed at Leipic by Abraham Lamberg. An imperial privilege appears, for the first time, in the Franckfort Sep- tember catalogue of 1616; "cum gratia et privilegio spe- ciali S. Caf. Maj. Proflat apud J. Kruigerum Auggutanum." Some imperial permissions, however, may be of an earlier date. Reimann (ubi supra) says, that, after Wilier's death, the cata- logue was published by the Leipic book-seller,Henning Groffle, and by his son and grandson. The council of Franck- fort caused several regulations to be issued replacing cata- logues; of which an account may be seen in "D'Orth's Treatise on the Imperial Fairs at Franckfort." After the business of book-selling was drawn from Franckfort to Leip- ice, occasioned principally by the restrictions to which it was subjected at the former place by the censors, no more cata- logues were printed there; and the shops in Book-street were gradually converted into taverns. See Bookseller.

In perusing these old catalogues, the sudden and great in- crease of books may well excite astonishment; and when we reflect that a great, perhaps the greater, part of them no longer exist, this perihableness of human labours will pro- duce the same emotions with those which arise in the mind, when we read in a church-yard the names and titles of per- sons long since moulder'd into dust. In the 16th century there were few libraries; and these, which did not contain many books, were in monasteries, and confined principally of theological, philosophical, and historial works, with a few; however, on jurisprudence and medicine; while those which treated of agriculture, manufactures, and trade, were thought unworthy of the notice of the learned, and of being restored in large collections. The number of these works was, nevertheless, far from being inconsiderable; and, at any rate, many of them would have been of great use, as they would have served to illustrate the instructive history of the arts. Catalogues which might have occasioned inquiries after books that may be still somewhere preferred, have suffered the fate of tombstones, which, being wafted and crumbled to pieces, by the destroying hand of time, become no longer legible. A complete series of them is no where to be found. The loss, however, might in some measure be supplied by two works, that are now exceedingly scarce; viz. those of Clefs and Daudius; who, by the desire of some book-sellers, collected together, as Georg did at a later pe- riod, all the catalogues published at the different fairs, in dif- ferent years. The work of Clefs has the following title: "Unius fascil ejusque virorum litteratorum monumentis tum florentissimi, tum fertillissimi, ab anno 1550 ad 1632 mundinarum autumnalium..." and is divided into five parts. The first catalogue, partam ex bibliotheca, was first published in 1602. The work of Daudius, printed in several 4to. volumes, for the first time in 1611, and afterwards in 1625, is much larger, more complete, and more methodical. The first part is entitled "Bibliotheca clasica, five catalogus officialis, in quo singul- iarum facultatum ac professionum libros, quin in quavis fere lingua extant—recententer;" which is the annual publication of the authors, is called "Bibliotheca clasica, five catalogus officialis, in quo philophici artiumque ad humanorum, poetici et maius libri, quin ad annum 1624 continentur." This part contains Latin books, with an index of all the authors that are mentioned. A small volume, without an index, is entitled, "Bibliotheca clasica, five catalogus officialis librorum peregrinis linguis usufulibus scriptorum;" and a third part, containing an index of the authors, is called "Bibliotheca librorum Germanic- rum clasica;" 1625. This work of Daudius, though it mentions many books which were never printed, and though many titles, names, and dates are given incorrectly, well de- serves the attention of those who wish to acquaint themselves with the history of literature; and it was undoubtedly of use to Hailer, when he composed his Bibliotheca. See on this subject Beckmann's Hill of Inventions, vol. iii.

Catalogues of books are digested in different manners; some according to the order of the times when the books were printed, as that of Maitaire; others according to their form and size, as the common book-sellers' catalogues; others according to the alphabetical order of the authors' names, as Hyde's catalogue of the Bodleian library; others according to the alphabetical order of subjects or books which are called real or classical catalogues, as those of Lipenius and Daudius; lastly, others are digested in a mixed method, partaking of several of the former, as de Seine's catalogue of cardinal Sluis' library, which is first divided according to the subjects or sciences, and afterwards the books in each are reckoned alphabetically.

The most applauded of all catalogues is that of Thuanus's library, in which are included the advantages of all the rest. It was first drawn up by the two Puteani in the alphabetical order, then digested according to the sciences and subjects, by Libri Bulialdus, and published by P. Questin at Paris in 1679, and reprinted, though incorrectly, at Hamburgh in 1704. The books are here ranged with judicious under their several sciences and subjects, regard being still had to the nation, secta, age, &c. of each writer. And, in- deed, that only the best and choicest books in every subject are found here, and the most valuable editions. Yet the catalogue of M. le Tellier, archbishop of Rheims' library, made by M. Clement, is not inferior to any published in our age, either on account of the number and choice of the books or the method of its disposition.
CATALOGUE.

One advantage, peculiar to this catalogue, is the multitude of anonymous or pseudonymous authors detected in it, scarcely to be met with elsewhere. Some even prefer it to Thumma's catalogue, as containing a greater variety of classes and books on particular subjects. Bibliotheca Thummat. Par. 1679, Svo. 2 vols. and Hamb. 1704, fol. and 8vo.

The conditions required in a catalogue are, that it indicate at the same time the order of the authors and of the matters, the form of the book, the number of volumes, the chronological order of the editions, the language in which it is written, and its place in the library; so that all these circumstances may appear at once, in the shortest, clearest, and exactest manner possible. In this view, all the catalogues yet made will be found to be defective.

An anonymous French writer has hit down a new plan of a catalogue, which shall unite all the advantages, and avoid all the inconveniences of the old. Let. à l'Abbé * * *, sur un Nouveau Projet de Catalogue de Bibliothèque. Par 1712.

The Jefuits of Antwerp have given us a catalogue of the popes; which makes what they call their Propylæum.

Catalogue of the stars, is a list of the fixed stars, disposed according to some order in their several constellations; with the longitudes, latitudes, right ascensions, &c. of each.

Catalogues of the stars have been usually restricted to two forms: in the first and most ancient, the stars were clasped in their respective constellations; in the latter, they followed one another, in a continued series, according to their right ascensions, or the order in which they transfix the meridian. All the catalogues, from the most ancient to that of Flamsteed inclusively, were of the first of these forms; but most of those which have been since constructed are of the latter form, as being much more convenient for the greatest variety of useful purposes. Another catalogue of a third kind has lately been formed, in which the stars are disposed in classes according to zones, or their degrees of polar distance.

The first who undertook to reduce the fixed stars into a catalogue, was Hipparchus Rhodes, about one hundred and twenty-eight years before Christ; in which he made use of the observations of Timocharis and Ariffinus, for about 180 years before him. Pliny informs us (N. H. lib. n. c. 207) that he upon the appearance of a new star, began to doubt whether there might not be changes among the fixed stars, and therefore made a catalogue of them, setting down the place and magnitude of each star, so that if, in future time, any new stars should appear, or any of those already observed by him should increase or be diminished in magnitude, or should totally disappear, such changes might be known to succeeding ages. Ptolemy retained Hipparchus's catalogue, containing 1022 stars, with some few alterations; though he himself made many observations, with a view to a new catalogue, A. D. 149. Ptolemy tells us, that he added 2° 40' to the longitudes of Hipparchus, in order to reduce them, from the beginning of the 12th year B.C. (the epoch for which Hipparchus had given them), to the beginning of the year 137 after Christ, or the 5th of Antoninus Pius. This allowance is after the rate of one degree in 100 years, the quantity of the precension which was found by Hipparchus, from comparing his own observations of Spica Virginis with those which had been made of the same star by Timocharis, about 140 years before; and hence it is manifest that Ptolemy depended on no observations made by himself in this business, but reflected wholly on such as had been made by those two excellent astronomers, three centuries before his time. If he had made any observations himself, he must have found that the quantity which he allowed was too small, by a whole degree at the least; the true quantity of the precension for 245 years (the difference of the epochs being 3° 42' 22''), and then allow for the precension from that time to this. This catalogue, as we have it in Ptolemy, contains 1026 stars, in 45 constellations; but, according to Pliny (N. H. c. 47) it contained 1650 stars, in 72 constellations. This author, however, is so subject to error, that little attention has been paid to what he has on the subject; and it has generally been concluded that the catalogue never contained more stars than are to be found in Ptolemy; especially as none of the copies, which the Arabs have left us, contain more. About the year of Christ 885, Albotegni, a Syrian, brought down this catalogue to his time. The most ancient catalogue which the Chinese now have was made in the year of Christ 1560. The Arabians are the first who, after Ptolemy, observed the stars, and noted down their places. The learned Dr. Hyde mentions several of their catalogues; and he published the most considerable of them, with a Latin translation and notes, at Paris in 1662.

This catalogue was made by Ubigh Beig, a prince of Tartary, and grandson of the famous Tamerlane, from his own observations at Samarkand; it contains the places of 1022, or according to some, 1166 stars, adapted to the beginning of the 81st year of the Hegira, or the year 1437 after Christ. The third person who made a catalogue of the stars from his own observations was Tycho Brahe; who determined the places of 777 stars, for the year 1600. His Progymnasmata, published in 1604, contained only this number, and his Opera omnia, printed in 1648, contain no more. However the places of 223 more stars had then been deduced from his own observations by Kepler, and published with those of the former 777, at the end of the Rudolphine tables, in 1627. The places of the stars, in this catalogue, are adjusted to the end of the year 1600. Kepler added to the 1000 stars observed by Tycho those of Ptolemy's catalogue, which he had omitted, together with those of the new southern constellations, from other authors; so that his whole catalogue amounts to about 1165; their places being computed for the year 1600. About the same time with Tycho, William, landgrave of Hesse, with the aid of his mathematicians, Christopher Rothmannus and Julius Burgius, determined at Samarcand 450 fixed stars, by his own observations, with their places rectified for the year 1593; which Hevelius prefers to those of Tycho. This catalogue was first published by Willebrand Stellhus in 1618, and is said to have contained the places of 490 stars; but the copy of it which we have in the third volume of Flandrean's "Historia Cynclus," contains no more than 578. Ricciolus, in his "Alrtronomia Reformata," determined the place of 101 stars for the year 1700, from his own observations; for the rest he followed Tycho's catalogue, altering it where he thought fit. In the year 1607, Dr. Halley, in the island of St. Helena, observed 350 southern stars, not visible in our horizon. The same labour was also repeated by P. Noel in 1716, who published a new catalogue of the same stars constructed for the year 1687.

In 1603, John Bayer, in his "Uranometria," published a catalogue of 1150 stars, at Augsburg in Germany; and here the situations of the stars, with respect to the constellations in which they are placed, are expressed in words; but their longitudes and latitudes are exhibited by means of maps, in which the figures of the constellations are drawn, and their stars put down in their proper places, and of their respective...
CATALOGUE.

In the catalogue, however, of the publication, as well as the authors having marked every star with a number, the brightest or largest star in each constellation being always denoted by the first letter in the Greek alphabet, the next in degree of brightness, by the second letter, and so on: and when the same number is denoted for the number of stars in that constellation, then the same letter is marked by Roman letters; the third brightness of the stars being still expressed by the order of the letters. By these means, we are enabled not only to refer to every star in the heavens, with great readiness and precision, but to express, likewise, its relative brightness to other stars in the same constellation and, in the same degree, its magnitude also. This invention is so useful, that Flamsteed, in his catalogue, adapted Bayes's letters, as far as he went; Bode has also done the same upon his globes of the largest size, and also upon his pendulums; and it is followed by most astronomers since his time. Bayer cannot be supposed to have formed this catalogue from his own observations. The places of such stars as are visible in Europe were taken from the catalogues of Ptolemy and Tycho Brahe; and with respect to those which are about the south pole, he tells us, that they are partly taken from the observations of Americo Vespucci, partly from those of Andrew Cornall, and partly from those of Peter de Medina; and that Peter Theodore, a most infantil mariner, first formed them into catalogues, and published them. In 1677, John Hevelius of Dantzig, published his "Machina Celesitis," which, among other curious and valuable articles, contains a catalogue of the fixed stars. This work is very rare; as the greatest part of the impression was burned with his observatory and instruments, on the 20th of September, 1679. The catalogue is said to have contained the places of 1683 stars, of which 1553 were observed by himself; but as it stands in the "Historia Celesitis" of Flamsteed (1725), it contains only 1520 stars. Their places are rectified to the end of the year 1696. The most complete catalogue that ever was given from the labours of one man is the British catalogue, deduced from the observations of the Rev. John Flamsteed, the first royal astronomer at Greenwich; who for many years devoted himself wholly to that business. As there was nothing wanting either in the observer or the apparatus, we may consider this as a perfect work, so far as it extends. It is, however, to be regretted that the impression did not pass through his own hands; that now extant was published by authority, but without the author's consent. We have two editions of this catalogue; the first in 1712, which is generally called Dr. Halley's edition, because he was employed as the editor by Prince George of Denmark, at whose expense it was printed. This edition contains only 2680 stars: owing, possibly, to its having been published without the consent, and, it is apprehended, contrary to the wishes of Mr. Flamsteed, who might not, on that account, contribute all the materials for it, which he could have done. It is, however, more correct in some instances, than that which was published in 1725, by Mr. Flamsteed's executors, in pursuance of his will; but this latter contains the places of 2934 stars, and is that to which astronomers generally refer. The stars in both are adapted to the beginning of the year 1690. They are distinguished into seven degrees of magnitude (of which those of the 7th degree are telecopic) in their proper constellations. To the left is added Mr. Sharp's catalogue of the southern stars not visible in our hemisphere, adapted to the year 1726. See vol. iii. of the "Historia Celesitis," in which are printed the catalogues of Ptolemy, Ulugh Brigh, Tycho, the prince of H. s., and Hevelius; together with an account of each of them in the "Prolegomena." In 1752, M. de l'Academy of Sciences at Berlin, published a very extensive catalogue of the fixed stars, collected from the observatories of Flamsteed, Bradley, Hevelius, Tohino Mayer, de la Caille, Meiner, La Monnier, D'Arquen, and other astronomers; in which the places of the stars, amounting in number to 5638, are given for the beginning of the year 1750. This catalogue, which is a very valuable work, though there is reason to apprehend that the individual stars are more than once, is accompanied by a celestial atlas, or set of maps of the constellations, engraved in a very delicate and beautiful manner.

In all the catalogues already enumerated, the stars are classified in constellations. In the following catalogues they succeed each other according to the order in which they transect the meridian, without any regard to the constellation to which they belong; the name of the constellation being given with a description of the star's situation in it. The first catalogue of the stars, as we conceive, that was printed in this form, or in the order of their right ascensions, is that of M. de la Caille, given at the beginning of his Ephemerides, for the 10 years between 1755 and 1765; and printed in 1756. It contains the right ascensions and declinations of 567 stars, adapted to the beginning of the year 1756. In 1757 he published his "Alcironomia Fundamenta," in which is a catalogue of the right ascensions and declinations of 598 stars, adapted likewise to the beginning of 1756. In 1763, the year immediately succeeding that of his death, the "Calum Aulfrak Stelliferum" of the same author was published; and this contains a catalogue of the places of 1942 stars, all situated to the southward of the tropic of Capricorn, and observed by the same indefatigable astronomer while he was at the Cape of Good Hope in 1751 and 1752. The places of these are given for the beginning of the year 1750. In the same year, the Ephemerides for the 10 years between 1756 and 1775 were published; in the introduction to which the places of 515 zodiacal stars are given, all deduced from his own observations. The stars in this catalogue are rectified to the beginning of the year 1755. The nautical almanac for 1773 contains a catalogue of 388 stars, in right ascension, declination, longitude, and latitude, derived from the observations of the late Rev. Dr. Bradley, and adjusted to the beginning of the year 1750. It has been since, viz. in 1798, republished with corrections by Dr. Hornsby, in the first volume of Bradley's observations. These make but a small part of what might have been deduced from the labours of that great man, if his representatives had not withheld the reft from the public. Mr. Wollaston, (ubi infra) informs us, that Dr. Bradley had the whole British catalogue calculated to the year 1744; and that traces may be observed in it of his having examined almost every star in it. He adds, from satisfactory information, that Dr. Bradley observed the British catalogue twice through: first with the old instruments of the royal observatory, previous to 1750, and afterwards with the new ones. The 598 stars above-mentioned were carefully rectified for the year 1750 by Mr. G. Gilpin. For a brief account of the state of Dr. Bradley's papers, see the article Bradley. In 1775, a thin volume, containing several papers of the late celebrated Tobias Mayer, of Gotingen, was published, under the title of "Opera Inedita," and among the rest, a catalogue of the right ascension and declination of 498 stars, which may be occulted by the moon and planets. It is adapted to the beginning of the year 1756; and, from the known
CATALOGUE.

fill and accuracy of its author, is much valued. At the end of the first volume of "Astronomical Observations made at the Royal Observatory at Greenwich," published in 1776, Dr. Maskelyne, the present astronomer royal, has given a catalogue of the places of 34 principal stars, in right ascension and north polar distance, adapted to the beginning of the year 1770; and which, being the result of several years' repeated observations, made with the utmost care, and the best instruments, may be presumed to be exceedingly accurate. In 1776, a work was published at Berlin, entitled "Receuil de Tables Astronomiques," in which is contained a very large catalogue of stars from Hevelius, Flamsteed, M. de la Caille, and Dr. Bradley, with their latitudes and longitudes, for the beginning of 1800; with a catalogue of the southern stars of M. de la Caille, of double stars, of changeful stars, and of nebulous stars: a work very useful for the practical astronomer. To these may be added Dr. Herschel's catalogue of double stars, printed in the Philosophical Transactions for 1782 and 1783; M. Meffier's nebulae and clusters of stars, published in the "Connoissance des Temps" for 1784; and Dr. Herschel's catalogue of the same kind, given in the Philosophical Transactions for 1786. In 1789, Mr. Francis Wollaston published in folio a "Specimen of a general astronomical Catalogue, arranged in Zones of north-polar Dillance, and adapted to January 1, 1790." In forming this catalogue, Mr. Wollaston has not made any use of those which precede Flamsteed, except in a small part that of Hevelius; but all the stars in the British catalogue of 1725 are infected, as well as those which are in the third catalogue of M. de la Caille, those of Dr. Bradley in the Nautical Almanac for 1773, of M. Mayer, of Dr. Maskelyne, the double stars of Dr. Herschel, M. Meffier's nebulae, and all those of Dr. Herschel, excepting his 2d and 3d classes, that is, all those which are capable of being discerned with any telescopes inferior to his own. This work contains five distinct catalogues; viz. Dr. Maskelyne's new catalogue of 36 principal fixed stars; a general catalogue of all the stars, in zones of north-polar distance; an index to the general catalogue; a catalogue of all the stars in the order in which they pass the meridian; and a catalogue of zodiacal stars, in longitude and latitude.

The first catalogue contains the right ascensions in time, the annual precession of right ascension in time, and the annual proper motion, both in time and in degrees, for 1725, and also the zone to which it belongs in the second catalogue. These circumstances are deduced from a multitude of observations, recently made, with the utmost care and circumpection, by the astronomer royal, for the purpose of determining, when compared with his former settlement of the same stars in 1770, whether those stars have any motion of their own, and what it is. That the fixed stars, as they are usually called, have a proper motion of their own, has long been suspected; and it was supposed that it had even been detected in Arcturus: but this motion is certainly so small, that no observations, made before Dr. Bradley's time, were sufficient to exhibit it; and the series of twenty years, which our present ingenious and indefatigable astronomer royal has yet been able to obtain, seems much too short to determine it with any great degree of accuracy, even in the present improved state of astronomical instruments. The observations, however, sufficiently indicate such a motion in all the stars, and one which is very considerable in Arcturus.

The second catalogue, or that in zones, as its disposition is entirely new, will require some explanation. All the stars which are situated within 10 degrees of the north pole are collected together, and inserted in a catalogue by themselves, according to the order in which they pass the meridian; and this is called the first zone. The second zone contains all the stars which are situated at a greater distance from the north pole than 10 degrees, and at a less distance than 15 degrees, disposed in the same manner. The third zone contains all the stars which are distant between 15 and 20 degrees from the north pole; but hence, till the author comes within 20 degrees of the north pole, the zones are but one degree in breadth, that is, the fourth zone contains all the stars which are at the distance of more than 20 degrees from the north pole, and less than 21 degrees, disposed in the order in which they pass the meridian, and so on. The stars which are at a less distance from the north pole than 20 degrees, are disposed, like those which are at the same distance from the north pole, into two zones, each 5 degrees broad, and into one which is 10 degrees broad: so that the whole number of the stars is distributed into 145 distinct catalogues, or zones; and in each of these the stars follow one another in the order in which they pass the meridian.

Each of these catalogues employs nine columns: the first contains the right ascension of the stars, in degrees, for the 1st of January 1790; the second, the precession of right ascension, in the same manner; the third, their right ascensions in time; and the fourth, the precession in time. The fifth contains the star's distance from the north pole; the sixth, its precession in north-polar distance. In the seventh, the magnitude is expressed; the eighth contains the number, name, or character of the star, together with the name of the observer by whom its position was ascertained; and the ninth column contains short notes, intended to call the attention of observers to certain circumstances there mentioned, in order that they may either be disproved or verified by future observations. Where the situation of a star has been given by different observers, as is the case in most, each of their situations is given, reduced to the same time, (January the 1st, 1790,) and set down in the order in which their observations were made. By these means, it is readily seen how far different observers agree with each other, and wherein they disagree.

Mr. Wollaston's reason for thinking that a catalogue of the fixed stars would be more useful in this form than in any other, is stated in the Phil. Trans. vol. lxxiv. p. 181, and vol. lxxv. p. 346; where the author proposes frequent examinations of the heavens, as the means of detecting any alterations which may happen among the fixed stars. In this business, every astronomer was invited to take a part, and to examine a certain number of zones, (each one degree in breadth,) with a telescope of a large field, mounted on a polar axis, and furnished with a fylam of wires in its focus. This telescope being directed to the proper parallel of declination, and fixed there, the business of the observer would be, to take the transit of all the stars which passed the field of the telescope, at the several wires in its focus; which were disposed as to give both the difference of right ascension and declination between them; and for such a purpose, this catalogue is evidently well adapted.

The third catalogue is called, an index to the stars in the British catalogue, referring to the zone of north-polar distance, in which each star is to be found. This catalogue contains only the stars in the British catalogue of 1725, arranged in constellations; and the stars in each constellation follow one another in the same order as in that catalogue; but the constellations are disposed alphabetically. The catalogue employs three columns: the first containing the number of the star, as it stands in the British catalogue; the second,
Second, Bayer's letter of reference, where the star has one; and the third, the number of the zone to which the star belongs in the second catalogue, reckoning from the north pole: but the reader must take care that he is not misled with regard to the import of this last column: the author does not mean, by the number there put down, the number of the zones as they stand in his catalogue, but the number of the zones in which it would have been, if every one of his zones had been no more than one degree in breadth; so that his first zone, (as described above) is to be considered as containing 10 of the zones in the second catalogue; and the second and third zones must be considered as each containing five.

The fourth catalogue contains the stars of the British catalogue, of de la Caille's southern catalogue, and about eighty stars from Hevelius's catalogue, which were omitted by Flamsteed, all arranged in one continued series, according to the order in which they are on the meridian. This catalogue employs five columns: the first containing the star's right ascension in time, for the 1st of January 1752; the second, the star's distance from the north pole, for the same time; the third, the magnitude of the star; and the fourth, the number, name, or character of the star, and the constellation in which it is placed.

The fifth catalogue gives the longitudes and latitudes of such stars as are situated within nine degrees of the ecliptic, arranged in the order of their longitudes. It contains all the stars which are to be found within these limits, in the catalogues of Flamsteed, Bradley, Mayer, and the small catalogue of de la Caille, at page 28 of his "Almanach Fundamental." This catalogue employs three columns: the longitude of the star, reduced to the beginning of 1750; latitudes in the first column; the second contains the latitudes of such stars as are on the north side of the ecliptic; and the third gives the latitudes of such as are on the south side of it. The fourth column exhibits the magnitude of the star; and the fifth, the number, name, or character of it, and the name of the observer who assigned its situation. Where any star has been observed by two or more persons, the result of each of their observations, (reduced to the same epocha,) is inserted, in the order in which their observations were made.

In 1792, Dr. Francisco de Zach published at Gotha, "Tabulæ Motuum Soles," to which is annexed a new catalogue of the principal fixed stars from his own observations, made in the years 1787, 1788, 1789, 1790, 1792. This catalogue contains the right ascension and declination, with the magnitudes and annual variations in right ascension of 351 principal stars, adapted to the beginning of the year 1800. The catalogues of the places of Dr. Bradley's, 55 fixed stars, adapted to the beginning of the year 1793; of those of M. de la Caille, 51 stellar stars, adapted to the beginning of the year 1765, of the same author's, 87 principal stars in the heavens, adapted to the year 1750; of Zach's 381 principal fixed stars, adapted to the beginning of the year 1800; of the same author's declinations of 163 principal fixed stars, with their annual variations, adapted to the beginning of the year 1800; and of Mayer's 902 principal fixed stars, adapted to the year 1792; are published by prof. Vincent in the 2d volume of his Astronomie. M. de la Lande has published a new catalogue of more than 12,000 stars in the volumes of the "Connoissance des Temps," from the year 7 (1790) to the year 12. Almost all these are stars which had not been before observed. M. C. Vidal has lately communicated to the lyceum of Tonlouse a catalogue of 889 auroral stars, from the 5th to the 7th magnitude inclusively. Every star has been observed three times, and all are reduced to a mean position, regard being had to the effect of refraction, the aberration of light, and the rotation of the earth's axis. The mean position of all these stars has been calculated to a common period, viz. Jan. 1, 1798; the equation and precession of the equinoxes being previously allowed for. The place of M. Vidal's observation was Mersoupi; a situation admirably suited to his purpose, by the fertility of its atmosphere and the excellence of the instruments with which its observatory is furnished, and commanding nearly fix degrees of the heavens northwards more than Paris. On this account C. Lalande, and his nephew C. François Lalande, in their grand work of completing a catalogue of 38,000 stars, have engaged M. Vidal to form a catalogue of the auroral stars, which he has executed with great success and admirable precision. From the history of astronomy for 1800, by Jerome de Lalande, it appears that M. F. Lalande has terminated the labour, commenced August 5, 1789, and determined the places of 50,000 stars from the pole to two or three degrees below the tropic of Capricorn. The examination of the heavens is still vigorously prosecuted by the European astronomers, comformably to the plan and wishes of Mr. Wallaston; and from the industry and accuracy with which their observations are conducted, we may expect the happiest result with regard to our knowledge of the stars and other celestial bodies.

CATALOGUES OF THE BIBLE. See BIBLE, CANON, AND TESTAMENT.

CATALONGAY, in Botany, the name given by some authors to the plant which produces the faba fontani Ignati, or St. Ignatius's beans of the shops.

CATALONIA, in Geography, a province of Spain, bounded on the north by France, from which it is separated by the Pyreneé, on the east and south-east by the Mediterranean, on the south-west by the province of Valencia, and on the west by Arragon. Its form is nearly that of a triangle; the base towards the Mediterranean being about 100 miles in length, the side towards France 125, and that towards Arragon 140 miles. Catalonia, towards the shores of the Mediterranean, has many convenient sea-ports; the inland country is in general mountainous, particularly in the northern part towards France, but intermixed with a variety of spacious plain and fertile valleys. The mountains are covered with large forests of tall trees, such as the oak, the ever-green oak, the beech, the pine, the fir, the chestnut, and many others, besides cork trees, shrubs, and medicinal plants. The soil is rendered productive by the industry of the inhabitants, so that Catalonia is reckoned one of the best cultivated provinces in Spain; and it yields a plentiful supply of corn, wine, oil, flax, hemp, licorice, and many other gourmandies. Of grapes, wines, nuts, almonds, raisins, and cork are shipped annually in vast quantities on the coast, for the merchants who reside in Barcelona. The wines are Mataro, Villanova, Sitges, Valls, and Granatcche. The price varies according to the season; but when it is highest, we may reckon Mataro at 20 dollars, or 480l., the hoghead, including the Spanish duties; Villanova, 15 dollars; Granatcche, 40. All these are red. The following white wines are, Sitges, 54; Valls, 20 dollars; but the common price is 12 1/2 dollars per hoghead for both the Mataro and Villanova. When brandy is dearer, it is sold, duty free, at 57 dollars, or 8l. 11s. the four cargos or pipe of 124 gallons English, Hollands proof, or 12 43l. per gallon; but it is sometimes sold at 100. Catalonia furnishes 35,000 pipes of brandy, and 2000 of wine, besides 50,000
50,000 bags of nuts, containing three bushels each, at 20s. the bag. Of the above about 4000 pipes of brandy, and some silk, go to Guernsey and Alderney, and the rest to France, all to be smuggled into England. The merchants also export wrought wools, printed cottons, woollen goods, small arms, and spicce; the last article, however, is contraband. Their imports are, corn, fish, woollen goods, hardware, and oil of vitriol. The articles prohibited are, beer, cider, lead, hogs, haberdashery, muslins, and cottons; but of the two last, immense quantities are smuggled into this province. The mountainous districts have quarries of marble of all colours, crystal, balabos, amethysts, and lapis lazuli. Gold dust has been found among the sands of one or two miles inland, and there are arroyos, copper, lead, tin, iron, silver, one of gold, alum, vitriol, and salt, and many of coal. On the eastern coast they likewise fish for coral. Provisions of every kind are excellent. The climate is mild in the plains, the cold on the mountains is supportable, and the air is pure. It is neither so hot as Andalusia, nor so cold as Alturas, and the northern part of Spain; being sheltered on the north by the Pyrenees, and on the east by the sea. This temperature, joined to the many streams and rivers with which the country abounds, renders it very fertile and delightful. The inhabitants are hardy, courageous, industrious, active, vigorous, and good soldiers, but apt to be discontented. The miquelets are a sort of soldiers, whose province it is to guard the pales of the mountains and to protect travellers; but they are often extortionate in their demands of recompense.

In Catalonia, as in France, with which province this was formerly connected, accounts are kept in livers, lols, and deniers; 12 deniers making a sol, and 20 sols a livre. But in reckoning by the money of the province, nominal and real, there is great perplexity. If we reckon the peso or current dollar at 30½ florins, the hard dollar will be four, the current pils ge 12; and the pils of gold, 15½. See Coins. As to the measures in Catalonia, 12 carots make one quarter, which is two bushels, English measure. Sixteen carots make a carga of wine or brandy, which is about 30 gallons English, and is reckoned to be 12 arrobas. 100 quarters make one menubo. In estimating the weights of this province, eight ounces make a marc, being ½ heavier than in Catalonia; 12 ounces make a pound; 20 pounds one arroba; four arrobas one quintal, which is 93 pounds English, or 91 pounds Catalan; 155 pounds make 122 pounds English.

In the beginning of the last century they reckoned in Catalonia 1059,866 houses, and only 38,1490 inhabitants; but the province had then been ravaged by civil war. In 1763 the bishops, in their account of the population, made the following return: viz. men, 189,571; women, 182,753; boxes, 3,157; girls, 22,661; clergy, regular and secular, 14,435; in all, one million and thirty thousand two hundred and forty-five. Since that time the population has not decreased; and yet, in the returns to government, A.D. 1787, the number of inhabitants is fixed at only 80,610. Of these 953 are under vassals, and 12,966 are knights. These accounts, so different from one another, without any assignable cause of deficiency in the latter, show, that, notwithstanding the most vigilant attention on the part of government, they always fall short of the actual population, because it is the interest of every family, parish, and district, to conceal their numbers, in order to avoid the taxation. Catalonia enjoys the privilege of exemption from the taxes called alcavals, cintes, and millones; in lieu of which the inhabitants pay 10 per cent. on all rents, belonging to individuals or communities, and on the suppoised gains of merchants and mechanics. They are subject also to some other charges on labour and manufacture, and on cattle. The whole amount of the taxes collected in Catalonia was, A.D. 1721, 488,567½ florins. But as the revenue of Spain is more than doubled since that period, if we allow the same increase for Catalonia, we may fix the revenue arising from this province at least less than a million florins; which, according to the computed population, is 205, annually for each person; whereas, taking the whole province together, the Spaniards pay no more than 108, each per annum. Considering the rapid circulation of money in this province, and the universal affluence resulting from it, with the peculiar advantages and resources of the Catalans, this contribution, though relatively heavy, is comparatively light; for being freed from the flagrating influence of the alcavals, cintes, and millones, they enjoy a decided superiority over provinces which have never claimed the fame indulgence. Unfettered by these impolite restraints, and permitted to set their own value on their commodities exposed to sale; their industry is free, and not like that of less-favoured provinces, crippled in all its operations. In addition to these immunities, the great number of troops, quartered in Catalonia, not only gives to the farmers and manufacturers a ready market for their commodities, but contributes much to maintain good order in the province. For near two centuries previous to the accession of the present family, Catalonia was infested with banditti, who, by robbing and plundering passers, interrupted the safe and easy communication of the cities with each other, and prevented, in a great measure, the interior commerce of the country. But Philip II. stationed a considerable detachment of his troops in this doubtful part of his dominions; and these not only restored good order, but revived commerce by a quick and certain demand for all the productions of industry. Besides, the popular prejudice in Catalonia is favourable to commerce; for here arts and manufacturers are as much honoured and respected as in other provinces they are defiled. In conference of this their trade is brisk; the vessels employed to carry it on are more than 1000; and government can always depend upon 18,000 seamen, who are registered and always ready to obey the summons in cases of emergency.

Moreover, what contributes most to the wealth and prosperity of Catalonia is the power, which gentlemen of landed property have over their estates to grant a particular species of lease, called "Establishment by enfeetive contracts." By this kind of contract, the great proprietor, inheriting more land than he can cultivate in profit, has power to grant any given quantity for a term of years, either absolute or conditional, either for lives or in perpetuity, always reserving a quit rent, like our copy-holds, with a relief on every succession, a fine on the alienation of the land, and other feignid rights dependent on the cultum of the district, such as tithes, mills, public-houses, the obligation to plough his land, to furnish him with teams, and to pay hearth-money, with other contributions, by way of commutation for ancient lettered services. The tenure in Catalonia is evidently feudal. All property in land is traced up to the king, and is held by knights' service from the crown, subject to relief, to fines, and to escheat. Under the royal grant, the great lords claim, not merely tithes of all lands not being freehold, with quit-rents and fines, mills, and public-houses, but the right of appointing magistrates and receiving tolls on the pillage of cattle over their estates. To the power retained by them of making enfeetive contracts has been, in reason, been attributed the cultivation of such waste lands as are inestimable of tillage, and the consequent increase of population. Industry has been promoted, new families have been
CATALONIA, in Botany, the Indian name of a North American plant, referred to Linnæus to the genus bigno-

nia, (see BIGNONIA CATALPA); but as the plants included in

this genus differ considerably from each other, it has been

divided by Julliff and Ventenat into four, jucaranda, ca-
taluca, tecoma, and bignonia. Of calatalpa, the French

naturalists give the following character. Cal. two-cleft. Cor.

bell-shaped; tube divided; border four-lobed, unequal.

Stam. two, fertile, three, barren. Stigma bilobellate. Capsule

resembling a bilque, long, cylindrical, two-valved; part

tion opposite to the valves. Seeds with a membranous

appendage at the tip and base. Trees, withimple, ternate,

whorled leaves and pinched flowers. Julliff refers to it, bi-

gnonia catalpa of Linnæus, and bignonia longiflora of Jacquin.

CATALAS, Catalla, denote good or chaste's.

CATAMARAN, in Sea Language, is also called Dalza, or Balfa, for an account of which see the article Boat.

CATAMENIA, from αερ and μη, month, in Medicine, women's monthly purgations, called also menstru, which see.

CATAMITE, a boy kept for fodomitical practices.

CATAANA, in Ancient Geography, a town of Asia, in Syria, situate, according to Ptolemy, in Commagena.

CATAMARAN, or CATAMORAN, in Sea Language, is also called Dalza, or Balfa, for an account of which see the article Boat.

CATERAMENIA, from αερ and μη, month, in Medicine, women's monthly purgations, called also menstru, which see.

CATERINITE, a boy kept for sodomitical practices.

CATANA, in Ancient Geography, a town of Sicily, on the eastern coast of the island, in a gulf of the same name. Thucydides says, that this city was founded seven years after Syracuse, by the Chalcidians, from Naxus. Strabo also mentions it, and says, that it was repaired by Augustus, and became a Roman colony. Pliny and Ptolemy give it this title. Strabo reports that this city lost its first inhabitants; but that Hiero, tyrant of Syracuse, placed others in it, and changed its name into that of Catana; assuming the glory of being its founder. It still bore this name; when Dionysius, to revenge himself for the successes which it had given to the revolted inhabitants of Syracuse, levelled its walls, and bestowed its territory on the Campanians; and immediately after the decease of Hiero, the Catanea expelled those whom he had established there, and demolished the tomb of the tyrant, and the city regained its ancient name. It fell into the hands of the Romans among their earliest acquisitions in Sicily, and became the residence of a praetor. To make it worthy of such an honour, it was adorned with sumptuous buildings, and every convenience was procured to supply the natural and artificial wants of life. It was destroyed by Pompey's son, but rebuilt, with superior magnificence, by Augustus. The reign of Deceass is famous, in the history of this city, for the martyrdom of its patrons, St. Agatha, whose intercession is implored on every emergency. She is piously believed, says Swinburne, to have preserved Catana from being overwhelmed by torrents of lava, or shaken to pieces by earthquakes; yet its ancient edifices are covered by repeated streams of volcanic matter, and almost every edifice, even her own church, has been thrown to the ground. In the reign of William the Good, 20,000 Catamians, with their pastor at their head, were destryed before the sacred veil could be properly placed to check the flames. In the 17th century Catana was twice demolished. Cecco, speaking of the riches and beauty of this city, adds, that it had a temple dedicated to
CAT

Ceres, in which was preserved an image of this goddess; but that only women were allowed admission, and that it was guarded by young females. See CATANIA.

CATANANDROMI, in Leibnitz, a term of the same significiation with the more common word anadromi, the distinctive term of a set of fishes, which at times leave the fresh water for the salt, and afterwards return to the fresh water again. See ANADROMOUS.

Gen. Ch. Cat. common, imbricate, top-shaped; scales numerous, long, egg-shaped, acute, concave, fan-shaped, thinning, permanent. Cat. common, uniform; florets all with lamens and a pill, numerous ligulate, linear, torch-shaped, five-toothed. Stamin. filaments five, cavernous, very short; anthers forming a hollow cylinder. Pili. germ oblong; style filiform, the length of the filaments; stigma bifid, reflexed. Peric. the permanent calyx. Screw solitary, egg-shaped, crowned with a five-leafed, chaffy, appressed pappus or calyce. Recap. chaffy. Eff. Ch. Receptacle chaffy. Calyx imbricate. Pappus consisting of five chaffy awned leaves.

Propagation and Culture. The first species may be propagated by slips planted in pots filled with light sandy soil, or in warm borders, under the shelter of walls, palis, or hedges. But it succeeds better when raised from seeds sown in March, in a border of good warm earth, and afterwards transplanted into pots or borders where it is to remain for flowering. The third species may also be readily raised from seeds; but, as it has little beauty, it is not often kept in gardens. Mill.

CATANADAMES, or CANTADIUS, in Geography, a province of the island of Luzon or Manilla, consisting of a small island to the most south-easterly part of Luzon; its southern point being almost parallel with Siurian. Its shape is triangular, about 30 leagues in compass, and 10 in length.

As it is exposed to the north wind, it is always stormy; and it lies so near the Entuacadero, or mouth of the channel of St. Bernard, that some pilots mistaking it, and apprehending that they were entering the mouth of the Strait, have found themselves among dangerous flats, which encumber the island about a mulecot-shot from the shore, and suffered shipwreck. This island abounds in rice, oil of palms, cocaos, honey, and wax. It has several rivers that are dangerous to crofs, in the channel of which is found gold, brought down from the mountains by the floods. The largest of these is called Catandangan, and by the Spaniards Catanduanes, whence the island took its name. The chief employment of the natives is the carrying of wood, and the making of light boats, which they sell at Mindora, Caleleya, Balayan, and other places. They still make one very large, without any deck, and not nailed, but fewed together with Indian canes, and then others lefs and lefs, one within another, and thus they transport them to league. The people paint themfelves; they are warlike, and excellent sailors; and if a boat be overft, they leap into the water and immediately turn it. Appreheending fluch accidents, they carry their provisions in the following manner: they clap their hands and tied to the fides of the boats. Their habitation is only a half-way, which reaches down to the knees. The women are of a manueline size, and apply themselves as much as the men to tillage and fishing. They are modestly clad in a coat or jerkin, and a long mantle. Their hair is tied on the crown of the head, forming a knot like a rope. On the forehead they wear a plate of gold two fingers' broad, lined with taffeta; in their ears three gold pendants. On their ankles they have rings, which make a tinkling noise as they move.

CATANGIUS SINUS, in Ancient Geography, a gulf of Asia Minor, in the Thracian Dorphorun.

CATANHEDE, in Geography, a town of Portugal, in the province of Beira.

CATANI, in Ancient Geography, a people of Asia, in the vicinity of the Cappin Sea, according to Pliny.

CATANIA, or CATANEA, a town of Sicily, in the valley of Noto, near the foot of mount Aetna. This city has frequently suffered in ancient and modern times, from the eruptions of this mountain. See AETNA and CATANA. The materials of which the modern city is built are such as might be expected in a volcanized country, where laves of any other than a volcanic nature are not to be found, but at a considerable distance. The edifices, both public and private, and even the walls of the city, are principally of lava; which has furnished materials not only for the modern Catania, but also for the more ancient city, which was entirely destroyed by an earthquake in the year 1693; at least its ruins, when dug up, have all been found to consist of lava. Those who have taken a view of the surface of the territory of Catana have every where met with immense accumulations of lava; among which the most conspicuous are the remains of that torrent which, burrying from one of the fides of Aetna in 1669, inundated a space 14 miles in length, and nearly four in breadth, rofe over the walls of Catania, burrying under it a part of the city, and at length precipitated itself into the sea. The prince of Bicolor has employed great labour and expense in digging down to the ruins. We defend, says Mr. Swinburne, into baths, tepidures, an amphitheatre, and a theatre, all much injured by the cataclysms that have befallen them. They were erected on old beds of lava, and even built with square pieces of the same substance, which in no inulence appears to have been fitted by the contact of new lavas. The fciara, or laves of cold lava.
lava, have constantly proved as strong a barrier against the
flowing torrent of fire, as any other stone could have been,
though some authors are of opinion, that the hot matter
would melt the old maf, and incorporate with it. Nothing
less than the fertility of its territory could have inspired
the inhabitants with the courage, or rather the obstinacy,
to build and rebuild in a situation which derives no advantage
from the sea; which is without a river and without fortifi-
cations; exposed to all sorts of natural misfortunes, and
continually threatened with the dreadul calamities which
have already proved so destructive. And yet in the course
of the last century it has revived with great splendour, and
when all the houses are finished, it will be a very handsome
city. In the progress of its improvement it has acquired
more the features of a metropolis and royal residence than
Palermo. Its principal streets are long, straight, and wide,
and well paved with lava; but they are so divided, that in
the middle of the day this burning town is totally without
shade, and almost impassable. If its wealthy inhabitants had
possessed a greater degree of taste; if, instead of huge pa-
laces, and large churches of an oblong and fan形 archi-
tecture the buildings had been erected in a simple and noble
style, Catania might have been one of the most magnificent
cities in the kingdom of Naples. The market-place, how-
ever, is without beauty; it is a square cut off at the
angles, and decorated with arches supported by marble
columns. In the centre of the great square formed by the
town-hall, seminary, and cathedral, are two antique frag-
ments, very happily grouped: they consist in a part of an
Egyptian obelisk of granite, with hieroglyphic characters;
placed on the back of an elephant formed of lava, the an-
cient symbol of Catania. The cathedral erected by the
abbot Angerus in 1694, and endowed by earl Roger with
the territories of Catania and Atina, has suffered so much
by earthquakes, that little of the original structure remains,
and the modern parts have hardly any thing, except their
materials, to recommend them. The other religious edifices
of the city are profusely ornamented, but in a bad taste.
The Benedictine convent of St. Nicholas is the largest be-
longing to that or any other religious order. Every part
has been rebuilt since the earthquake of 1697. The church
is a noble fabric, though it has many defects in the design
and execution; and is accounted the largest in Sicily. The
organ, constructed by a Neapolitan priest, is much esteemed
by connoisseurs in musical instruments. The tones of all
sorts of wind and strung instruments are imitated by it with
the most perfect illusion. One wing of the monastery is ap-
propriated to a considerable museum of antiquity and natural
history. This museum is magnificent, and amidst a variety
of trailing objects it contains some statues in bronze, of as
perfect purity and beauty as those of the cabinet of Pariti,
carved vases of most elegant form, and very curious lamps.
The prince of Biscario, to whom the modern Catania is in-
debted for many of its improvements, has also formed a very
magnificent museum. His collection consists of specimens
of the most curious subjects in antiquity which Catania and
Sicily produce: such as the remains of architecture, Minoan
ornaments, Roman and Grecian materials for building; sculp-
ture, among which, a single colossal Torso, found at Catana,
may be ranked with the most beautiful pieces of antiquity;
a collection of carthen vases, peculiarly valuable for the
number, the forms, and preservation of the figures repre-
sented on them: another of antique bronzes; the natural
history of marine productions, plants, fishes, and fishes; and
the productions of the earth, such as minerals, vegetables,
volcanic matters, marbles, precious stones, and animals:—
the whole arranged in an order which exhibits fience,
taste, and industry. You see likewise in this museum a
series of arms, armour, and singular columns. In this city
there is also a third museum, the pavior and founder of
which is the chevalier Genet: the valuable contents of
which are enumerated by Spallanezzi. One of the greatest
curiosities at Catania is the Villa Scarra, belonging to the
prince of Biscario. Upon the black impenetrable surface
of the lava, which isosued from 37°E in 1694, this prince has
laid the plan of a garden, built houses, planted trees in foil
brought hither from other places, and formed two large
ponds of fresh water. Supplied by springs that ooze through
the lava. The pools of the Villa are llocked with fish and
water-fowl, and are preferred from the fury of the neigh-
bouring sea by a strong pier, which is the only separation
between the salt and fresh water.

The number of public edifices that are crowded together
in so small a space, has left little room for the houses of
individuals; and from this circumstance it has been inferred,
that Catania has been embellished at different periods, or
that the private houses were extremely small in comparison
with the public buildings; or that the ancient city was more
ornamented than extensive, and, consequently, more rich
than populous. The modern town is somewhat of the same
kind. Although its population be estimated at 20 or
30,000, and by the Catamians themselves at double this
number, yet nothing is seen in the streets but convents,
churches, and palaces, separated by a few private houses.
Catania is the see of a bishop, suffragan of Monreal, whose
revenues are very considerable; 1200l. sterling per annum
being derived, as it is laid, from the sale of snow collected
on mount Etna. This city has also an university, the only
one in the island, and the nursery of all the lawyers. N.
l. lat. 37°30', E. long. 15°19', Swinburne's Travels,
vol. iv. Brydone's Travels, vol. i. Spallanezzi's Travels,
vol. i. De non's Travels.

CATANIDIS PRONONTORIUM, in Ancient Geography, a
province of Africa Minor, in the vicinity of the isle of
Lebos, toward the Arginae islands, according to Di Dorous
Siculus.

CATANII, a people of Arabia Deserta.
CATANITAE, a people placed by Ptolemy in Arabia
Felix.

CATANZARO, in Geography, a town of Naples, in
the province of Calabria Ultra, the seat of a governor and
tribune of justice, the see of a bishop, suffragan of Reggio.
It is built on a mountain, and has manufactures of silk
velvets and cottons. This town was built in 961 by order
of the emperor Nicephorus Phocas, as a post of strength
against the Saracens, to which its situation on an eminence,
in the pass between the mountains and sea, adapted it. In
1551 it attained to the dignity of capital, formerly the right
of Reggio. It contains 12,000 inhabitants, who live by the
law, and the trade of corn, wine, and oil. The college of the
late John is a handsome building, and possesses a good statue
of St. Ignatius, by Forzza, and a very fine picture repre-
senting St. Domenico distinguishing bread to the poor, 9 miles
N.E. of Squillace. N. lat. 37° 9', E. long. 18° 16'.

CATAO, a town of Aia, in Tiburt; 15 miles W.S.W.
of Y sbo:

CATANOIA, in Ancient Geography, a province of Asia,
in Armenia Minor, between Tauris and Antiochus. Strabo
places it in a province in Cappadocia, because Armenia Minor
once made a part of Cappadocia; and he says that Antares
the 1. king of Cappadocia joined Catanoia to Cappadocia.
It is situated to the north of Cilicia Cappadocia, and traversed
from the N.E. to the S.W. by the Rarus. Two principal
towns were Tatara and Comana Cappadocias. The
Pyramus
Pyramus had its source in the mountains of the eastern part.

CATAPAN, or CATIFAN, a name the later Greeks, about the twelfth century, gave the governor of their dominions in Italy.

Ugellinus and others say, catapan was the name with capitateus; formed from it by metathesis, or transposition: others derive it from κατα, justa, and σαπο, onum; in which sense, catapan was a governor-general, or magirstrate, who had the direction of all: others will have it derived from καταωμενη, that is, next after the emperor. In which sense, catapan was a second mailler, feconlus dominus. Du-Cange derives it from κατετεμον, captain, which the Greeks applied to every governor, and every man of quality.

CATAPELTA, an instrument of punishment, in use among the ancients. It consisted of a kind of planks, composed of planks, between which the criminal was crushed to death.

CATAPELTA, in Ancient Writers, more frequently written catapulca, which fee.

CATAPHORONICUS, in Music, synonymous with cataphorica, which fee.

CATAPHORA, in a theme of the heavens, an appellation given to the houses falling from the third, sixth, ninth, and twelfth angles. In which sense the word stands opposed to anaephora.

CATAPHORA, in Medicine, a term formerly used to denote a variety of lethargy, or coma, with which it may be confounded as nearly synonymous. It signifies a lesser degree of sopor than the term Carus (which fee), or a lesser approach to the state of complete apoplexy. But these distinctions are now discarded as useless, since the nature, causes, and treatment of all must be similar; they are not different diseases, but only different degrees of the same disease. Sauvages defines the cataphora, "Status somnolentus facile excitabilis, sine febre, delirio, et oblivione." Nofol, Meth. clafs vii. ord. v.

CATAPHRACTA, from κατα, and φαρακτος, I fortify, or arm, in the Ancient Military Art, a cuirass, or heavy defensive armour, composed of plates or links of iron, so curiously fastened and arranged on strong cloth or leather, like plumes, that they preferred the same appearance in all motions, and left no part of the body exposed. It was formerly used sometimes both by infantry and cavalry, and when by the latter, it was generally made to cover the horse as well as his rider. It was anciently used by the Persians, Sarmatians, and others. It was frequently made to cover only the breast. The Romans adopted it early for their foot, and, according to Vegetius, retained the use of it till the time of Gratian, when the Roman discipline becoming greatly relaxed, and military exercises with laborious duty being chiefly discontinued, their foot thought the cataphracta, as well as the helmet, too great a load for them to carry, and therefore threw both aside. But he tells us, that by thus leaving their breasts and heads exposed and unprotected, they were, when fighting against the Goths, frequently destroyed by the multitude of the archers of those barbarians. He very emphatically observes, that whilst they declined military fatigue, and the trouble of carrying armour sufficient for their protection, they were in a most disgraceful manner killed like sheep. Hence it would appear, that the Romans were overcome chiefly by the bow, after they had laid aside their defensive armour. His words are the following: "Licet exemplum Gotthorum et Alanorum, Humororumque equitum arma praeceptor pedes tamen confitat esse nudatos. Ab urbe enim condita uique ad tempus D. Gratiani, et cataphractis et galcis muniabant pedestri exercitus. Sed cum campellis exercitatio, interventi neugentilia deindeque essaire, gravia videri arma copernunt, quae raro utique milites inducant. Itaque ab imperatore potius, primo cataphractas, deinde caifides depone; ine detectis pectoribus et capitibus, condedit contra Gotthos milites nofri, multitudine fagittariorum fape deleti sunt; nec poll tot clades, quae ut ifte ad tantarum urbamar excedia pervenerunt, cuipiam cura fuit, vel cataphractas vel galcas pedetribus reddere. Ita fit, ut non de pagno, fed de fugis cognit, qui in acie audt exporantur ad vulnera. Quod enim pedes fagittarius fine cataphracta, fine gales, qui cum arcu feutum tenere non potest, fatisfiat? Quod ipsis diacumen atque figniferi, qui finitima manu holidak gubernant, in procell facient, quo et capita nulla efficent, et pedes? Sed gravis pedes loricæ videtur, et gales fortes, rario medianti arma raro tractanti. Ceterum quotidianus usus non laborat, etiam fit onerola gecluverit. Sed illi qui laborem in portandis veteribus munimentis armorum, ferro non pollunt, detectis corporibus et vulnera fulminare coguntur et mortes; et, quot ctit gravis (et turpis) aut capi, aut certa fuga remplicantur prodere. Sic dum exercitum laboromque declinant, cum maximò dededere trucidandur ut preces."

In this passage Vegetius ascribes the success of the Goths against the Romans without their defensive armour chiefly to the great multitude of their archers. Even in the defence of modern fortifications there are situations in which we are convinced the bow and the arrow would have greatly the advantage of the musquet and bayonet, as in casedem galleries, in the counterscarps of ditches, &c. where musquetry often becomes ufeles on account of the smoke. And were it necessary to defend such a very inclosed country as this, many occurrences might arise, in which a certain number of good archers might be of more real ufe for the purpose of defence than the number of our belt musquetry. Tacitus, Hist. lib. i. cap. 79. Veget. de Re Mil. lib. i. cap. 25.

CATAPHRAXTI, among Surgeons, denotes a bandage of the thorax; thus denominated from its resemblance to a Roman tablet-blase, called cataphracta. See BANDAGE.

CATAPHRAXTIÆ NAXES, vessels armed and covered in fight, so that they could not be easily damaged by the enemy. They were covered over with boards or planks, on which the folders were placed to defend them: the rowsers sitting underneath, thus screened from the enemies' weapons.

CATAPHRACTI, or CATAPHRACTARII, perfons fitted with cataphracta. The term, however, is most commonly employed to denote an ancient species of cuirassiers, or horsemen, covered completely, as well as their horses, with such armour as is described in the article Cataphracta, which fee. The Persians made ufe of such cavalry: after them the Greeks; and then the Latins. Antichus had 3000 of them when he marched against Scipio Africanus. And as the Romans copied after the Greeks, notwithstanding their hatred of them, in things they thought useful and advantageous, there is every reason to suppose that they borrowed from them that institution. The same meaning is affixed to the term Crespellarii.

CATAPHRACIUS, in Zoology. See DASYPUS.

CATAPHRACCIUS Pegge, in Ichthiologist. See COTTUS Cataphractus.

CATAPHRYGIANUS, in Ecclesiastical History, a sect in the second century, so called as being of the country of Phyrgia. They were orthodox in every thing, setting aside this, that they took Montanus for a prophet, and Pricilla and...
C A T

And Maximilla for true prophetesses, to be confuted in every thing relating to religion; as supposing the Holy Spirit had abandoned the church. See MONTANIST.

CATAPLASM, in Surgery, a poultice, or external application of a pulpy consistence, more or less composed of substances possessing a medicinal quality, and thence denominated antiseptic, emollient, diffusive, anodyne, alfringent, stimulating, maturing, repellant, &c. Cataplasms have their name from κατα, "illining," to spread or belmear; and are therefore always supposed to be somewhat coherent or tenacious.

They usually consist of farinaceous ingredients or mucilaginous vegetable matters, which are mingled with gums, balsams, resins, eggs, honey, &c., and stiffened by the addition of vinegar, water, or milk, and generally applied warm. Ignorance and caprice, however, have introduced a vast Farrago of substances into compositions of this class; but judicious and experienced surgeons have limited them very considerably, and much simplified the form of their cataplasms.

The practitioner who keeps in mind the particular object he has in view, whether to communicate heat, cold, moisture, or some peculiar medicinal virtue, will not be at a loss to find appropriate materials for his purpose; in the Pharmacopoeia of the Chirurgics of Mr. Houillon are contained many formulae of this nature, adapted to various occasions.

CATAPOTIA, from καταποτία, "I pass, dry medicines, in a form fit to be swallowed whole; otherwise called pills.

CATAPPA, in Botany, Rumph. Gert. See TERMINALIA.

CATAPTEA, in Ancient Geography, a town of Asia Minor, in Bithynia, seated on the Euxine sea.

CATAPULTA, from καταποτίς and πέλης, in Ancient Military Language. Much diversity of opinion has existed among modern writers, in regard to the catapulta and ballista; some representing the former as having been employed to throw stones and bulks, and the latter to throw arrows, darts, javelins, pointed poles, &c.; others revering these applications of them; whilst some contend that each of them was made use of for both purposes. The chevalier de Foldard, whom many of the French writers have followed on this subject, in his "Traité de l'Attaque et de la Défense des Places des Anciens" speaks of these machines in the following words.

"Polybe dit formellement par tout, où il parle de ces deux machines (la baliste et la catapulta) que la baliste jettoit des durds, et la catapulta des pierres."

"La catapulta, comme la baliste, avait différents noms. Les Grecs ont appelée d'une façon, et les Romains d'une autre, chaque nation comme il lui a plu; César l'appelle tantôt catapulta, tantôt onager, onagre. Les Grecs de la moindre antiquité appellent tantot l'un tantot l'autre, jamais machine n'a fourbu tant de différents noms. J'aurais peur de compter une douzaine tout au moins, qui ont côtoyé toutes les nations. Je confies qu'on les a adoptés tous, mais du moins ont-ils eu le fer de prendre dans la description de la machine, car le nom n'y fait rien, et ne change rien à la chose, des que nous en concevons la structure et le principe du mouvement."" 

"Le scorpion ne fut jamais la catapulta, comme une infinité de commentateurs l'ont cru; ce n'est que la baliste; car quel rapport peut avoir la catapulta avec cet animal?"

"Végèce dit qu'on nommait autrefois l'scorpion, ce que de fon temps on appelle manubilia; c'est l'arbalète dont on commence a fe servir du temps de nos pers, et que nous avons abandonné depuis l'invention de nos fusils, ou de nos mousquets, quoique cette arme, toute prevention a part, fut infaillible plus meurtriere et plus avantagée, que ne le font nos fusils, ses coups plus courts et plus affuré, et la force au moins égale. Végèce prouve affez, que le scorpion etoit la baliste des anciens. Cela se voit dans César en plusieurs endroits de ses commentaires, car il emploie indifferemment ces deux termes pour signifier la meme machine; mais il distingue toujours collect de la catapulta: César in cafbris, dit Hirtius, scorpionum catapultarum magnam num habebat."

"Avant que d'entrer dans l'explication de notre catapulta, ou pour mieux dire de celle des anciens, je crois, que le lecteur ne fera pas faché de voir le celle d'Ammian Macellin, Liv. xxiii, en éclaircissant ce que nous paroit obscur et embarrassé dans le texte de cet historien. Cette hardiesse nous doit etre permise, lorsqu'elle ne va pas au delà des bornes raisonnables." His translation follows.

"La catapulta est comporte de deux poutres carrées, d'ici cet historien, qui se joignent à leurs extrémités par deux travers. Aux deux cotés et vers le milieu de leur courbure, on pratique deux trous arrondis opposés l'un à l'autre, et larges à proportion du poids qu'on veut jeter; c'est dans ces deux trous que l'on fait passer un cordage repiqué en plusieurs tiges qui passent défis et cœliaux deux chevilles de fer qui portent cette espèce d'écheveau de cordes. Au milieu de ce cordage filé et partagé par les deux chevilles de fer, on introduit à leur centre le bout d'une piece de bois ou bras fait en manière d'axe de charrette. Lorsqu'il est question de s'en servir, l'on entortille et l'on bande les cordes également des deux cotés; et de pur que la force du bande et des cordes entortillées ne lâche, on tient fixées les deux chevilles par un ancré: alors on balance le bras par le bout d'en haut par le moien d'un moulinet, et ce bout est retenu par une dentée; on met alors la pierre à l'extremité de ce bras qui forme un cuilleron (bowl or spoon). Un homme lâche alors la dentée d'un coupe de mailette, et fait partir le bras qui pousse la pierre d'une force extraordinaire, parce qu'il va donner et choquer dans le plus fort de son mouvement contre un montant, au milieu duquel il y a un couffinet rampl de paille hachée."

"And he complements that, who have written before him on the subject, in the following manner.

"S'il nous est permis de dire librement ce que nous pensons, ceux qui nous ont donné de la catapulta, entre autres Lipsic, Choul, Fabreç, Perrault, n'ont rien produit que d'imageraire.

"We far agree in opinion with Foldard that the real and original use of the catapulta was to throw stones, and that of the ballista to throw darts, &c. But we cannot help observing, that he mitiques Polybus in asserting that that historian constantly makes this distinction between these two machines whenever he mentions them. For at the siege of Thebes of Phthisis by Philip, where he makes Polybus say there were 150 catapulta and 25 ballista, that writer does not mention ballista at all. His words are these. ""]

"That is, 150 catapults and 25 stone-throwing machines being collected or brought together, &c. (Philip) advanced towards Thebes. Now the catapulta and ballista, as distinguished from the catapulta, was not the balista, but the onager, which threw stones by means of a woodenulus pole, or beam, and a chamfr or flyng pendred at the end thereof for receiving the stones. This machine might have been so constructed as to throw stones of any size. The καταποτία καταποτία τοπ ραβιολα, and the multitude of projectiles, which Mr. Hampton has translated, "darts etchargéd without interruption," might lead an inexperienced reader to suppose that there were ballista there, from which they were thrown. But this could not have been the case even
even according to his own translation of the Greek words denoting the machines, of which there were 25 distinguished from the 150 catapults, and which he expressly calls machines for throwing stones. Tolaed's assertion, then, on this point is altogether unfounded.

In like manner the words "εκ των ἀποκαλύφθησεν συντελετέων λεγόντων," and there were three places, stations, or batteries, for stone-throwers, used by Polybius, when speaking of the siege of Eginthus by Philip, are without any reason assigned by Cato by "et erant ibi tres flatti arboris locandis habilitis," and by Mr. Hampson, "and in these (trenches) there were three batteries of balista."

Folard also roundly and unreservedly affirms that Julius Cesar calls the same machine for times catapulta and sometimes onager. The truth, however, is, that Cesar does not make any mention at all of the onager. But his authority may be considered as decisive in regard to the use that was made both of the balista and the catapulta, and the distinction, in this respect, between the two machines. He mentions the balista only once, viz. in the second chart, or section of his second book, "De Bello civili," when speaking of the siege of Marseilles, by his lieutenant, C. Trbonius. His words are these: "Sim tamen antiquus in oppido omnium rerum ad bellum armamenta, tantaque multitudine armamenta, et ex eo in multa contextus minime vi minime fullimentum proficit. Allores cum pedum xii cubitalium praefixi, atque ibi maxima balistica meliorque quattuor ordinis erat dispositio in seletturum."

From this passage it is evident that even the largest balista were employed to throw long pointed poles, &c. and such like missiles. Of the catapulta he also makes mention only once, which he does in these words: "antiqua ex catapulta latericio differtur," which clearly shew, that the catapulta were in contradistinction to the balista employed for throwing stones.

Vegetius does not mention the catapulta; but he expressly tells us, that the scorpiones were called manubalista, or hand-balista, in his time. They were so called, no doubt, from such a machine's being manageable by one person.

And, besides him, Vitruvius informs us, that the scorpio and onager were different machines, though it appears from Ammianus Marcellinus, that the name of scorpion was also given to the onager.

Folard taking it for granted, that the catapulta and the onager were the same machine with different names, has translated as above a passage on the onager in the twenty-third book of that author, in such a manner as to make it serve for this supposition. What he calls his catapulta is neither the catapulta nor the onager of the ancients. It has a large wooden flasus, pole, or beam, with a lade or spout at the end of it for holding a fluid. This flasus is then let loose and throws a stone, which is violently turned on the ends of the beam at the top, and must from this either hit or itself in pieces, and so shake the other parts of the machine as to render the whole useless.

It has no string or cord, which that writer expressly says the onager had, in these words: "Summariaque ejus habet (ubi levis) quinque ferreti copulatam, et quibus pendet flasus vel ferrea finita." It is only necessary indeed to turn to the passage in A. Marcellinus to be satisfied, that the chevalier has translated it very carelessly.

The following extract respecting the frame of the machine is from Heron of Ctesiphon Telefacta.

"Due ligne accordant quadrata et equilata, quae scutorum depugnamentis, id est, transferuntur, idem atque eis consociato, ex quibus dene in extremitatibus cardine insitent, qui in lineas quadratas immitti in exteriorum partem pertingent, ut ait in ipsorum centinatarum foraminibus cuccoli adiacet p piam totum fortiolium continent. Extrematibus vero quadratorum lignorum faculce, quae transferuntur motum

lubent, septentrion, in quibus sunt foraminis, per quae vetusti trajectancar, five ad extrematibus, five in medio, per quos vericentur. Superant autem quadrata lignae ipsa depugnament ad superiorem patern." This author represents it as a machine of the cross-bow kind with two straight arms, one end of each of which is fastened in the upright cordage, and the other ends are joined by a cord or some other substance, answering the same purpose as the firing of a bow.

The catapulta was certainly of the large cross-bow kind, and when used acted like a pellet bow. The flasus was rectangular and consisted of two beams placed longitudinally, and connected together with cross-beams. On or near the middle of each of the side pieces there was an upright post erected. These two poles were mortised, or let into a strong cross-beam at top, parallel to, and directly below which there was also a cross-beam for upright cordage, which was framed both above and below by means of crowns put into the holes of the circular iron capitals, which had strong iron cross-pieces, smooth at top, to prevent their chafing the same, of which there were two sets or coils separate and distinct from each other, equally distant from the centres of the said cross-beams, and passing through the upper one, and either round pieces of iron fastened to the beam below, and cross-pieces of iron in moveable capitals as in the beam above. The two arms forming the bow lay horizontally. The inner ends of them were inserted in the upright cordage; and the outer ends were united by a bow-string which was drawn back by a windlass or capstan at the hinder end of the machine. When the cord or other substance forming the bow-string was drawn sufficiently back, it was held by a catch and iron pin, from which, when the machine was going to be discharged, it was disengaged by the stroke of a hammer or mallet. Under the bow there was a table or platform on a foot of universal joint, by which it was elevated in front when necessary and also moved a little to the right or left between the upright cordage.

There is now at Gibraltar a catapult, which was con- structed at the desire of the late Lord Heathfield under the direction of that very eminent military antiquarian, the present General Melville. It was for throwing stones a very little way over the edge of the rock in a particular place, where the Spaniards used to refer to the foot of it, and where shells thrown from mortars could not injure or annoy them. See the drawing of the said machine. Artillery, Plate II.

The catapulta and balista were both of them machines of the cross-bow kind and resembled each other in their general construction and moving powers, but were differently mounted for the different purposes to which they were applied or made use of. With the bow-string of the catapulta there was a cord or string farther or net-work for receiving the stones or bullets, that were to be thrown by it; and the table under it was plain or smooth; whereas in the balista, the table had a groove or channel in it for the arrows, darts, poles, &c. that were to be propelled or thrown forward. Their general form being almost similar, it is most probable the frame of the in long often confounded with each other even by some of the later Roman authors.

CATAPUTIA NISIS, in Ancient Geography, an episcopal see of Africa in Numidia.

CATARA, in Geography, a town of Arabia, 76 miles S.E. of El Carif.

CATARA, in Ancient Geography, an episcopal town of Asia Minor, in 1162.

CATARABON, a river of Upper Germany, which, ac-
CATARACT, in Hydrography, a fall or precipice in the channel, or bed of a river, caused by rocks, or other obstructions, stopping the course of its stream: from whence the water falls with an increas'd noise and impetuosity. The word comes from *acies*, a tumble down with violence; compounded of *ac-, aque*, water, and *tenere*, to throw down. Such are the cataracts of the Nile, the Tanabue, Bacone, &c.

Of the various cataracts of the Nile, two of the most remarkable are formed by the fall of the water between two mountains, which descends with such rapidity and noise, that the inhabitants within the sound of them are said to be deafened. Mr. Bruce (Travels in Abyssinia, vol. iii. p. 425) particularly describes the cataract of the Nile near the village of Alatta on the borders of the kingdom of Begemder, S.E. of the lake Tzana or Demeba. The Nile, he says, is here confined between two rocks, and runs in a deep trough, with great roaring and impetuous violence. The height of this cataract has been somewhat exaggerated by the missionaries who report the fall to be about fifty feet; but Bruce states it at about forty feet. The river, increased by rains, when he observed it, fell in one sheet of water, without any interval, about half an English mile in breadth, with a force and noise that were truly terrible, and which illumined him and for a time made him perfectly dizzy. A thick foam, or haze, covered the fall all around, and hung over the course of the stream both above and below, marking its track though the water was not seen. For an account of the cataract of Syene; see Syene. For the cataract of Assar; see Assar.

The most extraordinary cataract of the Rhine is that near Schaffhausen, the height of which is estimated by Mr. Coxe at only 50 feet: but M. Ramond, his elegant French translator, observes, that the quantity of water, which varies according to the season, has some influence upon the height, and a considerable effect upon the aspects of this fall. Those who have seen it at the periods when the snows disolve will admit the exactness of that description, which this ingenious traveller thinks exaggerated, and only true of remote times. M. Ramond has been assured that the height of the cataract, in these circumstances, is not less than 80 feet. About three or four Italian miles east of Terni in Italy, there is a famous waterfall in the river Velino, near the place where it flows out of the Lago delle Marmore. The mountain on which it takes its course before its fall is very high, and environed on both sides by much higher mountains. The falling of the river's bed, as soon as it comes out of the lake, causes a very rapid stream, that collects itself into three successive cascades, the last and loftiest of which seems to be 200 feet high. The noise of this cataract cannot be heard without alarm; and from the bottom a white mist rises and fills the air to a considerable height. When the river clears itself of the rocks, between which these cascades are formed, it falls into the Nera about 100 paces distant. The grand waterfall is called the "Calcata delle Marmore." In the Wologda, in Muscovy, there are two cataracts near Ladoga, which see. The Zaire, an African river in Congo, commences with a large cataract, which falls from the top of a mountain. In Japan, which is very mountainous, many rivulets form by their junction considerable rivers, in which are large and surprising cataracts. The most remarkable is that of the lake Togitz, or Iacon, which, being surrounded on all sides by high mountains, has no outlet for its waters excepting three different apertures, from which they fall down in cataracts, with a dreadful violence and noise; thence the three streams, running, run down with a prodigious impetuosity, by a narrow channel through a deep valley, over rocks and precipices into the sea. The greatest natural curiosities of the known world are the cataracts of Lower Canada, at the distance of 15 miles from the town of Niagara." Mr. Weld, in his "Travels through Lower Canada (vol. ii.)" has presented to his readers four engraved views of these falls, taken from different points of observation. The most stupendous of these is that on the north-western or British side of the Niagara river, commonly called the "Great or Horse-shoe Fall," from its bearing some resemblance to the shape of a horse-shoe. The height of this is only 122 feet, whereas the two others (the river being divided by islands into three distinct collateral falls) are each 170 feet high: but to its inferior height it is principally indebted for its grandeur; the precipice, and of course the bed of the river above it, being so much lower at one side than at the other, by far the greater part of the water of the river finds its way to the low side, and rushes down with greater velocity at that side than it does at the other, as the rapids above the precipice are strongest there. From the centre of the Horse-shoe Fall, arises a prodigious cloud or mist, that may be seen at the distance of several miles, and that exhibits, when the sun shines above it, a beautiful rainbow. The extent of this fall, ascertained by the eye, is estimated at no less than 600 yards in circumference. The island which separates it from the next fall is supposed to be about 350 yards wide; the second fall is about 50 yards wide; the next island about 30 yards; and the third, commonly called the "Fort Schloper Fall," from its being situated towards the side of the river on which that fort stands, is computed at the same measure with the large island. The whole extent of the precipice, therefore, including the islands, is, according to these estimates, 1335 yards. Some have supposed, that the line of the falls altogether exceeds an English mile. The quantity of water, carried down the falls, is prodigious; being found by a moderate calculation to be 670,255 tons per minute. The Fort Schloper Fall is skirted at bottom by milk-white foam, which ascends in thick volumes from the rocks; but it is not seen to rise above the fall like a cloud of smoke, as is the case at the Horse-shoe Fall; nevertheless, the spray is so considerable that it descends on the opposite side of the river like rain. Below these falls the whirlpools and commotions of the waters are so tremendous, as to render navigation impracticable for miles; and immediately above them the river is much narrower than it is higher up. The river, however, runs even, and is navigable with safety for batteaux; nor, as far as Fort Chippeewa, which is about three miles above the falls, but upon a nearer access the waters are so much agitated, that, unless a boat keep in the middle of the river and is dexterously managed, it must be dashed to pieces; however, with such management it may pass down to an island which divides the river at the falls. Since the falls of Niagara were first discovered, they have very much receded, on account of the disintegrity of the rocks which form the precipice. Within the memory of many of the present inhabitants of the country, the falls have receded several yards. It is not an improbable conjecture, that they were originally situated at Queenstown. Tradition reports that the great fall, instead of having been in the form of a horse-shoe, once projected in the middle; but for a century past it has remained nearly in the present form. The falls of Niagara are much less difficult of access now than they were some years ago. The most favourable season for visiting them is about the middle of September; for then the woods are seen in all their glory, beautifully variegated with the rich tints of autumn, and the spectator is not then annoyed with vermin. In the summer season you meet with rattle
At the valley of the lakes of Cumberland there are several considerable cataracts or cascades; that called "Sourmilk Force," near the bottom of Buttermere lake, is supposed to fall upwards of 300 yards. These cataracts are also rivalled by a remarkable fall of the Teco, on the west of the county of Durham, over which is a bridge supplied by chains, seldom passed but by the adventurous miners; and in this connection we might mention Aigarth Force in Yorkshire. The principality of Wales abounds with falls of water, cascades, or cataracts, as they may be severally called, which afford amusement to the curious traveller. In the vale of Neath, the scenery of which is very romantic, there are several cascades, that are worthy of notice; but those of the river Hepsey claim particular attention. In the most considerable of these, near the junction of the rivers Hepsey and Melta, a broad sheet of water projects over an abrupt ledge of rock to the depth of 50 feet. Four others occur within an eighth part of a mile from the first. The principal of these is about 25 feet in height, and the smallest about ten. These four are all seen at once; but a bend of the river prevents a view of the great cascade. If the eye were visible at one point of view, they would nearly rival the great fall of the Mynach in Cardiganshire, below the Devil's bridge; for though they would still be very inferior in point of height, the Hepsey is much broader than the Mynach, and in that respect would have the advantage with regard to grandeur. At a small distance the brink of a precipice disdoses the great fall of the river Melta, which is broader than that of the Hepsey, and 70 feet high. This project as suddenly as the others, and, carrying a larger body of water, with greater violence. It is, therefore, more awful and tremendous, but unaccompanied with those circumstances of variety and beauty which adorn and enlighten its rival cataract. In the vicinity of Neath, at a place called Melin court, there is a magnificent fall of the Cledagh from the height of 80 feet. With the exception of the Mynach fall, this is the largest in South Wales, and unrivalled in its accompaniments, considered as an enclosed scene. The cascade at Llado in Cardiganshire, which has a continued fall of about 100 feet, is an interesting object in the scenery of that spot, which has been justly celebrated on account of the improvements introduced and still carried on by Thomas Johnes, esq., its proprietor. The fall of the Mynach, at the Devil's bridge, has already been mentioned. This stream forms its furious passage through masses and fragments of opposing rocks, hollowing out deep cavities, which are filled with unfathomed waters, and which contribute to increase the gloom of a recess, impervious to sunshine. The depth, from the precipit bridge to the head of the river, is 144 feet. This cascade comprehends four different falls, each of which is received into a deep and agitated pool at the bottom, but is diminished to the eye of the observer as to melt the four into one continued cascade. The first fall takes place about 40 yards south-west of the bridge, where the river is confined to narrow limits by the rocks; it is carried about six feet over the ridge, and projected into a basin at the depth of 18 feet. Its next leap is 60 feet, and the third is again diminished to 20, when it encounters rocks of prodigious size, through which it struggles to the edge of the largest cataract, and pours in one unbroken torrent down a precipice of 110 feet. The mer, therefore, falls 208 perpendicular feet, without allowing for the declivity of the valley. The river, in addition to this 144 feet, the perpendicular depth from the bridge to the junction of the Mynach and Ryddle is 322 feet or upwards. At a small distance, in a recess seldom frequented, is the fall of the Ryddle. The most remarkable cataract in North Wales are the following: In Merionethshire, at Dol-y-Menylllyn, near Llanfylltyd, is "Rhaiadr-du," or the black cataract, which is a double fall of about 60 feet high, where the water foams with a thundering noise down some black rocks, giving to the scene a singular appearance; which is increased by being covered in many places with a pure white lichen. The torrent falls into a small deep basin, from whence it dashes itself along its rugged channel. About one mile from this is another cataract, called "Rhaiadr-a-Mawddach," situated in a river of that name, where the stream forces itself down a rock, about 60 feet high, in which the stream is three times broken in its fall to the basin round which the rocks and trees form a kind of amphitheatre. Near the latter is "Pityll y Cain," which is by far the highest and most magnificent of the three: it consists of a narrow stream, which rushes down a vast rock of the height at least of 150 feet, whose horizontal frate run into irregular feet through its whole breadth, forming a mural front; but its picturesque beauty is much injured by its regularity. The immense fragments of broken rocks, scattered round in every direction at the foot of the fall, communicate a pleasing effect, which is further heightened by the agreeable tints of oaks and beech foliage, and, upon the whole, possesses much local beauty and romantic scenery. The most remarkable cataract in Wales is that called "Pityll-Rhaiadr," in the extremity of the vale that lies about four miles from the village of Llanrhiaid ya Mochnant, on the borders of the counties of Montgomery and Denbigh. This cataract is formed by the river Rhiaid, which falls from almost a perpendicular crag 210 feet high, and pales foaming through a natural arch or open basin, between two prominent sides, into a small basin at the bottom; whence it rolls over small rocks, though a woody vale, into the Severn or Tanad, a branch of the former. Some have estimated its whole height at 240 feet. The upper part of the cataract, when the sun shines upon it, is visible to a great distance; while its silver appearance gives a degree of singularity to many of the views. Dr. Worthington, formerly vicar of Llanrhiaid, erected a small room near the foot of the rock, for the use of visitors, who bring their own refreshments with them: this is frequently praised for its convenience and great utility in these sequestered and
CATARACT.

Strabo tells us that a cataract, which we call a cataracta, and what we call a cataract, the ancient Greeks called a cataracta. Herophilus has a theory that the cataracta is a species of fluid and vitreous humor, which he uses the word to mean a fluid; signifying, by cataract, a vitreous motion of the element.

Cataracta, from catarrh, catarrh, to cataract, in Surgery, is a term, obstinate, or considerable fluid, produced by an eye, and situated behind the pupil, which, upon the repulsion of the eye, moves, and is expelled through the aperture of the iris. The fluid of this opacity is called the cataracta, and its cavity it is generally said, and as we suspect by false glasses; and it is usually appears in a very high degree. At full impulsion it is made into the cornea, if all the objects are removed, and its length entirely uncovered; at the same time the cavity behind the pupil is increased by the effects of light and vision.

According to the different fates of the cataract, it is distinguished into several species. When the eye is exposed to the cataracta, it is termed cataracta; when it is not, it is termed cataracta; in which case it may occupy the whole cornea, or only the anterior or posterior membranes. Sometimes both the capture and the lens are opaque, when it is termed a mixed cataracta. Sometimes there is a preternatural accumulation of Morgagni's fluid, which becomes milk-white and opaque. All these species refer to the cataracta, or its cavity, and are therefore comprehended under the term of the cataracta; but when the opacity is found in other parts of the eye, it is termed the cataracta of the eye, which is divided into four species. The first species is, when pus or some other opaque substance is collected in the anterior chamber of the eye, or a mass, which fills up the pupil, or fixes itself upon the anterior membrane of the capsule of the lens. In the second, the hyaloid membrane becomes opaque. In the third species, a brown membrane is found in the eye, which lies upon the anterior part of the capsule, and is termed oborial cataracta by those who consider it an elongation of the choroid membrane; though it is probably produced only by the pigment. The fourth species is that in which occurs with infants who are born with a cataract, and is named cataracta papillaris; but it would more properly be called papillai cataracta.

In the cataracta, the lens is sometimes converted into a fluid which resembles milk or jellies. Sometimes the capsule becomes opaque and thickened, and separates from the neighboring parts so that, when extracted, it appears like a round sack filled with milk. In this case the cataract is termed opaque; it is sometimes seen in the fetus among the infant, and if it occurs perfectly movable in the eye, and tremble upon the slightest motion of the eye, or of the substance behind the pupil. Sometimes the lens presents its natural shape, and that its surface becomes flint and pupil; sometimes it is firm, like a bone and hard, and the harder it becomes the thinner and flatter it is. In this case, the cataract as generally an ad. yellow, or brown, colour. Sometimes the cataracta has the appearance of a thick jelly, congealed in milk or new-made cheese. Not unfrequently the lens partakes at the same time of all these different degrees of confidence.

In the cataracta, the lens generally becomes also opaque; the posterior membrane of the capsule is rarely, but most frequently the anterior alone, opaque. When the opacity behind the pupil appears white and milky, when white and yellow points or specks are observed in it; when the opacity is placed in the redness or the eye, and black rings seen around the circumference; when the opacity arises suddenly; or when only a portion of the pupil becomes opaque, we may suspect the disease to have its seat in the capsule. When the opacity, according to the place, is opaque, it is probably situated in the anterior membrane of the capsule; but when it arises behind the pupil, it may be considered as partaking of the cataracta. In these cases, we may expect that the capsule is away opaque.

The boundary cataracta is a cataracta opaque, produced after the operation of retacking on the eyelids, or when the eye is in a state of inflammation, or when there is a state of ulceration of the eye. Sometimes the opacity, which occurs at the operation of retaking, or which occurs after a cataract, produced by the operation of retaking, is cut from the lens and drawn out into a transparent mass. Sometimes also the white point produced after the operation of retaking has been performed in consequence of the capsule, which has been left behind, becoming opaque.

Cataracta is always of the cataracta, either in parts or with an opacity of the cataracta fluid, and in this the capsule has always some preternatural adhesions with the surrounding parts. These adhesions may be produced in a thousand manners. The cataracta, for example, differs from the lens, or it has formed adhesions at its posterior part with the hyaloid membrane, or at its anterior part with the iris. The cataracta, which is produced merely by a preternatural accumulation of the fluid of Morgagni, is rare; as in this case the capsule and the lens are generally at the same time both opaque, though, in some cases, the accumulation of the fluid is the sole cause of the opacity of the lens as well as its capsule being transparent. The different species of opaque cataracta are upon the whole but rarely observed.

Before these principal species of cataracta, which require particular attention in the operation, there are also other varieties which demand less attention. To these belong, for example, the diversities of the colour of the cataracta, which sometimes is milky, sometimes of a pearl colour, always, brown, yellow, greenish, or even black. It was formerly also imagined, that the cataracta, in the progress of its becoming opaque, was first tinted to a certain degree, and then again gradually hardened. In its soft state it was termed white, and after it had acquired a certain degree of hardness it was called mature. In conformity with this theory, a recent cataracta was always supposed to be white, and one of the black, afterwards yellow, but this opinion has been proved to be without foundation. When the opacity does not occupy the whole pupil, but only half, or a portion of it, it is termed partial. Sometimes one only observes a white opaque streak behind the pupil. All these partial opinions have that in the capsule of the cataracta.

More important is the compound cataracta, and it may be combined with the other varieties of the eye, which are partly ed to be discovered, and partly do not impede the cure of the cataracta; the amanra cut excepted, which not only fulfills the attention, but the operation for the cataracta, but for quiescence is also difficult to be discovered. Nevertheless, the knowledge of this latter complication is particularly necessary with respect to the prognosis, for although amanra
CATARACT.

roofs presents no obstacle to the operation for the cataract, the patient cannot, however, expect to have his sight restored by surgical means, says Cattell.

With respect to the causes of the cataract, it is either a local complaint, or a consequence of some constitutional disease of the body. To the causes of cataract belong—external violence, wounds, bruises, concussion, the action of fire, acid vapours, inflammations, metastatic or morbid matter, various diseases of the eye, and too much exertion of the organ, immoderate indulgence in venereal pleasures, excessive dish king; also artificial, scrophulous, scorbutic, and venereal atheroma, hereditary disposition, and age; and in the latter cases the operation is least likely to be productive of benefit than in the first. Finally, there also occurs a congenital cataract, which is commonly fluid; but in other respects equally curable with any other species of cataract. The disease may occur in every constitution, under every mode of living, and at every period of life; but it is more frequent in persons advanced in years, than in young people. When from any cause, internal or external, a cataract is produced in one of the eyes, it generally occurs gradually, within a longer or a shorter period, in the other eye also; in many cases, however, the other eye remains free from disease during the patient's life.

The cure of the cataract depends almost entirely upon chymical affinities; though it has in some cases been known to have been cured, without any operation, merely by internal remedies, or even spontaneously; yea, when the cataract endures, proceeds from internal causes, which can be removed by medicines; for example, when it is of an atheritic, general, scrophulous, &c. origin, and when the cataract depends entirely upon the opacity of the capsule. The crystalline cataract can hardly b: cured by internal remedies; though it is probable that the milky may in some cases be diffused.

When the cataract proceeds from internal causes, such as a venereal, arthritic, &c. taint, such remedies are to be employed as counteract these causes; and when no internal cause can be detected, and the cataract seems to be of a local nature, such remedies are to be employed as are thought to possess a divergent power. Mercury has most frequently been employed with success; perhaps because a venereal taint is one of the most frequent internal causes of cataract. A complete opacity behind the pupil, proceeding from an arthritic taint, has been cured, within the space of four weeks, by the internal exhibition of vit. antm. and sect. tint., and the external application of decoct. cont. med. Cataracts, probably those of a scrophulous origin, have been cured by means of Peruvian bark and cinaet. In one instance a cataract was cured during the administration of an ointment for the itch, when a pioric eruption made its appearance.

Amongst the resolutent remedies, those which blandly recommended by the tell of experience are mercury, various antimonials prepared as tartar, alkalii, ether, and extr. brum. and sect. tint. Electricity has also been used with success. Both millepedes, encaustic, artificial ultrices, and various excaco or lightening mixtures, combined with mercury, are likewise generally recommended.

The operation, which in the majority of cases is the only remedy remaining for us to try, is not always admissible, or its success is more or less to be expected. The surgeon must examine the cataract before him with great attention, in order that he may form a proper prognosis; but even under such favourable circumstances, he ought not to promise his patient any thing with certainty, as even under such circumstances the operation sometimes fails of success.

The operation is altogether inadmissible when the patient is an infant; when he has long been troubled with oblitinate and frequent head-ache; when his face is of a red copper-like colour; his eyes inflamed, painful, and unable to bear the light, and have long continued in this condition; when the patient is actually afflicted with phthismatic or arthritic symptoms; when he is disturbed with cough; when the diseased eye is preternaturally large and dropical, or preternaturally small and atropic; and when the cataract has formed a complete adhesion with the iris at all points.

When an eye is affected with cataract, we ought never to operate, as long as the patient is not almost entirely deprived of sight in that eye, unless it should be rendered necessary by some peculiarly urgent symptoms. It is like to be commonly unavoidable to perform the operation when the patient is blind only in one eye, and the other possesses its perfect p. res of vision.

The operation is attended with difficulty, or its event is doubtful, when the patient, without any symptoms of amaurosis, distingues the light from darknes in an indifferent manner, or not at all: when the cataract arises from external causes, such as a bruise, a blow, or mere y a violent inflammation; when the full appearance of the cataract has been attended with violent head-ache and ophtalmia; when it is membranous, or adhering at any point; when the patient is of a cachectic habit, and the cataract has arisen from some external cause which could only be removed, before the operation.

Mr. Stoll never undertook the extraction of the lens, with persons who were affected with rheumatic or arthritic piles, who laboured under head-ache, or hemiplegia, who were affected with pains in the temples and eyes, with frequent erythrasmas, or oblitinate cough, or eruptions in the face, or where the teeth and gums were in a very diseased condition, or where the corma in either of the eyes began to grow opaque, or were dilated, and varicose vesicles passed through the eye; as in these cases it generally had unfortunate consequences, the facility of vision being either weakened, or entirely destroyed, after the operation.

We may expect that the operation will prove successful, when the patient is in other respects perfectly healthy; when the cataract has not been produced by some permanent internal cause; when the patient can perfectly distinguish between light and darknes; when during the commencement of the disease the patient has not been affected with frequent head aches and inflammations of the eyes; when the motion and form of the pupil are perfectly in their natural state; when the cataract is situated at the proper distance behind the pupil, and eye is in other respects entirely sound and without blemish. But great are the advantages which are both operation produces, it is still all necessary that the want of the crystalline lens should be supplied to the patient by the use of a convex cataract lens; as there are few who are able, after the operation, to read without the aid of such a glass. See Optics.

The tedious and careful preparations which surgeons make in order to prevent the inflammation which is apprehended from the operation, are not only uneccessary, but also very prejudicial. All that the surgeon can do with otherwise healthy patients consists in the following means:

1. He must endeavour to draw off and correct the anxiety and dread of the patient by every possible method; he must not delay the operation long; and even though its success should seem to him to be doubtful, he should endeavour to inspire his patient with hope; he should make him what is as much as possible, and prevent his thoughts from dwelling upon the operation; he should remove every thing that may give too great an air of solemnity to the operation, and not inform his patient long before hand of the hour fixed upon for the purpose; when the patient is time-
CATARACT.

routh, he ought to take, half an hour before the operation, 15 or 20 drops of lindanum in a little wine; and, finally, the operation should be performed without any unnecesary preparation and parade.

2. Only when the patient is very phlethoric, and used to blood-letting, a vein may be opened.

3. For two or three days before the operation, the patient should use a leaf nothing diet than usual, and carefully avoid whatever can produce irritation, colic, or disturbance of the prime vix. The patient should particularly avoid all the occasional causes of rheumatic and catarhal affection.

4. When there is cause to suspect an accumulation of feculent matter in the alimentary canal, a gentle purgative is indeed necessary; and, unless it should be contra-indicated by particular circumstances, some mercurial preparation of this kind is far preferable to the common purgative salts.

But when the patient is troubled with any complaints which might influence the success of the operation, these must be removed, as far as may be done, by means of remedies adapted to their nature and causes. No particular fean of the year is exclusively favourable to the operation, all that is required being that the patient should be kept in a moderate temperature, which may be imparted to the atmosphere about him at any season. But when the patient is rheumatic or gouty, the summer is the most favourable season for the operation.

In this operation, much depends upon the convenient position both of the surgeon and patient. The surgeon, when he operates, must sit upon a high, and the patient upon a low chair, so that the head of the latter may be placed opposite to the shoulders of the former. The legs of the patient must be stretched out under the chair upon which the surgeon sits, and the head of the former must be quite close to the breast of the latter. In order to render his hand more steady, the surgeon must place one foot upon the frame of the chair upon which the patient sits, rest the elbow of the arm with which he operates upon his knee, and press his hand close to the cheek of the patient.

The surgeon ought to fit near to one of the windows of the chamber, and direct the curtains to be drawn before the others. The patient should sit in such a situation that the light may fall obliquely over his nose into his eye. The chair upon which the patient sits should have a high perpendicular back, against which his head should rest perfectly close, in order that he may not be able to flint back with it during the operation.

The eye upon which the operation is not performed, ought, especially if the patient is able to see with it, to be covered with a fillet. An assistant, who stands behind the patient, lays one of his hands, for example the right, if the operation is performed on the left eye, under the chin of the patient, and raises it a little upwards, so that the face of the patient is directed somewhat upwards, and presses his head to the back of the chair, or if he sits upon one that has no back, or only a low one, to his own breast. The assistant applies his other hand to the patient's forehead, and draws the superior eyelid upwards with the fore and middle fingers of the same hand. The inferior eyelid the operator himself draws downwards with the fore and middle finger of the hand with which he does not operate.

When the line of separation between the patient's two eyelids is not sufficiently long, when the patient is very restless, and the dexterity of the assistant cannot be depended upon, it will be best to let the superior eyelid be drawn upwards by means of a broad silver hook. This hook may be formed most conveniently of a double flexible silver wire. Some also draw the inferior eyelid downwards by means of a double hook, applying the superior hook to the eyelid and suspending a moderately heavy weight to the inferior.

Mr. Barth has lately proposed a method of operating, adapted for skilful operators, according to which he omits all the preparations hitherto mentioned. He ufs no chair either for the operator or the patient, neither does he employ an assistant, nor make use of any hook. He directs the patient to lean lading against the wall of the chamber, in such a position that the light may fall obliquely upon the eye on which he is to operate. He then performs the operation in the following manner. After having placed the four fingers of his right hand (supposing the operation to be performed upon the left eye) upon the anterior part of the hairy scalp of the same side of the head, he draws the upper eyelid as much as he can upwards with the thumb of the same hand; he then places the thumb of his left hand upon the lower eyelid, draws it downwards as much as possible, and presses it with the sufficient degree of force upon the inferior margin of the socket; immediately after having done this, he pulls the point of the fore finger of his left hand under the thumb of his right, fixed in the position above-mentioned, as far as the upper eyelid, which he raises still higher up with the finger, and presses it as much as is necessary to the bottom of the socket, more or less outwards or inwards, in proportion to the necessity there for pressing the ball of the eye. All this is done to the external parts of the eye, without touching the ball. The eyelids being secured in this manner, he orders the patient, as usual, to direct his eye in the proper position, and touches the cornea repeatedly with the tip of his lancet, at the same time giving the patient to understand that he is not about to operate. By this means he induces the patient (who generally is mollified with his head and eyes at the time when the first puncture is made, not on account of the pain which it occasions, but from fear of the danger in which he thinks his eye is), to remain quiet whilst this puncture is made, thinking the operator is still only examining the parts. But in order to keep him equally quiet whilst he proceeds to make the incision, he endeavours to throw him into a state of suspension by suddenly menacing him with impending danger. Having thus made the first puncture, he endeavours, with deliberate speed, to push his lancet towards the point at which it is again to be brought out, in such a manner as not to suffer the ball of the eye to slide too far towards the internal canthus, and to render the incision of a just length; though, as is well known, it ought rather to be too long than short. When he has once got hold of the cornea by bringing out the point of his lancet at the proper spot, and the eye remains in its proper situation, he continues the incision till he has completed it. But when the ball of the eye has rolled farther in any direction than it should, he brings it, as he has it now in his command, into the position necessary for completing the incision. But when he cannot reach the point for the outward puncture, without the cornea being some where in a great measure concealed, he is generally able, by a rapid and experienced comparative observation of the direction of the lancet, and the still visible cornea, to arrive at this point, blindfold as it were, and to complete the incision without damaging either the angle of the eye or the iris. For, entirely to withdraw the lancet (especially for those operators who are not able immediately to find again the entrance and exit-puncture, and to complete the incision without injury to the iris), is always a fault, though a melancholy, alternative; which, particularly where it renders it necessary to defer the completion of the operation to another day, frequently disappoints the practitioner of the reputation which he hoped to acquire by it.

Meffs.
CATARACT.

Meffes, Arneman and Conradi also deviate from the common practice, in letting the patient sit during the operation, whilst they perform it standing; as they conceive this posture to be the best and most convenient for the operator. In this manner, Mr. Conradi says he can adapt his own height to that of the patient more accurately and conveniently; and by pressing his arm to the patient's side, and his hand to the cheek of the patient, his hand loses nothing of its readiness.

The operation for the cataract is performed either by depression or extraction. In the first, the operator presses the opaque lens out of its natural situation down to the bottom of the eye-ball, so that it may no longer be opposite to the pupil, and consequently no more obstruct the admission of the rays of light into the eye. In the second, he entirely extracts the lens through an artificial orifice in the membranes of the eye. Each of these methods has its peculiar advantages and disadvantages: some consider the one, and some the other, to deserve the preference. The method by depression is indubitably preferable in all cases in which dangerous symptoms are to be apprehended from the extraction of the lens; as when there is cause to fear a violent inflammation; when the patient is very timorous, and the eye very refractive; when the cornea is very flat, and the pupil very irritable, so as to contract with unusual force; and when not only the lens but the capsule also is opaque. Depression is likewise said to be preferable when mercurial remedies have been previously employed. In cases of cataract proceeding from rachitic metaffase, it has been advised always to employ the method of depression. Moreover, its greatest advantage consists in the circumstance, that even though it should not have succeeded, it may be repeated without danger, without proving an impediment to the operation of extraction being performed, even though various attempts at depression have proved unsuccessful; whilst, on the contrary, when the operation of extraction has been performed, without removing the object of the patient, there remains very little hope that he will ever recover it.

For performing the operation of depression, needles particularly prepared for the purpose, and provided with handles, are necessary. These needles are made of different forms, the principal of which are the round and the two-edged; of these the latter is preferred in all cases the preference. Before the needle is introduced into the eye, it should be dipped in oil, or else moistened with saliva. It must be held, like a pen, between the thumb, fore and middle fingers, quite close to the foremoat end of the handle. The hand must be applied close to the side of the patient's face, which generally renders the eye refractive for a moment, in which case we must take care not to frighten the patient still more by repeated injunctions to keep his eye quiet; but rather let the patient alone for some moments, till his eye again becomes quiet, which it generally does in a very short time. As soon as the eye remains quiet in a position convenient for the operation, the needle is thrust quickly, but cautiously, into the eye, namely into the albuginea, at the external angle of the eye, a line from the margin of the transparent cornea, and rather more than a line under the centre. When a two-edged needle is used, it is thrust forward in such a manner, that one of its flat sides is directed upwards and the other downwards, and one of its sharp edges anteriorly, and the other posteriorly. But lest the point of the needle should hit upon the lens, and pull it, if hard, into the internal canthus, the needle must never be pushed through in a perfectly straight direction, but always directed somewhat towards the posterior part of the eye, so as to bring its point behind the lens, in such a manner that it cannot be seen beyond the pupil. As soon as the needle has been thrust through the membranes of the eye, the operator stops for a moment, till the eye has again become quiet; he then gradually turns the needle, at the same time thrusting it deeper into the eye, in such a manner, that now one of its edges is turned upwards and the other downwards. He pushes the needle obliquely backwards, and so deep into the eye, as to bring its point behind the crystalline lens, and a little beyond its centre. As soon as the needle has been pushed far enough, the surgeon raises its point, and applies it to the upper margin of the crystalline lens, so that one of the flat sides is directed upwards and the other downwards, lying upon the crystalline lens; and in making these turns he is directed by the black Stoke on the handle of his needle. He now presses the lens downwards and backwards, but by no means right perpendicularly. During this operation, he observes the opaque substance sinking down behind the pupil, and the needle following it. It is, however, to be always kept in mind, that the point of the needle cannot be raised within the eye, except by depressing its external handle, and vice versa.

When the surgeon has depressed the lens to a sufficient depth, he waits a moment before he again raises the needle. After having raised it as high as the middle of the pupil, helikewise waits for a few moments, before he draws it out of the eye, in order to see whether the lens again follows the needle; should that be the case, he repeats the operation of depression. Should it not follow the needle, he withdraws this instrument slowly out of the eye, in the same manner as he had introduced it, namely with one of its flat sides directed upwards and the other downwards.

Sometimes the lens penetrates forwards into the pupil, as often as it is pressed upon with the needle, in spite of all the pains that may be taken to pull it backwards and downwards. In this case, our belt method will be, immediately to determine upon another mode of operating which shall be mentioned hereafter. When the requisite caution is not used, the lens sometimes passes through the pupil into the anterior chamber of the eye, in which case it must be extracted. All the methods that have been proposed for drawing back the lens through the pupil, and afterwards depressing it, are inadmissible. Sometimes the lens, after it has been depressed, constantly rises up again with the point of the needle; and in these cases it is to be presumed that the point of the needle may sometimes have been pushed into the lens, so as always to raise it up again when it is elevated. This may probably occur most easily, when the needle has not been pushed far enough into the eye; and when it does occur, the lens will always be observed to rise together with the point of the needle. In order to obviate this trifling difficulty, nothing more is necessary than to draw the needle a little out of the eye, and then repeat the operation.

Mr. Willburg has endeavoured to improve the operation of depressing the cataract, so that the lens may easily be loofened, and depressed without lacerating it, its rising up again prevented, or at least rendered a rare occurrence, and its being injured by the point of the needle, as much as possible guarded against. He directs us rather to turn round than depress the lens, so as to direct its anterior surface upwards, but its posterior straight downwards, and its inferior margin downwards. For this purpose, the point of the needle, after having been introduced into the eye in the above-mentioned manner, is to be raised, moved round the superior margin of the lens, and applied, with one of its flat sides directed towards the iris, and the other towards the lens, to the anterior surface of the crystalline lens, a little above the centre; upon which the whole lens must be pressed gently backwards.
Cataract.

backwards; in order to loosen it from its adhesions; and then the needle is to be applied a little higher and nearer to the superior margin of the lens, and by a proper part of the lens pressed downwards and backwards; and in this manner the whole lens is to be laid at the bottom of the eye in a horizontal direction. In operating according to this method, we may also use the round needle instead of the two-edged one; only when that is done, we must not insist it so near to the edge of the temporal cornea as we did the flat, but at two lines distance at least, in order that the point of the needle may be able to follow the superior margin of the lens backwards into the eye, during the operation. Or it may be still more advantageously introduced by the operator's flaring the patient's eye, by being placed over and above the lens; and then turning over the upper part of the lens, to push the needle gradually deeper into the eye, that its point may follow the upper part of the lens backwards into the eye.

The surgeon should operate upon the patient's left eye with his right, and upon his right eye with his left hand; since all the proclivities that have been made for operating upon the right eye with the right hand, as for example, by the operator's flogging behind the patient, or giving a crooked needle, tend rather to render the operation more difficult than to facilitate it. At first, it is possible to operate with the common cataract needle upon the right eye, over the patient's nose, and consequently with the right hand, provided that during the operation the eye be turned a good deal outwards; unless the patient's eyes were very deeply seated and his nose very large. However, the power of operating with the left hand also is easily obtained by a little practice.

After the operation, particularly during the first days, but also for some time longer, the patient should cautiously observe two rules; namely, to avoid all violent and quick motion, or concussions of the head, and body, and he must be cautions never to place his head in a low dependent position, and least of all to bend it backwards. Coughing and blowing of the nose are said to hinder the depression of the lens, and must consequently be avoided altogether after the operation. Vomiting, which is frequently a sympathetic consequence of the operation, must be prevented by the use of opium. It is not necessary that the patient should cautiously lie up in a back; but he may either walk, sit, or lie down however, whenever he changes his posture, he ought always to do it gradually and cautiously.

The membraneous cataract, which proceeds from an opacity of the capsule of the crystalline lens, when it is first discovered before opening the operation, is removed in the same manner as in this cataract in which the crystalline lens is turned down; its capsule is always depreessed together with it. The operation itself is this; we may assume it as a rule, wherever the capsule is opaque, always to press the turning down of the lens to every other method of operating. Should the capsule in these instances, even break whilst we are depressing the lens, it must be entirely depressed together with the lens; it may be pressed downwards afterwards by hand. A two-edged needle of such a kind, always to be preferred to a round one, should always hold the capsule.

The secondary cataract seldom occurs after the operation of depression, and when it does take place, we ought not to be too hasty in undertaking a second operation; as it frequently disappears spontaneously, in a gradual manner, and sometimes yields to internal remedies. The secondary cataract is either in consequence of an inflammation of the capsule, in which case it generally comes on soon after the operation, and is attended with violent inflammation of the whole ball of the eye, and sometimes disappears together with that inflammation; or, if it still remains behind, yields to the operation of vitiolocaries, and the internal use of different remedies, especially antimonials, camphor, cinchona, varieties of flux. If, or it is an effect of the continual astringent, vernal, or serpiginous action which caused the first opacity; and then it generally comes on late, say, ever more years after the operation; being sometimes attended with inflammation of the eye, and at other times not. If this case, the internal medicaments, adapted to the particular case of the eye, are now and then of use.

When these remedies produce no advantage, the surgeon may attempt a second method of operating, in which he must divide the capsular membrane; but when this cannot be done, the surgeon must cure it. To cure it, in order to secure an access for the rays of light to enter the eye, for which purpose the two-edged needle is more convenient and sufficient than the round one. The same operation is also necessary in the various species of furious cataracts, especially in the opacity of the crystalline membrane; only, in this case we are not to attempt to divide the membrane, but rather to lacerate and perforate it, in order to form an aperture through which the rays of light may enter.

The secondary cataract is attended with more or less difficulty in the operation, according to its different species. The first species, namely, when the capsule adheres to the lens, is attended with no difficulty at all; nor do we even discover it while we are dividing the lens.

In the second species, when the capsule adheres to the hyaloid membrane, every thing depends upon separating the capsule from the subsistence of the vitreous humour, which is performed by moving the needle several times behind the lens, upwards as far as the superior margin of the lens, and downwards to its inferior margin. By this means it is evident that the separation may be effected, especially if we use a two-edged needle, and direct one of its edges upwards and the other downwards, whilst we are performing the operation.

When, in the third species, the whole anterior surface of the cataract adheres to the iris, we ought rather to omit the operation, as it will scarcely be possible to effect the separation; and should it be possible, it might become inefficient, in consequence of the inflammation that is to be apprehended. But when the cataract adheres to the iris, and a few points only, the operation probably may prove successful; but in this case, it will be best not merely to move the needle up and down behind the lens, according to Warber's method, but also to apply it alternately to the posterior and inferior margin of the lens, and alternately to raise and depress it, in order to loosen its pretentious adherence. Should this measure not be insufficient, all that is left for us to do, is to pass the needle round the superior margin of the lens into the posterior chamber of the eye, and then to press it down, with a view to separate the adhesion of thick parts.

In the last species, we may also operate with the needle. As in most cases, we are immediately deprived of the needle at the centre of the capsule, it will be the best method immediately to open the anterior membrane of the capsule with it, and to effect its division so as to flow into the aqueous humour. We must, however, not merely puncture the crystalline membrane, but also, by moving the needle upwards, downwards, and laterally, form a considerable aperture; and if not entirely, yet in a great measure to lacerate and destroy it, which may likewise be most conveniently performed with a two-edged needle.

The milky or gelatinous subsistence which has found its way out of the capsule into the aqueous humour, generally renders...
renders this turbid, but in general it gradually becomes again clear. However, when there is to large a quantity of the milky fluid as to render the aqueous humour altogether opaque, it seems to be molli advisable to evacuate the watery fluid, together with whatever remains of the opaque substance, by an aperture in the cornea. If we know with certainty beforehand, that the cataract is of a fluid consistence, we may, with a view of entirely avoiding the lesion of the vitreous humour behind the cataract, and shortening the operation, thrust the needle at once into the eye, in such a manner as to make it penetrate straight into the capsule, and then perforate its anterior membrane in the manner before-mentioned. Nay, it has been advised in this case, even to thrust the needle through the transparent cornea and pupil, to open the anterior membrane of the capsule, and let out the fluid.

When the soft cheesy cataract has some degree of consistence, and the capsule is not very thin or easily lacerated, the lens palls downwards to the bottom of the eye together with its capsule, and the operation may be easily and successfully completed according to the ordinary method; though, on account of the greater violence done to the vitreous humour, its event is always doubtful. When the cataract is very soft and the capsule thin, the needle is generally forced behind the pupil, in the middle of the lens; and in this case it will be best, as in the fluid cataract when the needle is forced in the capsule, to perforate the anterior membrane of the capsule with its point, to enlarge the orifice sufficiently to procure a free passage for the aqueous humour into the capsule, in order that it may diffuse the lens, and then to roll the needle round between the fingers, in order to break the lens into several small pieces, and thereby to promote its diffusion and complete absorption. If we see beforehand, with certainty, that the cataract is soft, we ought, in order to prevent the lesion of the vitreous humour, rather immediately to thrust the needle through in such a manner as to make it penetrate into the capsule, and then destroy the lens and open the capsule. Should we, however, observe, after some time has elapsed, that there remain behind more solid portions of the lens, which do not seem likely to be dissolved, we have it still in our power to open the cornea and extract them.

The haemorrhage which occurs either during or after the operation, arises perhaps from injuring a vessel in the tunica conjunctiva or the choroid membrane, or else from a lesion of the iris or ciliary processes. The haemorrhage from the conjunctiva may sometimes be prevented by rubbing the eye, at the external canthus, with the finger, before we introduce the needle. This haemorrhage is, nevertheless, of little consequence, and generally ceases gradually, even when it excites a spreading chymosis. The haemorrhage from the choroidal membrane is, indeed, most easily excited by a two-edged needle, but it is then also least to be dreaded, as the blood is always discharged externally through the small incision in the sclerotics. Moreover, a haemorrhage will seldom occur, even though we use a two-edged needle, provided we introduce it according to the method above directed, namely, with one of its flat sides directed upwards and the other downwards. Though, when the round needle is used, a haemorrhage more rarely occurs; yet, should it occur, it is also more dangerous, as the blood cannot be discharged externally through the small puncture that has been made with the needle. However, a small quantity of extravasated blood is soon re-absorbed under the use of general remedies. When the bleeding proceeds from the iris or ciliary processes, the blood generally penetrates immediately into the anterior and posterior chamber of the eye, and imparts a red tinge, more or less deep, to the aqueous humour. Should the haemorrhage (which, indeed, rarely happens) be very profuse and of long continuance, as may be known from the deep, opaque, and continually augmenting redness of the aqueous humour, we ought to draw the needle as soon as possible out of the eye, open the transparent cornea, and let out the aqueous humour together with the extravasated blood. When the haemorrhage is slight, it is no impediment to the operation, and the extravasation soon disappears under the use of antiphlogistic remedies, though we should always be very attentive to check the violent inflammation which may supervene. The small puncture in the membranes of the eye generally heals up without any difficulty; and when, as sometimes happens, a little fungous excrecence arises, this commonly yields soon to the application of allotropic remedies.

Of extracting the cataract.

The operation by extraction requires the same preparation and position both of the patient, surgeon, and assistant, as have already been directed for the operation of deprevision; the prognosis also depends upon the same circumstances: but with regard to this operation, the following particulars are to be observed. In patients, whose eyes are situated very deep in the head, and the division of the eye-lids is very short, the operation is always attended with some difficulty; whilist, on the contrary, it is always easier in proportion as the eye-lids are more open and the ball of the eye more prominent. In persons whose cornea is uncommonly convex, and consequently the anterior chamber of the eye large, the operation is particularly easy and secure; whilst on the contrary, with those persons whose cornea is flat, it is always attended with the danger of injuring the iris. When the eye is very reftless, it is likewise difficult and dangerous; and in children it is sometimes entirely impracticable. Whatever the consistence of the cataract may be, it may always be extracted, though this can be done more easily when it is firm. The fluid cataract generally discharges itself as soon as the capsule is opened, but frequently a portion of opaque matter remains behind, which must be extracted separately. The work for extracting is the soft or cheesy cataract, which either is protruded at once and entirely, in which case, as it is generally very large, it diftends the pupil to a great degree, and requires a strong and continued pressure to be made upon the eye; or it breaks, and must be extracted piece-meal. When the pupil is wide, open, and moveable, we may, after the conjunctiva, expect an easy and successful operation. When it is very small, but yet moveable, it does not, indeed, hinder the operation, but it renders the paffage of the lens difficult. Alto, when it is small and immovable, the operation may still be performed, provided it does not at the same time adhere to the lens. When it does not dilate itself during the operation, it perhaps admits of being widened with the lancet. When the pupil is large and immovable, provided this does not proceed from amaurosis, there can be no objection against the operation.

With a view to render the operation as accurate as possible, several means have been proposed for fixing the eye in an immovable position. La Faye's method of fixing the eye, by means of the middle finger of the hand with which the inferior eyelid is drawn downwards; Beranger's double hook, and the small forceps which Jac Car employed for laying hold of the conjunctiva; are rough expedients, by which the eye is very much irritated and inflamed. A better mode is Panart's spike, to which Calaumata gave the form of an S, whereby the assistant is enabled to lay the hand in which he holds the instrument upon the cheek of the patient, and moderate the pressure which it gives to the eye. But
As, with this contrivance of the instrument, four hands must always be applied to the check of the patient, which is very inconvenient both to him and to the operator, this spike has been fixed to a thimble or ring, which is put upon the middle finger of the hand with which the lower eyelid is drawn downwards. Even this instrument, however, is still defective: Mr. Demours has lately proposed another, which has great advantages over all that had before been invented. It represents a thimble, with a wide opening before and behind, which, when put upon the finger, covers only both sides of it, leaving the back and inner side of the finger entirely bare. From the superior central point a small hook proceeds, first perpendicularly upwards, and then horizontally sideways.

The advantages of this instrument are, that the finger which draws down the lower eyelid also applies the hook, and consequently no more fingers are required than in the ordinary operation. As the finger is applied close to the patient's cheek, the operator has it in his power to moderate the degree of pressure with which the hook is introduced into the eye more than he can with other instruments of this kind.

And, finally, the inner side of the finger, which touches the lid and ball of the eye is bare, and consequently lies soft upon the eyelid. It likewise always remains in the operator's option, after he has applied the instrument to his finger, whether to introduce the hook or not, as he may think proper. The hook must be inserted at the same place at which Pamart's spike is usually inserted; namely, as Mr. Gleize advises, into the conjunctiva at the side of the superior margin of the cornea in the inner angle of the eye.

However, all these, and several other instruments of the same kind, as perfect and well adapted to this purpose as they may appear, are in most cases productive of far more injury and inconvenience than benefit; and it likewise always is a difficult task for the surgeon to operate at one and the same time with both hands, and pay the necessary attention to each. In fact these instruments are in most cases really superfluous. For the voluntary as well as the involuntary motion of the eye may be checked by other and gentler means, some of which have already been mentioned. In order entirely to obviate the necessity of fixing the eye, for performing the operation for the cataract, Mr. Mina visits his patient twice a day for some time before he undertakes the operation, and places himself with his lancet in his hand before him, just as if he was about to operate. He directs him to turn his eyes in various directions, and endeavours to render him so practised in doing this as to be able to obey him without being terrified. In the space of 12 or 14 days the eye becomes so easy and obedient, as never to require any instrument for fixing it during the operation.

As to the position of the patient and operator, the fame applies here that has been said in speaking of the operation of coughing, and in the same manner also are the eyelids to be opened and secured. The operator holds his lancet like a writing pen, and pressures the hand in which he holds it as close as possible to the patient's cheek. As soon as the eye is in a position convenient for the operation, the lancet must be thrust in suddenly, in the same manner as the needle. The incision into the cornea through which the lens is to be extracted, must be circular; beginning rather above the centre of the cornea towards the external angle of the eye, and extending through its lower half as far as its middle towards the inner canthus, at all points a quarter of a line from the albuginea, and furthering the lower half of the conjunctiva in such a manner as to form a flap of the form of a crescent. In order to form this incision, the lancet is introduced with its edge downwards and its back upwards, at the external canthus of the eye, a quarter of a line from the albuginea, into the transparent cornea; it is then thrust, in the direction of the transverse diameter of the cornea, through the anterior chamber, in such a manner that its point comes out again from the cornea, in the inner angle of the eye, at the same distance from the albuginea. This incision forms an orifice which is as large as the transverse diameter of the cornea, that is, as large as it ought and can be; it is no where opposite to the pupil, and, consequently, if it should have a cicatrix, vision will not thereby be impeded. When we can foresee with certainty that the cataract is hard and small, or fluid or very soft, and consequently that no large orifice will be necessary for its extraction, we may introduce the lancet and bring it out again at the distance of half a line from the margin of the cornea, and thereby greatly diminish the danger of injuring the iris. When the cornea is very flat, its distance from the iris very small, and consequently the anterior chamber of the eye also very small, there is great danger of injuring the iris; on which account the operator is necessitated, in making his incision into the cornea, to keep as far as possible from the iris. When, on the contrary, the cataract is very large, the surgeon must rather be careful to make the incision sufficiently large, than attend too much to the possibility of injuring the iris.

In making this incision, we are particularly to attend to the rule, that the aqueous humour must not be suffered to flow out till after the incision into the cornea has been completed. With the view to prevent this occurrence, only one instrument must be used for the operation, and the lancet or knife with which the incision into the cornea is made, must possess the following properties: the blade, from the point towards the handle, must increase, not abruptly, but gradually and regularly, both in breadth and thickness, in order that as it penetrates deeper into the cornea and the anterior chamber of the eye, the wound of the cornea may not only be gradually lengthened, but at the same time also so accurately filled up as entirely to prevent the aqueous humour from issuing through it; moreover, the blade must be at its widest part as broad as the half of the cornea, that is, three lines. We must be particularly attentive not to suffer the instrument to lose these dimensions in sharpening it. The blade of the lancet must be from 1 to ½ inches in length. For were it longer, the surgeon would not be able to apply the hand in which he holds it close to the cheek of the patient, at the beginning of the operation. The handle must be so long, that when the instrument is held like a pen, it can be firmly upon the back of the hand. Both sides of the blade must be slightly convex, partly in order that the blade may have the requisite degree of strength, and partly that it may accurately fill up the wound of the cornea. When the sides of the blade are flat, the aqueous humour always issues out along them. The back of the lancet must be blunt, but by no means thick and broad; it must also be rectilinear, not curved and bending.

The operator holding the knife in the manner already described, and applying his hand to the cheek of the patient, thrusts in the point of the instrument, as soon as the eye is directed straight forwards, but at the same time a little upwards and outwards. The lancet is first directed straight forwards, with its point towards the iris; so as to form a right angle with that part of the cornea into which it is inserted. As soon as the point of the lancet has arrived at the chamber of the eye (of which, however, the operator ought to be perfectly certain, for if it has not, he pushes the point between the lamelle of the cornea in turning the lancet), he changes the direction of the lancet, so as to turn its point directly towards that place in the cornea at which it is to be brought out again at the internal angle of the eye. In this direction
Cataract.

direction the lancet is thrust slowly, and without turning it any more, straight through the anterior chamber of the eye. The lancet, after it has once been pushed into the eye, must on no account be retracted, though ever so little, as this can never be done without letting out the aqueous humour. It must always be thrust with an uninterrupted course through the anterior chamber of the eye. The knife must be put into the cornea in such a manner that its back is directed a little towards the iris, and its edge from off it. Should the operator by mistake have thrust in the lancet in a faulty direction, this must immediately be corrected before he proceeds to pull it further. Only he must take care not to turn the lancet too suddenly, or else the aqueous humour will certainly flow out too soon; he should therefore rectify the direction of his lancet gradually, whilst he is thrusting it deeper into the eye.

Though all these rules should be observed, the incision sometimes happens to be too small, which is owing either to the motion of the eye towards the inner canthus, or to the iris coming before the edge of the lancet. The latter very embarrassing circumstance may be prevented, by removing all unnecessary pressure or irritation from the eye, according to the rules before mentioned, by thrusting in the lancet at a proper distance from the margin of the cornea, and by preventing the too early discharge of the aqueous humour. Should the iris nevertheless come to be situated opposite to the point of the lancet, it must not be retracted, as this would occasion a discharge of the aqueous humour, and a still greater protrusion of the iris; but it ought also not to be thrust in further, as in that case the iris would be injured. If the surgeon is not able, in this case, to bring the point of his lancet over the iris, by moving it a little forwards towards the cornea, his best method will be, to prefix the lancet straight downwards, without moving it either forwards or backwards, and in this manner to complete only half of the incision, that is, to make an incision resembling only a quarter of a circle, and afterwards to enlarge this with the scissors.

When the iris comes under the edge of the lancet, the back of it should be turned strongly towards the iris, and the edge forwards towards the cornea, in order to remove the edge from the iris, and complete the incision. In this case, indeed, the incision never goes so far downwards as it ought; however, it may afterwards be enlarged if it be too short, and we may full hope that it will not leave behind any opaque cicatrix, which would certainly be some impediment to vision.

If, after the lancet has been thrust through the anterior chamber, the eye should turn towards the inner canthus, the incision cannot be completed in the proper manner; in which case one of three expedients may be adopted. As soon as the operator perceives that the eye begins to turn, he may immediately apply the instrument for fixing it; or he may endeavour to draw back the eye from the canthus with the lancet inserted in it, and then complete the incision; or he may dill from the attempt to complete the incision with the lancet, prefers the lancet straight downwards, so as to separate only a quarter of the cornea, and afterwards enlarge the incision with the scissors.

The incision in the cornea may be too small in three different ways. It may either be only a quarter of a circle, with its beginning externally at the middle, and its termination downwards at the middle of the cornea; or the incision may approach more or less towards a rectilinear direction, that is, with its middle too far distant from the lower margin and too near to the pupil; or, finally, the termination of the incision at the inner angle, though in the middle of the cornea, may be too far from its margin, and too near to the pupil. In the first case, which is the most favourable, the enlargement is performed by a double incision, that is, by an incision first in a horizontal direction, and afterwards directed obliquely upwards and outwards. The two latter cases are most embarrassing. In the second case, to bring the incision as near as possible to its proper length and form, its two ends must be lengthened straight upwards. In the third case, the best practice is to enlarge the inner end of the wound obliquely upwards. When the incision is so mulbenep that it is impracticable to enlarge it, the best method will be to detach from the operation for the present, and after having suffered the wound to heal, to repeat it again in some days time.

Each of these cases the wound may best be enlarged with the scissors, the handle of which ought to be short, in order that the surgeon may apply the hand in which he holds them close to the cheek of the patient. Their points should be smooth and round, in order to avoid injuring the iris, when they are introduced into the anterior chamber of the eye.

As soon as the incision into the cornea has been completed, the capsule must be opened by means of some cutting instrument, for which purpose La Faye's Cystitome seems to be very well adapted. The blade, as well as the sheath in which it is concealed, must be thin and narrow, in order that they may be easily introduced into the pupil without injuring the iris. Two rings are attached to the two sides of the instrument. In using it the fore-finger is put into one and the middle finger into the other ring, whilst the thumb is applied below to the knob, and in this manner it may be held steady and secure. It is held in the right hand, which is applied to the patient's cheek; the flap of the cornea is raised by means of the sheath, introduced into the pupil, upon which the blade is repeatedly pushed out of the sheath, and whilst this is done, the instrument is moved backwards, and forwards, upwards and downwards. This being done, the blade is suffered to draw back completely into the sheath, and the cystitome is withdrawn from the eye. Only we must take care, in applying this instrument, not to press it too forcibly against the lens. In order that the blade may be prevented from being thrust too far out of the sheath, a director is adapted to it, which enables the operator, by screwing it higher or lower, to determine with accuracy how far the blade can be protruded out of the sheath.

However, as this part of the operation, even though we use the instrument just described, is always attended with much difficulty and danger, Mr. Siegerilh has invented a new instrument for performing it. This is a knife with a straight back, and with a blade gradually increasing in breadth, both of the sides of which are gently convex; but which differs from all others in this circumstance, that its point terminates in a thin two-edged needle, full half an inch in length, and of equal thickness and breadth from its point to the blade of the knife. At the place where the needle terminates, and the blade of the instrument begins, it is very sharp, and does not form an abrupt angle, but the needle gradually extends and lofts itself in the blade; it this construction be not observed, the instrument cannot be pushed forwards without much difficulty, after it has penetrated into the cornea as far as the abovementioned point.

This knife is thrust, according to the ordinary method, into the outer chamber of the eye, till its point is opposite to the pupil. The point is then pressed down into the operation for the present, and the capsule opened, after which the knife is drawn back a little, the point again raised up, and the pupil, and then the incision in the eye is completed according to the usual method. Thus, with a single instrument, and with the same operation, both the cornea and the capsule
Cataract.

capsule are opened, and the operator is spared the trouble and danger of having to open the capsule with another instrument and by another operation, after having completed the incision in the cornea. Only in case the crystalline membrane is opaque, or the pupil contracts strongly during the passage of the knife through it, or when any obstacle prevents the capsule from being opened during the incision of the cornea, it will be advisable to defer the opening of it till after the incision has been completed.

As soon as the crystalline membrane is cut through, the lens is protruded into the pupil, and dilated it forcibly, and by a small pressure with the finger, applied to the lower part of the ball of the eye, it is forced through the pupil and out of the eye. We shall, however, take great care to apply this pressure in a gradual manner, otherwise as the lens is suddenly forced out of the eye, it dilates the pupil so suddenly as to lacerate or render it paralytic; in the latter case the pupil loses its power of motion, or its form is changed, and both are generally attended with injury to the fune of vision. Hence much depends upon our moderating the pressure applied to the eye, and increasing it in a gentle and gradual manner.

It is a very embarrassing circumstance, when, after the incision has been made into the cornea, the pupil is violently contracted, and does not dilate, even though a strong pressure is applied to the eye. As in this case we can seldom obtain our purpose by using force, which indeed it will not be advisable to attempt; our best method will be to close the patient’s eyelids for some moments, as the pupil sometimes dilates spontaneously after a short time, or upon the application of gentle pressure. Should it still remain obstinately contracted, we may apply externally to the eyelids a cataplasm with saffron, camphor, milk, etc. hydrastis, albu. cit. papav. alba or extr. belladonn.; but if the contraction still continues after several hours have elapsed, and cannot be removed by the application of moderate pressure, it will be better either to deprest the lens, or to enlarge the pupil at both sides by two small cuts with the scissors than to incur a greater danger by applying more violent pressure to the eye.

Whilst we are pressure the lens out of the eye, it may not be amiss to darken the chamber a little; but as soon as it has been extracted, it ought to be as light as possible, in order that we may be able accurately to examine whether the pupil be completely clean, as sometimes some opaque substancc remains behind, which, if not extracted, will subsequently be more or less an impediment to vision. Whilst we are making this examination, the light should fall obliquely upon the eye, left the reflection from the pupil might prevent the surgeon from observing any opaque substance that may exist there, particularly as even after the most careful examination some opaque substance may still remain undiscovered in the eye.

Any thing of this kind that may be found still remaining in the eye, must be extracted by means of David’s spoon. This spoon must be wide and curved, every where smooth and even, and made either of silver or gold. When the spoon is introduced, a gentle pressure must be applied to the eye, below the cornea (but with great caution), so as to let the vitreous humour in; the instrument should be directed towards the pupil and facilitate the introduction of the flask. During its introduction the concave face of the spoon must be directed towards the cornea, and the convexity backward towards the capsule. When we have brought the opaque substance into the hollow of the corneum, we should let the anterior and superior margin of the instrument slide downwards, along the internal surface of the cornea, and out of the eye. Sometimes it is not necessary that the spoon should be introduced into the eye; as, by gently stroking the cornea with the convex side of the corneum from above downwards, and at the same time applying a gentle pressure with the fingers below the cornea, all the remaining opaque particles may be brought out of the eye without irritation. This operation must, however, be performed with great care, lest a prolapsus of the vitreous humour should be produced.

When the eye is so reflexed that the spoon cannot be introduced without injuring the internal parts of the eye; when repeated experiments to lay hold of and extract the remaining opaque particles with the spoon have miscarried; when the operation has already been introduced several times, and the extraction has generally been attended with irritation and difficulty, and only a very small quantity of opaque matter remains behind; it is better to suffer what is left of the cataract to continue in the eye, than by repeated introductions of the corneum and to expose the patient to the danger of a violent inflammation and insinuation of this eye.

Sometimes also this happens without any particular accidental cause, in which case the vitreous humour is generally found to be preternaturally thin and dissolv. It is also frequently protruded, when the capsule of the crystalline lens has not been opened by means of a cutting instrument, but burst by the accidental or intentional pressure of the finger. And even after the operation has been completed, we cannot be secure against this accident, as it sometimes occurs, from various causes, several hours, may, or often, days, after the operation. Many methods have indeed been proposed for preventing this occurrence, but they are all inadequate, as most depends upon shunning the occasional causes, which for the greater part are of that nature that they may very well be avoided. When the eye is in a spasmodic state after the operation, quieting and sedative remedies should be applied to the eye, and also exhibited internally; during the first days after the operation, the patient should be directed not to open his eyes without necessity, and should it be necessary for him to open them, to do it as cautiously as possible, and finally, during the first nights after the operation, he ought to have some person to attend him, in order to prevent him from rubbing, or in any way pressuring his eyes.

But though the greatest skill and caution should be employed, we are not always secure against this accident; however it is frequently unattended with any bad consequence, may even sometimes it is productive of advantage, and may commonly be soon removed. Moreover the loss of a small portion of the vitreous humour is generally restored in the space of a few days; nay, influences have even been known in which half of it has been lost, and yet the eye has after some time recovered its natural size, and the patient his perfect fovea.
CATARACT.

Some indeed recommend immediately to cut off the part of the vitreous humour that is protruded during the operation, with the scissors, near to the cornea; but this practice is very much to be reprehended: on the contrary our bell method will be, as soon as we see it protruded, immediately to let the patient shut his eyes, and without mind of the protrusion, to bind up the eye. The wound of the cornea gradually contracts, and recovers the protruded portion of the vitreous humour, as if by means of a ligature. The wound of the cornea, at the place where it has been kept open longer than elsewhere by the protruded portion of the vitreous humour, generally remains for some time opaque, white, thick and misapen; but these irregularities generally disappear sooner or later under the external use of a lotion containing vitriolated zinc, or acetated ceru.

When the vitreous humour is not protruded till after the operation, and the eye has been bandaged, it is frequently not discovered till the eye is again opened, on the 8th or 10th day. But it is seldom of any consequence that we are able to discover the protrusion earlier, since even though we should discover it, we can do nothing to remedy it, but must leave the whole to nature.

When the cataract has formed such extensive adhesions with the iris, that the patient cannot direct the light from darkness; when the cataract is situated immediately behind the pupil, and this is angular, preternaturally small, and quite immovable, the probability of the operation not succeeding is so great, that we had better not undertake it. But when the patient's eye is still sensible to the impression of light at one side or the other; when the cataract on that side is not quite close to the pupil, and the pupil has lost some degree of mobility at this point; and while it moves becomes oblique, angular and wrinkled; the adhesion of the cataract with the iris is not so considerable as to deprive us of all hopes of succeeding with the operation: only in giving our prognosis we must not forget the difficulties with which it is likely to be attended.

In order to separate the cataract from the iris, we introduce a flat probe, pretty much curved towards the point, into the anterior chamber of the eye, between the cataract and the iris; and then endeavour, partly by turning the probe round its axis, and partly by pressing against it the cataract, as to push it back from the iris, to separate these two parts at the points where they adhere.

The adhesion of the lens with its capsule cannot be discovered before the operation; and should it ever be discovered, it would be impossible to separate the parts. Sometimes the lens is protruded, together with its capsule, upon the application of slight pressure, and then this species of cataract requires no particularity of operation. The third species of the adhering cataract, in which the lens has formed adhesions not only with its capsule, but also with the hyaloid membrane, may be suspected to exist; if, after the incision into the cornea has been judiciously made, and we are convinced that the capsule has been properly opened by means of La Faye's Cyph tome, the lens shews no disposition to be protruded upon pressure applied first gently and gradually increased, even though the pupil be dilatable, and presents no obstacle to the passage of the lens.

The best method of separating this species of cataract is, to introduce a round cataract needle through the pupil into the posterior chamber of the eye, and giving it a rotary motion with the fingers, to push it into the centre of the lens; then to move the lens by means of the needle, at first gently, but, by degrees, somewhat more firmly, in every direction, upwards and downwards, right and left; after which the needle is again to be withdrawn from the eye, and the eye pressed with the finger, in the usual manner, to promote the passage of the lens through the pupil. Frequently the lens protrudes readily; and when it does not, the former manœuvre is to be repeated; and should it still remain immovable, it will be advisable to defit from the operation.

When, in the membranous cataract, the anterior membrane of the capsule is opaque, no deviation from the ordinary mode of operating is required; or, if any, it is only that in opening the capsule, the crystalline membrane should be cut a little more open than usual. As soon as this has been done, the lens falls into the pupil, and must be extracted whether it be opaque or not. When, after the extraction of the crystalline lens, the orifice in the opaque membrane of the capsule is not sufficiently large, and its opaque edges can be distinctly seen in the pupil, we may, perhaps, attempt to seize and extract them by means of a very small forceps. If we know with certainty before the operation, that the anterior membrane is opaque, we may also, after opening the cornea, introduce a small pair of forceps into the pupil, lay hold of and extract the anterior membrane of the capsule with it, and then project the lens.

When, after the lens has been extracted, the pupil remains equally opaque, and this opacity is situated farther behind the pupil than before; when the preternatural colour of the pupil is not exactly the same after the operation as it was before; when the opacity resembles a convex surface anteriorly; or when the crystalline lens that has been extracted is transparent, and the pupil remains still equally opaque as it was before the operation, there is reason to believe, that the posterior membrane of the capsule, or the hyaloid membrane, is opaque: only we must be well assured that the opacity of the pupil does not proceed from any thick mucus remaining behind the capsule. And this will probably be the best practice, to perforate the posterior membrane of the capsule, with the syringe or some other instrument, repeatedly, and as completely as possible; at the same time gently pressing the finger upon the eye below the cornea, in order to bring the opaque membrane nearer to the pupil, to dilate the pupil, to expose the greater part of the opaque membrane, and thus to be able to make a larger orifice in it. When, in performing this operation, the vitreous humour protrudes, it is not only advantageous, but some surgeons think it is even advisable to promote this protrusion by a gentle and cautious pressure upon the eye.

The secondary cataract, which takes place soon after the operation, sometimes within a few days, always supervenes during a violent inflammation, and frequently also disappears together with it. Every thing which tends to prevent the inflammation of the eye after the operation, as also what tends most powerfully to remove it after it has come on, tends equally to prevent and remove the secondary cataract. As long as the eye still appears red, there is always ground to hope that the secondary cataract will disappear, together with the inflammation, under the use of cold lumbar lotions, and other antiphlogistic remedies. And should it even remain behind the inflammation, we may still hope that it will gradually vanish, with the use of internal diuretic means, especially sulph. aurat. antimon. mercury, cutant, etc. But when the secondary cataract comes on later, frequently months or even years after the operation, it is an effect of some internal cause; and this cause, which is generally of an arthritic kind, then requires remedies particularly adapted to counteract it. When these means produce no benefit, the cornea might be opened a second time, and the opaque capsule extracted the more easily and successfully, as in this case there has been no previous inflammation; and, consequently,
consequently, adhesions of the capsule with the neighbouring part are not so much to be apprehended as in the former case.

As the symptoms of the membranous cataract are frequently very uncertain, and as the opacity of the posterior membrane of the capsule cannot possibly be discovered before the operation, if the lens be likewise opaque; and, consequently, however favourable the circumstances may appear, the event of the operation is always precarious; the bell practice will be always to extract the capsule at the same time with the lens. For this purpose, nothing more is necessary than to omit the opening of the capsule, and after the incision into the cornea has been made, immediately to press out gradually both lens and capsule by a cautious application of pressure. Sometimes the capsule, after having been entirely protruded, together with the lens, out of the orifice in the cornea, still remains adhering a little to the vitreous humour. In this case, it must be carefully separated by means of Daviel’s spoon, and at the same time we must be cautious not to draw forwards the vitreous humour. But though this operation may frequently be performed with great facility and success, it is, nevertheless, often combined with so many difficulties, that it will scarcely be generally adopted.

The iris always protrudes more or less forwards during the operation, approaching nearer to the cornea; and sometimes it becomes diffusely convex. The more this takes place, the greater is the danger of injuring the iris, for sometimes, in spite of all the caution that may be used, it gets before the point and under the edge of the instrument, especially when part of the aqueous humour is lost. When the latter circumstance is observed to take place, the edge of the lancet must immediately be turned a little upwards, and thus the incision completed; which, in this case, does not become altogether of the form of a crescent, but, however, is generally still sufficiently large for the extraction of the lens. When the iris gets before the point of a knife, the point need only to be inclined a little backwards towards the cornea, in order to remove it from the iris, and as soon as this is done, it may be pulled a little farther forwards, but afterwards again moved downwards, and thrust completely through in the common direction. When this cannot well be accomplished, the lancet ought to be pricked straight downwards, without pulling it forwards, and thus half of the incision completed, which may afterwards be finished with the scissors. Otherwise, the lesion of the iris is seldom attended with very bad consequences, as experience has shewn that it may be injured in various ways without producing violent inflammation.

Of the symptoms particularly to be apprehended after the operation, inflammation is the chief, on which account it will be far more safe for us to endeavour to prevent it, than to rely upon the remedies usually recommended for diminishing it. In order to prevent it, the following rules are principally to be observed, besides those preparatory to the operation:

As soon as the lens has been got out of the eye, and the pupil is clean, the eye must be dried, and all attempts, particularly repeated ones, to investigate the power of vision which the eye has acquired, are to be wholly omitted. Should the flap that has been cut out of the cornea be re-verted, it must be reduced by means of Daviel’s spoon into its natural situation, so as to make it fit close at every point. When any part, for example the lower part of the iris, projects a little out of the wound, it must be gently pressed back by means of Daviel’s spoon, in order that the lips of the wound may fit close together. But when the eye is suffered to close, the upper eyelid must first be permitted to fall down as low as possible, in order that it may cover the whole cornea, before we allow the lower eyelid to rise upwards; for otherwise the latter sometimes gets under the flap of the cornea and produces violent irritation.

The dressings ought properly not to press the eye in the smallest degree, nor leave any access for the air or light to the eye. For this purpose, a very thin compress is applied, which must be long, and broad enough to reach at the bottom, as far as the check, at the side, as far as the nose, and at the superior extremity to the eye-brows. This compress is generally secured by means of the monocular bandage. When we have no other end in view in applying the dressings, than to close the eye, the upper eyelid may be fastened to the lower by means of two narrow slips of adhesive plaster.

Besides these, we may also, with a view to keep the rays of light from the eye, apply an eye-bandage that occasions but little pressure, and which consists of a roller to which a compress is attached, to hang down loose over the eye upon which the operation has been performed.

The patient may choose his posture as he finds most convenient, after the operation; that is, he may either lie down in bed, or sit upon the chair; only he must avoid all confusions or violent motions of the head and body, and not suffer his head to fall forwards. But it is indispensible necessarily, during the first nights after the operation, that the patient should have some peron to watch before him, in order to prevent his lying in his sleep upon the wounded eye, or applying his hands to it either to rub or press it.

When the patient experiences no disagreeable sensation at all in his eye after the operation, it will be best to abatin entirely from the use of external remedies, and merely to apply dry bandages. If, on the contrary, he experiences various symptoms that require attention, some external applications are, indeed, necessary, but they ought always to be adapted to the particular state of the eye; consequently, they are not to be exclusively emollient, as some recommend, or spirituous, as is recommended by others. The same applies also to the use of internal remedies, the choice of which is like wise to be directed according to the peculiar state of the symptoms that supervene upon the operation; and consequently, none can be recommended indiscriminately.

When no troublesome symptoms are observed, and the patient feels himself in all respects well, no internal remedies are required; and all that can and ought to be done, with a view to prevent inflammation and other symptoms, is to recommend repose to the patient, to remove all accidental causes or irritation, to direct a strictly antiphlogistic regimen, and daily to administer one or two gently opening injections.

The wound of the cornea generally unites within the space of 48 hours, during which the aqueous humour flows out. Should this discharge continue longer, we may suppose some preternatural cause of it to exist in the eye, and examine it in order to find it out. When the aqueous humour ceases to be dischargd at the proper time, and the patient experiences no pain or other troublesome symptom about his eye, the eye ought not to be opened before the eighth day; at farthest, it may be opened on the tenth day, even though no bad symptoms be present; and afterwards it must be opened daily, and gradually accustomed to the air and light.

However it is not always in our power, by the observance of these general rules, to prevent the inflammation and other troublesome symptoms; and it is always necessary to pay the greatest attention to the particular state of the patient. Sometimes he experiences, soon after the operation, tension, and pain; sometimes he is very languish and debilitated; sometimes he is deprested and low-spirited without any apparent cause; sometimes he is affected with great anxiety or vomiting, or colic pains, or obstruction and
an inflamed state of the abdominal visera; and sometimes he is attacked with spasmodic horrors. Whilst these spasmodic symptoms continue, most patients complain that the eye is very red, and moves backwards and forwards. Some imagine they see light or other appearances before the eye upon which the operation has been performed, notwithstanding that it is covered with the bandages. Sometimes the eyelids open themselves against the will of the patient. In this spasmodic state, external and internal feeding and antispasmodic remedies are necessary; such as warm pediluvia, warm fomentations applied to the abdomen, frequent emollient injections; internally, a mixture of ammonial wine and tincture of opium, or extract of hyoscyamus, &c. When the eye is very red, we may apply to it a thin-issued, warm cataplasm of bread-crumbs, elder-flowers, fennuin, &c. or frequently moisten the comfits with a decoction of cap. papav. alb. and flor. malv. &c.

Sometimes, (especially when the eye has suffered much during the operation,) it becomes painful immediately after the operation, and at the same time the palpe is irritated, full, quick, the patient red, heated, &c. in which case we must endeavour to moderate the violence of the impending inflammation by immediately letting blood, and by administering nitrous remedies, cooling laxatives, glycerins, &c. Sometimes there appear symptoms indicative of an effusion of bile, such as a foul tinge, a bitter, disagreeable taste in the mouth, a sense of pain and weight in the forehead, vertigo, &c. in which case the irritating bile must be timely evacuated by means of purgatives and emetics, in order to prevent fever and inflammation.

Should an inflammation of the eye come on in spite of all the caution that we may use to prevent it, it is to be treated according to the manner directed under the article Ophthal-mia. When, after the inflammation has been removed, a languid redness remains for a long time in the eye, whilst the sense of viton is weak, and the cornea dull, and tears are discharged from the eye, these symptoms may be owing to the application of the bandages having been too long continued: and in this case the eye must be opened and washed: with fresh water. Sometimes at the end of the inflammation an acrid watery fluid flows out of the eye, which keeps it for a long time red, painful, and inordinately sensible to the light.

Sometimes, in the cataract, the vessels of the retina and choroida are varicose, in which case, shortly after the operation, a hemorrhage may supervene, which is profuse, but generally ceases spontaneously; however, in these cases the operation is seldom successful. Sometimes a small vehicle full of water, which is transparent, very tenue, and fenible, projects out of the wound of the cornea, some days after the operation; this can only be cut off with the scissors close to the cornea; but sometimes the vehicle returns again.

When the edges, especially the superior edges, of the wound of the cornea become white, thick, and foet, or actually suppurate in a small degree, the external application of fumery remedies is to be recommended. When the cornea is dim after the operation, white vitriol may be employed.

The patient must be very cautious in making use of his newly-recovered power of vision, as the eye is not able immediately to support the action of a strong light. At first, therefore, it will be proper to let him have his eye open for only one hour in the morning and evening, or till he feels that it becomes fatigued, irritable, or even painful. After some days the patient may be suffered to remain during the whole day, with his eyes open, in not too light a chamber; and when at length he goes into the open air, he should for some time have his eyes covered with a piece of black crape.

Finally, we ought to mention the method which Mr. Conradi has proposed, for performing the operation of crouching in a similar manner, which is grounded upon the gradual dissolution of the cataract. According to his method, we are to introduce into the cornea a small, lancelet-like, cataract-needle, (in the same manner as the knife in the operation of extraction, only at a little greater distance from the iris;) then to bring its point into the pupil and open the capsule, after which the needle is to be withdrawn, and flight bandages applied to the eye for two or three days, as in that space of time the small wound of the cornea in general disappears entirely. After this, we are to await the gradual dissolution of the lens. The needle used for this purpose needs not be quite so long as Richter's cataract knife, and not more than 1½ or two lines in breadth. It ought not to be thicker than is necessary in order to render the blade sufficiently strong, and it ought to be two-edged throughout half of its length.

The advantages of this method of operating are said to consist in the following circumstances: it is much more easily performed than the others; the very small and insignificant wound of the cornea produces none of the troublesome symptoms that are to be apprehended partly during, and partly after, the extraction and depression of the lens. Should the cataract not be dissolved within eight or twelve weeks, any other operation may still be performed upon it equally well as if the former puncture had never been made. Bernhein's Handbuch für Wundartzte, Leip. 1799.

As this article would be extended to a disproportionate length, if we were to subjoin all the observations which relate to cataract, it is our design to offer some further remarks, (chiefly including the practice of English surgeons,) under the two heads of Crouching and Extracting; to which we therefore refer our readers.

CATARACTA, in Ancient Geography, a town of Italy, in the country of the Sammites, according to Diodorus Siculis, who says that it was taken by the Romans.

CATARACTA, in Ornithology; cataractae, Gefn.; cataractae, Aldr. &c.; synonymous names among old naturalists for the flaua gall, Larus cataractae, which bee.

CATARACTE, in Military Language, signifies a wooden grate, lattice, or portcullis, made in the form of a harrow, with several pieces of timber laid lengthwise and crosswise, and strongly fastened together, armed with iron spikes. It is let down by means of a moulinet or roller, to which it is fastened by a rope, to cover any breach or opening that is made by a petard or otherwise. It is not to good, however, for this purpose as an argus, which is composed of several long and thick pieces of timber that are armed with iron at the bottom, are about six inches apart from one another, and are in line manner fastened perpendicularly by a rope, but have no crofs pieces except those that are fastened across them near the top to keep them steady, and in their respective places. For the cataracte may be prevented from coming down by setting a piece of wood upright in one of the grooves, made in the door-cake or gate for it to slide in, or by placing a piece of wood upright, or nearly so, against the gate, or by putting a chevulet under it.

The cataracte goes also by the name of herse or harrow, and sometimes under the denomination of faruisine. Both the besiegers and besieged, for want of chevaux de frise to throw into the ways or roads where cavalry mult pafs, and on the breaches where the infantry enter, make use of them occasionally.
CATARACTES, in Ancient Geography, a river, so called from its impetuous, which seems to have been the same with the Matian. Qu intus Curtius, // ir. ch 1. § 3. Ptol. v. p. c. 16.

CATARACTONIUM, Catarrhonium, or Catarrho, a town of the life of Albion, placed by Ptolemy in the country of the Brigants. In the second route of Antonine's itinerary it is placed between Laritrig (Bows) and Harpham (Nashop). And, without doubt, is the present Catrach near Richmond, in Yorkshire.

CATARACTUM, a river in the island of Crete.

CATARI, a people placed by Ptolemy in Panonia.

See His soppus lophanthos.

Cataria folii cordalos, Hall. hclv. 246. — Herba. Dod. pempe. 99. See Nepeta cataria.

Cataria Montana, Busk. Cent. See Dracoccephalum Si buicium.

CATARINGA, in Geography, a town of the island of Boroco, on a river of the same name.

CATARRH, in Medicine, definor, diffiliato, from καθαρήν, define, I flow down, a disease which consists principally in an unusual discharge of mucus from the membranes lining the nose, throat, or bronchica {the branches of the trachea} or windpipe, leading to the air-cells of the lungs, accompanied generally with fever. From its well known and universal cause, except when epidemic, the disease is commonly denominated a cold.

The attack of catarrh is usually marked by a sense of fulness about the nose and forehead, and of a tightening of the passage of the nostrils, which is either accompanied, or soon followed, by a discharge of a thin, watery, and somewhat acrid fluid, from the Schneiderian membrane lining those passages. There are also a dull pain and a sense of weight in the head, from which the Roman physicians gave their symptoms the appellation of gravido. Hippocrates, probably from the heat and acrimony of the discharge, deformed them under the term of coros, which has been deduced from καθαρός, caput, and γέννα. Ballis. Sometimes cold flourrings, or a sense of chilliness, are among the first symptoms. The eyes are frequently slightly inflamed, with some degree of stiffness in their motion, and an increased and acrimonious secretion from the lacrimal glands. There is a frequent disposition to feeze from the irritation of the rostrils, and the voice becomes more obtuse in consequence of the impediment to the passage of the air through them. The discharge gradually becomes more copious and thicker, sometimes assuming an appearance similar to that of pus; and, after a course of some days, gradually diminishes and disappears. In the mean time a sense of roughness is felt in the throat, and a troublesome irritation about the glottis or entrance of the wind-pipe, which excites a dry and slight cough; some pains are felt about the chest, but especially under the sternum; the neck, back, and limbs are also sometimes affected with pains resembling those of rheumatism; there is a sense of general latitude; the pulse is quickened, especially towards evening; the appetite fails, and some degree of thirst arises, and the palate is depredated. In a short time the febrile symptoms abate, generally after a free perspiration; an exertion of mucus, at first thin and in small quantity, gradually becoming more thick and copious, attends the cough, which becomes less frequent and less laborious, until all the symptoms disappear.

The disease is obvious, consists in an inflammation of the membranes which line the nose and the passages to the lungs; the thickening of the membrane, by which the passages become flattened, being produced by the increased flow of blood to the vessels, which also gives rise to the increased of the mucus secretion. The ancients imagined that this discharge proceeded from the head, and was determined to the membrane of the different passages by circumstances; hence the name of the disease, which, among the Greeks and Romans, termed infusion; and hence Celsus thus begins his account of the different forms of the disease: "Difiillat autem humor de capite interdum in nasos, quod lene eff; interdum in facies, quod peius est; interdum etiam in pulmonem, quod pneumica est." Lib. iv. cap. 4.

The mode of operation of cold on the body, when it gives rise to catarrh, has been variously explained by different writers. It has been most generally said to consist in a suppression of the perspiration, by which the matter that should have been thrown off by the cutaneous vessels is carried back, and determined upon the membranes, subject to this inflammation. This has been particularly stated by Dr. Cullen, upon his favourite notion of a balance of circulation between the external and internal parts, especially between the lungs and the skin. But this mechanical account of the fact is somewhat unsatisfactory. The matter of perspiration, and the mucus produced in the catarrhal state of the membranes of the nostrils and bronchiae, are altogether different in nature, and are elaborated by the vesicles of the skin and of those membranes respectively. There cannot therefore be a transportation of a matter, which should be discharged by the one, back again through the circulating mafs, to be excreted by the other. All that the external application of cold can produce, is a diminution of the action of the cutaneous vessels by which a larger proportion of blood must circulate to the internal parts; but how this should be determined upon the membrane of the nose it is not easy to explain. An application of cold to the skin, indeed, is not necessary to produce catarrh, according to an observation stated by Mr. Mudge; who caution people in health, from trying his "Inhaler" with cold water, as breathing through it for a short time will almost infallibly produce a catarrh. In this case, then, the speculations on the suppression of the cutaneous discharge, and on the balance of circulation, are altogether nugatory.

Dr. John Brown, on the other hand, denied that catarrh was the immediate result of the operation of cold, and affirmed that it was rather the consequence of the subsequent application of heat. As in other epidemic diseases, the excitability of the body having been accumulated or increased by the application of cold, which is but the absence of the stimulus of heat, when that stimulus is again applied, it produces the inflammatory action, which in one case constitutes catarrh in another pleurisy, and so on. This hypothesis, however, is not, we believe, generally true; as many people must have had experience of the commencement of the symptoms of catarrh, even during the exposure to cold, which excited it. It is not easy, in this, as in many other forms of disease, to give any account of its production that may be completely satisfactory.

The immediate number of people, who suffer repeated attacks of catarrh with impunity, is a proof, as Dr. Cullen has observed, that the disease is generally devoid of danger. But this is far from being the case invariably. In any state of constitution,
constitution, if it be neglected, or if cold is repeatedly applied during its course, it may lead to inflammation of the lungs, and all its dangerous consequences. In old people, and those of relaxed and debilitated habits, it thus often goes on to a fatal form of peripneumonia, which has been called peripneumonia notata, in which a rapid effusion takes place into the cells of the lungs, which suddenly depresses the powers of life, and often proves fatal. In those who are predisposed to pulmonary consumption a neglected catarrh frequently lays the first foundation for, or accelerates the approach of the disease; and in others a permanent asthma has been often traced to some cause, or is a constant and troublesome dyspnoea. In the old and infirm, it has been occasionally observed to induce hydrothorax, or dropy of the chest, and sometimes even to bring on a general dropsy. So that, although simple catarrh is a slight complaint, when carefully attended to, great numbers die of its occasional consequences: an observation which strongly points out the necessity of not neglecting it.

In common cases of the disease, when the symptoms are moderate, it is merely necessary to avoid any exposure to cold, to dispense with the use of animal food, and of wine, and fermented liquors, and to drink freely of gruel or some diluting liquor, by which a gentle perspiration may be kept up. Saline diaphoretic medicines may be administered; and to those of weak habits a little thin wine-whiskey may be proper. A few days will generally remove every symptom under this management. When the symptoms are more violent, the disease must be treated as a flight degree of pneumonia, or pulmonary inflammation; the antiphlogistic regimen must be more strictly adhered to; and more active remedies employed. The most useful expedient, especially if there is pain in the chest, is the application of blisters to some part of the thorax. For allaying the cough, which is often troublesome, and produces considerable irritation by the mechanical agitation of the body, mucilaginous medicines are useful; they are less disagreeable to the stomack, in general, than oily medicines, or even permaects. The stimulant expectorants, such as gum ammoniac, fœtis, volatile alkalis, &c. are frequently employed for the same purpose; but their efficacy is doubtful. If the inflammatory symptoms are considerable, they are probably hurtful. When the inflammatory condition is allayed, opium constitutes the most effectual remedy for the cough; but there is little doubt, that the free use of it, from the early stage of a severe catarrh, has contributed to render it extremely obli- nate, and sometimes to extend it to a severe pneumonia. When properly used, opium not only allays the irritation of a frequent cough, but seems to contribute even to render the expectoration more free and easy: by diminishing the feebility of the parts, it produces a temporary suppression of the expectoration, during which the mucus and exhaling fluid of the lungs accumulate, and are then removed with greater facility.

An expedient has been suggested by Mr. Mudge of Plymouth, which he terms "a radical cure for a catarrhal cough;" namely, the inhalation of the vapour of warm water into the lungs, by means of an instrument, which he calls an "Inhaler." He observes, that when the inhaler is used in the very recent and ordinary state of the cough, viz. the evening of the attack, the patient is sure of being prof- fered with an immediate cure; fo sudden, indeed, that it is more than probable he will cough no more than once or twice perhaps the succeeding morning, to discharges a fluid that is drained into the branches of the bronchus, and which, as the thinner parts have during the night evaporated, is easily

and with a very gentle effort, spits off in a concocted state."

p. 179. Mr. Mudge's inhaler is now to be procured in the shops. Where there is a fene of rawness in the trachea, the beam alleviates the uneasiness considerably, and in most cafes relieves the cough; but in some instances it rather aggravates the symptoms and oppresses respiration.

Where the catarrh is violent, the patient must of course avoid every source of irritation which may tend to render the symptoms more inflammatory; such as great heat, exertions of body, stimulating diet, &c.; and the bowels must be kept moderately loose.

The best means of removing the chronic remains of a catarrhal affections is by some exercise of dietetics diligently employed, according to Dr. Cullen; and the best means of securing the patient from a recurrence of the disease after a recovery, is by the use of warm clothing, especially by casing the body in flannel, as the susceptibility of the skin to the impression of cold is sometimes very great, particularly where much perpiration has been excited.

Catarrh chronic, or catarrhus senilis, as it is sometimes denominated, differs so much from simple catarrh in its nature, and requisite mode of treatment, as to render a distinct consideration of it necessary. In old people, of relaxed constitution, catarrh, after being frequently repeated, becomes at length almost habitual, and is much aggravated by cold fefons, or by occasional exposure. The mucous glands of the bronchiae pour out a large quantity of fluid, and this secretion contributes in every way to increase the debility of the patient: not only by a diminution of the circulating mafs, but by clogging up the air cells, and thus preventing a free and regular circulation through the lungs, and a proper change in the blood, and by rendering great exertions necessary, to expel the load of mucus from the lungs, which exhaust his strength. Hence the symptoms of this form of catarrh are, a constant, harassing cough, with a copious ex- pectoration of viscid mucus; great difficulty of breathing; a fene of load, fullness, and constriction in the breast, with much anxiety; a feeble, labouring, and often irregular, pulse; a slightly livid tinge in the lips and cheeks; inability of much exertion; occasional vertige; and loudness of spi- rits, with languor, loss of appetite, &c.

The object of medicine in simple catarrh, in young and strong habits, is to avoid, or to allay any tendency to in- flammation, to support a diaphoresis, and to obviate par- ticular symptoms as they occur: but in the chronic form of the disease, the chief object obviously is to enable the patient to free his lungs from the load of accumulating mucus, to lessen the fetidness, and to support his strength. Ex-pectorants, emetics, blisters, gentler sudorifics and stimulants, are the remedies which seem best adapted for these pur- poses.

Of the expectorant medicines, the active or stimulant ones, such as have been called incidentia, must be employed; as gum ammoniac, afebrile, &c. Where the heat of the body is not much increased, the volatile alkali is extremely beneficial, and when combined with fœtis, or the gum-refine just mentioned, it appears to afford the most effectual alleviation to the expectoration, and also contributes to sup- port the strength. When the mucus becomes hard and difficult to be moved, the inhalation of the beam of warm water is sometimes of material benefit in softening and loosening it. But the most considerable and immediate relief is frequently obtained from emetics, which not only evacuate the contents of the stomack, but also of the bronchial vesicles, and excite a diaphoresis. Blisters too are often productive of relief, especially where there is any particular
pain of the breast: they seem also to promote expectoration. Antimoniales are occasionally useful, but chiefly where some degree of feverishness is present.

While these medicines are administered with a view to relieve the lungs, we should endeavour to support the general strength of the patient. A light and nutritious diet should be taken, such as milk; and the chamber of the invalid should be well supplied with a pure air, by which the important function of respiration may be aided. Rest should be also obtained from the exhausting exertions of conglag; with which view a small quantity of opium may be combined with the volatile alkali, or other expectorants, which will counteract the detrimental effects that might ensue from opium given alone.

CATARRH epidemico. See INFLUENZA.

CATARRHAL. Fever signifies that form of catarrh, in which the symptoms of general fever are considerable, and which requires a strict adherence to the antiphlogistic method of treatment. See CATARRH.

CATARRHUS SUFFOCATIVUS, of some of the older authors, is the more active form of the catarrh of old people, or the peripneumonia nataa which ensues, when this catarrh is aggravated by a fresh application of cold. It was so denominated, because it often terminates speedily by inducing suffocation. See Chronic CATARRH.

CATARRHUS VEFEA, a term used by Lienstaud and other writers to designate a diffuse, which consists in a copious discharge of mucus from the bladder along with the urine. Other authors, especially the neologists, have applied various other denominations to the same complaint. Sauvages, by a word of folicism, has described it under the terms of pyuria mucosa, and P. vesica. (Nofol. Method. clais ix. ord in. genus 28.) Linnaeus denominates it gula, and defines it simply, "Urine viscosa: medicina." (Clas ix. ord. iv.) Dr. Cullen considers it under the genus dyuria, species 6. D. mucosa. And Hoffman has detailed a case at length, under the title of "Rarus vesicæ morbus," in his Commentaries. In the Rev. Med. Cent. II. cas. 93. By some it has been termed cyllibrhea.

The patient is troubled with a frequent desire of making water, which passes with some difficulty, and in a small stream. He feels a painful sensation of fulness about the neck of the bladder, which extends, together with a sense of great heat, along the urethra. The urine has a whitish, milky appearance when emitted, and frequently contains many floating filaments; and after standing some time, a thick, viscous mucus, not unlike the white of eggs, is deposited in the vesicle.

A discharge of mucus from the bladder is frequently a consequence of the existence of a calculus in that organ, and is generally enumerated among the symptoms of that complaint. And other discharges, as of purulent matter, or foams, occasionally occur from the same cause, or from ulcerations and injuries of the substance of the bladder. These disorders can only be removed by curing the original disease, of which they are merely symptoms. But there are several cases on record; and other examples must have occurred to the observation of every experienced practitioner, in which such discharges with the urine appeared to arise from some particular condition of the internal surface of the bladder, which, without any extraordinary or morbid irritation, poured out the unusual secretion. Such cases have continued for some time; and, either by the aid of medicine, or the efforts of the constitution, have at length terminated in perfect health. The remedies recommended for the relief of this discharge, have been chiefly such as are obviously carried in part to the bladder, and probably exert some stimulus there; such are the various balsams, especially balsamum copaiba; the oil of turpentine, &c. Linnaeus affirms that he has seen the disease cured by a copious use of onions in diet. On the same principle the catarrhides might perhaps be usefully administered. Hoffmann recommends two medicines, which he thinks he has found beneficial; these are a compound of essence of canisilla with essence of amber; and amber prepared in the form of a dry powder with delicately kahl, or oil of taster percliquium. Alkaline medicines, as in other irritations of the bladder, have been found to give relief; and the uva ursi has also been recommended. It must be added, however, that, in some cases, a variety of medicines has been successively tried with little benefit; and, after they were altogether relinquished, a spontaneous cure has ensued. Hoffmann suspects the propriety of avoiding great corporeal agitations, particularly on horseback, and of dispelling with the use of strong liquors.

CATARRZENA, in Ancient Geography, a country of Asia, in Greater Armeria, placed by Ptolemy in the vicinity of the Mochic mountains.

CATASARCA, from κατα, under, and σαρκα, flesh, in the Greek Church, denotes the undermost altar-cloth, or that next the altar; which see.

Over the catarrhae is the antimonia; which see.

CATASCOPIUM, from κατασκοπις, I explore, in Antiquity, an exploratory vessel, answering in some measure to a briggante among us. See BRIGANTINE.

We find cataspeum used in this sense by Cicero, ad Attic. lib v. ep. 11.

CATASCOPIUS, in Antiquity, denotes a spy; which see.

In Ecclesiastical Writers, catescupons is said sometimes to denote an archdeacon.

CATASTA from κατατο, I place, in Antiquity, a wooden scaffold, wherein flaves were placed for use, erected, that those deposited to purchase might flee every limb and part. The word was also used for an elevation, on which peracons were executed; and for an engine of torture, otherwise called equeus.

The catasta do not appear to have been the same with the equeus, but rather a kind of frame or scaffold, on which the equeus was mounted, to render the executions more public and visible. Prudentius calls the eratitis, or grid-iron, on which some of the martyrs were broiled, "ignea catasata."

CATASTASIS, in Poetry, the third part of the ancient drama; being that wherein the intrigue or action, set on foot in the epistles, is supported, carried on, and heightened, till it be ripe for the unravelling in the catastrophe. The word comes from κατασταθεν, conflation; this being, as it were, the mean, tenor, flat, or conclusion of the piece.

CATASTROMATA, from καταστρωμα, I cover, in Ancient Military Writers, a fort of scaffolds or buildings, in ships of war, wherein the soldiers were posted for their defence in fight. The catastromata appear to have been chiefly erected over the head and stern of the vessel, it being in these parts that the soldiers were most commonly posted.

CATASTROPHE, from κατασχεί, I finish, in Poetry, the change or revolution of a dramatic poem; or the turn which unravels the intrigue, and terminates the piece. The catastrophe made the fourth and last part in the ancient drama, or that immediately succeeding the catastals; or, its seat in modern tragedy is the fifth act. See Act.

The catastrophe is either simple, or complex; whence also the fable and action are denominated. In the first there is no change in the state of the principal persons, nor any discovery or unravelling; the plot being only a mere paffage out of
of agitation, to quiet and repose. This catastrophe is rather accommodated to the nature of the epopee, than of tragedy. Indeed, we meet with it in some of the ancients; but it is rejected by the moderns. In the fcond, the principal per-
son undergoes a change of fortune; sometimes by means of a discovery, and sometimes without. Mr. Dryden thinks a
catastrophe resulting from a mere change in the sentiments and
refolutions of a person, without any further machinery, may be so managed as to become exceeding beautiful, nay
preferable to any other. The qualifications of this change, or
perpetia, are, that it be probable and necessary: in
order to be probable, it is required to be the natural re-
result or effect of the foregoing actions; i.e. it must
spring from the subject itself, or take its rise from the
incident; and not to be introduced merely to serve a
turn. The discovery in the catastrophe must have the fame
qualifications as the catastrophe itself, of which it is a
principal part: it must be both probable and necessary.
To be probable, it must spring out of the subject itself; nor
be effected by means of marks or tokens, rings, bracelets,
or by mere recollection, as is frequently done, both by
the ancients and moderns. To be necessary, it must never leave
the persons it concerns in the same sentiments they had be-
fore, but always produce either love or hatred. Sometimes
the change confils in the discovery; sometimes it follows
at a distance; and sometimes results immediately from it,
which last is the most beautiful kind.
Boffu divides the catastrophe, at least, with regard to the
epopee, into the unravelling, or denouement, and the achiev-
ment, or finishing; the last of which he makes the result of the
first, and to confit in the hero’s passage out of a state of
trouble and agitation, to quiet and quiet. This period is
but a point without extent or duration; in which it differs
from the first, which comprehends every thing after the
knot, or plot laid. He adds, that there are several unravell-
ings in the piece; because there are several knots, which
beget one another: the finishing is the end of the last un-
ravelling.
The ancients were fond of unravellings, which turned
upon what is called an “Anagnorisis,” or, a discovery of
some person to be different from what he was taken to be.
When such discoveries are artfully conducted, and puced
in critical situations, they are extremely striking; such as
that famous one in Sophocles; which makes the whole sub-
ject of his Oedipus Tyrannus, and which is, undoubtedly,
the fullest of fulfilment, agitation, and terror, that ever was
exhibited on any stage. Among the moderns, two of the
most distinguished Anagogies are those contained in Vol-
taire’s Merope, and Mr. Home’s Douglas; both of which are
great master-pieces of the kind.
Another rule concerning the catastrophe is, that it ought
always to be simple; to depend on few events, and to
include but few persons. Passion never rises so high when it
is divided among many objects, as when it is directed
towards one, or a few. And it is still more checked,
if the incidents be so complex and intricate, that the
understanding is put on the stretch to trace them, when
the heart should be wholly delivered up to emotion. Dr.
Blair observes, that the catastrophe of the Mourning Bride
offends against both the preceding rules. In the last place,
the catastrophe ought to be the reign of pure sentiment and
passion. In proportion as it approaches, every thing should
warm and glow. No long discourses; no cold reasonings;
no parade of genius in the midst of thofe frolic and awful
events, that close fome of the great revolutions of human
fortune. There, if any where, the poet must be fimple,
are excellent. The words, indeed, except those of the canons, which confid of small portions of the Psalms and other parts of Scripture, in Latin (which seems to imply that they were set before the reformation), are, in general, devoid of wit, humour, poetry, and common sense. But our lyric poetry, during the 16th and part of the 17th century, was in a barbarous state, and far inferior to the music of the times. But the compilers seemd so little fulcious about the words they had to set, as frequently to prefer the fillables of omission "Ut re mi fa fol la; hey down down, derry down!" or merely, fa la, to songs of Spencer and Shakespeare.

The second collection of catches, Hilton ventured to publish in 1652, in spite of the Psalm-roaring, and fanatic gloom which then prevailed, under the title of "Cath that Cat can," or a choice collection of catches, round, and canons, for three and four voices. They helped to solace the royalists in private, during the triumphs of their enemies, and suppletion of all public amusements. Though many of these rounds and catches were afterwards reprinted by Playford, and retailed in later collections; the book, which is of a small oblong form, is not only scarce, but valuable; as it contains several canons and ingenious compositions which are not yet common.

The third publication of catches had John Playford for editor, in 1667, under the same title as that of Hilton; "Cath that Cat can," or the musical companion: which was, indeed, but a second edition. However, in a second part to this publication, there appeared dialogues, glee, ayres, and ballads, of two, three, and four voices, wholly different from Hilton's second part, which consists of about 40 hymns and canons.

But we must not terminate this article without an honourable and grateful mention of the round, or glory, or glee, of Purcell, of which the humour, ingenuity, and melody, were so congruent with the national taste, as to render them almost the sole productions of that facetious kind that were in general use for near four-score years. And though the countenance and premiums hallowed of late years upon this species of composition, as well as modern refinements in melody and performance, have given birth to many glee of a more elegant, graceful, and exalted kind, than any which Purcell produced; yet he forms hardly ever to have been equalled in the wit, pleasantry, and contrivance of his catches.

Canons, rounds, and catches were never published in score till after the institution of the Catch-Club, in 1762. This society was first suggested by the then earl of Eglington, Lord March, the present duke of Queenbury, and — Mylne, esq. who soon imbibed their manners the lords Sandwicb, Oxenf, Fortescue, &c. &c. This institution has given birth to many excellent glee, in parer harmony and more polished melody than those of former times could boast; but of catches and canons the stock has not been equally augmented. Purcell's catches are still the bell models of that species of composition; and except Dr. William Haves's pleasant canon, "Let's drink and let's sing together," Bird's "Non nobis Domine" is the only canon that has continued in constant favour and circulation, among all our efforts at similar productions.

Catch, in the Confinution of Canals, is the same with Counter-drain; and sometimes it denotes a fort of levels or feeders for a river.

Catch, in Botany. See Lychnis.

Catch-land, in Agriculture, is a name given to such common field-land as is not certainly known to which parishes it belongs; and, therefore, the minister who first gets the tithes of it enjoys it for the year.

Catchpole, or Catchpole, (one that catches by the pole,) a term now used, by way of reproach, for a bailiff's follower, or attendant. Anciently, it was a term of credit, applied to those we now call sequents of the chase, bailiffs, or any other that use to arrest men on any account.

Catch-word, amon Printers, denotes the last word of a page, which is put also at the top of the succeeding page, in order to show how the leaves and fleets follow each other, and facilitate the foldmg and binding.

The French sometimes only put the catch-words at the end of each fleet, or even quire or gatherings.

Catch, in Hush, is a term made use of in the practice of irrigation, to signify the method of turning the cuts and trenches for throwing the water of springs and small streams over such lands as lie on the fides, slopes, and declivities of hills.

Catch-work meadow, that fort of meadow which is formed by turning the water of a spring or a streamlet along the slope of a hill or declivity, to as to water the lands between the cut or main carriage, and the original water-course, which, in this instance, becomes the main drain. This is sometimes effected in particular cases, partly by making the new-cut level, and stepping it at the end; so that when it is full, the water may run out at the side, and flood the land below it. But, as the water would soon cease to run equally for any great length, and would wash the land out in gutters, it has been found necessary, according to the Agricultural Survey of the county of Wilshire, to cut small parallel trenches or carriages, at distances of 20 or 30 feet, to catch the water again; and each of these being likewise stepped at its end, its the water over its side, and distributes it till it is caught by the next, and so on over all the intermediate beds, to the main drain at the bottom of the meadow, which receives the water, and carries it on to water another meadow below; or, if it can be so contrived, another part of the same meadow, on a lower level. And in order to draw the water out of these parallel trenches or carriages, and lay the intermediate beds dry, a narrow deep drain crosses them at right angles, about every nine or ten poles' length, and leads from the main-carriage at top to the main-drain at the bottom of the meadow. When this meadow is to be watered, the ends of the carriages adjoining the cross-drains are slopped with turf dug on the spot, and the water thrown over as much of the meadow as it will cover well at a time, which the watermen call a pitch of work; and when it is necessary to lay this pitch dry, they take out the turfs and let the water into the drains, and proceed to water another pitch.

This fort of watered meadow is seldom expensive. The stream of water being usually small and easily manageable few hatches are requisite; and the land lying on a declivity much less manual labour is necessary to throw the water over it regularly, and especially to get it off again, than in other forts of watered meadows. The expense of forcing such meadow-lands is, in general, from about three to five pounds the acre; while the improvement is frequently from fifteen to forty fillings the acre, and the usual charge for keeping up the works and watering the lands, which is mostly done by the acre, seldom comes to higher than seven or twinnance. See Irrigation, and Watering of Land.

CATCHER, Crab-Catcher, in Ornithology, the name by which Sloane distinguishes alcedo aegypt, var. Z., Martin- fecheur de la Loufiane de Buffon.
CATCHER, Spider-Catcher, ardea muraria, is so named by Willughby.

CATCHES, in Clock Work, thefe parts of a clock that hold by hooking, and catching hold.

CATCH-OWL, in Geography, one of the Nicobar islands. N. lat. 7° 57'. E. long. 93° 58'.

CATCHWANNA, a town of Hindoostan, in the country of Agimere; 36 miles W.N.W. of Agimere.

CATEAU CAMBRÉSIS, or Le Cateau. a town of France, in the department of the North, and chief place of a canton, in the district of Cambray, belonging, before the revolution, to the archbishop of Cambray, and exempt from imposts. In 1790, a treaty of peace was made here between Henry II. king of France, and Philip II. king of Spain; 15 miles S.E. of Cambray. The place contains 4000, and the canton 17,626 inhabitants; the territory commences 162½ kilometres, and 16 communes. Near this place the French were defeated, in 1794, by the prince of Coburg, with the loss of 5000 killed.

CATECHESIS, from καταγωγή, I teach first principles, in a general sense, denotes an instruction given any person in the first rudiments of an art or science, but more particularly in the principles of the Christian religion.

Those who give such instructions are called catechists, and those who receive them catechumens.

Catechism is also used for a book containing the rudiments of the Christian religion, adapted to the use and instruction of novices. See Catechism.

The catechisms of St. Cyril, are the principal works of that father.

CATECHETIC, or CATECHETICAL, something that relates to oral instruction in the rudiments of Christianity. In the early ages of the church there were catechetical schools, wherein sacred learning and philosophy were taught. There were public auditories, distinct from the church, but probably adjoining to it. In a novel of the emperor Leo, they are called μαθηματικα, and represented as a sort of edifices belonging to the church. St. Ambrose speaks of these auditories as held in the baptistery. *Bingham. Orig. Eclef. lib. iii. cap. 16. § 4."

Catechism, Catechismus, in its primary sense, an instruction or instruction in the principles of the Christian religion, delivered oral, written, and so as to require frequent repetitions from the disciple or hearer of what had been said. Anecdotally, the candidates of baptism were only to be instructed in the secrets of their religion by tradition, oral word, without writing; as had also been the usage among the Egyptian priests, and the British and Gaulish druids, who only communicated the mystery of their theology by word of mouth. *Shaftebury. Charact. vol. iii. p. 241. not.

Catechism is more frequently used in modern times, for an elementary book, wherein the principal articles of religion are summarily delivered in the way of question and answer.

CATECHIST, Catecista, he that catechizes, i.e. instructs novices in the principles of religion.

Catechist more particularly denotes a person appointed by the church to instruct those intended for baptism, by word of mouth, in the fundamental articles of the Christian faith.

The catechists of churches were ministers usually distinct from the bishops and prebys, and had their auditories or catechumenae apart. Their business was to instruct the catechumens, and prepare them for the reception of baptism, but the catechists did not constitute any distinct order of the clergy, but where chosen out of any other order.

CATECHU, in Botany. See ARECA.

Catechu, in Chemistry and the Materia Medica, or Terra Japonica, (improperly so called,) is an extract prepared in several parts of India from a species of Mixtosia, by decoction of the inner wood, evaporation, and infillation in the sun. The tree is called in the Bahar province coira, and the name given to the extract in the country is catechu, cateh, or catechou.

Mr. Kerr gives the following account of its preparation. (Med. Observations, vol. v.) After the trees are felled, all the exterior white part of the wood is cut off and rejected. The inner wood, which is red, is then cut into chips and boiled with water, till half of it is evaporated. This strong decoction is then poured off, without straining, into a shallow earthen vessel, and evaporated to one third by fuel, after which the thorough drying is completed by the heat of the sun, the soft extract being spread on a mat, and exposed to the air.

There are two varieties of catechu brought to this country, that from Bombay and that from Bengal, each differing but slightly from the other in chemical qualities.

Catechu is of a reddish brown colour, sometimes nearly black, shining in its substance, and without smell. When taken in the mouth, it gives an astringent and rather bitter taste, which is far exceeded by a peculiar sweetness, which is very permanent, and by no means disagreeable. It dissolves slowly and totally in the mouth, the foreign impurities excepted.

By the analysis of Mr. Davy. (Phil. Trans, for 1803,) it appears, that there is very little difference between the two species, and they are both very remarkable for containing a larger portion of tan than any other vegetable matter, the gall not at all excepted.

Catechu is almost totally soluble in hot water. This solution is of a deep reddish brown, and slightly reddens litmus. By adding the solution of sinflafs or other animal jelly, a very copious precipitate is formed indicating a large quantity of tan; and the solutions of iron strike a deep black, showing the presence of gallic acid. Besides these two important ingredients, catechu contains a peculiar extract, and also a substance resembling mucilage. The latter is left nearly pure after the action of alcohol, which dissolves all the other ingredients. This mucilage scarcely differs from common gum mucilage, which is also procured from another species of mimosa. The extractive matter of catechu is soluble in water, but less easily than the tan is, and hence, they may be separated almost with accuracy, by repeatedly pouring cold water on the powdered catechu, and allowing it to remain only a short time in digestion. The tan will be known to be exhausted, when the water, the last added, no longer gives any precipitate with solution of sinflafs, after which the red extract is left nearly pure, most of the mucilage being also dissolved by the water. This refractory extract is but slightly astringent, but considerably sweet.

Mr. Davy found that 200 grains of the Bombay catechu contained about 100 of tan, 68 of extract, and 13 of mucilage, with 10 of earthy refuse. The same quantity of the Bengal catechu contained of the above substances, in the same order, 97 grains, 73, 16, and 14.

Catechu is used largely in the East, medicinally, but especially when mixed with the betel-nut, for chewing, a practice almost universal over the Indian continent.

In this country it is employed medicinally in those cases in which a mild unirritating and powerful astringent is required, as in immoderate alvine flux, autumnal diarrhoeas, &c. It is one of the most useful medicines of this kind, and is employed either in watery solution, or tincture.
The former is the mildest form, and is prepared almost im-
mediately by pouring hot water on the powdered catechu.
With this indication it may be usefully joined with the bit-
ter, tincture, and aromatic barks.
It is also used in the form of troches, mixed with gum-
arabic and sugar, to dissolve slowly in the mouth, and in this
form it often much affords the cleanliness of the voice, in per-
sons that have occasion to speak long in public. Catechu is
bodily, applied externally as a topical alligator, to ulcers in
the mouth, and other parts of the body.

CATECHUMEN, composed of κατάφορος and μένων, in
Ecclesiastical History, a candidate for baptism; or, a per-
son who prepares himself for receiving it. Towards the end of
the first century Christians were divided into two orders,
distinguished by the names of believers and catechumens.
The latter, as contradistinguished from the former (see Be-
lievers), were such as had not yet been dedicated to
God and Christ by baptism, and were, therefore, admitted
neither to the public prayers, nor to the holy communion,
nor to the ecclesiastical assemblies. They were distinguished
from the fidelis, or believers, not only by name, but also
by their place in the church: being dispensed with the peni-
tents, in the portico or gallery at the extremity of the
church, opposite to the choir. As they were not allowed
to assist at the celebration of the eucharist, the deacon
discharged them, after sermon, with this formula, proclaimed
three times, "Ite, Catechumeni; mihi eum." Catechumens
formed the lowest order of Christians in the primitive church;
and were admitted into this state by the imposition of hands,
and the sign of the cross. The children of believing pa-
 rents, it is said, were admitted as catechumens, as soon as
they were capable of instruction, but it is not certain at
what age those of heathen parents might be admitted; nor
does the time of their continuance in this state seem to have
been fixed by any general rules. The methods of instructing
the catechumens differed according to their various capacities.
The catechumens, in whom the force of natural reason was small, were
 taught nothing more than the fundamental principles and truths,
which are, as it were, the basis of Christianitv. Those, on
the contrary, whose instructors judged capable of com-
prehending, in some measure, the whole system of divine
truth, were furnished with superior degrees of knowledge;
and nothing was concealed from them, which could have any
tendency to render them firm in their profession, and to assist
them in arriving at Christian perfection. The care of in-
structing such was committed to persons who were distin-
guished by their gravity and wisdom, and also by their
learning and judgment. Hence it was, that the ancient
doctors generally divide their flock into two classes; the
one, comprehending such as were solidity and thoroughly
instructed; the other, those who were acquainted with little
more than the first principles of religion; nor do they deny
that the methods of instruction applied to these two sorts of
persons were extremely different.

There were divers orders or degrees of catechumens in
those churches and ages where the term of catechizing for
two or three years was observed; but ecclesiastical writers
are not agreed as to the precise number and appellations of
these different orders. Some, however, have reckoned four
orders: the first were those that were instructed privately
without the church, and who were kept at a distance for
some time from the privilege of entering the church, in
order to make them more solicitous for obtaining it. Those
of the second degree were the "audientes," or "auditeurs,"
(see AUDIENTS), so called from the being admitted to hear
sermons, and the scriptures read in the church; but not
allowed to join in the prayers. The third and lowest was to have
comprehended the catechumens, denominated "genu-slec-
tentes," because they received imposition of hands kneeling.
Those of the fourth order were the "competentes," (see Com-
petentes) and "clerici," denoting the immediate can-
didates for baptism, or such as were appointed to be bap-
tized at the next approaching festival; before which, they
were strictly examined as to their proficiency in the several
branches of catechetical exercises. After examination they
were exercised for twenty days, and laid under an obliga-
tion of fasting and confession: for some days before baptism
they wore a veil; and it was customary to touch their ears,
saying "ephebae," he opened; and also to anoint their eyes
with clay; both which ceremonies professed to be imitations
of the practice of our Saviour, and intended to shadow out
the catechumens their true condition before and after
their admission into the Christian church.

CATECHUMENUM, a name given to an upper gal-
lerly in the ancient churches. The name catechumen
was also given to a port of school-house near the church,
where the catechumens met to receive the instruction of the
catechist.

CATEGOREMA, from καταγωγήν, I declare, is defined
a noun substantivum, so absolute and independent, that it may
stand at the head of a class apart.

CATEGOREMA properly denotes the name whereby a
category, or class of beings, is represented. See Cate-
Gory.

CATEGORIE, in Literary History. Aristotle has a book
extant under the title of καταγωγήν, which Curio, Tor-
flexus, Vives, and others, deny to be written by him, and
ascribe to Andronicus; but without much foundation, since
that work is cited as Aristotle's by Simplicius, Ammonius,
and Lucianus.

CATEGORIAES, a minister in the Greek church,
whose business is to publish or proclaim the festal days. He
had also the care of the lights, and to see the church kept
clean.

CATEGORICAL, in a general sense, is applied to those
things ranged under a category.

Categorical, also imports a thing to be absolute,
and not restrained to conditions. In which sense it stands
opposed to hypothetical and conditional. A catego-
rical answer denotes an express and pertinent answer, made
to any question or objection proposed.

CATEGORUMENUM, denotes the predicate, or
that part of a proposition which is affirmed of the subjeet.
Some mistakenly call this categoria.

CATEGORY, in Logic, a syllem, or syllembge, of all
the beings contained under any genus, or kind; ranged
in order. The word category was borrowed by the schools
from the forum, or courts of justice; for as, in a trial, the
plaintiff or prosecutor in accusing the criminal, or prisoner,
must charge him expressly, or affirm that he did this or that
in positive terms: whence the word category, viz. from κατα-
γωγήν, to aver, or declare a charge of accusation: so in
the doctrine of categories every higher may be expressly and
absolutely predicated, or affirmed, of every lower.
The school philosophers distribute all beings, all the ob-
jects of our thoughts or ideas, into certain genera, or classes,
in order to get a more distinct and precise notion thereof;
which classes the Greeks call categories, and the Latin pre-
dicaments: and which Mr. Harris has styled in the title of his
work, Philosophical Arrangements.

The ancients, after Aristotle, generally make ten cate-
gories; under the first all substances are comprised; and all
accidents or attributes under the nine last; viz. quantity,
quality,
CATENA, in a general sense, a chain.

CATENA, in Anatomy, a muscle, otherwise called Tibialis anticus.

CATENA, in Ecclesiastical Writers, denotes a sort of commentary on scripture, composed of separate passages or interpretations of the fathers, reduced to the order of chapters and verses of the book. The first who used catena in this sense was Thomas de Aquinas. The reason of the appellation seems to be this: that a chain consists of several links connected together, so do these commentaries consist of a number of different passages, or the sentences and expostulations of different writers, tacked together so as to form one work. Fabr. Bibl. Grac. tom. vii. lib. v. cap. 17.

CATENARIA, in the Higher Geometry, a mechanical curve line, which, a chain, or rope, forms itself into, by its own weight, when hung freely, between two points of suspension, whether those points be horizontal or not. It is otherwise called the Elipolle curve.

The nature of this curve was investigated by Galilei, who opposed it to be the same with the parabola; but though Jungius detected this mistake, its true nature was not discovered till the year 1697, when M. J. Bernoulli published it as a problem in the Acta Eruditorum. Dr. D. Gregory, in 1697, published a method of investigating the properties before discovered by Bernoulli and Leibnitz; (Phil. Trans. ab. vol. i. p. 59, &c.) where he undertakes to show, that an inverted catenaria is the belt figure for an arch. Bernoulli Opera, vol. i. p. 48, &c. and vol. iii. p. 491, &c. Cotes's Harm. Medc. p. 108. To conceive the general nature or character of this curve, suppose a line heavy and flexible (See Plate Geom. III. fig. 49), the two extremes of which, F and D, are firmly fixed in those points; by its weight it is bent into a certain curve FAD, which is called the catenaria.

Let BD and dD be parallel to the horizon, A B, its axis, perpendicular to the horizon and to BD, and D d parallel to A B; and the points B, b infinitely near to each other. From the laws of mechanics, any three powers in equilibrio, are to one another as the lines parallel to the lines of their direction (or inclined in any given angle), and terminated by their mutual concourse: hence, if D d expresses the absolute gravity of the particle D d (as it will, if we allow the chain to be every way uniform), then D d will express that part of the gravity, that acts perpendicularly upon D d; and by the means of which, this particle endeavours to reduce itself into a vertical position: and as it proceeds from the ponderous line DA, it is, ceteris paribus, proportional to the line A D, which is the cause of it. Further, the lineola dD will express the force which acts against that portion of the particle D d, by which it endeavoureth to reduce itself into a position perpendicular to the horizon, and binds it from doing so. This force is constant, being no other than the reitance of the point A; and may therefore be expressed by any given right line a. Supposing the curve FAD, therefore, as before, whose vertex (the lowest point of the catena) is A, axis AB, ordinate BD; &c; it is evident, then, that the forces of nature, that act upon this curve, are the same as those which act upon a straight line; and hence that the curve, if given, may be applied to a straight line.

\[ x : y : z : a, \text{ or } ax = yz \text{ i.e. } y = ax. \]

From this fundamental equation, we may easily deduce by proper analogy, or similar combinations of the terms, this other property; \[ x = \sqrt{a^2 + y^2} \text{ or } z = \sqrt{a^2 + z^2}, \text{ or } a^2 = a^2 + z^2. \]
\[ z^2 = \sqrt{a + z^2}, \text{ or } z = \frac{\sqrt{a} \pm z}{a + 2z} \text{; and the fluents of } \\
\text{these give } x = \sqrt{a + z^2}. \text{ But, at the vertex of the curve, } \\
\text{where } x = a, \text{ and } z = 0, \text{ this becomes } a = \sqrt{a + z} = a; \text{ and, } \\
\text{therefore, by correction, the true equation of the fluents } \\
is x = \sqrt{a + x^2} - a, \text{ or } a + x = \sqrt{a + z^2}; \text{ and hence } \\
\text{also } z = \sqrt{a + x^2} - a = \sqrt{ax + x}, \text{ and } a = \frac{z^2 - a}{x}. \]

Any of these expressions will give the equation of the curve in terms of the arc and its absciss, in which it appears, that \( a + x \) represent the hypotenuse of a right-angled triangle, whose two legs are \( a \) and \( z \). So that if in \( BA \) and \( HI \), parallel to \( BD \), and representing the direction in which the tension at \( A \) acts, produced, there be taken \( AD = a, \text{ and } \angle AHI = \text{ the curve } z \text{ or } \angle ABD \); then will the hypotenuse \( DF = a + x \) or \( DB \); and hence, any two of these three, \( a, x, z \), being given, the third is given also.

Again, from the first simple property, viz. \( \hat{x} : \hat{y} : : z : a, \) or \( a \hat{x} = \hat{z} \); by substituting the value of \( z \) above found, it becomes \( a \hat{x} = \sqrt{2ax + x^2} \), or \( \hat{z} = \frac{\sqrt{2ax + x^2}}{a} \)
and the fluent of this equation is \( y = 2a \times \text{hyp. log. of } \sqrt{x + \sqrt{2ax + x^2}} \).
But, at the vertex of the curve, where \( x = a, \) and \( y = a, \) this becomes \( a = 2a \times \text{hyp. log. of } \sqrt{\frac{x}{a}} \); therefore the correct equation of the fluents is \( y = 2a \times \text{hyp. log. of } \sqrt{\frac{x}{a} + \sqrt{\frac{2ax + x^2}{a}}} \); an equation to the curve also, in terms of \( x \) and \( y \), but not in simple algebraic terms.

This last equation, however, may be brought to much simpler terms in different ways; as, finally, by squaring the logarithmic quantity, and dividing its coefficient by \( z \), then \( y = a \times \text{hyp. log. of } \frac{a + x + \sqrt{2ax + x^2}}{a} = a \times \text{hyp. log. } \frac{a + x + z}{a} \); and secondly, by multiplying both numerator and denominator by \( \sqrt{2a + x} - \sqrt{x} \), then squaring the product, and dividing the coefficient by \( 2z \), which gives \( y = a \times \text{hyp. log. of } \frac{\sqrt{2ax + x^2} + a}{\sqrt{2ax + x^2} - a} = a \times \text{hyp. log. } \frac{z + x}{z - x} \) = \( z \times \text{hyp. log. } \frac{z + a}{a - z} \).

Catenation, in Medicine and Physiology, from catena, a chain, a term employed by Dr. Darwin, and adopted by some other modern writers, to express the connection or association of certain actions of animal bodies. "All animal motions which have occurred at the same time, or in immediate succession, become so connected, that when one of them is reproduced, the other has a tendency to accompany or succeed it." Zoonomia, sect. iv. 7.

This law of the animal economy, which Dr. Darwin has illustrated, is one of important consideration, not only with the physiologist, but with the practical physician. All the mechanical arts of man confind in the acquisition of these catenations, by which the motions of many of his muscles become gradually linked together in trains, tribes, or circles of motion. However difficult the first attempt at these combinations may be, the force of the catenations is pointed out by this circumstance, that when they have been once formed by frequent repetitions, we can exert our attention strongly on other objects, and the concatenated circle of motions will not herelases proceed in due order, as whilst we are thinking on any subject, we use a variety of muscles in walking along the street, or directing a horde on which we ride. This may be most satisfactorily exemplified in the art of playing on a musical instrument; and when we recollect," says the author of Zoonomia, "the variety of mechanic arts which are performed by associated trains of muscular actions extended with the effects they produce, as in knitting, netting, weaving; and the greater variety of associated trains of ideas caused or catenated by volitions or sensations. As in our hourly modes of reasoning, or imagining, or recollecting, we shall gain some idea of the innumerable concatenated trains and circles of action, which form the tenor of our lives, and which began will only cease entirely with them." Sect. xvii. 2.

In beginning to learn music, we first voluntarily apply ourselves to the characters of the music book, and endeavour by many repetitions to catenate them with the proportions of sound of which they are symbols. The ideas excited by the musical characters are directly connected with the keys of the harpsichord, and much effort is necessary to produce every note with the proper finger, and in its due place and time; till at length a train of voluntary exertions becomes concatenated with certain irritations. As the various notes by frequent repetitions become connected in the order in which they are produced, not only the musical symbols of crotchets and quavers, but the auditory notes and tones, at the same time, become to many inceptive or synchronous links in this circle of concatenated actions. At length the motions of the fingers become concatenated with the musical characters, and those no sooner strike the eye, than the finger presses down the key, without any voluntary attention between them; the activity of the hand being connected with the irritation of the figure of the musical symbol on the eye. But not only is this facility acquired, we can even play with great exactness accustomed tunes, and think, and converse, at the same time on other subjects. To the same tendency to catenation of motions, the odd habits and singularities of individuals are to be attributed.

In diseases the catenation of motions is frequently conspicuous, and contributes to prolong their continuance. Thus in typhus fever, even if it commences with violence, the affection of cold water on the body of the patient, or the exhibition of a strong emetic, will often completely interrupt the progress of the disease, if referred to within the first three days; but if the febrile action, however flight, be allowed to continue longer, they become so strongly catenated, that no expedient is sufficient to diffuse the associated trains.

By some extension of the meaning of the term, many other animal actions are said to be catenated with our daily habits of life, or with certain portions of time, or degrees of exhaustion, and. Thus, if the pain of hunger be not relieved by taking food at the usual time, it is liable to cease till the next period of time, or other habits recur. "Our times even of repirauation are not only governed by the stimulus of the blood in the lungs, or our deficit of breath air, but also by our attention to the hourly objects before us. Hence, when a person is carnally contemplating an idea of grief, he forgets to breathe, till the sensibility of his lungs becomes very urgent; and then a high succeeds for the purpose of more forcibly pulling forwards the blood, which is accumulated in the lungs."

Upon the same principle our periods of sleeping and waking, of evacuating the bowels, and, are much regulated; and hence the propriety of Mr. Locke's recommendation for obviating colicnities. The periods of female menstruation are catenated with longer but more regular times. In diseases the
the hectic and quotidion fever obey the intervals of solar or lunar periods; the tertian is connected with a solar interval of 48 hours; the quartan with one of 72. Similar periods are observed in gout, in schila, hemicrania, in hemocephalies, often, and in returns of arterial hemorrhages; and they recur in lunacy, whenever its name has been derived. See Darwin _Zoology_, vol. i. feol. xvi.

**CATTENENSES.** _In Ancient Geography_, a people of Afa, in Pamphylia, who, according to Strabo, inhabited the territory of Selga.

**CATERER.** See Purveyor.

**CATERGI,** the name of the public carriers in the Grand Seignor's dominions, who give credit to the merchants, and others, as a security that they will carry their goods, or not set out with them.

**CATERPILLAR.** _In Botany._ See _Scorpigus._

**CATERPILLAR, in Entomology._ More properly _Larva_, the worm-like plate in which all the lepidopterous, and most other insects appear on quitting the egg. See _Larva_, article _Entomology._

**CATERPILLAR, in Gardening._ A well-known highly destructive insect, that frequently does great injury to various sorts of trees of the fruit and other kinds, by stripping them of their foliage, and preventing the setting of the fruits.

There are several kinds; but those that are most destructive to vegetables and fruits in the garden or field are the yellowish-green, the black, and the dark rough-finned leathery sorts. The first is generated from the eggs of the white butterfly, deposited upon the leaves and other parts of the plants. Those of the second sort mostly thaw themselves in March, when the weather is dry, upon trees of the pear, apple, and other kinds, sometimes contained in large webs: they deposit their eggs on the leaves, and in the crevices of the bark of the trees, from which new insects are generated during the summer months. Mr. Hitchfop sees some of them to remain in these situations during the winter; having found them in nail-holes and under pieces of old bark in February. The last is generated in the middle of the enclosed leaves of different sorts of plants; such as those of the cabbage, broccoli, and other similar kinds. These produce much mischief by eating through the leaves and other parts of the plants. Darwin observes that there are two breeds of these insects in the year, the larve of the first devouring the spring leaves, and those of the second the summer flowers. Various methods have been attempted for destroying the different sorts of caterpillars, both such as are destructive to elegant plants, and to trees of the fruit kinds. With respect to the first, much advantage may be gained by a careful attention in picking them off from the leaves or other parts of the plants on their first appearance. The beds or other places where the vegetables grow should also be carefully examined early in the mornings, in order to destroy them before they retire into the holes and crevices that conceal them during the day-time; and as they are in general the most prevalent when the weather is dry, it seems not improbable that considerable benefit may be obtained by watering the plants frequently, both with common water, and with such liquids as contain ammonia or volatile alkali, either from the effects of such waterings on the caterpillars themselves, or from their promoting the growth of the plants in so vigorous and rapid a manner as to render them incapable of being devoured by them.

Mr. Forsyth advises that during the winter and spring months, every _chrysalis_ that can be discovered, either under the coverings of walls, on gates or palings, and about the eaves, doors, and windows of houseties, should be completely removed and destroyed. Where caterpillars abound, all the leaves that are affected should be removed with care, and swept up in order to be destroyed by fire, or formed into a compost with other substances.

The ten-threaded caterpillar is eagerly sought after by birds, and is capable of being easily destroyed; but when neglected, the _ova_ are deposited in great abundance in the latter part of summer, as about July, on the undersides of the leaves in rows, with little white specks, and quickly hatched on account of the heat of the season, the young caterpillars coming forth in swarms to destroy the autumnal leaves. At this season they may be picked off the infected leaves, and their generation be by that means prevented.

Bushes or plants that are much affected with caterpillars one year, are extremely liable to be attacked with them afterwards.

In the first essay, or with fruit-trees, the bell method of preventing them from being infested is, according to Mr. Forsyth, to scrape the stems with a piece of bone or wood, made in the form of a knife, taking care not to bruise the bark; and afterwards to wash the tree and wall with an equal quantity of soapuds and urine mixed, and a soon as the leaves are off the trees in autumn, they should be raked and swept up; then carried to the melon ground, and mixed up with other leaves and dung for hot-beds;" by this means a great number of eggs of insects that are deposited on the under sides of the leaves may be got rid of. Afterwards all the items of the trees, and all the ends of the boughs, should be washed, taking care not to hurt the buds; in doing this, it is observed, that what falls will destroy the flags that take shelter on the offsets of the walls and in the borders, before they are dug for planting lettuces, endive, &c. This washing should be repeated about the beginning of February, which will destroy any eggs of different insects that may still remain about the trees. A painter's brush may be used for laying the mixture on the trees, and a soft broom or brush made of the ends of garden matting for washing the wall. The matting seems preferable, as being loft and flexible, it will enter the holes and clefts. And the mixture that falls on the borders and offsets of the walls, in this second washing, will destroy those flags and insects that made their appearance early. The items and branches of the trees may be washed two or three times, or oftener, in the spring, before the buds begin to swell; but the branches must not be rubbed after the trees come into flower: they may, however, be sprinkled over with the mixture from a watering pot with a rose just before the buds begin to open, but by no means after they are open; as it would, by its glutinous nature, render the bloom liable to be torched by the sun. These washings, &c. are recommended for all trees, standards as well as those on walls; particularly apple, cherry, and plum-trees. Where any caterpillars remain, they may be discovered by the curling of the leaves; for every curled leaf has one or more caterpillar, or other insect in it; such leaves should therefore be carefully pulled off, and the insects crushed, as when neglected they frequently devour every leaf, leaving the tree quite naked, and of course destroy the fruit for that season at least.

In order to remove the gregarious sorts of caterpillars, which are inclosed in great numbers in nets or bags refracting strong cobwebs, and fixed to the branches of trees or shrubs, the nets should be carefully picked off, and the insects crushed, by which will numbers of them may be destroyed. After the trees have been thus cleared, they should be washed as above, to destroy those TAGRALLERS that may still remain on them. But after the trees come into flower, instead of washing them with urine and soapuds, they should be
CATERPILLAR.

be well watered with clear lime-water, and cleaned with tobacco-water.

It is remarked by Mr. Forfyth, that as there are several forts of moths, that in the caterpillar state are very hurtful to plums and other fruit-trees, it would be a great advantage to destroy them on their first appearance. In clearing trees from insects of other kinds, caterpillars should also be carefully looked for and picked off. They will be found sheltering at the ends of the shoots in the flowers, and at the bottoms of the footstalks of the flowers. It is added, that there are two or three forts that infest fruit-trees, two of a brown and one of a green colour.

The success of this method of clearing and washing has been very evident in the practice of Mr. Forfyth, in different forts of apple-trees, they recovering themselves afterwards in a rapid manner.

It has long been a common opinion that cold and severe frosts have considerable effects in destroying caterpillars as well as the larve and eggs of different insects; but the experiments of Reaumur and Bonnet seem to shew that this is not the case, as on the former subjecting a parcel of young caterpillars to a degree of cold lowered to fifteen degrees below zero on his thermometer, according to Dr. Anderson, they suffered no injury; and the latter found the same thing to be the case with the common cabbage caterpillar, and also the chrysalis of the common butterfly. It seems therefore not improbable but that cold frosty winters produce the good effects that are generally said to be found from them, in destroying these animals, by preventing them from obtaining food in that proportion which is necessary for their existence. The circumstance of long frosts being the most effectual is also favourable to the same supposition.

With respect to the gooseberry caterpillar, a method that has been recommended as successful by Dr. Anderson, is to notice the bushes with care in passing through the garden, towards the beginning of June, and whenever the appearance of a leaf stripped by the caterpillar is perceived, instantly to examine the place with a view to eradicate the disease. It will always be perceived that the first appearance of this malady is towards the bottom of the bushes. If one leaf be eaten up, you may be assured the caterpillar has been there; and if leaves be made with care it will invariably be found. This is a gregarious reptile, and while they are young they herd very close together; so that at this early period, the whole nest will frequently be found upon one leaf, and by picking off that leaf the whole destroyed at once. As they advance in size they grow more hardy, and separate more, and therefore spread upon a number of leaves at once; but before they have attained the size of half an inch in length; they are generally found in large clusters, and may be easily destroyed. Their progress is always from the bottom upwards; and this will generally be found upon those leaves, on the same branch, that are immediately above those that have been already eaten and abandoned, leaving only the hard ribs of the leaf flaying. They always fix on the under side of the leaf, and begin to gnaw off its edges. If they have but newly fixed on the leaf, no indication of them will be perceived there when viewed from above, but if the leaf bit be seen wanting, on one side of a leaf, it may be concluded they are there. These leaves and all others suspected should be pulled off, by pinching away the footstalk, with the thumb gently, so as not to shake them off; though they adhere to it so firmly when thus small, as not to be easily disengaged from it. If there be several leaves in one tuft, they may be all taken off at once; or if the malady appears upon a young shoot of this year (which is very apt with the cafe), the safest and shortest way is to take away the whole branch entirely.

All the leaves, thus picked off, should be either carried away in a basket, or laid in a heap upon the ground at some distance from the bush, and crushed by the foot before they are left, for it is an active reptile, and if left in life, may regain the tree afterwards. If this operation be performed with due attention, at a sufficiently early period, few will escape; nor is it a tedious process, for the most part twenty or thirty large bushes may be thus cleared by one person in the space of an hour, not one of which would perhaps have been left with a single leaf upon it, had previous means been bellowed upon them. But it is not right, says he, to trust to once searching only; for in spite of ever so much attention, it will often happen that a whole loaded leaf will escape unnoticed; and more frequently a few flakes will pass unobserved. It is right, therefore, to look at the bushes afterwards, to see if any more leaves are eaten, and to pick them off after the same manner. This becomes the more necessary, because the eyes do not all hatch at one time, so that a whole broad may be hatched after your first look, which would of course totally escape were it no farther attended to. The task is easy if taken in time, and may thousands may be thus destroyed in the space of an hour; but if they be once suffered to disperse, and have fixed themselves among the middle of the bushes, among the small leaves that sprang out of the old wood, the task then becomes much more difficult. It is advised that those who wish to try the efficacy of this mode of proceeding should never depend upon the efforts of others to ascertain whether it is effectual or not. They may order servants to practise it; but if they wish never to be deceived, let them make choice of one, two, or more bushes, to be picked by themselves only, and they will thus, with little trouble, satisfy themselves whether it is practicable or not, and can check their servants if they attempt to impose on them.

In the third volume of an useful periodical work, the Farmer's Magazine, some observations are offered on the destruction of this caterpillar by the use of tobacco. The writer says, he has tried the effect of tobacco juice, and of quick-vine, both to bushes and cabbages, to destroy these insects, but without accomplishing the end in view; he took every different method that solicitude could suggest or mediate attention could execute; and that smoking with brimstone has been lately recommended. This method he has also attempted, but without success. He applied quicklime in two ways, first by wetting the infected bush or cabbage with a watering can, and then sprinkled on it powdered quicklime; and secondly by putting quick-lime into a watering can, with which the infected bush or plant was sprinkled; but also with little effect. It is further stated that tobacco is noxious to all the insect tribe. Gardeners scatter the flake of it upon their hot beds and on their flower-beds, where delicate plants become in danger of being destroyed by minute vermin, which completely answer the purpose. A pinch of snuff put upon the back of a frog or toad, occasions in these reptiles instant convulsions and death. One might therefore, he says, expect that the application of tobacco, or snuff, to bushes infested with caterpillars, would be attended with a powerful effect. But having applied it to his bushes in both ways, in which he tried the quick-lime, he found it unavailing; for caterpillars, though easily crushed to death, are otherwise wonderfully tenacious of life. Failing in these modes of application of those remedies, he wished
CAT

wished to see what power they had to destroy caterpillars, when applied to them in the clofett possible manner. With this view he put a small quantity of tobacco fmut into one plate, and some quick lime into the other. Into thefe he put a number of caterpillars; but they having crawled off without being hurt, he mixed these articles with water. Out of this folution the insects also crawled, feemingly unhurt; he then prevented them from getting out of the liquor, and they expired. This was fatisfactory evidence to him that caterpillars cannot be destroyed by any ordinary application of tobacco or quick-lime to a bufh on which they fwarm. Afterwards he tried how far the fmoke of brim- ftonle is benefial to these insects, by the following experiment. He put a dozen of them on a plate, over this he inverted a bowl which had in it some burning brimftonle. This did not kill the caterpillars, which made him have recourse to a more effectual method of confining the vapour. He placed a few of these insects in a small bottle, into which, having fhut a bit of paper with inflamed sulphur, he flopped the aperture of the bottle with a cork. The effect of the vapour then became too powerful for any animal life to refill, and the insects died. This experiment, however, convinced him that the fmoke of brimftonle cannot be effectually applied for exterminating caterpillars on bufhes. Defparing of fuc- cess from any mode of general destruction of these vermin, he fet fervants and others to work to pick them off as above, or rather to crefh them on the bufhes. This effectual method at first glance may, he fays, appear an infurmountable labour; but let it be tried, and it will be found by no means fo tedious or laborious as at first imagined. Indeed it is a matter of absolute neceffity, and as such is practifed by fome gardeners, who know well, that if a fwarm of cater- pillars, on any one bufh, are not quickly destroyed, they will go over and ruin every bufh and berry in the garden. Not only will black currant bufhes, which they are not fo fond of, become a prey to their voracity, but he has had experience of the fame vermin adjoining to peach trees, and other fruit trees. Nor is there any tree, though even dif- tant, that they will not rob of its leaves, rather than want food for their voracious appetites. Neither is this all, for if thefe vermin are left to plunder and to live, they infallibly fecure an abundant potterinity to destroy all the small fruit of the enfluing and fecceeding summers." The only effectual means are, he fays, by picking them off as directed above, the labour of which may, it is fuppofed, be somewhat abridged by fhaking well the infected bufh, and craving with the foot thefe caterpillars that fall to the ground. The writer is informed that the Meffirs. Culley, thofe ac- tive and enterprising farmers, on the fame principle, make the caterpillars be hand-picked from their extensive crops of turnips. And it is remarked that cabbages and greens may in general be prevented from caterpillars by plucking off the large under-ground leaves (which may be given to cows) in the month of Angulf, or when the common white butterfly begins to appear in numbers. Thofe butterflies lay their eggs, which produce the cabbage caterpillar, on the under fide of the large leaves of the cabbage and kale plants. There is also said to be another remedy, which he cannot anfwcr for. The learned professor of natural hiftory in the university of Edinburgh has alwears him, that fowing beans among cabbages will greatly prevent the breeding of these worms. It is faid the butterfly has an antipathy to the flavour of beans. And he adds that "the moths (phalaenae grofiflariae of Linnaeus) from which the gooseberry and currant caterpillars (which are the fame) are bred, are fmall, having yellow bodies, with many black spots, and their wings white, with yellow fprays fpotted with black. They appear in the month of July, in the evenings, and ought to be carefally killed by all attentive gardeners. They fly far fom the bufhes on which they deposit their eggs. They live about twenty days, during which (for many of the moth tribe have not even months) they eat little or none. The eggs, which are yellow, are glued below the clefts, and under the larger arms near the bottom, and fometimes on the leaves of the bufhes that are proper for ferving the young progeny for food. One moth produces upwards of one hundred and fifty eggs; the young worms generally appear, he thinks, in spring, but they are frequently hatched in autumn. He has obferved the young in great numbers devouring the leaves of the gooseberry bufh as early as the 14th of Augufi, that is about three weeks after the eggs are laid. They fometimes eat up the embryo of the new leaves and flowers of the bufh in October, which renders any hope of fruit for the ensuing year abfolute. Neither the fruit or snow of winter deftructs them. He has taken particular notice of fome of their remaining on a currant bufh, without being afected with cold or fummer, from November till March. During winter, and the early parts of spring, they lurk in clufters below the cleft, and then is the time they ought to be crefh. At all times, till they are ready to go into the intermediate, or nymph fiate, pre- vious to their being changed into moths, they have, though ordinarily voracious, a vail power of living without food. If put into a box, even in fummer, they will not fecom the worfe for being kept without meat."

Another writer in the fame work has found great advantage from the ufe of sulphur venum in deftructing thefe cater- pillars, after other methods had failed. "It was ufed," fays he, "in the following manner: the bufh was firll light- ly sprinkled with water, fo as to moiften the upper part of the leaves, and immediately after dried with the sulphur, which was put into a tin box, with the lid perforated like a pepper holder. The moiftening of the leaves made the sulphur adhere to them; and the weather continuing dry, it remained upon them. The confequence was, that by next morning not a fingle caterpillar could be feen upon any of the bufhes that had been fo treated, unless in crevices, or upon fome of the grains that it had not reached. Hitherto, he fays, the sulphur does not appear to have been at all hurtful to the foliage, as the bufhes, to which it was ap- plied, were in the fame fate of forwardness, and look equally well as others that were not infected with the vermin. To ensure success, it feems efficient, he fays, that the sulphur fhould be ufed in dry weather, as, if rain fall immediately after the application, it will be washed off and its effect leffened."

It is ingeniously fuggedted by Mr. Forsyth, that by a better and more intimate acquaintance with the habits and economy of thefe animals, we might, probably, be enabled to difcover more certain methods of deftructing them.

**CATERPILLAR Eaters**, in *Entomology*; see ICHNEUMON.

**CATERVA, in Ancient Military Writers**, a term ufed in speaking of the Gaulish or Celtiberian armies, denoting a body of *COCO* armed men.

The word caterva, or catavernus, is also frequently ufed by ancient writers to denote a party or corps of soldiers in disord or disarray: by which it fands distinguished from cohors or turma, which were in good order.

Gen. Ch. Cal. terminal superior, very small, four-toothed, acute, permanent. Cor. monopetalous, funnel-shaped; tube long, tapering, gradually enlarging upwards; border semi-quadrid, broad, erect, flat. Stam. filaments four, within the neck of the tube; anthers oblong, erect, rather longer than the corolla. Pest. germ inferior, roundish; style filiform, the length of the corolla; stigma simple. Peric. berry oval, crowned, one-celled (two-celled, Vahl). Seeds many, angular.

Eff. Ch. Cor. monopetalous, funnel-shaped, very long, superior; stamens within the throat of the corolla. Berry many-seeded, two-celled, Wild.

Sp. 1. C. spinosa, Linn. Sp. Pl. Lam. Illh. Pl. lxvi. fig. 1. Curtis, Bot. Mag. Pl. 131. (C. longiflora, Swartz. Prod. 35. Prunus spinosa, &c. Catley carol. tab. 100.) “Tube of the corolla very long; berries oval.” A shrub. Stem, twelve or fourteen feet high, about four inches thick; bark smooth, of a greenish ruficet colour; wood tough and hard. Leaves small, renfolding of both, growing in clusters, with intervals of about an inch; each cluster accompanied by two sharp plant thorns. Flowers live or fix inches long, yellowish, pendulous, solitary in the axis of the upper leaves. Fruit the size of a pullet's egg; with a smooth yellow skin, and a pulp like that of a ripe apple, which has all grateful tastes and a pleasant smell. Found by Catley near Naffiun, Town, in Providence, one of the Bahama islands, who brought seeds to England. 2. C. parviflora, Willd. Mart. Swartz. Prod. 32. Vahl. fymb. ii. p. 31. Eclog. i. p. 12. Lam. Illh. Pl. lxvi. fig. 2. bad. (Rhamnus foliis buxiceis, &c. Sloane, Jan. 2. tab. 207, fig. 1.) “Tube of the corolla four-corrugated, abbreviated; berries roundish.” A native of Jamaica. Obs. Swartz, though at first he received this species as a catechu, has since made it a distinct genus, which he calls celosanthes, with the following character: Cal. very small, four-clft; Cor. tubular, border curved, four toothed. Stam. four. Pest. germ superior; stile bident. Peric. drupe white, one-celled. A branched, thorny shrub. Leaves opposite, nearly sessile, roundish. Flowers, some solitary; at the extremity of the young pinnas, abortive; others in the axils of the leaves fertile. Bofc. in Nov. Dict. art. Scolofanthe.

Propagation and culture. The first species has been propagated in England both by seeds and cuttings. The seeds succeed best when they are brought over in the entire fruit preferred in sand. They should be sown in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanner's bark. The plants will appear in about six weeks if the seeds were good, and the pots have been occasionally, but sparingly watered. It will then generally be proper to turn over the tan to the bottom; and if the heat be not sufficient, to increase it by adding a little fresh tan. When the pots are plunged again into the tan-bed, they should be supplied with fresh water every day according to the warmth of the season, and frequently refreshed with water in small quantities; if the weather prove cold, the glasses should be covered with mats every evening. In the autumn the pots should be removed into the house, and plunged into the tan-bed; during the winter the plants should be watered with great caution; and in the spring should be carefully taken up and planted in separate pots which should be plunged into a fresh hot-bed of tanner's bark. In former they should have a good deal of air; but in autumn they must be removed into the house, where they should afterwards constantly remain, and be treated like other tender exotic plants.

The cuttings should be planted during the months of June and July, in small pots filled with light earth, plunged into a moderate hot-bed of bark, and closely covered with small bell-jarfs. In two or three months they will put out roots, when they should be transplanted into separate pots, and treated as the seedling plants. Miller.

CATESBY, Mark, in Biography, an eminent English naturalist, was born about the latter end of 1679, or the beginning of 1680. An early propensity to the study of nature first led him to London, in which he emphatically styles “the centre of science,” and afterwards impelled him to search further scenes of information on this favourite subject in distant parts of the globe. Having some relations in Virginia, he visited that country in 1712, where he remained seven years, industriously employing himself in collecting the various productions of the country, and occasionally transmitting seeds and specimens of plants to his correspondents in England, and particularly to Dr. William Sherard. On his return to England in 1719, he was encouraged by the alliance of several of the nobility, of Sir Hans Sloane, Dr. Sherard, and other naturalists, to return to America, with the professed design of describing, delineating, and painting the more curious objects of nature. He arrived in Carolina, which was selected as the place of his residence, in 1722; and having first examined the lower parts of the country, on occasional excursions from Charleston, he afterwards resided for some time, among the Indians in the mountainous regions at land and Fort Moore; and he also extended his researches through Georgia and Florida. Having spent nearly three years on the continent, he visited the Bahama islands; and residing in the Isle of Providence, he prosecuted his plan, and made various collections of fishes and submarine productions. After his return to England in 1726, being well received by his patrons, he acquired the art of etching; and, retiring to Hoxton, he devoted his time to the completion of his great work, which he published in numbers, of 20 plants each. The figures were etched by himself, from his own paintings; and the coloured copies were done under his own inspection. Although his attention was principally restricted to plants, yet most of his plates exhibit some subject of the animal kingdom. The first number appeared towards the close of the year 1730; and the fifth volume, consisting of 100 plates, was finished in 1732; the second in 1743; and the appendix, of 20 plates, in 1748. Of each number, a regular account, written by Dr. Cromwell Mortimer, secretary of the Royal Society, was laid before the society as it appeared, and printed in the Philosophical Transactions. The whole work is entitled, “The Natural History of Carolina, Florida, and the Bahama Islands, &c.,” and is comprised in two volumes, imperial folio. It contains descriptions of many curious and important articles of food, medicine, domestic economy, and ornamental culture; and has been allowed to be the most splendid work of its kind that had then been published in England, or even on the continent; that of Mad. Merian excepted. The principal defect of the work is the want of a separate delineation of all the parts of the flower, the nectaries and importune of which, however, the plate of botanical science at the time did not suggest. This work has been republished in 1754 and in 1771; and, to the last edition, a Linnaean index has been annexed. Soon after his second return from America, Mr. Catesby was elected a fellow of the Royal Society, and lived in social and friendly intercourse with many of the most respectable members of that body; being "greatly esteemed for his modesty, ingenuity, and upright behaviour." He was the author of a paper, printed in the 44th volume of the Philosophical Transactions, "On Birds
CAT

Birds of Passage," in which he proves the reality of their emigrating in search of proper food, from a variety of observations which he had an opportunity of making during his voyages across the Atlantic. He died in London in 1749, at the age of 79, leaving a widow and two children. His name has been perpetuated by Dr. Gronovius, in the plant called "Catharum." Pulcneyi's Hist. and Biog. Sketches of the Progress of Botany in England, vol. ii. ch. 44.

CATFALL, in Ship-Rigging, denotes the rope that forms the tackle for heaving up the anchor from the water's edge to the bow. It receives through the sheaves at the outer end of the cat-head (which see,) and through the sheaves of the cat-block alternately.

CATFINTHVOE, in Geography, a bay on the north-east coast of the island of Shetland; 10 miles N. of Lerwick.

CATHA, in Botany, Forlk. Arab. See Celastrus edulis, and poniforus.

CATHA, in Ancient Geography, a people of India, mentioned by Arrian, who says, that they feded the most hand- some man among them for their king; that they were valiant, and surpassed their neighbours with regard to their experience in the military art; and that their females had the custom of burning themselves after the death of their husbands. Strabo adds, that they determined, within two months after the birth of a child, whether his form was so perfect as to render him worthy of being preferred; other- wise they destroyed him. They are also said to have tinged their beards with various colours by way of ornament; and their marriages were the result of mutual choice on the part of the contracting parties. See CATHAIA.

CATHA, a town of India, mentioned by Steph. Byz.

CATHERETICS, in Surgery, καθαρισμόν, from καθαρίζω, to remove; corrosive remedies which destroy and eat off superficial flabby, by chemically decomposing its natural texture. Catharetics have been otherwise denominated fumigaciou medicines, q. d. flab-eaters; such as red precipitate of mercury, burnt alum, verdigris, preparations of vitrol, &c. &c. which differ only in degree from cauteries, or ephelatic applications, these latter being much more violent and destructive in their operation. Dr. Cullen observes that, as the operation of the different medicines of this class is not always the same, nor their different operations well explained, the propriety of the general term may be doubtful.

CATHAIA, or CATHA, in Geography, a country in the north-eastern part of Asia, about the precise situation of which authors are not agreed. Some have supposed that it was the country of the Sophites, and that it was called by Curtius Sophites; and they place it between the rivers Hydapse and Aecines, where lay the extensive and rich country of Porus, containing about 300 cities. Others lay that it lay beyond the Aecines and Hydaspes, on the borders of the territory of Porus, a confin of the Porus who was captured by Alexander. Arrian says, that Sangala, which probably lay between Lahore and Moulton, was a city of great strength and importance in the country of the Cathari. Diodorus Siculus calls the same people "Cateth," or "Katheri," and they may very easily be recognized under the name of "Catry," in Thvenet; that is, the "Kutry" tribe, or "Rajpoot." Thvenot, speaking of the people of Moulton, says, "there is a tribe of Gentiles (i. e. Gentoo, or Hindoo,) here, called Catry, or Rajpoot; and this is properly their country, from whence they spread all over the Indies. Diidorus Siculus marks them by the custom of their women burning themselves alive, on the funeral piles of their husbands. From Arrian we learn that the Cathai were confederated with the Malti and Ox- drace, that is, the people of Moulton and Outech, and which lay to the S.W. of the place where Alexander might be appr. to cross the Hydaspes (or Rave) in his way into India: Sangala, therefore, lies to the S.W. of Lahore; and as to its distance, Alexander reached it the third day after crossing the Hydaspes, and for these three marches it will be sufficient to allow 48 road miles or 76 geogra- phical miles in horizontal distance. Although no idea is given in Arrian, Diodorus, or Quintus Curtius, of the distance between Sangala and the Hydaspes; yet we may col- lect from Arrian's manner of speaking, that they were not near each other. Diodorus places the kingdom of Sophites and of Phleges between the Cathari and the Hydaspes; and hence we may infer that there was a considerable space be- tween them. See Sangala. In the name of this country the learned Bryant (Annu. Mythol. vol. iii. p. 552) perceive traces of the Cuthie migration. One of the most considerable colonies, (he says,) which went from Babylonia, was that of the Indi, or Sindi; who had been further distin- guished by the name of the Eastern Ethiopians. They settled between the Indus and Ganges; and one of their principal regions was Cathaia, rendered Cathaia by the Greeks. They traded in linen and other commodities, and carried on an ex- tensive commerce with the provinces to the south. A large body of them pulled inland towards the north, under the name of Sace, or Saccians; who ranged very high and got possession of Sogdiana, and the regions upon the Jaxartes. From thence they extended themselves easterly quite to the ocean. They were (says Bryant) of the Cuthie race, and represented as great archers; and their country was called Saciana and Cathia. The chief city was Saciana. Theie people got possession of the upper part of China, which they denominated Cathia; and this learned writer fuggests, that Japan was in some degree peopled by them.

CATHARA, a town of Asia, in Meopotamia, situated near the Tigris, according to Ptolemy.

CATHARCLIDORUS REGIO, a country placed by Pliny in the mountains which lie to the west of the Indi- ans.

CATHARI, in Ecclesiastical Writers, ancient Chriftians, who made profef$ of greater purity in discipline and sanctity of life than others. The appellation cathari was chief- ly given to the sect of Novatians. In after-times, how- ever, the same was also applied to several other sects, who pretended to extraordinary purity, and particularly to a fanatical sect, who came from Greece into Italy, and were first discovered in the Milanese about the middle of the 16th century. They were called in France, and other countries, Albigenses, Bonshommes, Paterini, and Publicans. See also Paulicians and Puritans.

These Cathari held many tenets of the Manichean heresies, blended with other opinions, common to them and the Vau- dois, against the doctrines, and hierarchy, and fabulous practices of the church of Rome. The Cathari, however, were entirely free from the Manichean errors, and would not have conformed to a public confession of the Roman Cath- olic doctrines, as the true Christian faith, even to their own lives. But the Cathari thought it lawful to dif- femble in these points, and had secret or inward doctrines. It appears that on their examination before the inquisi- torial commissioners at Toulouse, they scrupled to swear to their belief of opinions which they falsely prof$ed; yet, at the end of a written declaration of their faith, they in- fected words which in reality amounted to an oath. But though they adopted many incoherencies and absurdities among
among their articles of belief, the severe inquisition which their undertakers could not discover a single evidence of any criminal act, punishable by the law courts, that could be alleged against them. However, in 1479, the council of Lateran issued a canon, for communicating to the Cathari in the southern parts of France, as audacious heretics, who openly propagated their notions, and likewise all who afforded them protection or harbour in their houses or lands, or carried on traffic with them; declaring, that any persons who should die in that faith should have no benefit from any indulgence granted to them, nor from any oblation made for them, nor be allowed Christian burial. After all, it is certain that many, who held none of the errors of the Cathari, but only joined them in opposing the flagrant corruptions of the church of Rome, were, in the following century, confounded with them, and involved in the massacre, which, under the orders of Simon de Montfort, the general of the pope, deleted all the south of France with innocent blood. See the articles above cited, and particularly Ambiguitas.

Cathari, of Cathari, in Ancient Geography, a people of India. See Catharia.

Catharine of France, in Biography, the youngest child of Charles VI. and Isabella of Bavaria, was born in 1421, and in 1429, by the conditions of the treaty of Troyes, married to Henry V. king of England, then declared successor to the crown of France. In consequence of this marriage she became mother to Henry VI. crowned in his cradle king of both countries. After the death of Henry V. Catharine formed a connection with Sir Owen Tudor, a gentleman of Wales, of small fortune, but descended from the ancient princes of the country. By a clandestine marriage with him, she had two sons, the eldest of whom, Edward earl of Richmond, was father of Henry VII. king of England, the first of the line of Tudors. Catharine died in 1448, and was buried at Westminister. Hume's Hist. vol. iii. Moret.

Catharine of Arragon, the fourth daughter of Ferdinand and Isabella, king and queen of Castile and Arragon, was born in 1453, and married in 1501, in pursuance of a design that had been projected and negotiated for 7 years, to Arthur, prince of Wales, son of Henry VII. At this time the prince was nearly 16 years of age, and the infanta 19. In a few months after this marriage, the young prince fickened and died, much regretted by the nation. Henry, deists of continuing his alliance with Spain, and also unwilling to renounce Catharine's dowry, which was 200,000 ducats, obliged his second son Henry, whom he created prince of Wales, to be contracted to the infanta. The prince, who was then a youth of 12 years of age, refited this intersection to the utmost of his power; but the king was invincible, and the espousals were at length, by means of the pope's dispensation, contructed between the parties. Immediately after the accession of Henry VIII. to the crown, in 1509, the king began to deliberate on his former engagements. The previous marriage of Catharine with his brother, and the inequality of their years, were the chief objections urged against his espousing her; but, on the other hand, the advantages of her known virtue, modesty, and sweetness of disposition were insisted on; the affection which she bore to the king; the large dowry to which she was entitled as princes of Wales; the interest of cementing a close alliance with Spain; the necessity of finding some confederate to counterbalance the power of France; and the expediency of fulfilling the engagements of the late king, were considerations which determined the council, though contrary to the opinion of the primates, to give Henry their advice for celebrating the marriage. Notwithstanding the submissive defence paid to papal authority before the reformation, the principles of the people were in general adverse to a confederacy between such near relations, as Henry and his brother's widow; and the late king, though he had betrothed his son, at the age of 12 years, gave evident proofs of his intention to avail himself of a proper opportunity of nullifying the contract. He ordered the young prince, as soon as he came of age, to enter a protestation against the marriage; and on his death-bed, he charged him, as his last injunction, not to make an alliance with the inconstant, and expose himself to such insufferable objections. In the year 1527 several circumstances occurred which combined to excite scruples in the king's mind concerning the lawfulness of his marriage. The states of Calabria had opposed the emperor Charles's espousals with Mary, Henry's daughter, and, among other objections, had insisted on the legitimate birth of the young prince. And when the negociations were afterwards opened with France, and mention was made of betrothing her to Francis, or the duke of Orleans, the bishop of Trabou, the French ambassador, revived the same objections. These events naturally raised some doubts in Henry's mind, and they concurred, with other causses, which tended much to increase his remorse, and to render his conscience more scrupulous. The queen was fix years older than the king; and the decay of her beauty, together with particular infirmities and defects, had contributed, notwithstanding her blameless character and deportment, to render her person unacceptable to him. Though she had borne him several children, they all died in early infancy; except one daughter, Mary, afterwards queen of England; and he was the more struck with this misfortune, because the curse of being childless is the very threatening, contained in the Mosaic law, against him who espouses his brother's widow. The succession too of the crown was a consideration that occurred to every one, whenever the lawfulness of Henry's marriage was called in question; and it was apprehended, that if doubts of Mary's legitimacy concurred with the weakness of her sex, the king of Scots, the next heir, would advance his pretensions, and might throw the kingdom into confusion. Besides, Anne Boleyn had lately appeared at court, as maid of honour to the queen, and had acquired an entire absence over her affections. The king was thus impelled, both by his private passions, and by motives of public interest, to seek the dissolution of his inauspicious, and, as it was deemed, unlawful marriage with Catharine. The archbishop of Canterbury was consulted, and he was required to advise with his brethren. All the prelates of England, except Fisher, bishop of Rochester, unanimously declared, under their hands and seals, that they deemed the king's marriage unlawful. Wolsey also fortified the king's scruples; partly with a view of promoting a total breach with the emperor, Catharine's nephew; partly disfours of connecting the king more closely with Francis, by marrying him with the duchesses of Alençon, sister to that monarch; and perhaps too somewhat disgraced with the queen herself, who had reproved him for certain freedoms, unbecoming his character and station. Accordingly Henry determined to apply to the pope, Clement VII. for a divorce. He founded his application, not on any general doubt concerning the papal power to permit marriage in the nearer degrees of consanguinity, but on particular grounds of inutility in the bull, which Julius had granted for this particular marriage. It had been made in the preamble, that the bull had been granted upon Henry's application; though, it was known, that at that time he was under 12 years of age. It was also affirmed, as another motive for the bull, that the marriage was requisite in order to preserve peace between the two crowns; though it is certain, that no ground or appearance of quarrel then subsisted between them. That
These late premises in Julins's bull seemed to afford Clement a sufficient reason or pretence for annulling it, and granting Henry a dispensation for a second marriage. Clement, though at first disposed to favour Henry's application, and though he actually concerted measures for its successful issue, was overawed and embarrassed in his proceedings by the interference of the emperor, Charles V, Catharine's nephew; and the negotiation was protracted to such a length as to tire Henry's patience, and to induce him to adopt other measures for accelerating the accomplishment of his wishes.

The pope, imported by the English ministers, put into their hands a commission to Wolsey, as legate, in conjunction with the archbishop of Canterbury, or any other English prelate, to examine the validity of the king's marriage, and of Julius's dispensation. He also granted them a provisional dispensation for the king's marriage with any other person, and promised to issue a declaral bull, annulling the marriage with Catharine; but he enjoined secrecy, and conjured them not to publish these papers, or to make any farther use of them, till his affairs with regard to the emperor were in such a train as to secure his liberty and independence. After considerable hesitation and delay, the legates, Campeggio and Wolsey, to whom the pope had granted a new commission for the trial of the king's marriage, opened their court in London, May 31st, 1729, and cited the king and queen to appear before it. They both professed themselves, and the king answered to his name, when called; but the queen, instead of answering to her's, rote from her seat, and throwing herself at the king's feet, made a very pathetic harangue, which her virtue, her dignity, and her misfortunes rendered the more affecting. She concluded with declaring, that she would not submit her cause to be tried by a court, whose de
dependence on her enemies was too visible, even to allow her any hopes of obtaining from them an equitable or impartial decision. She then rose, and making the king a low reverence, she departed from the court, and never would again appear in it.

After her departure, the king did her the justice to acknowledge, that she had ever been a dutiful and affectionate wife, and that the whole tenor of her behaviour had been conformable to the strictest rules of probity and honour. He only inflected on his own favours with regard to the lawfulness of their marriage; and he explained the origin, the progres,

...
the marriage with queen Anne was established and confirmed. 

Catharine had removed from Dunblane to Kilmarnock castle in the county of Huntingdon, where she was forced with a lingering illness, which at last brought her to her grave. She died on the 6th of January 1556, in the 57th year of her age. A little before she expired, she wrote a very tender letter to the king, in which she addressed him as "her most dear lord, king, and husband," and insinuated upon him counsels of moral and religious prudence; concluding with these words: "I make this vow, that many eyes desire you above all things." The king is said to have shed tears on occasion of receiving this last tender proof of Catharine's affection. In her retreat she is said to have composed some devotional treatises. 

Catharine De Medicis, queen of France, was the only daughter of Lorezo de Medici, duke of Umani, and of Magdalen de la Tour. She was born at Florence in 1544, and by the influence of her uncle, pope Clement VII., was married in 1554 to Henry, duke of Orleans, son of Francis I. 

She contributed, in a high degree, by her personal and mental accomplishments, to adorn the splendid court of her father-in-law, and by her comeliness and discrimination contrived to ingratiate herself with persons of opposite characters and interests. At the death of Francis I., her husband succeeded to the crown under the title of Henry II., and she became queen. Although she had been barren for the first ten years after her marriage, she had afterwards ten children; three of her sons being successively kings of France, and one daughter queen of Navarre. During Henry's life, she devoted herself to the education of her children; and in this employment she gained that ascendancy over them, which enabled her for a long time to maintain supreme authority. Upon the death of her husband, in 1559, her son, Francis II., succeeded to the throne, at the age of 16 years; and during his reign, though she was obliged to concur in some degree with the violent and perfecuting measures of the family of the Guises, they were not irreconcilable to her inclinations, and she manifested her desire of more moderate proceedings, by raising to the pontiff of chancellor, the virtuous Michael de l'Hôpital. In 1562, Henry II. was succeeded by his brother, Charles IX., in his eleventh year. 

Catharine still maintained her authority, and, in order to counteract the power of the Guises, inclined to the party of the king of Navarre and the associated princes. Upon the death of the duke of Guise in 1562, the two contending parties, that had occasioned a civil war, were reconciled; and Catharine, puffed up with pride, began to display in their full extent her difflamatory politics. Whilst she courted the catholics, she laid plots for the total destruction of the Huguenots, the consequence of which was the renewal of civil war; and she pursued such a course of difflamation and treachery, in her attempts to destroy that party which could not be subdued by force of arms, and received such abundance from her execrable son, whom she had initiated in every art of dissimulation, as to prepare the way for that massacre on St. Bartholomew's day, 1572, which has doomed to infamy the name of Catharine de Medecis, one of its chief contrivers. Instead of this compounding the troubles of France, every thing remained in a tumultuous state during the remainder of this reign, which was terminated by the death of Charles in 1574. Upon this event Catharine was declared regent, till the return of her next son, Henry III., from Poland, of which kingdom he had been elected the sovereign. In this high official character, she exerted herself with wisdom and vigour, in preventing those disturbances which the collision of existing parties had a tendency to produce, and thus delivered the kingdom to her son in a condition, which, with prudence and virtue, on his part might have augmented a prosperous reign. But he had derived his principles from her instruction, and his conduct was formed on her example of infidelity and dissimulation. His own character was such, that it warranted no confidence in any measures of which she had the direction. The party of the Guises revived; the league was formed; war was renewed with the protestants, and during the prevalence of public disorders, aggravated by Henry's attachment to his minions on the one hand, and the popularity of the Guises on the other, Catharine lost her authority, and she lived only to lament the misgovernment of her son, as the result of the inhuman policy, which she had laboured to inculcate. Soon after the alienation of the duke of Guise, from the guilt and reproach of which she endeavoured to exculpate herself with strong excrecences, Catharine, having incurred the detestation of all parties, died in January 1589, in her 50th year. Under a dispensation of having been concerned in the duke's murder, notwithstanding all her protestations, the Pantins threatened to throw her body, if it was brought into their city for interment, into the river or common sewer. On her death-bed she is said to have given excellent advice to her son; though little conformable to her former precepts and example. 

"Catharine de Medicis," as one of her biographers eloquently chose to account of her, "is said to have been puffed up, in a degree superior to any woman of her time, of all the arts of simulation and allurement, of all the graces of her sex, and the splendid qualities of her station; she was affable, courteous, magnificent, and a liberal encourager of learning and the polite arts. She was likewise endowed with extraordinary courage and preference of mind, strong judgment, and great fertility in expediency. But she had the common fault of her country, of aiming at excessive refinement of policy; and by alternately caressing and hidng with every party, she in the end lost the confidence of all. With respect to her moral qualities, there is nothing diabolical in the human character with which she has not been charged by her enemies; and even her friends are obliged to make large concessions on this head. Scarcely preserving the decorum of her sex, she was loose and voluptuous in her own conduct, and was continually attended by a train of beauties, whose compliant charms she employed in debauching those minds which she could not gain by the common allurements of interest. Nearly indifferent to modes of religion, she was much addicted to superstitious of the darkest kind; and believed in and employed the delusive practices of magic and judicial astrology. The depth of her dissimulation, and bloody train of her perilous policy, have sufficiently been shown in the fletch of her actions; and many inferences might be brought of the savage pleasure or indifference with which she viewed the cruelties she had dictated. Perhaps the heaviest charge against her is the detestable principles in which she brought up her children, whom she early immured to blood and perfidy, while she weakened their minds by debauchery, that she might the longer maintain her power over them. Accordingly, except Francis, who can fearlessly be said to have displayed any character, her other sons, Charles, Henry, and the duke of Alençon, were compounds of every thing abominable and deplorable. To conclude, the historian Davila, who was peculiarly attached to her service, and favoured by her, terminates a copious eulogy on her personal and mental qualifications, with confessing that she was totally void of faith, and more indifferent to the shedding of human blood than became a woman. Moreri. Nouv. Dict. Hist. Mod. Un. Hist. vol. xx. p. 373; &c. vol. xxi. p. 1. 45. Gen. Blig. 

Catha-
CATHARINE.

Catharine I., empress of Russia, was of obscure origin, being a natural daughter of a country girl at Ringen, a small village upon the lake of Viretche, near Dorpi, in Livonia, and where she was born, according to her own account, on the 6th of April, 1689, but according to other more probable statements, in the year 1685. Count Rofen, a lieutenant-colonel in the Swedish service, and proprietor of the village of Ringen, supported, according to the custom of the country, both the mother and child; and the reason was supposed to be her father. At the age of three years she lost her mother; and, Rofen dying about the same time, she was left in a condition to direct, that she was received by the chief of the parish into his house. Soon afterwards Guick, a Lutheran minister of Masenburgh took her under his protection and employed her in attending his children. In 1701, she married a dignitary of the Swedish garrison of Masenburgh, who, as some few, lived with her eight days after their marriage; but others have alleged, that on the morning of the wedding her husband was sent with a detachment for Riga, so that the marriage was never consummated. At the time, however, when Masenburgh surrendered to the Russians, the dignitary was absent, and Catharine left him as more. On the capture of this place general Bauer saw her among the prisoners, and being smitten with her beauty, took her to his house, where she superseded his domestic affairs, and was supposed to be his mistress. In a little while she passed into the family of Prince Mentchikof, who was no less her admirer than the general, and she lived with him till the year 1704; when she became the mistress of Peter the Great, and gained such an interest in his affections, by her unremitting attention, by the gentleness of her disposition, and by the vivacity of her temper, that the emperor, who was thusfoothed in his occasional intervals of gloom, voluptuous, and even madness, privately married her in 1710 or 1711. From this time she became his constant companion in his journeys into foreign countries, and in all his military expeditions. In 1711, she attended him in his campaign against the Turks; and the peace of Pruth, which released the Russian army from certain destruction, has been ascribed to her powerful interposition. The occasion was this: when the emperor had led his troops into a very dangerous situation, he formed the desperate resolution of cutting his way through the Turkish army in the night; and retiring to his tent in an agony of despair, he gave positive orders that no one should be admitted, under pain of death. In this important juncture, the principal officers, and the vice-chancellor Shafiroot, assembled in the presence of Catharine, and drew up certain preliminaries for the purpose of obtaining a truce from the grand vizir. Pliant petitioners were immediately dispatched, without the knowledge of Peter, to the vizir, and a peace was obtained on more reasonable conditions than could have been expected. With these conditions Catharine, notwithstanding the orders issued by Peter, entered his tent, and obtained his signature. By this conduct she gained great popularity, and the emperor himself specified her behaviour at Pruth, as one of the reasons which induced him to crown her publicly at Moscowa with his own hand. In 1712, her marriage, which had taken place secretly in the preceding year at Lawerof in Poland, was publicly solemnized at Peterburgh. Catharine maintained her influence undiminished until a short time before the death of Peter, when an event occurred, which might have occasioned a total rupture, if death had not intervened. The emperor, probably not unapprized of some of her amours, suspected that she had an illicit connection with Mons, her first chamberlain. Having concerted measures for making a discovery, he surprised Catharine in an arbour of the garden with her favourite; while his father, madame Balke, who was first lady of the bed-chamber, was in company with a page, upon the watch without the arbour. Peter bruck Catharine with a cane, and then retired without uttering a single word. Soon after Mons and his follower were taken into custody. The former was examined, on a charge of bribery, in the presence of major-general Utchakov, and being threatened with the torture, he confessed the corruption had to his charge; and he was beheaded. His father received five strokes of the knout, and was banished too. Soon after, two of her sons, who were chamberlains, were also detached, and sent as common soldiers among the Russian troops, in Rossua. On the day subsequent to the execution of the sentence, Peter conveyed Catharine in a room covered with the green stuff, to which was nailed the head of Mons, and the corpul, without changing colour at this godful object, exclaimed, "What a pity it is, that there is so much corruption among courtiers!" This event happened in the year 1724, when she had been publicly crowned at Moscowa, and had received the imperial insignia from the czar's own hands. As it was followed by his death, and Catharine recalled madame Balke, she was suspected of shortening the days of her husband by poison. But, notwithstanding the critical situation of Catharine at the time of his decease, and her subsequent elevation, this charge is destitute of proof; for the nature of the disorder with which Peter had been long afflicted, and the peculiar symptoms of his last illness, sufficiently account for his death, without recurring to poison. As it had been decreed in 1722, that the reigning sovereign should have the power of appointing his successor, Peter ought to have made provision accordingly; but his last illness, and the circumstances of excruciating torture attending it, prevented the performance of this necessary duty. Amidst the cabals which succeeded his death, Catharine, by means of her friends, claimed the throne in right of her coronation and inauguration at Moscowa; and these recent acts on the part of Peter were interpreted by them as a sufficient proof of his intentions. The art of Catharine, and the activity of Mentchikof, ultimately prevailed against the party, which supported the claims of Peter Alexowitz, the czar's grandson; and, notwithstanding her mean and base origin, she was established on the throne of the czars of Russia, to the prejudice of its linear heirs. The empress, who had neither inclination nor abilities to direct the helm of government, placed implicit confidence in Mentchikof, the original author of her good fortune, and the sole influent of her elevation to the throne; and the reign of Catharine was, in fact, the reign of this confidential favourite. To her humanity and compassion, which were distinguishing features in her character, may be imputed the recall of many exiles from Siberia, as well as the demolition of the wheels and gibbets on which the bodies of criminals had been exposed during the severe reign of her husband. She generally professed in the course of her short administration the plans of Peter for the improvement of his dominions; and in 1725 completed the institution of an order of knighthood for the reward of those who had signalized themselves in the service of their country. See ALEXANDER NEVSKY. Her life, during her short reign, was very irregular; averse from business, she would frequently pass whole nights in the open air, and indulged to excess in the use of Todays's wine and strong liquors. These irregularities, joined to a career and a droop, hastened her end; and she died on the 17th of May, 1727, a little more than two years after her accession to the throne, and in the 39th year of her age. The personal attractions and mental abilities of this empress have been much exaggerated.
aggravated by her pugnacity. In her person she was under the middle size, and in her youth delicate and well-formed, but as she advanced in years inclined to corpulency. She had a fair complexion, dark eyes, and light hair, which she was accustomed to dye black. She could neither read nor write. She is said, however, to have maintained the pomp of majesty united with an air of ease and grandeur; and Peter himself frequently expressed his admiration at the propriety with which she occupied her high station, without forgetting that she was not born to that dignity. Her culpable qualities, after all the abatements of panegyric, were generally acknowledged. She was humane in an exemplary degree, good-natured and obliging in her temper and manners, and duly mindful of the grand offices which had been performed for her in her low condition. She avoided herself of her ascendancy over Peter, in softening the asperity of his passions and restraining their violence; insomuch that a word from her, in behalf of a wretch, who was about to be sacrificed to his anger, would instantaneously disarm him; and if he determined to indulge his resentment, he would give orders for the execution when she was absent, for fear she should plead for the victim. Upon the whole she merited the honourable title, bellowed upon her by the celebrated Metternich, of "the Mediatrix between the monarch and his subjects." Coxe's Travels in Russia, vol. ii. ch. ii.

CATHERINE II. empress of Russia, originally denominated Sophia Augusta Frederica, was the daughter of Christian Augustus, prince of Anhalt-Zerbit-Dornburg, and of the princess of Holstein, a woman eminent for talents and beauty. She was born at Stettin in Prussian Pomerania, May 2, 1729, educated by her mother, and in early life distinguished by her good humour, intelligence, and spirit. During the first 15 years of her life, she lived alternately in Stettin and in Dornburg, or Zerbit, occasionally accompanying her mother in several little journeys, which much contributed to the forming of her mind and manners; and at this period, she devoted her time to reading, reflection, learning, and employment. About the beginning of the year 1744, she visited Berlin, and continued her journey to Russia. Her access to the court of Peterburg was rendered easy by the marriage which had been projected between the empress Elizabeth, and her mother's brother, the prince of Holstein-Lutin, but which the premature death of the latter had prevented; and her mother, fully apprized of the tender remembrance preferred by Elizabeth for her brother, resolved to avail herself of it for securing a throne to her daughter. Accordingly, Elizabeth received the young princes with a partial regard; and determined to accomplish a matrimonial union between her nephew, the grand-duke, afterwards Peter III. and Sophia; who, though instructed, under the tuition of her mother, in the Lutheran doctrines, embraced the religion of the Greek church, and on this occasion changed her name to that of Cartharine Alexienna. As soon as the choice of Elizabeth had been announced to the council and to the foreign ministers, the day was fixed for the nuptials, and preparations were arranged for its celebration in a manner worthy of the heir of the throne of Russia. A circumstance, however, occurred, which retarded this wished-for event. The grand-duke was feizd with the small pox, which, being of a very malignant nature, endangered his life; and to much deformed the comeliness of his face, as to render it for a time disfigured, and almost hideous. This metamorphosis produced a horror in the mind of the young princes at the first interview, which, however, she had sufficient art to disguise, and which proved no impediment in the way of their speedy union. The empress contemplated this alliance with pleasure; the princes of Zerbit was painfully delicious to see it concluded; and the sensations of ambition acting more powerfully on the heart of Catherine than the will of her mother, and that of the empress, did not allow her a moment's reflection. In 1745 the nuptials were accordingly solemnized; but, notwithstanding the attachment which was to unit the grand-duke and the princes from the first moment of their meeting, their love was fated to be of no long duration; nevertheless, they lived for some time with an apparently good understanding, which Catherine supported as long as she conceived it to be necessary. Their dispositions and their accomplishments, however, were very different: whilst Peter blushed at the superiorities of his wife, she often blushed at seeing him so little worthy of her; and, incapable of making each other happy, their mutual dislike was soon visible to those who frequented the court; it every day increased, and became more and more apparent. Whilst the enemies of Peter contrived to excite prejudices against him in the mind of the empress, and he was led by various artifices on their part, and by the jealousy manifested by Elizabeth, to retire from court, and to indulge himself in the vices of drinking and gaming, Catherine was busily employed in gaining partisans from the most powerful perfons of the court. Her violent disposition to pleasure was controlld by views of ambition; and if she did not succeed so far as to captivate the friendship of the empress, she at least extorted her esteem. The princes of Zerbit, at the same time, abused the confidence reposing in her by the empress; and taking advantage of the influence she had acquired, she mixed in the intrigues of the courtiers, made herself the dispencer of imperial favours, and preyed into the secrets of the most important concerns. Her arrogance disfigured the favourites, and her curiosity was vexations to the ministers. At length they united together to rout the jealousy of the empress, and by degrees induced her not only to withdraw her misplaced confidence, but to order those that the princes should quit the empire. Catherine herself regretted her mother's departure; but the hope of the throne which had fortified her against other misfortunes, supported her under this; and love soon became a source of confolations, which heightened those which pride administered. In the number of those who formed the parties of the grand duke, Soltikof, the prince's chamberlain, was particularly distinguished by his taste for the arts, as well as by the graces of his person; and vanity, perhaps, more than love, led him to conceive the nefarious design of captivating the heart of Catherine. His continued attentions at length produced effect; he became master of the affections of the grand duchess; and the pallion which was at first regarded on his part, grew up into a real attachment; their mutual partiality, avowed to each other, became too unguarded to be concealed from the courtiers, who envied the preference that wounded their pride. They therefore determined to communicate to the empress their fulpicion of an amour between the chamberlain and the grand duchess. Elizabeth, though of an amorous disposition herself, declared, in the first bursts of her indignation, that Soltikof should pay for his temerity by an exile into Siberia: the chamberlain contrived to avoid the danger that menaced him by complaining to the grand duke of the calumnies that had been so audaciously spread; and by requesting that, in order to furnish no farther pretence to the jealousy of his enemies, and to calm the mind of the empress, he might obtain permission to retire to Moscow. The credulous prince, thus deluded, ordered him to remain in his station, and in an audience with the empress, vindicated the innocence of Soltikof, with so much vehemence and by such a variety of arguments, that Elizabeth herself was inclined to ascribe to envy the injurious
CATHERINE.

rious reports that had been circulated against him. Catharine also pleaded his case, and that of her own honour, with so much eloquence, that her victory over the empress was more complete than that of the grand duke. The interference between Soltikof and the grand-duchess was renewed and continued; and Catharine acquired boldness from her successes, and from the example of Elizabeth, whose manners were becoming daily more and more corrupt, and who, engaging from day to day in some new follies, seemed to afford some excuse for her passion. In 1755, when Soltikof thought himself perfectly secure, the grand chancellor Bethucchef contrived his ruin, and prevailed with the empress to appoint him minister pleni potentiary from the court of Russia to Hamburg, where he was to reside. He also counteracted the influence which the grand duchess was induced to employ for his recall; and her ambition imposed silence on her. For some time they corresponded with each other; but in 1755 the young count Stanilus Poniatowski suppressed Soltikof in the attachment of Catharine, and in the following year they declared to one another their mutual affection, and confided on the means of inducing their inclinations without restraint. The empress Elizabeth was soon informed of this new intrigue of her adoptive niece, and the ordered Poniatowski to quit Russia without delay. The chancellor Bethucchef, in the mean while, was gradually strengthening his party with that of the grand duchess; and in 1756 he engaged count De Bruhl, prime minister of the king of Poland, to procure the nomination of Poniatowski as minister pleni potentiary of the republic and king of Poland to the empress Catharine. This measure having succeeded, the pleni potentiary arrived, and Catharine made so little secret of the intimacy fulfilling between them, that public report was very loud to his prejudice. The grand duke was the only man at court who knew nothing of what was passing. His time was wholly occupied in attending the ufeles manœuvres and painful exercices of his soldiers, and when these were finished, in indulging the exccees of the table, and boasting, in the delirium of intemperance, that he would one day be conqueror of the north, and the rival of the Persian hero. At length, however, the jealousy of Peter was alarmed; and no time was lost in follicrizing the usurps of the husband into proofs of the inidelity of the wife, in her love for the Polander, and the criminal correspondence they mutually entertained. The prince was overwhelmed with grief and conftration; forbade the grand duchess to be seen with Poniatowski; and hastening to the empress, besought her to avenge the affront he had received; informing her, at the same time, that the grand chancellor had not only favoured the misconduct of the grand duchess, but had repeatedly betrayed the confidence of his imperial aunt. Elizabeth, moved at the forrows of her nephew, and incited at the treachery of Bethucchef, gave orders to arrest him; and in the sequel he was deprived of his place, tried, pronounced guilty of high treason, and sentenced to death, which sentence was afterwards commuted for banishment to an exile 120 webs beyond Mol- cow. Catharine, apprehending everything from the resentment of her husband, and forsaken by her courtiers, was reduced to a very diffreited and almost hopeless situation. In the year 1761, the health of Elizabeth began vividly to decline, and the necessity of repolf, added to her natural in- dolence, made her more negligent than ever of the affairs of government. Woroizof was grand chancellor, and on him depended the conduct of the public business; and the empress, hardly able to pursue her ordinary dilifications, amused herself with the idle tales that were brought her of the amorous revels of her nephew Peter with one of the daughters of Woroizof. Catharine renewed his efforts for a reconciliation with the empress; but she would listen to no accommodation, except on the most mortifying conditions. It was afterwards proposed to her by a message from Elizabeth, to confess her guilt, and to submit to the divorce of her husband and the empress. From this moment Catharine fummoned up all her pride. She purposely avoided appearing at court, kept close to her apartments, and asked leave of the empress to retire into Germany: a permission which she knew would not be granted; because, well apprised of the extreme fondness of Elizabeth for the young Paul Petrovitch, she had no reason to apprehend that the princes would consent to the departure of the mother of a child, who would thereby be exposed to the hazard of being hereafter declared illegitimate. The tratagem succeeded, and an accommodation soon ensued. At the very moment when she was thought on the brink of irremediate disgrace, to the great astonishment of the court, she made her appearance at the theatre, by the side of the empress, who carefully drew upon her the notice of the spectators by the particularity of her attentions. The ambition of Catharine was routed by Elizabeth’s approaching dissoluition, and she felt the necessity of conciliating the popular favour by an exterior of piety, which, by those who bel knew her, was suppos’d not to proceed from her heart. However, she was punctual in frequenting the churches at the flated times of public devotion; but more particularly at the prayers that were now daily put up for impairing the re-establishment of the health of the empress. She employed herself also for several days in the form of the procession following the emperor as well as that of the oath to be taken by the troops. At length, on Christmas day, 1761, the empress Elizabeth expired; and Peter III. ascended the throne. In the beginning of his reign his conduct was not only blame- less, but laudable; he appeared to be suddenly transformed into a different being; as grand duke, he had been inconsistent, impetuous, and wild; but as Peter III. he appeared equitable, patient, and enlightened. He was kind to all who had been attached to the late empress; he continued in their posts all the great officers of state; and he pardoned all his enemies. The grand duchesses received from him the most flattering flulations and marks of the greatest confidence. He seemed to forget the wrongs he had suffered in the elegancies of her mind, and the force of her genius. He passed a great part of the day in her apartments, dif- coursed with her in a free and friendly manner, and consulted her on all affairs of delicacy and importance. The courtiers were surprized, and congratulated Catharine on her happy lot. Catharine was almost the only person who was not deceived. She knew that her husband was not capable of govern- ing by himself, and she was too well acquainted with his character to mistake that for benevolence, which was only weakness. The first measures of his government were popu- lar and auspicious. Unsteady and capricious in his temper, his private and public conduct was variable and fluctuating, and indicated that levity of disposition which was the predominant feature in his character. His un- friendly attachment to the king of Prussia gave offence to his subjects, led him to flight all the foreign ministers, excepting the Prussian envoy Mr. Keith, the British ambassador, and occasioned alterations in his plan of conduct and government, which created a great number of enemies, and evinced, that if he had sometimes good intentions, he was deficient in judgment, and especially in that energy of character so ne- cessary for the ruler of a nation. Together with the wifef plans, he often adopted such as were uflefs, and others that were even dangerous. The defe of making improvements induced him impatiently to hazard premature reformation. By converting the wilif politicians of the church
CATHARINE.

church into domains of the crown, and assigning to the clergy yearly films, and by other measures of an ecclesiastical nature, he invited a numerous class of men, whose influence was very extensive. His enemies forged a report from one end of the empire to the other, that he had only gone to embrace the Greek communion in order to exalt himself for filling the throne; but that he was still a Lutheran at heart, of which he was every day giving fresh proofs, by showing a profound contempt for the rites, the ceremonies, and the religion of the Russians. It was abundantly proved, that he never spake but with disdain of the Russian empire, and never mentioned the Germans but with contempt. All these reports, circulated with artifice, soon ascended from the prince those hearts which the full measures of his reign had attached to him. To the army, also, he gave great offence, by manifesting a decided preference of the German soldiers to the Russian troops, and by a variety of other measures, which were subjects of general animosity. But still, he disapproved all parties by his declared intent of taking by force of arms the duchy of Schleswick, on which the kings of Denmark had seized to the prejudice of the dukes of Holstein.

Many of his measures were adopted in direct opposition to the court of the king of Prussia, who was well acquainted with the character of Peter and that of Catharine, and who had long foreseen that event which afterwards happened. Moreover, Peter indifferently refused his former habits; frequently palling the whole day in drinking and smoking amidst a company of base courtiers, most of whom were eagerly seeking his ruin, and perfidiously applauding his fantastical humour, and his most dangerous innovations.

His behaviour to the empress was no less inconsistent than other parts of his conduct. Whilst he was paying homage to the superiority of her mind, he would allow to escape from him some intimations of the indignation which had taken possession of his breast on account of the wrongs he had suffered. In the most sacred and pompous ceremonies of the Russian church, in, e.g., as the benediction of the waters (see Construction), he caused her to appear adorned with all the marks of imperial dignity, while he contented himself with following her train in the rank of a simple colonel, as if he intended to show to his people, that she was born to govern, and that it was his province to obey. At court he would often have her to execute the whole of the representation; while he, dressed in the uniform of his regiment, respectfully came and presented to her his officers, whom he called his comrades. But this apparent honour conferred on the empress was of no long duration. As soon as he thought himself well settled on the throne, he no longer concealed his indifference, and he sometimes manifested it in the most humiliating manner.

At the time of the celebration of the peace with the king of Prussia, Peter, who, during the exhibition of the works, was seated by the side of Catharine, on facing the counts Woronzof, his mistress, paiz by, called to her, and made her sit down by his side; upon which Catharine immediately retired, without any endeavours to detain her being vouchsafed on the part of her husband. Other instances of mortification occurred, which Catharine felt to such a degree, that her tears interfered the spectators, while the hauteur of Peter excited their indignation. It was by such treatment, however, that the hopes of the empress revived. She opposed to his flights and rovings great circumspection and regularity of address; and she gained the hearts, which the emperor was losing. Instructed from her infancy in the arts of dissimulation, she affected, in the sight of the multitude, sentiments very foreign to her mind. The pupils of the philosophers affirmed the air of a bigot; the fecondly replied every day to the churches of Peterburg, praying with all the semblance of a sincere and fervent devotion, punctual in the most superfluous practices of the Greek religion, according the poor with beneficence, and treating the pages with reverence; who did not fail afterwards to prove her prof from hour to hour. In the apartments of the prince the mode of life pursued by this married pair was not very distant from that of their public conduct.

While Peter III. was shut up with the counts Woronzof, Mr. Keith, and Prussian officers, and others of his favourites; while he was, to far hence from his rank as to be familiar with buffoons, and to make them at times sit at table with him; the empress kept her court with a mixture of dignity and affability which charmed all who approached her; and she particularly directed her attention to those persons, who, by their reputation, courage, or intrigues, might serve her cause. By such acts of immodesty as we have now related, the ex-Emperor did not only the greater number of the Russians, but almost all the agents from foreign courts. Having concluded a treaty with the king of Prussia, Peter III. caused the peace to be declared with the greatest magnificence; and in the midst of their festivities, he summoned a particular attention to the counts Woronzof, who was always painting a picture of accordance over him, and who found means to induce the ex-Emperor, by flattering at one time, by flattering at another, and sometimes by a degree of daring insolence which led her even to boast him: to renew the promise he had made, while he was only a grand duke, that he would marry her, and place her in the room of Catharine on the throne of Russia. Proud of this hope, she had the imprudence to boast of it; and this imprudence brought on her ruin. Peter III. no less infernal than the counts, did not disguise his intention to repulse Catharine; and to declare the illegitimacy of her son, Paul Petrovitch. He determined, however, to cover this act of delupinism with an appearance of jealouy; fondly imagining, that when he published to the world the proofs of the imbecility of Catharine, his conduct would gain the approbation of all his subjects and the retreat of Europe. Hopeless of an heir, on account of a certain imbecility which was attributed to him, though he lived openly with the counts Woronzof, held frequent audiences with a handsome page-dancer of Peterburg, and had various companions of great fortune; he caused a regular project for supplying the place of Paul Petrovitch. He determined to adopt prince Ivan, who had been deposed by Elizabeth, to declare him his successor, and to unite him in marriage with the young princess of Holstein-Beck, who was then at St. Peterburgh, and whom he cherished as his daughter. But such were the indications of the ex-Emperor, that they revived from day to day the hopes of Catharine; and the designs he had formed against her, for part of which was well known, emboldened her to run all hazards in order to prevent them. Dismayed for Peterhof, and lodged in one of the apartments of the palace that was most retired, she bade for days in meditating the project for precipitating her husband from the throne, and her arrival in the company of a peculiar intimate, whom she had made the most trusted of the conspirators. Gregory Orlof, to that was his name, poiffled neither the advantages of birth nor those of education; but he had received from nature what are often found more useful, courage and beauty. He had a soul in the artillery, while his two brothers were only common soldiers in the infantry of guards; he had also been elected by Count Peter Salavat, grand-master of the artillery, as aide-de-camp; and for his merit he had one of the most illustrious and the handsomest women of the court, the princess Kirakin, who preferred him to his general. The general, however, having furnished them together, threatened to exert his merit for procuring the banishment of Orlof to Siberia. The story of this adventure reached the retreat
in which Catherine was compelled to do penance; and her
capability to feel him being excelled, was gratified by the
con−
currence of Catherine Ivanova, the most ingenuous of con−
fidantes, and the last terpomys of daemons. After repeated
interviews, the empress unveiled to Orlof, of whose hold−
nels and discretion she had previously assured herself, the am−
bitious designs which she had been projecting. Orlof com−
piled with her wishes; entered into a conspiracy with her,
and engaged his brothers, together with several officers,
by whose instrumentality he gained to his party some com−
panies of guards; but without imparting to them his real design.
Catherine was only grand-duches when her connection with
Orlof commenced; and her correspondence with him, as
well as with other officers, was carried on with no less act
than fæces. Some of the courtiers also participated her favours;
but not having sufficient confidence in their tithe to,
the more made them her friends, without dictating to them
her secret. Lieutenant-general Velibons was one of those
whom she particularly distinguished. When she was seated
on the throne, she attached to her interest the remainder of
those conspirators, at the head of whom Doloch and the
Shuvalof had inactively appeared, and of whom the het−
man Kurin Razumofsky, the prince Volkonok, nephew of
the exiled Doloch, and major-general of the guards, and
Count Panin, were the most powerful supporters. She had
also been able to form another conspiracy, contrived by the
young princes Dalhoff, who, at the early age of 16 years,
was singularly active and impetuous. At the sacrifice of
these several actions went without the knowledge of
each other; and Catherine, who directed and animated them
all, seemed to have no share in the plot. Princes Dalhoff
had in her train an adventurous Podmonte, named Odart,
whom penury and the hopes of making his fortune had
brought to St. Petersburg; and by her interest, the empress,
for the sake of him the title of private secretary; in consequence of which appointment, Odart be−
came one of her confidents in her ambitious designs. The
princes Dalhoff and Odart contrived to engage Razu−
mofsky, count Panin, prince Volkonok, and the archbishop
of Novgorod in their party. Gleb, whom the czar had
raised from the lowest forms of chicane to the important
place of procurer-general to the senate, joined this band of
conspirators. The aim of all those who severally contrived
against Peter III. was to dethrone him; but they had dif−
ferent sentiments with regard to the proper mode of re−
commencing their purpose. Panin, Razumofsky, and Orlof
thought it best to begin by feizing his person at Peterhof,
the imperial palace, intuate on the shore of the Cronstadt
gulf, at the conclusion of one of those orgies which could
not fail to take place on his coming thither to celebrate the
anniversary of St. Peter and St. Paul. One of the conspir−
ators, lieutenant Patlick, the most fervent of his country−
men, lured on affixing him with a pegard in the
mild of his court, and actually lay in wait for this purpose;
but he was disappointed in his design. The conspirators,
who differed as to the means of destroying the czar, were
still his agreed on the manner of supplanting his place.
Catherine adored to the pole pollution of the supreme autho−
rit; and this pretention was supported by the princes
Dalhoff and Orlof. Panin, on the other hand, proposed,
that the should govern only in the name of regent; and that
the tute of emperor should devolve on the young grand duke
Paul Petrovitch. And in this opinion the hetman Razu−
mofsky concurred. Those who wanted to confer the su−
preme power on Catherine, vied with each other in their
endeavours to induce count Panin to alter his mind; and if
their efforts had not been aided by the court's passion for
the princes Dalhoff, they would have proved altogether
ineffectual. The conspirators being agreed, proceeded to
deal means for the execution of their plans. While the
friends of Catherine received confiding information of the
movements of the czar, she was ignorant of all their proceed−
ings. Expecting, in indulgent security, the felicities of
Peterhof, to which we have already adverted, her majesty
was gone to pass some days at his country palace of
Oroevanum, whither he was accompanied by some of the
handsomest women of the court, and where he had purposed
to cause the empris to be arrested. In the mean while
some persons, who had perceived the a plot against the czar
was in agitation, advertised him of it; but he disregarded
the information, and could not be prevailed on to seize
the traitors. However, when the conspirators were about to
accomplish their design on the arrival of the czar at Pet−
erhof, their plot was discovered, and Paliakk was arrested;
so that it became necessary to hasten its execution; the time of
action was the silence of the night, without allowing the
emperor an opportunity for forming an inclination to prevent
him, by the troops and the people time arm for his de−
fence. Catherine, under a pretence of leaving the apart−
ments at the palace free for the festival that was to be cele−
brate', in reality with the view of facilitating her own
escape, was lodged in a remote underground, called Mon−
pisa; there, at the extremity of the garden, on the shore
of the Gulf of Finland. Here she had a small boat, which
might occasionally be of service in the secret visits of her fa−
vourites, and the facilitating her own escape into Sweden, if
the conspiracy should be discovered. At the hour of two in
the morning, when the conspirators were in a profound sleep,
she was suddenly roufed by a feller, unknown to her, who
delivered a note from princes Dalhoff, and accompanied it
with a declaration; "Your majesty has not a moment to
lire; get ready to follow me!" upon which he immediately
disappeared. Catherine, astonished and terrified, called
Ivanova; and having disguised themselves by their draps,
so that they could not be known by the females about the
palace, they hastened to a carriage that was waiting for
them at the garden-gate. As soon as the conspirators had fet−
herself in it, Alexey Orlof, one of the conspirators, took
the reins, and set off at full speed. An accident happened
to the horses, which retarded their flight, and threw them
into confusion. Their danger was imminent; and they re−
solved to make the best of their way on foot; but they had
not proceeded far before they met with a light country cart,
which conveyed them with speed and pricity to Petersburg.
Catherine, worn out with fatigue and anxiety, but sufficiently
full-polished to allude a felate and tranquil air, arrived in
the city at 7 in the morning, on the 9th of July, N.S. 1762.
She was received by a small band of fellers with elanorous
flavours of joy; and though their number was small, they
were to be in her defence. Their example was soon fol−
lowed by other fellers, who, with one consent, declared her
hegemon. The oath of the troops was received on a cruci−
fix, fished from the altar by the chaplain of the regiment of
Infanof; and the Simeon'sky and the Probagin sky
guards joined those of Ilushof. In the interval of two
hours the conspirators came surrounded by 2000 warriors,
and a great part of the inhabitants of Petersburg, who me−
chanically followed the motions of the fellers, and were eager to appalid them. The hetman Razumofsky advised
her to repair to the church of Kazan, whether she was at−
tended with a vast concourse of spectators, who mingled
their acclamations with the shouts of the fellers, and
where the archbishop of Novgorod, accompanied by a
great number of priests, let the imperial crown on her head,
proclaimed her with a loud voice foreign of all the Russians, by the name of Catharine the Second, and declared, at the same time, that young grand-duke, Paul Peterovitch, her successor. A Te Deum was then chanted, accorded with the flour of bread, to the Musiz, of the cavity. Thronged then repaired to the palace that had been occupied by Elizabeth, and for several hourscrowds of peelod men, who told on their knees before it, and took the oath of allegiance. Before the end of the day, Catharine had already sent in a few of the troops; the city was in a formidable state of defence; strict order everywhere prevailed; and not one drop of blood was shed. While the empress retained in the palace, the feet for her Paul Peterovitch, and held him in the balcony of the palace to the view of the people, whose acclamations were redoubled at the sight of the child, thinking that in him they beheld the new emperor. The principal nobles, who had taken no share in the conspiracy, as soon as they heard of it in the morning, retired to the palace, and united their lamentation and oaths of fidelity to those which the empress had just been requiring to Catharine. A manifesto was disseminated through the city, and a notification was delivered to the foreign minister of the day that they were to be admitted to present their compliments of congratulation on the event that had taken place. The troops, immediately supplied with beer and brandy, expressed their satisfaction by reiterated vociferations of Acclamation and by toiling up their hats and caps; but one regiment of cavalry, of which Peter III. had been colonel while he was grand-duke, and which he had incorporated with the guards on his accession to the throne, took no participation in this tumultuous joy. The officers having refused obedience to Catharine, were put under arrest, and replaced by the officers of other regiments. Peerless of this regiment, the ruling party began to march the troops from the city, to proceed against the czar. Peter III. had yet no suspicion of the important event that had occurred. Such and so unaccountable was his security, that he set out, after having received some intimations of the conspiracy, from Oranienbaum in a calash, with his mistresses, his favourites, and the women of his court, for Peterhof, to be present at the grand festivities already mentioned. In the way, Gudovitch, the general aide-de-camp, met one of the chamberlains of the empress, by whom he was informed of her escape, and of the perplexity that had, in consequence of it, filled the whole palace of Peterhof; and upon communicating the intelligence to Peter, he turned pale, and appeared much agitated. On his arrival at Peterhof, his agitation and confusion increased, when he found that the empress had actually left the palace; he was afraid to ask any questions, and his attendants could not summon resolution to give him any information. At length he received the certain and unacceptable tidings of the revolution that had been accomplished; and the chamberlain Woronzof offered his services to hasten to Petersburg, engaging to bring the empress back. The chancellor, entering the palace, found Catharine surrounded by a multitude of people in the act of doing homage; and forgetting his duty, he took the oath with the rest. He was permitted, however, at his earnest request, to return to his house, under the guard of some trusted officers; and thus secured himself from the vindictive spirit of the patriots of Catharine, and from the suspicions of the czar. After the departure of the chancellor, Peter became a prey to the most distressing anxieties, and he every instant received from fresh intelligence of the progress of the revolution. He was increas'd and irrefutably with regard to the meditations that were proper to be purposed at this interesting crisis. Although his Holiness the guards were firmly attached to him, and the veteran marshal Munich offered to dik everything for his service, he remained hesitating and undecided; and after a fruitless attempts to gain possession of the fortresses of Cronstadt, and adopting from other measures, equally unavailing, for concluding the escape, he found it not only expedient, but absolutely necessary to accede unconditionally to her will. The empress deputed count Pahlen to announce to him her purpose; and he was compelled to sign a most humiliating act of abdication, in which he declared his conviction of his inability to govern the state, either as a sovereign, or in any other capacity, and of the defects in which his continuance as the head of affairs would inevitably involve it. While the nature to this fatal act was obtained, Count Pahlen hastened to Peterhof, and Peter seemed to enjoy a greater composure of mind. In the evening, however, an officer with a letter in his hand came and conveyed him prisoner to Rospcha, a small imperial palace, at the distance of about 20 versts from Peterhof.

This was effected in one day and without shedding a single drop of blood, a revolution of immense importance. The unfortunate emperor enjoyed the power of which he made improper use, no longer than six months. Upon his removal from Peterhof, he was blind to the fate that awaited him. He sent a message to Catharine, requesting that he might retain in his service the negro, who had been attached to him, and who argued him with his irregularities, together with a dog, of which he was fond, his violin, a bible, and a few romances; offering her that, disgusted at the wickedness of mankind, he would henceforward devote himself to a philosophical life. Not one of these requells was granted. After he had been at Rospcha six days without the knowledge of any persons besides the chieftains of the conspirators, and the soldiers by whom he was guarded, Alexius Orlof, accompanied by Teplof, came to him with the news of his speedy deliverance, and asked permission to dine with him. While the officer amused the czar with some trifling discourse, his chief filled the wine-glasses, which are usually brought in the northern countries before dinner, and poured a poisonous mixture into that which he intended for the prince. The czar, without distruction, swallowed the potion; on which he was seized with the most excruciating pains; and on being offered a second glass, on pretence of its giving him relief, he refused it with reproaches on him that offered it. Being prevailed to take another glass, when he called for milk, a French valet-de-chambre, who was greatly attached to him, ran in; and throwing himself into his arms, he said, in a faint tone of voice, "It was not enough then to prevent me from reigning in Sweden, and to deprive me of the crown of Ruffia! I must also be put to death." The valet-de-chambre interceded in his behalf; but the two ministers forced him out of the room, and continued their ill treatment of him. In the midst of the tumult, the younger of the princes Baratinsky, who commanded the guard, entered; Orlof, who, in a struggle, had thrown down the emperor, was pressing upon his breast with both his knees, and firmly gripping his throat with his hand. In this situation the two other affairless threw a napkin with a running knot round his neck, and put an end to his life by strangulation, July 17th, just one week after the revolution. These particulars are confirmed by the account of one who was in the confidence of prince Petropkin, who is erroneously said to have been present on the occasion. It was, however, announced to the nation, that Peter had died of an hiliaroidal cancer. When Catharine received the news of Peter's death, she appeared at court, whether he was going, with a tranquil air; and afterwards
Catharine.

Afterwards shut herself up with Orloff, Panin, Razumovsky, Golenis, and some other confidential persons, to deliberate whether the senate and people should be immediately acquainted with the death of the emperor, or whether it might not be more advisable to wait for that purpose till the ensuing day; the latter alternative was adopted. When the news of this event was communicated to the public at large, the empress rode from her seat with her eyes fulfilled with tears; she dismissed the courtiers and foreign ministers, that herself up in her apartment, and for several days exhibited tokens of real and profound grief. The body of the unfortunate exar was brought to Peterburg, and exposd for three days in the church of the monastery of St. Alexander Nevsky, and buried before the relics of the altar. The Holstein soldiers, were, on the day following that of the interment, embarked for their own country; prince George, whom Peter III. had constituted duke of Courland, was obliged to renounce that title; but he was compensated by the empress with the administration of Holstein, where he settled, and ever after served Catharine with fidelity and zeal. The chancellor Belutschef, the most invertebrate enemy of Peter, was recalled from exile, and restored to his rank of field marshal, and to his place in the council, with an annual pension of 20,000 rubles. Several other exiles and prisoners were on this occasion set free; but neither Ivan nor any of his family. Biren, who had been recalled by Peter, was reinstated by Catharine in his dukedom of Courland, where he favoured, to the utmost of his power, the views which the empress had already formed on Poland. Catharine, with a magnanimity which did her honour, wisely manifested no resentment against the few who had preferred their attachment to Peter, and received to favour marshal Munich, who readily transferred his fidelity from the dead to the living. She even pardoned her rival, countess Woronzof, and allowed her to retain the fruits of her lover's munificence.

Although none of the sovereigns of Europe were ignorant of the steps by which Catharine had mounted the throne, they made no hesitation in acknowledging her title. Whilst she was endeavouring to secure peace with the kings of Europe, she neglected no measure that was likely to preserve it within her own empire. In the month of September she took a journey to Moscow, for the purpose of celebrating her coronation in that ancient capital of the empire. Her numerous cavalcade made a pompous entrance into the city; but she was received in a manner that showed she was far from possessing the hearts of all her subjects. As soon as she was crowned in the presence of the follietry and the people of the court, she hastened her departure, though she indulgiously concealed her chagrin, and re-took the road to Peterburg. The precepts and promotions which were made on occasion of the coronation, fell mostly to the share of her adherents in the late revolution. The revolts and conspiracies that disquieted the commencement of her reign were suppressed without much difficulty; and the only fearful that were exercised on the occasion were a few banishments to Siberia. To foreign courts Catharine displayed all the greatness of her character; and at home, combining policy with firmness, she found means to soothe the most dangerous of the priests, and to put a stop to the cabals of the monks. She recalled to court priests Dafiikov, whom she had ordered to Moscow; and the Senate the Piedmontese Oliart, who had incurred the hatred of the whole court. The health of the young grand duke was established; and the flattering expectations that were justly raised by the good conduct of that prince drew off the public attention from the unfortunate Ivan; and the Rollans accommodated themselves to a yoke, which they had in vain attempted to shake off. Ambition, however, did not extinguish in the breast of Catharine the love of pleasure. By the latter she gained the increasing attachment of her courtiers; nevertheless, she could surrender pleasure when the more ardent concerns of government demanded her attention. She alluded at all the deliberations of the council, read the dispatches from her ambassadors, either dictated or dictated with her own hand the answers that were sent to them, and afterwards attended to all the particulars of their execution. Jealous, says one of her biographers, of old renown, she felt before her the example of those illustrious monarchs who effaced their weaknesses by the grandeur of their exploits; and, with the infirmities of men, merited and obtained the grateful acknowledgments of all succeeding times, as the friends and benefactors of the human race. She followed the maxims which she frequently quoted: "We should be conform in our plans. It is better to do amiss than to alter our purpose. None but fools are irrefolent."

Catharine ratified the peace, which her husband had negotiated, with Prussia, and also with Denmark. As soon as she was securely established on the throne, she meditated a variety of enterprises and plans of improvement, which would serve to divert the attention of her subjects from the measures by which the late revolution had been effected, and which, in the refult, would redound to her own glory and the benefit of her country. She applied with unremitting affability and care to the administration of her large estates, the advancement of commerce, the augmentation of the marine, and especially to the means of recovering the finances, without being reduced to the necessity of obviating a parn ominous economy. After engaging in buffets with her ministers, she would frequently converse, in private, with Belutschef and Munich. With one she found politics and the resources of the several courts of Europe, and the other communicatd to her the plan he had been meditating, during his exile in Siberia, for driving the Turks from Constantinople; a plan, the object of which was singularly gratifying to the aspiring mind of Catharine, and which, about 37 years after, seemed to have been on the point of being effected. In many of her manifestoes and ukases, she adopted a style that admirably expressed a regard to justice and to the actual interest of her subjects. When she banished to Siberia for life an officer of the government-chancery of Novgorod, on account of his having taken money for administering the oath of allegiance, she at the same time imposed a severe degree against bribery and extortion. By an ukase, dated Moscow, Oct. 13, 1762, she confirmed the abolition of the secret-inquisition-chancery; rightly judging that she could obtain the love and attachment of the people by better means than by the encouragement of spies and informers; and, therefore, she was no sooner seated on the throne, but she put a complete end to the political inquisition. At the abolition of this inquisition, the objects of which were at first the capital crimes of high treason, attempts against religion, and treason against the state, but which afterwards extended its jurisdiction, Catharine settled the practice to be pursued in future, in the ordinary tribunal, under charges of state crimes, and so plainly and distinctly determined the particular cases of delinquency against the person of the sovereign, and against the welfare of the state, that there remained no room for malicious and unfather interpretations. The crimes denominated religious were entirely suppressed. Catharine further ordained that the truth should be investigated entirely without torture; and, with Frederic of Prussia,
CATHERINE.

Prussia, the like wise exhibited, in this reign, a model for the rest of Europe. Her criminal laws have, throughout a mild and gentle spirit; and though the laws were, like Elizabeth, only a maw to punish no one with death yet, during her long reign, a fortune of death was extremely rare. Catharine, in order to meet her instead of life in her country, declined, by a masquer, that called herself welcome and fragrant in the Russian empire; and so under her accession she restored to life. She marked out the districts that were most coveted, and specified, by particular notices, which were to be, and which not. All land, &c. and what all the lands that she should include, and what the Flows might yield. Besides, she encouraged persons to come and settle for a new purpose in the Russian empire, in whatever country they would. Such a man came, artisans, and the like persons. In order to increase the population, or more properly to eradicate a physical and moral ends of deportation, the conduct of the foundling and beggar hospital at Moscow, and afterwards of another at St. Petersburg. She also founded the medical college of the empire in the latter city. In the year 1770, when Catharine was alarmedit with various plots against her person and the state, she was bailed in all the leading and useful measures of government with as much calmness and solidity as if her reign was to be everlasting. She founded colleges and hospitals in every part of her empire. She encouraged commerce and industry; and ordered new ships of war to be put upon the flocks. The beneficial consequence of the spirit she manifested, and of the regulations she adopted, have been since manifested in a variety of instances. Courland, on the Baltic, with its havens, was subjected by her to the Russian sceptre; and on the opposite side of Europe the Euxine laves her extensive conquests; Ochakov, the Cerchio, the Cram, and the Cuban, bear witness to the force of her arms. The failure of her fleet of commerce and of war are spread even in the Mediterranean. On the Greek side the Russian banners are displayed. Her troops opened a road into Egypt, and thence, in 1772, fought in support of Ali Bey, against the Turks. The free inhabitants of the extreme north-eastern point of Asia, the Tchiechsians, were at length obliged to submit; and a channel of no great width (the Strait of the Bering) there only divides the empire from America. A multitude of Russian vessels, in the northern part of the Southern ocean, the Kurile, and five additional acquisitions, connect it with other states, and even with the continent of the fourth quarter of the world; and even upon that the Russians have got a firm footing. The increase of navigation by these acquisitions, and the very lucrative commerce of the furs here procured, the costly skins of the sea otter, and other animals, is of the usual consequence. The differences that arose with China in 1778, were at length composed, and no carriage go from Moscow to Pekin, yet the merchants of these two great empires perceive their trade together, and perhaps better, in the frontier towns of Kiachta and Manchuria. Orenburg, in Asiatic Russia, is excellently situated for commercial intercourse with the East Indies; the caravans require only three months for the whole journey; accordingly, at the half-way thither, at Bak, a town in Extrastia, or Khorasan, Russian and East-Indian caravans already meet together. From this detail we perceive, in part, the benefits resulting to Russia from the commercial spirit of the empress, and from the commercial regulations she established. Towards the end of the year 1763, Catharine gave a proper form to the supreme college of the empire, the healing senate, which had been instituted by Peter I. She divided it into six departments, of which the four former had their seat in St. Petersburg, and the two latter in Moscoy.

With a view to the introduction and diffusion of science and literature among her subjects, she established several useful institutions: the catalogue of persons in various departments of science, and endeavored to give their future employment or own country; she caused herself in numerous instances of letters, which they communicated for the benefit of emigration. When on the throne of Poland had become vacant by the death of Augustus II., in the beginning of the present century, Catharine despised the arts and talents and wealth, which she had in her native country to her advantage. At the turn he made a tour through Lithuania, Poland, and Russia; but, during her residence in the northern kingdom, she was informed that the Flows had been invaded by a great body of troops, which she was not able to resist. Her son, who had been placed on the throne, the minister-general was the king of Poland, his mother, and his whole family, was confined in the fortress of Schillenburg; from this place he was transported together with his family, to the fortress of Riga; from Riga they were conveyed to Danemanda, and afterwards to Oranienburg, a town built by Montefich, in the cold province of Voronech. There he was separated from his family, and being arrested at Smolensk, in his way to Germany, under the conduct of a monk who released him from prison, he was for some time confined in a monastery in the Valdai, near the road that leads from St. Petersburg to Moscow; and, in 1756, by order of the empress Elizabeth, who wished to see him, was removed to Schillenburg, where he had been placed immediately on his dethronement. Here he was so closely confined, that he never was allowed access to the open air, or to the light of day; a lamp was kept constantly burning in his cell; and, as no clock was to be seen or heard, he knew no difference between night and day. His interior guard, a captain and a lieutenant, were shut up in the same cell, but were not permitted to hold any intercourse with him. It is no wonder, therefore, that his ignorance much be burdened on his eye. Elizabeth indeed had caused him once to be brought in a coach over to Peterburgh, and there saw and conversed with him. Peter II., when he proposed to restore him to the throne, accompanied Catharine too. Just after the commencement of her reign, had a conversation with him, in order, as stated in her manifesto of the 28th of August, 1764, to make a judgment of his understanding and talents, in both which respects he found him extremely deficient. At the period to which we now refer, he was arrived at the age of 24 years; and, whatever might have been his incapacity, he was at the moment for exciting dangerous commotions; and from the depth of his dungeon, he afforded hopes to those who held the present usurpation in abhorrence. Accordingly, whilst the regiment of Smolensk was in garrison, in the town of Schillenburg, a sub-lieutenant, of the family of Mironech, formed the bold plan of setting him at liberty, and raising him to the empire. But the two officers, who slept with him in his cell, had a disinterested order signed by the empress, enjoining them to put the unhappy prince to death, whenever any instruction should be made
made in his favour, provided that it could not otherwise be quelled. Mirovitch, having gained the concurrence of a few associats, pointed a piece of artillery at the door of the dungeon, where the prince was confined, and prepared to batter the place; but at that instant the door opened, and he entered, un molested with his whole forces. In the meanwhile the officers who guarded Ivan, after previous consolatation, determined to affililate the unfortunate captive, who, though asked, defended himself for a considerable time. Although his hand had been pierced through, and his body was covered with wounds, he seized the sword from one of the monitors, and broke it; but while he was struggling to get the piece out of his hand, the other flabbbed him from behind, and threw him down. He who had his sword broken, now plunged his bayonet into his body, and several times repeating his blow, the unhappy prince expired: they then opened the door, and presented to Mirovitch the bleeding body of the murdered prince, and also the order by which they were authorized to put him to death, if any attempt should be made to convey him away. Mirovitch, struck with horror, started back some paces; and after expressing his grief for the event that had occurred, surrendered himself to the governor, who confined him and his accomplices. Mirovitch was afterwards condemned to death, and publicly executed in pursuance of his sentence. The inferior actors, on this occasion, being 50 in number, did not suffer death, but were subjected to other punishments, perhaps not less severe. The officers, who afflictiated the prince, were amply rewarded for their fidelity, in consideration of their good intentions with respect to the tranquility of the state. Some have asserted that Mirovitch had been secretly instigated to this attempt for the rescue of the prince by the court, and thus to justify the execution of the orders that had been previously given to the guard; but the punishment of Mirovitch, and the confession which he is said to have made, that the scheme was wholly his own contrivance, seem to acquit the empress of this horrid crime. On the other hand, it has been alleged that his behaviour during his trial, and the composure with which he walked to the scaffold, on which his sentence was to be executed, manifested a kind of assurance, that he should obtain a pardon, which, report says, had been actually promised. But if he entertained this hope, he was cruelly deceived; the time of his execution was accelerated, and the unhappy wretch, if he had before been the instrument, was now the victim of a barbarous policy. Tho'who was charged in the former point of view were atonified that the empress should suffer him to be put to death. But how could she have screened him from punishment without manifestly drawing upon herself the charge of having prompted his crime? And if she were really concerned in it, can it be thought that she would hesitate a moment in getting rid of a witness who would have exposed her to everlasting vexation? Soon after this shocking event, Catharine, whose throne was now established, returned to Petersburg from her journey through the conquered provinces; and, on her entry into the city, she was surrounded by an immense concourse of people, who endeavored to find out by her countenance what was passing in her heart; but always mitem of herself, the face of that princes was ever covered with smiles. Her step was as firm, and her front as serene as those of persons who feel no inward reproaches usually are. The beneficial effects of the empress's regulations and establishments, for the internal administration of government, were every day becoming more apparent in all parts of Russia: she exerted herself to the utmost in giving new spirit to the commerce of her country, in augmenting her navy, and above all, in softening the manners of the people, who were not yet far advanced in civilization; but the progress of her institutions was at first slow, and it was much retarded by want of zeal on the part of the great personages of the empire, and by the spirit of division that continued to reign in Petersburg. What most afflicted the empress was the misunderstanding that prevailed between her favourite Orloff, and her chief minister Panin. In order to silence murmurs of a political nature, and to divert the disaffected, she displayed her table for splendour and magnificence, by a species of entertainment called a "carnival," consisting of tilts and tournaments, sumptuous entertainments, repeated with considerable variations for several days, and vying in pomp and pageantry with any of the feats of ancient chivalry. But Catharine knew also to employ more worthy means for establishing her authority. She skillfully conducted herself in making reforms, and in the establishment of useful institutions. She corrected the tribunals, founded schools, built hospitals, and planted colonies. She endeavored to infuse into her people a love for the laws, and to soften their manners by instruction. Jealous of a power that knew no bounds, greedy of every species of glory, she was determined to be at once both conqueror and legislator. Amidst conspiracies formed for overturning her throne, occupied with preparations for war, which seemed sufficient to arrest her whole attention, and yet finding time for attachments of gravity, she was unmindful of nothing that could attract the reverence of mankind, and captivate their admiration. The perplexed and uncertain jurisprudence of Russia engaged her particular attention; and she resolved to apply a remedy to the various disorders that occurred in this department of the state. Although the success of her patriotic attempt has not yet been complete, yet, in consequence of it, the laws of the Russian empire have been much simplified, and the administration of justice is become much milder and more impartial. Having formed the senate and the colleges into separate departments, and having augmented the emoluments of the judges, in order to deprive them of all pretext or excuse for either negligence or prevarication; she set herself to work on a new code of laws. With this view she summoned deputies to Moscow from all parts of her vast empire, that she might obtain their ideas on the laws that were fitted for their peculiar exigencies; and the herself repaired to that ancient capital. When they were assembled, she wished to leave them in possession of uncontrolled liberty, and therefore, though she attended in the hall where they met, and could see and hear all that passed, the herself was not perceived. The instructions, which she had previously composed, with the assistance of Mathonius and Rozetsky, and which had been chiefly taken from the writings of Montefiquieu and some others of the French philosophers, were translated into the Russian language from the original French, and the business of the assembly was begun by the perusal of them. The original copy, almost entirely in the handwriting of Catharine, has since been deposited, enclosed in a magnificent cage of silver gilt, in an apartment of the Imperial Academy of Sciences at St. Petersburg. Copies of these instructions were afterwards dispatched to the sovereigns, whose approbation Catharine most coveted. They complimented her on her laborious enterprise, and made no hesitation in pronouncing that it would be an eternal monument to her glory. It unequivocally redounds much to the praise of the empress, that these institutions are founded on the principles of an enlightened humanity; and that, though autocratix, and possessing unlimited power, she recognizes no legitimate authority but that which is founded on justice; and that every particular in her laws.
CATHERINE.

laws has a tendency to enervate despotic, and to render a just authority respectable. Her purpose was to form a field, and not an arbitrary legislation. Her whole plan was directed to prevent all those who governed her from exercising a capricious and cruel authority, by subduing them to inviolable laws, which no authority should be able to infringe. The empress, proceeding in other respects on the same enlarged and enlightened plan, continued to cultivate and encourage the arts and sciences; to make her empire an asylum to the learned and ingenuous; and to reform the manners and instruct the minds of the people, through the extent of its most distant provinces. The transit of Venus, which happened in 1769, afforded an opportunity of exhibiting as well the munificence of Catherine as the attention she paid to astronomy. It may seem surprising, however, that the empress was not driven to build her fame upon a solid basis, she made it a matter of much importance to obtain from all the powers of Europe the title of imperial majesty, which some of them had refused her. About the middle of the year 1767, the empress conceived the useful project of sending several learned men to travel into the interior of her immense territories, for the purpose of determining the geographical position of the principal places, of marking their temperature, and of examining into the nature of their soil, their productions, their wealth, as well as the manners and characters of the several people by whom they are inhabited. The felicity of the learned travellers defined for this expedition, the helps that were granted them, and the excellent instructions that were given them, will be a lasting honour to the Academy of Sciences, by which they were appointed. About this time, viz. in 1768, the court of Catherine became the asylum of the sciences, to which she invited learned men from every part of Europe. She encouraged artists and scholars of all denominations; she granted new privileges to the Academy of Sciences, and exhorted the members to add the names of several celebrated foreigners to those which already conferred a lustre on their society. Nor was she less attentive to the Academy of Arts, by increasing the number of its pupils, and adding such regulations as tended more than ever to the attainment of the end for which it was endowed. See Academy. For the further encouragement of the fine arts in her dominions, the empress assigned an annual sum of 5000 rubles for the translation of foreign works into the Russian language. The improvement of the state of physic was another important object of her concern; and in order to give the highest possible function to the salutary practice of inoculating for the small pox, the hercelf submitted to the operation under the care of an English practitioner, and the perfuaded the grand duke to follow her example. In 1768, Dr. T. Dimoldile, of Hertford, was invited to Russia for the purpose of introducing inoculation: upon the recovery of the grand duke, Catherine rewarded his services by creating him a baron of the Russian empire, and appointing him counsellor of state and physician to her imperial majesty, with a pension of 5000 roubles a year. To be paid him in England; besides 10,000 roubles, which he immediately received; and she also presented him with a miniature picture of herself, and another of the grand duke as a memorial of his services. Her majesty likewise expressed her approbation of the conduct of his son, by conferring on him the same title, and ordering him to be presented with a superb gold snuff-box, richly set with diamonds. On December the 3d, 1768, a thanksgiving service was performed in the chapel of the palace on account of her majesty's recovery and that of the grand duke from the small-pox: and the senate decreed, that this event should be folemned by an anniver- sary festival, which has been regularly observed ever since.

With regard to her foreign relations, whilst she was giving law to Poland, amusing Austria, conciliating the friendship of Prussia, and treating with England, she was also tampering with the other courts of Europe, and labouring efficaciously towards very soon making herself dreaded by them.

Her schemes of foreign grandeur, which compose so great a part of her history, commenced with her violent and arbitrary interference in the affairs of Poland, which in 1768 caused the Ottoman Porte to declare war against her; but he was not unequal to the contest, which in its progress brought on a series of disorders to the Turks. They lost several battles on the Pruth, Dniester, and Danube, with the towns of Bender and Ackerman, the capital of Bessarabia. The news of these signal successes augmented the pride and strengthened the security of Catherine. The disaffected, who surrounded her throne, dared no longer to conspire against a princess, who was triumphing at such a distance over her most formidable enemies. The provinces of Walachia, Moldavia, and Bessarabia, submitting to the Russian arms, sent deputies to Peterbourg to do homage to the empress; who received them with magnificence, and loaded them with benefits. Whille the Turks were thus harassed by land, and the fleets of the empress were triumphing on the Euxine, she resolved to attack them even in the isles of Greece. With this view, in September 1769, two squadrons of Russian men of war sailed from Archangel and Revel, which were soon followed by others from the Baltic, and entered their hitherto unattempted course for the Mediterranean. The fleet now consisting of 20 sail of the line, 6 frigates, several transports, a number of bomb-ketches, galleys, and vessels with troops for land-service, left the Baltic, crossed the North sea, passed the straits of Gibraltar, and after having been dispersed by a tempest, collected again, and displayed in the Archipelago its victorious flag. This fleet was commanded by admiral Spiridof, but that admiral himself was under the orders of Alexey Orlof, whose share in the Russian revolution had advanced him all at once from the low condition of a simple soldier to the rank of general, and whose audacity served him instead of experience and talents. This naval expedition of Russia forms a remarkable era in the history of marine tactics. Before the arrival of this fleet, some secret agents had been disposing the Greeks to rise up in arms. They were led to expect the Russians as their deliverers; and at the instant when their squadron had gained the height of Cape Matapan (formerly the promontory of Tenaros), the whole Archipelago thought itself free. The Maimots, descendants of the ancient Lacedemonians, were the first that took up arms; their example was soon followed by their neighbours; and the Turks were massacred in several of the isles. But the latter cruelly revenge themselves for the insurrection of the Greeks. Some thousands of these miserable people were exterminated by the fabre of the Janizaries.

The squadron of Spiridof was soon joined by that of Elphinston, a native of England, vice-admiral in the Russian service, and far more capable of commanding than the officer under whose orders he served. To this double squadron was opposed that of the captain-pacha Haffan, surnamed Gazi, or the victorious, by the sultan on account of the courage he displayed in the engagement with Spiridof. This Turkish admiral first forced the Russians to retire from Lemnos; but the two fleets afterwards met in the channel that separates the isle of Scio from Natolia; and a very furious engagement ensued. The Turks, though possessing a superior navy, were compelled to shelter themselves in the narrow bay of Tchurfene, near Lemnos, where some of them ran aground, and the others were so pressed for room, that it
Catherine.

was impossible for them to act. The Russians, perceiving their disadvantageous situation, sent among them some fire-ships, under the conduct of the admirals Elphinston and Greig; and commanded by lieutenant Dagdale, all British officers, and destroyed their whole fleet. After the total destruction of the Turkish squadron, the Russian fleets of Paros; whence they might easily command all the Grecian shores, where no single vessel was suffered to appear without lowering its topsails. This great success, however, was not improved as might have been expected by Alexius Orlof, the emperor's hero and supreme commander in the Mediterranean; for though a new squadron was fitted out to reinforce that which was already in the Archipelago, the Dardanelles, which were the keys of Conflantinople, remained secure; for, as the winter season came on, the Russians were obliged to quit their flation in these seas, and the trade through the straits was of course again opened. Crim Tartary, however, was entirely conquered by the Russians, whose fleets rode triumphant on the Black Sea; and the grand vizir was attacked in his camp, and routed with great slaughter. A terrible plague at Moscow, and other domestic disaffairs, counterbalanced in the estimate of true policy these foreign advantages. In 1772, the most iniquitous measure, the division of a large part of Poland between the three bordering powers, Russia, Prussia, and Austria, which had been long projected, and for which preparations were made by the advances of their several armies into the country, avowedly took place in the face of Europe, which was shamefully passive to fo great a violation of all public faith and equity. While Catherine was acquiring by negotiations a part of the provinces of Poland, her armies continued to ravage the frontiers of Turkey; and the war was not terminated till the year 1774, when the grand vizir, being inviolated on all sides by the Russian armies, was reduced to the necessity of signing a peace; of which the principal conditions were, the independence of the Crimea, the free navigation of the Russians on the Euxine and through the Dardanelles, with the stipulation that they should never have more than one armed vessel in the seas of Conflantinople, and a cession to them of that tract of land that lies on the Euxine between the Dog and the Danube. Russia, retaining Azof, Toganok, Kerchef, and Kinhurn, restored the rest of her conquests. Russia also obtained a large sum of money to defray the expenses of the war, and the title of "peditah," or empress, was no longer refined to the Russian monarch. Nothing could exceed the joy and felicity which prevailed at Peterburg upon the confirmation of this happy peace. The empress ordered eight days to be devoted to public feasts and rejoicing; liberal rewards to be distributed as usual; the prison doors to be opened for the release of all, who were not charged with high treason; and the return of all exiles from Siberia, who had been banished since the year 1746. But, notwithstanding the external prosperity of the Russian empire, many circumstances combined to produce internal distresses. The finances of the country were in a disordered state; succours from England were procured by granting immense advantages to its commerce; the pillar had made dreadful ravages at Moscow and in the adjacent countries, and had extended its fatal influence to the army and navy; the provinces of Kazan, Astrachan, and Orenburg, were a prey to revolt, which menaced even Moscow; and a remarkable emigration was charging countries that were flourishing with commerce into woe and deflected tracts. All these circumstances rendered an accommodation with the Turks peculiarly acceptable. But besides these grievances which must induce the empress to rejoice in the establishment of peace, an open rebellion, and its attendant, a civil war, distracted the Russian empire. This calamity originated in Asia, and extended to Moscow; the author of it was Pugatschef, a Cossack, born at Simoveife, a village on the borders of the Don. He had served as a common soldier in the army in 1756; he made the campaign of 1769 against the Turks, and fought under general Panin at the siege of Bender; and the treachery that town he applied for his dismission, which was refused; umpiring that Pugatschef had fled to Poland and obtained concealment and an asylum among some hermits of the Greek confession. These hermits, perceiving or assigning some resemblance to Peter III., encouraged him to assume his name and character. The imposture was carried on for some time in Little Russia, and a number of followers attached themselves to this deceiver, who had combined professions of fanaticity and self-denial with his delusion. Among the inhabitants of the banks of the Yaik, since called Ural, he formed a strong party of Cossacks, whom he engaged to accompany him into the mountains of Caucasus, with the assurance that they would there find powerful succours. Being arreted for inciting the people to sedition and committed to prison, he was frequently visited by the popes, who furnished him with money, and thus enabled him to corrupt his guards, and to make his escape. Having by various arts of imposture collected a formidable party, he publicly declared that he was the emperor Peter III., delivered by a miracle from the hands of his adversaries. This revolt was a favourable diversion to the Turks, and in 1773 wrought powerfully in their behalf. Pugatschef, besides assuming the name and character of Peter III., had sufficient deficiency to perceive, that it would much favour his design to blend religious pretences or prejudices with the political motives which might operate towards bringing on a revolution. Other circumstances concurred to crowisure, his imposture, and to inculcate the number of his adherents. The rebellion, intrigued by this impostor obtained a general spread; and at length Catherine was much alarmed, and seriously set about checking its progress. She published manifestos and ukases, and Pugatschef did the fame, affixing to these the name of Peter III. By one of these he reaffirmed all the boors; and he caused rubies to be struck with his effigy, and this inscription: Peter III., emperor, and autocrat of all the Russias; and on the reverse, Redivivus et ulor. This revolt, the particulars of which we cannot detail at length, after causing great devastations, and the loss of many lives, was finally terminated by the capture of Pugatschef at the close of the year 1774, and his subsequent decapitation. It has been jutting alleged, as a proof of the mildness of Catherine's administration, that this atrocious rebel was executed without torture. Five of his principal accomplices were likewise beheaded; three others were hanged; and 18 more underwent the knout, and were banished to Siberia. Catherine, during the tumultuous state of the empire, employed herself in promoting its internal welfare, by encouraging the sciences and the arts of peace; and soon after the punishment of Pugatschef, she had a fresh opportunity of displaying her clemency, by granting a pardon to men, who were justly defearing of capital punishment; they were the treasurers of the empire, who had embezzled the public money. She had overcome what was naturally irascible and violent in her temper, and had learnt patience and lenity from the efforts of philosophy. Notwithstanding the heavy burdens incurred by her foreign and domestic wars, she took off most of the taxes that were laid for their support; and, as if the strength and riches of government in her country increased with its expense, she also abolished a number of the ancient taxes, which were considered either as discouraging to ari-
Catherine.

culture, or oppressive to particular provinces or orders of the people. She allotted large sums of money, free of interest, and for a specified term of years, to those provinces which were ruined by the late rebellion. She likewise established a number of other regulations, that tended to the security, advantage, and happiness of her subjects; abolishing pernicious distinctions, destroying numerous monopolies, reforming the cruelty of punishment, removing oppressive or inopportune restrictions or prohibitions; and restoring mankind to a more equitable degree of equality, in the different ranks in which they occupy in society. Imprisoned debtors were, under certain circumstances, released from confinement; and all the heirs of the debtors to the crown were discharged from their bonds and obligations. The insurgents every where returned to their duty; nor were the victims to justice numerous. As a general famine prevailed in the defeated countries, government was at great expense and trouble in supplying them with corn and meal from the magazines at Moscow and other places; and various methods were devised for preventing the progress of famine. The comprehensive mind of the empress, which had been occupied in the extension and establishment of its external force, in laying the foundations of a philosophical system of legislation, in the improvement of education, in the diffusion of illumination and taste, and in the reformation of numerous abuses, directed its views to the important object of forming a constitution for Russia. See Petersburg and Russia.

In the year 1775, when peace was established abroad, and every thing was quiet at home, Catherine employed herself in cultivating the arts of peace, in the improvement of the country, and in opening the minds of her subjects; and in the prosecution of those objects she found Potemkin useful, that he soon acquired an attendant that was almost abode. To him all persons looked as the dispenser of all bounty, and the source of all honours. Every day he acquired some new dignity or some accession of revenue; he attained the most important post in the Russian empire; and he politicled an authority scarcely compatible with that of a superior. Catherine was not unappreived of his ambition and love of power; and, therefore, the wished to retain Gregory Orlof, her former favourite, though he requelled permission to retire from the court, as a check on the petulance and audacity of his rival. After having long opposed Panin to Orlof, she now thought of opposing Orlof to Potemkin.

The independence of Crim Tartary soon produced an open rupture between the Turkish and Ruffian parties; and in 1778 it produced a declaration of war. From the measures that were pursued it sufficiently appeared, that the ambition of the empress would not be satisfied till she had gained entire possession of that peninsula. Her intrigues in the neighbouring courts of Denmark and Sweden tended to render these powers little more than dependencies on her crown; however in 1780 her influence over them was employed in establishing the famous "armed neutrality," the purpose of which was to protect the commercial rights of neutral states, then continually violated by the belligerent powers, and particularly by England, which availed itself of its superiority at its, in preventing France and Spain from receiving naval forces from the Baltic. In this year Catherine had an interview at Mohilow with the emperor of Germany, Joseph II., and they travelled together in familiar intercourse into Russia; the prince of Prussia (afterwards Frederic William II.) also visited her court; and it was customary for the neighbouring princes to make visits of policy or curiosity to Petersburg, where they were always treated with a magnificence not paralleled in any other part of Europe. In 1781, Catherine, with a view of affording an asylum to the persecuted order of Jesuits, and probably imagining that all the Jesuits of Europe and America would bring into White Russia their treasures and their industry, erected a Roman Catholic archbishopric at Mohilow, for the spiritual government of her subjects of that persuasion, and also gave him a Jesuit coadjutor. But whatever might be her expectations, the foils of Paraguay never found their way to Mohilow. This establishment, however, evinced a mind, like that of the king of Prussia, superior to religious prejudices; and, considered merely with a view to the exercise of religion, it was laudable. This year was marked by an event which indicated Catherine's respect for the memory of Peter the Great, whom the affected to imitate: it was the erection at Peterburg of his famous equestrian statue, which was executed by Stephen Falconet of Paris. This artist conceived the design of having for the pedestal of his statue a huge and rugged rock, in order to indicate to posterity, whence the heroic legislator had set out and what obstacles he surmounted. This rock, the height of which from the horizon line was 21 feet by 43 in length, and 34 in breadth, was conveyed, with great labour, from a bay on the gulf of Finland to Peterburg, through the distance of 11 versts, or about 41,250 English feet. On the side next the senate it has this Latin inscription, which is in a style of sublime and proud simplicity: "Petro primo, Catharina secunda, " Catherine the second to Peter the first."

In the following year, 1783, Catherine augmented the splendour of her court, by instituting the new order of St. Volodymir, or Vladimir. This year gratified the ambition of Catherine with regard to the Crimea. Having acquired, without a war, the sovereignty of the Crimea, the isle of Taman, and a great part of the Kuban, she called the former of these countries Taurida, and the other Caucasian. Thus Catherine gained a point of much importance towards the main object of her own ambition, as well as that of her prime minister Potemkin, i.e. the defraction of the Turkish empire in Europe; in the view of which she had named the grand-duke's second son Constantine, and had put him into the hands of Greek nurses, that he might be thoroughly acquainted with the language of his future subjects. Indulged by Potemkin, the empress formed a design, in 1787, of being splendidly crowned in her new dominions "queen of Taurida;" but the expense being objected to by some of her courtiers, she contented herself with making a grand progress through them. At her new city of Cherson, she had a second interview with the emperor Joseph. She then traversed the Crimea, and returned to Moscow, having left traces in her progress of her munificence and condescension. This oscillations tour was probably one cause of the new rupture with the Turkish court, which imprisoned the Russian minister in the Seven Towers, and commenced the war. In this bloody contest the emperor of Germany engaged as ally to Russia, and the king of Sweden as ally to the Porte. The latter prevented the empress from sending a fleet into the Meditarranean; and even endangered Peterburg itself by a sudden incursion into Finland. The danger, however, was averted by the empress's own vigorous exertions, by the defeat of some of Guitavus's troops, who would not fight against the Russians, and by an attack of Sweden, on the part of the prince of Denmark, who proceeded as far as Gottenburgh. The Turkish army, though superior to that of the emperor, could not resist the efforts of the Russian generals. Potemkin at the head of a numerous army, and a large train of artillery, laid siege to Odchakof, and it was at length taken by force, with the loss of 25,000 Turks and
CATHARINE.

and 12,000 Ruffians. Catharine regarded the capture of this strong town an event of much importance, that she liberally rewarded Potemkin, and conferred honorary distinctions on prince Repnin and general Suwarof, and the other commanders concerned in reducing it. During the progress of this war, the Turks lost many important places, and their naval force on the Enixine was almost annihilated.

In the conflicts between the Russian and Swedish fleets in the Baltic, the former were generally victorious; but they terminated in 1790 in a separate peace. The war with the Turks was prolonged; the strong fortresses of Ismail was stormed by Suwarof and taken with the loss of 15,000 Ruffians; and the armies of Catharine obtained, though with the expenditure of many lives, several decisive victories.

The empress, however, perceived that even her conquests were ruinous, and that peace was defirable; but she had too much pride to sue for it, and therefore she chose to continue fighting. At length she determined to close the war, and engaged Count Berndorf, the Danish minister, to negotiate the preliminaries of peace with the cabinets of Berlin, of London, and of the Hague. By his mediation, an accommodation was settled between these three powers and Russia; and they agreed to propose to the Ottoman Porte the terms offered by the empress, declaring, that if the Turks would not accept of these conditions, they would abandon their cause, and leave them to prosecute the war alone against Russia. A congress was assembled at Shitilova; and the negotiators having removed to Galatich, the preliminaries of peace were signed, on the 9th of January 1792, by prince Repnin and the grand vizir. The definitive treaty, concluded at Yally, soon after followed. In the war, this happily terminated, it has been calculated, that Austria lost 100,000 soldiers, and expended 300 millions of florins. Russia lost 200,000 men, 5 ships of the line, 7 frigates, and 80 smaller vessels, and expended 200 millions of rubles.

The Turks lost 330,000 men, 6 ships of the line, 4 frigates, with several other vessels, and expended 250 millions of piastras. Sweden had expended 70 millions of rix-dollars, and lost 12 ships of the line, 3 frigates, and 40 smaller vessels of war. After signing the treaty, Bezborodko declared, that the empress gave up her claim to the 14 millions of piastras which the Porte had stipulated to pay her as an indemnity for the expenses of the war; and the Ottoman plenipotentiaries justly felt the admiration of an act of generosity in so truly imperial. By this treaty of peace, the Porte declared that it was to be for the future the limit of the two empires. The English prime-minister manifested a strong desire to compel Russia to restore Otchakov to the Turks, but not being supported by the nation, this point was conceded, and Russia retained that important place and its territory.

Before the conclusion of this treaty, Catharine offered her prime-minister, prince Potemkin, who died the 15th of October 1791, at the age of 52, in the vicinity of Yally, and was buried at Cherion. In consequence of this loss, the empress employed herself with singular activity in the administration of the empire; devoting to public business 15 hours together, and dividing among her ministers the direction of the affairs which had belonged to Potemkin. When the revolution in France began to agitate the crowned heads of Europe, the empress, and the king of Sweden, seem to have been the first who formed a resolution of opposing it by force of arms. But when Catharine perceived that the hazard and difficulty of this enterprise were encountered by the nearer powers of Prussia and Austria, she directed her attention to Poland, and exerted herself in checking and subduing the new spirit of liberty which was rising in that country. For this purpose she marched an army thither, overcame all resistance, annulled the new constitution, and finally broke the spirit of the Poles by the dreadful massacre made on the inhabitants of the suburbs of Warsaw under the obdurate Suwarof. A new division of the country between the three former pillagers ensued, which at length totally blotted out Poland from the map of Europe. See Poland.

Catharine, having conquered, either by her arms or by her intrigues, almost one half of Poland, the Crimea, the Kuban, and a part of the frontiers of Turkey, had no occasion for recurring to armaments and battles in order to usurp another rich and well-peopled country. Her intrigues were sufficient to gain possession of Courland and Semigalia. Whilst she was thus extending her territories, she was not remiss in manifesting her adherence to the new principles propagated in France, by ostentatious attention to the forms of religion, and by a cordial reception of noble emigrants from that country, and by sending a squadron of men of war to co-operate with the British fleet. Insured to conquer, she turned her arms against Persia; and under pretence of defending Loff-Ali-khan, an offspring of the race of the Shahs, the want of which was to be avenged on Aga-Mahmud, and to gain possession of the provinces which border on the Caspian. With this view, her general Zuhow, at the head of a numerous army, penetrated into the province of Daghestan, and, after a short siege, made himself master of Derbent. Her success in this quarter inspired her with the hopes of obtaining a greater triumph. Having concluded a treaty with Great Britain and Austria, called the triple alliance, and signed in February 1795, she thus secured the assistance of these two powers against Turkey, and flattered herself with the full accomplishment of her darling project, which was that of driving the Ottomans out of Europe, and of reigning in Constantinople. In this case the immense empire of Catharine would have had for its frontiers the Thracian Bosphorus to the south, the gulf of Bothnia to the north, the Vistula to the west, and the sea of Japan to the east. But death disappointed her hopes, and put a flop to that career of her ambition which nothing else could restrain.

In the course of her life, she had seldom experienced any illness, which was probably owing to her even and cheerful temper. On the morning of the 6th of November 1796, she was in good spirits, and having taken her coffee as usual, she retired to her closet; but not returning so soon as her attendants expected, they began to be alarmed; and on entering the outer room where she was, they found her fainted on the parquet, with her feet against the door, and speechless. Her majesty's chief physician, Dr. Roperfon, being sent for, he pronounced her attack to be a fit of apoplexy; and having ordered her to be twice bled, she obtained temporary relief; but she was unable to utter a single word, and at 10 o'clock in the evening of the following day she expired. She was succeeded by the grand duke, her son, who was immediately proclaimed emperor, by the name of Paul I. Her remains were deposited in the tomb of the unfortunate Peter III. in the church of the monastery of St. Alexander Neufky. On the coffin of that prince the emperor cauful to be placed the imperial crown, which was fetched from Moscow for this purpose; the coffin was then laid in state by the side of that of the empress, with a true-love knot reaching from one to the other, on which was inscribed in Russian characters: "Divided in life—United in death." Alexis Orlof and prince Baratinly, the two assassins of Peter III. were ordered to stand, one on each side of his coffin, as chief inquirers. The former betrayed no signs of emotion; but the latter seemed to be overwhelmed with grief, and could scarcely be prevented from falling into a swoon.
Catherine.

a frown. When this act of punishment was concluded, Orlof received permission to travel, and Baturinsky was ordered never more to appear at court.

Catherine II. had been handsome in her youth; and at the age of 25 years she preserved some remains of beauty, connected with a peculiar gracefulness and majesty. Her stature was of the middle size, somewhat corpulent, but well proportioned; and as she carried her head very high and raised her neck, she appeared very tall; she had an open face, an aquiline nose, an agreeable mouth, and her chin, though large, was not square. Her hair was auburn, her eye-brows black (brown, says Rulhier); and rather thick; and her blue eyes (animated hazel eyes, says Rulhier, discovering shades of blue), indicated a genialness which was often affected, but more frequently a mixture of pride. Hautifulness, says Rulhier, was the true character of her physiognomy. The grace and kindness, which she was likewise visible in, seemed, to the penetrating observer, only the effect of an extreme degree of pleasing; and these seducing expressions manifested too perceptibly even the design of seducing. A painter, deformed of expressing this character by an allegory, proposed to represent her under the figure of a charming nymph, who, with one hand extended, presents wreaths of flowers, and in the other, which she holds behind her, conceals a lighted torch. The empress was usually dressed in the Russian manner. She wore a green gown (green being the favourite colour with the Russians), somewhat short, forming in front a kind of vest, and with close sleeves reaching to the wrist. Her hair, slightly powdered, flowed upon her shoulders, topped with a small cap covered with diamonds. In the latter years of her life she used much rouge; for was still deformed of preventing the impression of time from being visible in her countenance; and the always practised the frivolted temperance, making a light breakfast and a moderate dinner, and never eating any supper. In her private life, the good humour and confidence with which she inspired all about her, seemed to keep her in perpetual youth, playfulness, and gaiety. Her engaging conversation and familiar manners placed all those who had constant access to her, or affiliated at her toilet, perfectly at their ease; but the moment when she had put on her gloves to make her appearance in the neighboring apartments, she assumed a sedate demeanour, and a very different countenance. From being an agreeable and facetious woman, she appeared all at once the revered and majestical empress. A person, who then saw her, would spontaneously pronounce, "This is indeed the Semiramis of the north." Her mode of faluting was dignified and graceful; by a slight inclination of the body, not without grace, but with a smile at command, that came and vanished with the bow.

As to the character of Catherine, it may be sufficiently estimated by the history of her actions. Her reign, for herself and her court, had been brilliant and happy; but the last years of it were particularly disfarrising for the people and the empire. She governed too much by her favourites; and these, with their dependents and subordinate officers, became petty despots. The two most celebrated of these favourites were count Gregory Orlof and prince Potemkin; the former was a coarse vulgar man, of surprising, muscular strength and brutal manners; the other, more refined, was introduced in Russia that fort of fame which is attached to conquests and military exploits. Let the reader judge from the following statements, what honors and emoluments these favourites and others of a similar description possessed, and how they must have abused the confidence of the emperors, and pillaged the country in order to acquire them. The dignities and titles conferred by Catherine on prince Potemkin may be seen in the annexed summary: "Knight of the principal orders of Poland, of Sweden, Poland, and of all the orders of Russia; field marshal, commander in chief of all the Russian armies; chief general of the cavalry; chief admiral of the fleets of the Black Sea, of the Sea of Azof, and of the Caspian; senator, and president of the college of war; governor-general of Ekatariino-zavodoff and of Taurida; adjutant-general, and actual chamberlain of the empress; inspector-general of the armies; colonel of the Preobrazhenky guards; chef-du-corps of the horseguards; colonel of the regiment of cuirassiers of that name, of the dragoons of Peterburg, and the grenadiers of Ekaterinopol; chief of all the workshpops of arms and foundries of common; grand hetman of the Cossacks," &c. &c. &c.

Thesubjoined statement exhibits the sums of money which the favourites of Catherine received from her during her reign, or rather which they wrested in various ways from the poor peafantry, her subjects:

Total of boors 68,800

This statement does not include those given to Potemkin, to Lanjoski, nor to Zavodoff, three favourites beloved by Catherine, and to whom, of course, she gave the moll.

During this reign, almost all the people in office and authority were fortunate adventurers. If we except the Solikoffs, we shall find at this period no family of distinction in favour.

With respect to the government of Catherine, it was as mild and moderate, within the immediate circle of her influence, as it was arbitrary and terrible at a distance. Whoever, directly or indirectly, enjoyed the protection of the favourite, exercised, wherever he was situated, the most undisguised tyranny. He inflicted his superior, trampled on his inferiors, and violated justice, order, and the "ukafes," with impunity. The emperors having usurped a throne, which they were debarred of retaining, was under the necessity of treating their accomplices with kindness. Being a foreigner in the empire over which she reigned, she endeavoured
to identify herself with the natives by adopting and even
flattering its tastes and its prejudices. She often knew how
to reward, but never could resolve to punish, and it was
futile by suffering her power to be abused, that she succeed-
ed in preventing it.

The spirit of toleration that animated the whole of Ca-
tharine's administration exhibits a very remarkable and al-
most singular phenomenon in a despotic government. Not-
withstanding all opposition, the emperors adhered to the refo-
lution they had formed at the commencement of her reign;
and, from that moment to the day of her death, not one in-
stance occurred, of a human being suffering, in any respect
whatever, on account of his religious opinions. Towards
heretics she always evinced great bounty of disposition.

"Poor wretches," she once said, smiling, "since we know that
they are to suffer so much and so long in the world to come, it
is but reasonable that we should endeavour, by all means, to
make their situation here as comfortable to them as we can."

Not only the conquered provinces were protected in the free
exercice of their religion, but Lutherans, Calvinists, Mor-
avian brethren, Papists, Mahometans, Heathens, and people
of all countries and persuasions, might aspire to any post un-
der government, and hold any civil or military employment
or dignity, if they were but worthy, or deemed worthy of
it. The intolerant of more polished nations might go to the
provinces of Lithuania, Livonia, Finland, and Russia, to take
leaves of moderation and Christian forbearance. But
at Peterburg the general and peculiar feature in the public
character is toleration; and this virtue has there acquired so
general and extensive a sway that it is not easy to find a spot
of earth upon the globe, where, in this respect, a man may
more quietly pass his days than at St. Peterburg.

The emperors, not satisfied (as we have already observed)
with having appointed a catholic archbishop, and established
a seminary of Jefuits at Mohilow, and with having supported
toleration in the Crimea, gave to her people almost every
year some solemn inculcation of the protection they granted to
the liberty of worship. On the day of the beneficent of the
waters, her confessor, by her orders, invited to his house
the ecclesiastics of all communions, and gave them a grand
entertainment, which Catharine called "the dinner of tolera-
tion."

It has been calculated, that the offices of religion
are performed in Peterburg in 14 different languages.

Catharine had two passions which never left her but with
her last breath; the love of the other sex, which degenerated
into licentiousness, and the love of glory, which linked to
vanity. B. the former of these passions she was never so far
governed as to become a Medallina; but she often disgraced
both her rank and sex, and continued to her by habit what
she had been from constitution. By the second, she was led
to undertake many laudable projects, which were seldom
completed; and to engage in unjust wars, from which she
declared that kind of fame which is the usual result of success.

The generosity of Catharine, the splendour of her reign,
the magnificence of her court, her institutions, her monu-
ments, and her wars, were precisely to Russia what the age
of Louis XIV. was to Europe; but considered individually,
Catharine was greater than that prince. The French formed
the glory of Louis; Catharine formed that of the Russians.
She had not, like him, the advantage of reigning over a po-
lished people; nor was she surrounded from infancy by great
and accomplished characters. She had some subtle ambas-
dadors, not unskilled in the diplomatic art, and some fortu-
nate generals; but Romanzof, Panin, and Potemkin except-
ed, the could not boast a single man of genius; for the wit,
cunning, and dexterity of some of her ministers, the feicio-
cious valour of Suvarof, the dastile capacity of a Repnin,
the favour of a Zubof, the readines of a Bebendrofko, and the
affability of a Nicholas Soltikof, fearlessly defer ce to be ad-
mitted as excellencies. It was not that Russia did not pro-
duce men of merit; but Catharine feared such men, and
they kept at a distance from her. We may conclude, there-
fore, that all her measures were her own, and particularly all
the good she did. It should be recollected that in her pri-
ivate character, notwithstanding all the misfortunes and
abuses that call a shade over her brilliant reign, she appeared
to be thoroughly humane and generous, as all who ap-
proached her experienced; all who were admitted to her in-
timacy were delighted with the good humoured fallacies of her
wit: all who lived with her were happy. Her manners
were gay and licentious, but she still preferred an exterior de-
corum, and even her favourites always treated her with re-
spect. Her love never excited disgust, nor her familiarity con-
tempt. She might be deceived, won, seduced; but she
would never suffer herself to be governed. Her active and
regular life, her moderation, firmness, fortitude, and even her
temperance, are moral qualities which it would be highly unju-
sal to sacrifice to popularity. Her greatest might the not have been,
if her heart had been as well governed as her mind.It
she reigned over the Russians less despotic though her self;
but she was never hurried away by anger; never a prey to dejection,
and never indulged int rantours of immoderate joy. Ca-
price, ill-humour, and petulance, as they formed no part of her
character, were never perceived in her conduet. "I will
not decide," says the writer who has thus sketched the out-
lines of her character, "whether the she was truly great, but
she was certainly beloved." Her crimes, it is said, were the
crimes of her nation, not of her heart: the terrible butcheries
of Imaill and of Praga appeared, to her court, to be huma-
nity itself. If she had known misfortune she might probably
have possessed the purest virtues; but she was spoiled by the
unvaried prosperity of her arms. Vanity, that fatal rock to
women, was jo to Catharine; and her reign will ever bear
the distinguing characteristic of her sex. But, in what-
ever light she is considered, she will ever be placed in the
first rank among those who by their genius, their talents,
and especially, by their success, have attracted the admira-
tion of mankind. Her sex, giving a holder relief to the
great qualities displayed by her on the throne, will place her
above all comparison in history; and we must recur to the
fabulous ages of an Isis and a Semiramis, to find a woman
who has executed, or rather undertaken such daring projects.
Whilom none forsook her in noble and useful influtions,
in the patronage of science and of the arts, and in the promo-
tion of the arts by which a nation is civilized and excated;
and whilst by the travels of Plato, Socrates, and other
philosophers and naturalists, she obtained an extensive ac-
quaintance with the various parts and productions of her
vast empire; she seems to have been too much seduced by
splendid novelties, and by her affinuity and zeal in the pur-
chase of expensive rarities throughout Europe, she merely
sacrificed to her vanity, and sunk the wife and benefi-
cent sovereign into the collector of toys and trinkets, Mifled
by an extravagant confidence in her own abilities, and jea-
ious of every kind of fame, she was desirous of acquiring
the reputation of an author, and of thus sharing in the ho-
our which Frederic of Prussia had obtained by his writings.
She accordingly wrote her celebrated "Instructions for a
Code of Laws;" several moral tales and allegories, for the
education of her grand-children; and a number of dramatic
pieces and proverbs, which were acted and admired at the
Hemitage. Her grand and futile undertaking of collect-ing
ing a number of words from 300 different languages, and forming them into a dictionary, was never executed. Of all her writings, her letters to Voltaire are certainly the best. They are more interesting than those of the old philosophical courtier himself, who repeats in his letters the same ideas and compliments in a hundred different forms, and excites her continually to drive the Turks out of Europe, instead of advising her to render her own subjects free and happy. Catharine was neither fond of poetry nor of music; and she often confounded it. She could not even endure the noise of the orchestra between the acts of a play, and therefore commonly silenced it. At her Taurian palace the concerts constantly dined with the two pictures of the sackings of Otehakof and Hissain before her eyes, in which Cazanova has represented, with hideous accuracy, the blood flowing in streams, the limbs torn from the bodies, and all palpitating, the demoralized fury of the slaughterers, and the convulsive agonies of the slaughtered. It was upon these scenes of horror that her attention and imagination were fixed, while Gaiaparni and Mandini were displaying their vocal powers, or Sarti was conducting a concert in her presence.

Previous to the death of Catharine the monuments of her reign resembled already so many wrecks and dilapidations: colleges, colonies, education, establishments, manufactories, hospitals, canals, towns, fortresses, every thing had been begun, and every thing given up before it was finished. As soon as a project entered her head, all preceding ones gave place, and her thoughts were fixed on that alone, till some new idea was started and drew off her attention. She abandoned her code, to drive the Turks out of Europe. After the glorious peace of Kaimardgi, she feemed for a time to attend to the interior administration of her affairs; but the whole was presently forgotten, that she might be queen of Tauris. Her next project was the re-establishment of the throne of Confinante; to which succeeded that of stabbing and punishing the king of Sweden. Afterwards the invasion of Poland became her ruling passion; and then a second Pogarinf might have arrived at the gates of Petersburg without forcing her to relinquish her hold. She died, again meditating the destruction of Sweden, the ruin of Prussia, and mortifying at the faceleafs of France and republicanize. Thus was the incessantly led away by some new passion still stronger in its influence than the preceding, so as to neglect her government, both in its whole and in its parts. This mania of Catharine, of planning every thing and completing nothing, drew from Joseph II. a very threat and satirical remark. During his travels in Taurida, he was invited by the emperors to place the second throne of the land of Ekatarinofal, of which she had herself, with great parade, laid the first. On his return, he said, "I have finished in a single day a very important business with the emperors of Russia; she has laid the first stone of a city, and I have laid the last."

We shall close this sketch of the character of Catharine with observing, that with all her varied and contradictory qualities, she seems to have obtained the love as well as the reverence of her subjects in general; who forgot her private crimes and the evils of her bloody wars, in her greatness and apparent regard to the public good. Coxe's Travels, vol. i. and ii. Tooke's Life of Catherine II. in 3 vols. Ruliere, Hist. des Ancêtres sur la Régence de Ruliere, &c. Paris, 1797. Segur, Vie de Catherine II. Imperatrice de Russie, &c. 2 vols. Svo. Paris, of which an enlarged translation in English was printed in three vols. Svo. 1798. Secret Memoirs of the Court of Petersburg, &c. translated from the French.

Catharine of Sienna, St. was born in the city, whence her name was derived, in 1347; and having vowed virginity at eight years of age, affronted the Dominican habit. Pretending to extraordinary revelations, and disdaining by her piety and charity, she obtained considerable influence; so that she succeeded in effecting a reconciliation between the Florentines and pope Gregory XI., by whom they had been excommunicated, and in persuading this pontiff to restore the papal seat to Rome, after it had subsisted 72 years at Avignon. During the tetch of that afterwards took place, Catharine adhered to Urban VI. She died in 1380, and in 1464, was canonized by pope Pius II. Of her works there are extant a volume of "Italian Letters," written to popes, princes, cardinals, &c. first printed at Venice in 1506, and translated into French in 1644; "Six Treatises on the Providence of God;" "A Discourse on the Annunciation of the Blessed Virgin;" and a treatise entitled "The Divine Doctrine delivered by the Eternal Father speaking to the Spirit," with some other devotional pieces. Du Pin. Ecl. Hist. vol. v. p. 73. See Fraternity of St. Catharine.

Catharine of Bologna, St. a nun of the order of St. Clare, was born at Bologna in 1413, and became, in consequence of her reputation for sanctity, inferior of the monastery of the order to which she belonged, in her native city, and which was completed before her death, in 1453. Besides other writings in Latin and Italian, her own "Revelations" were left, sealed, to her confessor. She was canonized by Clement VII. Du Pin. Ecl. Hist. vol. v. p. 84.

Catharine, Fraternity of St., at Sienna, a fort of religious society instituted in that city, in honour of St. Catharine, a saint famous for her revelations, and for her marriage with John Chriß, whose wedding-ring is still preserved as a valuable relic. This fraternity yearly endows a certain number of destitute virgins, and has the privilege of redeeming annually two criminals condemned for murder, and the same number of debtors, by paying their debts.

Catharine, Knights of St., of Mount Sinai, an ancient military order, erected for the assistance and protection of pilgrims going to pay their devotions to the body of St. Catharine, a virgin of Alexandria, distinguished for her learning, and said to have suffered martyrdom under Maximin.

The body of the martyr having been discovered on mount Sinai, caused a great concourse of pilgrims; and travelling being very dangerous, by reason of the Arabs, an order of knighthood was erected in 4067, on the model of that of the Holy Sepulchre, and under the patronage of St. Catharine: the knights of which obliged themselves by oath to guard the body of the saint, to keep the roads secure, observe the rule of St. Basil, and obey their grand master. Their habit was white, and on it were represented the instruments of martyrdom whereby the saint had suffered; viz., a half wheel armed with spikes, and traversed with a sword stained with blood.

Catharine, order of St., in Modern History, belongs to ladies of the first quality in the Russian court. It was instituted in 1714, by Catharine wife of Peter the Great, in memory of his signal escape from the Turks in 1711, or as others lay, by Peter, in honour of his wife Catharine, on account of the assistance which she gave him in the camp on the Truth.

The emblem of this order is a medal of gold, enriched with diamonds, having on one side the image of St. Catherine, and on the other a cross pattée, enamelled. This is worn pendant to a broad white ribbon resting on the right shoulder, and brought under the left arm. On the left breast
a company at Lisbon. This company has, upon the coast, three considerable establishments, where they take about 400 whales every year, the produce of which, both in oil and spermaceti, is sent to Lisbon by way of Rio-Janeiro. The approach of ships to this island is very easy; as at 18 leagues in the offing there are 66 fathoms of water, over a bottom of soft mud, gradually sloping till within four cables' length of the shore, where there are full four fathoms of water. The ordinary channel is between the island of Álvaredo and the north point of St. Catharine; but there is another between the islands of Gal and Álvaredo, which, however, has not yet been sufficiently explored. The best anchorage is half a league from Porto-I'll, in 6 x fathoms, and oozzy bottom; the citadel bearing S. 3° W., the fort on the larger point S. 6° E. There are several watering places both on the island and the continent; and that creek may be chosen where the wind renders the landing most easy. The navigation of boats is very difficult in this harbour, which is two leagues wide as far as the bright where the town islands; and there is a violent surf always breaking on the lee-shore. The tides are very irregular; and the flood comes in between the two channels lying north and south. Up to this height it rises but three feet. In this harbour provisions of every kind may be easily and cheaply procured, as they are very plentiful. A large ox cooks eight piasters, a hog of 150 lb. weight costs four, and turkeys are sold for a piaster the pair. Fish may be obtained in abundance by merely throwing the net. Oranges are sold at the rate of 500 for less than half a piaster, and vegetables of every kind are reasonable. The inhabitants are very hospitable, and their manners are gentle and obliging; but they are very superstitious, and jealous of their wives, who never appear in public. The government is in this island, as it is in all the Portuguese colonies, purely military. It has three forts, which form nearly an equilateral triangle, the bale of which is to the northward, and the vertex towards the south. That to the east is upon the N.E. point of St. Catharine, about 1/4 of a league from the Perroquet island; that to the west, which is the most considerable, is on an islet near the continent of America, and the third is upon the largest of the two islands called "Les Ratones." The road, which is open only to the N.E. winds, is sheltered to the east by the island of St. Catharine, and on the west by the continent; on the south by the land both of the island and the continent, which approach so near, that they leave between them only a strait of less than 300 toises wide. Its entrance cannot by any means be shut against ships of war of any rate or construction. It is so extensive that although the forts are mounted with guns of a great calibre, ships may anchor there very commodiously and securely, out of the reach of those guns. The principal fort, which is in fact only a large enclosed battery, is situated on a little island, of moderate elevation above the level of the sea, at about 300 toises from the terra firma, and opposite a ridge much higher than itself, is capable of making a regular defence; yet this fort is the butt of honour, where the general officer, who commands the whole settlement, would fix his quarters in case of an attack; but in time of peace he resides at "Nossa Senhora del Defeito," a town that is absolutely open, and only defended by a small battery, 3 barbette, on the island of St. Catharine, and on the extreme-west point of the little strait above-mentioned, behind which the town is built. The garrison of the principal fort was, in 1755, composed of 50 men, badly clothed and ill paid, under the command of a captain. Traffic's Voyage, vol. i. and ii.

CATHARINENBURGH, or ECHETERINBURG, N. a province.
CATHARTIC

a province of Asiatic Russia, formerly included in the government of Tobolik, and since constituting one of the two provinces of the government of Perm. This is also the name of one of the seven districts of the province, seated on the river Iset, not far from its origin. Near Catharinem- 
burch are gold mines; the ore is very marial, commonly of a cubic form in a quartz matrix; and the gold is extracted by washing. The annual produce of pure gold never exceeded 300 pounds, and was commonly much less; in 1772 it was only 100 pounds. The gold is obtained at the rate of 40 guineas per pound; when coined, it produces 68l. 5s. so that the profit is not very considerable. At Catharinem- 
burch the crown has established a mint for coining the copper, produced from the imperial and private foundries, into that species of money which is current throughout Russia, and is transported by water to Moscow, Petersburg, and other parts. The value of copper money, annually coined, is 400,000L. The crown receives a pood of this metal upon an average at 1l. 2s. 6d. and influxes it, when fruck, at 3l. 4s.; so that government gains upon the copper coinage 257,625L. The town is seated upon the river Iset, which runs through it, and is regularly built in the German manner. It was begun by Peter I. in 1723, and finished in 1726 by his comfort the czarina Catharine, from whom it derived its name. This town may be reckoned the centre of all the Siberian mine 
works belonging to the crown; and on this account it is the residence of the director of the Siberian mines, who issues out his instructions to the sub-directors, and pays their accounts.

CATHARINESLAF, CATHARINOSLAV, or ECAT- 
TERINOSLAF, a government of Russia, which contains the greatest part of that territory which was wrested by the late empress Catharine II. from the Turks, and comprises New Russia, the former government of Azof, and Crimea Tartary. It is divided into two provinces, viz. Catharinesla, including New Russia and Azof, and comprehending 14 districts, and Taurida or Crime Tartary. It is also the name of one of the districts of the province, seated on the Dnieper.

CATHARINESLAF, CATHARINOSLAV, or the "glory of Catharine," the capital of the province built by the late em 
press, and seated near the spot where the small river Kiltzin falls into the Samara. It is colonized by many Greeks and Armenians from Crime Tartary, and by others who served in the preceding war against the Turks; 78 miles N.E. of Cherfon. N. lat. 47°23'E. long. 35°15'.

CATHARMA, from καθαρμός, I expiate, in Antiquity, some miserable or flagitious wretch, sacrificed to the gods, as an expiation for the plague, or other calamity. Such was the prophet Jonas, cast into the sea; and such, as some have suppos'd, does St. Paul with himself to be. See Accu-

cursed.

CATHARMA, καθάρμος, from καθάρω, to purge, in Medicine, imports the excrements purged from any part of the body; as the stomach, intestines, or bladder.

CATHARMOS, in Medicine, of the same derivation, implicts purgation by medicines, or the cure of a disorder by superfluous ceremonies or sacrifices. The cure of the king's evil, by the royal touch, if such a thing had been effected, might be said to be performed by a catharmos.

CATHarpins, in the Rigging of a Ship. See Cat-
harpins.

CATHARTIC Extract. See Extractum cathar-
ticum.

Cathartic salt, ful catharticum amarum, a denomination given to what we improperly call Epsom salt.

Cathartic medicines, are those substances which quicken and increase the evacuation from the intestines by fluid. Medicines of this class have been employed by physicians since the first dawn of physic; and have been administered with various views and intentions, according to the prevalent theories of the time, or the favourite doctrines of individuals. Those who were tainted with the sects of judicial astro-
logy, preferred purgatives at certain times and feasts; conceiving that they would prove more beneficial or hurtful, according to the conjunction or opposition of the planets, or the age of the moon. Those again, who were partial to the doctrines of the humoral pathology, employed cathartics with the intention of expelling peccant matter which had been lepamed from the mafs of fluids by an appropriate fer-
mentation. The same pathologists taught that different cathartics possessed distinct powers, and moved different fluids by a specific action. Hence they have denominated some of these substances ebolagogues, others phlegmagogues, hydragogues, and melanosogues, as they were supposed to expel more particularly bile, phlegm, water, &c.; and they have displayed much apparent fagacity, in selecting the cat-
arthic adapted to the expulsion of the fluid prevalent at the time. But these doctrines are now exploded, and the specific operation is not confirmed by subsequent expe-
rience.

Modern physicians have two objects in view in the admi-
istration of cathartic medicines; the one is to empty the bowels simply, or to bring off their contents, which are out of the course of the circulation, and therefore, already, in a manner, extraneous to the body; the other is to excite an increased secretion of fluids into the cavity of the intestines, or, in other words, to induce purging. The medicines thus employed have generally been allotted into two classes; those which produce the former effect, being denominated laxatives, and those conducting to the latter, purgatives.

The operation of a purgative medicine on the intestinal canal may be considered as three-fold. In the first place, it stimulates the muscular fibres of the intestines, quickens their action, and therefore augments the natural peristaltic motion of the bowels, by which means their present contents are more quickly propelled and discharged. Secondly, it stimulates the exhalent vessels, which terminate in the inner coat of the intestines, and excites them to pour out a more copious discharge of fluids; and also the mouths of the excretory ducts of the mucous glands, by which the natural mucus of the intestines is much increased; and hence the evacuations by foalre are not only quicker, but the faecal matter is thinner and more abundant. And, thirdly, the foals are rendered still more copious, by an additional portion of the fluids furnished by the neighbouring vifera, the liver, pancreas, &c. to which the stimulus of a purgative, especially of the more active ones, extends. These effects are probably communicated to the whole range of the intestinal canal, from the upper orifice of the stomach to the lower extremity of the rectum, or anus.

From this view of the immediate effects of cathartic medicines upon the intestines, their utility in some diseases, and their injurious tendency in others, as well as the necessity of varying their degree of activity under different circumstances, will be readily understood.

If we consider the great length of the alimentary canal, and the number of vessels and mucous follicles, as well as the larger ducts from the liver and pancreas, which open upon its inner surface, it will be obvious that purgatives, even of a moderate stimulating power, by opening at once all these outlets, may occasion a great general evaporation and diminu-
tion of the fluids of the body. Hence, in acute inflammatory diseases, where over-dilution of the vessels is to be avoided, and the preternatural increase of the active powers of the system is to be restrained, the evacuation of the intestines by purging is (next to blood-letting) the most powerful expe-
di
dine, and generally makes an important part of what is called the cooling or anti-phlogistic plan of treatment. When purgatives are given with this intention, however, the principle must be pursued with some limitation, and those of the mott acid and drastic nature must be avoided; because the diminution of general titillus produced by the depletion of the vessels, and the expulsion of the faces, would be counteracted by the extraordinary irritation of an acid purge.

Another circumstance apparently results from the evacuation by purging, which renders it of considerable importance in particular diseases; namely, a change in the distribution of the blood to the different parts of the system. It seems to follow, of necessity, that if an evacuation be made from one set of vessels, the afflux of fluids to these will be increased in order to supply it, and, consequently, the afflux to other parts of the system will be diminished. 

Upon this principle, Dr. Cullen explains the utility of purgatives in disorders of the head, which arise from over-tumors or over-activity of the vessels of the brain; such as apoplexy, and other comatose affectations, mania, phreny, head-ach, &c. The afflux of fluids in the vessels of the abdomen, which supply the intestine, being increased by purging, the afflux will be proportionally diminished in the vessels which carry blood to the head, and both the quantity and impetus of the blood in the head will thus be lessened. (Cullen, Mater. Med. vol. ii.)

In the same way he partly explains the good effects of cathartics in the small pox, and other cutaneous diseases, from the balance of the distribution of the fluids between the internal parts and the external surface. But it is probable that they are more useful by removing the local irritation of the faces, and occasioning a considerable depletion, and a consequent diminution of fever in the system at large. For in diseases of the skin, unconnected with fever, their good effects are very inconsiderable.

Whenever the contents of the intestines are morbidly retained, whether in consequence of a flowness of the peritonic motion, from a torpor of the moving fibres; or from a laxity of the intestines, which permits the faces to accumulate; or from a deficiency of bile; or from habitual neglect of regular evacuation; (see Constipation,) the use of cathartics of one kind or the other is indicated, in order to prevent the accretion of more serious complaints, which will ultimately result from the colitivencs. The nature of the caufe, or the concomitant circumstances will point out the particular sort of medicine, which may be most appropriately employed. If the colitivencs, for instance, be accompanied with a flaccid habit, or with symptoms of nervous mobility, or much flatulence, and irregular distention of the bowels, some of the warmer aromatic laxatives should be administered. If the secretion of bile appear to be deficient, mercurial and aloetic medicines, the latter of which tend to supply the deficiency, and the former to relieve the bilious secretion, should be preferred.

In those cases, however, in which the morbid retention of faces is not habitual, but accidental, and accompanied with some more acute symptoms;—as with violent pain, constricting the colic;—with pain, tenesmus, and filmy or bloody floof, as in dysenteric;—or with pain and acute fever, as in inflammation of the bowels—cathartics, though absolutely necessary, must be varied in their nature and mode of administration, after a cautious view of the circumstances. In colic, for example, they will be of little advantage in many cases, and more especially in the colic produced by lead, until the painful spasmatic contraction of the bowels has been relaxed by the previous use of opiates. In dysenteric, they must be combined or alternated with opiates, otherwise the irritation which they occasion, in that tender state of the intestines, will counterbalance the effects of the evacuation, and keep up the symptoms of the disease. And in enteritis, or inflammation of the coats of the alimentary canal, the same irritation will tend to increase the inflammatory condition, and the consequent constrictions, and therefore impede, rather than expedite, the evacuation of the fecal matter, if they be employed before blood-letting and other remedies have reduced the inflammatory state. See Cole, Dysentery, Sec.

In a work lately published by an excellent practical physician, Dr. James Hamilton of Edinburgh, a degree of importance is assigned to cathartic medicines, in the treatment of several diseases, which they have not hitherto been considered as entitled to. Independently of the generally admitted opinion, that a loaded and constricted state of the intestinal canal is a common cause of general bad health, he maintains that this state usually accompanies and aggravates the other symptoms of fever; and that it is also the immediate cause, or a leading and permanent symptom, of certain disorders peculiar to children and young people; there are chorea, or St. Vitus's dance; marasmus; chlorosis, or green sickness; Ilesematema, or vomiting of blood; and even in Hysteria, and some chronic nervous diseases. In these diseases he never uses medicines in a purging dose; his intention being simply to expel the present contents of the intestines, and not to increase the secretion of the fluids into them. He considers gylters as inefficient expedients for moving and conveying off, through the whole extent of the intestines, the feculent matter, rendered offensive and irritating, especially in fevers, by coniposition, and by the changed nature of the secreted fluids, which seems to take place in the febrile state. In Typhus fever, he says, "it is now some years since I have left off almost entirely the practice of ordering emetics and gylters. I trust that purgation of inferior regular saline evacuation: for this purpose, however, a daily purgative is not always required. Thus I think I conduct the treatment of typhus fever to a favourable issue, with more certainty, and with the greater ease and comfort of the patient." We have had an opportunity, in a few instances, of verifying in a very satisfactory manner this important practice.

Chorea, or St. Vitus's dance, has been almost invariably treated with tonic medicines, especially with bark and metallic preparations, and with various stimulants and antispasmodics. It is unnecessary to say with how little effect in general. In every instance Dr. Hamilton has found that a large quantity of black and offensive feculent matter was collected in the bowels, and his plan of cure has consisted in a regular exhibition of laxatives, until the stools (which in all the diseases before mentioned should be regularly examined by the practitioner) assumed their natural appearance. With this intention the practitioner must persevere firmly in his measures, especially in the confirmed state of chorea; for if he relaxes he will be unsuccessful. By this treatment, which consisted in giving three grains of calomel, with six, eight, or ten, of jalap, daily, "Chorea is speedily cured, generally in ten days or a fortnight."

By means of the fame, or similar medicines, exhibited in the same way, he has speedily succeded in removing the symptoms of chlorosis; and hematemesis; and of some other hypochondriacal and nervous complaints, and he attributes the relief, which patients under these disorders derive from drinking mineral waters, to their purgative qualities, rather than to any other property which they may in a flight degree possess. (See Observations on the Utility and Administration of Purgative Medicines.)

When morbid or extraneous bodies are introduced into or generated
generated in the intestines, as in the case of worms, &c. cathartics are obviously indicated. But it should be observed, that the indiscriminate use of active purgatives in these cases, especially in young and delicate children, is often productive of more harm to the constitution, than the worms which they are intended to expel. They should be administered sparingly, and at some intervals; sufficient time being interposed for the operation of medicines, which may be deleterious to the animal, and of which, by augmenting the intestines, may prevent that morbid production of mucus, which is probably a serious danger to their generation.

Cathartics, either in a laxative or purgative degree, are useful in several other complaints, partly by exciting the intestines to evacuation, and partly in consequence of the extension of their stimuluses to the neighbouring visceras of the abdomen: as in jaundice, indigestion, impregnation of the medes, &c.

Another important operation of cathartic medicines remains to be noticed: namely, the stimulus they exert on the absorbent vessels, by which these vessels are excited to an unusual action, and thus to take up fluids which are morbidly effused. The fact is undeniable, whatever may be the principles on which it is explained. Dr. Cullen observes, on this subject, that, "as in every cavity of the body there is an exhalation and inhalation, or absorption, constantly going on, it is presumed that there is some balance constantly preferred between the secretory and absorbent powers; so that if the former are increased, the latter will be allo; and, therefore, that when the secretions are, upon occasion, much increased, the action of the absorbents may be particularly excited. This explains why purging often excites the action of the absorbents, to take up more copiously the fluids that were otherwise flagrant in the adipose membrane, or other cavities of the body, and thereby often proves a cure of dropsy." (Mater. Med. vol. ii. p. 56 c.) This explanation is perhaps, little more than an explicit statement of the fact. It is certain, however, that afeties, or dropsy of the abdomen, has been often affected by means of acid, cathatic purgatives, such as gamboge, feaminey, &c.; when diuretic remedies have failed. But it is obvious that these remedies can only be administered to those, who retain considerable strength of constitution, debilitated neither by inveterate intemperance, old age, nor a long disease.

Cathartic medicines may be introduced into the alimentary canal either by the mouth, or by the inferior aperture in the form of clyster. The preceding observations apply to the former mode of administering them. The latter must be adopted in those cases, in which the stomach is unable to retain, or would be injured by irritating medicines; as in colic, or inflammation of the stomach, and in febrile complaints attended with extreme debility, especially in the latter stages; since by this mode the contents of the lower parts of the intestines are finely evacuated, without any filaments to the secreting vessels, and with little or no irritation of the system at large. See CLYSTER.

In delicate and irritable constitutions the ill effects of an active purgative may be considerably diminished, without impairing its evacuating power, by combining a portion of opium with it. The nausea and griping, which are excited by some species of cathartics, may be alleviated by the addition of some aromatic medicine; or by the minute division of the sublimate by means of triturations with some other; as of jalap with crystals of tartar, &c.; or by giving it in divided doses at short intervals. This last mode is generally to be preferred with regard to very drastic cathartics; by which means the full effect is enfeebled, and any severe or dangerous degree of irritation is avoided.

CATHAY, in Geography, an ancient name of China; which see.

CATHEDRA, in a general sense, a chair.
The word is more particularly used for a professor's chair, and a preacher's pulpit.

CATHEDRAL, in a church wherein is a bishop's see, or throne, in a church.

CATHEDRAL, a phrase used in speaking of the solemn dictates or decisions of prelates, chiefly the popes, delivered in their pontifical capacity.
The advocates for the papacy maintain, that the pope is infallible, ex cathedra, a term of ancient theology entirely unknown to the ancients. Even those who used it do not agree in the explication of it.

CATHEDRAL, a church wherein is a bishop's see, or seat. See Church and Bishop.
The word comes from the Greek καθήδρα, chair, of κάθειν, to sit.
The denomination cathedral seems to have taken its rise from the manner of sitting in the ancient churches, or assemblies of primitive Christians; in these the council, i.e. the elders and priests, was called presbyterium; at their head was the bishop, who held the place of chairman, cathedrals, or cathedricus; and the prebendaries, who sat on either side, were also called by the ancient fathers episcoporum. The episcopal authority did not reside in the bishop alone, but in all the prebendaries, of whom the bishop was president.

A cathedral, therefore, originally, was different from what it is now; the Christians, till the time of Constantine, having no liberty to build any temple; by their churches, they only meant their assemblies; and by cathedrals, nothing more than consistorys:—which appears the vanity of some authors, especially the Spaniards, who pretend their cathedrals to have been built in the times of the apostles.

CATHEDRAL SERVICE. At the beginning of the reformation, the whole English choral service, including the process, prayers, and responses, was set to musical notes, and first published in 1550, by John Marbecke, organist of Windfor. The premature reforming zeal of this musician, nearly made a martyr of him, in the time of Henry VIII. He had, indeed, the honour of being condemned to the stake, with three other persons, who were burnt for hereby, but was pardoned by the intercession of Sir Humphrey Falker.

His notation of the English cathedral service was published under the following title:

The Booke of Common-prayer. noted. 1550.

Imprinted by Richard Grafton, Printer to the Kings Majestie, cum privilegio ad imprimentum solam.

As this book is become very scarce, we shall present the reader with a considerable extract from it.

"In this booke is conteyned so muche of the order of common-prayer, as is to be forre in churches; wherein are used only these iii fortres of notes."
CATHEDRAL SERVICE.

The first note is a breve note, and is a breve. The second is a square note, and is a semibreve. The iii, a pryeke and is a mynymme, and where there is a pryeke by the square note, that pryeke is half as muche as the note that goeth before it. The iii is a close, and is only used at the end of a verse."

• Strained, or stretched out: perhaps from its being the longest note used in chanting. Junius makes breve and strain synonymous.

MATTINS.

The Quere with the Priest.

O 

O Lorde open thou my Lippes

And my Mouth shal shew forth thy Praif.

Te Deum Laudamus.

We prayfe the, O Lorde, we knowlege the to be the Lorde.

All the earth doth worship the, the Father everlast ing.

To the al Angels cry aloud, the Heavens, and all the Powers therin.

To the Che-ru-bim, and Ser-aphin, continu ally

do cye, Ho-ly, Ho-ly, Ho-ly, Lorde God of Sa-ba-oth.
CATHEDRAL SERVICE.

Heaven and Earth are full of the Majesty of thy Glory.

The glorious Company of the Apostles pray the.

The goodly fellowship of the Prophettes, pray the.

The noble Army of Martyrs pray the. The Holy Church throughout all the World doth knowlege the. The Father of an infinite Majesty. Thy honorable, true, and onlye Sonne.

Also the Holy Ghost the Comforter. Thou art the Kyng of Glory, O Christ. Thou art the everlast- ing Sonne of the Father.

When thou tookest upon the to deliver Man thou didst not abhorre the Virgins Wombe. When thou haddest overcome the sharpnes of Death, thou didst open the Kyngdome of Heaven to all believers.
CATHEDRAL SERVICE.

Thou sittest on the right hand of God, in the Glorye of the Father.

We believe that thou shalt come to be our Judge. We therefore pray

the, helpe thy serrauntas whom thou haft redeemed with thy preci-

ous bloud. Make them to be nominated wyth thy Saints in Glorye e-

verlafting. O Lorde, save thy people, and bleffe thyne heri-

tage.

Governe them and lift them up for ever. Day by Day we magni-

ifie the And we worshipp thy Name ever World wythout end.

Vouchsafe, O Lorde to kepe us this Day without Sinne. O Lorde have

Mercy upon us, have Mercy upon us. O Lorde lett thy

Mercy lighten upon us, as our trufl is in The. O Lord

in The have I trusted, lett me never be confounded.
CATHEDRAL SERVICE.

After the Second Lesson of these that follow.

Benedictus Dominus.

Blef fed be the Lorde God of If - ra - el

The same Chant repeated to the end.

for he hath Visit - ed and Redeem - ed his People, &c.

Blef fed be the Lorde God of If - ra - el for he hath

Vi - si - ted and Re - de - med his People, &c. to the end.

In this manner the whole Morning and Evening Service, as it is now Chanted, is set; except the Litany. At the end is the name of John Marbeck.

At this time, the plain-song of the Romish church in the chants of the principal hymns and responses, remained nearly the same, as may be seen in comparing the Te Deum laudamus, and other parts of the cathedral service, in this publication, with the missals, graduals, and antiphonaries of those times. The chant to the Te Deum, as published by Melbournus, {Antiquae Mus. Ant. Sept. Amst. 1652. Vide pref. Lectioni benevoli,} from a copy nearly as ancient as the hymn itself, and another example of the same Canto Ferro, given by Glareanus, {Dodecad. p. 110.} in 1547, correspond exactly with that which was retained by Marbeck, at the time of the reformation: as the mode, the dominant, and medius, are all the same; nor is the least deviation discoverable, except where the different number of syllables in the translation required it, and which affect the melody no more, than those slight changes which happen in the manner of use of any two choirs in singing the same chants, or even in adjusting different hands of any song to the same tune.

Marbeck was admitted, in 1549, to the degree of bachelor in music, at Oxford, according to Anthony Wood, {Faiti Oxon.} who erroneously calls him James Marbeck: he is honourably mentioned by Bale, because he had been perverted by the Catholics, and his name is omitted by Pitts, for the same reason.

It seems as if we may safely conclude, that the chief part of such portions of Scripture, or hymns of the church, as have been set by English musicians to Latin words, were produced before the reformation, or, at least, in queen Mary's time; that is, before the year 1555, when queen Elizabeth ascended the throne, by which time a school of counterpoint was formed in this country, that was equal, at least, to that of any other part of Europe. A reason, however, may be assigned for the choral music of every Christian country approaching perfection by nearly equal strides.

Before the reformation, as there was but one religion, there was but one kind of music in Europe, which was plain chant, and the difficult built upon that foundation; and as this music was likewise only applied to one language, the Latin, it accounts for the compositions of Italy, France, Spain, Germany, Flanders, and England, keeping pace with each other, in style and elegance. All the arts seem to have been the companions, if not the producers, of successful commerce; and they will, in general, be found to have pursued the same course, which an admirable modern historian has so well delineated: {Hist. of Charles V. vol. i. sect. 1.} that is, like commerce, they will be found, upon inquiry, to have appeared first in Italy; then in the Hapsburg towns; next in the Netherlands; and by transplantation, during the 16th century, when commerce became general, to have grown, flourished, matured, and diffused their influence, in every part of Europe.

If this were a place to illustrate such an idea, it would be easy to shew, that ecclesiastical music, in the middle ages, was all derived from the papal chapel, and court of Rome; that counterpoint was first cultivated for their use; that it travelled thence to the Hapsburg towns, and the Netherlands, where the influence, which flowed from successful commerce, afforded encouragement and leisure for its cultivation; till about the middle of the 16th century, when, by the general intercourse which traffic and the new art of printing introduced, all the improvements in harmony, which had been made in Italy and the Low Countries, were communicated to every other part of Europe; which not only stimulated the natives to adopt and imitate them, but to improve and render them more perfect, by their own inventions and refinements.
CATHERETIC, doctor, doctor cathedricus, denotes a doctor poissif-id of a chair or fellowship in some of the universities of Spain.

They say a cathedratic doctot of Salamancii, of Alcala, &c.

CATHEDRATICUM, in Ecclesiastical Writers, denotes a sum of money, amounting to two shillings, annually paid by the inferior clergy to their bishop, or as often as he visited his diocese, ob honorem cathedrae, i.e. as an argument of their subjection, and for the honour of the bishop's seat or cathedra. This was otherwise denominated fxsoulaticum, and by modern writers procurament.

CATHEDRATICUM also denotes a sum which bishops newly ordained gave partly to bishops or patriarchs, by whom they were consecrated, and partly to the clerks and notaries who officiated on the occasion.

This was also called disponen, as being given on account of the throne, or chair, they had now obtained, and fxsoulaticum, or synodals.

Bishops consecrated by patriarchs or metropolitans, provided their church was not worth less than thirty pounds of gold, to make a hundred solidi by way of cathedraticum.

CATHETHM, in Geography, a town of Arabia, 80 miles S. of Baffira, and 170 N. of El Cattif. N. lat. 29°. E. long. 47°. 14'.

CATHENON. See CATHETIN.

CATHERETIC. See CATHEDRATIC.

CATHETERINA, SANTA, in Geography, a small Grecian island, which seems to have been detached from the south point of the island of Rhodes. It is a remnant of the land which joined it to another country, in like manner inhabited, and which bears the name of the island of Scarpanto.

CATHETERINE, in Biography. See CATHARINE.

CATHERINE, St. in Geography, a pleasant island in the harbour of Sunbury, and state of Georgia, in North America. Alfo, a small productive island on the south coast of St. Domingo, 20 leagues E. of the town of St. Domingo.

CATHETER'S TOWN, a town of America, in the flate of New York, and county of Ontario, situate 3 miles S. of the S. extremity of Seneca lake.

CATHETER Bay lies at the E. end of the island of Jersey, southward of the point so called, and affords a good road in well country winds.

CATHETER, St. Cap., lies on the W. coast of Africa, in S. lat. 24° 5', and E. long. 10° 38'.

CATHETER'S Fords lies in the straits of Magellan, near the cape end. N. lat. 52° 48'. W. long. 67° 57'.

CATHETER'S island, an island of America, on the coast of Florida. N. lat. 31° 30'. W. long. 81° 41'. Alfo, an island off the coast of Honduras. See PROVIDENCE island.

CATHETER Sound lies, with a small island of the fame name, on the coast of Georgia, in N. America, in 31° 10' N. lat.

CATHETER'S St. Tower, a sea-mark on the summit of St. Catherine's hill down, on the back of the Isle of Wight, about 750 feet higher than high-water mark. N. lat. 50° 34'. W. long. 1° 19'.

CATHERLOUGH. See CARLOW.

CATHETER, in Surgery, a curved tube employed for drawing off the urine, or injecting fluids into the bladder. The term catheter is derived from cathoire, dimittus, to thrust into; and although it signifies a hollow instrument, or syphon, for the above purpose, in the writings of Celsius, Galen, and Paulus Aegineta, this word has a very different meaning in Vol. VII.

the works of Hippocrates, who uses it to denote a piece of twisted cotton or lint introduced into ulcers. Vide Defin. Medic. Gorherr.

It appears from lib. vii. cap. 26, of Corn. Celsius's surgical work, that catheters were formed at first of polished copper or brass, though the Arabians made them of silver, lead, tin, or leather; and there can be no doubt that they were used by the ancients, not only for drawing off the urine, but for the purpose of removing obstructions in the urethra, as we now employ bougies: this is further evident from a passage in Galen, De Locis Afficectis, lib. i. where he treats of caremules in the urinary passage. See likewise Galeni De Math. Med. lib. v. cap. v.

It is also perfectly certain (notwithstanding the late claims of Mr. Jeffes Foot, in his treatise upon the "Vesica Lotura," that the older surgeons were accustomed, on various occasions, to inject the bladder through a catheter or cannula, precisely in the manner we administer an enema. Vide Paulus Aegineta, lib. vi. cap. 59. "De Catheterifino & Civitatis Vesica," likewise, Albucasis, lib. ii. fect. 59. "De Modo Vesica Liquorem Syringa infundendi, & de Forma Instrumen- torum ad loc idoneorum." Gorherrus describes the operation of using the catheter as follows: "Ea aStoqpee; tell administrationes chirurgicæ ratio qua injicimus per Ca- theterem in vesicam id quod ad ejus curacionem convenit; vel "examinus id quod impedit ne urina reddatur, fove con- cussus intus fangus fit, five aliud quipppiam, recto fiphone "immisso, quom Graeci catisterg vocant." For a particular account of the ancient modes of injecting the urinary bladder, and to the instructive reader more especially to the 55th section of Albucasis, already quoted, and to Avi- cenna, lib. in. Fen. 19. Traet. 2. cap. 9. This practice was continued by several surgeons of the middle age, but soon afterwards appears to have been generally neglected, until it was revived by Le Dran.

Although the original use of the catheter null necessarily have required it to be made of a tubular form, it is strange that this instrument has been described by many respectable French surgeons as a solid instrument! Thus, for example, M. Sue (in his Dict. de Chir.) expressly says, "Mal-a-propos confond-on le ca- theter avec la fonde: Le catheter n'a point de cavité intéri- sure; mais seulement une canniule qui regne tout le long de fa partie convexe, au lieu que le fonde est creuse inte- rieurement. Le premier instrument fera a connoître les pieux qui font dans la vessie, & sa fonde l'opération de la "taille. Le second fera à évacuer l’urine contournée dans la "vessie. Il est vrai que, dans plusieurs cas, celui-ci peut "supprimer à l'autre, mais non pas le premier au second." Again he tells us, "Le cathéterisme n'ira autre chose que "la vindicatidion du cathèter dans la vessie, p. ur s'affurer de l'"existence d'une pierre, ou faire l'opération de la taille "et on pas pour évacuer l'urine; ce qui peut se faire "qu'avec la fonde."

In the old French Encyclopédie, M. Louis says, that "some authors are accustomed to give the name of catheter "moreparticularly to a grooved sound which serves to "conduct the lithotome in the operation of cutting for the "fome!" whereas, by all English surgeons, this instrument is called a stiff. (See Article Lithotomy.) The sound is a stiff steel instrument, without any groove: the stiff is made of the same form and materials as the sound, but is grooved on its convex side; and the catheter is hollow throughout its whole extent, whatever materials it may be made of. The sound and the stiff are always curved to the shape of the urethra, and are inflexible; but the catheter may be made either of a rigid or a yielding substance; and in the

former

former case it must also be curved like the found. The flexible catheters are now generally made of wove linen cylinders, covered with a coat of chiaie gum; the blad must be fabricated hitherto by M. Bernard of Paris, but they are at present well manufactured by Mr. Walsh of London. Their size and form vary, according to the sex or age of the patient. Bernard, in his dictionary of surgery, gives the following account of this instrument, as it is fabricated in Germany.—"One of the most useful inventions which have been made with respect to these instruments, is to construct them of chiaie gum, and the merit of this invention is to be ascribed, without doubt, to Mr. Theden. (Neue Beun- kungen u. Erfahrungen, &c. Th. ii. Berlin, 1782, pag. 113.) They were afterwards improved by a silver-smith at Paris, of the name of Bernard, who directed not to apply the dif- solved chiaie gum to a wire-cylinder, as Mr. Theden had done, but to one made of knitted silk; and these catheters certainly deserve to be recommended in preference to all others. But with respect to their price, the elastic catheters that are prepared by Prof. Pickel, (Richter's Chirurg. Bibliothek. ii. vi. p. 512.) of Würzburg, deserve particular recommendation. These consist of silk cylinders plaited or worked upon a probe, and afterwards covered with the following varnish. Three parts of white lead, one part, or fugar of lead with boiled hulled oil, which is the common varnish used by cabinet makers, mixed with one part of melted amber, and the same quantity of oil of turpentine. With this varnish he spredes the silk cylinders, and repeats this three times as soon as the former coating has dried in the open air; after which he puts the catheters into a baker's oven 24 hours, when bread has been baked in it the last time, and when it retains the temperature of 60°—70° Reaum. Here he lets them remain 10 or 12 hours. When he has taken the catheter out of the oven, he rubs the ine- qualities off a little with pumice stone, leaves up of the end, cuts into it the oblong lateral aperture, and then spredes it 12 or 15 times more with the varnish formerly mentioned. Every time, however, the catheter must be well dried in the open air before the varnish is spread upon it again, and after every third coating which it has received, it must be put again into the bake oven, so that in all it must have received from 15 to 18 coatings with varnish, and have been laid five or six times in the oven. The end is smoothed off well; each of these catheters costs a dollar.

The flexible catheters possess great advantages over those made of metal. For, in the first place, they can be introduced much more easily than the metal ones, even by an unpractised hand. 2. They may be suffered to remain in the urethra and bladder as long as is necessary, without occasioning much inconvenience. 3. There is no danger of injuring the tender surface of the urethra with them, or of pieces breaking off and remaining behind. 4. They may be used equally conveniently both for children and adults.

Another very important use may be made of elastic catheters in all cases in which the introduction of nourishment by the mouth is impeded or obstructed, as in wounds of the pharynx, in tetanus, hydrophobia, &c. In such cases an elastic catheter is introduced through the nose into the cesophagus, where it may be suffered to remain without occasioning any material inconvenience to the patient; and nourishment and drink may thus be introduced through it into the patient's stomach. In applying the instrument, it easily happens that the end of the tube gets into the larynx instead of the pharynx. This error is generally discovered merely by the circumstance that the flame of a candle, when held before the external aperture of the tube, is thrown into violent motion.—Dr. Hales describes a catheter of a new structure, contrived for the more advantageous injection of li- mithotomies into the bladder. Its cavity is divided lengthways by a thin partition into two separate channels, which end in two diverging branches. By one of these branches the menstruum is to be injected into the bladder, in the common, or rather in the hydraulic way, while it returns mixed with urine by the other. Hales, Hist. kat. p. 512.

There is likewise a description in the Philosophical Trans- actions, vol. xxiii. p. 492, of an ingenious catheter invented by M. Le Cat, at Rouen; and other surgeons have recommended an instrument made of silver-wire, flattened, and turned spirally, so as to be hollow and flexible. These contrivances are certainly very specious, but they are too complex to be useful in ordinary practice.

Concerning the introduction of the catheter into the ur- inary bladder, see the following article.

CATHETERISM, is the act of passing a catheter into the urinary bladder, with a view to draw off the urine, or to facilitate the introduction of fluids into the bladder by means of a syringe.

The introduction of a flexible catheter, of elastic gum, such as is in common use among surgeons, can scarcely give any trouble; unless there be a considerable obstriction in the urethra, which may prove the occasion of inexpressible difficulties. The observations which follow are intended chiefly to apply to the silver male catheter, which is generally used in cases requiring an evacuation of urine, or the injection of some fluid into the bladder. This little opera- tion, simple as it may appear to an inexperienced by-stander, is, in fact, sometimes one of the most perplexing to men of real ability, and therefore deserves the young surgeon's particular attention.

"I do not know," says Mr. John Bell, in his Principles, of Surgery, vol. ii. p. 269., "that even the operation of lithotomy itself is more difficult than that of introducing the catheter; more important it cannot be, than an operation which gives relief in accidents and difficulties so extremely common and so very afflicting." The first cause of embarrassment in performing this operation arises often from the incumbent position of the patient, which renders it necessary (at least surgeons have generally thought it necessary) to pass the catheter with its concave part towards the abdomen. This position, however, except in male subjects requiring lithotomy, is seldom the most eligible; as we have found a standing posture by far the most convenient for the operator's accommodation, provided the patient is not exceedingly fat and corpulent.

Support the surgeon sits on a low chair, or kneels on his right knee, while the patient stands before him, leaning against something immovable. The operator then holds the penis with the middle finger of his left hand, and the glans with the fore finger and thumb of the same hand; chiefly in order to expose the orifice of the urethra. The handle of the catheter, previously oiled, he holds with his forefinger, thumb, and middle finger of the other hand, and directs it in such a manner that its straight pollicier part is placed near the belly of the patient, and parallel with the axis of his body; and he thus introduces its point into the orifice of the urethra. The surgeon then draws the penis gently towards him and extends it, pushing the catheter forwards at the same time with the utmost caution, till its point has arrived at the bend of the os pubis; and in order now to introduce the catheter completely into the curvature of the urethra, the operator must suddenly deprefs the hand, with which he holds the upper part of the catheter, towards the thighs, and thus raise up the point of the instrument; so that it paffes behind the pubis, into the bladder itself. In
CAT

In the other method, the operator gives the catheter such a direction, with the hand next to the patient's thighs, as to turn the elevated convex part of the instrument upwards, and to place the strait part under the belly before the thighs: the point of the catheter is then cautiously introduced into the orifice of the urethra and the bladder, whilst the penis is somewhat extended with the other hand. When the point of the catheter has arrived at the place where the urethra pâlies under the os pubis, the operator must turn both the catheter and the penis, fo as to make both describe a semicircle: this he does by turning them towards the groin at the opposite side; and from hence towards the belly; in which motion the point of the catheter must remain in the centre, as it were, round which the other parts revolve. At last the hand with which the catheter is directed, must be lowered a little, and the rest of the operation completed in the same manner as before. These two methods of introducing the catheter, differ only in this, that in the first the introduction is performed at once; but in the second (which is conceitedly termed "fonder par le tour du maître") it is done by two different manoeuvres, and consequently the operation is unnecessarily lengthened.

CATHETOLIPES, in Natural History, the name of a genus of fishes of the clafs of the Selenite, but differing from the common kinds in the disposition of the constituent plates.

The word is derived from cathetos, perpendicular, and lens, a scale or plate, and expresses a lot of these bodies whole plates are ranged perpendiculariy. All the known Selenites, except those of this genus, are composed of a number of parallel plates, or thin flakes, ranged evenly horizontally on one another.

CATHETO-PLATEUS, in Ichthyology, a term with its opposite, which is plagio-plates, very much used by Arcted, in his description of fishes, but not adopted by Lamans, or more recent ichthyologists; they may be explained in English by the two familiar words, compressed and deformed. The heads of fishes are the parts principally characterized by these terms.

CATHETUS, in Architecture, is a perpendicular line, supposed to pass through the middle of a cylindrical body, as a column.

Cathetus is sometimes applied to a line in the Ionic capital, passing perpendiculariy through the eye or centre of the volute. This is otherwise called the axis of the volute, which see.

CATHETUS, in Botany, Lourcino; Flor. Cochinich. Clafs and order, dicac monandria.

A shrub. Leaves falcate, small, oval, entire, flat, smooth. Flowers axillary, solitary, very small. A native of Cochinchina.

CATHETUS, in Geometry, a perpendicular, or a line, or radius, falling perpendiculariy on another line, or surface.

Thus, the catheti of a right-angled triangle, are the two sides that include the right angle.

Cathetus of incidence, in Catoptrics, is a right line drawn from a radiant point, perpendicular to the reflecting line, or the plane of the speculum, or mirror.

Cathetus of reflection, or of the eye, a right line drawn from the eye, or from any point of a reflected ray, perpendicular to the plane of reflection, or of the speculum. See Reflection.

CATHMANDU, or Cathmandu, in Geography, the capital of an independent kingdom in the kingdom of Nepal or Nepaul, in Hindoostan, situate to the northward of the plain of Nepal, 107 geographical miles of N. of Mainly, that is, in N. lat. 28° 6'. This city contains about 13,000 houses; and the kingdom extends, from south to north, to the distance of 12 or 13 days' journey, as far as the borders of Tibet; and it is almost as extensive from east to west. The king of Cathmandu has always about 50,000 soldiers in his service. To the eastward of Cathmandu, at the distance of two or three miles, is a place called "Tolu," by which flows a small river, the water of which is esteemed holy, according to the superstitious ideas of the inhabitants; and thither they carry perfons of high rank, when they are thought to be at the point of death. At this place is a temple, which is not inferior to the best and richest in any of the capital cities. They have also a tradition, that at Tolu, as well as two or three other places in Nepal, valuable treasures are concealed under ground; but no one is permitted to make use of them, except the king, and that only in cases of need.

These treasures, it is said, have been thus accumulated: when any temple had become very rich from the offerings of the people, it was destroyed, and deep vaults dug under ground, one above another, in which the gold, silver, gilt copper, jewels, and every thing of value were deposited. At Cathmandu, on one side of the royal garden, there is a large fountain, in which is one of their idols, called "Narayan." This idol is of blue stone, crowned, and sleeping on a matreans of the fame kind of stone; and both the idol and the matreans appear, as if they floated upon the water. This stone machine is very large, about 15 or 20 feet long, and proportionably broad, but well wrought and in good repair.

In a wall of the royal palace, there is a fline of a single piece, about 15 feet long, and four or five feet thick, on the top of which are four square holes at equal distances from each other. On the inside of the wall they pour water into the holes, and on the court-side, each hole having a closed canal, every person may draw water to drink. At the foot of the stone is a large ladder, by which people ascend to drink; but the curiosity of the stone confists in its being quite covered with characters of different languages cut upon it. Some lines contain the characters of the language of the country; others, the characters of Tibet; others, Peria: others, Greek; besides several others of different nations: and in the middle there is a line of Roman characters; but none of the inhabitants know how they came there, nor do they know whether or not any European had ever been in Nepal before the missionaries, who arrived there in the beginning of the last century. They are manifestly two French names of feacons, with an English word between them. To the northward of the city of Cathmandu is a hill called "Sinsh," upon which are some tombs of the Lamas of Tibet, and other people of high rank of the same nation. The monuments are constructed in various forms; two or three of them are pyramidal, very high and well ornamented. Round their rim are remarkable stones covered with characters, which probably are the inscriptions of some of the inhabitants of Tibet, whose bones were interred there. The natives of Nepal regard the hill as sacred, and conceive that it is protected by their idols; and, therefore, they never fire any troops there for its defence, although it is a post of great importance, and only at a short mile's distance from the city. Adjoining to the tomb they have
CATHOLIC, from καθολικός, and δοξος, abode, denotes a thing that is universal, or general. Some have said, that Theodosius the Great first introduced the term catholic into the church; appointing by an edict, that the title should be applied, by way of pre-eminence, to those churches which adhered to the council of Nice, in exclusion of the Arians, &c.—Catholicism, however, soon changed hands; for under the emperor Constans, Arianism became so predominant, that the Arians were called the catholic. But the term was used much more anciently, as by Polycarp and Ignatius.

"ubi fuere ipsi Christi, dixit ipse ecclesia catholic." The Romish church now affirms the distinguishing appellation of the catholic church. See Church.

The term catholic, or Roman catholic, is now fashioned by law (see the title to the act of 31 Geo. III., c. 52.) as well as by common usage, to denote the religion formerly called Popery; and the professors of it usually denominated Papists. See Papists and Popery.

Catholic Epistles, in Biblical History, a denomination given to seven epistles of the New Testament, figuring universal or general, because they are not written to the believers of one city, or country, or to particular persons, as St. Paul's epistles are, but to Christians in general, or to Christians of several countries. This is the case of five, or the greater part of them, with which the two others are joined. When the first epistle of Peter, and the first of St. John, were called catholic by the most early Christian writers, the two smaller of St. John were unknown, or not generally received. The antiquity of this denomination is easily ascertained. They were so called in the time of Eusebius (H. E. l. ii. c. 23. l. vi. c. 14.) and, probably, before. Of this fact we have good proof. For St. John's first epistle is several times called a catholic epistle by Origen in his remaining Greek works, as well as in others. It is likewise so called several times by Dionysius, bishop of Alexandria. Athanasius, Epiphanius, and later Greek writers received seven epistles, which they called catholic. They are so called likewise by Jerome. The epistles bearing this appellation are, one of James, two of Peter, three of John, and one of Jude; but they are cited in a different order by ancient authors. Of these epistles two only, viz. the first of St. Peter, and the first of St. John, were universally received in the time of Eusebius; though the rest were then well known. All the seven were received by Athanasius, Epiphanius, Jerome, Augustine, and many other writers. However, the Syrian churches received only three of these epistles; nor does it appear, that more were received by Chrysostom or Theodoret. These epistles were also called canonical by Cassiodorus, about the middle of the sixth century, and by the writers of the prologue to these epistles, ascribed (erroneously) to Jerome. The propriety of this latter appellation is not satisfactorily ascertained. Du Pin says, that some Latins have called these epistles canonical, either confounding the name with catholic, or else to denote, that they also are a part of the canon of the books of the New Testament. See Epistle.

Catholic furnace, is a little furnace, so contrived, as to be fit for all kinds of operations, which do not require an intense fire.

Catholic kings, is a title which has long been hereditary to the kings of Spain. Mariana pretends, that Reccared first received this title after he had destroyed Arianism in his kingdom, and that it is found in the council of Toledo for the year 589. Vafec afcribes the origin of it to Alphonfus in 738. Some allege that it has been used only since the time of Ferdinand and Isabella. Colombie says it was given them on occasion of the expulsion of the Moors. The Boedamites pretend, it was given by their predecessors, the Visigoth kings of Spain; and that Alexander VI. only renewed it to Ferdinand and Isabella. Others say, that Philip de Valois first bore the title; which was given him after his death, by the ecclesiastics, on account of his favouring their interests.

In some epistles of the ancient popes, the title catholic is given to the kings of France, and of Jerusalem, as well as to several patriarchs and primates.

CATHOLICA, in Geography, a town of Italy, in the province of Romagna. It derived its name from being the place whither the orthodox bishops retired in the year 359, after being ousted by the Arian party, in the council of Rimini; 9 miles S.S.E. of Rimini.

Catholic, La., a town of Sicily, in the Val di Mazara, situate in a spacious plain open to the sea, and shut up on the north side by a broken theatre of mountains. It is the chief town of the district. It was founded in 1612 out of several small hamlets by Francis Istar, lord of the soil, but is now possessed by the family of Bonanni, who take the title of princes of La Catholic. The number of its inhabitants exceeds 7000. The prince of La Catholic derives from Sicilian an annual income of 14,000 crowns.

Catholiciani, in Middle Age Writers, the officials or ministrants of the catholic, or receivers of the taxes of a diocese, sometimes also denominated Cæsarians.

Catholicon, in Pharmacy, a kind of soft purgative electuary; so called, as being supposed universal; or a purger of all humours.

Different authors give different recipes for it:—that called Catholicon Nicolai was long in use; it consists of sixteen ingredients, the chief whereof are:—mari di, cassia, fera, and rhubarb. It was called the double catholicon, when there was a double portion of fera and rhubarb.

The Catholicon for effusions, only differs from this, in that it had no rhubarb, and that honey was used in it instead of sugar.

Catholicus, the title of a dignitary, or magistrare, under the Roman emperors, who had part of the administration, and particularly the care and receipt of the revenues and taxes in Roman dioceses.

The catholics were the same with what was denominated by the Latins procurator, and rationalis Caesaris. Such was the catholics of the diocese of Africa, mentioned by Eusebius, and other ancient writers.

Catholicus, among Ecclesiastical Writers, an appellation given to the princes or metropolitans of several churches in Asia, subject to the see of Antich; but whose jurisdiction and dioceses are of such extent that they have assumed the title of catholic, q. d. universal bishops. See Private.

Cathion, in Ancient Geography, an island of Greece, S. of the Peloponnessus, in the gulf of Lacedemon.

Caticardamna, a town of India, on this side of the Ganges, according to Ptolemy.

Cathieh, in Geography, a town of Egypt, near the coast of the Mediterranean, 70 miles N.N.E. of Suez, and 130 miles N.E. of Cairo. Lat. 35° 7', E. long. 31° 30'.

Catif, or Katif, El, a town of Arabia, in the province of Lachfa, seated on the coast of the Persian gulf, at the distance of about 5 German miles from the Isle of Bahrein. The inhabitants earn their subsistence by the pearl-fishery. When any are too poor to fish at their own risk.
CATHOLICS, in Ancient Geography, a fountain from which proceeded the stream called "Aqua Petronia," which was a rite of Italy that discharged itself into the Tiber.

CATILINE. Lucius Sergius, in Biography, was descended from the illustrious patrician family of Sergii at Rome, but rendered infamous by a series of debaucheries, incests, murders, and the most atrocious crimes. He began his licentious career at an early age, by debauching a female of distinction, and afterwards marrying the daughter he had by her. He was also accused of holding a criminal intercourse with a vestal, the filter of Terentia, Cicero's wife, and of murdering his own brother, whose name he prevailed upon Sylla to inflict in the list of professed perfous for the purpose of justifying his crime. During the fainéant administration of Sylla, he was the chief instrument of his cruelties, and headed a band of affilius, who dragged out of the houses and temples perfous, whose names were inscribed in the list of profersons, and cruelly murdered them in the presence of his employer. He was also active in fearing out and afflicting many knights and senators, before they knew they were proscribèd. As a recompense of these savage servics, and in consideration of his birth and brutal courage, he was advanced, by the favour of the dictator, to the principal dignities of the state. Accordingly, he had been questor, legate in Macedonia under C. Curio, and prætor in Africa; but in all these employments, he had disgraced himself by his debaucheries and enormous oppressions. As he had dissipated his patrimony, and was overloaded with debts notwithstanding his uncontrouled exactions, he had no prospect of retrieving his affairs but by the subversion of the state; and he, therefore, seized all opportunities that occurred for exciting and promoting civil confusion. Upon his return from Africa, B.C. 67, he formed a conspiracy with other discontented and turbulent perfous for murdering the confiule, Aurelius Cotta and Manlius Torquatus, together with the greatest part of the senators, and violently feizing the government. This plot, though the execution of it was twice repeated, proved unsuccessful, in consequence of a mistake in the signal on the part of Catiline; and he was therefore under a necessity of deferring the accomplishment of his purpose to a future period. Having strengthened his party by the accession of a great number of senators and knights, of debauched young persons in the city, and of old soldiers and officers of Sylla's army, who had reduced themselves to indigence by the profuse expenditure of all the gains of their oppressions, he concerted a more extensive plan for the total subversion of the commonwealth. With a view to the more easy and certain execution of it, he offered himself a candidate for the confiuleship, and had Cicero for his competitor. In the mean while, the conspiracy of Catiline had been discovered to Cicero by Fulvia, a woman of distinction, who had discomfoured her family by a criminal correspondence with Quintus Curtius, one of the party concerned; and this discovery, though not fully authenticated, had excited suspicions against Catiline, which defeated his election, and favoured that of Cicero, his avowed adversary. A.U.C. 651, B.C. 65; Catiline, enraged by the success of his rival, determined to offer himself a second time for the confiuleate, and prepared for an open rebellion, in case of his failure.

With this view he borrowed large sums of money, and engaged Manlius, one of Sylla's old officers, who then resided at Puteoli, to make levies of soldiers throughout Etruria. Lucullus, however, whom Pompey had succeeded in the East, being informed of these hostile preparations, made a report of them to the senate, and affid the confiule with all his intercess in the prosecution of the traitor. Cicero also kept up a correspondence with Fulvia, and had even gained over some of the conspirators, who, pursuant to his directions, pretended to be the most ardent promoters of the plot. By means of this information, he discovered the designs of Catiline, the various sentiments of his accomplices, their number and quality, and the general, as well as the private, views of each of the conspirators. By them he was informed, that on a day appointed the conspirators were to set fire to several parts of the city; and that, during the confusion and uproar, which was general a conflagration would occur, some were to murder the chief men of the city in their houses, others to assemble the mutinous populace, seize the Capitol, and fortify themselves there, till Manlius should arrive from Etruria with his veterans. Two Roman knights were appointed to murder Cicero in his own house; but the confiule, previously informed of every thing that had passed in their affair, summoned the senate, and boldly apprized the confiule fathers, in Catiline's presence, of the danger to which they were all exposed. The senate, having been made acquainted with the whole plot, issued a public decree, according to an ancient form, which had been observed in times of national danger, "that the confiules should take care that the republic suffer no detriment." Cicero, thus invested with ample power, adopted every necessary measure for keeping in awe the principal cities in Italy, and for guarding Rome, the capital; and the senate, by his advice, promised not only a pardon, but ample rewards, to any of the conspirators, who should make further discoveries of this detestable attempt. Although the confiule might, on his own knowledge, have condemned Catiline and his accomplices to death without appeal, this would have been a pernicious measure; and he thought it more advisable to induce Catiline to leave Rome, and take refuge in Manlius's camp near Puteoli. With this view he addressed the senate, and pronounced, in the presence of Catiline, that most severe and spirited invective, still extant under the title of the first oration against Catiline, in which he lays open all his murderous designs, affiures him that they are fully known and guarded against, and exhorts him to leave that city which can no longer endure his presence. Catiline, retaining full possession of himself, with an air of great plausibility intreated the senate not to credit the accusations of a declared enemy, who had not in Rome so much as a house of his own, and who was attempting to raise his own character by the defeat of a conspiracy forged by himself, and thus to acquire the title of defender of his country. When he proceeded to invectives against the confiule, he was interrupted by the clamours of the whole assembly, and the senate-houfe echoed with the names of incendiary, parricide, and enemy to his country. Stung with these reproaches, and foaming with rage, Catiline exclaimed, "Since you have provoked me to the utmost, I will not perish alone, but will enjoy the satisfaction of involving those who have sworn my ruin in the same destruction with myself." Having thus spoken, he left the senate-houfe, and accompanied by about 3000 men, hastened to the camp of Manlius in the vicinity of Puteoli. Here he allured the command of the troops, together with all the enigms of a suprême magifrate, being preceded by lectors, carrying their axes and fasces. The senate, as soon as information was received of this act of open rebellion, declared Catiline and Manlius enemies of their country;
CAT

COUNTRY; and gave orders, that Antonius, the adherent of Caesar, in the present ship, should take the field with a pro-

confederacy, and that Cicero should continue in Rome to

watch the motions of the conspirators. Some of the party,

who still remained in the city, made an attempt to attach to

their cause the ambassadors of the Allobroges, who were then

at Rome, and thus to obtain assistance from Transalpine

Gaul; but these ambassadors, by the intervention of Sanyo,

the protector of their nation, communicated the whole affair
to Cicero; and he instructed them to proceed in the negoti-

ation, and to obtain the draft of a written treaty, subscribed

with the names of the conspirators. Cicero, being informed

of the ambuscades by the intervention of the Allobroges or Vultureus, who

had undertook to conduct them to Catiline, in order to ob-
tain his ratification of the treaty, were stopped in the way,

and brought back to Rome, with all the papers which either

the Allobroges or Vultureus had in their custody. Cicero,

having thus got into his possession undeniable proofs of the

conspiracy, dispatched proper officers to arrest Lentulus,

Gabinus, Cathegus, and Statilius, and to commit them to

safe custody. He then assembled the senate, in the tempo-

re of Concord, hid before the assembly the proofs of the plot,

and having obtained a decree for the execution of the crim-

nals at a subsequent meeting, ordered them to be capitally

punished.

During these transactions at Rome, Catiline resolved to

lead his army into Transalpine Gaul, where he expected

very general support; but he was prevented from accom-

plishing his purpose by Q. Metellus Caesar, who, leaving

Piemont, which he had guarded the last year, posted him-

self with three legions at the foot of the Alps, while An-

tonius followed Catiline in the rear, who, busied in by

two bodies of troops, made a retrograde march, and falling

in with the proconsul near Pildes, now Pilloa, in Tuscan,

offered him battle. Antonius, who had formerly been of

Catiline’s faction, appeared unwilling to engage; but his

troops, infilling on being led to action, he pretended indis-

position, and devolved the command on his lieutenant Pe-

tricus, a veteran of tried and distinguished valor. The

engagement was fierce and obstinate; but at length, when

Manlius and another commanding officer were killed, it ter-

minated, after a long and dubious contest, in favor of Pe-

tricus, who was left master of the field. Catiline, having loit-

ered Manlius and his associates, during the engagement, found

himself unable to rally the fugitives; and, therefore, deter-

mining not to survive the ruin of his party, threw himself

into the midst of the victorious enemy, where he was found

among the dead bodies of those whom he had slain, still

breathing, and retaining in his countenance the traces of

that ravenous valor which distinguished his character. Thus

the Catiline conspiracy, which was detected by Cic-

ero in October, was terminated in December. B. C. 63: The character of Catiline has been sufficiently deline-

ated in the orations of Cicero; and his portrait is thus
drawn by the strong pen of Sallust: "His powers of mind
and body were extraordinary, but his disposition had

and depraved. From his youth he took delight in civil

contests, murders, rapines, and indignities, and caused him-

self to be the source of all. His constitution was, be-
yond credibility, patient of hunger, cold, and hardships.

In temper he was daring, deceitful, capable of every
kind of duplicity and dissimulation, greedy of the property
of others, lavish of his own, ardent in his desires, plausible,

rather than deep, in discourse. His boundless soul al-
ways aimed at things immoderate, excessive, and out of

probability." In after times he appears to have served as an

example of desperate and flagitious traitor; and Virgil has

irreverently fixed his doom, in making him the figure by

which punishment the regions of Tartarus are delineated on the

field of Aeolus.

"—— et te, Catilina, minaci

Pendentem scapula, Pyrrorumque ora tremens." 

Ann. viii. 668.

"There Catiline, o'er-hung a mountain's brow,

And flound'ring' view'd the Furies glare below."

CATIMBRIUM, Juf. See Globb. 

CATINA, in Ancient Geography, a town of Pelopon-

neas, in Arcadia. Play.

tab. 263. fig. 1 and 2. Trees, the fructification of which

Cor. unknown. Stam. filaments numerous. Pelt. unknown.
Peric. drupe as large as an orange or citron, crowned with

the very small calyx, fibrous within, rich covered, with
vehicles, which contain an aromatic effusive oil; nut

brittle, kernel reddish, veined. Leaves most commonly op-

posite, oval, oblong, entire, beak-lined with transparent

points. Fruit axillary. These trees grow on the banks of

rivers in Guiana. There are two species; one of which

bears a round, the other an elongated fruit.

CATKIN, the English name of a species of infracer-

ence, called by Linnaeus amenum, and improperly con-

firmed by him as a species of calyx. It consists of nu-

merous chaffy scales, containing either the fashion or pulp

separately, or very rarely both together, and ranged along

a slender flake, which is the common receptacle. The

older botanists it was styled julus, nymphaeum, and ca-

tulus. The latter term, corresponding with the English

catkin and the French chaton, is derived from its fancied

resemblance to a cat's tail. The amethystaceous plants con-

stitute the sixteenth natural order of Linnaeus in his Phi-

losophia Botanica, and the fiftieth in his polished lectures

published by Giseke. In the latter work he orders the fol-

lowing genera: Ficus, papulus, platanus, floccana; fic-

gas, juglans, quercus, corvus, carpinus, betula, myrica, 

pietatis, cinnothornum. Julicinus and Ventenat have also a

natural order of the same name which is thus divided by

Julicinus; 1. With hermaphrodite flowers; iothaurila, ul-

mus, celtis. 2. With dioecious flowers; ficas, populus, 

myrica. 3. With monocious flowers; betula, ca pinus, fa-

gas, quercus, corvus, liquidambur, platanus. The three

species of the first division have not their flowers in true
cats; and Ventenat observes that, although they have some

affinity with the ameteaceae, they may properly be placed

in a distinct order. Tournefort, Boerhaave, and

Rosen, have also a class or order distinguished by its ame-

eteaceous flowers; a character which the former extends to

the confine of Julicinus; but he, according to Ventenat,

although in many respects allied to the true ameteaceae,

have several peculiar important characters which neces-

sarily keep them distinct. Besides their difference in habit, the

confine have a cylindrical embryo, surrounded by a tender per-

perm;
C A T

perm; whereas the true amebenece have a flat embryo with-
out a periperm.

CATLENBURG, in Geography, a town and bailiwicks of
Germany, in the circle of Lower Saxony, and principa-
listy of Grubenhausen; 10 miles S.S.E. of Einbeck.

CATLIN, among Surgeons, is a dismembering knife, for
cutting off any corrupted part of a body. See Surgical
Plates on Amputation.

CAT-MINT, in Botany. See Nepeta cataria.

CATO, Marcus Porcius, distinguished by the appli-
ation of the Censor," in Biography, was born at Tusculum
in the year of Rome 519, B.C. 233; and was brought up
at a small farm near the country of the Sabines, possest by
his father, which he cultivated with his own hands. At the
age of 17 years, he made his first campaign under Fabius
Maximus, when Hannibal was ravaging Italy; and five
years afterwards he accompanied the name general in his
expedition against Tarentum. At the commencement of
his military career, he attracted notice by his singular sobriety,
valor, attention to discipline, and all the virtues of the an-
cient Roman soldier. On his return from the army, he
joined his domestics in the culture of his small estate, de-
voting himself at his leisure hours to the studv of eloquence
at home and to the practice of it in the adjacent cities,
where he pleased on behalf of those who applied to him.
His talents and virtues engaged the notice of Valerius Flae-
cus, who had lands contiguous to the small farm of Cato;
and who belonged to one of the most noble, affluent, and
powerful families of Rome. With the advice and under the
promised patronage of this rich neighbour, he determined
to try his fortune at Rome, where the successful eloquence
of his pleadings and the interest of his friend laid the foun-
dation of his future preferment. In his 30th year he served
as military tribune in Sicily; and he was afterwards quaestor
under Scipio in the African war; but disgrunted with the
splendid liberality and popular manners of this great man,
he came to Rome and joined with Fabius in acceding Scipio
before the senate. But though Scipio was honourably ac-
quitted and continued in his command, Cato gained elima-
tion with the public for his rigid economy. Besides, his
masculine train of rhetoric, which occasioned his being de-
nominated the Roman Demosthenes, gave him great influ-
ence in the assemblies of the people. Having passed through
the office of edile, he was appointed praetor in the province
of Sardinia; and in this station he displayed, in a very emi-

C A T

nent degree, his temperance, integrity, and rigid justice.
His predeceofers in this office had ruined the country, by
extortions for supplying the means of profusion; whereas
Cato distinguished himself by the simplicity of his habit,
table, and equipage, and never touched a single farthing of
the public money. At this time Sardinia abounded with
refiners, who, under a pretence of affiling private persons
with the loan of sums of money for particular occasions, ut-
terly ruined them; but Cato expelled from the island all
persons of this description. In the year of Rome 558,
B.C. 106, he was elected consul, in connection with his
friend Valerius Flaccus, and the Iberian Spain was assigned
to him as his province. But before his departure he vigo-
ously opposed the repeal of the Appian law, which re-
trained the propriety of the female sex to indulge in show
and ornament; but Valerius the tribune, having carried this
point against him, which he defended with his single voice,
he proceeded to his province, where he undertook the disci-
pline of his troops confining of new levies, and let them an
example of encountering every kind of hardship. His habit
was always plain; his provisions were the same with those
of the common soldiers; and he took part with them in the
labour of forming the entrenchments of his camp. Having
thus prepared his troops for contending with the natives,
who, in their previous wars with the Romans and Cartha-
ginians, had learned the military art, and who were naturally
brave and courageous, he dismissed his fleet, that his soldiers
might solely confide in their own valour. In this war he
obtained several victories, and by demolishing the forts the
the towns which he captured, he completely sub-
jected the province to the Roman dominion. To each of
the soldiers, besides the spoils, he gave a pound of silver
out of the rich booty which he acquired; and when some of
the officers expressed their surprise at his liberality, he told
them, "It is better that many of the Romans should return
home with silver, than a few only with gold." However,
he appropriated to his own use not part of the booty; but
continued to live in as frugal a manner as the meanest fol-
dier. At the close of the campaign, he failed back to
Rome with his troops, and next year was honoured with a
triumpb. Notwithstanding this merit, he still
continued freely to serve his country in the forum and the
field; and when the public service did not call for his active
concurrence, he enjoyed the pleasures of retirement, and de-
voted his hours of leisure to study. In the campaign of
M. Acilius Glabrio against Antiochus the Great in Greece,
Cato served as a military tribune; and by his advice and af-
flance enabled the confid to force the Syren's fortified
entrenchments in the pafs of Thermopylae, as the Persians
had formerly done, and to oblige him to abandon Greece,
and retire to Epirotis. About ten years after his confulate,
viz. in the year of Rome 569, B.C. 185, he offered himself
as a candidate for the office of Censor; but the known
feverity of his character alarmed the nobles, and they set up
fesn competitors against him; however, the people persisted
in the choice of Cato, and they nominated as his associate
his confular colleague, Valerius Flaccus. Many of the fe-
nators, who had been guilty of fex dalous enormities, were re-
fected; others were degraded on more frivolous grounds; and
Cato seems to have indulged a personal pique against the Cor-
nelian family, by taking from Scipio Ahiaticus the horse which
the public kept for him as a knight. The rigid cenfor ex-
cyed his office with great severity; he laid a heavy tax on rich
furniture, jewels, and all superfluities; and by such popular
acts, he made himself acceptable to the people, that they
created a flame to him in the Temple of Health. After the
expiration of his confulship, he merely attended his duty
as a private senator, and his advice was received with de-
sence and respect. The necility of destroying Car-
thage was a point which he always fervently inculcated;
and in his elimination this necessity seems to have been justi-
fied by the single circumstance, that Carthage was the in-
veterate foe and rival of Rome. Cato, considering the or-
iginal rude character of the Romans as the standard of per-
fection, fervently opposed every kind of innovation, and
for a long time refuted the introduction of Grecian letters
and philosophy into Rome. To this purpose he exerted
himself in hallowing the diffusion of Gnaecides the acade-
ic, and Diogenes the Stoic, who had been sent on a public
embassy from Athens. He feems, however, in his old age,
to have changed his opinion; as he became a convert to the
caufe of learning, and affiduoufly studied the Greek lan-
guage. He became a writer himself, and composed a va-
riety of works, of which the principal was a History of the
Roman affairs, and of the origin of all the cities of Italy,
from that circumstance entitled "Origines." A few frag-
ments of the seven books which he lived to finifh, are still
extant. He also published a large number of his orations,
letters, a treatise on the military art, and another on rural
affairs;
C A T O.

At this the latter, of which still remains, and is usually printed with the "Scriptores De Re Rustica."

Cato married for his first wife a woman of family, who was professed in her exercises, and perversely in her temper, and who therefore afforded sufficient exercise to his philosophy. By his wife, he had a son, whose education he himself conducted, but he would not allow him to be taught the learning of the Greeks, alleging, that the only study of a Roman ought to be, how to conquer, and how to govern conquered nations.

In his advanced years he was a widower, and not choosing to marry again, he took a young female slave to his bed, at which his son being displeased, he married the daughter of Salmin, who had been his secretary; and by her he had a son named Salamin, who was the grandson of Cato of Utica. The cen[or lived to an advanced age, and died in his 59th year, as some say, and according to others in his 91st, in the year of Rome 627, B. C. 149, at the commencement of the third Punic war, which his advice very much contributed to prevent. Cato was a great folder, an eloquent orator, a learned historian, and well skilled in rural affairs; but these accomplishments were counterbalanced by great defects, and very unamiable qualities. As a matter, he was flen and unfeeling, so that he considered his slaves as a fort of labouring animals, whom he wished to get rid of when exhausted by age and servitude. His economy degenerated into avarice; and though he was uncorrupt in the management of public money, he defended to very mean and unanswerable practices to amass a private fortune. For money lent he took exorbitant profits; and received even from his own male slaves a certain pecuniary consideration for the liberty of frequenting the females. He used to say to his son, that no man deserves any esteem till he had doubled his fortune. In public he was ever extolling continence; but he indulged his passions in private with a beautiful female slave; and it is also said that he was equally faulty in the excessive use of wine.

"Narratur et pri[ei Catonis, Sane more calulue virtues." Hor.

His public censures of private men seem sometimes to have originated from envy and personal pique; and thus we may account for his having been 44 times impeached, which probably would not have been the case if he had not provoked private resentment by the unjustifiable severity of his temper. However, on all these occasions he was acquitted by the people, in whose estimation his virtues preponderated his defects and vices; so that although he lived was held in extraordinary veneration, and his name has descended with honour to succeeding generations. Cicero exhibits him in an amiable point of view, by making him the principal speaker in his beautiful dialogue on old age, which some have considered as a kind of fancy portrait, founded, however, on the real traits of the man, though softened and embellished. Plutarch has made him the subject of one of his lives, and Cornelius Nepos, at the request of Atticus, wrote a particular account of him, of which a brief sketch only is extant. Plutarch, t. ii. Cicero, Livy, Corn. Nep. Anc. Un. Hill, vol. xi. Rollin's Rom. Hist. vol. iv. and v.

Cato, Marcus Porcius, Cato Minor of Plutarch, surname of Uthina, from the place of his death, was great grandnephew to Cato the Censor, the subject of the preceding article, and born about 94 years B.C. As he lost his parents at a very early age, he was brought up in the house of Dru[us, his maternal uncle, and a man of high rank and character. Whil[i he was a child, he manifested that readiness of temper and solidity of under[standing, which were the distinguishing features of his character; and though his apprehension was slow, his memory was tenacious. His passions, though seldom displayed by outward signs, were durable in their influence; and his inflexibility approached even to stubbornness. However, when his reason was convinced, he readily complied; and this was found by the instructors of his youth to be the only method for securing his obedience. Of his firm and unyielding temper, when he was an infant, Plutarch mentions a singular instance. The Italian allies of Rome having demanded admission to the right of citizenship, Pompeus Silo, one of their deputies for urging this claim, was a guest at the house of Dru[us, and in a jocose manner asked young Cato to recommend his fuit to his uncle. The child was silent; but expressed by his looks and an air of dislike in his countenance, that he would not comply with the wishes of Pompeus. Pompeus renewed his solicitations, but was unable to prevail. At length he took up the infant Cato in his arms, and carrying him to the window, threatened to k[t him fall out of it if he persisted in his refus[t. But fear was equally unavailing with intreaty. Pompeus, on letting him down in the room, exclaimed, "What an happiness it is for Italy, that thou art but a child! For if thou were at age, we should not have a single vote." At the age of 14, Cato was introduced by his tutor, Sarpedon, to the house of Sylia, the dictator, which, on account of the proclamations and cruelties of this tyrant, was a scene of torture and blood. Of blood he was also accused of sacrificing the heads of several noble victims that had been murdered carried out, and the bye-fandles secretly figuring on account of the horrid spectacle, he asked his tutor, why nobody killed such a tyrant. "It is," replied he, "because he is still more feared than hated." Cato exclaimed, "Give me a sword, that I may kill him, and deliver my country from slavery." He uttered these words with a tone of voice and an aspect that made his tutor tremble; and from this time he was very watchful of his pupil, lest he should attempt some rash and daring action.

Notwithstanding the firmness and intrepidity of Cato's temper, he was not unfe[ctible of tender emotions, nor deflute of kind affections. His love to his brother Capin was manifested on a variety of occasions, whilst he lived; and when he died, grief seemed to triumph over all his philosophy. He shed many tears whilst he embraced the dead body; for some time he indulged dejection and melancholy, and expended great sums in his funeral, and in erecting a monument of costly marble in the forum of Enus, a town of Thrace, where he died, nor did he quit his alca[t till he brought them into Italy. But though he was led by fraternal affection to incur this expense, and though in his mature years he received a considerable sum of money from his share of the paternal estate, the habits of his life were simple and frugal, and he cultivated the manners of a philosopher rather than those of a young patriarch. The course of his studies was adapted to his peculiar temper; and the principles of the Stoic philosophy, which he affluently cultivated, under Antipater of Tyre, habitually influenced his judgment, disposition, and conduct. With a view of being better qualified for defending the cause and claims of justice, and enforcing his wife and faithful counsellors, he studied eloquence; but his eloquence was altogether detrimental of artificial ornaments; it was simple and grave, and occasionally intermixed with dry humour and sarcasm. Cato not only cultivated his mind; but he inured himself to bodily exercise, and to every kind of fatigue and hardship, in order to acquire that corporeal strength and that firm tone of nerves which were suited to his mental disposition, and which would qualify him for the various active services to which he devoted
voted his life. He was also distinguished by his self-denial and temperance; and he avoided every kind of luxury in dress and in diet, which began very much to prevail among his countrymen. He has been charged, however, with occasional excesses in the use of wine; and his advocates have found it difficult altogether to exonerate him from the charge of drunkenness. The charge was strongly urged by Cæsar, who may be considered as an enemy; but as he was regarded by all Rome as a model of private as well as public virtue, and peculiarly distinguished for his temperance, we may infer that his conduct in this respect must have been manifestly exaggerated. Cicero, in his defence of him against Memmius, who accused him of passing whole nights in drinking, could only allege, that he could not reproach him with passing whole days at dice; and Seneca, his extrava-gant panegyrist, very absurdly says, “that it is more easy to make drunkards of virtue than Cato vicious.” In his dress he also affected singularity, and seemed to glory in counteracting the taste and fashion of the age in which he lived. We may also add, that he blended with that greatness of soul and confidence, which have been justly admired, a degree of haughtiness and contempt for others, attributable perhaps to the principles of his philosophy, which in a degree degraded his general character and rendered it less amiable. After all the allowances which truth and candour are constrained to admit in forming a general climate of his character, Cato has been justly considered as one of the most virtuous Pagans that ever lived. Cato acquired from inheritance an ample fortune; which he employed very differently from his ancestor, the Cenfors, in loans and gifts among his friends, without returning to duty for its increase. Dis- appointed in his first views of a matrimonial nature, by the prior claims of Metellus Scipio, he formed a connection of this kind with Attila, the daughter of Soranus, whom he repudiated for her infidelity, after having had two children by her. The first military service of Cato was in the “fer-vile war,” under the consul Gellius, against Spartacus; on which occasion his conduct was so much approved by his general, that he offered him some military rewards, which he declined, alleging, that he had done nothing that deserved such honours. Soon after he obtained a tribune’s commission, with which he went to the army in Macedonia under Rubrius. This general gave him the command of a legion, which became, in consequence of his sedulous attention to the morals as well as to the discipline of his men, the most orderly as well as the most martial in the service. It was at this time that his brother Capio died. When the term of his tributary service expired, he made the tour of Asia, without burdening the allies of Rome, which was too frequently done by the Jornades of Romans of distinction. At Ephesus he was introduced to Pompey, who received him with very distinguished tokens of respect; but though he paid him particular attention whilst he was present, he does not seem to have regretted his departure, as he did not wish to have his conduct inspected by so rigid an observer. After having visited the whole of Asia and Syria, Cato returned to Rome, accompanied by the celebrated Stoic philosopher, Athenodorus, who resided in his house. Having acquired those maxims of wisdom and habits of virtue which qualified him for the service of his country, he now wished to employ them for the benefit of the public. His philosophy, so far from aiming at that imaginary perfection, which confounds in abstraction from all the common duties of life, was such as the poet Lucretius represents:—

"patrisque impendere vitam, 
Nec sibi, sed toto geniturum se credere mundo."

Plat. ii. 322.

Vol. VII.

"To hold his being at his country's call, 
And deem his life was lent a common good for all."

Accordingly he first aspired to the office of quæstor, having previously studied with diligence the rights and duties of this office. Having succeeded in obtaining it, he began with reforming a variety of abuses, which had been introduced by his predecessors; and, headed by private covetousness, he brought all defectors to account with the public, and abolished such checks and orders that might effectually serve to prevent future fraud and peculation. One of the boldest and most popular acts which he performed was his of calling to first account the infamous affairs employed by Sylla and extrava-gantly recommended out of the funds of the treasury for the apprehension and murder of proscribed persons. These men he caused to refund their ill- acquired gains, reproaching them at the same time for their crimes, and inditing them for their atrocious murders before the criminal judges. Such were the integrity and fidelity, with which he discharged all the duties of his office, and such was the high estimation in which his conduct was held, that his name became in a manner proverbial for uprightness. To this purpose we may adduce the compliment paid to him by a popular orator, who, on objecting to the decision of a cause by the testimony of a single witness, said, “One man’s evidence is insufficient, were it even Cato’s.” His fidelity in performing the duty of a senator was no less exemplary than the discharge of his functions as quaëstor. He was the first in the senate, and the last that left it; and as he frequently passed a considerable interval of time, before the house was assembled, he brought a book, and read till it began to deliberate; nor did he ever quit the city during the sittings of the senate. Although he attached himself at this time to none of those who led the prevalent parties in the state, but rather opposed and suspected all, he inclined to that of the aristrocracy, from an opinion that the existence of the republic was chiefly endangered by men of great popular influence. No man was ever less governed by that ambition, which actuated the leaders of all parties, than Cato. Nevertheless, he thought it his duty to step forward, whenever he apprehended that his country needed his services. With these views he altered his purpose of retiring from the public scene, when Metellus Nepos, whom he knew to be a man of dangerous character, was offering himself for the office of tribune; and became a candidate, as his competitor. They were both chosen; and Cato, as tribune elect, served his country very essentially at the time of the conspiracy of Catiline. Concurring with Cicero in his measures for the safety of the state, he supported them by his influence, honoured him with the appellation of “Father of his country,” and by his eloquence counteracted the speech of Cæsar, who wished to throw lenity to the conspirators, and procure their capital condemnation. He afterwards opposed a motion of Metellus for recalling Pompey from Asia, that he might have the command against Catiline; but his opposition was followed by a tumult, excited by Metellus and aided by Cæsar, which very much endangered his life. After Pompey’s return to Rome Cato exerted himself in defeating his unconstitutional projects; and when the first triumvirate was formed, he alone perceived the danger that might result from such an union of power. When Cæsar proposed his agrarian law, Cato raised an outcry against it, alleging that it was not proper to disturb the public tranquillity, and that he did not so much apprehend the division of the lands, as the wages that would be required of the people by those who sought to inveigle them by this present. Cæsar, who was thencefal, was too much provoked.
provoked by the invincible opposition of Cato that he committed him to prison; but he was soon after released. Ciceron used many arguments to mollify the inflexibility of Cato's temper; and fearing that banishment might be the consequence of his continued opposition, addressed him with these words, "If Cato has no need of Rome, Rome has need of Cato." At length Cato yielded; the agrarian law was paused; and the triumvirs became irresistible. Their principal agent was Clodius; and as Cato refilled his measures, he determined to remove him from Rome. With this view, he expressed confidence in his integrity, and having obtained a decree for depriving Ptolomy, the king of Cyprus, of his dominions, on the ground of personal animosity and revenge, he alligned to Cato this odious employment, and obtained a law, inviting him with the authority of pretor, for the execution of his iniquitous purpose. Whilft Cnadius, a friend of Cato, was sent to acquaint Ptolomy with the determination of the Roman people, and to propose to him terms of surrender, he waited at Rhodes to learn the result of the negotiation. In the mean time Ptolomy, fairly apprised that resistance would be vain, preferred death by poison to acquiescence in this arbitrary decree. As soon as Cato heard of the event, he sent Brutus, his nephew, to secure the royal treasures; and having re-established the exiles of Byzantium, which was another object of his commission, he repaired to Cyprus, where he disposed of all the treasures he found amounting to near 7,000 talents or about 1,500,000 pounds sterling; referring to himself only a letter from Zeno, the founder of the Stoic sect. This wealth was safely transported to Rome, and lodged in the treasury; and it seems to have been a just retaliation of the iniquity of the measure by which it was procured on the part of the Roman people, that it was soon after feized by Cesar and employed in the destruction of their liberty. After Cato's return to Rome a content took place between Cicero and Cato, respecting the legitimacy of the confulsipn of Clodius, and the consequent validity of every thing that had been done by Cato in the island of Cyprus; but the interruption of friendship and coolness that were this occasioned between these two distinguished persons soon terminated.

We have already mentioned Cato's first marriage of Atilia and his subsequent divorce. When this event took place, he married Marcia, the daughter of his friend Philipus, with whom he seems to have lived in collabial harmony and by whom he had several children. However, at the time when she was actually pregnant, he resigned her to Hortensius at his request, and having obtained her father's consent, gave her away in marriage to his friend. This transaction, though altogether inconsistent with modern ideas and manners, was conducted with gravity and decorum, and seems to have occasioned no scandal. After the death of Hortensius, who bequeathed his large fortune to his widow, Cato took her again. In this case, as a new marriage ceremony was performed on both occasions, it cannot be justly said that Cato "left" his wife. Moreover, he only availed himself of the unlimited right of divorce allowed by the Roman law, in first surrendering his wife to Hortensius and then marrying her again as his widow. It has been said, however, that notwithstanding the established usage among the Romans, a person of Cato's dignity and character should not have functioned it by his example.

Cato, who still persisted in his opposition to the triumvirs, took an active part in the canvass of Domitius his sister's husband, for the confulsipn against Pompey and Caesar; but whilst they were soliciting votes in the Campus Martius, they fell into an ambuscade prepared by the rivals of Domitius, and Cato was wounded by the assassins. This intrepid Roman, who was not to be deterred by any violence from serving what he apprehended to be the cause of liberty, exposed himself to new danger by his irascible opposition to the Trebonian law, which proposed to afflict the confuls the government of Syria and of Spain for five years, with as many troops as they should judge proper, and with the power of making war and peace according to their own pleasure. After all the efforts of a constancy equally obstinate and fruitless, Cato was feized by the legates of Trebonius and conveyed to prison; but the tribune fearing the consequence of this unpopular measure, caused him soon to be released. The next, and the highest civil dignity, to which he was advanced, was that of pretor, and in the execution of this office he engaged the Senate to influe a decree against bribery; but Rome was reduced to such a state of corruption, that the decree offended both the candidates for offices who purchased votes, and the people who held them.

After the death of Caesar, the agents of Caesar were indolent in their exertion. On his death, Cato, perceiving that the power of Pompey would force his friends to counteract their efforts, diverted his ambitious friends from the plan they were purposing of making him dictator, and proposed the left obnoxious measure of creating him sole consul. Pompey was not inoffensive of his obligations; and Cato, who professed to have served him with a view to the interest of the public, took the liberty of giving him free advice, and of checking him when he thought his conduct was improper. In the following year Cato became a candidate for the confulsipn, but not condescending to make a popular canvas, he was rejected. The disappointment, though much regretted by Cicero, was lightly felt by Cato himself; and from this time he resolved never more to aspire to this dignity. On this occasion he observed, that an honest man, and good citizen, should not decline the administration of public affairs, when he was thought fit to be employed; but that he ought not to be immediately anxious and ardent in seeking it. In the year 50 B.C. the predictions of Cato were fulfilled by the commencement of the civil war. On the division of the provinces by the senate, he was appointed as propraetor to the government of Sicily, and in the discharge of his office he acted with his usual vigilance and diligence in fitting out ships and raising forces; but when Curio arrived there with three of Caesar's legions, he abandoned the island and removed to Pompey's camp at Dyrrachium, where he was left to guard the treasure and military stores, when Pompey had set out in pursuit of Caesar; and thus he was preferred from being present at the battle of Pharsalia. During their previous intercourse, it was his advice to procuretime the war, and thus to leave room for a negotiation; for to patriotic were his feelings, that he indulged no faction from anticipating the continuance of the contest, whatever might be the issue to the victor included; and after the victory at Dyrrachium he could not participate the joy and triumph manifested by others on the occasion. From the commencement of this contest, apprehending the loss of many brave citizens which it must unavoidably occasion, he neither shaved his beard, nor cut his hair, nor wore any other garb besides that which testified the anguish of his mind. His humanity was very signally displayed in prevailing upon Pompey and the council of war to pass an order, that no citizen subject to Rome should be touched, nor any Roman put to death, except in the field of battle. After the disastrous battle of Pharsalia, Cato failed with his troops to Coreya, where he offered the command to Cicero, as superior officer; but Cicero, conscious
Cato.

feous of his unfitness for the arduous and important undertaking, declined accepting it; upon which Cæcilius, the son of Pompey, was so provoked, that he drew his sword and would instantly have killed Cicero, if his hand had not been stayed by Cato, who conveyed the orator from the camp privately by night. From Cæcina, Cato proceeded to Africa, in order to join Pompey; but immediately on his arrival he received the news of his assassination. Adhering still to the cause of liberty, whilst he conceived any hope remaining, he proceeded with his troops to Cyrene; whence he pursued his march across the deserts, encountering many toils and dangers, with a view of joining Scipio, the father-in-law of Pompey, who had landed before him in Africa, and taken refuge with Juba, king of Mauretania. In this fatiguing and hazardous march, he exhibited every quality that was adapted to inspire his soldiers with elan and attachment, leading them for seven days on foot, and subjecting himself to hardships equal to those to which the meanest of them were exposed. At length a junction of the whole force was effected at Utica; and when a council arose concerning the lapsed command, Cato, representing the advantage which would result to the pro-confular dignity and auspicious name of Scipio, and pleaded all to acquiesce in his superiority. But he had afterwards reason to repent of his self-denial. As the inhabitants of Utica were justly suspect'd of entertaining a secret inclination for Cæsar's party, Juba, whose temper was violent and cruel, wished to destroy the city and exterminate its inhabitants, many of whom were Romans. Cato人性化 interposed, and, though Scipio concurred with Juba in opinion, he interwove with so much vehemence and indignation against so unparalleled an act of cruelty, that he put a stop to the execution of this barbarous project. At the desire of Scipio, and in compliance with the request of the inhabitants, Cato undertook to defend the city; and with this view he formed ample magazines of corn, repaired its walls, erected turrets, and prepared a fort of camp without, enclosed with a ditch and palisade, in which, after having taken away their arms, he lodged all the youth of Utica. As for the rest of the inhabitants, he kept them within the walls, strictly watching their motions, but at the same time protecting them from the inquests of his soldiers. From this place, thus stored and guarded, he furnished Scipio with arms, money, and provisions; and thus rendered it the grand magazine for the supply of the army. Whilist Cato was thus employed, Scipio and Labienus were opposed to Cæsar in the field. It was the decided opinion of Cato, that the war should be protracted; and to this purpose he repeatedly counsel'd Scipio not to engage in a general action with a commander of Cæsar's abilities; but Scipio rejected his advice with disdain; and the consequence of disregarding it was that almost the whole republican army was destroyed at Thapsus. This fatal battle was fought at the distance of about three days' journey from Utica; and this garrisoned city was the only place in Africa that had not submitted to the conqueror. Cato, having quelled the tumult of its inhabitants, and dispersed their alarms, assembled the council of three, which he had formed into a kind of senate, and exhorted them to unite, with their persons, property, and counsels, against the common enemy. With a firmness and prudence for which he was eminently distinguished in the moment of impending danger, he exerted his utmost efforts in calming their apprehensions, composing their differences, and animating their constancy. But his endeavours produced only a temporary effect, and served only to delay the threatened evil. Upon the arrival of Scipio's cavalry, which had retreated from the field of battle towards Utica, his hopes revived; but when he received from them a message, expressing their attachment to him, and their distrust of the Uticans, he was again alarmed: more especially when they represented their assistance in the defence of the city, on the savage condition of previously killing or expelling the suspected inhabitants. Cato thought this proposal no less unreasonable than cruel, and declined accepting it. Cæsar was now approaching, and the senators resolved to send deputies to him for the purpose of implo-ring his clemency; avowing at the same time that the first and principal object of their solicitations should be Cato, for whom if they failed in obtaining protection, they would not accept any pardon for themselves, but would fight in his defence to the last moment of their lives. Cato acknowledged himself obliged to them for their kind intentions, approved of their design of submitting to Cæsar, and advised them to lose no time. But he forbade them to make any mention of him in their solicitations. "It is for the varnish'd, said he, "to have recourse to supplications, and for those who have done injustice to use for pardon. As for me, I have been invincible during the whole course of my life, and I will not be vanquished afterwards on appearing as a friend to, and triumph over Cæsar by the superiority of justice and equity. It is he that is conquered; it is he that is overpowered; being this day attacked and convi'd of undeniable evidence (notwithstanding he has always denied it), of plotting against his country." The cavalry, who had impatiently waited the result of Cato's deliberations, were now leaving the city, and before they departed enriching themselves with plunder, which Cato made every possible effort to restrain; and as most of the senators preferred escaping by sea to putting themselves under the protection of Juba, Cato, perceiving that their danger was increased by the departure of the cavalry and the approach of Cæsar, took the last measures for halting and securing their retreat. His own resolution was fixed; and that was neither to ask of Cæsar, whom he regarded as an usurper, nor to dishonour himself by flight, and thus protract a fruitless contest. Having determined to put an end to his own existence, he prepared for the last scene by acts of kindness to his friends, and grave discourses with philosophers. In the last evening of his life, he first bathed and then laped in the midst of a large assembly of his friends, and the magistrates of the city, whom he had invited to this last interview. They sat late at table, and the conversation was lively, gay, and instructive, turning on certain points of moral philosophy. Step by step being ended and the company dismissed, he walked for some time, according to his usual practice, and then returned to his chamber, where he read Plato's dialogue, entitled "Phaedo," on the immortality of the soul. Having made a considerable progress in it, he looked for his sword, and found that it was withdrawn; his son having taken it away, while they were at supper. Upon this he called his slave to question him concerning his sword; but receiving no answer he resumed his reading. He again asked for his sword; but perceiving, when he had done reading, that it was not brought, he called all his slaves one after another, and raising his voice, inflent on their bringing it. "What," said he, with a great degree of indignation, "do my son and family conspire to deliver me to my enemy, unarmed and defenceless?" His son then appeared, accompanied by other friends, who besought him with tears, and in the most suppliant manner, to alter his purpose. Cato's indignation was more roused, and he vehemently remonstrated against their conduct. "Brave and generous son," said he, "why do you not put your father in chains? why do you not tie my hands behind me, till Cæsar come, and find me incapable of
of defence? Had I a mind to destroy myself, I could easily effect it without a sword; since by holding my breath for some moments, or only once dashing my head against the wall, I could dispatch myself, were I so disposed." Afterwards recovering his composure, he vindicated to the two philosophers, Demetrius and Apollodorus, who attended him, the ra
donableness of his purpose, and the folly of attempting to deprive a man, already determined, of the means of death. A young slave at length brought him his sword, which he drew and examined with attention; and finding it sharp and fit for execution, he said, "Now I am my own master." He then laid it down, took up his book, and read it from the beginning to the end. Plutarch affirms us, that he afterwards slept, and so soundly, that those who waited without, and listened at the door, heard him snore. Some, however, have questioned this fact, and ascribed to him an affectation of tranquillity, by which he hoped to augment the false glory which he expected to derive from a voluntary death. However this be, about midnight he dispatched one of his freedmen to the sea-side, in order to bring him information whether or not his friends had kept faith; and being told that the wind was very high and the sea rough, he expected great concern. He went again to the port to know, if any remained, and if they wanted any assistance, and during the absence of the messenger, renewed his sleep. Being at length assured that all was quiet in the port, he directed to be let alone, and then stabbed himself with his sword. The noise occasioned by his fall summoned his son and his friends into the chamber, where they found him still alive, but writhing in his blood, and part of his bowels hanging from the aperture in his body. Attempts were made, during a saving instant, to preserve his life by replacing his bowels and sewing up his wound; but as soon as he came to himself, he violently tore it open again, and instantly expired. This event happened in the year B.C. 45, when Cato had attained the age of 45 years. As soon as the news of his death was spread through the city, the Uticans loudly lamented it, and caused the air to resound again with encomiums on his character, as their benefactor and their favour. Notwithstanding Caesar's approach, they solemnized his obsequies with great pomp, and erected a monument to him near the sea-shore, where, in Plutarch's days, was a statue of Cato, holding a sword in his hand. When Caesar received information of his death, he is said to have exclaimed, "O Cato! I envy thee the glory of thy death; for thou hast envied me that of faving thy life." It would lead us into a wide field of discussion to state the arguments that have been used by some to extenuate and even to justify, and by others to criminate and condemn this late act of Cato. In judging concerning his conduct, we should advert to the principles of his philosophy. Professing to believe with the rest whole texts he embraced, that it might or might not, in particular circumstances, be expedient for a man to preserve or lay down his life, it remained with him to determine whether his own situation was such as to warrant the voluntary termination of his existence. But it has been alleged, in reference to this latter view of his case, that he acted insensitively with that virtue, on which he chiefly valued himself during the whole course of his life; and this was an invincible contumacy, superior to all events. The situation of his country, though discouraging, was not absolutely desperate. The remains of Pompey's party began to revive in Spain, and became afterwards very formidable. Cato, therefore, it is said, in conformity to his character, ought yet to have tried that resource, or waited for some unforeseen and unexpected change favourable to his views; and consequently by the act of suicide, while any hopes yet subsisted, or whilst there remained a possibility of some favourable revolution, he was deviating from his own principles, and abandoning too soon the cause of liberty. Some, indeed, have ascribed his death to that pride and inflexibility of temper, which the Stoical philosophy was adapted to produce and cherish. Accordingly it has been said, that he declined such an humiliation as that would have been of owing his life to Caesar, and that he might not be obliged to his enemy for it, he preferred depriving himself of it by an act of despair. It we appreciate his conduct by the principles of an enlightened theism, and more especially by those which we derive from our holy religion, we cannot hesitate in condemning it. See Suicide.

It was, however, for many ages, and has been by some in modern times, extolled as an act of heroism; and it gained among his countrymen a general admiration. Horace, though writing under Augustus, places the "noble death" of Cato (Catonis noble lethum, Carm. lib. i. od. 12) among the greatest and most honourable events of the Roman history. Plutarch's Cato Minor apud open, t. p. 755, &c. Sallust. Rullin's Rom. Hist. vol. vii. and ix.

Cato, Valerius, a Latin poet and grammarian, was a native of Gallia Narbonensis, and driven by a civil war which occurred in his country in the time of Sylla and Rome, where he opened a school of grammar and polite literature, that was frequented by perpions of the first rank. His friend, Marcus Furius Bibaceus, gives his eulogium in these two lines:

"Cato grammaticus, Latina fyren,
Qui folis legit, et facil poetas."

From the competence acquired by his professional labour, he fell into poverty, which he bore with great unanimity, and died at a very advanced age, B.C. 26. He was the author of several grammatical works, and some poems, one of which (if it be his) entitled "Dioses," expressive of his sorrow at quitting his native country and his Lydia, has reached our times. It was printed separately by Christo
der Arnold at Leyden, in 1652. 12mo, and is contained in Matteiace's Corpus Poetarum. Gen. Diog.

Cato's Difticha, in Literary History, a well-known metrical system of ethics, which has been erroneously ascribed by some to Cato the cenuror, and by others to Cato of Utica; although it is perfectly in the character of the former, and Aulus Gellius (lib. xi. cap. 2) has cited with commendation M. Cato's "Carmen de Moribus," which is altogether different from this. It is entitled "Difticha de Moribus ad Tillum," which are distributed into four books, under the name of Dionysius Cato. This work has been absurdly at
tributed by some writers to Seneca, and by others to Autol
ius. It is, however, more ancient than the time of the emperor Valentinian I., who died in 425. On the other hand, it was written after the appearance of Lucan's Pharan
ta, as the author, at the beginning of the second book, commends Virgil, Macer, Ovid, and Lucan. The name of Cato probably became prefixed to these disticha, in a lower age, by the efficacious ignorance of transcribers, and from the acquiescence of readers equally ignorant, as Marcus Cato had written a set of moral disticha. Whoever was the au
tor, this metrical system of ethics had attained the highest degree of elmination in the barbarous ages. John of Salisbury, in his "Polyo,cratium," mentions it as the favourite and established manual in the education of boys. It is also much applauded by Isidore, the old etymologist, Alcuin and Abelard; and it must be owned, that the writer, exclu
dive of the utility of his precepts, possisses the merit of a nervous
nervous and elegant brevity. It is perpetually quoted by Chaucer, who calls the writer Caton or Catonh; and Caton observes, that it is "the belle boke for to be taught to youre children in sheode." But he supposes the author to be Marcus Cato, whom he duly celebrates with the two Sici- pios, and other noble Romans. It was translated into Greek at Constantinople by Maximus Planudes; and at the restoration of learning in Europe, illustrated with a commentary by Erasmus, which is much extolled by Luther. There are also two or three French translations. Fabr. Bb. Lat. ii. p. 213. Wharton's Hist. of English Poetry, vol. ii. p. 168.

Cato, in Geography, a military township of New-York state in America, 22 miles S.E. of lake Ontario, and about 20 S. of Olavego fort.

Catoche, or Catochus, in Medicine, from κατόκας, ικουρόται, or διάτοι, are terms nearly synonymous with CATA- PELPS. Galen observes that the ancient physicians deno- minated the diseals Catochus, which the later authors have named catoche and catochaleps. The latter term was first used by Alciphidias. The ancients, however, it is obvious, did not distinguish the different forms of的形象, with that accuracy with which they are now discriminated, and hence there is considerable difficulty in ascertaining the precise meaning of their terms. It appears that the word catochus was applied by different writers, not only to cat- eleya, but to cato and to Tetanus, and perhaps to other disas, in which the voluntary power of muscular motion was diminished, or destroyed. Among modern ethologists, Dr. Cullen considers the catochus of Galen, as a variety of tetanus; and Sauages refers it to the same class; observing, however, that it differs from the tetanus; 1. in being a slow or chronic disease; and, 2. because it is not attended with vehement agitation of the breast and difficulty of breathing. It is equally difficult and unimportant now to affix a pre- cise signification to a word, which was never accurately ap- propriated by those who originally used it.

Catochites, in Natural History, the name of a fossil mentioned among the ancients, as having great virtues in medicine, and in the cure of wounds. It is said to have been found in Corsica; and Pliny records this remarkable property of it, that if the hand were held upon it for some time it would thich to it in the manner of glue. Hence it appears to have been a bitumen.

Catodon, in the Arctideni system of Ichthyology, the name given to a genus of cetaceous animals, the characters of which are these: the teeth are placed only in the lower jaw; there is no fin upon the back, and the futilous aperture is placed either in the head or the fin. — This genus is not admitted by Linnaeus; its genus Physeter comprehends these cetaceous animals which have teeth in the lower jaw, and none in the upper; and the species P. catodon is one of the two species of that genus, which has no dorsal fin.

Catoluca, in Ancient Geography, see Catadia.

Catomum, or Catomus, from κατόμος and ωμός, should- er, in Middle Age Writers, denotes that part of the body below the neck, and between the shoulders.

Catonella, in Geography, a large river in Africa, in the kingdom of Benguela, which runs into the river, called by the Portuguese Rio de las V BASES, or Cow's river. It is composed of three large branches united, and of a saltish nature: along the banks the natives dig large channels to receive its briny liquor, which is afterwards conducded into a good salt.

Catoptis, in Surgery, a disorder of the sight; more usually called myopia.

Catoptics, derived from κατάπτωσις, premium: of cata, and opta, vision; i.e., the science of reflex vision; or that branch of optics, which illustrates the laws and pro- perties of light, reflected from mirrors or spectacles.

The principles and laws of catoptics, as a distinct branch of optics, will be found under the articles, Reflection and Mirror. See also Light and Vision.

The principal authors who have treated of catoptics, among the ancients, are Euclid, Alhazen, and Vitello. Euclid's treatise is the first that is extant on this subject; it was published in Latin in 1604, by John Pena, and is included in Herigon's course of mathematics, and in Gregory's edition of the works of Euclid. Some, however, have sup- posed that this piece was not written by that great geome- trician; though it is ascribed to him by Proclus (lib. ii.) and by Marinus in his preface to Euclid's Data. See Euclid. Alhazen was an Arabic author, and composed a large volume of optics about the year 1080, in which he treats pretty fully of catoptics. See Alhazen. Vitello was a Polish writer, and composed another treatise on this subject about the year 1370. Among the moderns, many authors have either directly or indirectly treated of this sub- ject. Tacquet has demonstrated very much at length the properties of plane mirrors in the first book of his Catoptices, printed in the collection of his works in folio. Fabri has also written on this subject in his book, entitled "Synopsis Optica." James Gregory in his "Optica Promota," and particularly Dr. Isaac Barrow in his "Optical Lectures," have also directed their attention to the principles and laws of catoptics. Dr. Barrow, in the last mentioned work, has laid down and demonstrated the principles of this branch of optical science with peculiar accuracy and clearness; and deduced from them the properties of spherical mirrors, both concave and convex. We have also David Gregory's "Elements of Catoptics;" Wolfius's "Elements of Catoptics," Dr. Smith's elaborate work on optics, in which he has amply discussed the laws of catoptics; and many others of his note or of later date; either printed separately or compris- ed in those courses of mathematics and philosophy, both theoretical and experimental, to which we have occasion to refer in various parts of the dictionary.

Catoptic Dial, a dial which exhibits objects by reflect- ed rays. See Dial.

Catoptic Telescope, a telescope that exhibits objects by reflection. See Reflecting Telescope.

Catoptic Cistula, a machine or apparatus, whereby little bodies are represented extremely large, and near one extremely wide, and diffused through a vast space; with other agreeable phenomena; by means of mirrors, disposed by the laws of catoptics, in the concavity of a kind of chest. Of these there are various kinds, accommodated to the various intentions of the artificer: some multiply the ob- jects; some deform; some magnify, &c. — The structure of one or two of them will suffice to shew how many more may be made.

To make a catoptic cistula to represent several different forms of objects, when viewed at different times.

Provide a polygonous cistula, chest, or box, of the figure of the multilateral prism, ABCDEF (Plate IV. Optics, fig. 1.) and divide its cavity by diagonal planes E B, F C, D A.
DA, intersecting each other in the centre, into as many triangular locules, or cells, as the cheek has sides. Line these diagonal planes with plane mirrors: in the lateral planes make round holes, through which the eye may peer within the cells of the box. The holes are to be covered with plan glases, ground within-side, but not polished, to prevent the object, in the cells, from appearing too distinctly. In each cell are to be placed the different objects, whose images are to be exhibited; then covering up the top of the box with a thin transparent membrane, or parchment, to admit the light; the machine is complete.

For, from the laws of reflection, it follows, that the images of objects, placed within the angles of mirrors, are multiplied, and appear some more remote than others; whence the object, in one cell will appear to take up more room than is contained in the whole box. By looking, therefore, through one hole only, the object in one cell will be seen, but those multiplied, and diffused through a space much larger than the whole box; thus every new hole will afford a new focus: according to the different angles the mirrors make with each other, the representations will be different: if they be at an angle greater than a right one, the images will be monochromatic.

The retreatment that covers the machine, may be made pellucid, by washing it several times in a very clear ley, then in fair water, and bruising it tight, and exposing it to the air to dry. If it be desired to throw any colour on the objects, it may be done by colouring the parchment. Zahnus recommends verdigris ground in vinegar, for green; decoction of Brazil wood, for red, &c. He adds, that it ought to be varnished, to make it more pellucid.

To make a catoptic cistula to represent the objects within it prodigiously multiplied, and diffused through a vast space.

Make a polygonal cistula, or chest, as before, but without dividing the inner cavity into any apartments, or cells; (Plate IV. Op. fig. 2.) line the lateral planes CBH1, BHLA, ALMF, &c. with plane mirrors, and at the foramina, or apertures, pare off the tin and quicksilver, that the eye may see through: place any objects in the bottom M1. v. g. a bird in a cage, &c.

Here the eye looking through the aperture hi, will see each object placed at bottom, vastly multiplied, and the images removed at equal distances from one another. Hence, were a large multangular room, in a prince's palace, lined with large mirrors, over which were plain pellucid glases to admit the light; it is evident the effects would be very surprising and magnificent. For other modes of applying and combining mirrors, see MIRROK.

CATOPRITES, in Natural History, a name given by some writers to a stone of the marble kind, which, when polished, was capable of serving as a speculum, either flat, and only used to represent the images of things; or concave, and used as our reflecting burning-glases. The hard black marbles were most frequently used for this purpose; but sometimes the reddish ones, and sometimes one or other of the jaspers. All these were indiscriminately called by the name catoptrite, when put to this use.

CATOPTROMANCY, formed from κατ' οπτον τον θεον, speculum, and μαντις, divinius, a kind of divination among the ancients: so called, because it confided in the application of a mirror.

Ptolemaeus says, it was in use among the Achaïans; where those who were sick, and in danger of death, let down a mirror, or looking-glass, fastened by a thread, into a fountain, before the temple of Ceres; then, looking in the glass, if they saw a ghastly disfigured face, they took it as a sign of death; on the contrary, if the face appeared fresh and healthy, it was a token of recovery. Sometimes glases were used without water, and the images of things future, they saw, were represented in them.

CATO-SIMIUS, P. TIV. in Zoology. See Lemur Vulpes.

CATRA, or CATTRA, in Ancient Geography, a town of the island of Crete. Step. Byz.

CATRALEGUS, a town of Spain, placed by Ptolemy in Latitutia.

CATRENSIS, an episcopal see of Africa, in Mauritania Carnariae.

CATROPITE, See ADONITI.

CATROU, FRANCIS, in Biography, a learned and ingenuous writer, was born at Paris in 1619, entered among the J. fulls in 1637, and took his vows at the college of Bourges in 1654. He officiated as a preacher for 7 years, and then abandoning that office, on account of the difficulty of committing his sermons to memory, he devoted himself to literature, and was employed from 1701 for 12 years in writing for the "Journal de Trévoux." In 1752, he published "A general History of the Mogul Empire," from the Portuguese memoirs of Manouchi, a Venetian; to the third edition of which, in 1715, is annexed the reign of Aurungzebe. His "History of the Fanaticism of the Protestant Religion," containing only that of the Ambassadors, appeared in 1706; and in 1733 he added, in two volumes, of Daviafin and of the Quakers. His "Translation of Virgil in Prose, with historical and critical notes," began to be published in 1708, and was completed in 6 vols. 12mo. in 1716. With many defects and faults, this work displays both ingenuity and industry. The most elaborate performance of Catrou is his "Roman History, from the foundation of Rome," which employed the greatest part of his literary life, and in which he was assisted by his brother Jefuit, Julian Roulle. This appeared in 1737, with the notes, dissertations, medals, &c. In 20 volumes 4to, and, without these appendages, in 20 volumes 12mo. The history was brought down by Rouillé, after the death of Catron, in one volume 4to, to the end of Domitian's reign. The work displays great labour and research, and contains an ample and well-connected collection of facts; though the Ryle is affected, and not characteristic of a bold and dignified historian. It has been translated into Italian and English. Catron died in 1757, in the 75th year of his age, and retained to a very advanced period the force and vivacity of his imagination. Nouv. Dict. Hilt. Gen. Biog.

CATRY, in Geography, a particular sect of Hindus, mentioned by Thienot, who places them in the vicinity of Moulain, and who says that they spread from hence over all the Indies. He explains this tribe to mean "Rajputs," or warriors; that is, the Kutry tribe, properly Thees Catries, according to Rennell, were the Catheri of Diodorus Siculus, and the Cathii of Arrian; with whom Alexander contended on the border of the Mall. See CATRIA.

CATSAL, a town of Chinee Tartary; 28 miles W. of Cuchna.

CATSABANIA, in Ancient Geography, a country of Arabia Felix, according to Steph. Byz.; called by Strabo Catalonia.

CATFACK, or CUTFACK, in Geography, a country of Hindooftan, and capital of a district of the same name, in the province of Orissa. It is fented on the river Mahanuddy, and is an important port, as it lies in the only road between Bengal and the northern circars; and the possession of this city and its dependencies gives the Bari rajah more confidence in the eyes of the Bengal government, than even his extensive
extensive domain and central position in Hindoostan. It is distant 785 miles from Agra, 452 from Benares, 1034 from Bombay, 231 from Calcutta, 902 from Delhi, 951 from Hydabad, 641 from Lucknow, 779 from Madras, 482 from Nagpore, 822 from Oungum, and 968 from Poonah. N. lat. 20° 12'; E. long. 86° 1' 30".

CATTHUNK, one of the Elizabeth islands, in the state of Massachusetts.

CATTIAO, a town of Italy, in the Paduan territory; 5 miles S. of Padua.

CATTARO, or CATARO, a town of Dalmatia, capital of the territory of the same name, surrounded with thick walls, and defended by a cullée; the see of a bishop, suffragan of Bari. It is subject to the state of Venice, and seated on a gulf of the same name. N. lat. 42° 25'; E. long. 15° 19'.

CATTECORONDE, in the language of the Ceylonese, prickly cinnamon. This is a bark very much resembling cinnamon, but produced by a tree which differs very much in the shape of the leaves, and is full of sharp thorns, which the true cinnamon tree is not. The bark has nothing either of the taste or smell of cinnamon, though like it externally. The natives use the root, leaves, and bark of this tree externally, to soften fetid gums. Phil. Trans. N. 54o. See Cassia and Cinnamon.

CATTIGARA, or Scaggarac, in Geography, a large gulf of the North Sea, between North Jutland to the west, Norway to the east, and the islands of Zealand and Funen to the south, about 150 miles from north to south, and from 60 to 70 from east to west. This gulf is sprinkled with an astonishing number of rocks and islands. See Belts.

CATTINOM, a town of France, in the department of the Mofelle, and chief place of a canton in the district of Thionville. The place contains 1057, and the canton 14,876 inhabitants; the territory comprehends 297½ square miles and 47 communes.

CATTERTHUN, a remarkable Caledonian post, situated a few miles N. of the town of Brechin, in the county of Angus, in Scotland. Mr. Pennant represents it as a very strong post, and particularly describes its structure and dimensions. Near it is another similar fortification of inferior strength, called "Brown Catterthun," from the colour of the ramparts, which are composed only of earth: the other consisting of stones. The former is of an oval form; but that of the latter is circular. Catterthun denotes "Camp-town," and Mr. Pennant is of opinion, that these might have been occupied by the Caledonians before their engagement at the foot of the Grampian mountains with the Roman general Agricola.

CATTI, in Ancient Geography, a people of Germany, who lived in the vicinity of the Cherusci. They were a warlike people, and their infantry was reckoned the best in Germany. The most remarkable places of their country were Cattellum Cattorum and Manitium. Under the lower empire they were divided into two bands or cliques, one of which joined the Cherusci, and the other established itself in a district of the country of the Batavi.

CATTIER, ISAAC, in Biography, born at Paris in the early part of the 17th century, received his education at Montpelier, where he took his degree of doctor of medicine, in 1657. Returning to Paris, he was made physician in ordinary to the king, and ranked among the most eminent physicians of his time. He was author of several learned works: "On the Waters of Bourbon;" "On the Powder of Sympathy," which he did not admit to be possessed of the qualities attributed to it; "De Rheumatismo, ejus Na-
CATTLE.

The characteristic distinctions of the genus or kind, according to the very intelligent naturalist, Mr. Pennant, are that they are four cloven footed, with or without horns, the horns bending out laterally; eight cutting teeth in the lower jaw, and none in the upper; the skin along the lower side of the neck pendulous; rounded horns with a large space between their bases.

This species constitutes the principal particular breeds, being formed from the original and most remarkable divisions or distinctions; and the varieties are produced by the intercrossing of these, which, from their being accidental, as well as from the great diversity of soil, food, and climate, must obviously assume a vast diversity in respect to shape and size. Some of these varieties, whether original or acquired, have, however, been preserved in a permanent state by the efforts and attention of the careful breeder. But notwithstanding the variations produced in near cattle by the influence of climate, or the agency of other causes, the natural divisions which have been made in their kind by the naturalist is that of the ursi, or common bull of temperate climates in its native wild state, and the cibion or bull of the more hot regions, having a bunch between his shoulders, which in some of the latter is said to be of considerable weight and exquisite flavour, and to form the characteristic distinction of the animal: while the elevated crest, and in some cases the lion's mane, form nearly a characteristic mark of the common bull, the former of which being individually preferred to the ultimate stages of domestication, as is occasionally seen in the Duchess, Aldeneey, and other kinds or breeds.

Before we come to consider the various breeds and varieties of domesticated cattle in our own country, it may be of advantage to take notice of some particulars respecting those in others, that are the most remarkable.

In regard to the ursi, or native wild bull, it has in general a curled shaggy coat, especially on the forehead: the hair constantly long on the fore quarters, neck, and forehead, and depending from the chin; the neck elevated, thick and short, with the tail long, the eyes red and fiery; the horns thick and short. It grows to a large size, the female being larger than our largest bull, and is of a black colour.

The cibion has the same hairy appearance in his fore part only; his long shaggy mane forms a sort of beard under his chin, but he differs from the former in having a lump or bunch between his shoulders, and the tail and legs are short, the eyes fierce, the forehead large, and the horns extremely wide.

The former of these sorts of animals are dispersed over the more temperate and cold climates, and especially throughout America, probably imported from Europe; while the latter have spread over most of the more southern parts of the world; but with considerable diversity in respect to their size and form:—Those met with in the island of Madagascar, in Malabar, as well as other parts of India, in Persia, the Ukraine, Calmuck Tartary, the Upper Ethiopia, and in Abyssinia, being of the proper cibion or large kind; while those of Africa, the higher southern latitudes of India, and some parts of Arabia, are of the small dwarf or azere kind; in which the hair is more fine, glossy, soft, and beautiful, than that of the common cow:—The largest animals of the different sorts being constantly met with in those temperate situations or districts, where the supplies of water and herbage are the most regular and abundant.

In some of the former of the above countries the animals are known to a very large size, sometimes being wholly without horns, but in other cases with extremely large branching or pendulous ones, having a very great sub stance or thickness at the basis. They are in much estimation, especially the oxen, when of a fine white colour, for the purpose of quick draught in carriages. And in some of the more barren and less fruitful parts of the latter countries the frost is found extremely useful in carrying loads, though often not more than three feet in height.

The Indian cattle have been occasionally brought from their native situations, and blended with the breeds of this country.

The mule bull, which is found in the interior parts of North America, between Churchhill and Seal rivers, may perhaps be considered as a variety of the above sort produced by intercrossing with the wild European kind, as the wild bull of this part of the globe emits a musky scent. It is described as somewhat lower, but more bulky than the deer; the legs short, a small hump or bunch on the shoulder; the hair of a dull red colour, very fine, and so long as to reach the ground; beneath which the body is covered with an ash-coloured wool of exquisite fineness, capable of forming stockings finer than silk. The tail not more than three inches in length, being covered with long hairs, which the Equinamaus Indians convert into caps. The horns are close and large at the base, bending downwards, and turning out at the tips, being two feet in length or more.

The farbic, or grunting ox of Tartary and Thibet, where it is brought into a domestic state, from having the hump between the shoulders, and being capable of generating with the bullion, may obviously be considered to belong to that kind. The chief circumstance in which it differs, is that, instead of bowing, as in the ox kind, it has the peculiarity of grunting like the hog, but it varies in other particulars. It has the whole body covered with a very long hair, which hangs down below the knees, mostly of a black colour, except on the ridge of the back and the mane, which is white. The horns are short, upright, sharp, and slender at the extremities. The tail in the form of that of the horse, but white and bushy. It but or strikes with its head like the goat, and in its wild state is extremely unruly. The tail is held in high estimation for various purposes of ornament.

How far any of these foreign breeds or varieties of cattle are capable of being introduced with advantage into this country, remains to be further proved by the tests of actual experiment, in respect to the qualities or properties of hardiness, quickness of fattening, fineness of flavour in the meat, and many other points, as has been ingeniously suggested by Dr. Anderton.

In regard to the cattle of our own country, as they are not less numerous in their varieties than those of the foreign kinds, and of much more importance to the farmer in a variety of different points of view, but particularly in that of profit, the greatest care and attention should obviously be bellowed on the breeding, rearing, and providing such sorts as are the best suited to the particular nature of the farm, or land on which they are to be supported. And as no one particular breed is suitable for every situation or kind of farm, much circumspection should be employed in adapting them to the peculiar nature of the climate, situation, and soil.

The circumstances that are to be more particularly regarded, in respect to the breeds themselves, in so far as they interest the farmer, have been already explained, in considering the method of breeding this sort of live stock. See Breeding.

It is not well ascertained what were the primitive or original sorts of cattle in this island, but it seems probable from those breeds which have, from particular circumstances, remained
CATTLE.

railed without being much debated by the admixture of other sorts, such as the Highland, the Welsh, and the North Devon, as well as perhaps the Lancashire long-horns, that, in the more hilly regions and the low valleys, they con-
fiicted of the long and middle-horned varieties, perhaps without any of the short-horned sort, which have, probably, been once introduced from the opposite continent. Same, however, think, with much probability, that the long-horned sort was originally brought into this country from Ireland, from the native stock of that island consisting wholly of that breed, and that other breeds of foreign cattle, which have a facility of form and size of horn.

Poland is likewise supposed to have supplied the breed, which, from their having no horns, is termed the polled, though it is probable from the want of horns being a part of the generic character, that a mixture of this sort of cattle may have originally existed in the country, notwithstanding they are now blended and intermixed with others as not to leave a possibility of discovering the original.

It is probable that the primitive or original sorts of cattle have not deviated much from their standard terms, except in what has proceeded from an increase of size, bulk, and sublance, in consequence of being better supported from the improved state of husbandry, and their being blended and muddled into different varieties by crossing, and other means made use of by the breeder.

The numerous breeds and varieties of cattle which are to be found in different districts of this kingdom have been principally designated either from the appearances which they im mediately present to the farmer, or the places in which they are found to prevail in a state of the greatest perfection; though no very correct enumeration of them has hitherto been given, only a few of the more valuable and useful sorts having been fully described.

There are the long-horned or Lancashire breed; the middle-

horneed breed; the short-horned breed; the Welsh breed, the polled or Galloway breed; the Scotch breed; the Alderney or French breed; and the mild breed.

It has been observed by Mr. Culley, in his "Treatise on Live Stock," that the long-horned or Lancashire breed of cattle are distinguished from others by the length of their horns, the thickness and firm texture of their hides, the length and closeness of their hair, the large size of their hoofs, and coarse, leathery, thick necks; that they are like-

wise deeper made in their fore quarters, and lighter in their hind-quarters, than the other breeds in general. And Mr. Donaldson says that in size they are superior to the Suffolk 
ducks, but inferior to the short and middle-horned breeds. Mr. Culley thinks also further that they are narrower in their shape, less in point of weight than the short-horns, though better weighers in proportion to their size; and that the cows give considerably less milk, though it is said to afford more cream in proportion to the quantity.

These are more varied in colour than any of the other breeds; but whatever the colour be, they have gen-

erally a white streak along their back, which the breeders term flueck, and molly a white spot on the insole of the hoof. And in the bending of the horns there is an equal variety in this sort of cattle.

It is likewise remarked by the same author, that many peo-
ple contend that they are the native or original breed of this island. It is not easy, he says, to ascertain this matter; but if he may venture a conjecture, he thinks it is probable these have been the inhabitants of the open plain country; whilst the wild breed, or perhaps the Welsh and Scotch, possessed the woody, wild, and mountainous parts of the island. — "However," says he, "Lancashire at present, and for a Vol. VII.

long time past, has as much right to be called the mother country for long-horned cattle, as Lincolnshire has for the large long-wooled sheep; for though all or most of the cheese-dairies in Chezshire, Gloucetsershire, &c. and indeed the greatest part of the midland counties employ a kind of long-horned cows, yet they are only a shabby mixed breed, much inferior in size and figure to the Lancashire breed, from whence it is very probable they all originated." The author of "The present State of Husbandry in Great Bril-

tain," however, thinks it probable that the long-horned breed originated in the importations of cattle from the neighbouring country of Ireland; a few of this breed brought from that island, having been coupled with the ancient breeds of the district, produced the sort of cattle known by the name of the Lancashire or long-horned, and which now occupy a large portion of the idle lands of this kingdom. It is added, that besides Lancashire, the long-horned cattle are also very general in the counties of Warwick, Leicesters, Gloucetsers, Chelford, and several others of the midland coun-
ties; and what is surprising, and shows great attention in the one instance, and equal neglect in the other, this sort of cattle is said to be found in greater perfection in the coun-
ty of Leicesters than in the district whence they take their name. This has arisen, according to the obserbations of the author of the Treatise on Live Stock, from the graziers of those counties buying their bell bulls and heifers for many years past, before the people of Lancashire were well aware of it. "The former paid more attention to that kind which were of a true mould or horn, and quicker feeders; while the latter contented themselves with the old-fashioned, large, big-horned kind, which are not only flower feeders, but when fed, are not flesh good beef. In short, the little farmers in Lancashire, tempted by the high prices given them for their bell stock, had lost their valuable breed before they were sensible of it." It is evident that the original breed of this sort of cattle spread themselves from the great breeding districts of the northern parts of Lancashire, Wellmore, and Cumberland, into the extensive grazing and dairying districts of the midland counties, where they are at present met with in the most improved state.

It is affected that this breed is understood by graziers to be in general rather slow feeders, except that particular kind selected and recommended by the late Mr. Bakewell, which are said to eat less food than the others, to become remark-
able fat in a short space of time, and to lay their fat upon the most valuable parts, but have little tallow in them when kilned; and, when used in the dairy, give very little milk. This variety also differs from the rest of the long-horned cattle, in having very fine, clean, small bones in their legs, and thin hides. They are stated to be "a middle-sized, clean-boned, round-cased, kindly-looking cattle." It is supposed by Mr. Culley that the Irish cattle are a mixed breed between the long horns and the Welsh or Scotch, but more inclined to the long horns, though of less weight than those in this part of the kingdom.

It was from the midland long-horned breed of neat cattle that the late Mr. Bakewell selected the flock for his great improvements in these animals. Much attention had indeed been previously paid to the procuring and introducing of the bell cow flock of this sort into this district by others, and it was by selecting from these that Mr. Webster constituted the noted Canley flock. And from cows of this celebrated fort with Wellmoreland bulls the very intelligent breeder just mentioned commenced his plan, which, after breeding repeatedly from the bell of the same kind, confantly choos-
ing individuals with the roundest forms and smallest bones, he produced that variety, which has since acquired to high a character.
a character for their fattening property. It is, of course, obvious that this variety which has been denominated the Dibley or New Leicester, is principally cultivated for the purposes of the grazier, while the original long-horns have preferred their superiority for the retail. The size of this improved horn is considerable, and its utility sufficiently shown by the high prices that are frequently given for them.

There is a sort of mixed kind which are termed half long-horns, that are an useful sort of flock, and which will be noticed below.

The middle-borne... of cattle... as according to the author of the Treatise on Live Stock, most frequently met with in the south and south west parts of the kingdom, Suffex, Dorsetshire, Hampshire, Devonshire, &c, and the use also reached so far north as Forfarshire, in which district the breed: The breed of this sort of cattle are now to be found. The cattle of this breed that are met with in Devonshire are fied by Mr. Culley to be found in the greatest purity, and of the bell kind, in the vicinity of Barnthistle; there are of a red colour; if they have any white spots they reckon the breed impure, particularly if those spots run into one another; with a light dun round the eye, and the muzzle, of the same colour; fine in the bone, clean in the neck, horns of a medium length bent backwards, thin-faced and fine in the chops, wide in the hips, a tolerable barrel but rather flat on the sides, tail small and set on very high; they are thin-skinned, and silky in handling, feed at an early age, or arrive at maturity sooner than most other breeds; they are well fitted for draught, both as to hardiness and quick movement; and their shoulder points are beautifully fitted for the collar.

But according to Lord Somerville, who has given a full account of them in the "Annals of Agriculture," and who must be allowed to be no mean judge of this breed of cattle; they are, when described, "not as they might be in imaginary individuals, but as they really are found, in general, speaking of this as of all other breeds, that conclusions must not be drawn from the shape and size of the bulls, but from the general quality of their flesh. Certain it is (he says) that individually handomest bulls are often to be found in other breeds; and it is as certain, that this race, of which the British breeders are the most fond, of all the crossbreeds, or among the very few at Smithfield, where prejudice cannot find the way. And in forming an estimate of merit or demerit, the annual produce is to be the object attended to; this in oxen, which for superiority of grain, activity in labour beyond all competition, and what in horses is termed blood, will be found a right criterion to judge of the bulls which got them."

And that "beginning with the shape of the bull, in any very handomai individual, the horns is (he says) found neither dropping too low, nor rising too high, nor with points inverted, called here flag-headed; tapering at the points, and not too thick, or goary at the root; the colour yellow, or waxy. The eye clear, bright, and prominent; looking well behind and shewing much of the white;—a dead-eyed ox not often a good prover, or fine in skin;—in occasional variation of colour round it. Forehead flat, indented, and small;—this found almost universally in this breed, and is a point that shews much blood. Check small and muzzle fine;—if the forehead is fine the muzzle is so too. The nose of a clear yellow, if possible like the horn, or mottled:—a black nose always to be avoided; for although occasionally a black-nosed ox may bear a white, and die well, yet it is a point often demonstrative of a bad constitution, of such as turn foetures, or flinters provincially, and particularly when the cast of the coat is of too pale a colour. The nostril high and open. In respect of throat, the bulls of this breed are sometimes reproached with being throaty, or with the skin too profuse and pendulous. The hair curled, giving an apparent comfort to the head not to be found in the New Leicestref bulls, when carefully trimmed with scissors. The neck perhaps thick and goary in the estimation of strangers, with which property the oxen of this breed are not to be reproached, or they would not labour as they do."

"Generally speaking (he thinks) the bulls are relatively to oxen not of a large size; and it should be observed respecting size in general, that nature operating in food and climate is imperative, and will produce oxen proportioned to those two circumstances in due course of time, whatever may have been originally the form of the bulls and cows."

Here end (he says) the points wherein there is any essential difference between the bull and the ox; the variation in one is small and unessential; a remark which is, however, subject to limitation; for individual influences will occur, which it much too much attended to, would seem to establish a different rule.

"The neatest sort of form, and energy and vigour in labour, greatly, if not wholly, in this breed are (he supposes) from breeding by heifers and yearold and two years' old bulls. Although an old cow may produce a finer lamb than a younger one, yet the quality of vigour is unnecessary and extraneous (he says) to the sheep. This, (continues he) is a prejudice deeply rooted in the minds of all practical men, although much, in the estimation of some, may be given to climate."

"Compared with the horse, the shoulder is (he conceives) low. It should correspond with the general thicknefs of the animal; on no account projecting. If a bull is inclined, or bending towards each other, the point of the toe must be out; the point of his shoulder must be the same; and he must he low behind the withers, (an incorrigible point in an ox for feeding) and he must be, of necessity, a slow worker."

"The boholn is not sharp with a loofe, pendulous dewlap; but wide in form, and mellow in handling. In buying an ox great notice should be taken of the breadth of the boholn, and between the fore-legs, standing quite wide, the legs like straight pillars supporting a great burden. Much in buying is loll or gained by attention to this point: it is not for symmetry only, but implies strength and speed; a proportionate breadth of breast giving wind; and here we find (he says) the application to a working ox."

"The legs are straignt; and the more blood an ox shews, the smaller will they be. The circumstance of this breed shewing more blood than any other in the kingdom, has (he observes) been remarked by many persons ignorant of cattle, but deeply skilled in horses. The leg neither too long, nor too short: an undue length is to be avoided."

"Very much of a bullock's proof is admitted, (he adds) on all hands to depend on the size of the rib, rotundity of the barrel, and mellowness of the skin. These are the first points to handle in a lean and in a fat ox. The two hind ribs should be bold, prominent, and widely independent of each other. The skin rising easily from the ribs, mellow, and elastic, affording room to lay fat on below it. A man buying a lean ox would do well to handle him on both sides: it often happens, that the frame or barrel is not equally round on both; one being evidently to the eye and hand flatter than the other."

"The hips, or pins, lie so high as to be on a level with the brisk, either in a fat or lean ox; by no means dropping. The other the animal, the lower the upper flank drops, and consequently, the higher the hips appear. In this point of the
CATTLE.

The upper flank, a skilful judge will (he thinks) discover much of the inward properties of a fat bullock. The hind quarters from the pin to the catch, or point of the rump, should be long and well filled up: handling the centre of this space is a leading feature, in the estimation of choice judges, and ascertains more of the substantial quality of the flesh and fat of a beast than the prominence of fat so much admired by bad judges on the catch of the rump.

"The letting on of the tail is on a level with the back, something elevated, nothing depressed: size long, small, taper, and with a round bunch of hair at the bottom; the tail, as in a horse, denoting much of high blood.

"The galloways are not too much cut away, nor, as in the Holderness breed, heavy and loaded: bearing always in mind, that these oxen are not bred for inutility, but for wind, vigour, and strength: for although a breadth in the boarom, in as much as it is essential to wind, in a working animal, is beneficial; yet a load of flesh on this hind part tends nothing to activity; and being of second-rate quality, is not desirable for profit.

"In point of skin they are among the thinner classes, rather than the thicker. It is very rarely that an ox is found with a hard or wiry skin. Much depends on colour: the shades most admired are the mahogany; and the more glossy filkens, if smooth, the better. Those with curled hair are deemed excellent provers, and a very glossy mahogany pater, lighter, with curls like ripples on a smooth mill-pond, is also in the highest estimation. It is hard to say which of these is the best; all turning out such numbers of good fat oxen. The paler shades, if the eye is clear and good, will bear hard work, and prove as well as any. This rule only is absolute, that a pale skin, hard under hand, with a dark and dead eye, too often denote a fitter in hard work, and rarely under any indulgence, a good prover.

"Respecting the lower flank and the cod, they do not deserve that attention which many persons pay them, who consider these points of prime importance.

"The graziers like this breed (he says) best at five years old. The worked-out fleeces of the vale fall for more. At five years, than at six; but six is the proper age. At eight, nine, and ten, they are going back in all their points; and in their value after seven. No ox should be kept after seven, or, at most, after eight.

"They (the red cattle) are (he says) yoked at two or three years old, and lightly worked; labour increased at four; from that period till six full worked. Worked oxen attain a larger size than unworked; finish their growth generally at fix years old; but the larger size grow the longest.

From the actual experience of the noble writer, "the pole and yoke form the true lever of an ox, and he can draw a greater weight in yoke, than in collar and harness, particularly in a steep country. The bullocks never come home in the middle of the day; a bundle of hay is carried into the field; all the calves of this breed are reared."

Thee oxen are "(he says) parted with by the tillage farmers until the harky-fowling is over, and, in many cases, the turnip-ground once fird; yet they are grazed fat, in six or eight months, to the average weight of forty-five score: these, kept on, after Christmas, fattened on hay alone, which, in the grazing districts of the west, is held equally nutritious with any other fort of corn; oil-cake feeding not practised: these hay-fed oxen stand the drift to London without waste. Influences of marsh-feeding heifers bought in April or May, quite poor, fit for the butcher by the middle of July; in August uncommonly fine beef."

"The station of this breed begins (his lordship observes) at Barnstable, and is traced, by pursuing the line of the river Taw, as high as Chulmleigh, then to Tiverton on the Ex, Wellington, and nearly to Taunton. Then turning north, straight to the sea, over the eastern boundary of the Quantock hills, to Stoke Courcy; from which place, on the eastern extremity, to the mouth of the Barnstable river on the western, includes the whole, to the length of forty-five miles, and to the breadth across, from Tiverton to Minehead, of twenty two. To the east of this range, the breed gets into a mixture of Gloucester, Welles, Upper Somerset, &c. being a varied dairy sample; and more to the west, a Devon, working on the principle of the Cornish flock. To the south, the variety of the four harms is found; coarse, with a good deal of white, the brown, with black and white mixtures, of uncertain properties. Excentric, the highest point of the district thus defined, the country fishing from it in every direction, the source of all the rivers, and the head-quarters of all the cattle. At Bampton and Wyvelcomb, they are found in great perfection."

It is observed by Mr. Lawrence, in his "Treatise on Cattle," that "the red cattle of North Devon and Somerset are, without doubt, one of the original breeds, and one of those which has preferred most of its primitive form: the excellence of this for labour is best proved by the fact, that the fashionable substitution of horses has made no progress in the district of these cattle; by their high repute as feeders, and for the superior excellence of their beef, which has been acknowledged for ages."

It was remarked by Mr. Bakewell, that the Devonshire could not be improved by any cross with other breeds. This breed has been supposed to some run to too great length of leg, crooked behind, or fickle-harnessed, to be of insufficient general substance, as well as to be more apt to be in-bred, that is, crossed in the fore legs.

It is fudged, by the writer just mentioned, that, "by a proper selection from their own flock, they might be bred somewhat more square and substantial, without all detracting from their delicacy, flesh of blood, or spice. Their labouring powers might be thus increased, and their quantity of beef, without either debasing its fine qualities, or rendering necessary a larger portion of keep. These cattle have generally, for a century past, it is added, commanded the best price at Smithfield; but of late years the buyers there have strangely remarked, that although blood and fine form are very pleasing to the eye of the gentleman breeder, yet substance and weight are, and ever must be, the grand objects at market."

It is stated that "the Devonshire variety of this breed are the quickest working oxen in this country, and will trot well in harness; in point of strength, they stand in the fourth or fifth class. They have a greater resemblance to deer than any other breed of cattle. They are rather wide in the horns, in part inclining. Some, however, have regular middle horns, that is, neither short nor long, turned upwards and backwards at the points. As milkers, they are so far inferior to both the long and short-horns in quantity and quality of milk, that they are certainly no objects for the regular dairy. They have, however, been formerly used with success at Epping in Essex, in one or two instances; as a balance to which they are universally rejected by the dairies of their own and the neighbouring counties."

It has been stated by Mr. Young, "that the natt or polled Devonshire breed, in the neighbourhood of Barnstable, is coloured, middle-sized, thick-set, and apt to make fat, but
The Devonshire, being a hill cattle, are said to be much more hearty, and better winterers, than might be supposed from their appearance.

The Suffolks and Herefordshires are varieties of the middle-horned, or Devonshire breed of a greater size; the Herefordshire being the largest. Of these cattle Mr. Culley gives the following description. Colour red, fine hair, and very thin skin, neck and head clean, horns neither long nor short, rather turning up at the points; in general, well made in the hind quarters, wide across the hips, rump, and shoulders, and narrow on the spine; tolerateably straight along the back; ribs or sides lying flat, thin on the thigh, and bone not large. An ox, six years old, when fat, will weigh from 60 to 100 stone, from 14lb. to the stone, the fore-quarters being generally the heaviest. The oxen are mostly worked from three to six years old, sometimes seven, when they are turned off for castrating.

It is conceived by Mr. Lawrence that the Herefordshire variety of cattle, which at present are a mixed breed, are, in general, to be considered as having been originally of the Devonshire breed. And that "its great size is probably derived from an intermixture with the heaviest of the Welsh or Shropshire breeds."

According to Mr. Marshall, "this variety has the countenance pleasant, cheerful, open; the forehead broad; eye full and lively; horns bright, taper, and spreading; head small; chap lean; neck long and tapering; chest deep; hocks broad, and projecting forward; shoulder-bone thin, flat, no way protuberant in bone, but full and mellow in flesh; chest full; loin broad; hips standing wide, and level with the spine; quarters long and wide at the neck; rump even with the general level of the back, not drooping, nor standing high and sharp above the quarters; tail slender, and neatly haired; barrel round and roomy, the carcases throughout deep and well spread; ribs broad, standing close and flat on the outer surface, forming a smooth even barrel, the hindmost large and of full length; round bone, small, firm, not prominent; thigh clean, and regularly tapering; legs upright, and short; bone below the knee and hough small; feet of middle size; cord and twist round and full; flank large; flesh everywhere; mellow, soft, yielding pleasantly to the touch, especially on the chine, the shoulder, and the ribs; hide mellow, supple, of a middle thickens, and loose on the navel and hock; coat neatly haired, bright and silky, colour a middle red, with a bold face, characteristic of the true Hereford breed."

However, Mr. Lawrence says, "of late years, considerable improvements of bone have been observed even in the best Hereford cattle; a circumstance which is of trifling importance, as they have proved themselves of such superior excellence, that no possible crosses could probably improve them."

It is supposed that the breeders should reflect on the importance of preserving the old blood in a state of greatest purity as possible, as they possess, for some purposes, the most valuable breed of cattle in the kingdom, and have been very judicious and fortunate, in nicely blending the elements of each variety; but they ought not to forget, that, by further mingling and crossing with inferior stock, they may, by degrees, recede from the great eminence they have attained. Should, however, a cross become really necessary, from too much coarseness or over-size, the Devonshire or Norman bulls are supposed the proper ones.

It is added, that "the great distinguishing properties of the oxen of this district are, the great produce of beef, quick feeding in proportion to their growth and size, and the union of strength and speed in labour. It is observed that, with respect to the most profitable return in quantity of beef, it may be presumed no breed in England can stand in competition with this, and they have accordingly been most successful at the annual prize fairs. They also are said to command the full price alive or dead."

It has been stated that the weight of Mr. Weftcar's ox, which carried the prize at the Smithfield show in December, 1802, was as follows:

Though the short horns are of larger size than those, they do not feed so quickly, and require more keep than the Herefordshire fort, which vary very conveniently as to size, but require to be well kept. They are the most powerful draught oxen, being speedy enough for any work, either in the plough or cart, and generally walk sufficiently quick. It is said that they are docile and tractable, and, if trained with temper and kindnes, will drive to an inch with reins. But "as milkers they have nothing particular to boast."

Mr. Lawrence thinks the old Gloucestershire Red and Brown were middle-horned, flowing blood, and reenabling, in a considerable degree, the South Devon, but of a more square and substantial form. They were, however, he supposes, a mixed breed, which flowed much Welsh blood, and were, it may be presumed, more apt to fatten than milk, since they have given way to the long-horned species in that dairy country. It would be difficult, he thinks, at this time, to find any genuine specimens of this old variety.

The Suffolks are of the same breed of cattle, Mr. Drayton says, in high estimation for beef and labour, and, in some degree, for milk; in which latter respect, they are inferior to the Devonshire and Herefordforts, to which they are related. They are a mixed breed, in which much Welsh crossing is sufficiently obvious; but equal pains do not seem to have been taken in their improvement as with the Herefordshire kind. They may be easily found in a state of original purity as to form. This fort are very flat and deep, generally red or brown in colour, and show much blood; both wide and middle-horned, the points turned upwards and backwards; of various sizes, but the largest generally for too coarse in the bone, and of insufficient width or substance for their great depth of carcases. They yet, he thinks, need no alien crosses; having all the materials of improvement within themselves, unless, indeed, to remedy the excessive fatness in some, a Hereford cross might be useful. Their speed appears to him remarkably great, and he doubts whether even the Dons are, in that respect, superior; they are, in the mean time, equal in power,
power to the cultivation of the heaviest clays, and to draught over the deepest roads; in temper somewhat quick, like the Devons. These different varieties of the middle-horned breed of cattle are said, for their particular excellencies, to deserve the utmost care from breeders, and to be one of the first objects of national interest, to spread them through the country as beasts of labour.

He supposes that the Kentish Homedreds, which are raised from dairy heifers, are of a mixed breed, the Suffotx generally forming the base, crossed with Welsh long-horns, Alderney, &c. A variety is, he says, thus raised of excellent butter-cows of a small size; and he fuggels it to the breeders of that district whether it may not be worth while to establish and render the breed permanent.

A good specimen of a bull of this sort raised from Suffotx bulls, introduced into that county about forty years ago, was remarkable for shortness of the leg, length of carcases, and vast sub stance; the bone somewhat coarse, and crooked in the hams. It is observed by the name writer that of, the white cattle of Surrey, mentioned by old authors, he knows nothing, nor does he believe it was ever a breeding country. The notion may have arisen, he thinks, from some temporary introduction of Alderney, or other flock of light colour. * In facts, he is it said, that some gentleman, about fifty years since, brought up from Lincolnshire, into Surrey, a lot of white cows, very large milkers, and that the same kind were at that time kept in Suffolk; they were probably, he thinks, of Dutch extraction.*

The author of the "Present State of Husbandry in Great Britain" remarks, that when all the properties which should attach to a useful breed of cattle are considered, the middle-horned may be said, as a general variety, to come nearer to perfection than any other in England. They are of a large size, well formed, and in disposition to fatten, they are probably, he thinks, much on a par with the short-horned, and generally superior to the Suffolk. As dairy cattle, they are also as valuable as any that fall under the description of quick feeders; for although they give a less quantity of milk than the Suffolk or the long-horned, it is said to be of a richer quality.

The short-horned breed of cattle, according to Mr. Collie, differs from the other breeds in the shortness of their horns, in being wider and thicker in their form or mould, consequently feeding to the root weight, in according by much the greatest quantity of tallow when fattened, in having very thin hides, and much less hair upon them than any other breed, except the Alderney; but that the most essential difference, he thinks, consists in the quantity of milk they give beyond any other breed; there being influences of cows of this breed giving 36 quarts of milk per day, and of 48 firkins of butter being made from a dairy of 12 cows; but the more general quantity is 3 firkins per cow in a season, and 24 quarts of milk per day. The great quantity of milk, thinness of their hides, and little hair, are, he says, probably the reasons why they are tenderer than all the other kinds, except the Alderney.

It is said of this kind, and he supposes very truly, that they eat more food than any of the other breeds; nor can we, he says, wonder at this, when we consider that they excel in these three valuable particulars, viz. in affording the greatest quantity of beef, tallow, and milk. Their colours are much varied; but the generality of them are red and white mixed, or what the breeders call flecked, and, when properly mixed, a very pleasing and agreeable colour. They are chiefly to be found in Lincolnshire, and the eastern parts of the counties of York, Durham, Northumberland, and Berwick. And this breed, in consequence of its having been originally imported from Holland, is, he adds, frequently called the Dutch, and sometimes the Hordernesf breed, from a place of that name in Yorkshire, where it would seem it was first established in this kingdom. Delitute of the exertion and agility of the middle-horned breed, says Mr. Donaldson, they are not so well adapted for the cart or the plough. And considering their size, and the quantity of food they devour, it is probable, he thinks, that they are inferior to any of the above-mentioned; and, when compared with the Suffolk duns, greatly so. Much attention, he observes, was formerly bestowed by the graziers in the midland districts on the improvement of the long-horned breed of cattle; and probably a greater number of eminent breeders have lately embarked in the laudable undertaking of improving the short-horned breed; and from their knowledge, affability, and exertions, much may be expected. Mr. Charles Collings at Kettnes, near Darlington, in Yorkshire, is supposed at present in possession of the bell breed of short-horned cattle in England.

There are many reasons, says the author of the "Treatise on Live Stock," for thinking this breed has been imported from the continent. First, because they are still in many places called the Dutch breed. Secondly, because we find very few of these cattle any where in this island, except along the eastern coast, facing those parts of the continent where the same kind of cattle is still bred, and reaching from the southern extremity of Lincolnshire to the borders of Scotland. The long horns and these have met upon the mountains which separate Yorkshire from Lancashire, &c. and by crossing have produced a mixed breed, called half-long-horns; a very heavy, strong, and not unsatisfactory kind of cattle; but we do not find that the one kind has spread further west, nor the other further east. This breed, says he, like most others, is better and worse in different districts; not so much from the good or bad qualities of the land, as from a want of attention in the breeders."

It has been observed, that the northern short-horned species is the largest breed in the island, the Herefords being the next. They are an original breed, but whether those of the northern counties are or not, cannot at present be ascertained; "that is to say, whether they are aboriginal, or were imported in very early times, as we know they continually been during several centuries."

Contrary to the long-horns, this breed has great depth of carcases; but with ample substance, large bone, thin hide, and gives much milk, which is not distinguished for its richness. They are not of first-rate character as labouring cattle, as has been seen, which, nevertheless, the Holdernesf variety, Mr. Lawrence says, seems to promise by their form. "We look, continues he, to the coarse, square, Dutch beefy breed, as the basis of this species. In many parts of the north, they remain, he adds, still coarse, and by no means equally disposed to large milking. The common Lincolnshire cattle are coarse in head and horn, large boxed, high upon the leg, and, to borrow a jockey phrase, ragged liped. Equally coarse internally, but producing flesh in great quantity. The Lincoln neat cattle, in fact, plainly, he thinks, demands a Bakewellian improvement, such as their sheep have received. The most accurately marked and distinguishable permanent varieties of the northern short-horns appear to him to be the Holdernesf and Lincolnshire. Collie, says he, tells us, that amongst the old flock there were some with black flesh, which would grow, but never fatten, provincially called heirs; these were to be known by the rotundity of their flaps, approaching, in many respects, that of an ill-formed ear-horfe. And the extreme coarseness and size of the northern short horns led, he thinks, to the introduction of Norman or Alderney bulls at some period of the 18th century, with the precise date of which we are unacquainted." And he supposes "there never was a more fortunate crofs,
as in no other country, excels so excellent a breed of cattle, including all the useful properties. In one, perhaps, the most important, respect, great milking, they are, say, better, superior, and even without rivals. Their beef is finer than that of the old short-horned breed, and they bear much earlier and quicker, carminghill a vast depth of natural flesh, and tallow within in the first degree. They have both fat and strength enough (he supposes) for labour, and their shoulders are well formed and well polished for draught. Being beautifully variegated in colour, spotted, striped, sometimes fleeced red and white, or black, or brown and white, they make a fine park flock. From their superior quality of milk, they rival, in his opinion, the belt long-horns in the cheese and butter dairies, and for fucking are unrivalled. It may be presumed (he says) they are at least equal to the Herefords in the stall, at all points: and there seems but one respect in which they are, in any considerable degree, inferior to any breed which can be named, which is fineness of flesh; in that particular, it is obvious, they can never equal certain other breeds without the entire overthrow of their Dutch basis by a repetition of the Norman or some other cross, which would go to destroy the present superior breed. An occasional mixture, however, of Norman blood may, he says, keep the Holdernses flack sufficiently fine, and prevent its degeneration on the other side; or a selection might be made of very elegantly shaped and fine-boned Holdernses cows, with the view of improvement. There are well known as the flack generally kept by the London cow-keepers. They have small short horns, in the shape of a half-ring, rather a long plain head, fine linn, the legs seldom too long, the carcase large but compact, good back and loin, the general figure square. They are not the species of flock for short keep, however small their size; indeed they are said to be good consumers. But this high character of the Holdernses cattle (he defers) should be received with considerable reserve. It relates to the cows chiefly, and to a selection of the oxen; to what they ought, and might be, rather than what they generally are. They are too often, he thinks, "the worst shaped cattle in the island, and perhaps the least profitable. Long, paint, deep carcasses, without adequate substance, placed upon high hills of the coarsest timber; low feeders, never fat, and the flesh excessively coarse. The feeding such ill-shaped flock must (he farther observes) be immensely disadvantageous, and is particularly disgraceful in districts which produce the best models." The short object, in respect to their improvement, is (he supposes) to shorten the legs; "which might be effected (he thinks) by a conjunction of the best Teeswater and Holdernses bulls, with selected short-legged cows. It is a striking fact (obviously he supposes) indicative of a rapidly increasing population, that, notwithstanding unprecedented prices, encouragement, and improvements, florce cattle are at this instant so scarce, that many graziers must come short of their necessary quantity." The following statement has been given, by the author of the "Treatise on Live Stock," as the weight of a five years old bull of the Teeswater fort killed in 1793, allowing 14 lb. to the stone.

It is added, by Mr. Lawrence, that the belt and quickest feeders of this breed are not remarkable for milking, and that the Teeswater short-horns are a valuable variety of the Teeswater fort.

It is believed, by the same writer, that the northern half long-horns are the immediate produce of a conjunction of the long and short-horns, which mixed, of necessity, frequently happen upon, and in the vicinity of those mountains which separate the native districts of the two kinds. The horns of this variety, he thinks, generally run out pretty straight and even, unlike those which are called middle or short-horns. They are a large and long breed of cattle, partaking equally, as may be supposed, of the qualities of each species, and hence ought to be good dairy cattle, as uniting quality and quantity of milk, and size; in fact, he has been assured, by an intelligent Effex dairy-man, that they have the belt title to such character, and many years since, when cow-stock was at a low rate, he preferred going to the price of 16 or 17 guineas a piece, for this description. They are not, he thinks, so permanently established and generally known as their originals.

And the "northern or Yorkshire polled cattle have (according to him) the same qualities as the short-horned, carrying vallublance, and some he has seen lately are of great size, although in that particular they are not conveniently various. In his opinion they are a most excellent breed, and well merit improvement, with the view of labour, by a selection of the finest breed and most active individuals. From the shape of these polled cattle, they hold a strict affinity in all respects with the short-horned, amongst which they are found; and it seems that various breeds of horned cattle are attended with horned, but perfectly congenial varieties."

The Berwickshire cattle have probably, he says, a relation to this breed, having been improved by Teeswater bulls from Northumberland. They rife, at three years old, to fifty, or perhaps nearly eighty stones, of fourteen pounds, and at five or six from the last to one hundred and twenty. The bell cows affording so high as six gallons of milk in the day. The ox is defterred as having a "long face, open countenance, clean and small, turned up, curving, and spreading horns, straight flanks, straight and round along the back, free and deep in the ribs, short legs, thighs turned out, open boned." This breed in the improved fort is highly valuable.

The Welsf breed of cattle, especially such as are found in Cardiganshire, are, the author of modern agriculture says, mostly black, with thick horns turned upward; of a small size, clean boned, of a good shape, especially where the native breed has not been injured by injudicious crossing with others from England. They are hardy and active; and in great request in the southern counties of England, on account of their being quick feeders. The quantity of milk which the cows of this breed afford is trifling; but they are, upon the whole, a breed well adapted to that country, although not capable of very great improvement: which might be effected with more certainty, and to a greater extent, he thinks, by selecting the bell individuals of the native breed, than by bringing others possessing probably very different qualities from England. But the author of a late treatise on cattle supposes that there may have been originally two different breeds, in this district of the kingdom, as the mountain kind having large wide horns, thick hides, and much bone in proportion to their size; the cows affording but little milk; and the low land or southern fort, which are of a larger size and finer form, having middle horns, being in some instances good milkers, those of some parts, as Glamorganshire, being in high estimation for the purpose of draught on the lighter forms of hilly lands. In general, he thinks, the cattle of this district are, however, deep
deep and flat in form, "some of them cloaddy and of great
substance also."

Thoue of the above part, Pembroke and Montgomery-
sire, are considered as the most valuable forts of the
cattle of this part of the kingdom.

It is suppos'd by the principal deffics in tllse cattle are,
at present, the want of substance, and great length of leg;
the remedy of which is suppos'd to be a Herefordshire crois
in the view of beef or labour. Their appearances in the
different counties of this breeding district, are flated by a
late writer somewhat as below.

The original Carmarthenshire fort, Mr. Lawrence says, is
"black, coarse, ill formed, short and thick, having wide
horns of great substance at the base. The cattle, in coarse,
small in the mountain districts, and of large size in the vales,
in good keeper."

"The improvers there," he adds, "have tried various croiscs.
Hereford, Shropshire, Leicelcr, Pembroke, Glamorgan,
but they fail without the defired succses. The produce of a Pembroke heifer and Hereford bull, is, he says,
the favourite flock in this county, where, in truth, the
prior object ought to be an improvement of keep."

The Glamorganfhire cattle are, according to the fame wrir-
tors, "in the cows rather small, of light bone, in colour
black or brown, handfome, and shew much blood. They
milk well, and feed quick, and are used as breed of labour:
they need no improvement from alien croiscs (he thinks); but
there are inferior varieties of them, from being mixed with the
flock of the borders. This breed (he supposcs) prevails
in Monmouthshire, and is to be found at the fairs and
markets of Pontypool."

But the Pembrokefhire cattle are, he says, "coal black,
sometimes dark brown, fnced, or white towards the tail;
some have white faces. They were originally finer than at
prefent, probably the fame race as the Glamorgans, which
some of the Pembroke cows resembe at this time: but the
breed has been crois'd with the old Leicelcr, with the view
of obtaining milk, in which the improvers did not succeed so
well; as in rendering their flock coarse, bony, and unfit for
labour. If butcher was the object, they had better, he thinks,
probably, have retained the imported long horns unmixed.
This crois accounts (he supposcs) for the Pembrokes being
fnced, and having long and round carcasses. They gene-
rally labour on the roads, yoked with horses, and their jour-
nies are performed with a speed unknown elsewhere. But
the Pembroke ox is too leggy, but he becomes early ripe,
and will make fat at four years old. He attains the weight of
80 to 130, or 140 fone London weight, and is faid to
fland his drift or journey better than any from Wales,
where he finds a preference particularly in the counties ad-
joning the metropolis. Two year old Pembroke bulls are
bought up at the fairs, at coniderable prices, by the im-
provers of the neighbouring counties."

The native Brecknockshire fort are, he thinks, "much the
fame as those of Carmarthen and Pembroke; but being
crois'd with Hereford, and one with Devonfhire bulls,
labour seems to be the object, and with fuch croiscs and a
attention to good keep, a very excellent breed may (he believes)
be rais'd."

And the Carmarthenfhire breed are a smaller variety of the
Pembroke and Carmarthen forts; accoiding to the fame wrir-
tor, being harder, and les milk}' than most breeds.

The Radnorshire forts are, Mr. Lawrence obferves, "dark
red, and brindled in consequence (he supposcs) of the origi-
nal black stock being crois'd with the bulls of Hereford and
Shropshire, which are adjoining counties. Although these
crois produced flock too large for the hills, they make ex-
cellent cattle, in good keeper, and of coniderable size, namely,
from 100 to 130 fone London weight. But it is faid that
the produce of the Hereford crois has not the charactcrific
bald face."

The Montgomeryshire fort are in the favourite colour blood
red, with a sticky face. The oxen from this county pro-
duce good prices.

The Merianshire fort are, according to Mr. Lawrence,
a small and ill shaped breed, faid to be the work in Wales;
but in Mr. Cobet's improvements, in crois'ing with good Eng-
lish flock, much advantage has, he fays, been obtained.

The Carnarvonfhire is a Hardy native fort, which has been
formerly crois'd and improved by English bulls and cows,
some of the New Leicelcr and Warwickshire kinds. The
improvement succeeded, and with a small additional expec-
tion in rearing, the flock has been found sufficiently hardy,
ether on the mountains or plains; and the improved cattle at
wo or three years old, are, in the opinion of the above wrir-
tor, worth more by two or three pounds than the original
breeds.

The Denbighshire and Flintfhire forts have, he fays, been
crois'd and mixed with thofe of England. There are
fome good milch cows in these forts, which give fix or seven
gallons per day, three or four months after calving.

The Anglefs fort is, he obferves, "a small black breed, with
wide and thick horns, being prevalent there, and in far greater
purity than in most other parts of Wales. This hardy race is
preferred on account of the coftant winter expofure, and
defect of winter provifion, and also because they are ap-
proved by the purchasers. An English crois has been at-
tempted without succcs, which was a neceffary reflult, un-
lefs the keep were at the fame time improved. The breed-
ers decline keeping any cattle beyond the age of three years,
not finding themselves reimbursed the charge of another year.
The weight, when fat, at three or four years old, from 60
to 120 fone, the fore quarters being the heaviest. No crois
could (Mr. Lawrence supposcs) poifibly improve thofe flanders,
unless bulls could be found of superior form, and equally
hardy; fuch are, perhaps (he fays) to be fought for in the
life of Sky."

The famc writer thinks, that, in the quality of the Welsh
cattle, generally, there is no appearance of improvement of
late years, notwithstanding the encouragement held out by
prices, of which no former age can furnish a precedent.
Indubitably the want of winter keep, and a good winter
fyme, is, he thinks, the chief caufe of this deffic.

According to the above writer, the Shropshire wide-horns,
which are large, square, deep, and bony, with thick hides,
in colour brindled red and brown, the horns branching, points
turned upward and backward, are used for labour, and faid to
be better milkers than their neighbours of Herefordshire,
with which they are doublets, he fays, often blended. Of
the origin of this variety no accounts, he obferves, are ex-
tant, or how long they have been a permanent or establis-
hed breed. It has, probably, he supposcs, originated in a mix-
ture of the old long horns, the Welsh, and the red breed of the
western district.

According to Mr. Culley, the polled or Galloping breed of cattle are a very valuable breed, and feem to be, in we fgt
and size, as much les than the long-horns, as they are than the
short-horns; they generally weigh from 50 to 60 fone.
Some particular ones reach 70 and upwards; but their most
feffential difference from every other breed of cattle is, their
having no horns at all: some few indeed. In every other re-
pect polls, have two little knobs or examing horns from
two to four inches long, hanging down loose from the folow
parts that other cattle's horns grow, and are joined to the
head by a little loose skin and flesh. In mob other respects, except
CATTLE.

except in that of wanting horns, these cattle resemble the long-horns, both in colour and shape; only they are shorter in their form, which probably makes them weigh less. Their hides seem to be in a medium between the two last-mentioned breeds, not so thick as the long-horns, nor so thin as the short-horns; but like the bell feeding kind of long-horns, they lay their fat upon the most valuable parts, and their beef is well marbled, or mixed with fat.

We find, he says, a few of this breed straggling through different parts of England: amongst the rest, he remembers the herd of Darlington having had a very handsome variety of them, finely gabled with red and white. But we must, he says, look for the original of these in Galloway, a large district in the south-west of Scotland, where they are mostly bred upon the moors or hilly country, and grazed upon the lands nearer the sea, until rising four or five years old, when the graziers and drovers take them up in great numbers to the fairs in Norfolk and Suffolk, previous to the turrip-feeding season, from whence the greatest part are again removed in the winter and spring, when fat, to supply the amazing consumption of the capital, where they are readily sold at high prices; few or no cattle selling so high in Smithfield market, from their being nice cutters up, owing to their laying the fat upon the most valuable parts; a great excellence in all feeding cattle. It is an uncommon thing, in this refined market, says he, to see one of these little bullocks outsell a coarse Lincolnshire ox, though the latter be heavier by several scores. And he has been informed, from good authority, that the polled cows are very good milkers, in proportion to their size, and the milk of a rich quality, yielding much more butter from a given quantity of milk than the short-horns; and also that the oxen and spayed heifers answer well for the draught; which certainly adds to the value of this excellent breed. But though the generality of the cattle of the above district are polled, yet they have several with horns, which, they say, are a bailard or mongrel breed, by crossing with long-horned bulls from Wigtown and Cumberland. They prefer the polled ones, and of these the black or dark brindled ones, to any other; and all allow them to be the original breed of the country. The breeders in Galloway complain of their old breed being lost, or at least much worn out; probably by want of proper attention in the breeder.

Mr. Lawrence supposes that the moors of Mungaff and Glelone are the only places where this fort of cattle at present exist in their original purity, and that they are generally thinner in the hind quarters than those which have been crossed with other breeds. They are likewise prevalent in Dumfriesshire, especially on the Nithdale side.

There are frequently among the common Galloway cattle foam that are white faced and pied, with small grizzly horns, which is supposed to be from a mixture of Dutch or English short-horned bulls, and to “extract 20 per cent. from the worth of the beast.”

In respect to form, according to the above writer, this fort of cattle are broad and square in the shoulders, long and round bodied, but deep, straight and broad on the back, with a thick flabby coat, the legs of a middle length, with large hocks. It is added, that the pelvis, or hinder part beneath the tail, and between the two bones, is frequently too narrow in the case of this fort, from which they want strength, and occasionally fail in bringing forth their calves.

The even of this fort, as well as the spayed heifers, make middling fixed beef, which is of an excellent quality. It is supposed that all the calves of this fort are reared in their native district, and more of the females spayed than of any other breed, the operation being performed on the yealings in the month of May. This fort of cattle are usually foud at about two years and a half old, the graziers in England being supposed to take off 3,000 head annually.

It is probable that this useful fort of neat cattle might be much improved in its native district, by having better accommodation and protection during the severity of the winter season, and a more abundant supply of different sorts of food.

The Suffolk breed is so called from its being the prevailing kind of neat cattle in the county of Suffolk, and which some may think a distinct fort, but which Mr. Culley is inclined to believe no more than a variety of the Galloway breed; which might easily, he says, take place from the great connection that has long subsisted between the Scotch Galloway drovers of cattle and the Suffolk and Norfolk feeders or graziers of them. Both kinds are in general polled; and though the Suffolks are almost all half duns, while the others are of various colours, yet this might at first proceed from a partiality to that colour. But from whatever place or cause this variety took its rise, they are, he says, at present a very useful kind of little cattle, particularly for the dairy; and great numbers of them are employed in that line, in some parts of Suffolk, where, perhaps, the bell butter and the worst cheese in the kingdom are made. The cows give great quantities of milk. Mr. Young states that they give in common 24 quarts a day, which is nearly equal to the bell short-horned cows. We find the cows of this kind, like all other deep milkers, very lean, very plain in their forms, and very big-bellied. The weight of this breed of cattle is about 35 stone on an average.

These are said to have a lighter colour, and to be smaller and finer in the bone than the Galloway fort; and to be long, with a large carpals, clean throat, the neck tapering to the head, the tail thin, and the legs rather short. They are excellent for the purposes of milking, whether for the dairy or private use; though the milk is probably less rich than that of either the Alderney or long-horned forts. It has been suggested that this breed is incapable of being rendered more valuable by the art of crossing.

The Scotch breed of cattle are, according to Mr. Culley, still less in proportion to the polled cattle than they are to the long-horns; this breed are also covered with a long close coat of hair, like the pulles and long-horns; and, like these, their beef is fine grained, well flavoured, and mixed or marbled, but not so handsomely on the outside of the beef when killed, being not of so bright a colour, and often spotted with black, even upon the bell parts, except when made very fat. When grazed, they feed very readily, their weight in general being from 24 to 35 stone. The most prevalent colour is black; some are brindled or dun; but the breeders here, like those in Galloway, prefer the black ones. Their hardy animals are in possession of all that extensive and mountainous country called the Highlands of Scotland, together with the western isles, bounded on all sides by the sea and the Grampian hills; the latter of which begin on the north side of the Firth of Clyde, and run parallel into the sea near Aberdeen. This fort of cattle are frequently termed kyler in that part of the country; probably from a district in Ayrshire, called Kyle, where they prevail much. But all the lowlands of Scotland, except Galloway, have a mixed breed of cattle; towards Cumberland they are half long-horns, half polls; on the borders of Northumberland they are mixed with short-horns until you reach Tivottdale, where they become altogether a coarse kind of short-horned, or what the Yorkshire jobbers call runts, except a few pretty good short-horned cattle, bred in that pleasant and the country,
country, the Tweed side. This same kind of ruffish coarse breed continues all the way to the forth of Firth. Crossing this narrow sea into Fifeshire, you would at first imagine the Fife cattle a distinct breed, from their upright white horns, being exceedingly light lyered, and thin thigthed; but he is pretty clear it is only from their being more nearly allied to the Kylies, or Scotch breed, and consequently having left of the coarse kind of short-horns in them. The cattle all along this coast continue to change more and more, growing still less, until upon the edges of the mountains they become quite of the Kylies kind; but still much inferior to that pure, unmixed, valuable breed of Kybotes which we meet with on the more northern and western Highlands, and all the isles; but particularly in the Isle of Skye, and that tract of country called Kintail. It is in these two districts that you meet with the native breed of Kybotes: a hardy, industrious, and excellent breed of cattle, calculated in every respect to thrive in a cold, exposed, mountainous country, and better adapted to the cold regions where they are bred than any other kind we are acquainted with. Thee cattle are driven to the southern counties in great numbers every autumn; many into the western districts of Yorkshire; but the greatest part are sent into Norfolk, Suffolk, Essex, and other parts in the south of England, where they are fattened, and either slaughtered at their home-markets or sent to Smithfield.

The great demand for this breed in the southern parts of the isle has rendered its improvement more attended to than formerly, and attempts have been made by different spirited breeders by crossing Ise of Skye cows with bulls of the long-horned kind.

Though it is allowed that the beef of the Kylies is superior to that of others, it is believed by some that there is a deficiency in respect to quantity on the acre, so that it be the beef it is not the least expensive.

The Highland cattle sometimes, however, rise to a considerable weight, especially when crossed with the larger breeds. The bulls of the Isle of Skye fort are held in high estimation by the breeders and improvers of this kind of cattle, the principal distinguishing marks of which are fine eyes and horns, with a thick pile, and not thick thigthed. They excel in the quality of the milk, but with regard to the quantity, should be crossed with the Norman or some other breed that is known to afford a large quantity of milk. This property is likewise said to be increased by crossing with the Tibet fort. The Highland cattle are hardy, and very little subject to diseases of any sort.

The Orkney Islands are said to contain a small breed that are good milkers, and which afford beef of a good quality; but they are a badly formed fort.

The Fifeshire fort are of considerable size, being of a black colour, lively and upthorned. They feed with expedition, and are fitted for labour, being held in high estimation by the graziers in the southern parts of the kingdom. As milkers, they are valuable for the quality of milk and fluidness of continuing beef, rather than the quantity. It is probable that they might be improved in this last respect by crossing with those smaller breeds that produce it in larger quantities.

The Renfrew, Ayrshire, or what are termed the Dutch fort, are considered, in relation to their size, the most valuable for the purpose of milking in the island, excelling equally in the quantity and quality. Mr. Lawrence says they produce "from 3 to 7 gallons per day," and that they "have the character of being the best possible poor man's cows," from their ability to shift on very scanty keep. In appearance they are, he says, small and ill-looking, with the shape and pile of Highlanders, yet bearing more resemblance to the Dutch than to any native Scotch breed. Their horns, he adds, "are short and small, standing remarkably irregular and awkward; the colour generally pied, or of a handy red. They appear unthritty and thin like the Alderney, even in the bull, and the few which are bred up to oxen make but a poor figure in grazing, feebly reaching the common weight of Kybotes." He "apprehends thisainty race to be the result of crossing the cows of the country with Alderney bulls; the cows, perhaps, having previously a portion of Dutch blood."

The Alderney or French breed of cattle is moody to be met with, according to the author of the "Treatise on Live Stock," about the feats of our nobility and gentry, upon account of their giving exceedingly rich milk. He imagines this breed to be too delicate and tender ever to be much attended to by British farmers, because they are not able to bear the cold of the isle, particularly the north-east parts of it. They are very fine-honed in general, light red or yellow in colour, and their beef generally yellow or very high-coloured, though very fine in the grain, and well-flavoured. They make themselves very fast, and none of them are in the least subject to typhus, or have black fleck. He has seen some very useful cattle bred from a cross between an Alderney cow and a short-horned bull. See Alderney Cattle.

The Wild breed of cattle, from their being untamable, can, in the opinion of Mr. Colley, only be kept within walls or good fences; consequently very few of them are at present to be met with, except in the parks of gentlemen, who keep them for ornament, and as a curiosity: there at Chilham—Castle in Northumberland, a feat belonging to the Earl of Tankerville, are, he says, innumerable of a coarse white colour, with black muzzles; the whole of the inside of the ear, and about one third of the outside from the tips downward; red; horns white, with black tips, very fine, and bent upwards; some of the bull have a thin upright mane, about an inch and a half or two inches long. The weight of the oxen of this breed is from 35 to 45 stone, and the cows from 25 to 35 stone, the four quarters, 10 lb. to the stone.—The beef is finely marbled, and of excellent flavour. From the nature of their pasture, and the frequent agitation they are put to by the curiosity of strangers, it is scarcely to be expected that they should get very fat: yet the six-years old oxen yield generally very good beef, from whence it may be fairly supposed, he thinks, that in proper situations they would feed well. When the cows calve, they hide their calves for a week or ten days in some sequestered situation, and go and suckle them two or three times a day. If any person come near the calves, they close their heads close to the ground, and he like a bare in form to hide themselves: this is a proof of their native wildness. The dams will not allow any person to touch their calves, without attaching them with an impetuous and savage ferocity.

It would from clear from the above general descriptions of the different breeds of cattle, that all the forts taken notice of are not equally profitable to the breeder. the rearer, the dairyman, the graver, the butcher, or the consumer. Some have greater adaptation to fatten than others. Some, being cleaner housed and better formed, have less offal. Some give a greater quantity of milk than others. In a word, some of the particular properties for which cattle are estimable are more discernible in one breed than in another.

Whether, says Mr. Donaldson, these can be all united in the same animal, or whether a breed of cattle,possessing all the requisite qualifications, would be equally suitable to all situations, are questions not easy to be determined. In regard to the first, says he, it seems universally agreed, that
CATTLE.

there are two species for which cattle are offered with advantage; that called the long-horned breed, and a tendency to yield a large quantity of milk. The form of the animal is remarkable for the first is very different from that of the other; in place of being large in the back, and big in the belly, as in all great milkers, it is long-ridged and light-bellied; in a word, its body is bastard formed, while that of the other is more fitted to embrace a loose collar with the wide side downwards. It is not possible, therefore, that the properties of two breeds of cattle, so opposite in form and general appearance, can ever be united in the same animal. If a large quantity of milk be required, by its quality, is the object, the dairymen must content himself with such plain-looking animals as have been described above. And as the milk of all cows is well known not to be of the same quality, it appears, he says, highly probable that in proportion as the cow of the walking tribe exceeds those that are more disposed to fatten in quantity, is nearly the same proportion will their milk be inferior in quality. If this should prove to be the case, the superiority of the quick feeders, one would suppose, says he, to be completely established; as while cattle of this description are confederally better for the purposes of the graziers, the butchers and the consumers, they would, if this point were determined in their favour, be also more valuable for the dairy. No person will think of affording, that a gallon or two of whey or of butter-milk extra (for the question, he thinks, comes to that) is a sufficient reason for preferring a breed of plain-looking, ill-formed cattle, to one that, except in this particular, is more valuable in every respect. In a word, no person who pretends to a knowledge of the different breeds of cattle, will think of supporting an opinion so erroneous, as that cattle which are disposed to fatten quickly, and at an early age, that, from the superior excellence of their form, have a small proportion of oil, or what the breeders call non-chillant, and that although they yield not a large quantity of milk, yet make up that deficiency in the richness of its quality, are no more valuable than those which have nothing to recommend them, but the single property of being great milkers.

It has been remarked by the author of the "Treatise on Live Stock," in comparing the breeds of long and short-horned cattle, that the long-horns excel in the thickness and firmness of the hide, in the length and coarseness of the hair, in their flesh being finer grained and more mixed and marbled than that of the short-horns, in weighing more in proportion to their size, and in giving richer milk; but they are inferior to the short-horns in giving a large quantity of milk, in weighing less upon the whole, in affording less lassow, when killed, in being generally flower feeders, and in being coarser made and more leathery or bullish in the under side of the neck. In few words, says he, the long-horns excel in the hide, hair, and quality of the beef; the short-horns in the quantity of beef, tallow, and milk. Each breed has long had, and probably may have, their particular advantages in different situations. Why not, the thick, firm bones, and long loose-fet hair of the one kind, be a protection and security against those impetuous winds and heavy rains to which the west coast of this island is so subject; while the more regular feasons and mild climate upon the east coast are more favorable to the constitution of the short-horns?—When he says the long-horns exceed the short-horns in the quality of the beef, he means that preference is only due to the particular variety of long-horns, feeleated, improved, and recommended by that attentive breeder Mr. Bakewell: for, as to the long-horned breed, in common, he is inclined to think their beef rather in

"superior, to that of the generality of short-horns; and there is no doubt, he adds, but a breed of short-horned cattle might be selected equal, if not superior, to even that very kind of the best of Mr. Bakewell, provided the breeders, or herdsmen, would pay as much attention to the case as he and his neighbors have done to the long-horns. But it has been the misfortune of the short-horned breeders to pursue the largest and biggest boned ones for the beef, without considering that those and the belt that pay the most may not be for the same quantity of fat. However, the idea of our short-horned breeders being now more open to conviction, we may hope in a few years to see great improvements made in that breed of cattle. Such rapid improvement has indeed taken place in the breeding of short-horned cattle, that he has reason to think they must soon surpass their rivals the long-horns. But he adds that, notwithstanding these two breeds have hitherto been in possession of the best part of the island, he is inclined to think that the Galloway cattle, and even the Scotch or Kyloes, might be bred with advantage in many situations, so as to be more profitable than either the short-horns or the long-horns: he has a very high opinion of both these breeds of cattle, as true quick feeders, and being kindly-fed, or excellent eating beef, which character they have established in the first market in the island.

He is likewise of opinion that the Scotch or Kyloes are better adapted to cold, exposed, hilly, mountainous situations, than any other breed we have; and that particular breeds are probably best adapted to particular situations; on which grounds he recommends to breeders of cattle to find out which breed is the most profitable and best suited to their situations, and to endeavour to improve that breed to the utmost, rather than to try to unite the particular qualities of two or more distinct breeds by crossing, which is a precarious practice; for, says he, we generally find the produce inherit the coarseness of both breeds, and rarely attain the good properties which the pure distinct breeds individually possess.

It must be plain from what has been already advanced, that, in order to have good cattle of any breed, particular regard must be paid in selecting those that are the most complete and perfect in their form, shape, and other qualities, to breed from them. See Breeding, Bull, and Cow.

The author of the Rural Economy of Yorkshire has well remarked, that the horn is a good criterion for distinguishing the different species, if the term be applicable, of cattle. It is a permanent specific character. The colour, though not altogether accidental, is changeable; and neither the form nor the flesh is permanently characteristic of any particular species. Good form and good flesh may be found in every species; though they are by no means equally prevalent, nor equally excellent in all; but a horn six inches long was never yet produced by the Cawston long-horn breed; nor one a yard long by the Holburns' breed. And the middle-horned breed of Herefordshire, Suffolk, and other parts of the island, appears to be as distinct a species as either of the former. He is not, however, a bigot to horns of any shape or length; as he would as soon judge of a man's heart by the length of his fingers, as of the value of a bell-lock by the length of his horns. If his flesh be good, and well laid on, and his ossa be proportionably small; if he thrive well, fatten kindly at an early age, or work to a late one if required; he would much rather have him entirely without horns, than with any which enthusiasm can point out. But the horn, as a permanent specific character of cattle, may in some varieties,
varieties, have its use as a criterion. Thus, fays he, supposing a male and female of superior form and flesh, and with horns resembling each other as nearly as the horns of males and females of the same variety naturally do, no matter whether short or long, sharp or clubbed, rasing or falling; and supposing a variety to be cultivated from this parentage, it is highly probable that the horns of the parents would continue for a while to be characteristic of the true breed, and might by inferior judges be depended upon, in some degree, as a criterion. But full, fays he, it is indisputable that horns remain the same while the flesh and fattening quality change; but every man of superior judgment will depend more upon the form and handle of the carcass, than upon the length and turn of the horn. For it is a notorious fact, that the individuals of a given variety may have exactly the same horns, without having exactly either the same fashion or the same flesh. If, however, there be any criterion or point of a beat which may be universally depended upon as a guide to the grazer, it is, he thinks, the eye, not the horn. The eye is a mirror in which the health and habit of the animal, at least, may be seen with a degree of certainty.

In respect to the rearing of cattle, different methods are pursued in different districts; but it is obvious that the better they are fed, at an early period, the better flock they will, in general, make. The rearing of cattle is become, in the opinion of Mr. Marshall, as stated in the Rural Economy of Norfolk, a subject of the first importance to this country; as an universal and growing fearc of neat flock is experienced, more or less, throughout the kingdom. He has, therefore, paid more than common attention to the rearing of calves, (the first and most difficult part of the bullocks) in this district; not only as being a primary object in the Earl-Norfolk system, but because the practice there is, in many respects, peculiar to the country. The number, he fays, varies with the quantity of meadow or other natural grafsland belonging to a given farm; and sometimes, but not always, with the time at which the cows happen to come in. Some farmers “bring up” all the year round; rearing every calf they have drop. Others rear in winter, only fattening their summer calves for the ped-markets; or, at a distance from them, for the butcher. Norfolk farmers, in general, begin early in winter to rear their calves; some fo early as Michaelmas; in general, if their cows come in before Christmas; not only as being fully aware of the advantage of rearing early, but in order that they may rear as many of their own calves as possible; drove calves being always hazardous and sometimes scarce. No distinction is made as to sex: males and females are equally objects of rearing, and are both, occasionally, subjected to califation; it being a prevailing custom to fpare all heifers intended to be tattened at three years old; but such as are intended to be finit in at two years old, are he and let, greatly generally let “open,” as are, of course, such as are intended for the dairy. There are two reasons, he obferves, for this practice: they are prevented from taking the bull too early, and thereby frustrating the main intention; and by this precaution they lie more quietly; and are kept from roving at the time of fattening. This may be one reason why fpared heifers are thought to fat more kindly at three years old, and to be better felled than open heifers. The method of treatment depends, in some measure, on the time of rearing. The rearing of the young animals in winter requires more milk than the later ones.

The particular practices that are followed in different places, in respect to the treatment of calves in rearing them, have been defcribed more fully under the head to which they belong. See Calves, Rearing of.

In the management of young cattle, it is remarked by Mr. Donaldson, that the method of managing them during the first winter is pretty generally the same in every part of the kingdom. They are almost always housed; sometimes housed up to the falling of the leaf; but more frequently allowed to remain at freedom. The way of feeding them in England is chiefly with hay, or hay and straw mixed; and in Scotland, sometimes hay, but more frequently draw and turnips. They are mostly turned out on some of the inferior pastures on the farm the following summer, and maintained the second winter on straw in the straw-yard, or in houses or fields erected for the purpose. Some farmers in the more northern parts of the kingdom, from being situated at a distance from any market at which they can dispose of falf-fed beef, very frequently give a considerable part of their turn-up-crop to their young cattle. This is, he thinks, an excellent practice; and one that ought to be followed even by those who, from being better situated in regard to markets, can adopt other methods of using turnips to advantage. The benefit of green winter food for live flock is so great, that there is, probably, he fays, no way in which turnips can be used, by which the farm or the farmer would reap greater benefit, than by giving the young cattle a daily allowance during the first two or three winters. There is but very little variation in the management of young cattle from this during the time they remain in the breeders’ possession, which must be longer or shorter, according to the peculiar circumstances of the cafe and the nature of the farm. In some districts, he further observes, it is the usual practice to allow the young heifers to take the bull at two years old; in which cafe, tho’, which are not necessary for keeping up the flock are disposed of the following spring, before they drop their calves. And where the practice of ploughing with oxen is continued, or has been a second time introduced, young oxen are broken into work in the course of the second summer; this, however, is by no means common, as, he fays, probably nine-tenths of the cattle reared in Great Britain remain in the breeder’s possession till the spring of the third year. The young cows are then disposed of to the dairy-farmers, who often do not breed a sufficient number to supply themselves; or to the cottagers, who have the mean of keeping a cow in summer, but not in winter. And the young oxen are sold, either for the purpose of supplying the ox teams, where they are full kept; or to the graziers, who sometimes fatten them for the butcher in the course of the grails-season, but more frequently content themselves with only putting them in condition to be falf-fed during the following winter. The premature age at which such cattle as are not employed in the operations of husbandry are now fattened, is, he thinks, a positive evidence of the fecrity of that species of live flock. Exclufive of the cattle fed in the plough or the cart, which are permitted to live a year or two longer, the oxen in this country are, in general, killed before they are four years old;—an age at which, it is well known, an ox does not fatten to the greatest advantage. And Mr. Marshall fays, that in Norfolk, when the lettertnheld and fhubbies are finitd, the yearlings, provincially “huds;” are put to turnips; either as followers to the bullocks, or have some fedd turnips thrown to them; in either cafe, they fleep in the par-yard, and generally have a separate par of fattened them; though sometimes they are paired with the two-year-olds. In the yard, the bot of the “rovst” is allowed them, and, perhaps, a little ordmary hay; it being a maxim,
a maxim, pretty generally adopted among good farmers, to keep their young flock as well as they can the first winter. In spring and summer they follow the bullocks, and run in the meadows; or, if these be wanting, are sometimes sent out to summer pastures in the fields, or grazing-grounds. The two-year-olds run in the fubblebers, and broken pastures till Michaelmas, or until turnips can be laped them when they generally follow the bullocks. In winter they are always “parred” at night; sometimes with the the cows; sometimes with the bullocks; sometimes alone. Good farmers generally keep them separate: if parred with the bullocks, they rob them; if with the cows, they are liable to be “horned,” and are never at rest; except while the cows are eating up the bell of the fodder. Some farmers, when turnips run short, “put out” their two-year-olds in winter; and others, when they are plentiful, “graze,” that is, fat their two-year-olds. In general, however, they are “kept over years,” on meadows or fays, or are sent to the meadows or grazing-grounds, as situations and circumstances point out; and, at Michaelmas, are put to traps as fattening cattle. The argument price for two-year-olds, from May-day to Michaelmas, varies with the keep.

On the management of young flock it is also observed, in the Rural Economy of Yorkshire, that they are invariably housed the first winter; generally loose, and moly indulged with the bell hay the farm will afford. Their fummer pasture is such as convenience will allow them; frequently of a secondary nature. In the open-field state, the common was generally their fummer pasture. The second winter oat-straw is the common fodder of young cattle; generally tied by the neck in hovels, or under fides. Their fummer pasture, common, woolly catte, rough grounds, or whatever fect suits their owner’s convenience. At two years old the fleers, provincially “lots,” are generally broke-in to the yoke; but are not, by good husbandmen, worked much at that age. At two years also the heifers, provincially “whis,” are generally put to the bull. This, however, is not an inviable practice. In the state of commonage they were frequently kept from the bull until they were three years old: now, in the state of inclosure and improvement, and at the present high rents, they are frequently suffered to take the bull when yearlings, bringing calves at two years old. This, says he, is an interceting subject in the management of cattle. Farmers in every distirct differ in their opinions respecting it. The arguments for bringing heifers in at two years old are, that they come sooner to profit; and that farmers cannot afford, at the present rate of rent, to let them run, unprofitably, until they be three years old. On the other hand, the argument in favour of keeping them in at three years old is, that, not being flintered in their growth, they make larger, finer cows than those which are suffered to bear calves at a more early age. But we have not yet met with any man who even attempts to prove which of the two is, upon the whole, the more profitable practice. The gardener, he remarks, seems to be well aware that, suffering a tree to bear fruit too early, checks its growth; and there may be some analogy, in this respect, between vegetables and animals. But even admitting this, if the cow receive no injury, as to thriving, calving, milking, nor any other that of being checked, in point of size, the objection appears to fail. If, however, early production check not only the cow but her progeny likewise, an objection, no doubt, will lie against it. He has long been of opinion that it is, in general, the farmer’s interest to let his heifers take the bull whenever nature prompts them. There is, undoubtedly, some present profit arising from their coming in at an early age; and whether a middle-sized cow may not afterwards afford as much neat profit as one of larger frame, is certainly an undetermined point. Much, however, depends upon keep. A traveling heifer will not take the bull at a year old. Nor ought any yearling heifer, which has taken the bull, ever afterwards to be flintered in keep. If she be ill kept, while with calf, there will be danger at, or after the time of her calving. If afterwards panicked, there will be danger of her not taking the bulb next year. Hence, he thinks, we may infer, with a degree of safety, that the propriety or impropriety of bringing heifers into milk at two years old depends principally upon soil and situation. On a good soil, and in a general climate, in which heifers do not experience a check from the time they are dropt, they ought, be it clearly of opinion, to be permitted to take the bull whenever nature prompts them. But in less genial situations, where I-an ill-heraged lands are to be pastured with young cattle, it appears to him equally evident, that heifers ought not, in strictness of management, to be suffered to come into milk before they be three years old.

Next cattle are capable of living a confiderable length of time, as fifteen or twenty years; but they are unfit for many purposes of the farmer after they become aged, and especially that of being employed as grazing flock; hence they are usually disposed of before they have attained their ninth year. For the purpose of breeding, they may, however, be kept much longer. With respect to the males, or bulls, where the chief object of the farmer is having good cattle flock, great attention should be paid to them, both in the rearing and their management afterwards, as well as to the form and kind. They should likewise be kept separate in a paddock inclosed for the purpose, and be constantly fed in the bull manner, and not be employed till they are three years old, when the cows should be separately admitted to them. Some farmers are, however, of opinion, that a little work does not in the least injure them, while it has the tendency of rendering them more tame and gentle.

But in other cases, as merely for the purpose of the dairy, where rearing the produce is not practiced, less attention is necessary with regard to these animals, it being of little consequence to the farmer, provided the cows be duly served. In these cases the bulls are, for the most part kept along with the cows, in sufficient proportion to the number of cows that may be kept. Under these circumstances they are seldom kept in any better manner than the cows; but it is probable that much loss may often be experienced by the dairy-farmer on this account, as it would seem proper that they should constantly be much better fed. In these circumstances they are often employed while very young, being frequently castrated, or what is termed jagged, in the third year of their age. The use of such young bulls is not, however, in general to be recommended. See Bull.

In respect to the management of the cows, it must of course vary in some measure according to circumstances, and the particular objects of the farmer. Such as are in calf should constantly have a sufficient supply of good food both during the summer and winter seasons, and in the latter should be well protected from the severity of the weather by proper houses, sheds, or fold-yards. With straw some other sorts of food should be combined, such as hay, turnips, cabbages, &c. as the milk is insufficient for keeping them in proper condition, and they will repay the increased expense of such keep, by their superior appearance, by the greater quantity and better quality of the milk, and by the better size and form of the young flock. Under the contr-
CATTLE.

In the same way they readily dwindle and become less valuable.

With regard to the feeding of putting cows to the bull, it is different, according to the views of the farmer; where his principal object is the milk, it is a matter of little consequence at what time they take the bull; but where the calves are to be reared, it is a point of material importance to have them dropped when the fawn begins to be warm, and there is a spring of young grass, as at that season they can be reared with the least trouble and expense, and in the most perfect manner. In the winter time this fort of buffaloes is attended with great expense, and the animals are often injured by the severity of the weather.

There is another point that ought likewise to be regarded in this fort of flocks, which is, that the cows should not be too greatly exhausted by milking them too long, or too near the period of their calving; but when they have good rich keep, they may be milked to a much later period without injury, than under the contrary circumstances. It is usual to let them become dry six weeks or two months before the period of their calving; but, with good keep, a month may be sufficient.

It is a bad practice to have bullocks in the same place with cows, as much injury may be done both to themselves and the cows, by their riding upon them. Some farmers think it a point of importance to preface cows to the bull with full udders.

It is of great utility in the management of cow flocks, that exact accounts be kept of the periods at which they receive the males, as well as of the times at which the young are brought forth. In large concerns, a fort of flocks should be kept for the purpose of entering various memoranda of this nature, as by such means accidents and uncertainty may be in a great measure prevented. As the time of calving approaches, more strict attention should be bestowed upon the cows, in order that, at the period of it, every necessary allowance may be afforded, and the welfare of the animals insured. It, however, rarely happens that any extraordinary aid is required where they are left wholly to themselves.

It is the practice of some farmers to lessen the quantity of food for a little while before the cows calve, from the idea that they do not succeed so well when they are in too high condition; but this is most probably a supposition which is not by any means well founded, as cows that are kept in good order are, in general, the least liable to accidents in these cases. It is of much consequence that, at these times, the cows be provided with due shelter, especially during the inclement parts of the year; as much injury is frequently done by letting them calve in exposed situations without any protection from the inclemency of the weather. See Cow.

Such young cattle flock as is intended for labour, should be gradually accustomed to be handled from infancy, and by that means be rendered perfectly tame and gentle, which will be of vast advantage afterwards when they are brought into labour. See Oxen and Team.

With regard to the management of cattle, there cannot be any doubt but that a large flock in feeding demands considerable and constant attendance, and that of steady and capable hands; as, unless a proper regard be paid to these respects, much confusion will occur, especially when fed in the fold-yard. Next to proper food, says the author of "Fourfeer's Cattle," the two great points in feeding animals to proof are, regularity, and a particular care of the weaker individuals. On this last account there ought ever to be plenty of troughs or rack-room, that too many may not feed together, in which very common cases the weaker are not only trampled down by the stronger, but they are worried, and become cowed and spiritless, than which there cannot be a more unfavourable state for thrif_these, there are ever compelled to shift with the worst part of the meat. This domineering spirit is so remarkably prevalent amongst horned cattle, that he has a hundred times observed the matter bulls running from crib to crib, and absolutely neglecting their own provender for the sake of driving the inferior ones from theirs. This is much oftener than suspected, the chief reason of that dilference to visible in a lot of beasts, after a winter's keep. It is like wise, he says, a very common and very shameful sight in a dairy of cows, to see several of them gored and wounded in a dozen places, merely from the attention of the owner, and the neglect of tipping the horns of those that butt. The weaker animals should be drawn and fed apart; and in crib-feeding in the yard it is a good method to tie up the matter-bulls at their meals. Where a sufficient number of cattle are not bred upon the farm, they are generally bought in at the neighbouring fairs to fat at spring, and about Michaelmas. Those bought in at spring will be fat in July, August, or September, according as they are forward, and there is keeping for them; and those which are bought in at Augulf, September, or October, must be either for sale in winter or in spring, and must be forward in flesh to be improved the beginning of winter, and kept up in flesh during the winter with burnet, hay, turnips, carrots, or other kinds of food, to be fit for a good market whenever it offers; or they must be young lean cattle, that may, by their growth, pay for their wintering, and be fit to fat the next summer. Some, upon ordinary land, buy in young Welsh heifers, which, if they prove with calf, they fall in spring, with a calf by their side for the dairy: and those that are not with calf they fatten; all which ways frequently turn to good account; but so well common all meet, either at Christmas, or in the spring, is one third part dearer than in summer; as all have not the convenience either of hay, turnips, &c. to fatten cattle with in winter; it is best to have them ready for the markets about these times.

The farmer who intends to graze cattle to the most advantage, should be particularly attentive to these three things: first, to raise a good quantity of artificial grases for hay and aftermaths. Secondly, to turn a good quantity of ground into rich pature, by feeding it, dunging it, and laying on it other manure, to make it fit for raising the bullock or heifer in the spring, when they come full from hay to grases, and to receive them with a vigorous aftermath, when other grases, as clover and other grases aftermath, go off. Thirdly, to have hedges or other buildings inclosed with close walls, to shelter the cattle in the winter from winds and rain. By adopting these methods in fattening cattle, the grazer, from having plenty of hay, will be enabled to purchase barren beals before the spring grases comes, when it is most likely they will be cheap, and may be bought to the best advantage, allowing for the value of the hay they may eat in conjunction with the purchase: and if, by winter-haying some meadow-ground after it has been kept high in heart by feeding, &c. he can, early in the spring, by April, or sooner, have a bite to take off such grazing-beals from hay to grases, it will be very advantageous before clovers can be ready, which, in many places, are seldom so till a week or a fortnight in May; and, by keeping such meadows for an aftermath, which, towards the end of summer, are in very good heart, he may support his bullocks, and carry them on when the strength of other grases fails. All fattening cattle, whether barren cows or oxen, require a proportional progression from coarser to better food, as they grow more and more into good flesh; otherwise, when half
CATTLE.

half fat, they will frequently go back, and the grazier will not, without great difficulty, be able to raise them again; which must be a great loss. See Grazing.

In regard to the feed: pursued with oxen, they are in milk places, where they are worked, turned off to fattening at two feasons of the year, which, in several respects, are very convenient. The first is about May-day, when the labour is pretty well over for the spring season; the spring corn being then generally all down. The second is the beginning of winter, as from the first of October to the middle of November, when the wheat and winter vetches are mostly put into the ground.

In regard to the various kinds of food with which cattle are generally fattened, it may be reduced under the following heads; grafs, turnips, grans, water from the distilleries, oil-cakes, corn, cut chaff, and a few other kinds.

The fattening cattle, according to Mr. Donaldson, are usually put to grafs in May or June, according to the season and situation in regard to climate. The period necessary for fattening an ox for the butcher depends on several circumstances; as the condition he was in when put to grafs, the nature of the pature, and many others; but in ordinary cases, an ox will be completely fattened in three months.

There is, he says, one method of fattening, connected with the grazing system, that the farmers in England are enabled, from the superior excellence of the climate, to adopt with success, which can never, he thinks, be attempted with propriety in Scotland. It is very common, at the close of the grafs season, when the fattening flock happens not to be fully in condition for the butchers, to render them so, by giving them hay two or three times a day in the field, or in hovels erected for the purpose, in which they have access at pleasure.

When turnips are employed for the purpose of fattening this sort of flock, especially if they are put up to the fulls in proper condition, which, considering the season of the year (November), must, with ordinary attention, always be the case, from 1 to 1½ weeks is fully sufficient to render them fit for market.

It is observed, that the fattening of cattle with grains may, in some respects, be considered as a branch of the distillery business; but yet there are some misbalances wherein those who cultivate farms practice it with a double view of obtaining a profit on the sale of the cattle, and the acquisition of a valuable treasure of useful manure. Mr. Adam, the renter of the farm of mount Not, near Streatham, in the county of Surry, has erected a very complete building, for the purpose chiefly of fattening cattle on grains. In this building, he, may sometimes be seen several hundred head of cattle.

And the method of fattening cattle with oil-cake, corn, cut chaff, &c. is practised in many of the English counties, with a degree of success sufficient to warrant farmers in other parts of the island to follow the same practice. The cattle are commonly put up to fatten at the end of the grafs season. The usual allowance of oil-cake, after it is broken in a large mortar, or, in the fruit districts, in a cider-mill, is about half a peck per day, which is given, one-half in the morning, and the other in the evening; to which is added hay, and in some cases ground corn, that is, oats and barley of inferior quality, and cut straw, provisionally "chaff." As bullocks fattened in this manner, get regularly five, sometimes six, meals a-day, it is sufficiently evident that, although it may be upon the whole an expensive mode of fattening, yet it must be both expeditious and effectual. But the subject of fattening cattle in the stall will be fully considered in another place. See Stall Feeding.

Mr. Marshall, in speaking of a Cottswold grazier, observes, that his fattening cattle are all tied up, some in single, some in double fulls. His reason for this practice is not altogether that of saving room; he is clearly of opinion that they do better, fatter faster, than bullocks which are kept in loose fulls. His reasoning is, he thinks, fair. Besides the indisputable advantage of their not being liable, in this case, to foul their meat and water; he holds out another which is not so obvious, but may nevertheless, perhaps, be equally true: cattle, which are tied up, are more calm (tamer, less wild) than those which are kept in loose fulls. A loose bullock (some loose bullocks at keat), when a stranger enters, has not the power of flight which a stall bullock commands. In the yards, look bullocks are equally liable to disturbance, and quietness is no doubt essential to quick fattening. Each bullock has two troughs, a small one for corn, a large one for hay, with a water trough, which runs the whole length of the shed, and is covered by a board; each bullock has a hole (large enough to admit the hoof) to drink at. The water trough (a hollow tree) forms, as it were, a top rail to the partition wall of the gangway. The others are beneath it, nearly level with the bed of the stall. The corn is ground, and given to them, mixed among cut hay, two or three times a day, beginning with half a peck, and increasing to about a peck a-day. The method of feeding with hay, which, in this instance, is practised, does, he says, the practizer infinite credit. He feeds his bullocks with hay as cart-horses are usually fed with corn; giving it to them by handfuls at once; never more than a time or the hands can grasp; continuing to feed them in this manner until they lie down, or till they refuse to eat. Thus they never have any hay to blow upon (the great objection against tying up bullocks); even at night, they have not a mouthful left before them. The leading principle of this practice is, that fattening cattle should never be cloyed with food; but should always eat with an appetite. In the morning they are fed with the word of hay (if any difference); for, being then hungry, they eat it with an appetite. Thus the hay is eaten up clean, and the bullocks are preferred in a thriving habit, while the extraordinary expense, where a number of cattle are fattened at once, is unconsiderable. In this case it is proper to appropriate a man's time to their attendance; and he might as well be employed in feeding them by handfuls, he thinks, until they lie down, as in cloying them with armfuls, and idling the rest of his time away.

According to the author of the Agricultural Report of Lincolnshire, about Haukthorn the larger farmers buy in beaifs in autumn; put them to coddil, and then feed with cake; and fell from Christmas to May-day; this is done for the sake of the dung, and it is thought if that is cleared that it answers well. Mr. Thorpe at Ketton, he says, fattens many beaifs every winter on cake; his landlord, Mr. Harrison, having built him for that purpose very convenient stalls, in a double range, with a gangway between their heads. They are in the Hereford style; the beaifs may be lofe or tied; a pump supplies water by troughs to colorls; the whole well executed. He has laid beaifs from three to 3½ a head, and 4½ in a beaif. The farm farmer has, on his farm at Overby, another bullock-house, in the same form nearly; here he fatts also on oil-cake; but the climax of it induced him to substitute luf-feed, built and mixed with barley meal; two quarts of barley, four hulds of luf-feed; and mixed, to give cold, in the form of a rich jelly; this quantity will go as far as half ton of cakes, colting lefs; when barley is not extravagantly high, that is, 24s. a quarter:— half
half a peck of linseed is boiled in four gallons of water. He inquired of Mr. Thorpe particularly if he had reason to expect for not lying beasts in their stalls, instead of giving them so much room separately; and he is clear they fatten much better: this necessity, however, he says, is not ascertained; for the question can hardly be considered as answered in any case where a farmer builds and a landlord pays. Mr. Thorpe buys his beasts at Lincoln; he thinks the Holderness too big for his purpose; but there is a very good crop of long and short-horns about Spilsby, which fatten kindly, and which he likes to buy. He is of opinion, from very considerable experience, and speaking of grazing in general, both summer and winter, that middling fixed beasts will pay better than large ones, for instance two of 50 stone will answer better than one of 100; they do not take so much food to bring them to their weight; and will do on worse pasture.

It is added, that at Knaith, in the same county, where the pasture is not of the finest quality, Mr. Dalton has fattened Teeswater beasts to 130 stone, at seven years old, and gave only half a ton of cake to each. He prefers this breed to any other he has tried. His beasts of 85 stone will be fat at five years from grafts, without any cake; and his regular return is seven a year, at four years old. The cows are good milkers in their own country, but here are not equal to Lincoln's. He is of opinion, in relation to the size of fattening animals, that an ox of 83 or 85 stone will not eat more than one of 50, and his bulshiff thinks he will not eat so much. At Bankside, Mr. Webster feeds his cows, and his team horses, with swelled turnips and cut chaff, with great success. Mr. Eliffeon, at Sudbrook, buys in about 30 bullocks annually; from April to Midsummer; which are put to grafts till a fortnight after Old Michaelmas; then he places them part in stalls, and part remains in grafts till near Christmas.—In the stalls, he feeds with cake and hay; they eat about 11/2 5 days a day, at 7 lb. each, and about half a ton of hay each beast; and are up about 10 weeks, some 12. They were bought in at 113 6 each (1788); and sold at about 200. In general, he reckons them to pay 100 6 each, which answers well. He prefers the short-horned breed, and has tried long-horned Clevans, but they did not answer at all. His bulshiff choises the finest boned ones he can get, clean heads and muzzles, wide in the hips, out in the ribs, and deep in the fore quarter. The greatest fault in the Lincoln short-horns is, he thinks, being thin in the backs and chine; it is not universal, but very common; but upon the whole they fatten kindly. He observes, that the oil-cake dung is uncommonly rich, so as by mixing to make the straw dange excellent. Mr. Moly, of Kitchel, fattens many beasts upon oil cake, even as far as buying 100 tons of cake in a year. He keeps them loose in a straw yard, and finds them do well without any hay, giving straw only in addition; and has fed beasts this fed at 40 guineas. The duke of Ancaster fattens many beasts; he buys in from Candlemas to Midsummer generally Scotch and Welsh bullocks of from 35 to 50 stone, sometimes larger; sells fat from Midsummer to December. He gives on an average, for the two last years, 81. 8s. or 81. each, and sells at 131. to 171. They are kept through the winter in the park, and go off at Midsummer, twelve months after. They have no fodder, except in a belt. North Wales, Pembroke, and Highland Scots, are found very little different in advantage; the Welsh grow rather more, and come to greater weight. The Ficks grow more than any, when they happen to be bought, but they require fodder, ring.

It is observed by the author of the Rural Economy of Norfolk, that the practice of fattening bullocks on turnips is now beginning to obtain in every part of the kingdom; but it may be said to be still in a state of infancy everywhere where except in Norfolk; therefore an accurate account of the practice of this parent country cannot fail of being useful to every other turnip-bred district. Impressed with this idea, he spared no pains, nor let slip any opportunity of making himself acquainted with the subject. The only species of cattle fattened in East Norfolk, he says, may be said to be the home-breds and Scots. Some Irish bulls have at different times, but not regularly, been brought into the country, and have generally done very well. In West Norfolk, great numbers of Lincolnshire and Yorkshire oxen were formerly, and some few, he believes, are now fattened; but in this district they have always been considered as much inferior to the Scotch and home-bred flock. Home-breds consist of fitters, spayed heifers, open heifers, barren cows, and running calves. The bull is a species of fattening cattle peculiar, perhaps, to this country. They are calves which are suffered to run with their dams until they be a twelvemonth or more old; the cow being all the while at head-keep, of which the calf partakes, as well as of the milk of its dam; while herself, in the mean time, generally gets fat enough to be sent to Smithfield with her calf (perhaps as heavy as herself) by her side. The Scotch cattle fattened in Norfolk consist of Galloway Scots, other Lowland Scots, Highlanders, and those of the Isle of Skye. The Galloway Scot is large, thick, short-legged, molly horns, and of a black or brindled colour; the flesh well grained, and the form altogether beautiful, chine full, back broad and level, quarter long and full at the nache, round barrel, deep girt, and the bone, head, and chimp, in general, fine. This he apprehends, is the genuine original Galloway Scot, and a principal part of the bullocks brought into Norfolk under that name is of this description; but the droves are generally adulterated with a mongrel foot, the produce of a cross with the long-horned breed. This species of adultery, he remarks, is said to be committed and encouraged by the nobility and landed gentlemen of the counties they are bred in; but the fact appears to be, that they have already one of the finest breeds of cattle in the world upon their estates; and it behoves them to hand it down to posterity as pure as they received it. In this age of improvement it might be laudable, he says, to endeavour to improve it to the utmost; not, however, by foreign admixtures, but by giving the most beautiful females to the most beautiful males of their own breed. They appear to him to have much to lose, but nothing to gain, from crossed, not even with the present long-horned breed of the Lowland counties. This species of Scotch cattle appears, he says, to be originally of the county of Galloway, which forms the southern extremity of Scotland; but they are now, it is said, propagated in other parts of the Lowlands, especially in the rich land counties of Lothian, in the neighbourhood of Edinburgh. He has known them fattened to 83 stone, and has been informed, from authority which he has no reason to doubt, that they have even reached near 100 stone, of 14 pounds each.

Lowland Scots are the ordinary breed of black cattle in the Lowland counties, size below the Galloways, and appear to be a mixture between these and the Highland Scots. Sixty stone is a good weight for a Lowland Scot. In form and inclination to fat they partake of the Galloway breed; the former, however, is seldom to near perfection as that of the true Galloway Scot. Lowland Scots are some of them horned, some of them polled; their colour black, or brindled, or can.

The Highland Scots seem to be a definite breed. The size is breadth that of the Lowland Scots; 42 to 52 stone is the ordinary weight of a Highland Scot. In form, flesh, and fattening quality the Highlanders resemble more the Galloway Scots, except that their backs in general are rounder,
CATTLE.

coarser, their bone proportionally larger, and in that they have in general, but not always, horns of the middle size, and mostly bent upward, like those of the Welsh cattle, but finer. In general appearance there is a strong resemblance (their horns apart) between the Highland Scotch and the black cattle of North Wales; but with respect to flesh and fattening quality, the main object, the comparison is greatly in favor of the Scotch breed, which the gentlemen of North Wales are said to fatten annually out of Scotland, or to buy them up at the English fairs to be fattened for their own tables.

Thole of the Isle of Skye appear to be only a variety of the Highland breed, contracted by full or climature, or both. They are, in point of size, the lowest in the gradation; but with regard to flesh and fattening, and growth while fattening, they may be said to stand foremost. He has known an Isle of Skye Scotch bought at 25 years old, for less than 40s., reach, in about 20 months, to 45 stone. At that age, says he, their growth in England is astonishing; owing, perhaps, not to more of their nature than to a change of climate and a change of food. Much, however, depends upon their age. If they be intended for immediate fattening, the age of four years is the most proper. An Isle of Skye or Highland Scotch at two or three years will grow, but he will not fatten; a five or six he will fatten, but he will not grow, while fattening, equal to a four-year-old bullock. At this age the weight of Isle of Skye Scotch, when fat, varies from 25 to 30 stone.

There are the four species or varieties of cattle which are brought by the Scotch drovers to the Norfolk fairs and which are bought up and fattened by the Norfolk farmers under the foregoing names. A comparative statement of the proceeds, expense, and profit attending the raising of three different kinds of Scotch cattle grazed in Norfolk, as given by Mr. Burton in the Appendix to the Agricultural Report of that county. The first is a bullock bought at St. Faith's for about 5s. turned of four years old, in such condition as is fit to be put immediately to turnips. This bullock is supposed to be brought to from 57 to 58 stone. He is put to turnips for about 24 weeks, the average expense of which, including turnips, carriage, and attendance, and in case of bad weather, when a little hay is unusually given, beside the turnips, cannot be reckoned less than 4s. per week; this brings him to 1s. 10s. and such a bullock generally will fetch about 4s. 7d. per stone of 12lb., which amounts to 14s. 10s. The second bullock is bought quite bare, about the same time as the former, for about 46s. and such a bullock generally will fetch about 5s. 7d. per stone of 12lb., which amounts to 15s. 7s. 6d. The third bullock is bought quite bare, about the same time as the former, for about 61s. and is a year younger than the former. He is first put into fiibles or ordinary grazes till the straw-yard is open, and then he is put to draw at night, and eat the offal turnips after the better beests in the day-time; his keep in this way 24 weeks, till May-day, may be at 1s. 6d. per week; he should then be put to marhor, or into good paturage, till a fettling after Michaelmas, which, say 28 weeks, at 2s. 3d. per week, is 31s. 3s.; he then goes to turnips, like the former bullocks, for 8 weeks at 3s. 11d., his aggregate charge is then 121 3s. His weight may be expected to be 44 stone, and value 31s. 10s. 6d.

The third is supposed to be purchased at Harlestone, in D.ember, a fine beast of the same age as the first, 31s. which goes immediately to straw and offal-turnips for about 8 weeks, at 1s. 6d. which is 12s. 3d.; then goes to full keeping, at turnips by day, and lies in the straw-yard at night, for about 10 weeks, at 2s. 6d., which is 12s. It is then put into the second year's hay, or good paturage, till harved, for about 20 weeks, at 3s. 6d. per week, which brings it to 11l. 11s. 9d. it will then have attained in general about 46 stone, at 2s. 7d. which will amount to 12l. 13s.

On this it is remarked, that the line deduction to be drawn is that the full pays 10 per cent. interest upon the capital laid out, as well as a fair price for every thing that it contains. That the second returns no interest for the original cost, but pays a fair price for what it consumes. That the third pays 15 per cent. for the original sum laid out, besides paying as the others for what is consumed. It is obvious that in this form the principal advantage is in the large supply of dung that is raised.

The author of Modern Agriculture has well observed, that, considering the early period at which the cattle of this country are generally slaughtered, it is not now of so much importance to lay down rules when to ascertain their age with precision, yet in many cases it must prove useful. The age of cattle, like that of horses, is discernible by their teeth. They lose the first fore-teeth at the age of 10 or 11 months; these are replaced by others of a larger size, and when about a year and a half old, the teeth next to those in the middle drop out. These are also replaced by others; and at the age of three years the others are renewed in like manner. They then appear white, even, and regular, and pretty long, becoming gradually black, unequal, and short, as the animal advances in age. Another mark by which to determine the age of cattle, is the appearance of the horn. Cattle shed their horns at the end of three years; and towards the root of the second set or horns there is a kind of ring or joint, formed every year that the animal lives afterwards; so that, reckoning three years for the top or plain part of the horn, and one for every interval between the rings or joints, the most ignorant person may, with considerable certainty, ascertain the age of any calf or cow that has horns.

The diseases of cattle make the subject of that art, called by the ancients aetia medii, and veterinaria, and by us farming.

The ancient riches consisted wholly in the number of cattle; whence it is supposed to be, that the Romans called money by a name formed from that of cattle: pecunia from pecus.

By the 6th article of the Union, no Scotch cattle brought into England shall be liable to any other duties but those to which cattle of England are liable. 7 Ann. c. 5. By 5 Geo. III. c. 13. made perpetual by 17 Geo. III. c. 8. all furs of cattle may be imported from Ireland duty free. By 5 Geo. III. c. 43. Lathis may be freely imported from the Island of Mann.

Factors, and those who sell cattle for others, are prohibited to buy any ox, steer, runt, cow, heifer, or calf, and to sell the same again alive in the same market or fair; or on pain of forfeiting double value, half to the king, and half to him who shall have them. 5 Geo. III. c. 4 3. Edw. VI. c. 19. 5 Ch. I. c. 4. See drovers.

Stealing of cattle, or killing them with an intent to steal any part of the carcasses, or afflicting in such offenses, are now made felony without benefit of clergy. See 14 Geo. III. c. 6. and 15 Geo. II. c. 34.

By cattle, in this act is to be understood any bull, cow, ox, steer, bullock, heifer, calf, sheep, and lamb, and no other cattle whatever. Stat. 13 and 16 Geo. II. c. 4. And every person who shall apprehend and procure to conviction any offender, shall have 10s. reward. See also black Act.

Cattle Farm, in Agriculture, is that sort of farm in which the principal object of the occupier is the profit of live stock in some way or other. And from the different modes in which advantage is derived from this kind of stock, it is obvious that they must be of several different kinds, as breeding farms, where the chief object is that of raising young animals of the several kinds for the purpose of sale; dairy farms, in which the main object is that of either milk, butter, or cheese, or the latter; the first being sometimes called cow-farms; grazing farms, when the chief point
CATTLE-SHED.

point is the fattening of different sorts of animals for the butcher; and suckling farms, as where the principal point of attention is the fattening of calves for the market. See Farm.

Cattle-Shed, in Rural Economy, is that sort of erection which is made use of for the purpose of containing cattle while feeding or otherwise. Houses of this kind are most readily and cheaply constructed when placed against other buildings or offices, and are of very different forms according to circumstances and situations. This sort of buildings may be used as cow-houses or feeding-houses, being built to answer either one purpose or the other, and they are either single or double: in the latter way a great many cattle may be accommodated at a very small expense.

The principal requisites in these buildings are, according to Mr. Beeton, the following: "4. That they be capable of being well aired. 3. That they be so constructed as to require the least possible labour in feeding the cattle and clearing away the dung. 3. That the stalls be formed as to keep the cattle as dry and clean as possible, with sufficient drains to carry away, and reservoirs to collect the urine and dung. He observes, with regard to the last requisite, that a free ventilation is as necessary in these buildings as in stables. How often do we see, he says, on entering a house where there are a good many cattle or cows, most of them, perhaps, in the highest state of perpiration, and smoking as if they had been at the hardiest labour? at the same time the whole timbers of the roof are completely wet by the condensed fumes arising from the heat and breath of the cattle. This can only happen in close buildings, which must undoubtedly be extremely unwholesome; and, he supposes, must prevent the cattle thriving so well as they might otherwise do. To a feeder of cattle, he says, he, who looks eagerly forward to the profits he is to reap, and who estimates every additional pound of weight that a bullough ought to take on each day, it would be well worth his attention to consider, whether any bullough, in a perpinating state, can fatten so well as when kept in a proper degree of temperature. He thinks it hard to reason he cannot. When such buildings are in the form of sheds, they are not so liable to this want of ventilation; but wherever the timbers above appear wet by the heat and perpiration of the cattle, it is an evident proof there should be some additional air-holes, which, in his humble opinion, ought principally to be in the roof, as recommended for stables. If there are gable ends, they should, he thinks, have a window in each, as high up as possible, with movable boards, as in granary windows, which may, by means of a cord or small rod, be easily opened or shut at pleasure. The advantages of this free and wholesome ventilation to the cattle must be very evident, and also to the preservation of the timbers of the building; for where the timbers are often wet in this manner, they cannot be of long duration, consequently the expense of repairing or renewing them would be greatly increased.

With respect to the second qualification, there are many different constructions of these buildings, but chiefly in the interior parts. "In many (he observes) the cattle are confined to sheds ranged along the wall at the distance of about three feet from each other, with a space of 18 or 20 inches between the wall and the sheds to lay their food in. This is a very general construction in many parts of the country; but it is somewhat remarkable (he says) in this as well as in many other things, that the plan most generally followed is the very worst that could have been thought of: according to this construction, except sometimes, when the cattle are fed from without, the feeder is obliged to go in among them to give them their food, which occasions a great waste of time as well as being attended with many other inconveniences. No construction can, he supposes, be more monstrous than when a sufficient space is left before the cattle, for the feeder to go with a large wheelerbrow to distribute their food. This may (he thinks) be obtained, either in single sheds, or in double ones, by making the cattle face each other, and leaving a free space of about four feet to admit a wheel-barrow," in the foddering of them.

He adds that the single ones may be formed as in Plate IV. fig. 3. Agriculture, in which A is the passage before the cattle, B the rack for their hay or straw. C a place for laying fodder or litter in occasionally. Or it may be constructed as in fig. 4. D the passage, E a perpendicular rack behind which are thin deals all along in the position F, for laying the hay upon; and under G is a square hole, opposite each flall, through which the cattle are fed from the passage D. This is a very good construction for this sort of shed, and is taken from the new offices of Mr. Bilton's, of Kilflaf in Shropshire, where economy in labour and convenience have been much attended to.

Double sheds may be constructed as in fig. 5, in which A is the passage; B, B are the flack to which the cattle are bound; C C are poles or pillars to support the roof. It might, he thinks, be an improvement here to adopt Mr. Bilton's plan, and make similar racks, with holes below, as is shown in fig. 4. Another way of constructing thefe double sheds is shown in fig. 6, by which a very convenient loft may be obtained in the roof. A is the passage between the cattle, and B the loft above, which, if clofe boarded, may serve many useful purposes. These double sheds, Mr. Beeton supposes, perhaps the best construction for feeding-houses, being not only the most commodious, but requiring less building for the same number of cattle than by having them all to face one way.

It is justly remarked, by the same writer, that where cattle are fed from the outside through holes left for that purpose, many inconveniences may arise, either in wet weather or in a severe frost, or by a heavy fall of snow. When they are fed within, no fort of weather can occasion any interruption, especially if there is a proper place adjoining, to keep the provender in security and under cover. In single sheds, it would be convenient to have a place above the cattle, as at B, fig. 6, for holding occasionally some hay or straw. This place might be boarded, and made to open from without by covers suspended on hinges, which, when opened, will afford an access for putting in the fodder from a cart. It would there be ready for the feeder to throw into the racks when required. The roof is in this case to be supported by poles or pillars about three or four feet high, on the top of the wall, and placed about eight or ten feet distant from each other, as at A, A, A, &c. fig. 1. in Plate V. B, B, B, &c. are the hinges of the covers, and C C, &c. the rings to raise them up. D is one of the covers open, which may be held up in various ways, as by a catch, F, fig. 2, movable on a small iron pin, the heaviest end, E, being within the fixed boards, and F without to catch in a hole in the cover, when opened.

In the third place, great attention is, he says, necessary to keep cattle clean and dry. The common method of taking away the dung in wheelbarrows is attended with a good deal of labour, and where there are many cattle or cows will require perhaps several men's attendance. If this labour can, therefore, be abridged, and one or two men's work saved by a proper construction of building, it will be a great advantage. This should be considered in the original design before the building is begun, and must be determined in a great measure.
mesure by the form and situation of the ground. If a proper receptacle can safely be had immediately behind the cattle, for throwing in the dung at once with a shovel, without wheeling it, this would be the easiest way, and will not only save trouble and expense, but if properly contrived, the dung will be the better for it. By the common method, the dung is, he says, in general so scattered about, and exposed to the weather, that a great part of its virtues is exhaled and lost; a matter of great importance to the farmer; for it is not merely the quantity, but the quality also of dung that is to be considered.

To preserve dung under cover would be attended with an expense in the construction of a proper place, that perhaps few would choose to go to; at the same time, there is no object of more consequence to the farmer than preferring the quality of his manure.

It is added that the facility of keeping cattle clean and dry, depends very much on the construction and paving of the flalls, of which there are various kinds. In many places, however, there is no such thing known as a flall for cows or oxen, they being bound to flakes, without any division whatever betwixt them. In some parts again, particularly in Cheshire and Lancashire, he observes cows are bound in pairs, at least there is but a very small division betwixt them, as will be seen by fig. 3 in Plate V. in which is a plan of these flalls: A.A.A., &c. being the flakes to which the cows are bound. In other parts they are not bound at all, but every cow or ox has a separate flall divided from the rest by rails of wood, that they cannot get out, and so narrow that they cannot even turn about. At fig. 4 is a plan of these flalls; S.S.S, &c. are the flalls. P is the passage betwixt them; T, T, &c. are the troughs out of which the cattle feed; At fig. 5 is an elevation of the rear of these flalls. RR is a rail that lifts out at the end of each flall. Sometimes there is a little door that opens, as at G. Fig. 6 is a section of these flalls, in which it will be observed there is a short rail or brace at A, to prevent the cattle touching each other with their horns. Some people are of opinion, that cattle feed much better and quicker in flalls of this kind than when they are not bound.

It is supposed that double flalls may be made without the short division, as already mentioned. The division between them, however, ought to be sufficiently boarded at the top, to prevent the cattle seeing their neighbours in the next flall. At each flake should be a trough for holding meat, and between these two troughs, another common to both cattle, for holding water, with which it may be supplied by a pipe communicating with a cistern or reservoir without.

These three troughs may be of stone, as in fig. 7, and all of one piece, if thought proper. A perpendicular rack for holding hay or straw may be placed over them, as represented in fig. 8, which is a section or view of one of the flalls, and fig. 1, is a plan. Perhaps it would be an improvement to divide them by a rail in the middle, as at AB, fig. 7, which would prevent the cattle turning too much about, and spreading their dung over the whole flall, for the more they are made to dung in the same place, the easier it will be to keep them clean. But although the double flalls here recommended are a good deal used for milk cows in different parts of England, yet they have in general only one trough for each cow, without any for water; nor indeed has he seen any with this convenience, except at Burleigh, in Rutlandshire, a seat of the earl of Winchelsea, where offices and farm-houses are on an excellent construction, being planned chiefly by himself.

In paving flalls for cattle, the same author remarks, "that there is generally too great a declivity made, which will cause them always to stand uneasy and uncomfortable; for, when feeding, there cannot be too much attention paid to their ease and comfort, as well as to their food. If they are constantly wet and dirty, or in pain by fouling in an unnatural position, it is impossible they can thrive so well as otherwise they might. Yet (says he) how little attention is there in general paid to this. One would almost be led to suppose it is the opinion of many, that if they stuff their cattle quite full of food, whatever may be its quality, it is all that is necessary. Sometimes they are chained so close to a flake that they can hardly move, and it is a practice in some places to fallen their heads between two flakes, by which they can neither lie down in comfort nor can they have it in their power to destroy or dislodge those tedious tormenting vermin which frequently prey upon them. Besides this, they are often suffered to be bemired on the back, and other smokings with heat for want of ventilation, or shivering with cold.

No animal can thrive well under such mismanagement, let his food be ever so plentiful, or of ever so good a quality; for, as an ingenious author says, to keep cattle clean and well littered, is to them half food. Cows are more easily kept clean than oxen, for they do not wet their flalls so much; but even oxen, when confined to flals nearly in the same place, cannot wet their flall above half way up, if properly constructed, and that generally about the middle. It is therefore clear, that if the moisiture is immediately conducted away, and prevented from spreading, the ox will be easily kept dry. The best way to do this is, (he thinks) in the manner described for paving the flalls of stables." See Stable.

The flalls of oxen or other cattle should, he says, "be paved in the same manner; but as their dung is of a more liquid nature than that of horses, it would be proper to have some commodious method to carry it off. Perhaps in some situations, where there is a proper declivity, this might be done by having an iron grating behind each ox or cow, immediately over the flall drain, and as nearly as can be judged to the place where the dung will drop, which by continuing the drain, or a wooden spout, to a pit or reservoir without, and giving it a sufficient slope, with the assistance of the other moisture, run and empty itself therein. If it should require the aid of a rake or hoe fitted to the drain, that may be easily applied, especially if those drains are made open and covered with a strong plank to take up when necessary. The moist dung being thus carried away, the remainder will be easily removed. — Something of this principle, suited properly to the situation of the place, would, (he thinks) have a great deal of labour, and very much facilitate the keeping of the cattle clean, and also be the means of saving a great deal of litter when scarce or dear. The advantage of proper drains to carry off the moisture from within the offices, and reservoirs for collecting it in, are therefore very obvious, as without such drains it cannot be expected that the offices or the cattle within them can be kept sufficiently dry."

But though these forms and modes of constructing cattle-flails and feeding-houses are, probably, the most frequently met with in different parts of the kingdom, they are often built on other places and in other forms, such as the circular and long square; the first of which, though rather more expensive in the construction, is probably the most economical in respect to labour, and the most convenient in the distribution of the food, especially where a great number of cattle are to be kept. In this case, the animals, contrary to the usual method, stand all round having their tails to the out wall, by which much convenience is afforded in throwing out the dung through crevices left for the purpose in
in the wall into covered pits made on the outside in order to receive it. The area or space within is converted to the use of feeding and attendance. There should be a room above in order to fake up different sorts of food that may be wanted for the animals, in order to complete the plan. The passage or gangway next the wall is left sufficiently large to permit the cattle to pass to and from their stalls; and the openings in the wall for the discharge of the dung should be contrived as to be capable of being shut up when the weather is fever.

The long square likewise admits of much room and convenience, and is a form in which many homies of this description have lately been erected. For this sort of shed the length of fifty or sixty feet affords room for a great number of cattle; the roof being made shelving, having the height of fourteen feet in the highest part and of seven feet in the lowest; the large space defined for the reception of the cattle being separated from that where the dung is to be deposited by a wall or some other convenient division. For the former the space of eighteen or twenty feet on the inside is sufficient to afford good room, the stalls being made each about twelve feet long, having the width of four feet, or four feet and a half; the gangways at the heads and behind the cattle being made three feet, or three feet and a half in breadth, doors being fixed to each, one for the admission of the animals, and the other for that of the persons who attend them. And when the buildings are of great length, it may be convenient to have doors at each end. There should likewise be troughs in each stall for the reception of water, which, where it can be made to run through them, is of great advantage; and boxes or mangers for particular sorts of food, as well as racks for hay, are also necessary to render them complete. The bottoms of the stalls may be formed of strong planking laid so as to have a very slight deflection, and be perforated with holes for the ready passage of the urine into the reservoir for it. There should be openings made in the wall behind the cattle, for the purpose of discharging the dung, between every two stalls of about two feet square, with proper shutters fitted to them; and also a wooden window of about the same size to each stall, to admit light and free ventilation, being placed as high as the house or shed will admit. The reservoir for the dung and urine should extend the whole length of the shed or building.

A shed on this plan has been found useful in practice by a person who has allowed much attention on the convenience of this sort of farm building. See Cow-House.

CATTU-GASTURI, in Botany, Rheed Mal. See Hibiscus elaterifolius.

CATTUPHUS, or Cossophus, in Ichthyology, a name given by Aristotle and other Greek writers to a species of Larbus of a bluish black colour; the Merula, and Turdus migratorius of some Latin authors. It is rather uncertain which of the Linnæan species is intended by those writers.

CATTUS, or Catinus catilucus, was in ancient history a sort of covered shed, sometimes fixed on wheels for the purpose of moving it, in some respects similar to the vina and pleuteus.

CATTUS-SCHIRAGAM, in Botany, Rheed Mal. See Conyza anthelmintica.

CATTUSE, in Geography, a town of America, in the state of Georgia; 12 miles W. of Tugeloo.

CATTU-TIRPALLI, in Botany, Rheed Mal. See Piper longum.

CATTUÆL, in Ancient Geography, a name given by Suidas to those who dug their habitations under ground; such were the Troglodytes.

CATTUCA, erroneously written calutus, carluc, a place of Gallia Narbonennis, between Alaxum and Apta Julia, according to the Itinerary of Antiquus.

CATULUS, an episcopal see of Africa, in Mauritania Caesariana.

CATULLUS-POLI, in Botany, Rheed Mal. See Pancratium zeleanium.

CATULLUS, Catus Valerius, in Biography, an eminent Latin poet, was descended from reputable parents, and born at or near Verona, about the year of Rome 608, B. C. 86. At Rome, where he settled at an early age, he formed an intimate acquaintance with some of the principal periphs in that city, as Cicero, Cinna, and Plancus, to whom he recommended himself by his wit and gaiety, and by the beauty of his poetical compositions, the obscurity and licentiousness of which seemed to have been no great hindrance to his reception among the ancient Romans. In some of his poems he attacked the private character of Caesars with severity, but a flight apologue effected a reconciliation; and Catullus was again admitted to his table. Although he accompanied his tutor Memmius to Bithynia, Rome seems to have been the seat of his settled residence; where he lived under the character of a wit and a man of pleasure. He published, however, a small villa at Tibur, whether he occasionally retired for relaxation, and he also speaks with an amiable enthusiasm of his paternal seat on the peninsula of Scirino, delightfully seated on the lake Benuca. He was much attached to a mistress, whom he has rendered immortal by the name of Lesbia, though her real name was Clodia. That the unshackled libertinism of Catullus had not extinguished in his breast the amiable feelings of fraternal love and friendship, we have sufficient evidence in the tender lines which he addressed to a friend on the death of a brother. The Euthychian chronicle has placed the death of Catullus in the year of Rome 69/6, B. C. 58; but as he alludes in a poem (Carm. iii.) to the consulate of Vatinius, in 707, he must have survived that period. In Blair's table his death is placed in the year of Rome 714, B. C. 40. Joseph Scaliger extends his life to 71 years, and consequently refers his death to the year of Rome 730, B. C. 15; but Mr. Bayle has examined his arguments for this date and refuted them.

The rank of one of the principal Latin poets is ascribed to Catullus by Ovid, who places him on a parallel with Virgil:

"Mantua Virgilio gaudet, Verona Catullo."

Amor. l. iii. el. 15.

Martial also acquiesces in the same opinion; (lib. xiv. Ep. 105.), and modern critics reckon him one of the most valuable examples of the golden age of pure Latinity. "He is the earliest remaining writer who gives specimens of a great variety of metrices; and his subjects and styles of writing are almost equally various. His peculiar excellence is thought to consist in the sweet and tender, combined with a sort of playful simplicity, and no pieces have been more frequently repeated than some of his short tributes of affection to Lesbia. They have, indeed, by their enduring diminutives, ferved as a model to a whole class of imitators. In other compositions Catullus aims at a higher flight, and exhibits much strength of imagination and expression, not without some of the harshness of a mode of composition not yet arrived at its due polish and correctness. His epigrammatic pieces are of various characters; but such are the licentiousness of idea and freedom of language in most of them, that nothing can be more offensive to moral purity. His amorous poems are likewise often in the extreme of warmth. Of his works we have extant, his "Liber Epigrammatum variomqum Popcatum," dedicated to Cornelius Nepos. His poems are divided into three books, one of lyrics, another...
of elegies, and a third of epigrams, which division appears in the edition of Venice, 1457, foll. The most approved editions of Catullus are those of Voëttius, Lond., 1663, 4to, with a commentary, and Utr. 1611; of Pulvinius, Patav., 1710, 4to, with annotations and an index; of Corradi, Ven., 1758; the "Variorum," by Grevius, with the poems of Tibullus and Propertius, Utr. 1683; and Mataria, in 1715, 12mo, and in the Corpus Poetorum, with Tibullus and Propertius, Lond., 1711, foll. A correct edition was printed a few years ago by an alderman of London; but not sold; and in 1705 was published an English translation, entitled "The Poems of Caius Valerius Catullus," in English verse, with the Latin text reviued, and classical notes, prefixed to which are engravings of Catullus and his friend Cornelius Nepos, 2 tols. Fabr. Bib. Lat. II. c. 5. p. 60.

CATULUS, in Libri quatuor, a name by which old authors have described the spotted dogfish, Aulakeus catulus of Linnaeus, which see.

CATURGIS, in Ancient Geography, a Celtic people, who inhabited the mountains of Gallia Lyonnaesis, or the Cottian Alps; placed by Ptolemy between Eburoinum and Vapincum. The country which they occupied was called in Latin "Cottia regnum," and in Celtic "Cou-rich," or "Catt-rich."

CATURGES, or CATURGIS, a town of Gallia Lyonnaesis, and the capital of the Caturges, between Eburoinum and Vapincum, according to the Itinerary of Antonine and the table of Peutinger, who names it "Caturimagus;" its modern name is thought to be Chorges.

CATURGICUS, a place of Gaul in Belgica Prima, N.W. of Naftum, on the route to Durocortorum.

CATURRACTONIUM, a town of the Brigantes in Britain, which was unquestionably the present Catterick near Richmond, in Yorkshire. In the time of the Romans it appears to have been a great city; and seems to have derived its name from a fort of cataract in its vicinity. Here one of the Roman highways crossed the river Swale. On its banks are the foundations of large walls, and a mount cast up to a great height. Many Roman coins and urns have been dug up here. The city was finally destroyed by the Danes.

Sp. 1. C. spiciflorus, Linn. Mant. Mart. Lam. Iluff. Pl. 8 05. (Azyaphila hispida, Burm. Flor. Ind. 303. tab. 61. fig. 1. Wart-Tuli, Rieh. Mal. 5. p. 63. tab. 32. Cauda feilis aggreditis abala, Rumph. Amb. 4. p. 84. tab. 17. fig.) "Spikes axillary, solitary, pendulous." A shrub. Stem from 15 to 20 feet high; wood white and close; bark thick, decoy, meagrous, modorous; pith yellow. Branches diffuse. Leaves alternate, petiolate, nearly heart-shaped, acute, bright green above; mulripal, hairy, with a few lateral nerves. Flowers in axillary, solitary, hispid, pendulous spikes; but, according to Burman, the spikes in most of the plants brought from the island of Java are not pendulous. Fruit round, yellowish-green, inohip. A native of the East Indies, where a conserve of the flowers is used in diarrhea, and all disorders arising from a laxity of the vaults. From a comparison of Rumphius's figures in tab. 36 and 37, with those of Riehd and Burman, J. Mareck infers that several species are confounded together. 2. C. acanthus, Mart. Lour. Cateh. 612. "Spikes axillary, upright; leaves oblong, somewhat serrated; stem climbing." An unarmed shrub. Stem long, branched, climbing, but without tendrils. Leaves alternate, acuminate, veined, smooth. Flowers very small, white, in close short spikes, with awl-shaped bracts; calyx of the male flower three-leaved. A native of the woods of Cochinchina.

CATURUS RAMIFERUS, Linn. Lam. See Boerema rami-fera.

CATUS, in Geography, a town of France, in the department of the Lot, and chief place of a canton in the district of Cahors; 32 leagues N.N.W. of Cahors. The place contains 4 244, and the canton 9927 inhabitants; the territory includes 200 kilometres and 16 communes.

CATUS PARSUS, in Zoology. See Felis pardalis.

CATUS ZIBITHICUS, a name given by some old writers to the civet, Vivera cvea of modern naturalists; called also by Gencer and others felis zibeth. The English name is civet, this being the animal which produces the perfume of that name: it is oftentimes, though improperly, called the civet-cat.

CATUSIACUM, in Ancient Geography, Claviers, a place of Gaul, in Belgica secunda, at some distance N. of Durocortorum.

CATUS-THIERN NARCAGEM, in Botany, Rieh. Mal. See Lamiola acidiflamma.

CATY WYCK, in Geography, a village of Holland, on the borders of the sea, near which the Rhine loses itself in the land. The Romans built a castle near this spot, and the rains may be sometimes seen, when the sea retards more than usual; 2 leagues N.W. from Leyden.

CATY, CATI, or CAITI, an East India weight, used especially in China. It is equivalent to one pound round and two drams English.

The cit is divided into sixteen taels, and the pie into an hundred caties.

The city is also used in Japan, Batavia, and other parts of the Indies, where it weighs more or less, according as it contains a greater or less number of taels; the city of Java is equivalent to twenty taels; that of Cambay to twenty-seven; the city of Siam is double that of China, and amounts to about 120 French pounds.

The Chinese also give the denomination city to the Simche shan.

CAYT is also a small weight whereby the lapidaries of the East weigh their emeralds, equivalent to three grains.

CAYT is also a money of account, used in Java, and some of the neighbouring islands, amounting to about nineteen florins Dutch money.

In the island of Sumatra, city is laid to denote a piece of money valued at fix shillings and eight pence Sterling.

CATZ, James, in Biography, an eminent Dutch flatem and poct, was born at Brunsvork-haven in Zealand, in 1777; and became so much attached to literature, that he resigned very elevated posts under the civil government for the sake of study and reflection. He was prevailed upon, however, by the States to undertake the arduous office of ambassador to England in the critical and tumultuous time of Cromwell. On his return he retired to one of his estates at Sargislet, where he died in 1660. His poems in Dutch, almost all of which are on moral topics, have been held in high
CAV

high estimation by his countrymen, and have passed through several editions. The latest edition was that of 1726, in 2 vols. fol. Nouv. Dift. Hist.

CATZENELNBÖGEN, or CATZENELNBÖGEN, Count of in Geography, a county of Germany, in the circle of the Upper Rhine, which devolved to the landgrave of Hesse in 1479, after the decease of Philip, the last count. It is composed of many districts, which, if they were united, would form a county 20 leagues long, and 10 broad; but the city of Mentz, with its territories, inhabited in this country, makes an interruption of 10 leagues. The Mayn, which runs through it, and divides it into Upper and Lower; the Upper belongs to the prince of Hesse-Darmstadt, and is called Darmstadt from the capital. The Lower county fell to the landgrave of Hesse-Rheinfels in 1498, except the town of Catenelnbögen, Bruchbach, and the castle of Marburg, which belong to Darmstadt.

CATZENELNBÖGEN, a town and castle of Germany, in the circle of the Upper Rhine, seated on a mountain which gives a name to a county belonging to the prince of Hesse-Darmstadt; in its vicinity are mines of iron; 28 miles N.W. of Mentz, and 22 E.S.E. of Coblenz.

CAVA, in Anatomy, is a name applied to some large veins. The superior or descending vena cava is the vessel which returns the blood from the head, upper extremities, and chest, to the right auricle of the heart. The inferior or ascending cava receives the blood from the lower extremities, abdomen, and pelvis, and pours it into the right auricle.

The vena cava hepatica are the returning veins of the liver, which join the inferior cava. For a description of these vessels, see Veins and Liver.

CAVA, in Ancient Geography, a large village of Afa, mentioned by Xenophon; and supposed to be in Bithynia.

CAVA, in Geography, one of the smaller Orkney islands, about a league S. from Pomona.

CAVA, LA, a town of Naples, in the province of Principato Citra, the fee of a bishop, immediately subj ect to the pope. Since a new road has united the Sorrentine promontory with the Apennines, which passes by Cava, it has brought to this city a concourse of travellers and merchants. It has been encouraged to trade by many valuable privileges, a cloth manufacture has improved it, and increased its population; and it carries on a great trade in silk and linen. It is distant 24 miles N.W. from Salerno. N. lat. 40° 20'. E. long. 14° 55'.

CAVADó, a river of Portugal, which runs into the sea near Epofenda.

CAVÆDIUM, in Architecture. This term, derived from the words caüa sedium, signifies a vacant space within the body of a house; it has therefore the same meaning with our word court. Vitruvius has a chapter upon cavædiums (lib. 6. cap. 3.) which he divides into five kinds, called, from their various forms, Tuscan, Corinthian, Tetralytyle, Displyvated, and Telfudinated. The Tuscan cavædium was a square court, with a roof projecting from the sides to shelter the walls, and convey the rain water towards the middle. The Corinthian cavædium was similar to the last, except that the roof, projecting further, was supported by columns under neath. The Tetralytyle was so called, from having four columns supporting the angles of the roof. The Displyvated was entirely open, having no roof projecting from the sides, and was therefore lighter and more agreeable for the windows of winter apartments to look into. The fifth kind was covered over, being telfudinated or vaulted; this manner was used when the span was not very great; and the space above was used for chambers or other apartments.

CAVAGIRO, in Ichthyology, a small fish found in the Mediterranean, which Ray describes as being something of the eel shape; but thinner and flatter. The same writer also calls it Tena rubra, and Friggia. This is the cepola Tana of recent authors, which see.

CAVAGLIA, in Geography, a town of Italy in the lordship of Vercelli; 16 miles W. of Vercelli.

CAVAILLON, a town of France, in the department of Aube, and chief place of a canton in the district of Avignon, situated on the Durance, in a pleasant and fertile country, and abounding with remains of Roman magnificence; 4 leagues S.E. of Avignon. The place contains 5196, and the canton 6075 inhabitants; the territory includes 146 square kilometres and 6 communes. N. lat. 45° 54'. E. long. 4° 17'.

CAVAILLON, a town on the south side of the fourth peninsula of the island of St. Domingo, in the West Indies, about three leagues N.E. of Les Cayes, and five W. by S. of St. Louis.

CAVALA, LA, a town of European Turkey, in the province of Romania; 30 miles E. of Emboli.

CAVALCADE, a pompous procession of an affamblage of people on horseback, with their equipages, &c. by way of parade in order to grace a triumph, a public entry, or the like.

CAVALCADOUR, or CAVALCADEUR, anciently denoted a riding-matter; but at present is diffused in that sense, and only employed to denote a sort of equerries, or officers who have the direction of princes' stables. The French say, ecuyer cavalcadeur of the king, the duke of Orleans, &c. Menage writes it cavalcadeur, and derives it from the Spanish cavalador, a horsemanship.

CAVALCANTI, BARTOLOMEW, in Biography, a learned Italian, the descendant of a noble family, was born at Florence in 1503; and having been led by the disturbances of his country to assume the profession of arms, he displayed his eloquence and his valour in an oration on liberty, which he pronounced in 1530; armed with a corselet. Taking part against the house of Medicis, he was under a necessity of withdrawing from his country after the offer of Duke Alexander and the election of Cofmo. He then settled at Rome, where he was employed by Pope Paul III. and his grandson Ottavio Farnese, in many important negociations. He also faithfully served Henry II. king of France in the cause of the Sienese, as long as they were able to defend their liberties. After the termination of the war between France and Spain, he retired to Padua, where he devoted himself altogether to literature, and where he died in 1592. His "Rhetoric," first printed in 1570, and several times reprinted, has been reckoned among the best works of the kind in that age, when it was the common fault to regard Aristotle as insinuable. His "Treatises on the best Forms of Republics ancient and modern," published in 1555, are also valued. He also wrote an Italian commentary on the first books of Aristotle's Poetics, and translated into Italian the "Caframetation of Polybius." Moreri. Gen. Biog."

CAVACANTI, GUIDO, one of the very early Italian scholars, was born of a family of rank at Florence, in the 13th century, and became the disciple of Brunetto Latini, and an intimate friend of Dante. His father, having been a free speculator in philosophy, was placed by Dante in his Inferno, among the condemned Epicureans in the lower regions;
CAV

rions; and Boccacio intimates, that the son was addicted
to familiar opinions. Guido was fond of a retired and con-
templative life, and attained among his countrymen a high
character both as a philosopher and a poet. In his pilgrim-
age to St. James of Compostella, he formed an anxious at-
tachment to a lady at Toulouse; but having taken part in
the contentions of his country against Carlo Donati, a prin-
cipal person of Florence, was in danger of assassination in his
pilgrimage.

In the year 1500 he was banished to Serrazzano;
but on account of the unhealthiness of the place, where he
fell sick, he was allowed to return to Florence, and died
there in that or the following year. His poems, for which
he is chiefly distinguished, are, allowing for the time, ele-
gant and correct. They consist of sonnets and canzonets,
and were printed at Florence in 1527, in a collection of an-

CAVALE, LA, in Geography, a small town on the northern
point of the island of Tallo, in the Archipelago, west
of the birth formed by Cape Aferea; the town projects
into the sea, and has some resemblance of a horse, whence its
name. This town, which was formerly called Bcrea, was
for a long time in possession of the Genoese and Venetians;
of late years it has become a very active point of the
Levant trade; its harbour, though not very safe, is frequent-
ed by ships which load there with corn, tobacco, and other
commodities.

CAVALE MAGGIORI, a town of Italy, in the prin-
cipality of Piedmont; 3 miles north of Savigliano, and 19
miles of Turin.

CAVALERI, a small island in European Turkey, in the
Archipelago between the south-west end of the island of
Negrupont, and the continent of Greece. N. lat. 38° 7'.
E. long. 24° 17'.

CAVALERIE, LA, a town of France in the depart-
ment of the Aveyron, and chief place of a canton in the dis-
trict of Millau, two leagues S.E. of Millau.

CAVALET, in the Glass Art, a small iron ring which
surrounds the lunella, or hole in the center of the floor,
in the tower of the leer, used for annealing glass vellts.

CAVALIA, a town of Africa, on the Ivory coast.

CAVALIER, in Military Language, a trooper, a man
of warfare or soldier, that serves and fights on horseback.
The appellation of maire or matter, has sometimes been
given to him. Thus they say, cette compagnie eet de trente
sur garante maire, non onps les officers, this company
consists of thirty or forty matters, exclusively of the officers.
This name is very old. And they inherit it from the men of
arms, the first corps of cavalry that was raised under
Charles VII. of France. These men at arms, who were
gentlemen, carried each of them into the field with him
three archers, one cutler, and one page or valet. The num-
ers of each were distinguished by so many matters, so many
archers, so many cutlers, and so many pages. When these
lait were sent on detachments, by themselves, some of the
gens d'armes commanded them. And the officers did
not march but with the gens d'armes alone. This term was
formerly confined or restrained to a knight or miles, and had
the same import or meaning as that which the French
at present annex to the word chevalier. The word now de-
notes any soldier that serves and combats on horseback; and
he is reckoned a good cavalier who takes particular care of
his horse and his equipage.

CAVALIER, the name in a military sense as Bachelor,
which title was formerly given to a young cavalier, who
had commenced his military career, served his first campaign,
and received the military chivalry.

CAVALIER, a term in Fortification, made use of to denote

a work raised generally within the body of the place from
ten to twelve or more feet higher than the rest of the works.
Its most common situation is within the baillon, and nearly
of the same form. It is sometimes placed in the gorge of a
baillon, and sometimes on the middle of a curtain, in which
case it is usually made somewhont in the form of a horse-shoe,
but a little flatter, or not to so much rounded, or circular.

The principal use of cavaliers is, to command all the ad-
jacent works, and the country around them. They are
federal or ever made but when there is a hill or rising ground,
which overlooks some of the works.

Sometimes the earth of the rampart fills up the whole
baillon, which is then called a full baillon; and sometimes
the rampart follows the moiler-line, or sight line, running
parallel to the parapet of the baillon, which is then called
an empty or hollow baillon. The empty spaces in hollow
baillons are convenient for magazines of powder and ammuni-
tion, and for various other purposes. But when the baillons
of a fortified place are full, and there are no eminences or
rising grounds near it, that command any parts of the
works, outworks, terraces or mounds of earth, called
 cavaliers, more or less raised as there occasion, are made
in them, which are sometimes walked round, and always have
like other works, a parapet for covering the cannon placed
in them for removing such exterior commands, or for defend-
ing the faces of the opposite baillons, as well as the baillons
themselves, in which they are raised, should the enemy make
lodgments in them. Such a cavalier is called cavalier de
baillon; and, when made nearly of the same figure with one,
forms a fort of double baillon, which is often attended with
great advantages. To construct such a cavalier in a baillon,
draw two right lines parallel to the faces of the baillon,
about twenty yards within, and distant from the fame; and
form, at this distance, an interior baillon, with flanks either
straight, or with orillons, similar to those of the outer baillon,
or the baillon itself, and you will get the magistral line of
the cavalier.

Cavaliers are often made on the middle of the curtains,
and near the parapet, in order to command a view of the field
from the place, to discover the enemy in his works, and
to double the fire which defends such parts of the town as may be attacked.
At other times when any parts of the place or works are liable to be enfladed, cavaliers are
raised to cover them against an infilade.

A work of this nature is sometimes erected in the ditch
of a fenny place, for the purpose of covering a gate, or
lodging a guard in it against surprises. It is then called a
horse-shoe, and when very irregular, pate.

Ever since the invention of modern fortification, cavaliers
have been in estimation and use in fortified towns, as
appears from Palma-Nova, Orih-Novo, the ezadel of Turin,
and various other places. They are raised considerably
higher than any other parts of the works; and as they have
different uses, or answer different purposes, they are also of
different figures, being sometimes rectangular, sometimes
round, sometimes oval, sometimes of the baillon form, &c.

For which, see Fortification, Pl. 1, fig. 2.
The principal advantages of cavaliers are these, that they
mekt a belief in his army as long as he is in the field, expose
him to the view of the beleaguered in his works, and
approaches, annoy him in his batteries, and oblige him to open
his trenches at a greater distance from the place than he other-
wise would. They subject him to this inconvenience, that, to
be under cover from them he must perform more labour
and make greater excavations to raise his trenches and other
works a good deal higher than he need do, were it not for
them, which, when there is but a small depth of soil and rock
under
under it, is attended with much difficulty. At the same
time he cannot, but with extreme difficulty, raise works in
the field sufficiently high to command them. They serve
also for covering those parts of the works or place, that are
exposed to an enfilade, and, when conveniently situated, al-
mock double the fire of the faces of the ballions. They
likewise answer for ferrying into the retranchments from
the moment the enemy makes a lodgment in the ballion.

Some engineers disapprove of them, alleging, that they
are of no great use or service, and do not contribute much
towards the defence of a place, because, being retired from
the out-works, they cannot keep the enemy at a distance.
Then they observe, that the height of these works is attended
with much inconvenience in different respects. First, in the raising of them, as it is difficult to heap up
earth upon earth in this manner, and afterwards place a
parapet at top of all; secondly, that they are butts for the
enemy to fire at; thirdly, that, besides this, in time of need,
and, when the enemy is near, they serve in no case for
the purposes of defence, because the men in them cannot
point their cannon on objects near and below them, without either
exposing themselves, or greatly diminishing the thickness of the
parapet; and, lastly, that they hinder the making of re-
tranchments in the ballions, and that when the enemy once
gets possession of them, he can turn them to a good account,
and make use of them to great advantage.

In answer to these objections, it may be very justly ob-
erved, that several engineers of reputation have made use of
them with great advantage, conscious that, when added
to good fortifications, they assuredly render it much flonger.
Thus, although they are retired within the body of the
place, their height remedies that defect, enabling them to see
and command whatever is in front of them. That the
difficulty of making them is not so great as has been sup-
posed, as they are actually to be found in many places, and
that it ought not to be objected to them, as they afford ad-
vantages much more than sufficient to counterbalance it.
And that as to their being butts for the enemy's cannon
to destroy and batter down, it ought to be considered that,
for this purpose, they must face his batteries, and raise them very
high, during which operations he is liable to be greatly an-
noyed and intercepted by the fire of the cavaliers, and to perform a great deal of labour before he can put his own in
a condition to do them any essential damage. And after
he has made them, they are subject to be more suddenly bat-
tered down by the cavaliers, than the cavaliers are by them,
as the one is composed of earth well settled and rammed,
and the others of earth, loose, and suddenly thrown up.

When there is but little soil on the outside of a fortified
place, the besieged may derive great advantages from such
works, as they can raise them before-hand at their leisure to
what height they choose, and may diminish the means and
power of the besiegers to injure them, by bringing the earth
from the outside for that purpose, which will compel the
enemy to bring earth and materials from a distance to raise his
batteries and approaches sufficiently high to counteract the
effects, and cover him from the command and fire of the ca-
valliers; an operation that must be always attended with
much loss of time, as well as great labour and fatigue.

Such works cannot fail to be useful by being high, since
when placed near the extremities of the curtains, they afford
a defence to the opposite ballions; and not only commanding
but ferrying to a distance, they can greatly injure and annoy the
enemy after he gets into the ditch, and compel him, when he is going to make the traverse, to raise it very high,
in order to put himself under cover. When they are thus
placed, they do not interfere with the making of retranche-
ments in the ballions, but furnish a very good defence for
them. To say that the enemy will be able to make use of
them, after he once gets possession of them, as so many citi-
dels against the town, city, or fortified place, is no argument
at all against the construction and use of them. For on the
same ground, it might be alleged, that we never ought to make
ballions. When it is considered, that after the besiegers
shall have taken all the ballions, and all the retranchments
within them, which they must do before they can become
masters of the cavaliers so situated, the place will hardly be
able to defend itself, whether there be cavaliers or not; and
when there are such works there will still remain this defence
after the great injury the enemy must have sustained by them
before he was able to force all these other works.

It may not be improper to observe, that it would not,
however, be advisable to introduce cavaliers as a principal component part of the works of the body of a place, or to
revet them like ballions, and employ them as such. For
when the ballions of a fortification are at too great distances
one from another to furnish a good mutual defence, or when
the curtains are excessively long, it is better to place ravelins
before them than to introduce cavaliers into the middles of
them.

The height of cavaliers above the level of the rampart,
must depend on convenience and the purposes for which
they are raised or erected. It ought to be from 10 to 15 feet or
more. The length of one should be at least 14 fathoms,
in order to receive conveniently 4 or 6 pieces of cannon,
and its breadth 6 fathoms, for them to have room to recoil in,
and to be served commodiously. The said height in such
works is exclusive of that of the parapet, which should look
outwards, or towards the field, like that of the rampart, and
ought to be 4 feet 4 inches high, and from 15 to 20 feet thick.
On the part looking towards the town, a very thin parapet is
all that is necessary, and the slope or ascent there, for carry-
ning the guns up should be from 10 to 12 feet broad.

When there are hills or eminences near the works, cavaliers
are sometimes made sufficiently large to hold 10 or 12 guns
each and are raised much higher.

Different forms of cavaliers are respectively best adapted
to different purposes, and much depends in this respect on
the judgment and knowledge of the engineer who constructs
them. The round or circular form, however, is exceedingly
good. Of all figures under the same periphery it contains
the greatest area. The fire from it is equally distributed in
every direction, which is not the case with that from the
rectangle, square, &c. A cavalier of this form is less ex-
pended and less liable to be ruined or battered down in any
particular place than one in the form of a rectilinear figure.
The fame advantages are in a great measure attributable to
one of an oval form, as it differs but little from the circular.
The exterior slope of the parapet ought always to be con-
siderable, particularly if it be made of loose or bad earth; and
is ought ato that of the cavalier itself to be, wherever it is
not faced with masonry.

Some are for placing them in the entrance or gorge of the
ballion, between the two flanks. This position enables
them to fire and to defend the faces of the opposite ballions.
But it interferes with the retranchments in these works, and
is too much retired from their fallant angles for commanding
effectually the parts without the body of the place. Thosc
in the citadel of Turin are thus situated, but it is in order to
command the town.

Cavaliers placed near the extremities of the curtains neither
hinder the erection nor occupy the places of other defences,
but rather increasing them have a great command of the
traverse, which the besiegers make for approaching the
ballion.
battered, to be very proper for placing them in.

The capital of a cavalier placed at the middle of a curtain, should be at right angles to the same. Its lateral angle should be nearly a right one, which will enable the faces containing it to furnish a pretty exact and good defence to those faces of the two fortifications that are opposite to them. The middle of the curtain is a bad position for a cavalier, when it is otherwise constructed. No cavalier, indeed, placed on the middle of a curtain ought to be raised high above the rampart; for if it be, its fire along the faces of the adjoining balistons will be too plunging to produce much effect. And, on the other hand, if it be kept low, it cannot command the field much better than the curtain itself. For these reasons the middle of the curtain does not appear to be an eligible or advantageous situation for a cavalier.

That a plunging shot is not near so destructive and annoying as a horizontal one, or one nearly so, is a truth so obvious that it hardly needs in need of demonstration. For a shot fired horizontally or from a very small elevation greater and bound above, and may hurt or injure fifty objects in its progress, but its force is entirely spent; whereas one fired from a considerable height at an object at a moderate distance, or from a small height at one very near, never fails if it can bury itself. But let A K, &c., represent the line of the horizon, A B the altitude of any place, work, or height above the same, and let A D, A F, A M, A K, be different distances on the horizontal line, from the foot A, thereof. Now if E G be the height of an object, at which a gun is to fire from B, G O be drawn parallel to A K, and from the points I, N, O, where G O intercepts B D, B M, B K, right lines I H, N L, O a be drawn parallel to A B, the relative degrees of the extent of offence in firing from B at an object of the height, E G, placed at the points E, H, I, L, &c., will be as E D, H F, I L, &c., and A K respectively, or as the tangents of the angles A B D, A B F, A B M, A B K, to the radius E G.

The chances then of hitting an object of a given height from B, at different distances from A, will, ejusdem generis, be as the tangents of the angles, which lines drawn from B along the top of the object at these distances to meet A K, form with A B, to the height of the object as radius. But if it be considered that a shot fired from B meeting the surface of the earth at D or F will bury itself if the ground admit of it; whereas, meeting the surface at M or K it may have a first, second, and even third grace, in each of which it may hit and injure almost a number of objects, it will be found, that the chance of doing mischief is greatly beyond the foregoing ratio in favour of the shot that is fired horizontally. Heights create dead parts for some distance in front of them, which is the cause why troops in ascending them are generally exposed to but little danger from fire-arms and fascines as little less.

In main: places cavaliers are placed either in the balistons or on the curtains, according as their situations are best calculated for enabling them to command a view of the sea, and to fire on shipping at a distance. Wherever a cavalier is placed within the body of the place, there should be a passage of 6 or 8 feet between the parapet and it, for the convenience of the folliers, and to prevent its rains when it is battered, from falling into the ditch.

Some are for placing cavaliers without the body of the place, beyond the places of arms. But this seems to be a bad plan, as they must in such situations be raised very high, be revetted, and after all can furnish no flankings defences to other work.

CAVALLERI

CAVALLERI. 

Cavalier de trinche. 

Trench-cavalier, is a work raised by the besiegers, of earth, and such other materials as they can make conveniently procure, as gabions, &c. Sometimes halfway between the termination of the flanks and the covert-way; sometimes only a third part of the breadth of the flanks distant from the covert-way; and sometimes close on the very crest or highest part of the flanks. It is difficult to establish such a work. It cannot, indeed, well be done without batteries a ricochet to embush completely the covert-way. But when the cavaliers de trinche are once well established, they present frequent issuing, and soon compel the besieged to retire within the body of the place. For it is then easy to push on three trenches or approaches to the flanks and distances of the covert-way, and to make at these angles small lodgments in the forms of circular arcs, by means of which the besieged may be driven entirely out of the places of arms, and from which the besiegers can extend their lodgments to the right and to the left, in directions parallel to the branches of the covert-way, or middle of the flanks, and about three totes distant from the same; which thickens of earth of will serve as a parapet to their lodgments, and shelter them from the fire of the cannon of the place.

In order to oblige the besieged to abandon their cavaliers, or to make them fall to diminish the brilliances of their fire, it is necessary to keep almost continually throwing large shells into them. These damage them materially, diminish the guns on the batteries in them, break the carriages, and prevent the besieged from re-placing or re-establishing them, without great loss, if they persist in working on the cavaliers.

If the cavaliers of the besieged be revetted and in the batteries it is also necessary to bother them with heavy cannon, in order so to fill up with the rubbish and ruins that part of the rampart, which is at the foot of each, as not to leave sufficient space for them to retreat themselves to oppose the assault or attack of the balistons.

When the miners once get so far as to penetrate into the earth of the rampart, and into that of a cavalier, they should make use of mines to throw as much as they can of the earth of both into the ditch, to affight in filling it up. After that, they should continue working on the breach, to render it practicable and of ease access, after which the besieged having no retreat, either in the balistons or in the cavalier, will naturally surrender, to avoid having the place stormed or carried by assault.

Should the besiegers, however, be driven to the necessity of forming the balistons, they will as soon as they reach the top of the rampart make small lodgments at the foot of the cavalier, on each side of the breach to support that of the top of the breach in the cavalier. 

CAVALLERI A CIVIL. 

This is an application given by the Italians to the large square towers, which they make over the gates of cities for the purpose of placing cannon on them.

The ancient raised cavaliers or terraces of wood and earth against the walls of towns they were besieging, in order to throw fire, darts, &c. into them.

CAVALLERI, EMILIO DEL, a Roman gentleman, who first set the dialogue, of an oratorio, or sacred drama, to narrative music, or recitative. This oratorio was entitled, 'Del Animas e dels Corp,' and was performed at Rome in 1600, the same year that Rinuccini's 'Offen, the first opera, was set by Jacopo Peri at Florence, and performed to popular music: so that the Italians themselves are unable to determine which was the inventor of the musical declamation called recitative, which has been cultivated and composed in the musical dramas of Italy, sacred and secular, ever since; and which
which, though attempted in other dialects elsewhere, seems to suit no language but that of the country where it had its birth. See Recitative, Opera, and Oration.

CAVALLERS, or Cavalliers, in English History, the appellation given by one of the parties in the ill-advised time of Charles I. called the Round-Heads, on account of the short cutp hair which they wore, to another party composed of reduced officers, and young gentlemen of the inns of court, who offered their service to the king. Under these party names the different factions rendezvoused, and familiarized their mutual hatred. See Tories.

CAVALLERI, or Cavallerius, Bonaventura, in Biography, an eminent Italian mathematician, was born at Milan in 1508, and entered at an early age into the order of Jesuites or Hieronymites. In the course of his studies he manifested such talents, that his superiors, after he had taken orders, thought proper to send him to Pisa in order to enjoy the advantages of the university established in that city. Cavallari at first regretted this change of situation; however, it was to this circumstance that he owed the celebrity which he afterwards acquired. Here, with the advice of Benedict Cailli, the disciple and friend of Galileo, he applied to the study of geometry, in order to relieve the pains of the gout to which he was subject; and in this science he made such progress, and acquired such an accurate acquaintance with the ancient geometers, that Cailli and Galileo concurred in predicting the eminence at which he afterwards arrived. Soon after this period he invented his method of indivisibles. In 1629 he communicated to some ingenuous persons and to the magistrates of Bologna, his treatise of indivisibles and another on the conic sections; and thus he obtained the honour of succeeding Maginius as professor in the university, in the year 1629. See INDIVISIBLES. Besides his celebrated work on indivisibles, entitled, "Geometria Indivisibilius communium solidorum novi quidam Ratione promotis," and published at Bologna in 1635, 4to. and again in 1653; he also published a treatise on conic sections, under the title of "La Spechio Utitorio overo Trattato delle Settoni Comiche," or "De Speculo Utitorio, &c." Bologna, 4to. 1632; a system of trigonometry under the title of "Diriectorum generale Urametricum," 4to. 1632, including an account of logarithms, together with tables of the logarithms of common numbers and trigonometrical tables of natural sines, and logarithmic lines, tangents, sines, and versed lines; of which a new and enlarged edition was published at Bologna in 1643, 4to. entitled, "Trigonometria Planam ac Sphaerica, Linearem ac Logarithmica, &c.;" a "Compendium Regularum de Triangulis," and a "Centuria Problematum Altronomorum." He was also the author of a treatise of astrologry, entitled "Rota Planetaria," and published under the appellation of Sylvius Philomantus; and this publication was the more surprising, as he was an enemy of judicial astrology. The bulk of his works was entitled "Exercitationes Geometricae," 4to. Bonon, 1647, and contains exercises on the method of indivisibles; answers to the objections of Guldinus; the use of indivisibles in Cooke's powers, or Algebra, and in considerations about gravity; with a miscellaneous collection of problems. Towards the close of this year, 1647, he died a martyr to the gout, which had deprived him of the use of his fingers. Montucla, Hist. des Math. vol. ii p. 57, &c.

CAVALLERIA, among the Ancient Spanish, a kind of tax, or impost on the inhabitants of great towns and cities, for the support of horsemen.

CAVALLEROS, in Geography, a town of North America, on the north-west part of the bay of Panama; 75 miles S.W. of Panama. Vol. VII.

CAVALLES, a cluster of small islands in the Southern Pacific ocean, near the coast of New Zealand; 3 leagues N.W. from Point Pocock.

CAVALLI, Francesco, a Venetian dramatic composer, who furnished the theatres of Venice, between the year 1630 and 1666, with 35 operas. Of his genius, science, and fertility, we are now unable to judge, except by Erfinenza, one of his operas that has been preferred in England, and which having examined, we find the music as good as that of any of the time and kind. And indeed, the number of his operas is a strong exogage upon his genius, in a city where the musical drama was more cultivated in the 17th century, than in any other part of Italy.

CAVALLI Marino, in Natural History. These are described by old writers as being little dried animals about the length of a man's thumb, found on the sea-coast near Ponzolli. The head, they observe, resembles that of a horse, and the body terminates in a tail like that of a shrimp. Women, it is said, use them to increase their milk; and apply them as an anodyne for the breast. Drunk with vinegar and honey they are applied as a plasher to the part bitten by a mad dog. This species of fish is also found on the other side of Italy, along the coast of the Adriatic; but not in such abundance. The marine animal, to curiously described, is no doubt the small species of Syngnathus or pipe-fish, known among modern naturalists by the name of Hippocampus. See Syngnathus Hippocampus.

CAVALLINI, Pietro, in Biography, a historical painter of the thirteenth century, was born at Rome in 1259, and became the disciple of Giotto. The number of his paintings is said to have amounted to 1500, and his pigny was no less extraordinary than his affability as an artist, in consequence of which he has been esteemed as a saint. His principal works are at Rome, where he assisted Giotto in the celebrated picture in Mosaic, which is over the grand entrance into the church of St. Peter; his performance in fresco was in the church of San Cavali at Rome; in which he represented the Virgin and child above, surrounded with glory, and below was the figure of Octavian, and also that of the Sybil, directing the eye and the attention of the emperor to the figures in the air. It has been suggested by Mr. Vertue (Ice Anecdotes of Painting, vol. i. p. 17) that the thron of Edward the Confessor, and the crosier erected to the memory of queen Eleanor, were constructed from the designs of Cavallini by Abbot Ware; and he supposes Cavallini to be the inventor of Mosaic, alleging that Giotto was 20 years younger than the other. But this appears, by the testimony of Vafari, and of other writers, to be anachronism; as Giotto was three years older than Cavallini, and was, in reality, his instructor in the art of Mosaic. Besides, the abbot Ware died 1283, when Cavallini was only four years old, and eight years before the death of queen Eleanor, who died in 1291. Pilkington, an enemy of judicial astrology.

CAJALLO, in Geography, a sea-port town of America in the province of Venezuela, on Terra Firme, or island of Darien, 27 miles N.E. of St. Jago de Leon. It is well fortified, and in a former war was unsuccessfully attacked by Commodore Knowles. S. lat. 10° 15'; W. long. 80° 12'.

CAVAZOS d' Enix, two small islands in the Atlantic near the coast of Portugal, about half a league S.S.W. of Espofenda. N. lat. 41° 46'; W. long. 8° 6'.

CAVAQUET. This is the name given to a particular found of the trumpet, which the cavalry make use of on approaching towns or passing through them.

CAVALRY, in French chevalerie, or cavalierie, in Military Language, a body or bodies of troops, who serve and fight on horseback. Of these there are different descrip-
Cavalry.

Before the year 1668 the regiments of French cavalry consisted of two, three, four squadrons; each squadron consisted of three companies, and each company of a captain, a lieutenant, a marshal des Logis (quarter master) and fifty maitres (troopers).

During the war of 1668 their ancient regiments were divided into squadrons, and every squadron consisted of four companies. A company consisted of 40 maitres, and had four officers, as formerly. The new regiments consisted each of four squadrons, of which each had three companies. And each company was composed of 55 maitres and four officers.

During the war of 1704 the squadrons consisted each of four companies; and each company had 35 maitres and four officers.

Before the breaking out of the war of 1744 each regiment of their cavalry consisted of four squadrons; each squadron of four companies; and each company of 25 maitres.

During the war the companies were increased each to 35 men. The regiment de Royal Allemands, and that de Rolen, consisted each of six squadrons, and each squadron of three companies of 35 men each. The regiment of Fitzjames had four squadrons, and each squadron three companies of 45 men each. That of Nassau had the same number of squadrons and companies, but each company had 50 maitres.

The ordnance of the 8th of March 1749 reduced the cavalry to 129 squadrons, consisting each of four companies, and each company of 35 maitres.

The ordnance of the 25th of March 1776 made each regiment consist of four squadrons of cavalry, and one of light-horse, of one company each. By the 11th article of that ordinance there was attached to each regiment of cavalry a squadron under the title of an auxiliary squadron, for the purpose of replacing, in time of war, the men, that might be deficient or wanting in the squadrons of cavalry or light-horse.

The ordnance of the 8th of August, 1784, made some alterations in this arrangement, and made each regiment of cavalry consist of four squadrons, and each squadron of one company. By it both a peace and a war establishment was prescribed. But in both the one and the other the number of officers and non-commissioned officers of all ranks, was to be the same.

By it also the six regiments of light-horse were reunited to the cavalry, and every regulation for them was preferred. And they were to retain the rank they then held among themselves, and with regard to the other regiments of cavalry.

The offensive arms of the cavalry are, the pikiol, the carbine, the blunderbuss, the fusil and bayonet, the sword and the sabre.

The defensive arms of the cavalry are the calotte or leather cap, the plate, and the demi-cuirass, or half cuirass.

As the Franks, before they conquered Gaul, had but very little cavalry, it is probable they employed in their armies by degrees the Gallic cavalry, which possessed much reputation, and for a long time had formed the most numerous part of the Roman cavalry. Clodius, at the battle of Tolbiac, fought at the head of his cavalry, and in 537 Theodobert carried home with him on his expedition into Italy. At the battle of Tours, in 732, we are told, that the French army consisted of 60,000 foot, and 15,000 horse, which last-mentioned body had neither boots nor defensive armour, and had no other offensive weapon than the lance or javelin.

Under Pepin, in 768, the number of their cavalry was augmented.
CAVALRY.

augmented. Under Charlemagne its number almost equalled that of their infantry. This probably was owing to the vast extent of his empire and the insurrections, that were constantly taking place in it, which required prompt and expeditious movements from one place to another. In his time the horsemen or cavaliers were armed with swords, and coats of mail made of small rings, inter-wrought or connected like links together.

Towards the end of the second race of French monarchs, and the beginning of the third, their armies were almost entirely composed of cavalry; a circumstance which arose out of the nature of their situation. Not willing to confide the defence of their country to the body of the people, who were then herd or slaves, it was left in a great measure solely to the nobility, who would not serve but on horseback. They, accordingly, formed a corps of cavalry or horse, to which the name of gendarmes was given. The gendarmes were armed with curassés, bracelets, cuisses, greaves, gauntletts, helmets, with the lance, the sword, and the hatchet. Their horses were covered with plates of iron, or with thongs of leather. The infantry were employed in going after forage, raising up the wounded gendarmes, and in performing similar services.

The cavalry, that got the name of light, was composed of the vaillants whom the señores or nobility carried along with them. They had not all the arms of the gendarmes, and did not fight in the same line with them. They were furnished with very little defensive armour; they carried the hatchet, the club, and sword, and worked nearly as hussars do.

Louis le Gros, having establisht communities, formed from that milicia, in 1018, some light horse. But there was no regular formation or establishment of cavalry in France before the time of Charles VII., who made one under the name or appellation of compagnies d'ordonnance, and one of infantry, at the same time under that of Francs-archers. Then the cavalry assumed a more regular form, and fought in squadrons; whereas, before that time they had not been accustomed to fight but in a single rank, because no one of the nobles that composed it chose to stand behind another.

The d'armes is the first corps of French cavalry next to that of the Maison du Roi, and has always been remarkably distinguished for its valour and intrepidity. Charles V. having applied to Francis I. in 1552, to lend him a number of them and the vaillantous corps of foot that followed him in repulsing the Turks by whom he was at that time hard pressed, received for answer from the French monarch to the effect of his demands, ' that he was not a banker;' and to the second, 'that his gendarmery never fought but with their king at their head.'

In 1445, Charles VII. observing the difficulties he experienced in assembling the noblesse, who then composed the French cavalry, the continual wars they were engaged in having exhausted their means of supporting the expense, and wishing, for various good reasons, to have a corps of cavalry that should be constantly engaged in his service, and which he could dispose of at all times, and on all occasions, as he might think proper, created or formed fifteen companies, to whom he gave the name of hommes d'armes d'ordonnance du Roi. These companies were composed of the bravest and most experienced men in military service then in the kingdom. Each of these companies consisted of 100 lancers, or hommes d'armes, and each homme d'armes had five followers or aids, viz., three archers, one cutler, and one page or valet. Each company then contained 600 men, all mounted on horseback; and the fifteen companies formed together a body of 9000 cavalry. This was the commencement of a standing army in Europe. That sagacious king set the example to other monarchs, and pointed out to them the most effectual method of not only counterbalancing, but also of lowering, by degrees, the exorbitant power of their nobles.

The officers of these companies were all lieutenants of the first distinction. The hommes d'armes, or matières, themselves were gentlemen, and their followers were obliged to wear the livery of the captain of the company to which they belonged. For this purpose they ornamented their coats with the colours that composed it.

This uniformity of drays in each company was established that they might be known in action, and that they were guilty of any irregularities: whence proceeded this uniformity in clothing that has been since established among troops in every nation. These companies afterwards diminished, in regard to the number of men in each, but always retained their reputation for valour. This diminution was occasioned by the establishment of a confederable body of light horse or cavalry, in which several of the gendarmes accepted of employment; to that under the reign of Henry IV. the armour cap-a-pie having been abolished, the gendarmes ceased to be distinguished from the other cavalry but by their name and prerogatives. At last under the reign of Louis XIV., at the time of the peace of the Pyrénées, all these ancient companies were reduced to the four first, of which the king chose to be captain, and to some others that belonged to the princes of the blood. These last were suppressed as the princes died. The fame king afterwards, however, augmented that corps to the number of sixteen companies, at which establishment it was continued.

The Scotch company of gendarmes du Roi was the only one that remained of the fifteen which Charles VII. established in 1445. It had the appellation of cent lances, or the hundred lances, and was unquestionably the oldest troop in the kingdom. It possessed some privileges superior to those of the Scotch body guards, though these held the first rank, and was always held in such high estimation, that, so long as it was composed of Scotchmen, it was commanded by Scotch noblemen of the first qualification, and even by several of the blood royal. The tons even of the kings chose to bear the title of captain of that company, which, of right, belonged to them, as appears from several treaties, and the example of the duke of York, afterwards king of England, under the title of James II.; who was captain of it in 1607. And it was not till after he resigned the command of it, that it was commanded by a French seigneur.

Under Henry IV. there were carabiniers, who did not form a separate corps, but were put by fitties into the companies of light horse, and had no other captains or cornets, than the captains and cornets of these companies. These carabiniers, under Louis XIII., formed regiments, and were diffused in separate corps, in the same manner as the carabiniers, who were distributed among the regiments of light cavalry, were, in the reign of Louis XIV., formed into regiments of carabiniers. Since his time the French cavalry has consisted of different bodies. Some were in companies, others in corps or regiments. The body guards of the king, the gendarmes, the light horse, the mulletiers, have been on the footing of companies, and have not formed regiments. The rest of their cavalry have been distributed in regiments commanded by colonels, and gone under the general name of light cavalry, which, however, is distinct from the compagnies des chevaux légers d'ordonnance.

The Spanish cavalry is naturally good. And were it properly disciplin'd and taught to make: the best s of its
force, there are hardly any troops that could stand its shock.

The Turks, the Tartars, the Arabs, and even the Moors themselves, or the people of the kingdoms of Fez and Morocco, have excellent horses for cavalry as well as the Spaniards. But their fabrics, though of a good temper, are not so useful or so well calculated for doing execution, as the Spanish sword, or even the swords of the Germans. Besides the advantage of good and fleet horses, they fit to front on the stirrup, that they can stand up quite straight at a full gallop, and, supporting themselves with their stirrups, can make a better stroke than those who use long ones, and at a greater distance.

The Turkish cavalry owes its origin to the Scythians, a race of people, that were always fond of making war on horseback, and transmitted that passion to the Turks.

The Sultans too tyrannized over their new subjects, after conquering them, as even to deprive them of their lands, and appropriate them to the maintenance and support, not only of the *seravatuly* infantry, and the marine, but also to that of the cavalry. At the same time they left the conquered countries divided into and distinguished by the names of kingdoms, provinces, great and small departments; and sufficed for each of these districts particular and distinct orders, touching the prompt raising of the militia and the support of the cavalry.

Their cavalry is not all on the same footing in regard to pay. It is divided into the cavalry *capacibly*, the cavalry *topably*, the cavalry *ferratuly*, and the cavalry *de tribut*.

The cavalry *capacibly* or *topably* pays no lands, but are paid by the grand sultan, and serve as a guard to his person. Their number amounts to about 15,000, one half of whom are called *fitehataris*, and are distinguished by a yellow standard or cornet, and the other half are called *fiphasis* or *fiphasis*, who are distinguished by a red cornet or standard. Originally these last served the first. But having in an engagement given astonishing proofs of valour to the flame and disgrace of these, whose servants they had been, they were formed into a separate and distinct corps. Their offensive armours confull chiefly of the fabric and the lance, which they call *mijrak*. They frequently also carry bows and arrows, and sometimes pithos and carbines. And they make use of the long dart or javelin, called *gerit*, which they handle with much address and dexterity, catching it up from the ground, when their horses are even at full speed, if they mis their aim in throwing it at the enemy. When the grand feignor takes the field in person, it is customary to make a present of 5000 aspers each *fiphas* to enable him to purchase bows and arrows.

When the *fiphas* are on a march, they follow their standard without observing any certain order, advancing in a confused manner in small bodies, sometimes in the van of their own corps, and sometimes in the rear.

Besides these two bodies of *fiphas*, there are four others, who are not called on to serve but when the urgent necessities of the state render their services absolutely necessary. The first of these are called *feg-uduf*, and carry a standard red and white; the second *fod-uduf*, and carry a standard white and yellow; the third *faz-uduf*, with a green standard, and the fourth *fod-uduf*, with a white one. All these *fiphas* receive a daily pay, from 10 to 20 aspers, and are liable to perform every kind of service.

There are likewise *fiphas* called *timarissi*, who are obliged to serve at their own expense as soon as the *beglershes* or governors of provinces command them, in consequence of the lands they possess, the revenues of which are appropriated to this service. Of these there are two kinds, the one called *reglerelis*, and the others *fischerelis*.

The *Tezkerahs* receive the grants of their *timars* from the court of the grand feignor. But the greatest revenue of one of them must not exceed 10000 aspers.

The *Tezkerah* take their letters patent from the *beglershey*; and the revenue of one of their *timars* is commonly from 3000 to 6000 aspers.

The *Chousen* also form a branch of the cavalry *capacibly*. They are people of the court as well as of war, carrying, like aides-de-camp or adjutants, the orders of the sultan, the vizier, or other general, to the officers of the army, whether these be verbal or in writing. They escort the couriers dispatched on affairs of importance, and serve themselves when it is necessary. They are always within reach of the vizier, and affect to pass for inferior *eques*. Their chief, called *Chousen-basy*, is immediately about the vizier.

The cavalry *topably* or *topably* is, properly speaking, that which the officers of the countries subject to the Ottoman empire support out of the revenues of the lands called Maly-mukata. These officers not only pay this cavalry, but also furnish them with provisions under the name of *uyjor*, which exactly signifies *theirs*.

The cavalry *ferratuly* is a militia defined to guard the frontiers. They are obliged to remain on the confines of the Ottoman empire, both to prevent incursions by the enemy and to act as escorts when wanted.

The horsemen of this corps, on the frontiers of Hungary between the Imperialists and the Turks, were the choicest and very bravest men. They are commanded by one or more officers called *alaybche*, who arrive at these commands by the valour and experience in war. They are, for the most part, natives of the environs of the frontiers, that, from their knowledge of them, they may be the more expert in guarding them against inroads or incursions. Besides the Turks they speak the Hungarian and Scelvonian languages.

The cavalry *de tribut*, or tribute cavalry, is so called from its being furnished by provinces, where the people are not only tributary to, but even slaves of the empire, as they can have no particular prince to govern them, but those only who are entirely subject, in all respects, to the will of the *porta*. The government can change them, depose them, and nominate them at pleasure. These princes are moreover obliged to appoint the sultan as their absolute sovereign, and to do homage to him as his vassals. Bessarabia, Moldavia, and Walachia, are of this number.

*Of the advantage, use, and application of cavalry.>*

In open, plain, extensive, and level countries, or in those that are intersected with deserts, there always have been, and ever must be, a considerable proportion of cavalry employed on all enterprises, and on operations, both of offence and defence, on account of their singular utility and the necessity of making use of them. They are singularly useful in protecting the wings and centre of an army; for engaging in an open plain; for furnishing detachments; for elcorts; for forming blockades; for intercepting supplies intended for places beleaguered; for foraging; for scouring a country; for procuring intelligence; for the speedy conveyance of dispatches; for heralding and fatiguing an enemy’s army; for covering a retreat; &c. &c. Cavalry, indeed, is so peculiarly useful and necessary for a great variety of operations, in countries where it can act successfully, and to advantage, that it has in all ages been held by the greatest generals in high estimation. The very successful services, which troops of this description have performed, show the vast number of decisive
CAVALRY.

effive advantages, that have been obtained by means of them, in the most important battles, of which history, ancient and modern, furnishes the details, the unanimous testimony in their favour of authors regarded as judges of military affairs, and masters in the art of war, prove beyond the possibility of contradiction, that cavalry is not only useful, but absolutely necessary in armies. The great Turenne used to say, that it was with good cavalry that one could so molest and harass an enemy's army, as to ruin it by degrees. It is, however, often attended with inconveniences to have a great number of cavalry, as you cannot take the field with a numerous body of them till there is grass or green forage for the horses. The Turks, whose military force consists greatly in cavalry, on this very account, open their campaigns later than other people, and retire from the field sooner. Besides a very great number of cavalry occasions such a prodigious consumption of forage as sometimes to compel a general to quit an advantageous camp or position contrary to his inclination, or former than he wishes, from other considerations.

It ought also to be remembered that open and level countries only are favourable for the operations of cavalry. And they cannot be maintained but at a great expense. Accordingly in mountainous countries, and flats that were small and at the same time not very fertile, rich or wealthy, there have generally been but few cavalry. The military force of Switzerland has for the most part consisted chiefly of infantry. In the flats of Greece, if we except Thessaly, a great part of which was level, rich, and fertile, their cavalry formed but an inconsiderable proportion of their forces.

The Thracians were dextrous horsemen, and carried the discipline and arms both offensive and defensive of their cavalry to great perfection. The other parts of Greece imitated them. And from the Greeks the Romans borrowed the arms and armour for their cavalry, who, as Polibius expressly informs us in his sixth book, were in his time armed exactly as those of the Greeks. His words on this subject are the following:

"The manner in which these troops (the Roman cavalry), are armed, is at this time the same as that of the Greeks. But anciently it was very different. For, firstly, they wore no armour upon their bodies; but were covered in the time of action with only an under garment. In this method they were able indeed to defend from their horses, or leap up again upon them with greater quickness and facility. But as they were almost naked, they were too much exposed to danger in all close engagements. The men also, that were left among them in former times, were in a double respect very unfit for service. First, as they were of a slender make and always trembled in the hand, it not only was extremely difficult to direct them with exactness towards the determined mark, but very frequently even before their points had reached the enemy, the greatest part of them were shaken into pieces by the bare motion of the horses. Add to this, that these spears not being armed with iron at the lower end, were formed to strike only with the point, and when they were broken by this stroke were afterwards incapable of any further use. Their buckler was made of the hide of an ox, and in form was not unlike to those globular dishes that are used in sacrifices. But this was also of too inferior a texture for defence. And as it was at first not very capable of service, it afterwards became wholly useless when the substance of it had been softened and relaxed by rain. The Romans therefore having observed these defects, soon changed their weapons for the armour of the Greeks. For the Grecian spear which is firm and stable, not only serves to make the first push or stroke with the point in just direction and with sure effect, but with the help of the hand at the opposite end, may, when turned, be employed against the enemy with equal readiness and force. In the same manner also the Grecian shields, being strong in texture and capable of being held in a fixed position, are alike serviceable both for attack and for defence. These advantages were soon perceived and the arms adopted by the cavalry. For the Romans above all other people are excellent in admitting foreign customs that are preferable to their own."

It was by using both ends of such a spear that Philopomen killed Machandas the tyrant of Sparta at the battle of Mantinea.

The fame judicious historian in his remarks on the battle of Cannae, in which the Romans left 70,000 men on the field, observes that the Carthaginians on that occasion, as well as in other battles they fought under Hannibal with the Romans, were chiefly indebted for the victory to the numbers of their cavalry; and that hence succeeding ages would be able clearly to perceive, that in time of war it is far more advantageous to have a great superiority of cavalry, with no more than half the infantry, than an army that is in all its parts equal to that of the enemy. In that action the Romans had eighty thousand foot and somewhat more than fix thousand Ufors; and the Carthaginians had somewhat more than forty thousand infantry, including the Gauls and Spaniards, and about ten thousand cavalry.

At the battle of Trebia, Hannibal had upwards of ten thousand cavalry, the Gauls included, whereas Tiberius had only about four thousand. On the other hand Hannibal had only about 20,000 infantry, whereas Tiberius had 36,000.

In the action near the Ticinus between the Roman and Carthaginian cavalry and light infantry, Hannibal had a superior number of horse. There is a circumstance, however, that ought not to be lost sight of, namely, that Polibius, in making these observations, supposes the armies to be acting in an open country or in one favourable for the operations of cavalry. For he expressly tells us, that Publius, after his defeat near the Ticinus as the country round him was all flat and open, and the Carthaginians superior in their cavalry, marched in file through the plains, repelled the Po, and then went and encamped near Placentia, a colony of the Romans. He also informs us, that at the battle of Trebia, the ground that lay between the Roman and Carthaginian camps, was a smooth and naked plain; but that the banks of the river were considerably high and covered with close shrubs and bushes, which suggested to Hannibal the idea of an ambush. We likewise learn from him, that the country where the battle of Canus was fought, was all plain and open, and that on this very account, and the superiority of the Carthaginians in cavalry, the consul Emilus thought it would be prudent to decline a general engagement till he could draw the enemy to some other ground where the infantry might bear the chief part in the action. For the same reason, the prudent and sagacious Fabius kept along the sides of the hills, observing the motions of the enemy, without advancing into the open plains. The battle of Zama, too, was fought in an open and level country. And Scipio Africanus was chiefly indebted for the victory there gained over Hannibal, which terminated the obstinate and long contended struggle between Rome and Carthage, for the sovereignty of the world, to his superiority in cavalry. It must therefore certainly be allowed, that a superior number of good cavalry is of prodigious moment in a country or in situations where it can act to advantage. But on the other hand it must also be allowed, that in a woody, mountainous, broken, aperut, and uneven country, where it cannot act to advantage, it is very little useful, and leaf of all in an enclosed country like Great Britain, which in this respect is widely different from
from the continent of Europe or indeed any other country. Any person acquainted with military manoeuvres, accustomed to reflect on them attentively, must be sensible that cavalry cannot be employed to advantage in either attacking or defending this country, and that therefore for the purposes of national defence, a very small proportion of them indeed is necessary. He must also be equally sensible, that neither the Prussian nor German tactics can be of any utility, or even be made use of in carrying on military operations in this country; and that therefore in defending it, that very constitutional, and at the same time very considerable part of our force, called the volunteers, as well as the militia, if properly employed and disposed of in the moment of invasion, should it ever arrive, will be equal, if not superior to our regular forces, particularly in their own counties. The same reasoning will extend to our numerous horse-artillery, which in most situations could, in case of invasion, be of little or no use in defending this very and singularly enclosed country, in which no operation, or even series of operations of an invading enemy can prove decisive, if we only adopt the proper mode of defence.

It was anciently the custom of the Romans to choose their cavalry as well as their infantry, and to add two hundred harquebuses to every four hundred foot. But in the time of Polybius, the citizens from whom the cavalry was taken or selected were first enrolled, having been before appointed by the censors according to the rate of their revenue. And three hundred of them were assigned to every legion, which then consisted of 4200 foot. The number of the Roman cavalry then in his time bore but a small proportion to that of their infantry, being to it in the ratio of only 3 to 12 or 1 to 7, whilst the cavalry of the allies was to their infantry in the ratio of 1 to 7.

Scipio Africanus, after taking New Carthage in Spain by storm, paid great attention to his cavalry before he took the field with them, and even introduced among them a new system of evolution, discipline, and exercise, which is described by Polybius in his tenth book, and is well deserving of the most serious attention of cavalry-officers even at this day.

The order of battle now generally adopted and practised in Europe, is to place the cavalry on the wings, and the infantry in the centre, each to be full armed or equipped by itself alone, instead of assembling them in such a manner as to make them furnish mutual support and assistance to each other. The placing of the cavalry in a line with the infantry on its flanks certainly retards the motions of the whole, as no part of the line can advance unless the whole does.

Marshal Saxe in his order of battle therefore places small bodies of cavalry, not only behind his infantry in the centre of his first and second lines, but also in the reserve, at the distance of about thirty paces; and half way between his two lines of cavalry, on the wings, battalions armed with pikes and formed into squares with large intervals between them, for the free movements of the horse and for the facility of their rallying under cover of and behind these battalions in square, if broken or repulsed. He also places transversely between his two lines of infantry and nearly in the directions of right lines joining their extremities, battalions drawn up in the usual depth to flank those in square, and to cover the flanks of his infantry.

General Lloyd being decidedly of opinion, that cavalry should never appear till the moment it is brought into action, places none of it in the wings, but the whole of it in two lines behind the infantry. This last he forms in such a manner as to leave an interval of 150 yards between every two battalions. His first line of cavalry is placed in separate squadrons at a proper distance behind his infantry, and opposite to the intervals between the battalions. And his second line of cavalry is, in like manner, placed in separate squadrons at a proper distance from and opposite to the intervals between those of the first. His flanks he covers with battalions in the rectangular form, armed with pikes, and at right angles to his line of infantry. In front of his army he has two lines of square redoubts with one angle of each towards the enemy; and in front of each of his battalions he has an enfilade, leaving however sufficient intervals for the whole to manœuvre on.

Cavan, in Geography, an inland county of the province of Ulster, Ireland, situated midway between the Atlantic ocean, and the Irish sea. The extremities of the county being but 14 miles distant from either of these waters. It is bounded on the north by the county of Fermanagh; on the north-east and south by Monaghan, on the south by Meath, Westmeath, and Longford, and on the west by Leitrim. Its greatest length from east to west is 40 Irish miles (51 English); and its greatest breadth from north to south 22 miles (28 English). Its area is 470 square miles (775 English) or 371,000 acres (483,573 acres. English mean) (of which about 50,000 may be ranked as mountain, bog, or water. The number of house in 1791 was 184,152, from which we may esteem the population at about 90,000, which is 5 to 1 house, and much less in proportion to the number of acres than that of some other northern counties. The number of parishes, according to Dr. Beaufort, is 39, of which 26 with 24 churches are in the dioce of Kilmore, 3 in the dioce of Ardagh, and one in that of Meath. It lends only the two county members to the house of commons, the boroughs of Cavan and Belturbet having lost the privilege of being represented in concert of the union. The face of the county is very irregular, being entirely hill and dale without any extent of level; in some places it is rocky, but excepting the mountains and water very little under actual water. To the north and west the prospect is bleak, dreary, and much exposed, but in the other parts, especially on the banks of the Erne, it is not well sheltered and woody, but the scenery is highly picturesque and engaging. Numerous lakes of great extent and beauty adorn the interior, and, generally speaking, the features of the country are strikingly diversified for ornamental improvements. The barriers of the county on the north and west are highly marked by Slieve-Rushehill, and the mountains of Ballynagoragh; and Bruce Hill is a striking feature in the southern extremity. The climate is cold, chilly and boisterous, but not unwholesome, and the inhabitants, benefited to it, are a hardy race, remarkable for good health and longevity. The soil is not fertile, though considerably engaged in tillage; it is chiefly a stiff brown clay, over heavy yellow argillaceous subfrusta, and produces naturally a coarse hardy failure. Wheat is very little cultivated, but there is great abundance of oats. The mountainous parts contain several minerals; in Quill mountain is a rich iron mine, and there are also found lead ore, manganese, coal, fuller's earth, pipe-clay, and other substances which may hereafter be turned to a good account. There are also some mineral waters, especially the sulphureous one at Swanling bar. See Swanling Bar.

The principal river is the Erne which crosses the county from south to north, and receives some small streams in its way to the celebrated lough of the same name in the county of Fermanagh. The lakes are numerous; some of them very extensive sheets of water, which cover several hundred acres. Many of them are dry in summer, and others considerably less than in winter, so that by proper management much land might be reclaimed, and the falls are such that a considerable supply of water might be conveyed to a canal that
that would connect Coote-hill and Cavan with Lough Erne. Such a canal, besides the conveyance of manufactures, would facilitate the carriage of lime-stone, which is much wanted for manure. The lime manufacture is carried on in this county, and the average tale of lime manufactured in it is valued at about 100,000l. The principal bleach-greens are in the neighbourhood of Coote hill, and Killeenmuhdra. The average value of land is about 17s. the acre. This county was formerly called Leoigillie, and also O’Kelly’s country, from the Irish family which possessed it. It was forfeited at the beginning of the reign of James I.; when it was divided amongst English and Scotch undertakers, forfeters, and natives. Some changes were made by Oliver Cromwell, but many of the allotments are at present possessed by the descendants of James’s letters. The afflizes are held, and other public burdens transferred at the town of Cavan. Cooe’s Stat. Acc. of Cavan, Beaumont’s Memoir, Transactions of Dublin Society, &c.

Cavan, the afflize town of the preceding county, is a poilt and market town, but has no manufacture, nor is it in any way of importance. There is an endowed school with an income of eight hundred a year in lands, set in the same manner as bishops’ lands, secured to it at the time of settling the county, and the presentation to which is with government. Until the act of union Cavan returned two members to parliament. Distance N.W. from Dublin 54Irish miles. N. lat. 54°, W. long. 7° 16′.

Cavan, a place in the county of Donegal, Ireland, near Lifford, where Mr. Maffon erected a temporary observatory by the Royal Society in 1769 for the purpose of observing the transit of Venus. From a number of observations made during a residence of near eight months, he determined the longitude of this place to be 7° 23′ W.; and the latitude to be 54° 51′ 41″ N.; and thus afforded an important datum for the construction of future maps of the county, of which Dr. Beaumont has availed himself.

CAVANA, or CABANA, in Ancient Geography, a town of Arabia Felix, according to Ptolemy.

CAVARES, or CAVART, in Ancient Geography, a people of Gallia Narbonensis, who inhabited the bank of the Rhone opposite to that occupied by the Volsci. Ptolemy assigns them the colonies of Aranzio and Cabilio, and some others. Strabo represents them as a very powerful people, who held in subjection several others. They pillaged the districts of the towns of Orange, Avignon, Cavaillon, and Carpentras.

CAVATINA, Ital. cut off. This term in Myice, when in times of Da Capo, when almost every opera song has a second strain in a different key from the first, implied a short air without a second part, is now seldom used as a section of an air, but as an entire air of short duration.

CAVATUM Sub, in the Materia Medica, a term used by some of the old Roman writers, as a name for the finest sort of fal gemma.

CAVAZATES, in Geography, a town of the island of Cuba; 130 miles E. of Havana.

CAVATION, or CAVATION, called also CAVING, in Architecture, the underdigging, or hollowing of the earth, for the foundation of a building. Pandrose lays, it ought to be the sixth part of the height of the whole building. See Foundation.

CAUB, in Geography, a town of Germany, in the pata-
tinate of the Rhine; seated on the Rhine; 10 miles S. of Coblenz, and 28 W. of Mentz.

CAUC, a river in the illiuns of Darien, which has its source in common with lsa Magdalena, in the lake Papes, near the 35th degree of S. latitude, and which falls into this latter river.

CAUCAS, in Ancient Geography, Cosa, a town of Ilithier Spain, S.W. of Ronda. Appian speaking of the treatment which this place received from Lucullus, against the faith of treaties, calls the glory which the Romans derived from it “hateful glory.” The emperor Theodosius was a native of this city. The Itineraries place it on the route of Segas. According to Appian, it seems to have been situated between the Tagus and Darius. The position of the modern Cosa is that which has been above assigned to it.

CAUCADEBE, a people of Asia, in Sarmatia, placed by Pliny near the river Lagonas.

Gen. Ch. Cal. Umbel univalve, unequal, with very few rays; umbel partial with more rays, the exterior ones larger. Involucres univalve; leaflets generally the number of the rays, undivided, lanceolate, membranous at the edge, egg-shaped, short; sometimes none. Inv. partial, with similar leaflets, longer than the rays, often five. Perianth proper, five-toothed, protruded. Cor. univalve irregular, radiate; flowers of the disc generally abortive. Cor. proper of the disc, male, small; petals five, inflamed-cordate, equal; of the ray, hermaphrodite; petals five, inflamed-cordate; unequal, outer one the largest, bifid. Stam. Filaments five, equal; anthers small. Pist. Germ oblong, scabrous, inferior; styles two, awl-shaped; stigmas two, spreading, obtuse. Peric. Fruit ovate-oblong, longitudinally finitied, in pulp with rigid bristles. Seeds two, oblong, convex on one side, flat on the other.

Eff. Ch. Leaflets of the involucres undivided. Corolla radiate; flowers of the disc male. Fruit somewhat egg-shaped, lirated, armed with rigid bristles.

Widl. 1. Gard. tab. 20, fig. 5. Linn. Illuf. Pl. 152. fig. 1. Jacob. Inv. tab. 54. (C. umbellus planis; Hal. her. 742. C. areniscus echinata magnoc flore; Bauh. pin. 152. Tourn. 253. Knotted flax or baffard parfley. "Umbels lateral, simple, nearly fefile; items prolate." Rose annual, small. Stems branch- ed, leafy, fruticat, roughfih with reflexed hairs. Leaves somewhat glaucous, twice-winged; pinnules pinnatifid and gatthed. Umbel opposite the leaves, solitary. Flowers white, or reddifh, small, clustered, on short peduncles, surrounded by the linear hairy leaflets of the involucre. Seeds small; outer ones mucicrated with length,aight, rough, rigid hairs; inner ones rough with warly points. Whither the latter are abortive has not yet been determined. Dr. Smith. A native of England and the south of Europe on the bor- ders of corn fields, and on banks; flowering from May to August. Caucausus, in Ancient Geography, the name of the highest and most extensive range of mountains in the northern part of Asia; and which the ancients erroneously con- sidered as a mountain Taurus. See Tauros. According to Strabo (tom. ii. p. 762) this mountain ex- tended from the Euxine to the Caipian sea, including, as within a wall, the ilithmus that separated thefe seas. It divided Albania and Iberia towards the fouth from the level country of the Sarmatians on the north; and abounded with various kinds of trees, some of which were used in the construction of ships. According to Herodotus (lib. i. and III.) it commenced above the territory of Colchis, and bounded the northern part of the Caipian sea. Procopus says, that the eastern limit of this mountain had two defiles, one of which was called the "Caipian way," and the other the "Cau- cian way." Thefe defiles served as a paffage to the Huns when they invaded the territories of the Periains and Romans. Piny says, that Seleucus Nicator had formed a project of joining the Euxine and Caipian fears by a wall; and it is also said that Antiochus Soter or Antiochus Thesus executed Nicator's project. This wall fink into ruin after the fall of the Selcuces. Herodotus mentions the two paffages in this mountain; and he fays that the Scythians and Cimmerians made ufe of them in their incursions into Upper and Minor Asia. They are also mentioned by Pliny, Tacitus, and Lucan. The ancient mythologists report that Prometheus was bound on this mountain for having flen fire from heaven, and that Hercules came hither to release him; and it is reported by some historians, among whom is Strabo, that the river of this mountain brought down gold sand, which was collected in sheep-skins. The inhabitants of this mountain region were very numerous, and formed, as some fay, 70, and according to others 300, different na- tions, who fpoke various languages, and subdivided upon the flith of wild beafs, fruit, and milk, having, on account of their uncultivated and savage manners, no intercourse with one another. The appellation of Caucausus is fuppofed to have been transmitted to the Greeks by their intercourse with the Periains, in whole language ca-ton cob signifies a mountain; whence, it is said, was formed Cob-car, or the mountain of the Chafas, an ancient and formidable tribe, who inhabited this immense range from the caipian limits of India, to the confines of Peria, and probably as far as the Euxine and Mediterranean fia. Captain Willford informs us (Atalic Refferuces, vol. vi. p. 455) that the Chafas are often men- tioned in the sacred books of the Hindus. Their defendants still inhabit the fame regions, and are called to this day by the fame name. They belonged to the clans of warriors, but they are now confidered as the lowest of the four classes; having been thus degraded, according to the initiates of Memn, by their omifion of the holy rites, and by feeing no Brahmins. Il- dorus (Orig. i. 14. c. 28.) fays, that Caucausus, in the caipian languages, signifies white; and that a mountain close to it is called Caffs by the Scythians, in which language it signifies snow and whites.
The Caucasian mountains have been well described by Russian travelers. They present a range from the mouth of the river Cuban to the north-west to the estuary of the river Kur, or the Caspian sea, to the south-east. A chain probably extends from Caucasian south-west to the vicinity of the bay of Scanderoon. This range seems to have been the Araratian of antiquity, various portions of which have been known by different names. At the other extremity of the Caucasus either branch out into Persia, which they pervade from north-west to south-east, but terminating in the deserts of the south-eastern part of Persia, or, at least, imperfectly connected with the mountains of Timbers-Kh., that it would be difficult to trace any continuous line. Much less can they be regarded as an extension of Mount Taurus, which terminates at the Tauric Passes and deserts of Albania. The Caucasian mountains, as far as they have yet been explored on the Russian side, are an alpine range, extending between the Euxine and the Caspian, from west to east, about 500 miles in length, about 35 English miles, and towards the north and south in a country 5 miles in breadth, at the greatest elevation of the chain, which is covered with perpetual ice. Its breadth on the northern declivity extends about 52 miles, and runs along the prodigious height of the chain, which, taken in the quadrature, measure, one thousand English miles; being bounded on the east by the Sinuera, and on the west by the Valakan mountains. The Marshol von Ruffia, who remained in these regions a considerable time, and took pains in investigating them, states the extent of the Caucasus, in length, from its western extreme at Ghowat to Targirn, 52 German miles, and in breadth, on the side adjoining the Caspian sea, 53 miles in the middle, (where the river Terek to the north and Arakhal to the south form a division between the caucasian and western half); and in the western part, along the Porta Cumana, a celebrated narrow part, 350 miles. The key ridges of the Caucasus, as well as the others, at their highest points, consist mainly of granite; the sides leaning towards the next mountains, of all kinds of slate, and the outward sides of lime-stone, &c. The alpine chain, formed by the highest sides, covered with snow, or ice, and exhibiting, in some open situations, bold rock without vegetation, or trees, seemed to Goldbladt not more than from 5 to 7 miles in breadth. The two sides which compose the main mountain, measured from north to north, or right across, on an average, more than 70 miles; and the north side is visibly finer or higher, than the heaths, as it declines in a far narrower or smaller breadth, or rather only by the side towards one part. The lime-stone mountains run in a flat clayey field of 20 miles breadth, gradually declinings till it ends in a precipitous side of 2 miles breadth, which consists almost wholly of the same rocks; this again runs out in a steep plan about 3 miles broad, in which numerous fountains arise. In this part common flat and narrow caves exist; and in the provinces of the river Baksan, we have seen volcanic springs, some in the mountains, some in the plains. The latter are caused by earthquakes, and are very hot. Specimens of coal and copper are occasionally found in the mountains but more frequently in the plains, at the foot of the mountains.
Caucasus, in Ancient Geography, a part of the island of Chios, mentioned by Herodotus; pp. c. 37.

Caucasus, province of, in Geography, one of the governments of Russia, in the southern region, comprises the Cuban, and all that district to the east and south now in the possession of Russia, between the rivers Don and Cuban, and between the Capan and Euxine, extending as far as the confines of Georgia, and continually augmented by the inroads and subjugation of the wandering hordes of mountanous Caucasus. By the treaty concluded between Catherine II. of Russia and the Ottoman Porte, June 21, 1782, authenticated by the seal of government, Jan. 5th, 1784, the provinces of the Crimea and the Cuban, to the empire gave the ancient names of Taurid and Caucasus, were annexed to the Russian dominions.

Caucabhene, in Ancient Geography, a people of Arabia Deserta, according to Ptolomy.

Caucumilli, in Geography, a small island belonging to the Turks, in the Mediterranean; 20 miles S.W. of Stanchio. N. lat. 36° 32'. E. long. 26° 26'.

Cauci, in Ancient Geography. See Cauchi. An ancient people of Ireland under this denomination, according to Ptolomy, are supposed by Camden to have inhabited the present county of Wicklow; and they are said by Mr. Ledwich to have come, with the Menapi, direct from Germany to Ireland.

Cauchi Nummi, a base sort of coin, current under the lower empire; thus called because concane, like a little cup, from the barbarous Latin, caesus, a cup. Halander and Murerius are mistaken in saying this coin was so called from having the figure of a cup on it. Du-Cange. The cauci are the name with what are popularly called among the Irishians, medallia de S. Eoinus, sometimes superstitiously worn by the women.

Caucoliberum, in Ancient Geography, a name given about the 7th century to a town of Gaul, now Collioure.

Caucun, in Botany, a name used by Pliny, and some other authors, for the equislinum, or horse-tail.

Caucun, in Ancient Geography, a river of Greece in the Peloponnæus, which fell by Dyme, and discharged itself into the Themus, according to Strabo. Alto, a maritime place of Sicily, 250 Itid from Syracuse; called Caura by Ptolomy.

Caucones, an ancient people of Paphlogonia, who inhabited the coast of the Euxine Sea from the Marianides to the river Parthenius, according to Strabo; but in other times this space was occupied in Bithynia. Some authors pretend that they were driven from Arcadia together with the Pelasgi, and that they had been wanderers like them. Others say, that they were Scythians; and others say, that they were Macedonians. One part of this nation settled in Greece near Dyme, in the district of Depradum and the Lower Elide. Another part occupied the territory of the Lepeantes and Cyparisians, and the town of Macta in Tithynia. Herodotus speaks of these lads (lib. i. c. 145) and gives them the name of Pylilites to distinguish them from those of the Lower Elide near Imya. Homer mentions the Caucones; who were Paphlogonians, and who came to the succour of Troy.

Caucus, in Ichthyology, a species of carp about eighteen inches in length, that inhabits the fresh waters of Chili. Moison describes it in his natural history of that country, as having thirteen rays in the anal fin; the body tuberous, and slightly tinged with silver. See Cypriaus Caucus.

Cauda, in a general sense. See Tail.

Cauda is sometimes also used in Anatomy to denote the EITORS.

Cauda Boris, in Ancient Geography, a promontory of the island of Cyprus, called by Ptolomy, and placed by M. d'Avzile at Boos Ura to the north west.

Cauda Carpiorni, in Aeronomy, a fixed star of the fourth magnitude, in the tail of Cepheus, called also by the Arabs, Duce Algeid; marked by Bayer.

Cauda Carl, a fixed star of the third magnitude; called also by the Arabs, Duce Kattos; marked by Bayer.

Cauda Cygni, a fixed star of the second magnitude, in the Swan's tail; called by the Arabs, Duce Addër, or Al-Ciigiyd, marked by Bayer.

Cauda Delphica, a fixed star of the third magnitude, in the tail of the Dolphin; marked by Bayer.

Cauda Draconis, the Dragon's tail, the name of the moon's southern or descending node.

Cauda Equina, in Anatomy, a name applied to that portion of the medulla spinalis, which is contained in the lumbar vertebrae, and the canal of the sacrlium. For a description of this, with the rest of the spinal marrow, see Brain.

Cauda Equina also denotes a medicinal herb, whose leaves are reputed to have a strengthening virtue. This, in English, is called the horse-tail. The official kind is more particularly called by botanists equisium major, in English, the great marsh-horse-tail.

Cauda Leonis, in Aeronomy, a fixed star of the first magnitude in the Lion's tail; called also by the Arabs, Duce Eldëd, and marked by Bayer. It is called also Lucinda Gouda.

Cauda Urae Majoris, a fixed star of the third magnitude,
in the extreme part of the tail of the Great Bear; called also by the Arabs, Alistab and Benenade, and marked a by Bayer.

CAUDA Ufæ Minoris, a fixed star of the third magnitude, in the extreme part of the tail of the Lesser Bear; called also the polar star, and by the Arabs, Alwadah, marked a by Bayer.

CAUDAMATRIS, in Geography, a town of the island of Ceylon; 64 miles N.W. of Candy.

CAUDAR, a river of Spain, which runs into the Xucar a little above Cuencia.

CAUDATUM, in Counceology, a species of Bucinum with an ovate shell surrounded with roundish ribs; the beaks a little prominent. Knorr, &c.

This shell is fusiform, umbilicated, with a large aperture, the lip of which is plaited and toothed within; spire with fix short inflated whorls. The length is three fourths of an inch; very thin, of a flavous colour, brownish in the ribs, with five horizontal lines in the whorls of the spire.

CAUDATUS, Lat. in Music, a musical note with a tail to it; as a minuet to distinguish it from a minuette, which is round. In the early period of counterpoint, a tail added to a note made it of double its natural length; as a tail to a breve made it a long  \( \text{\textcopyright} \). See the ancient time table.

CAUDABEC, in Geography, a town of France, in the department of the Lower Seine, and chief place of a canton in the district of Yver in the Seine, surrounded with walls, flanked with towers; a town, though not large, populous and commercial; 5 leagues W. of Rouen, and 8 E. of Havre. The place contains 2500 and the canton 15,674 inhabitants; the territory comprehends 210 kilometres and 18 commons. N. lat. 49° 33'. E. long. 0° 37'.

CAUDABEC, in Manufacture and Commerce, a fort of hats, thus called from the town of Caudabec above mentioned, where they manufacture a great number of them. They are made of lamb's wool, of the hair or down of ostriches, or of camel's hair.

CAUDEC, in Ornithology, the name given by Buffon in his natural history of birds to the Gmelinian mystacica caudex, and yellow crowned fly-catcher of Latham. Buffon in another work, Pl. enl., called it gobemouché tachete de Cayenne.

CAUDECOSTE, in Geography, a town of France, in the department of the Lot and Garonne, and district of Agen; 14 leagues S.E. of Agen.

CAUDEL CENSIS, in Ancient Geography, a people of Gallia Narbonensia, 8 of the Vingetian. They were the ancient inhabitants of Caducet, where has been found an inscription that adorned the front of a small temple or Frichetum, built near the place and dedicated to the goddess Desiva. Many medals of silver, and other curiosities, have been dug up at the same place.

CAUDEX. in Botany, is considered by Linnaeus as one part of the root of plants, of which the radicle is the other. It is divided by him into the caudex defensum, and the caudex ascenden. The caudex descendens is the black or main body of the root, gradually flinking downwards into the ground, and producing the radicles which extract the nourishment from the earth, and are the only essential part of the root; for annual plants have root frequently no defending caudex. The caudex ascenden is a continuation of the same, which gradually rising above the ground, and producing the proper herb of the plant, or the branches and leaves with their various appendages. There are many plants, both annual and biennial, in which it is not found.

In trees it is usually placed in the trunk in lumps the calix or flem; and as it has never been admitted into the popular idea of a root, it is nearly fallen into disuse. Indeed it was never much employed by Linnaeus himself in his practical works.

CAUDEX, in Gardening, a term, which, by some early writers on vegetation, signifies the item or trunk of a tree; but according to the later ones the floc or body of the root, part of which ascends and part descends. It has been observed by Mr. Darwin on the authority of Linnaeus, that the part which joins together the plumula, or leaf, and the radicle, or root-fibres, is called the caudex, when applied to entire plants; and may, therefore, be termed caudex generalis, when applied to buds. In herbaceous plants, the caudex is generally a broad, flat, circular plate, from the which the leaf-leaf ascends into the air, and the radicles or root-fibres descend into the earth. Thus the caudex of a plant of wheat lies between the stem and the radicles, at the base of the lowermost leaf, and occasionally produces new leaves and new radicles from its sides. Thus the caudex of the tulip lies beneath the principal bulb, and generates new smaller bulbs in the holom of each bulb-leaf; besides one principal or central bulb; the caudex of orchis, and of some ranunculacees lies above their bulbous roots; whereas the caudices of the buds of trees constitute the longitudinal filaments of the bark, reaching from the plumula or apex of the bud on the branch to the base of it, or to root-fibres under the soil. Nor, continues he, is this elongation of the caudices of the buds of trees unanalogous to what happens to some herbaceous plants; as in wheat, where the grain is buried two or three inches beneath the soil, an elongation of the caudex occurs almost up to the surface, where another set of fibrous roots is protruded, and the upright stem commences. The same happens to tulip-roots when planted too deep in the earth, as he has witnessed, and, as he supposes, to those of many other vegetables.

He is also of opinion, that the caudex of the buds of trees not only ascends and, as above described, but also ascends from each bud to that above it; as on the long shoots of vines, willows, and briers, in this respect resembling the wires of strawberries and other creeping plants. Thus the caudex of perennial herbaceous plants consists of a broad plate, buried beneath the soil to protect it from the frosts; while the caudex of buds of trees consists of a long vascular cord, extending from the bud on the branch to the radicle beneath the earth, and endures the winter frosts without injury. The long caudices of the individual buds of trees, which constitute their bark, are, he says, well seen in the cloth made from the mulberry bark brought from Otaheite. On inspecting this cloth the long fibres are seen in some places to adhere, where it is probable they occasionally inarticulate, like some of the vessels in animal bodies; because, when some buds are cut off, the neighbouring ones flourish with greater vigour, being supplied with more of the nutritious juice. This informs us, he says, why the upper bark of a tree grows downwards with so much greater expedition than the under one grows upwards to meet it; as the descending caudices of the individual buds are supplied directly with nutrient from the vegetable arteries, after the oxygenation of the blood (fleshy) in the branches; whereas the upper lines of the wound is nourished only by the lateral or intercostal vessels; which, he thinks, propinque us with an argument against the individuality of trees, and in favour of that of buds. See Bud.

CAUDI-CAROLINÆ, in Ancient Geography, a place of Italy, mentioned by Herodotus.
CAUDIES, in Geography, a town of France, in the department of the Eail Pyrenees, and district of Perpignan; 9 leagues N.W. of Perpignan.

CAUDIMANE, in Zoology. Some French naturalists discriminate by this name those animals which have the tail flexible, molinate, and prehensile, such as the Sapajou tribe of monkeys, &c.

CAUNO, in Natural History, or curculio, in Ancient Geography, a defile by which the Romans, after a defeat, were obliged to pass from Campania into Samnium, in 437, and where they preferred their lives under the humiliating condition of paffing under the jugum or yoke.

CAUDISONA Piperta, in Zoology, a name by which authors call the Rattle Snake.

CAUDIVERBERA Peruviana, the name given by Laurenti to the Greenlandic LACERTA CAUDIVERBERA, which see.

CAUDIVERBERA Egyptian, L. Aur., is variety β of the same species.

CAUDEA, in Ancient Geography, a small town of Italy, in Samnium, belonging to the Hirpini, on the route from Capua to Benevento. 

CAUDO, an island of the Mediterranean, in the neighbourhood of that of Crete. Suidas.

CAUDROT, in Geography, a town of France, in the department of the Gironde, and district of La Roche, seated on the Garonne; 3 miles W. of La Roche.

CAVE, a subterraneous hollow place of a certain extent. Some authors distinguish between a cave and a cavern, making the frill the effect of art, and the latter of nature. Caves were doubtless the primitive habitations; before men brought themselves to erect edifices above ground, they took shelter under it. The primitive manner of burial, was also to repulse bodies in caves, which appears to have been the origin of the catacombs. Phil. Trans. No. 244, p. 244.

Badsminton cave, in Wilts, consists of a series or row of uniform holes, wherein pieces of armour are said to have been found, whence they are by many supposed to have been tombs of ancient warriors.

Caves long continued the proper habitations of shepherds. Among the Romans, caves, etna, used to be consecrated to the nymphs, who were worshipped in caves, as other gods in the temples.

The Persians also worshipped their god Mithras in a natural cave, consecrated for the purpose by Zoroaster.

Kircher, after Gassendi, enumerates divers species of caves, divine, human, brutal, natural, and artificial.

Of natural caves, some are pellucid of a medicinal virtue, as the Grotto di Serpente; others are poisonous or medicinal; others are repulsive to metallic exhalations, and others with waters.

Divers oracular caves occur among the ancients, the fumes of which intoxicated the head, and produced a sort of boundless or madness, which was interpreted inspiration, prophecy, and divination. Such were the sacred caverns at Delphi, which inspired the Pythia. Such also was the Sybil's cave at Cumae in Campania, still shown near the lake Avenus: though Porcellius takes it this to be of modern date, and not the true Astrum Sybillae, so finely described by Virgil. Homer likewise gives a description of Antipates, the Cave of the Nymphs, on which Porphyry has a treatise still extant, containing many of the secrets of the heathen theology, both natural and symbolical. Virgil. Æn. lib. vi. Hom. Odys. lib. xiii.

The cave of the nymph Egeria, where Numa held nightly conversations with that deity, is still shown at Rome.

The cave of Trophonius, originally the mansion of that celebrated Bocotian, became afterwards famous for the oracle which Apollo delivered in it. Paulus, who visited it, gives a large description of the ceremonies observed by those who entered the cave to consult that god. Vide Potter Arch. lib. ii. cap. 10. p. 290, &c.

Cave, in Agriculture, is a term provincially employed to signify the raking off any coarse material, such as the short straw and ears of grain, from the corn in chaff on the barn-floor during the time of threshing, &c.

Cave, CAVEY, or COLT, is a term used for earth that sinks down from the banks of canals, &c.

CAVE, dead, live, in Mining. See Live cave.

CAVE-Hill, in Geography, one of the hills in the county of Antrim, Ireland, near the town of Belfast. It is found to be 1193 feet high.

CAVEA, the place in the ancient theatres where the spectators were seated. The cavea, called by the Greeks κάτοικοι, flowers concentrically arranged from the scene, σκηνή, which was the place for the actors. The cavea was divided by partitions into three equal parts, rising one over another: μεσονέα, app. int. for the people of quality, and magistrates; the middlemost, μέσον κατώ, for the community; and the uppermost, μόρφωτα, for the women.

As the theatres were open at top, porticoes were erected behind the cavea, where the audience might retire for shelter in case of rain.

CAVEA also denoted the middle part in amphitheatres, otherwise called ARENA.

CAVEA was also used for the cage or den of a wild beast, kept for the amphitheatres. See CAGE.

CAVEAR, CAVIAR, or KAVIAR, a kind of food or pickle, in great use, and reputed throughout Russia: and also introduced upon the English table.

It is formed from the Italian cavare, or barbarous Greek καταρρεύω, which signifies the same.

The cavear or caviar, called by the Russians ikra, is an article of great importance in its reference to the industry and commerce, as well as to the palates of the Russians, who derive great advantages from it, not merely as an article of trade, but also of diet, particularly during the three lents which they observe with great strictness. It is prepared in the parts about the Volga, the Ural, and the Caspian, of the roes of flurges, ilerets, fevugas, and fritinas. The lump of roe is the first thing taken out after cutting up the fish. A large beluga will yield above 5 pounds of roe; but this, on account of the quantity of viscus matter that is mixed with it, is not much esteemed. From a flurgeon never more than 30 pounds has been taken, and from the fevuga only 10 or 12. As of the beluga roe five eggs weigh a grain, so a large beluga has 6 or 7 millions of eggs. The different treatment of the roe determines the different quality of the caviar. The word fort is the common "profiled caviar," "paynsnaia ikra." In the preparation of this the roes are cleaned from the coarsest string and fibres, then salted with about two pounds of salt to the pound, and spread out upon mats in the sun to dry, which in fair weather requires about six hours, and in cloudy weather, at most, a day. It is afterwards trodden with the feet, the person who treats it having leatheren stockings. It is then put into tubs. To make this fort for sale, it is common to take the spoiled roes of dead fish thrown upon the shore, or such as are too greedy for other forts, and even the fragments and offals that would not pass through the sieve of the finer kind, felt it in boxes, and then tread it down in tight tubs. Such caviar colls in Astrakan half a ruble per pound. A better fort is that called the "grained or scafouded caviar," "Serulaia ikra," but this is too salt to suit every palate. When the roe is cleaned from the coarser particles, it is shaken into large troughs, salted with 8 or 10 pounds to the
CAV

polish, well welling it over and over, well mixed. It is
now ready for the finest or flecked net-work, through
which are drawn and orderly completely to separate the re-
mainder of the paint, thus, like the former, it is prefixed in
wedges of three, two and one rubles; and used for the hand of the common people during
the present day, is known by the religion of the country;
but it is not fit for every sort of picture. The clearness and
color of the painting, so called, is the style of a manner, to appear...;
and almost entirely of the edges of the tarsus, and does not easily be
collected if it is dominated from its preparation "mife-
of-in our."

After being cleaned, it is dipped in soot
burnt, till the grains re quire it. It is then hung up in long,
swallow pointed bags, of strong linen, resembling jelly bags,
which are half filled. About half a pound each, as thick
rows, and filled to the top by pouring in the brine. When
the branches are dried through, the bags, hanging on waxed
poles, are powerfully wrung with the hands, so after water
the material is wholly discharged, and now the ross
are worked to dry for 16 or 12 hours in the sun. These are
then packed in small canvas or tubs, and trampled down by a laborer
in leather stockings. This first requires the rice to be quite
fresh, and is the duxial, casso two rubles per paid, and
upwards. In winter the rice is dried, and mixed with
a great dainty. In general, the tvanced and cursed is in
the least that: a bit of cotton it will keep the nets
time.
Winter in large quantities or in cold weather are far
from the Volga to all parts. The method here used
fatting the rice is by pigging them. After being well cleaned.
and laden into casks, with a number of holes in the let
within which they are let to drain, and its laid at top,
or are made up in linen bags, till press in cold, with
fish-fur past over the surface, in order to keep it as much
as possible from corruption. The caviar is prepared in a
manner, in the other parts of the empire, where there have
left proper for the purpose. Among these are the red
the white salmon and the pike, from the roses of which
a reddish kind of caviar, "khrustaia iska."

They have been Fresco
CAV

in Caves', a long measure used in Portug.
and equal to 27:1 English inches.
CAVENDON, James, in Biography, an historical
writer, was born at Calliac near Medelin, in 1582, and
educated in the Academy of the Caracci, where he learned
design, attending also frequently the schools of Rubens
and Fontainot, to fill dy after the model. In order to acquire a
proper knowledge of painting, he went to Venice, and atten-
tively examined the pictures of Titian; and so that upon his
return to his own country, his performance was much
admired; and adjudged to posses an agreeable mixture of the
colors of the Caracci with the talent of Titian. For some time
in Bologna, the works of Cavendone were esteemed equal to
the masterpieces of Amedel. His talent was strong
and new, and the taste of his composing was natural and
beautiful; but at three different periods of his life, his
painter is said to have had three different manners: his
first excellent, his second colder, and his last treble
and very bold; which degradation has been ascried to the
effect of poverty, fortune, and bodily injury, and the
natural effect of age. In the church of St. Salvator, at
Bologna, there are several very capital performances of
Cavendone; but one of his best performances in the dean
of the Mendicants at Bologna, in which he represents
Petrus Rus and another saint on their knees, in the lower part
of the picture, and the Virgin and child in the clouds
attended by angels. This picture died in 1600, aged
53.
CAVENDON, or rather CAVE D; thus they call it:
Amsterdam, what we and the French style a lot of merchan-
dize.
CAVENDISH, or Candle, Thomas, in Biography, an eminent
painter and naval adventurer in the reign of
Elizabeth, was the son of William Cavendish, Esq.,
of Trinimel St. Martin, in Suffolk, where he was born,
and whose estate he inherited. But having confirmed
his property by early extravagance in his attendance on
the court, he determined to retrieve his losses by a
predatory voyage against the settlements of the Spaniards.
The fleet which he fitted out for this purpose con-
formed only of three vessels of 120, 60, and 40 tons,
manned with 125 persons of various qualities. Having
equipped this small squadron for a voyage of two years, be
CAV
He took the command, and sailed from Plymouth July 27, 1536. On reaching at Sierra Leona in Africa, he stretched over to the coast of South America, and ran along it as far as the mouth of thetraits of Magellan. Here he
found, at a place named by him Port Famin, the wreathed remains of a Spanish colony which had two years be-
fore been dispatched in order to form a settlement in that inhospitable climate. Having reached the South Sea, he
directed his course northwards, and notwithstanding various encounters with the Spaniards, which gave him an op-
portunity of displaying with his small number of men very dif-
tinguished valor, he succeeded in burning Paita, Aca-
pulco, and some other settlements, in taking and destroying
several ships, and ravaging the coasts of Chili, Peru, and
New Spain. At length, being off California in November
1578, he performed the extraordinary exploit of capturing,
with a force much reduced, the Spanish admiral's ship of
700 tons, well manned and richly laden.Resolved on com-
ing home with his bounty, he crossed the South Sea with
one of his two small vessels, the other being destroyed, to
the Ladrones in 45 days. Thence proceeding through the
Indian Archipelago, he paffed the straits of Java, and
having touched at the cape of Good Hope, arrived at
Plymouth, after having circumnavigated the globe in 2
years, 1 month, and 10 days, the shortest period in which
it had then been effected. In 1591, he planned an-
other expedition, and set sail August 21st with three sail-
tips, and two boats, suitably equipped. This adventure
was attended with various difficulties, which disconcerted
and defeated his projects; so that, his principal success was
the capture of the town of Santos in Brazil. With part of
his squadron, he entered the straits of Magellan in April,
1592; and being forced by the inaccessibility of the fafond to a
small bay, his men endured many hardships from the severity
of the cold, and want of provisions. Having lost many of
his crew, he relinquished his purpose of traversing the South
Sea, and proposed to proceed to China by the Cape of
Good Hope; but first returning to the coast of Brazil, he
suffered many losses by some rash attempts to plunder
ports which were prepared to resist him; and defeat-
ed by several of his men, and controlled in his schemes
by the mutiny of others, he was prevented from accomplish-
ing his purpose of returning to the straits of Magellan, and
returning to the South Sea. Sickness and gun-shot at length
terminated his life, probably whilst he was at sea in his way
to England. "From the relations we have of this naviga-
tor, he seems to have paffed great perfections, with a
true enterprising spirit, but not sufficiently under the control
CAVENDISH, William, duke of Newcastle, a distin-
guished leader of the king's party in the civil wars of Charles
I. He was the son of Sir Charles Cavendish, younger brother of
the first earl of Devonshire. He was born in 1572, and
educated by his father, who directed his attention to that
polite and solid literature, which in that age was thought a
proper accomplishment to high birth and rank. James I.
made him, when very young, a knight of the bath, and
when the death of his father devolved upon him a large
estate, he was raised in 1600, to the peerage, by the title of
baron Ogles, and viscount Mansfield. By Charles I.,
who honoured him with his favour, he was advanced to the high-
er title of earl of Newcastle-upon-Tyne. His attendance at
court insured him in expence beyond his income; but he
received some remuneration by the honourable trust, confi-
ed to him in 1638, of the tutelage of the prince of Wales,
and after onward Charles II. Some court intrigues induced him
to resign the honour in 1642. His attachment to the royal
cause, however, was unabated; and on the approach of
open hostilities between the crown and parliament, he offered
his services for securing the important poit and town of Heli,
which were then thought untenable. In 1643 he took
upon himself, in consequence of the king's order, the care
of the town of Newcastle and the four adjacent counties; and
was soon after invested with a commission, constituting him
general of all his majesty's forces raised north of Trent,
which, with very ample powers. With great abilities and expence
supplied by his private fortune, he trained a colossal ar
my, with which, for the time, he maintained the im-
portance of the king's cause in the north. In military matters
he chiefly depended upon the professional skill of lieutenant-
generals, some of Scots office of merit, while he himself
inclined to the country pleasures and literary society to
which he was attached. In believing circumstances he was
charged with a blamable provocation, and his appointment
of Sir W. Davenant, the poet, to the post of lieutenant-
general of the ordnance, redounded more to his honour as a
patron of literature than as a soldier. One of his most splen-
did actions was a complete victory obtained over Ferdinando
lord Fairfax on Adderton-hill near Bradford, which, how-
ever, he is said not to have improved to the best advantage.
On the advance of the Scots army into England, and its
junction with those of Fairfax and Manchester, the marquis
of Newcastle, for that was the rank to which he had been
promoted, threw himself into York, which was soon invested
by the three armies. After a siege of three months, he was
relieved by prince Rupert; but this prince resuming upon en-
gaging the enemy, and pending the king's positive orders for
the pursuit, the marquis opposed his intention; and the fatal
battle of Marston Moor, fought July 16, 1644, began with-
out his being previously apprized of it. Nevertheless he
took part in it with his usual valour, and his infantry was
almost totally destroyed. Mortified by this defeat, and de-
spairing of the royal cause, he took shipping at Scarborough,
and immediately left the kingdom, to which he did not re-
turn till the restoration. Antwerp was the place of his re-
sidence, where he suffered with equanimity and resignation
much pecuniary distress; though he was treated with great
respect by the government of the country, and was fre-
quently visited by the king. After an absence of 18
years, he returned with his royal master, who, in 1664,
conferred upon him the dignity of a dukedom. From this
time he lived for the most part in retirement, prosecuting his
favourite studies and endeavouring to repair his shattered
fortunes. He died December the 5th, 1667, in his 54th year,
and was buried together with his duchess, in Westminster
Abbey, where a very sumptuous monument is erected to
their memories. He left one son, in whom the title of New-
castle, in the Cavendish family, became extinct. His daugh-
ters formed connections by marriage with some of the
principal families of the kingdom. The duke of Newcastle
ranks among the noble authors of this country. His great
work is a book of topography, first printed at Antwerp in 1638;
and afterwards in a revised different form, in English, Lond., 1667, 4to. This has been reprinted, and it has been much commended by the judges of that art, and has been restored principally visible by the
five figures of Drayton. — 4to. He made frequent com-
modities, applauded at the time, and that exact text has
dence links into oblivion. — Biog. Brit.
CAVENDISH, MARGARET, the eldest of Newcastle, wife of
the preceding, was the daughter of Sir Charles Lascelles of
Lascelles, and to her time much esteemed for her beauty.
Distinguishing herself under the reign of her nephew by her
attachment to Italy, and visiting Oxford, where the court
lived.
faded, in 1643, she was appointed one of the maids of honour to queen Henrietta Maria. She accompanied her majesty to France, and at Paris first saw the marquis of Newcastle, then a widower, who married her in 1645. With him she lived in retirement during his exile; endearing herself to him by the charms of her conversation and the productions of her pen. Upon his reinstatement in his fortunes and honours, she principally devoted herself to the composition of plays, poems, letters, philosophical discourses, orations, &c. in which she became a very voluminous writer; her works at length amounting to 13 folios, 10 of which are in print.

She was more distinguished by her disposition to commit to paper any thoughts that occurred to her, however rude or trivial, than by her taste and judgment. So important in her own estimation were these thoughts, that she kept within a call a number of young ladies, who rote at any hour in the night when she summoned them, in order to pen down her meditations, lest she should forget them before morning. She seldom bethought the trouble of revising on her works, "left," as she said, "it should disturb her following conceptions." From the mercenary pedants of the age this folly obtained the most extravagant applause; and both at Oxford and Cambridge the poetry and philosophy of the duchess of Newcastle were applauded with boundless admiration. Her writings have long since been confounded to oblivion, and scarcely a fragment of them is fought after by the English scholar, except a few lines descriptive of melancholy, quoted in the Connoisseur, No. 69, and praised beyond their defect. The duchess had derived much greater honour from her first attention to domestic duties than from her writings. She died in January, 1673-4. Biog. Brit.

Cavendish, William, first duke of Devonshire, eminently for his patriotism, was the eldest son of William, third earl of Devonshire. He was born in 1640, educated with great care in classical literature, and brought into public life as knight of the shire for the county of Derby as soon as he was of age. On various occasions, public and private, he distinguished himself by his spirit and personal valor, and in 1677 commenced that steady opposition to the arbitrary measures of the ministers of Charles II., which caused him to be regarded as one of the most determined friends to the liberties of his country. Intimately connected with the patriotic lord Ruffell, he joined him in all constitutional proceedings for the security of free government and the Protestant religion; but as soon as he found a tendency in some of the opposition party to the adoption of illegal and dangerous measures, he withdrew from their meetings. Nevertheless he remained attached to lord Ruffell with an unbroken friendship; on his trial he appeared as a witness in his favour; and he even made the generous proposal of promoting his escape when under sentence of death, by changing clothes with him in prison; which lord Ruffell declined accepting. After the execution of that nobleman, lord Cavendish testified respect for his memory by marrying his eldest son to the daughter of his friend. In 1684, he succeeded to his father's title; and being regarded as one of the most formidable opponents of king James's arbitrary designs, attempts were made to intimidate him; but they were ineffectual. Having rashly struck a gentleman who had offended him within the verge of the court, he was fined in the exorbitant sum of 52,000l., and being obliged to give a bond for the payment of it, this was held as a pledge against him. He then retired into the country, and employed himself in improving his magnificent house at Chatsworth, where he displayed his taste in architecture and decoration. In this retirement, however, he was not inattentive to public events; and when he observed evident indications of a plotted design for subverting the religion and liberty of his country, he held conferences at Whittington, a village in his neighbourhood, with lords Danby and Delamere, and others, for the purpose of effecting the revolution. On the landing of the prince of Orange, the earl of Devonshire was one of the first who declared for him. He secured the town of Derby, and at Nottingham received the princes (afterwards queen) Anne, whom he conducted to her comfort at Oxford. He strenuously supported all the measures which led to the transferring of the crown to king William and queen Mary, and officiated as lord-high-steward at their coronation. In consequence of his zealous attachment to the royal pair, honours and dignities of various kinds were conferred upon him; and, in 1694, he was advanced to the title of marquis of Hartington and duke of Devonshire. Uncorrupted by these distinctions, he maintained a parliamentary conduct, that was free and independent; and whilst he firmly supported the throne, he occasionally refuted projects which he thought to be unjust. Under queen Anne he retained all his posts; and was appointed one of the commissioners for treating on the union with Scotland. He died in August, 1707, in the 67th year of his age; and the following inscription was, by his own direction, placed upon his monument:

William Dux Devon, Bonorum Principum Fidelis Subditus, Inimicus et Invisus Tyrannis.

William duke of Devonshire, a faithful subject to good princes, hating and hated by tyrants.

In love and fighting the duke of Devonshire had a strong tincture of the gallantry of the age. His manner was dignified; his spirit bold and free. He was well accomplished in polite arts and studies; and occasionally amused himself in poetical composition, of which two pieces were published; "An ode on the death of queen Mary," and "An allusion to the bishop of Cambrai's supplement to Homer." Biog. Brit. Gen. Biog.

CAVERIPATAM, in Geography, a town of Hindoostan, in the country of Mytore; 90 miles E. of Scringapatam, and 130 W.S.W. of Madras.

CAVERN. Caverns are, in a great measure, peculiar to mountains; and are seldom or never found in plains. They frequently occur in the Archipelago, and other islands; because islands generally consist of the limbs of mountains. Like precipices, they are formed by the boiling or crumbling of rocks, or like abysses, by the action of fire. Caverns may be produced by the same causes which occasion guls, apertures, or sinkings of the earth; and these sinkings are explosions of volcanoes, the action of inflammable vapours, and earthquakes, which create such communications in the earth, as must necessarily produce caverns, fissures, and hollows of every kind. The caverns of St. Patrick in Ireland is not to be considered as it is famous; and the fame observation will apply to the grotto del Cane in Italy, and to that of mount Beni-guazeval, in the kingdom of Fez, which throws out fire. In the county of Derby in England there is a very large cavern, which is much more capacious than the celebrated one of Bourenn, near the Back Forest of Bromwich. The entrance to this cavern, called the "Devil's hole," is larger than the door of any church; a small river runs through it; and after advancing in it some way, the vault of the cavern sinks so low that in order to proceed farther, it is necessary to lie flat in a beat; and to be pushed through the narrow passage by people employed for the purpose; and after getting through this avenue, the roof, or arch, of the cavern rises to a great height; and after
after walking a considerable way on the side of the river, the arch Unit again so low, as to touch the surface of the water. Here the cavern terminates. The river, which seems to have its source in this part of the cavern, swells occasionally, and transports heaps of sand, which, by accumulation, forms a kind of blind alley, the direction of which is different from that of the principal cavern. See Peak, Castle-, and Buxton. Other remarkable caverns are found in the northern ridge of English mountains. In the vale of King's Dale, on the western extremity of Yorkshire, is Yordas cave, which presents a subterraneous cascade; this cave is about 50 yards in length. But the most noted is Wethercot cave, not far from Ingleton. It is surrounded with trees and shrubs, in form resembling a lozenge, divided by an arch of limestone; in falling under which, you behold a large cascade, falling from a height of more than 20 yards; the length of this cave is about 60 yards, and the breadth 30. Among other curiosities of a similar kind, we may mention Hurle-pot, in Yorkshire, which is a round deep cavity, not 40 yards in diameter, almost surrounded with rocks about 30 feet perpendicular above its black waters, while the overbranching trees increase the horrors of the scene. The river Ribble near its origin sinks into a deep cavern; and silently pervades the mountains for about three miles. In Carniola, near Potspechio, there is a large cavern, in which is a subterraneous lake. Near Adelberg we meet with a cavern, in which a person may travel two German miles, and which contains several deep and tremendous precipices. The Mendip Hills in Somersetshire present extensive caverns, and very fine grottoes, near which are found veins of lead, and sometimes large oak trees, buried 15 fathoms deep. Woolley-hole in these hills, near Wells, is a stalactitic cavern of about 600 feet in length, divided by low passages into various apartments; one of which, called the hall, somewhat resembles a Gothic chapel, and is said to be 80 feet high; while the farther, denominated the parlour, is of moderate height, but extensive diameter. On the north-west side of the Mendip hills is a more remarkable curiosity, which is a subterraneous cavern, at the bottom of a deep ravine, near the little village of Berrington or Berrington. Here are found human bones gradually incorporating with the lime-lime rock; a constant dripping from the roof feeds the stalactitic beds of the bones. Several nodules contain perfect human skulls. At the further end, where the height is about 15 fathoms, there is a large conic stalactite, which nearly meets a pillar rising from the floor. This cave was very lately discovered; and as the matter increases so rapidly, it is conjectured that it would soon have been closed up. Hence it is probable that these bones are of no remote antiquity, and may, perhaps, be the remains of prime wretches who had taken shelter here from the cruelty of Jelliffies, after the insurrection of Monmouth. In the county of Gloucester, about five miles north of Bristol, there is a large cavern called "Pen-park-hole," supposed to have been an ancient mine, at the bottom of which are thirty-two fathoms of water. M. Buffon observes, that the Devil's hole, and other caverns, from which large springs or brooks issue, have been gradually formed by the operation of the water, and that their origin cannot be ascribed to earthquakes or volcanoes. One of the largest and most singular caverns with which we are acquainted is that of Antiparos, described by Mr. Tournefort. See Antiparos. The large cave in a mountain of Livadia, formerly famous for the oracles of Trophonius, is situated between the lakes of Livadia and the Sea, from which, at the nearest part, it is distant about 4 miles; and it has no less than 40 subterraneous passages, through which the waters run under the mountains.

See CAVE and GROTTO. In all countries, which are subject to earthquakes or volcanoes, caverns are frequent. The structure of most of the islands of the Archipelago is exceedingly cavernous. The islands in the Indian ocean, and particularly the Moluccas, appear to be chiefly supported upon vaults. The land of the Azores, and the Canaries of the Cape Verds, and, in general, of all small islands, is, in many places, hollow and full of caverns; because these islands, as we have already remarked, are the tops of mountains which have suffered great convulsions either from volcanoes, or by the action of the waters, of the fruits, and of other injuries of the weather. In the Cordeliers, where volcanoes and earthquakes are frequent, there are many caverns, precipices, and abysses. The famous labyrinth in the island of Crete is not the work of nature alone. M. Tournefort affirms us, that in many parts it exhibits traces of the operation of men; and it is probable that this is not the only cavern which has been enlarged by art. Mines and quarries are constantly dug, and after these have been long deserted, it is not easy to determine whether such excavations have been the effects of nature or of art. Some quarries are very extensive. That of Macbirth, for instance, is sufficient to shelter 50,000 men, and is supported by more than 1000 pillars, 20 feet high; and the earth and rock above are 25 fathoms thick. The salt-mines of Poland exhibit excavations still more extensive. See SALT.

CAVERNOSA corpora chitricidais, in Anatomy, two small bodies, resembling in structure, on a small scale, the cavernosa corpora of the male penis. See Generation, organs of.

CAVERNOSUM corpus uteritis, or more properly corpus uteritis corporis, a peculiar vesicular subterraneous of the greater part of the urethra in the male subject. See Generation, Organs of.

CAVERS, in the Language of Miners, are any poor people that go about the mines in Derbyshire, to beg or steal ore from the miners. They are punishable in the hergnait or minery court.

CAVITY, or CAVERNY, in Geography, a river of Hindostan, which rises in the Bednore country, passes by Seringapatam, Trichinopoly, &c. and discharges itself by three branches into the bay of Bengal.

CAVESAS, in Geography, a cluster of small islands in the Spanish main, a little to the east of Cape St. Blas. N. lat. 9° 20' to 9° 40'. W. long. 78° 20' to 78° 40'.

CAVESON, CAVEON, or CAVEZON, in Horsemanship, is an instrument of iron or other matter which is applied to the nose of a horse in order to tame him, by pressing hard on his nostrils and squeezing them.

The word is derived from the Spanish Cueva, or Ca i, head.

The caveons for breaking young horses are usually of iron, made nearly circular, of two or three pieces turning on joints; others are twisted, others are flat, others hollow in the middle, and indented like faws, called mordants: which last are now banished the academies. The rope and leather caveons serve for pasling the horse between two pillars.

An iron caveon spares a young horse's mouth in the breaking, since by means hereof he is accustomed to obey the hand, and bend the neck and shoulders, without injuring his mouth. All iron caveons are mounted on a head电子商务 and a throat-band, and two straps or reins, with three rings: through the middle ring, one rein is passed to make a horse work round a pillar, and through the two side rings the other two reins are passed, which the rider holds in his hand.
hand, or fastens to his saddle to keep the horse's head in
position. This kind of instrument has been employed and con-
considered from the earliest days of modern horsemanship, even
to the present time, as the most effectual, and almost the only
means of breaking and reducing a horse to subjection and
obedience. Cav-pons are variously constructed; but they differ
from each other in no essential point, except in being of
different degrees of mildness or severity: and, indeed, it is
astonishing to what an excess of cruelty they were carried in
order to answer the latter purpose. Being tied over the nose,
made of iron, and armed with sharp teeth, they harrowed
and tore the poor animal in a shocking manner. Nevertheless,
it was a sort of proverbial boast among the old horsemen, that
a "bloody nose" made a "good mouth;" their chief intention
being to refrain and bend the horse by the cavenon, and
to save the mouth at the expense of the nose: at the same time
cumbering the horse with both, without considering that
while they thought of favoring the mouth, by not making it
acquainted with the bitt, it could never, till it had been properly
worked and formed, be true and faithful to the hand; and that
in order to be made, it must first be prepared and seasoned:
and although a raw and ignorant mouth may be spoiled by
a rough and injudicious hand, yet there is no natural mouth,
however good, that does not require to be moulded, and
wrought upon by the bitt, before it can be brought to such
a temper and feeling as to act in a close and delicate corre-
respondence with the hand which is to govern it. Upon this
principle and mode of reasoning, it must follow, that if a
horse is to be worked only by means of the cavenon, and the
bitt is to be inactive, or lightly employed, let him be ever
so well dished to the cavenon, yet, when he comes to be
rode with the bitt alone, he ought sometimes to be, his
mouth, for want of practice, will be awkward and un-
formed, though years may have been spent to make him
otherwise complete. The cavenon, therefore, considered in
the most important view of it, and allowing it the most ex-
tensive merit, should never be used but as preparatory to the
bitt, and as an engine to bend and supple the horse. In this latter
office, it certainly can boast a power much superior to that
of the bitt, and such as entitle it to the greatest applause,
if it were not attended by one humble circumstance, that,
while it bends, it pulls down the head, and puts the horse
upon his shoulders. Notwithstanding this inconvenience, it is
certain, that if the services of the snaffle were not known,
the cavenon would deserve much praise; and as it is very
efficacious in bending and suppling the horse, it may at least
dispute precedence with the bitt; but the snaffle combines
both these advantages. Berenger's Hist. and Art of Horse-
manship, vol. ii. ch. 11. See Bit and Snaffle.
CAVETTO, in Architecture, a hollow member or mould-
ing containing a quadrant of a circle. It is frequently used
in cornices, see Plate XXI. Architecture. The word is Ita-
larian, and is no more than a diminutive of cavo, hollow.
CAUHQ ROY, in Natural History, a name given by the
natives of the East Indies to a sort of fowl which they
calculine, and afterwards give in large doses in the hicouche
and many other complaints. It is also used in dicing.
The Indians boil it in water, and dye or slain their cloths
with it, to make them appear different from others: it is
a kind of ochre, or clayey iron ore, and is found in great
abundance in the hills, and iron is sometimes extracted from
it.
CAVIA, in Zoology, a genus of quadrupeds that appear
to form an intermediate link between the murine and rabbit
tribes. The animals of the cavia genus have generally a flow
and sometimes leaping pace, and are observed to never
C M A V

curb. They live like the rest of the glives on vegetable
food, and in their natural state inhabit excavations in
red trees, or burrows which they dig in the earth.
The fore teeth of the cavia, which are two in number, are
enamelled; the grinders eight; toes on the fore feet, from three
to five; on the hinder feet, from four to five: tail either very
short, or none: eacvies, or collar bones, none.
Exlerben, Buffon, Gmelin, and other authors, describe
the following species of the cavia genus: C. Paca, Acculych,
Aguti, Iepicina, Americana, Aperca, Cubaya, Patathan-
ica, or Magelica, and Capibara.
CAVIA PACA, the spotted cavy, is tallied; the feet five-
feet: and the sides lined with yellowish. Erxleben—
M. Pacu, Linn.—Conusites Pacu, Brull.—Paca, Macrave.
—Lambia, Bancroft.
This species is near two feet in length; the form thick
and clumsy, and bearing some resemblance to that of a pig,
for which reason it has been sometimes called the hog rabbit.
The name paca is of Brazilian origin, being pronounced Pag
by the natives of that part of South America: the French
settlers in Surinam call it hrve aquagique, or the water hare.
The head is round; the muzzle short and black; the upper
jaw larger than the lower; and the lip divided like that of
the hare: the molaris are large; the whiskers long; the eyes
large and prominent, and of a brown colour; the ears short,
moderately large, round, and naked: the neck thick; the
body very plump, larger behind than before; and covered
with a soft, short, thinly scattered hair, of a mild brown colour,
departed on the back the throat, back, sides, and head, thick
and belly, dingy white, and on each side of the body are
large longitudinal rows of roundish, or slightly angular spots,
spotted contiguous to each other. The legs are short, and
the feet have five toes, four of which are armed with strong
and sharp claws; that on the fifth toe being very small. The
tail consists merely of a small cone, projection not more than
half an inch in length.
The spotted cavy inhabits Guiana, Brazil, Paraguay,
and other parts of South America, and appears to be common
throughout those countries, with the exception of Paraguay,
where, according to M. D'Azara, this animal is very rare.
It lives principally in burrows which it forms in the banks
of rivers, reeding in its hole during almost the whole day,
and venturing out in quest of food in the night. The flesh
of the paca is of a good flavour, and is held in esteem in South
America as an article of food, but is very fat. It is easily
domesticated, and in this state readily feeds on almost every
kind of vegetables. The female is said to produce but one
young at a birth. A variety of the paca entirely white has
been found near the river St. Francis.
CAVIA AGUTI, olive cavy. Tailed, with olive-coloured
body. Erxleben and Schreber.—Acuti, Buffon.—Olive
Cavy, Pennant.
This species, which is about half the size of a full grown
rabbit, inhabits the woods of Guiana. By some writers the
acouchy is considered as a variety of the aguti, from which
it differs in being somewhat smaller, rather thinner, and en-
tirely of an olive colour, paler, or more inclining to whith
beneath: the tail also is rather longer than in the aguti.
Both animal's are natives of the same parts of South Ame-
rica, and their manners are similar, except that, according to
M. de Borde, it does not attempt the water like the aguti.
M. de l'Obel observes that the acouchy produces but one
young at a birth. Its voice resembles that of Cavia cebuva,
or guinea-pig. This kind is easily tamed, and the flesh is
eatable. See Agouchy
CAVIA AGUTI, long-nosed cavy. Tailed; body tawny
brown; belly yellowish. Erxleben and Schreber.—Ala
Aguti.
CAV

*Agouti, Linn._—Caniculus agouti, Buff. —Agauna, Buff._
Long-nosed Cavy, Pennant.

The agouti is an inhabitant of South America, and the West Indies. It is the size of a rabbit; the body plump, and thicker behind than before; the head rather small and somewhat compressed laterally; snout long and rather sharp; nose divided at the tip, and the upper jaw longer than the lower; ears short, broad, naked, and rounded; neck rather long, but thick; legs thin, almost naked and blackish; the hind legs longer than the anterior ones, and furnished with only three toes; tail extremely short, naked, and sometimes fearfully visible; the whole of the animal covered with hard, strong, and shining hair, in general of a rufous brown colour with blackish freckles; rump-orange coloured.

Buffon observes that the agouti has the hair, scanty, and voracious appetite of the hog; and when fully fatigued hides the remainder of its food, like the fox, in different places. It takes delight in gnawing and spoiling whatever it comes near. When irritated, it bites fiercely; its hair stands erect along the back, and it strikes the ground violently with its hind feet. It does not, he remarks, dig holes like the rabbit, but lives in the hollows of trees. Roots, potatoes, yams, and fruits are its principal food. It uses its forepaws, like the squirrel, in carrying food to its mouth; runs swiftly up hill, or on even ground, but its fore-paws being shorter than its hinder ones, it is in danger of falling upon a declivity. The flesh of the agouti being nearly as good as that of the rabbit, and the skin of such a durable quality, as to form an excellent upper leather for shoes, the hunting of these animals is an object of attention among the Indians and negroes. They commonly go in search of them with dogs, or take them in traps; the natives know how to allure them by whistling or imitating their cries, and kill as many as they please. When they go among the sugar-canes they are easily taken, for fasting at every step in the straw and leaves which cover the ground, a man may easily overtake and kill them with a stick. When in the open country, it runs with great quickness before the dogs; and having gained his retreat nothing can force him to come out but smoke; for which purpose the hunters burn faggots and straw before the mouth of the hole, but the animal seldom quits the place of his concealment till the last extremity. The young agouti is easily tamed. When in a wild state they generally dwell in the woods, where the female chooses the most obscure parts, and there prepares a bed of leaves and grasa for her young. She usually brings forth two or three at a time, and in a day or two afterwards, she carries them in her mouth like a cat, into the hollow of some tree, where she fixes them for a short space of time, for they are soon in a condition to run about and provide for themselves. They multiply as fast as rabbits, producing three, four, and sometimes five young ones, every few days of the year. When in a domestic state they never remove to any great distance, and always return to the house; but constantly retain something of their wild disposition. In general they remain in their holes during the night, under the moon shines bright, but run about most part of the day.

See Aguti.

*Canis lupina, B of Gmelin, a supposed variety of the agouti, is described by Erxleben as having a tail, and the body of a rufous colour above, beneath white. —Mus lupinus, canis abbreviatus, palmi tetradoxyli albo albo. Linn. Syll. Nat. 15. —Caniculus lupina, &c. Bibron.—Jawa Lur, Cateo, B.—Zoon cavy, Pennant.

This differs from the agouti chiefly in being of a reddish colour above, with the back and belly white; the legs are long; the posterior part large, and the tail very short.
provided it be taken care of, and sheltered from the inclemency of the weather. This animal is frequently reared in Europe, and though very prolific, the attention they require is but poorly rewarded by the profits derived from them. The skin is of little or no value, and their flesh, which is indeed eaten by some people, is notwithstanding very indifferent. Buffon conceives this objection might be removed by rearing them in warrens, where they might have air, space to range in, and an agreeable choice of herbs. Those kept in houses have the same kind of bad taint with the house rabbit, while the flesh of those kept in gardens during summer is less disagreeable though still insipid. They willingly feed on a great variety of vegetable fishermen, and may be successfully reared on parsley, cabbage, and row-thistles. In winter they may be fed with bread, carrots, and various kinds of grain.

The guinea pig is an animal of very warm disposition, being in heat so early as five or six weeks old; their growth, however, is not completed before the end of eight or nine months. The females go with young three weeks, and they have been known to bring forth at the age of two months. The first litter consists only of four or five, the second of five or six, and afterwards they will sometimes have eleven or twelve. The female does not suckle her young more than twelve days, and when the male returns to her, which he never fails to do three weeks after the litter has filled, she drives them from her, and if they persist in following her often kills them. Thus these animals bring forth at least every two months, and as their young produce in the same period their multiplication is astonishing. In one year, says Buffon, a thousand might be produced from a single couple, but their consequent increase is checked by various means of destruction. They have no distinct sentiment but that of love, and when disputing for a particular female, they will throw themselves fiercely against the other, fight, and are sometimes killed in the contest before they will yield. In their quarrels they not only bite, but kick each other like hares with their hind feet. They pass their lives in eating, sleeping, and love; their sleep is short but frequent, they eat every hour, night and day, and indulge in their amours almost as often as they eat. It has been observed that the male and female seldom sleep at the same time; but seem alternately to watch each other, one sleeping while the other is feeding. They subsist on all kinds of herbs, especially parsley, which they prefer to either grain or bread; and they are also fond of apples and other kinds of fruit. Like the rabbit they eat little at a time, but precipitately and very often. They grunt like a pig; make a chirping noise when pleased with their females, and have a sharp loud cry when hurt, or irritated. They are very delicate in their constitution, and so chilly that it is difficult to preserve them through the winter, the place where they are kept during that season must be therefore warm and dry. When they feel cold, they assemble and press close together, and in this situation are sometimes found dead. They are naturally of a mild disposition, and in their manners are remarkably neat; they are frequently observed in the act of smoothing and dressing their fur in the same manner as a cat. This little animal is very easily tamed, but is seldom observed to swim any very lively attachment to its benefactors; neither is it distinguished by any remarkable degree of docility.

Cavia capybara, river cavy. Taüla; anterior feet three-toed and palmed, Schreber.—Sau Hydrocroris, Linn._Hydrocroris, Buffon.—Cavia capybara, Pallas.—Cavira, Buffon.—Thick-nosed caique, Penn.  

The capybara inhabits the eastern parts of South America, but is said to be more common in Brazil than in any other region. This animal grows to the length of two feet and a half, and weighs sometimes one hundred pounds. It feeds not only on various vegetables, and particularly on sugar canes, but also on fish, in which particular it differs from most animals of the Glires tribe. The habits of the cavy are adapted to its mode of life; it frequents fenny woods near large rivers, swimming with the same facility as the otter, and, like that animal, dragging its prey out of the water and eating it on the bank. Its excursions in quest of prey are made principally during the night.

In general, the cavy is considered as an animal of a gentle disposition, and is readily tamed and made familiar. The female produces but one young at a birth. These animals are said to go in pairs, and are naturally shy and timid. Their voice resembles the braying of an ass. The cavy runs but indifferently, on account of the length of the feet, and therefore commonly makes its escape by plunging into the water and swimming to a great distance. Buffon supposes from the number of its teeth this to be a prolific animal; but this is contradicted, and it is asserted to produce but one at a birth. The flesh has a rank and fishy taste, which renders it but an indifferent article of food.

The cavy has a large head, and a thick divided nose, with strong and large whiskers on each side; the ears are furnished with both the eyes large and black; the upper jaw longer than the lower; in each jaw are two very large and strong cutting teeth; and the grinders, which are eight, in each jaw, are divided into three flat surfaces on the upper part; the neck is very short; the body short and thick, and covered with coarse brown hair; the legs short; feet long, the forefoot divided into four toes, connected to each other by means of a small web at the base, and tipped with thick claws or rather hoofs at the extremities; the hind feet are formed in a similar manner, but are divided only into three toes. This animal sometimes, while feeding, sits up, in the manner of a squirrel, holding its food between its paws. It is said to commit considerable deviation in gardens during the night time, especially among the esculent vegetables.

Cavia Hudsonii of Klein, is the quadruped called Hystrix dorjuta, by Gmelin, Schreber, and other late authors.

Cavia capenosis of the twentieth edition of the Linnaean Sys. Nat. and of Pallas, is Hyrax capenosis of Gmelin, and Schreber.

Caviavana, in Geography, an island of the North Atlantic Ocean, under the equinoctial line, formed by the two mouths of the river Amazons, which surround it. W. long. 50° 30'.

Caviano, a town of Naples, in the province of Lavora; 7 miles N. of Naples.

Cavidos, or Cabidos, in Commerce, a Portuguese long measure, used in the measurement of cloth, linen, and the like; equivalent to two feet eleven inches, Paris measure.

Cavl, ca villatis, is defined by some a fallacious kind of reason, carrying some resemblance of truth, which a person, knowing its fallacy, advances in dispute for the sake of victory.

The art of framing sophisms or fallacies is called by Boe- thius, casselleo, or Casselleo, in Geography, a town of France, in the department of the Gard, and district of Uzes; 8 miles N.E. of Uzes.

Cavin, in Military Language, a hollow place or fort of ground fit for covering a body of troops or favouring the approaches to a place. Cavin near a place besieged are of great advantage.
advantage to the besiegers, as by means of them they can open the trenches nearer to it, construct places of arms, and station parties of cavalry for the protection of the workmen under cover from the fire of the place. A commandant or governor of a place, who attends to his duty and understands it properly, will know how to turn caunis to the disadvantage of the enemy, from the moment he perceives that the place he commands is menaced or in danger of being attacked.

CAVING. See Cavazion.

CAVINGS, in Agriculture, a term provincially applied to the rakings or coarc materials, as short straw, ears of grain, &c. collected from the corn in chaff, while thrashing.

CAVING CHAFF, the coarse chaffy draw or other similar material raked off from the grain after the operation of thrashing.

CAVING RAKE, the tool or implement employed in the above operation, and which is a sort of barn floor rake with a short head and teeth of considerable length.

CAVITA, in Geography, a port town of the island of Lacon, or Lucania, 3 leagues S. W. from Manila, the capital of the island. It was formerly a very considerable place; but as the great towns in the Philippine islands, as well as in Europe, have the small ones, there now remain in this place only the commandant of the arsenal, a contador or accountant, two port lieutenants, the commandant of the town, 150 soldiers in garrison, and the officers belonging to that corps. All the other inhabitants are metis (a species of mulattoes, half black, or the immediate offspring of a white man with a black woman), belonging to the mestizos, and form, together with their families, which are generally very numerous, a population of about 4,000 inhabitants divided between the town and the fuburb of St. Roch. There are two parishes, and three monasteries for men, each occupied by two ecclesiastics, though 30 might easily be accommodated. The Jesuits had formerly a very fine house, of which the trading company, established by the government, has obtained possession. In general, nothing is now seen here but ruins: the ancient edifices of stone are defaced, or occupied by Indians, who never repair them; and Cavita, the second town in the Philippine islands and capital of a province of the same name, is now only a paltry village, uninhabited by Spaniards, except the military officers, and those of the civil administration. In the port belonging to this town, the commandant has established an order and discipline which give it great reputation. La Perouse's Voyage, vol. i. p. 209, &c.

CAVITY, in Anatomy, is a term applied to several hollow spaces, lined by membranes and containing the different viscera of the body. As the extent of these cavities is bounded and defined by the membranes, which line them, and they have no external communication, they are frequently called the circumfered cavities of the body. These spaces are in every instance completely and accurately filled by the contained viscera; which generally have their surface covered by a reflected portion of the membrane which lines the cavity.

The surface of the viscera is in contact with that of the lining membrane, but is prevented from becoming actually adherent, by the secretion of a fluid from the exhalent arteries, by which the opposed surfaces are constantly prepared in a moist state. Hence it will be seen that the anatomical term cavity, in the sense which we have now mentioned, does not denote any void or empty space, and that it differs in that respect from the common acceptance of the term. The following cavities of this kind are found in the body: Cavity of the Abdomen; Pelvis; Pericardium; Thorax; and Tunica vaginalis testis; for a particular description of which the reader is referred to those articles—The various joints of the body present examples of similar cavities; they are lined, and circumfered by the capsular ligaments.

The word cavity is also frequently employed in oölology: where it is not only applied to larger and more circumfered spaces, as cavity of the cranium, cavity of the orbit, but also to the comparatively superficial impressions which contribute to the formation of joints, and which are denominated articular cavities of the bones. The same term is applied to the space included in any hollow part of the body: thus we have cavities of the heart, of the arteries and veins, of the stomach, intestines, &c. &c.

CAUK, or Cauk, formed probably of the German kaul, a spar, is used by miners in the Peak, to denote a coarse sort of spar; being a vitrified poudrous earth, or marmor metallicum, generally found near lead mines, which will draw a white line like chalk, or the galactites. Phil. Trans. vol. N° 119, p. 226. Phil. N° 39, p. 772. It is unalterable in acids, and fusible by fire. See Earth, ponderous. It is properly not a spar, but sparvary matter, rendered very coarse by being mixed with a large portion of earth. In some places it is found more clear and transparent than others: it approaches in this state to the nature of crystal, and is called bollard cauk, and bright cauk. Philos. Trans. vol. N° 47.

There is a singular process mentioned by Dr. Lister, which is that of vitrifying antimony by its means. This is done with great readiness and speed by it, and the glass, thus made, will produce some effect on other metals, which no other glass will, nor indeed any other preparation of antimony. The method of preparing it is this: take a pound of antimony, flux it clear; have ready a fine ounce or two of cauk in a lamp red hot; put it into the crucible to the melted antimony, and continue it in fusion: then call it into a clean mortar not greased, decanting the clear liquor from the lump of cauk. This process gives more than fifteen ounces of glafs of antimony, like polished steel, and bright as the moly refined quicksilver. The cauk, in the mean time, is found to be diminished. not increased in its weight, and will never flux with the antimony, though ever so strong fire be given it. This is a very odd mineral, and this learned author supposes it to be allied to those white, milky, and mineral juices which are found in mines. The effect of both is evidently the same; for the milky juice of lead mines vitrifies the whole body of antimony, in the same manner that the cauk does in this experiment. Phil. Trans. vol. N° 111.

That there is somewhat very peculiar in the cauk is plain from this effect on antimony, which no other thing of this kind is so peculiar of; for lapis calaminaris, flux with vivum, galactites, mundicia, alum ore, &c. and many other things, have been tried with antimony in the same manner, but not one of them has this effect.

CAUKING, in Architecture, signifies dove-tailing down. See Dove-tailing.

CAUKING TIME, in Falconry, a hawk's treading time. See Cauking.

CAUL, in Anatomy, is the part generally deprived under the term Osmentum. See Peritoneum.

CAUL, or Caul, among Mineralists, a reddish pink-coloured stone, found in the strata of the tin-mines. See Tin.

CAULCI, in Ancient Geography, a people of Germany placed by Strabo towards the ocean.

CAULEDON, from tavo, a gem, in Surgery, is applied to fractures which happen traumatically, wherein the parts of
the broken bone first attend, so as not to lie directly against each other.

CAULISCENT, in Botany, a term applied to such plants as have a stem.

CAULIAC, Gulde, or Guido de Cauliaco, in Biography, a celebrated author of the art of surgery, was born at a small town in the Cavalcuin, on the frontiers of the province of Aegypt in the early part of the fourteenth century. He studied medicine at Montpellier under Raymond de Malleres, and made such progress that he was early appointed teacher in surgery in that university. He was three years for Aegypt, and made phisiom to Pope Clement the Sixth. This was in the year 1348, at which time a dreadful pestilence brake out, which sundered every part of the then known world, and destroyed, it was thought, nearly a fourth part of its inhabitants. Under this prince, whose confidence he gained by his diligence and skill in the performance of his duty, he acquired considerable wealth; and with this wealth, such reputation for his abilities, that he was retained in the office of chief physician to the court, under Innocent the Sixth, and Urban the Fifth. It was during the pontificate of Urban, in the year 1443, that he composed or completed his "Magnus Chirurgiae," which gained him such reputation that Fallopius does not hesitate to compare him to Hippocrates. Cauliac not only restored the surgery that had been taught by the Greeks and by the Arabians, but, what Capulis did in anatomy, he improved what he found, and added considerably from his own flock. He first, Dough-faces taught that accidents over the eyebrows should be made longitudinally in the direction of the fibres of the muscles. He also described more accurately than had been done before, the lower end of the humerus, and the joint of the elbow. He revived the use of the trepan, and invented several instruments, of which he gave the figures; among them, a pair of forceps, to take up wounded arteries. His work may be considered, Haler says, as an abridgment of all that had been done on the subject of surgery before his time; it also contains the names and the practice of several writers on the art, whose works have perished, and who are not noticed by any other writer. His work, originally written in the Latin language, has been printed many times, and translated into all the modern languages. The first impression of it appeared at Venice, in the year 1497; in folio; an English translation of it was published in 1541. A copy of this edition was in the library of Sir Hans Sloane, now in the British Museum. Laurence Joubert published a translation of it into the French language, with explanatory notes and observations. At Lyon, in the year 1784, 4to. Haller Bib. Chirurg. Eluy. Dict. Hist.

CAULI, an appellation given to the juice drawn from the flaky of the flippers, contradistinguished from that drawn from the root of the same plant, which is called ribs.

Schrader makes the caulis the same with our asphodela.

CAULIC, in Ancient Geography, the name of a nation which inhabited the coast of the Ionian see. Steph. Byz.

CAULICOLES, CAULICULUS, in Architecture, denotes those eight lesser branches, or flanks, in the Corinthian capital, which spiring out from the four greater principal caulis, or flanks.

The word comes from the Latin caulis, the flank, or stem of a plant.

The volutes of this order are sustained by four caulis, or primary branches of leaves, from which arise their caulicles or lesser foliages.

Some authors confound the caulicles with the volutes themselves: some with the helices in the middle, and some with the principal flanks whence they arise.

CAULIFEROUS heres, are such as have a true calyx, flanks, or tubes, which a great many have not; as the capillaries, &c.

They are sometimes divided into caulifervis, and aculeis.

The former are either perfectly cauliforous, as cabbage; or imperfectly, as mullein.

CAULiflower, in Botany, See Brassica Clearea.

CAULIFLOWER, in Gardening, an excellent plant belonging to the genus Brassica. It is said to have been brought to this country from the island of Cyprus. By cultivation, this fine vegetable has lately been much improved in size, as well as in its other properties, and become common at our table during the greater part of the summer month, and even in the beginning of the autumn. See Brassica.

CAULUS, in Botany, a term applied to the leaver flanks, &c. of a plant when they proceed from the stem, in contradistinction to those which proceed from the root or branches.

Sp. 1. C. frugilis. Wild. Ann. Bot. vol. 2. tab. 1. fig. 2. (Napoli Lian. Sp. Pl. N. Minor. Alion. Peram. 2106. Schkuh. Bot. Lard. 2. tab. 256. Flavialis minor. Micheli gen. tab. 8. fig. 53.) "Leaves terete or opposite, linear and recurved, pricked, prickly-toothed, rigid." Roots diliform, quite simple, very long and perpendicular. Stem one to seven inches long, brancht from the base, diffusely spreading; branches dichotomous, smooth, compressed. Leaves as inch long or more, acute, proceeding from a round membranous flath/ teeth alternate, minute. Flowers axillary: ligulas one to three. The whole plant is very bushy. In so much that when fresh, the flalk and leaves will break to pieces if touched by the hand. Native of lakes and rivers in Italy, France, and Germany. 2. C. indica. Wild. Ann. Bot. tab. 2. "Leaves terete or opposite, linear and recurved, repand; younger ones bristle-toothed. Stem a foot and half or two feet long, spreading, round, hifiform, dichotomously brachiate. Leaves spreading, fraisht. Fowers axillary, fijllis; germ oblong; style bifid: ligulas tw: simple. It differs from the preceding species in being larger, flible, and not in the least brittle; its leaves are not recurved; when young, they have sharp, bristle-toothed teeth, which afterwards drop off, whence the full grown leaves become incanis at the border. A native of Transcaucass. 3. C. hispanic. Wild Ann. Bot. tab. 1. fig. 1. "Leaves in its, linear, toothed at the tip, spread." Stem a foot long, flame at extremities, branched, diliform, round. Branches all the doing quite towards the bottom. Fowers axillary fijllis; germ oblong; style bifid: ligulas tw: simple. A native of Persia. The whole plant in all the species is constantly immersed in water.
C A N I S

CAULIS, in Botany, a part of a plant which rises above the ground in a single stalk, and is common to annuals and perennials, though, as the vegetable botanist observes, in trees it has a peculiar name, and is called phragma, or trunk, in the common English sense of the word. The Latin writers seem to confine the term to the stem of herbaceous plants. According to Linnaeus, in his Philosophia Botanica, it is a species of trunk in its most extensive signification; denoting, in the language of the great Swedish botanist, the organ which multiplies the plant, or, in plantar language, that part in every plant which rises above the ground, and supports the parts of fructification, either with or without branches and leaves. See Trunk.

The caul is or item, in the Linnaean sense of the word, is the most common kind of trunk, that which supports some of the leaves, as well as the fructification; but Wildenow, in his Principles of Botany, confines the term to herbaceous plants, and considers the trunk as peculiar to trees and shrubs.

Stems are distinguished from each other as they are,

1. Simple, or proceed in a single unbroken form nearly to the summit of the plant. In this point of view they are either quite entire, i.e. without branches or nearly so, i.e. furnished with only a comparatively few branches, and those so small as not to destroy the integrity of the item. 2. Compound; to subdivided as nearly as to lose the appearance of a item. 3. Dichotomous; always divided into pairs as in vienam albulum, melolotus, valeriaca loculca, corn falled, &c. 4. Flexure, or bending in a zigzag manner, so as to form a number of alternate curves or very obtuse angles. 4. Climbing, (conclavia) too weak to support itself, and therefore lacking support from other bodies. 5. Twining, (vulgibus) ascending in a spiral direction round the item or branches of another plant, or any kind of foreign prop. In some plants, as in humulus, helix, lobeca, and tainus, the direction is from left to right, i.e. according to the course of the sun as seen by a spectator in our hemisphere with his face to the south; in others, as convolvulus, phascelus, &c. from right to left, or opposite to the course of the sun. 6. Erect; nearly perpendicular. 7. Noding; with the upper part bent outwards towards the horizon. 8. Incurved; with the upper part bent inwards. 9. Declining; bent downwards so as to form an arch. 10. Aftending; growing firft in an horizontal direction, and afterwards curving upwards. 11. Procurvunt; feeble and retting on the ground. 12. December; upright near the root, but afterwards bent down, fo that the greatest part of it is pro- cumbent. 13. Creeping, (repens); running along the ground, and here and there throwing out roots. 14. Serrantius; biflorus, almof. nakc2; or having leaves in bunches only at joints or knot, where it strikes root. 15. Rooting, (radicans); throwing out lateral radicles, by which it attaches itself to other plants for sustenance or support; as in cefulea, and hecera helix. 16. Paraffaria; growing entirely on other plants, as vicem, epidendrum, tillaedrina. 17. Articulated; having joints at certain distances. 18. Anasty, (nodulos); swollen at the joints. 19. Glandulatus; jointed, bending at the joints somewhat in the manner of the human knee. 20. Rund, (teres); cylindrical, without angles. 21. Half round, (fenitores); round on one side, and flat on the other. 22. Comprefled; having two opposite flat sides. 23. Aprialect; two-angled, compressed with sharp edges. 24. Angular; having more than two angles separated by angular or curved hollow spaces. 25. Trigemotus, &c. three-faced, &c. having the spaces between the angles perfectly flat. 26. Trigonous, &c. having the spaces between the angles convex. Linnaeus is by no means clear in his definitions of the last three terms, and is differently understood by different authors. Who have endeavoured to convert ours fo as to convey different and precise ideas; premising however, that an attention to the etymology of the words is more likely to confound than to enlighten, but for this we are not answerable.

CAULKING, CAURING, or CAURING, in Ship Building, the operation of driving a quantity of oakum, or old ropes untwisted and drawn afunder, into the seams of the planks; or into the intervals where the planks are joined to each other in the sides or decks of the ship, in order to prevent the entrance of water. After the oakum is driven very hard into these seams, it is covered with hot melted pitch or resin, to keep the water from rotting it. The firft among the ancients, who made use of pitch in caulking, were the inhabitants of Phenicia, afterwards called Corica. Wax and resin appear to have been commonly used previous to that period; and the Polis, at this time, use a sort of unctuous clay for the fame purpoze. Kennet derives the word from the barbarous Latin calcutta, a foot.

Caulking Irons, are iron chittels for driving the oakum into the seams. Some of these irons are broad, some round, and others grooved.

CAULNE, in Geography, a town of France, in the department of the North Coaals, and district of Dinans; 32 leagues S.W. of Dinans.

CAULON, CAULONIA, or VALLONIA, in Ancient Geography, a small town of Italy, situate on the cael cafl of Bruttium, N. of Locri, and S.W. of the promontory Co- centum. It was founded by a colony of Achaean, and for a time made a part of the territory of the Locrians Epiphysiane. This city was demolished, and its inhabitants transported into Sicily by Dionysius the tyrant about 400 years B.C. Ovid and Virgil mention it; but it did not subsist in the time of Ptolemy.

CAUM, a place of Spain, marked, in the Itinerary of Antonine, between Olca and Mercedeia.

CAUMAN, one of the branches of the river Ineis, near its mouth, according to Arrius.

CAUMONT, in Geography, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Bayeux; 4 leagues S.S.W. of Bayeux. The place contains 2171, and the Canton 1896 inhabitants: the territory comprehends 755 kilometres and 8 communes.

CAUNE, a town of France, and principal place of a district in the department of the Tarn; 3 leagues E.N.E. of Caures. The place contains 2488, and the canton 7351 inhabitants: the territory comprehends 285 kilometres and 8 communes.

CAUNES, Les, a town of France, in the department of Aude, and district of Carcassonne; 7 leagues W.N.W. of Narbonne, and 33 N.E. of Carcassonne.

CAUNENUS, in Ancient Geography, a son of Aia Mi- nor, in Lycaia.
CAUNGA, in Botany, Rhed. Mal. See Areca Cane.

CAUNGALASS-POINT, in Geography, a cape on the southern coast of Dingle bay, county of Kerry, Ireland. N. lat. 51° 58'. W. long. 10° 8'.

CAUNI, in Ancient Geography, a people of Mauritania, according to Ptolemy.

CAUNIA, the inhabitants of Caunia.

CAUNSRA-HEAD, in Geography, a cape of the county of Kerry, Ireland. N. lat. 52° 5' 30'. W. long. 10° 16'.

CAUNUS, a Sphinx in Entomology, a variety of the Fabrician Sphinx Audromachus, described by Cramer under this name.

CAUNS, in Ancient Geography, Montauis, a mountain of Spain, placed by Livi in Celtiberia. —Allo, a town in the island of Crete. Steph. Byz. —Allo, a town of Aiolia. —Allo, a town of Aisia Minor. in Ionia. —Allo, a town of Caria, on the southern side of the Dorile, called "Rhodos" or of the Rhodes. It was situated at the foot of mount Tarbelus, W. of the small Gulf of Glaucon. The account is proverbially fabulous in summer and autumn, on account of the extreme heat, and the evil was increased by the abundance of its fruits. Steph. Byz. says, that this city took its name from Caunus, known in fabulous history for his inceletious love of his litter Bibilis; whence the proverb denoting this sort of attachment, viz. a coaus, i.e.; Caunus Amor. This city was the native place of the celebrated painter Protegenes. The citadel, according to Strabo, was above the town, and called "Imbroi." It has been conjectured that the ancient Caunus has been occupied by the town now called Kajnez.

CAUHPICA, a town of Peribia, in the interior of the country, according to Ptolemy.

CAURARELE, Bistaur, and CAURALL SNAPE, of Latham, in Ornithology. See Areca Heias of Pallas and Gmelin.

CAURANANI, in Ancient Geography, a people of Arabia Felix, whose name denotes their wealth in cattle, according to Pliny.

CAURASTLE, a people of Spain, in Botica.

C. AUREUM, in Entomology, a species of Papilio, the wings of which are indented, tailed, fulvous with black spots; posterior pair marked beneath with a golden C. Fabricius. This insect inhabits Aha.

CAURIENSES, in Ancient Geography, a people of Spain in Lusitania, according to Pliny, who inhabited the town called by Ptolemy Caunium, which M. d'Anville places in the country of the Vettovenses, N.E. of Norba Cæzarea.

CAURIS, in Botany, a name by which certain authors formerly distinguished shells of the Cyprea genus. The word cauris is of Indian origin, being the name by which the small maccy-couris are known among the natives of the West Indian islands. It is from a false pronunciation of the word couris, that these shells are now called couries or gouries. See Cyprea.

CAURO, in Geography, a town of the island of Corfu, or the department of Golo; 9 miles E.S.E. of Ajazzo.

CAURROY, Francis Eustache du, in Biography, an eminent French musician, was born in 1549; and became master of the chapel to the kings Charles IX. Henry III. and IV., and also canon of the holy chapel in Paris, and prior of St. Auloi. By his contemporaries he was named the prince of musicians; and he was much beloved by cardinal du Perron, who frequently wrote verses for him to set to music, and composed a pourous epitaph for his tomb. He died in 1589, and was buried in the church of the Grands Augustins at Paris. Of his works, which seem never to have been known out of France, there remain a "Neffe for the Dead," for four voices, which used to be sung annually in the cathedral of Paris, on the commemoration of the faithful deceased; and a book called "Mélanges de la Musique de Lutetiae du Cauroy," Paris, 1616. This last is said to have been the origin of most of the Christmas carols sung in France. The merits of this composer will appear to a modern musical critic to have been much over-rated. Burney's Hist. of Music, vol. iii.

CAURSINES, Caursini, in English History, denote Italian bankers or money-changers, who flocked into England, France, and the Netherlands, about the year 1335, calling themselves the pope's merchants, but, by departing from the proper business of merchants, and becoming agents for the pope in his various transactions, they rendered themselves as odious as the Jews. According to Matthew Paris, a contemporary historian, they sometimes exacted no less than 60 per cent. interest per annum. This, together with their ostentations display of their riches, drew upon them a very severe proscription. They were several times banished the kingdom for their extortion, and re-admitted by the intered and intrigues of the popes. Mat. Paris, Hist. Ang. p. 272. Du-Cange.

They are also called caurini, caurcini, catarini, catarucini, and corsesi. Some will have the name formed from Caurs, Cahors, a city of France, where they flourished more than ordinarily. Others derive it from the Corsini, a family of wealthy merchants at Florence.

CAUS, in Ancient Geography, a village of Pellonnesus, in Arcadia, and in the country of Telephusia. According to Steph. Byz. and Pasianus, Eulalius was worshipped here under the appellation of "Causian.

CAUSA Matriumini praebuit, in Law, a writ that lies when a woman gives land to a man in fee, or for life, to the intent he shall marry her, and he refuses to do it in a reasonable time; and in such case for not performing the condition, the entry of the woman into the lands again has been adjudged lawful. The husband and wife may sue this writ against another, who ought to have married her.

CAUSA Nobis significates, a writ directed to the mayor of a town, &c. who being by the king's writ commanded to make seif of lands to the king's grantees, delays doing it. The writ requires him to show cause of the delay.

CAUSALITY, or Causation, in Metaphysics, the power or action of a cause in producing its effect.

It is a dispute among the school-philosophers, whether, and how the causality is distinguished from the cause and effect? Some held it a mode, or modal entity, superadded to the cause, &c. others contend for its being a cause itself, only considered primumvate and terminare, &c. See Cause.

CAUSALITY, in Metallurgy. See Casuality.

In the tin-works the causality is thrown in heaps upon banks, which in six or seven years they work over again, and receive a new supply of metal from it. Phil. Trans. No. 158, p. 352.

CAUSE, Causa, which contributes to the production of an effect; or that by virtue whereof a thing is done, or from which it proceeds.—In which sense, cause islands essentially related to effect.

In every part of natural philosophy, it is assumed as a fundamental principle or axiom, that no event or change comes to pass merely of itself, that is, without relation to any thing else; but that every change itself related to, and implies the existence and influence of something else, in consequence of which such change came to pass, and which may be regarded as the principle, beginning, or source of the change.
CAUSE.

chance referred to it. Accordingly, the term cause is usually employed to denote the supposed principle of change; and the term effect is applied to the change considered in its relation to the principle of change whence it proceeded; for it must be observed, that both these terms, as commonly used, are relative. The axiom or principle, to which we have above referred, is usually thus expressed; 

"For every effect there must be a cause."— Nothing exists, or nothing comes to pass, without a cause!—Nihii turpius philosopho quam mete line causa quotidem dicit.

This principle, which is the foundation of natural philosophy, has been regarded both as a physical and as a metaphysical axiom; that is, as expressing an important general fact with respect to the material world; metaphysical, as expressing a corresponding law of human thought, or something which all men of competent judgment think, and cannot help thinking. This axiom, however, though it must be admitted as unquestionably true, has not precluded a difference of opinion with regard to the meaning of the term cause, and the relation conceived to subsist between cause and effect. Mr. Hume is represented by Dr. Reid, as the first author, who maintained (ubi infra), that we have no other notion of a cause, but that it is something prior to the effect which has been found by experience to be constantly followed by the effect; but it will appear in the sequel of this article, that a similar opinion, at least with regard to physical causes and effects, has been maintained long before, as well as after his time. Accordingly, his theory regarded events as simply conjoined, and not connected together by any conceivable process, nor produced the one from the other by any operative principle. As all our reasonings concerning matter of fact seem to be founded on the relation of "cause and effect," it is of importance to investigate, and, if possible, to ascertain this relation. Mr. Hume affirms, as a general proposition, admitting of no exception, that the knowledge of this relation is not, in any instance, attained by reasonings a priori; but arises entirely from experience, when we find, that any particular objects are constantly conjoined with each other. Let an object, says this acute writer, be presented to a man of ever so strong natural reason and abilities; if that object be entirely new to him, he will not be able, by the most accurate examination of its sensible qualities, to discover any of its causes or effects; or, he says, can our reason, unaided by experience, ever draw any inference concerning real existence and matter of fact. This proposition, he alleges, will readily be admitted with regard to such objects, as we remember to have been once altogether unknown to us; since we must be conscious of the utter inability, which we then lay under of foretelling what would arise from them. Such events as bear little analogy to the common course of nature, and are also readily confounded to be known only by experience. The cause is, when an effect is supposed to depend upon an intricate machinery, or secret structure of parts, for we then do not hesitate in attributing all our knowledge of it to experience. But the same truth may not appear to have the same evidence, with regard to events which have become familiar to us from our first appearance in the world, which bear a close analogy to the whole course of nature, and which are supposed to depend on the simple qualities of objects without any secret structure of parts. Such effects we are apt to imagine that we may be able to discover by the mere operation of our reason, without experience. But, in order to convince us that all the laws of nature, and all the operations of bodies, without exception, are known only by experience, Mr. Hume suggests a variety of reflections. The mind, he says, can never possibly find the effect in the supposed cause, by the most accurate scrutiny; for the effect is totally different from the cause, and consequently can never be discovered by it. And as the first imagination or invention of a particular effect, in all natural operations, is arbitrary, where we do not consult experience; so must we also esteem the supposed vice or connection between the cause and effect, which binds them together, and renders it impossible, that any other effect could result from the operation of that cause. Moreover, after we have experience of the operations of cause and effect, our conclusions from that experience are not founded on reasoning, or any process of the understanding. For the author's illustration of this remark, and the evidence adduced in support of it, we must refer to his own reasonings ubi infra. Experience, says Dr. Brown, can inform us only of the past. But the relation of cause and effect has reference to future and invariable antecedence and sequence, of which our experience can inform us. We believe it, indeed, irresistibly; and the belief is not denied; it is only the attempt to found the belief on reason which this proposition opposes. He who affirms, that A will always be followed by B, affirms, more than he who affirms, that A has always been followed by B; and it is this addition which forms the very essence of the relation of cause and effect. Neither of the propositions includes the other; and, as they have no agreement, reason, which is the sense of agreement, cannot be applied to them. Till it be shewn, that the future is involved in the past, we must allow the truth of Mr. Hume's second proposition, that even after experience, the relation of cause and effect cannot be discovered by reason. Mr. Hume advances, in the course of his reasoning on this subject, a third proposition, which is, that the relation of cause and effect is an object of belief alone; and this, it has been said, must be admitted, if the two former propositions be received. This belief, not the result of reason, is derived from our nature, and, in its operation, is as certain and powerful as if it were an inference established by a reasoning process. As soon as we believe the relation of cause and effect, the idea of power arises; which idea confutes not in the antecedence of one event to another, which has been uniform in all preceding cases, but in the uniform and invariable antecedence that shall take place in all future cases.

A cause, says Dr. Priestley, a late zealous advocate for the doctrine of necessity, cannot be defined to be any thing but "such previous circumstances as are constantly followed by a certain effect;" the constancy of the result making us conclude, that there must be a sufficient reason in the nature of things, why it should be produced in those circumstances.

Another ingenious writer (professor Dugald Stewart) who seems to have adopted Hume's general theory with regard to causation, as it respects physical causes, observes, as a fact pretty generally admitted among philosophers, that there is no influence in which we are able to perceive a necessary connexion between two successive events; or to comprehend in what manner the one proceeds from the other. From experience, indeed, we learn that there are many events, which are constantly conjoined, so that the one invariably follows the other; but it is possible, for any thing we know to the contrary, that this connexion, though a constant one, as far as our observation has reached, may not be a necessary connexion; may, it is possible, that there may be no necessary connexions among any of the phenomena we see; and if there are any such connexions existing, we may rest assured that we shall never be able to discover them. This author remarks that the word cause is used, both by philosophers and the vulgar, in two senses that are widely different. When it is said, that every change in nature indicates the operation of a cause,
cause, the word cause expresses something which is supposed to be necessarily connected with the change; and without which it could not have happened. This may be called the metaphysical meaning of the word; and such causes may be called metaphysical or efficient causes. In natural philosophy, however, when we speak of one thing being the cause of another, all that we mean is, that the two are constantly conjoined; so that when we see the one, we may expect the other; these conjunctions we learn from experience alone; and without an acquaintance with them, we could not accommodate our conduct to the established course of nature. The causes, which are the objects of our investigation in natural philosophy, may, for the sake of distinction, be called physical causes. This doctrine, says this ingenious writer, concerning the object of natural philosophy, is not altogether agreeable to popular prejudices. It is a curious question, what gives rise to prejudices of this kind? In laying the argument for the existence of the duty, several modern philosophers have been at pains to illustrate that law of our nature, which leads us to refer every change we perceive in the universe to the operation of an efficient cause. This reference is not the result of reasoning, but necessarily accompanies the perception, so as to render it impossible for us to see the change, without feeling a conviction of the operation of some cause by which it was produced; much in the same manner in which we find it to be impossible to conceive a sensation, without being impressed with a belief of the existence of a sentient being. Hence it is, as professor Stewart conceives, that we find two events constantly conjoined, we are led to associate the idea of causing, or efficiency, with the former, and to refer it to that power or energy by which the change was produced; in consequence of which association, we are led to consider philosophy as the knowledge of efficient causes; and lose sight of the operation of the mind, in producing the phenomena of nature. By an association somewhat similar, we connect our sensations of colour with the primary qualities of bodies. In the same way we associate with inanimate matter the ideas of power, force, energy, and causation; which are all attributes of mind, and can exist in a mind only. Our language also, with respect to cause and effect, is borrowed by analogy from material objects; and hence we transfer to certain events the same language which we apply to connected objects. Thus, we speak of a connection between two events, and of a chain of causes and effects. This language is purely analogical, and our knowledge of physical events is restricted to the laws which regulate this succession; and yet it has misled the greater part of philosophers, and has had a surprising influence on the systems, which they have formed in various different departments of science. The maxim that nothing can act, but where it is and when it is, has been always admitted with respect to metaphysical or efficient causes. Whatever objects, says Mr. Hume, are considered as causes or effects, are contiguous; and nothing can operate in a time or place which is ever so little removed from those of its existence; we may therefore, he adds, consider the relation of contiguity as essential to that of causation. But admitting this maxim in relation to causes which are efficient, and which as such are necessarily connected with the effects, there is surely no good reason, professor Stewart conceives, for extending it to physical causes, of which we know nothing, but that they are the constant forerunners and signs of certain natural events. According to this doctrine, indeed, it may be improper to retain the expressions cause or effect, in natural philosophy; but as long as the present language upon the subject continues in use, the propriety of its application, in any particular instance, does not depend on the contiguity of the two events in place or time, but solely on this question, whether the one event be the constant and invariable forerunner of the other, so that it may be considered as its invariable sign. Notwithstanding, however, the evidence of this conclusion, philosophers have in general proceeded upon a contrary supposition; and have discovered an unwillingness, even in physics, to call one event the cause of another, if the shortest interval of space or time existed between them. In the case of motion, communicated by impulse, they have no scruple to call the impulse the cause of the motion; but they will not admit that one body can be the cause of motion in another, placed at a distance from it, unless a connection is carried on between them, by means of some intervening medium.

Mr. Hume's theory on the subject of causation, and the relation between cause and effect, has occasioned alarm, and excited an application that it fapped the foundation of those arguments and principles of reason, by which the existence and supposition of a Deity are illustrated and established. Hence his truth has been disputed and denied; and without considering that the fallacy of the system does not confound in his premises, but in the conclusion which he draws from them, it has been represented as favourable to infidelity, but it ought to be recolected, that the principle which has been frequently ascribed to Mr. Hume as his author, by both his followers and his opponents, or that of restricting the physical inquirer from tracing necessary connections or ascertaining the efficient causes of phenomena, is of much earlier date, and has been maintained by many of the most enlightened and the most sceptical of our modern philosophers; nor does its dangerous tendency seem to have been subjected till the publication of Mr. Hume's writings, and the great misapplication which he made of his premises for invalidating the argument for the existence of the Deity derived from his works. An opinion coinciding remarkably with that advanced and defended by Mr. Hume is ascribed to Socrates by Xenophon. The sophists in ancient Greece, like their successors in modern times, appear to have entertained some confused notions about a necessary connection between cause and effect, implying the existence of an operating principle in the cause; they required, says Xenophon, "ΤΑΙΝΑΝΑΙΑΝΤΑΙ ΕΙΔΗΝΕΙΕΝΤΕΝ." The same excellent writer informs us in what light Socrates regarded these things by whom such notions were adopted. "ΑΝΑ ΚΑΙ ΤΟΥΣ ΦΡΟΝΙΖΟΝΤΑΣ ΤΑ ΤΟΥΓΑΤΙΑ ΜΟΡΦΑΝΟΝΤΑΣ ΕΙΔΗΝΕΙΕΝΤΕΝ." Afterwards he adds, "ΕΙδομενος η τη μν ΦΑΓΙΤΩΣ ΕΙΔΗ, ότα να αντικ Και στου γενετο άναρητοι υπέρων." "If we except," says Dr. Barrow (Mathematical Lectures read at Cambridge), "the mutual causality and dependence of the terms of a mathematical demonstration, I do not think there is any other causality in the nature of things, wherein a necessary consequence can be founded. Logicians do indeed boast of I do not know what kind of demonstrations from external cause, either efficient or final; but without being able to shew one genuine example of any such: may, I imagine, it is impossible for them to do. For there can be no such connexion of an external efficient cause with its effect, (or at least none such can be understood by us) "through which, strictly speaking, the effect is necessarily supphed by the supposition of the efficient cause, or any determinate cause by the supposition of the effect." Heads afterwards, "therefore there can be no argumentation from an efficient cause to the effect, or from an effect to the cause which is lawfully necessary."

"All things," says Dr. Clarke (Works, vol. ii. p. 698, fol. ed.) "that are done in the world, are done either immediately by God himself, or by created intelligent beings; matter being evidently not at all capable of any laws or powers whatsoever, any more than it is capable of intelligence;"
CAUSE.

gence; excepting only this one negative power, that every part of it will, of itself, always and necessarily continue in that state, whether of rest or motion, wherein it is at present. So that all those things which we commonly say are the effects of the natural powers of matter and laws of motion, of gravitation, attraction, or the like, are indeed (if we will speak distinctly and properly) the effects of God's acting upon matter continually, and every moment, either immediately by himself, or mediate by some created intelligent beings. Consequently there is such a thing as what men commonly call the course of nature, or the powers of nature. The course of nature, truly and properly speaking, is nothing else but the will of God producing certain effects in a continued, regular, continual, and uniform manner.

Dr. Butler also, in his Discourse on the ignorance of Man (Sermons) has remarked, "that it is in general no more than effects that the most knowing are acquainted with; for as to causes they are as entirely in the dark as the most ignorant." "What are the laws," he continues, "by which matter acts on matter, but certain effects, which home, having obversed to be frequently repeated, have reduced to general rules?" "The laws of attraction and repellion," says Dr. Berkeley (Siris, p. 128.) "are to be regarded as laws of motion, and these only as rules or methods observed in the productions of natural effects, the efficient and final causes whereof are not of mechanical consideration." Certainly, if the explaining a phenomenon be to assign its proper efficient, final cause, it should seem the mechanical philosophers never explained any thing; their province being only to discover the laws of nature, that is, the general rules and methods of motion; and to account for particular phenomena, by reducing them under, or showing their conformity to such general rules."—With more to the same purpose. Professor Stewart has also cited a very remarkable passage from Mr. Locke (Ess. b. ii. c. 23. § 28, 29.), which shews clearly, that this eminent philosopher considered the connection between impulse and motion as a conjunction which we learn from experience only, and not as a consequence deducible from the consideration of impulse, by any reasoning à priori. The passage is the more curious, because it is particular application of Mr. Hume's doctrine, that has been generally supposed to furnish the strongest objection against it. Some of Mr. Hume's reasons concerning the nature of the connections among physical events coincide perfectly with those of Malebranche on the same subject; though they were employed by the last writer to support a very different conclusion.

The author of the "Procedure, Extent, and Limits of Human Understanding," (said to be Dr. Peter Brown, bishop of Cork), says it down as the first fundamental unerring rule in physics, that it is not within the compass of human understanding to assign a purely speculative reason for any one phenomenon in nature. By a purely speculative reason, the writer means, such as does not consist of any such cause as is possible by nature. "We find," indeed, he adds, "by observation and experience, that such and such effects are produced; but when we attempt to think of the reason why and the manner how the causes work those effects, then we are at a stand, and all our reasoning is precarious, or at best but probable conjecture."

At a still earlier period, Hobbes expressed himself (see his Tripos), with respect to physical connections, in terms so nearly approaching to Mr. Hume's, that it is difficult to suppose that they did not suggest to him the language which he has employed on that subject. "What we can experience," he remarks, "is nothing else but remembrance of what antecedents have been followed by what consequents." "No man," he continues, "can have in his mind a conception of the future; for the future is not yet; but of our conceptions of the past we make a future, or rather call past future, relatively," &c. &c. Lord Bacon also hath piously taken for granted the doctrine now under consideration, without formally flating it, in all his reasonings on the method of procuring philosophical discoveries; for if we could perceive in any instance the manner in which a cause produces its effect, we should be able to deduce the effect from its cause by reasoning à priori; the impossibility of which he every where strongly insinuates. "Homo naturæ minime intelligit et intellectu quantum de natura ordinem vel mente observaverit; nec amplius satis aut potissim. However, lord Bacon's metaphysical notions on this subject do not stem from other passages in his writings to have been very accurate.

The consistency of Mr. Hume's fundamental principle, independently of his application of it, with the most devout impressions concerning the existence and the power of God, is sufficiently evinced by the testimonies of the excellent writers already cited. If it be alleged, that the passages above quoted are furnislhed by authors prior to Mr. Hume, and who were not fully aware of the consequences which he afterwards deduced from them; the following authorities are collected from philosophers and divines of a later date.

"What we observe by our external senses," says Dr. Price (Review of the principal Questions and Difficulties in 'Morals'), "is properly no more than that one thing follows another, or the constant conjunction of certain events, so of the melting of wax, with placing it in the flame of a candle; and, in general, of such and such alterations in the qualities of bodies, with such and such circumstances of their situation. That one thing is the cause of another, of produces it by its own efficacy and operation, we never see."

"With regard to the phenomena of nature," says Dr. Reid (ubi infra), "the important end of knowing their causes, besides gratifying our curiosity, is, that we may know when to expect them, or how to bring them about. This is often of real importance in life; and this purpose is served by knowing what by the course of nature goes before them, and is connected with them; and this, therefore, we call the cause of such a phenomenon." See the sequel of this article.
The language of Mr. Hume, as professor Stewart observes, has even been adopted by philosophers, and by aesthetists as well as theists. The latter have represented natural events as parts of a great chain, the highest link of which is supported by the Deity. The former have pretended, that there is no absurdity in supposing the number of links to be infinite. Mr. Hume, the professor adds, had the merit of shewing clearly to philos. phers, that our common language, with respect to cause and effect, is merely analogical; and that if there be any links among physical events, they must for ever remain invisible to us. It is this part of his system be admitted, and if, at the same time, we admit the authority of that principle of the mind, which leads us to refer every change to an efficient cause; Mr. Hume's doctrine seems to be more favourable to theism than even the common notions upon this subject; as it keeps the Deity always in view, not only as the first, but as the constantly operating cause in nature, and as the great connecting principle among all the various phenomena which we observe; this, according to, was the conclusion which Malbranche deduced from principles very nearly the same with Mr. Hume's. That a necessary connection has been supposed to exist, among physical events by many philosophers, whom it would be unfair to charge with atheism, is a fact that must be allowed. It was the doctrine of the ancient fatalists, that all things above and below are linked together by an inevitable necessity, but they did not, therefore, deny the existence of God, as the "Cum fatum (says Seneca) nihil addit et quam fere implica conftarum, sic et prima omnium caufa ex quae eft extort pendens." 

"While we condemn, therefore, the conclusion of Mr. Hume (so far as it has a tendency to weaken the evidence for the existence of the Deity) as sophistical and false, we are constrained," says professor Stewart, "not by that justice which is due to his philosophical abilities, but by our fidelity to the cause for which we profess to combat, not to involve both conclusions and premises in the same condemnation."

Having stated Mr. Hume's theory of causation, and presented to the view of the reader some of those arguments and authorities which have been urged by his advocates, in order to vindicate it from those licentious conceptions with which it has been charged; we shall now give as concise an account as possible of the sentiments of those who have differed from him with regard to this subject. To the chief of such persons we may refer Dr. Reid, whose opinions and reasoning claim peculiar attention, and merit the distinct examination. They will probably be no less satisfactory to many of the readers of this article, than to the compiler of it. Every thing that begins to exist, says this excellent writer, must have a cause of its existence, which had power to give it existence; and every thing that undergoes any change, must have some cause of that change. This principle appears very early in the mind of man; and it is so universal and so firmly rooted in human nature, that the most determined scepticism cannot eradicate it. From this principle it follows, that every thing which undergoes any change, must either be the efficient cause of that change in itself, or it must be changed by some other being. In the first case it is said to have active power; and to all in producing that change. In the second case it is merely passive, or is acted upon; and the active power is in that being only which produces the change. The name of a cause, and of an agent, is properly given to that being only, which, by its active power, produces some change in itself, or in some other being. The change, whether it be of thought, of will, or of motion, is the effect. Active power, therefore, is a quality in the cause, which enables it to produce the effect; and the exertion of that active power in producing the effect, is called action, agency, efficiency. In order to the production of any effect, there must be in the cause not only power, but the exertion of that power: for power that is not exerted produces no effect. With regard to the opinion of Mr. Hume and his followers, who maintain, that a cause is only something prior to the effect, and constantly conjunct with it, Dr. Reid observes, that every man who understands the language knows, that neither priority, nor constant conjunction, nor both together, imply efficiency. Every man free from prejudice must assent to what Cicero has said: "Itaque non hic causa intelligi debet, ut qui cum quaeque antecedat, id et caufa fit, sed quaeque consequit antecedit." In common language we say, the sun rises and sets, and comes to the meridian, the moon changes, the大火 ebbs and flows, and the winds blow; and as languages were formed by persons who believed these objects to have life and active power in themselves, it was proper and natural to express their motions and changes by active verbs.

Our knowledge of the real causes of the phenomena of nature is very imperfect; but though our acquaintance with external objects must be grounded upon the information of our senses; yet causation and active power are not objects of sense, nor is it always the cause of a phenomenon which is prior to it, and constantly conjunct with it: otherwise night would be the cause of day, and day the cause of the following night. It is to this day problematical, whether all the phenomena of the material system be produced by the immediate operation of the first cause, according to the laws which his will determined, or whether subordinate causes are employed by him in the operations of nature; and if they be, what their nature, their number, and their different offices are? And whether, in all cases, they act by compulsion, or, in some, according to their disposition? In consequence of this imperfect knowledge of the real causes of the phenomena of nature, ingenious men who have been desirous of exploring and ascertaining them, have formed numberless conjectures and theories; and unwilling to confine their disappointment in the search of causes, they have vainly conceived every thing they stumbled upon to be a cause; and the proper notion of a cause is thus lost, by giving the name to numberless things which neither are nor can be causes. In a very ancient system, love and desire were made the causes of things; in the Pythagorean and Platonist system, matter, ideas, and an intelligent mind; by Aristotle, matter, form, and privation; Dr. Cartes thought that matter, and a certain quantity of motion given at first by the Almighty, are sufficient to account for all the phenomena of the natural world. Leibnitz conceived that the universe is made up of minds, active and percipient, which, by their active power received at first, produce all the changes they undergo. In the ordinary concerns of life this confusion of various things under the names of causes is of little moment and influence; although it may be very hurtful to found philosophy. A constant antecedent or concomitant of the phenomenon whose cause is sought, may answer the purpose of the inquirer, as well as if the real cause were known. In compliance with custom, says Dr. Reid, or perhaps to gratify the avidity of knowing the causes of things, we call the laws of nature causes and active powers. Thus we speak of the powers of gravitation, of magnetism, and of electricity. But persons of juster discernment perceive, that the laws of nature are not agents; they are not endowed with active power, and therefore cannot be the proper causes of events. They are only the rules according to which the unknown cause acts: hence it happens that the word cause, and other words bearing relation to it, become so ambiguous as to have, in a manner, lost their proper and original meaning; and yet,
CAUSE.

Yet we have no other words to express it. Every thing joined with the effect, and prior to it, is called its cause. An instrument, an occasion, a reason, a motive, an end, are called causes; and the related words, effect, agent, power, are extended in the same vague manner. Were it not, continue this ingenious writer, that the terms cause and agent have lost their proper meaning in the crowd of meanings that have been given them, we should immediately perceive a contradiction in the terms necessary cause and necessary agent.

If this necessity, thus combined with cause and agent, be attributed even to the Deity, it must follow, that there neither is, nor can be, a cause at all; that nothing acts, but every thing is acted upon; nothing moves, but every thing is moved; all is passion without action; all instrument without an agent; and that every thing that is, or was, or shall be, has that necessary existence in its seconf', which we commonly consider as the prerogative of the first cause. If it be evident, says Dr. Reid, that what begins to exist must have an efficient cause which had power to give or not to give it existence; and if it be true that effects well and widely fitted for the best purposes, demonstrate intelligence, wisdom, and goodness, in the efficient cause, as well as power, the proof of a Deity from these principles is very easy and obvious to all men that can reason. If, on the other hand, our belief, that every thing that begins to exist has a cause, be not only by experience; and if, as Mr. Hume maintains, the only notion of a cause be something prior to the effect, which experience has shown to be constantly joined with such an effect, I see not how from these principles, it is possible to prove the existence of an intelligent cause of the universe. Accordingly, Mr. Hume seems to reason jolly from his definition of a cause, when, in the person of an Epicurean, he maintains, that with regard to a cause of the universe, we can conclude nothing; because it is a fingular effect. We have no experience that such effects are always joined with such a cause. Nay, the cause which we assign to this effect, is a cause which no man hath seen nor can see; and therefore experience cannot inform us that it has ever been joined with any effect. Mr. Hume, according to Dr. Reid, seems to deduce a just inference from his definition of a cause, when he alleges that any thing may be the cause of any thing; since priority and constant conjunction are all that can be conceived in the notion of a cause.

The following consequences are stated by Dr. Reid, as deducible from Mr. Hume's definition of a cause. It follows, he says, that night is the cause of day, and day the cause of night; for no two things have more constantly followed each other since the beginning of the world. It follows also, friendly, that, for what we know, any thing may be the cause of any thing, since nothing is essential to a cause but its being constantly followed by the effect. What is unintelligible may be the cause of what is intelligible; folly may be the cause of wisdom, and evil of good; and all reasoning from the nature of the effect to the nature of the cause, and all reasoning from final causes, must be given up as fallacious. A third consequence from this definition is, that we have no reason to conclude, that every event must have a cause; for innumerable events happen, when it cannot be flown that there were certain previous circumstances that have constantly been followed by such an event. And though it were certain, that every event actually observed by us had a cause, it would not follow, that every event must have a cause; for it is contrary to the rules of logic to conclude, that because a thing always has been, therefore it must be; to reason from what is contingent to what is necessary. Fourthly, it would follow, that we have no reason to conclude that there was any cause of the creation of this world; for there were no previous circumstances that had been constantly followed by such an effect. And, for the same reason, it would follow from the definition that whatever was fingular in its nature, or the fult thing of its kind, could have no cause.

Having shown what he conceives to be the absurd and dangerous consequences that follow from Mr. Hume's definition of a cause, Dr. Reid proposes another not chargeable with such consequences. "Why," says he, "may not an efficient cause be defined to be a being that had power and will to produce the effect? The production of an effect requires active power, and active power, being a quality, must be in a being endowed with that power. Power without will produces no effect; but when there are conjoined, the effect must be produced. This, I think, is the proper meaning of the word cause, when it is used in metaphysics; and particularly when we affirm that every thing that begins to exist must have a cause; and when, by reasoning, we prove, that there must be an eternal first cause of all things. Was the world produced by previous circumstances which are continually followed by such an effect? Or, was it produced by a Being that had power to produce it, and willd its production?"

"In natural philosophy," says this ingenious writer, "the word cause is often used in very different senses. When an event is produced according to a known law of nature, the law of nature is called the cause of that event. But a law of nature is not the efficient cause of any event; it is only the rule, according to which the efficient cause acts. A law is a thing conceived in the mind of a rational being, not a thing that has a real existence; and therefore, like a motive, it can neither act nor be acted upon, and consequently cannot be an efficient cause. If there be no being that acts according to the law, it produces no effect."

It can hardly escape our observation, says Dr. Gregory, (ubi infra), that the notion of a cause, as explained by Dr. Reid, is very different from that commonly adopted by philosophers, either metaphysicians or physical inquirers;—so very different, indeed, that the axiom, "Every change or effect must have a cause," as understood by him, will fearfully be admitted even by physical inquirers; and will not only not be admitted by metaphysicians as a principle universally true, but will be regarded by many of them, especially by Dr. Priestley, and all the disciples of Mr. Hume, as universally false, and even impossible. Dr. Reid, like many preceding philosophers, had attended too much to one kind of cause, or principle of change, namely, what a man, or any other living being, is to his own voluntary actions, or to those changes which he produces directly in himself, and indirectly in other beings, by the occasional exertion of his own power. This kind of cause may be called, for distinction's sake, exclusively an agent. That there are such agents, and that many events are to be referred to them, as either wholly or partly their causes or principles of change, is allowed as not only certain, but even irrefutable. Nevertheless, Dr. Gregory will not allow, that all events, without exception, are to be referred to some such causes, and necessarily imply the operation of agents, and the exertion of power; because he neither perceives it as a self-evident necessary truth, nor has ever met with any evidence of it. To this author it appears, that Dr. Reid, and many philosophers, who have thought and argued nearly as he has done on this subject, have gone as far wrong on one side as Mr. Hume, Dr. Priestley, or M. Leibnitz, or, in general, all adherents of the doctrine of necessity, have done on the other. These philosophers have attended too much
to another kind of causé, called, by way of distinction, physical causé; as, e. g. what impulse is to motion, heat to expansion, fuscene, and evaporation, the earth to the fall of a stone towards it, the fun and moon to the tides, &c. That there are such causés, or, in other words, that we conceive some relation to subsist between the various things and events respectively that have been mentioned, which relation we are accustomed to express by the terms causé and effect, is as certain as that there are agents for other events.

However, it seems evident, that these two relations are some-how different from one another; and that both of them are very different, and easily distinguishable, from various other relations of event. When heat is said to be the causé of the melting of ice, a certain relation is supposed to subsist between the heat and that event; but very different from that between a man and any of his voluntary actions; different also from that between motive and action; different even from that between evidence and belief; different from that between the vital principle of a plant or animal, and its growth, its functions, and accidents; different from that between the various occasional or exciting causés, (such as air, water, light, heat, cold, contagion, poison, &c.) and the growth, the functions, and the accidents of plants and animals; different even, in some measure, from that between impulse and motion; and different from that between any body and the fall, or tendency to fall, of another body towards it. All these relations, and such like, are easily distinguishable from one another; and cannot be confounded, by any thinking and discerning person, with the simple relation of priority and succession among things and events; as, e. g. between the morning dawn and the rising of the sun. No man fully ever regarded the dawn as the causé of the rising of the sun, or night as the causé of day. But as the philosophy of Mr. Hume, adopted by other metaphysicians, and even his definitions and explanations of the relation between causé and effect, lead men to confound all these notions, it is expedient to keep in view the simple relation of priority and succession, even in our inquiries concerning causé; that we may then be the better enabled to perceive what more there is in the relation of every kind of causé and effect than merely of the sequence of the one to the other. Whilst philosophers have speculated concerning the nature and influence of causés, they have been prone to overlook some of the kinds of causés that have been mentioned, and to confound others of them; to attend chiefly to physical causés; to suppose that for every event, even for the voluntary action of a living person, there must be such a causé; to maintain that the relation of motive and action is essentially the same with that between physical causé and effect, and thereby to exclude, not only the necessity, but almost the possibility, of the operation of an agent, or causé of that kind which Dr. Reid, in the passages above cited, and which many other philosophers have thought universally necessary for the production of change. Dr. Gregory differs from the system both of Hume and Reid; from the latter, because he thinks there are many events which we have no reason whatever, either from the primary laws of human thought, or from particular observation, experiment, and induction, to refer to agents; and from the other, because there are many events, e. g. the voluntary actions of mankind, which, in his opinion, ought to be referred to agents as their proper and chief principles of change. When we refer the voluntary action of a person to the agent as the author of it, that is, as the causé, or principle of change, from which it proceeded, we cannot reasonably be charged with the absurdity, that there may be an event or effect without a causé. As little can we be charged with that absurdity, when we refer the melting of ice, and the boiling of water, to heat; and when we refer the falling of a stone to the ground, and the ebbing and flowing of the sea, to the influence of the earth on the stone, and of the fun and moon on the ocean, according to the principle of general gravitation. We have evidence sufficient, corresponding to the nature of the subject and the extent of our own faculties, to believe, that among things inanimate, and consequently incapable of power or activity, in the literal and common sense of the term, there are such relations that they may be mutually causé and principles of change to one another, without any exertion of power, or any operation of an agent directly for causing the change, for ought we know, may subsist among bodies remote from one another, as well as among those that are really or apparently in actual contact; and they may vary, both in kind and degree, according to the distances between the bodies. We know their relations, however, merely as matter of fact; but the result, in point of event, in any given case of the application of such causés, will be the same, whether the relation among the bodies be necessary, or contingent and arbitrary; provided only that it be established and constant. Some of the relations of event, particularly that of physical causé and effect, comprehending the circumstance of their concomitant conjunction, as it has been very properly called, which seems always to be implied in strict physical reasoning, as well as in the common notions, and actual conduct of mankind, are necessary, like those of quantity, which are the objects of mathematical reasoning; the opinion, that there must be an exertion, or power, or activity, to produce such events, would be not merely erroneous, but absurd; for, on that supposition, no power or agency would be requisite to produce them, any more than to produce the relations of geometry; and no power in heaven or earth could prevent them from being what they are. If such relations, comprehending the circumstance of concomitant conjunction, subsist only by the will but arbitrary appointment of the Supreme Being, who might, if he had thought fit, have made them different; still the necessity at least, if not the possibility, of any exertion of power, or of any agency, would be completely excluded; while some other relations of events, that do not comprehend the circumstance of the concomitant conjunction of the causé with its effect, but, on the contrary, imply their occasional and very frequent separation, as, e. g. the relation of motive and action, not only do not exclude, but absolutely require and imply the operation of an agent, and the exertion of power. The question, it should be remembered, is not whether body can act, either where it is, or where it is not; but simply whether it be consistent with the laws of human thought to believe, that such relations may subsist among bodies, either by necessity, or the nature of things, or by the arbitrary appointment of the Deity, that they shall, in certain circumstances, be mutually causé or principles of change to one another. Whatever may be thought of numberless other events, and of their causé, it must be admitted, says Dr. Gregory, that every voluntary action of a person does proceed from some exertion of active power, or some such causé as Dr. Reid supposes to be universally necessary for every change. See on the subject of this article, besides the authors whose works have already been cited, Hume's Essays, &c. vol. ii. p. 4. part i. § 7. part i. Stewart's Elements of the Philosophy of the Human Mind, ch. i. § 2. Notes C and D. A short statement of some important facts relative to the late Election of a Mathematical Professior in the University of Edinburgh, &c. 1855. Brown's Observations on the Nature and Tendency of the Doctrine of Mr.

CAUSE.  

First, is that which acts of itself, and from its own proper power or virtue.—In this sense, God is the only First Cause.

CAUSES, Second, are those which derive the power and faculty of acting, from a first cause.

CAUSES were distributed by Aristotle into four different kinds; viz. the efficient, the material, the final, and the formal. Efficient causes are the agents that produce certain effects. Material causes are the subjects on which the agent performs his operation, or through whose action which lie within the reach of the agent to influence. Final causes are the motives or purpoſes, which move to action, or the end for which any thing is done. See Motive.

The doctrine of final cause furnishes an obvious and unanswerable argument in proof of the existence of a Deity, infinitely wise and benevolent. This argument is admirably illustrated by Dr. Paly in his "Natural Theology," or "Evil æst. of the Existence and Attributes of the Deity, collected from the Appearances of Nature." Sw. 1802. This excellent work deserves unprejudiced and attentive perusal; and thus perused cannot fail to produce conviction in every mind. See God and Providence. Formal causes denote the changes relating from the operation of the agent; or that which determines a thing to be what it is, and distinguishes it from every thing else. See Form. Instead of dividing causes into these four kinds, it would be more proper to leave out matter and form, as not being properly causes; and the rest might be divided into four kinds, viz. emanative, efficient, intentional, and final; and these include all the various ideas of positive proper causes in the most natural and easy view and order. An emanative cause is when the effect flows from it without any action to produce it, supposing only that all obstructions be removed. Thus water flows from a spring, and heat from the fire. An efficient cause, which most properly describes the name of a cause, produces the effect by some sort of active power or natural agency. Of efficient causes there are many subrespective divisions. An infradivine cause is that which produces effect either by way of manifestation of truth, or direction in practice; and may be called manifestive or directive. A fūsive cause is properly fomething from without, which being apprehended by the mind, excites or incites a voluntary or free agent to act, and it operates either by intreaty or authority, by commands or counsels, by promises or threats, by rewards or punishments, by fear or hope, or any other motives; all which are called moral agency or influence. The end or design is one of the chief infradivine causes, and is usually called the final cause; of which the scholastics have given a variety of divisions. They have also given us several other distinctions and denominations of causes, which it is hardly necessary to enumerate. Accordingly causes are distinguished into physical, or natural, and moral. The former is that which produces a sensible corporal effect. See Cause, above. The latter is that which produces a real effect, but in things immaterial; thus repentance is the cause of forgiveness.

Others define a phænomenal cause to be that which produces its effect by a phænomenal virtue or natural influence; and a moral cause, that which determines the phænomenal cause, though not necessarily, to produce the effect, or which works by persuasion: in which sense, it is also called a styphosive, expository, and imputative cause. Thus, the sun is a phænomenal cause of light: a flame, that breaks the skull, is a phænomenal cause of death: and thus the advice, intreaty, commands, or menaces, which determine us, though not necessarily, to do, or not to do, any thing, are moral causes. In this sense, a moral cause is only applicable to a free intelligent agent; and it is this notion of a moral and phænomenal cause that is the most clear, and distinct.

CAUSES, again, are considered, either as universal, or particular; principal, or instrumental; total, or partial; universal, equivocal, &c. An universal cause is that, which, by the extent of its power, may produce all effects. Thus the sun, fire, and air, are universal causes of plants, herbs, and flowers; for by the same force of influences, each of them produces various and different effects. A particular cause is that which can only produce a single effect; or a certain kind of effects. Thus the particular seeds are the particular causes of each different herb and flower. To these, common and proper causes are nearly allied. A principal cause is that which gives motion to the instrument, or which does not operate beyond its own natural efficacy. An instrumental cause is that which is only the principal to produce its effect; or which is excited to produce an effect, beyond the measure of its own perfection. A total cause is that which produces the whole effect. A partial cause is that which occurs with some other in producing the effects. An equivocal cause is that which is of a different kind and denomination from its effect: as when a man writes a book, when a root produces a leaf and leaves, or when money buys land. An universal cause is that which is of the same kind and denomination with its effect: as when a lion produces a young lion, or when a fountain sends forth a stream of water, or when money being lent, gains money by interest. See Watts's Brief Scheme of Ontology, in his Works, vol. v. ch. 10.

CAUSES, Occasional, are only the occasions, not the direct causes of their effects. The Cartesians resolve all phænomenal causes into occasional ones. See Occasion.

The soul, say those phælosophers, is not able to act on the body; nor the body reciprocally on the soul: to keep up an interchange between them, God, on occasion of a motion of the body, impresses a sensation on the soul; and, on occasion of a sentiment of the soul, impresses a motion on the body; the motions, therefore, of the soul and body, are only occasional causes of what passes in the one or the other. Thus, say they, the stroke, or percussion, is only the occasional cause of the motion produced in the body by it; it is God the direct efficient cause. And thus the action of objects on our organs is not the efficient cause of our ideas and perceptions, but merely the occasional cause which determines God to act on the mind, according to the laws of the union of soul and body.

CAUSE, in Medicine, is usually considered in a sense somewhat complex, and different from the ordinary acceptation of the word. It signifies not merely those agents, which, when applied externally or introduced internally, excite, in the body or in some of its organs, a state of disease; but it is also employed to express the previous condition of the body, which renders it liable to disease, as well as that which constitutes the disease itself. Thus physicians have treated of the causes of diseases under the two heads of remote and proximate causes; the former of which they have again divided into predisposing and exciting, or occasional, causes.

The predisposing cause, is that which renders the body liable to be attacked by disease, or to be acted upon by an exciting cause; for the operation of an exciting cause alone is generally not sufficient to produce disease. Thus several persons may be exposed at the same time to the same external agents,
agents, e. g. to cold and moisture; in some these agents will excite disease, or on others they will act with impunity. In the former persons some circumstances must have existed, which rendered them liable to receive those morbid impressions; in the latter no such predisposition was present. Again, some of those, whom the exciting causes affected, may suffer one species of disease, and others a different species: thus one individual may be affected with rheumatism, another with catarh, a third with dysentery, and so on; a fact implying the existence of some peculiar condition of the body, or of the organs respectively attacked, which is justly deemed a predisposing cause of the particular malady, which may have occurred. In some instances the predisposition is obvious and well understood: thus one attack of rheumatism, pleurisy, or any inflammatory disorder, generally renders the body more liable to suffer a second: a peculiar formation of the chest, combined with a fair and delicate skin, with dark eyes, lively spirits, &c. implies a tendency to be affected with pulmonary consumption: and a phteritic habit, large head, short neck, very florid complexion, &c. portend a probable apoplexy. In such circumstances the kinds of exciting causes, which ought to be peculiarly avoided, are manifest; and by a careful attention to this suggestion, the diseases, with which the individuals are menaced, may be altogether warded off.

In some instances this predisposing condition of the body, after long continuance, becomes gradually a condition of actual disease, without the concurrence of any external exciting cause; or it becomes, in the language of some writers, itself an exciting cause of disease. In this light a general mobility or morbid irritability of the system, excessive plethora, &c. must be considered. The exciting or acutaneous cause is that agent which produces disease in the body already predisposed to receive it. There are some exciting causes, however, so powerful, as to occasion the most severe maladies, in the most vigorous constitutions, from which every predisposition to disease seems to be absent. Such are the poisons of small pox and syphilis, the extremes of heat and cold; and so forth. And again, an exciting cause which may not immediately induce disease, may, if frequently applied, undermine by degrees the strongest habit, and render it liable to various infirmities. Such are luxury, intemperance, exposure to inclemency of weather, &c.

The proximate cause is usually defined, that, "quae presens morbum fact, sublata tollit, mutata mutat." It is that condition or circumstance, from which the symptoms of a disease immediately originate, and on which they exclusively depend. The proximate cause of the generality of diseases is obscure; and this obscurity has led ingenious men to enter into a variety of speculations altogether fictile, and tending rather to mislead than to inform the mind; and in some inferences indeed altogether unintelligible.

Causa et Efficit, in Law. In most cases the law hath respect to the cause or beginning of a thing as the principal part, on which all other things are founded: and herein the next, and not the remote cause, is most looked upon, except it be in criminal and civil things: and therefore that which is not good at first, will not be so afterward; for such as is the cause, such is the effect: e. g. if an infant or feme covert make a will, and publish it, and afterwards die of full age, or folly, this will is of no force, on account of the original cause of infancy and coverture; &c. Finch 12. Where the cause ceaseth, the effect or thing will cease. Co. Litt. 13.

CAUSEDO. Cape, in Geography, lies on the south coast of the island of St. Domingo; 5 miles S. E. of St. Domingo.

 Causeway, or Causey, a massive concretion of flem, flakes, and laticines; or an elevation of flat, vitious earth, well beaten; serving either as a road, in wet marthny places; or as a mole, to retain the waters of a pond, or prevent a river from overflowing the lower ground.

The word comes from the French chaussée, anciently wrote chausée; and that from the Latin calcata, or calculus; according to Sommer, and Schulein, à calco.la. Bergier rather takes the word to have had its rife à peditum calicis, qui- bus terraror.

Causeway, collectum, or collect, more usually denotes a common hard raised way, maintained and repaired with stones and rubbish.

Causeway, Devil's, a famous work of this kind which ranges through the county of Northumberland, commonly supposed to be Roman, though Mr. Horlby suspects it to be of later times. Horlby, Brit. Rom. fabrics. cap. 2, p. 449.

Causeway, Giants, is a denomination given to a huge pile of flem pieces, in the district of Colesfane, Ireland. See Basalt and Giants' Causewry.

CAUSSADE, in Geography, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 12 miles N. E. of Montauban. The place contains 4142, and the Canton 13,183 inhabitants; the territory includes 225 Kilometers and 11 communes.

CAUSSINS, see Advocate.

CAUSSINS, Nicholas, in Biography, a learned French Jesuit, was born at Troyes in 1585; and having entered into the society of Jesuits at the age of 23 years, taught rhetoric with great reputation at their college. He afterwards became a popular preacher and writer, and was chosen confessor to Lewis XIII. For this situation he does not seem to have possessed the necessary talents; but more attentive to his duty than to the means of maintaining the good opinion of an all-powerful minister, he opposed cardinal de Richelieu in urging the king to recall the queen-mother, and not only lost his post but was exiled from the court to a town in Brittany. After the cardinal's death he returned to Paris, and died in the house of the society in 1624. Among his various works in French and Latin, the most popular of the former was his "La Cour Sainte" in 5 vols. 4to., indicating thepiety rather than judgment, but much read, and translated into several languages. His principal learned work is "De Eloquentia facra et humane," 1616, 4to., which was several times reprinted. It exhibits numerous examples of different fyles in writing. He also published "Electorum Symbolorum et Paschalarum historicarum Symposium," 1618, 4to.; "Disputes sur les quatre Livres des Rois, touchant l'Education des Princez," fol.; "Tragedies Sacree," 1620; "Apologie pour les Religieux de la Compagnie de Jésus," 1644, 4vo.; "La Vie heureuse des Filles devote," &c. 1642; "Symbolica Egyptianap Sapiencie," 1647, 4to., and some other works of devotion and controversy. Nou. Dict. Hiller.

CAUSTIA, in Antiquity, a kind of woollen cap used by the Macedonians; which was so strong as sometimes to serve instead of a helmet. Men. Acad. Inscript. vol. ii. p. 594.

CAUSTIC, Common, in Chemistry, a fixed alkalai deprived of aereal acid and most of its water. If the lixivium of the soap-bailers be evaporated to dryness in a silver or copper vessel, then fused in a crucible, poured out into a baloon, and when solid, cut into small pieces, it forms the common caustic which must be kept in a bottle to prevent its dislueing. When a piece of this alkalai is applied to the skin, for the space of three quarters of an hour, it corrod
rodes it; forming without doubt a fopanaceous compound with its fat parts. It was much used in making inks, before that practice was laid aside. See Caustic Alkali, and Caustic, infra.

Caustic, in Surgery, from *cau*; to burn, a substance, which, by its activity, will erode and consume the animal texture, wherever it is applied: the burning sensation it produces, and the astringent effects which are occasioned by its application, exactly accord with its name. (See Cathartics and Escharotics.) In some cases of ulcers and deep-set inflammation, particularly in chronic affections, the use of caustics is very considerable. The reader will find a few observations on the comparative ufe of caustics, in our article Access, under the head of "Various modes of opening ulcers." We shall here subjoin some remarks on their composition, and the method of employing them.

Caustics are used either in a solid or fluid form; but those which are fluid, can seldom be applied with all the requisite advantages. The stronger concentrated mineral acids are most frequently chosen by surgeons, when they use fluid caustical applications; as they are less liable to spread than an alkaline fluid, such as the aqua kali part of the London college, or the common lacticum causticum.

The solution of caustic alkali or potash, has, however, been often used as a solvent of the stone in the urinary bladder, (See Lithotriptic); for which purpose M. Fourcroy recommends applying the remedy by injecting into the bladder a tepid solution of potass or loda, so weak as to be borne in the mouth. Before it is injected, the bladder should be completely evacuated of urine, and washed out with warm water. After the solution has been injected, and retained half an hour or more, it may be voided and allowed to settle in a proper vessel. If, on the application of a little muriatic acid to the fluid, a precipitate be formed, we shall have reason to conclude that the calcina contain tnic acid, and that the alkali has acted on it.

The strongest caustic of a solid form, in general use among surgeons, is prepared as follows:—evaporate a solution of pure kali or potash in a clean iron vessel to a flake of dryness; after which let the flake matter, in a melted plate, be poured on a smooth iron plate, and divided into small pieces before it hardens, which must immediately be placed in a well flapped vial for use. This caustic is very apt to liqouity on exposure to the air; it is therefore usually managed, by the admixture of quick-lime, to render it less liable to defileuceness; but this procedure also weakens the causticity of the remedy, so that it is not so fit for surgical purposes.

Some practitioners will even dilute the caustic fluid more, before they use it, by the mixture of soft soap, &c. which forms a paste; and then apply this in the following manner: put several folds or layers of common adhesive plaster upon the part, through each of which a cut circular aperture for the reception of the paste. Then fill this hollow with the caustical substance, and let it remain for the space of six, seven, or eight hours, according to the effect desired; when it will be found to have penetrated sufficiently deep. Although this method has been sanctioned by the names of many eminent surgeons, it is very far from being the most eligible; as the pure kali rubbed on the skin about three or four minutes, will produce all the purposes wished for, and cannot extend itself or penetrate farther than is proper. The pain caused by this short process, is not to be compared to that of applying a milder caustic several hours together.

When the caustic has produced its full effect, there will be a portion of dead skin or flesh, called an efehar, which, by degrees, will separate and leave an opening. The part should be pusticed until the efehar is cast off; but should the separation of the dead skin be longer in taking place than the surgeon expects, he may puncture it through with a lancet, to facilitate the discharge of the confined matter.

When a superficial and more circumcised effect is required, the lunar caustic will be found preferable to the pure kali; as it is much less apt to dissolve, and therefore is easily managed even by an unfledged hand. The lunar caustic consists of a solution of pure fiver in nitrous acid, formed into long solid pieces, about the size of a goose-quill; which must be always moistened a little, before we apply them to the skin. A scurpil or half a dram of this substance, dissolved in an ounce of water, makes a useful lotion for languid phlegm; demes forte; or it may be now and then injected into fistulous ulcers, until the surface begins to suppurate freely.

The milder caustic substances, are burnt alum, vitriolated zinc, vitriolated copper, verdigris, &c. but they seldom produce much benefit without repeated application, as they are too weak to act upon a part which is not previously deprived of its cuticle.

Artificial caustics have likewise been employed by surgeons, especially in cancerous cases; but their superiority to more safe applications is very questionable; and it is certain that bad consequences have sometimes arisen from the use of them, even in the hands of skilful practitioners. See Home and Julland's Tracts on cancers.

Caustic Curve. See Curve.

Caustic, by reflection. See Caustic Curve.

Caustic, by refraction. See Caustic Curve.

Caustic gauze. See Burning gauze.

Caustic, Lunar, in Chemistry, improperly called "lapis infernalis," consists of the crystals of silver obtained by solution in nitrous acid, and afterwards fused in a crucible. It is prepared by dissolving very pure silver to saturation in nitrous acid, and separating the crystals by evaporation and cooling. These are to be fused in an earthy crucible, sufficiently large to admit of the frothing and swelling that happen at the commencement of the fusion. The heat must be gentle, because the crystals are very fusible, and the acid easily decomposed and driven off. It requires, however, to be somewhat raised after the ebullition has ceased. As soon as the matter is in quiet fusion, it is to be poured into a mould, consisting of five or six small cylindrical cavities, by which it acquires the form of small pencils, and may conveniently be held in a case instead of touching it with the fingers. The blackness of lunar caustic seems to arise from part of the acid being driven off, and a portion of the silver received. Its causticity or action on animal substances appears to depend on the strong diisposition of the silver to recover its metallic state, and consequently is a true combustion.

Causticity denotes a quality belonging to several substances, by the acrimony of which the parts of living animals may be corroded or destroyed; accordingly, all substances which have to bring a tendency to combine with the principles of organized bodies to destroy their texture, are laid to be caustic. The chief of these are the concentrated acids, pure alkalies, and the metallic salts. See Caustic, supra.

Causticum Antimoniale, the name given in the late London Dispensatory to what was before called biter of Antimony.

Causus, in Medicine, *causus*; from *caus*, I burn, a term applied by Hippocrates and other Greek writers, to an acute fever, accompanied by great heat of the skin. It is the
the same with the *fabris aurum* of the Latins. See Inflam-matory Fever.

CAUTERISATION, in Surgery, is the operation of burning any part of the body artificially by means of a hot iron.

CAUTERY, *cuvah*, is a surgical instrument made of iron, gold, or silver, which, after having been made red hot, exerts its cauterizing power upon the part to which it is applied; and it must be of various dimensions according to the purposes for which it is to be used. It is also termed the actual cautery.

The actual cautery was formerly much employed for stopping hemorrhages, by touching the wounded arteries with it. When this is used, we must, in order to avoid irritating and burning the neighbouring parts, place an iron tube or cannula upon the orifice of the artery, surrounded with cold wet cloths, through which the red hot iron is to be introduced, and the artery touched for a moment with it. Should it be practicable, we ought previously to stop the hemorrhage by means of the tourniquet, and dry the wound well. But as the eschar produced by the cautery may easily separate, and the hemorrhage return, the patient should lie quiet and be constantly watched; and in order to prevent the separation of the eschar, it may be frequently moistened with brodinc, and the impetus of the blood towards the part annihilated by the application of the tourniquet, or by blood-letting: and also in removing the dressings proper caution ought to be observed with respect to the cicatric.

In some cases the actual cautery is the only remedy that can be employed with effect; as when the bleeding vessel is deep situated, or when from any cause no other bloody remedy can be used: for example, in hemorrhages from under the tongue, from the sockets of the teeth, &c. The actual cautery is therefore a remedy which certainly deserves to be more frequently used than is generally done, especially in the irritation and pain which it occasions are by no means so great as is generally supposed. See Hemorrhage.

The actual cautery is moreover used in cases and enlargements of the bones; in caries of the teeth; in excrencences, especially of the gums; and in wounds produced by the bites of mad dogs, or venemous animals. Consult on this subject the dissertations of Mr. Le Cat concerning the use of fire in chirurgical diseases, and that of Mr. Spiritus concerning fire considered as a chirurgical remedy, Götting, 1784.

To this head belongs also the cauterisation with morsa, cotton, gun-powder, burning-glasses, or live coal. The morsa is prepared from the plant termed Artemisia vulgaris. It must lie for a very long time, even for whole years, in the shade to dry, after which the leaves and superior extremities are pounded and rubbed between the hands till they form a sort of cotton. For the purpose of perfuming it, the Chinese sometimes mix morsa with the ashes of the wood of aloes with the Artemisia. When this cotton has been purified from all coercive and foreign substances, it is rolled between the hands till it acquires the form of a cone, pointed at the top and broad at the base, like a pyramid. This pyramid is fastened with saliva to the skin, and set on fire; and when it has quite burnt down, it leaves an eschar upon the skin.

The cylinders of cotton, or Mr. Pantaleo's bougies, are prepared in the following manner. Take carded cotton, and form it, without twirling it close together, into cylinders four inches long, and one in diameter. The cylinder is next wrapped round with a piece of fire linen, four inches broad and three long, and the two ends are laid over each other and sewed together, so as to form a small plug. This is then cut through the middle with a pair of scissors, so as to form two cylinders. The rod of the cotton, which projects either at the top or bottom, is to be cut off with the scissors, close to the edge of the linen. In using these cylinders, the lower extremity is placed upon the skin, moistened a little with saliva, to make it adhere. The upper end is then kindled with a wax taper, and kept: burning by means of a fan or bellows, till it has quite burnt down. As soon as the heat penetrates it to the skin, the cotton is made to stick still farther to the part by means of the augmented perspiration.

The method proposed by Mr. Pfafel is still more convenient. The cotton having first been boiled in a strong solution of nitre, the cylinder after being once lighted, burns till it is quite consumed, so that there is no necessity for fanning or blowing the flame. If we confine the cylinder in a wide tube of strong pallboard, we may hold it between our fingers whilst it is burning, so as to prevent its falling down or injuring the neighbouring parts.

Of such cylinders we may apply one, two, or more, according to the circumstances, and yet the operation of the fire will never penetrate deeper than the skin. When the operation is finished, the burn part may be covered with ung. resin. flav. or balsamin spread upon a pledget. When the heat does not penetrate quite through the skin, and into the cellular sub stance, we frequently fail of our intention, on which account we must always see to it, that the cylinder burns down to its very last particle, as the end of the combustion is the most efficacious.

Cauterns have been employed with advantage in various diseases, but they are chiefly useful in arthritic and rheumatic pains, in which cases the pyramids of morsa, and especially the cotton cylinders, are preferable to the actual cautery. But before we proceed to the use of these applicatrix, we ought first to have tried every other proper remedy, and when these produce no benefit, we must employ the cautery. We ought always to place these substances exactly upon the part at which the pain is most violent. When the pain[L.19] flits, we must follow it with the cylinder whenever it seems itself. However, this method of cauterising is properly applicable only when the pain has actually seated itself in some particular part; for, as long as it is fugitive, we merely make it shift from its temporary seat to another, without suddenly removing it. Its most speedy and surprising effect is in the lumbago.

It is further useful also in cases of ulcers, and in lymphatic swellings of the joints. However, it is necessary that particular attention should be paid to the nature of the circumstances in applying it. When, for example, the white swelling is combined with a deep seated and violent pain, when there is cause to believe that the ligaera are attacked by an arthritis, rheumatic, or vesicular acenty, cauterification might tend to increase the evil; which might be the case in a still greater degree if the bones were enlarged and catious, or whenever the lymphatic tumour is the effect of some violent constitutional disease. It is most useful when the tumour is of a primary nature. But powerful as the effects of these cauterising cylinders are, there are some cases in which it is necessary to employ them repeatedly before the pain yields to their operation.

The method of burning with gun-powder is as follows: when (for example, after a person has been bit by a mad dog) the actual cautery cannot be employed, either on account of the irregular shape of the wound of the tear of the patient, gun-powder is sprinkled into the wound, and set fire to, as often as may be necessary.
CAU

The ancient surgeons with justice placed great dependence upon cauteries; only they are in some degree to be repre- hed for the abuse they sometimes made of them; as are the moderns also, for their too great neglect of these very efficacious remedies.

Actual cauteries are distinguished, according to their degrees of strength, from cauties; which are termed potential cauteries. The difference between the actual and the potential cautery consists in the circumstance, that though cautics produce an ulcer or crust, they do it in a much slower manner, and not till several hours have elapsed: whilst the actual cautery produces its effects instantaneously. The potential cautery is therefore applicable in none of those cases which require the actual cautery. See the article Caries, fab fucc.

CAUTING GUNGE, in Geography, a town of Hindoostan, in the country of Bahar, on the north side of the Ganges, opposite to Bar.

CAUTING Iron, among Farriers, an iron instrument, with wherewith they cautersite and tear the parts of a horse which require burning.

CAUTIO, in the Civil Law, denotes an assurance or securitie given or taken for any thing trusted.

CAUTIO, in Military Language, is an explanation given before the word of command, by which the attention of the soldiers is called to the regular and correct execution by all of them at the same time of the movement they are about to be directed to perform.

CAUTIOE, admitting, in Common Law, a writ which lies against a bishop who holds an excommunicated person in prison for contempt, notwithstanding he offers sufficient caution or security for obeying the commands of the church for the future. Reg. Orig. 66. And if a man be excommunicated, and taken by a writ of "significavit," and after offers caution to the bishop to obey the church, and the bishop refuseth it; the party may sue out this writ to the sheriff to go against the bishop and to warn him to take caution, &c. But if he has reason to doubt whether the sheriff will deliver him by that writ, the bishop may purchase another writ, directed to the sheriff, reining the cafe, &c. When the bishop hath taken caution, he is to certify the same in the chancery, and thereupon the party shall have a writ unto the sheriff to deliver him. New Nat. Brev. 143.

CAUTIORITY TOWNS, places of strength, which one prince or power puts into the possession of another as a security either for the payment of a debt, or performance of some other matter stipulated between them. Thus, when a profusion of expense was incurred by the elevation of the duke of Buckingham in the reign of James I. which was too great for his moderate revenue, the cautionary towns were delivered up to the Dutch, A.D. 1626. In the preceding reign, queen Elizabeth, when she lent the revolted Hoolanders large sums of money, required of them a proper deposit, as security for payment. The Dutch, in compliance with this demand, put her into possession of the three important forts of Flushing, Brille, and Rancekins. But James, in his present exigence, agreed to evacuate these fortresses, upon being paid only a third part of the money which was due; this measure occasioned a very general discontent.

CAUTORY, or FIRE-JUXTA, in Scots Law, denotes the obligation by which one person becomes engaged as security for another, that he shall either pay a sum or perform a deed. A cautoner for a sum of money may be bound, either simply as cautoner for the principal debtor, or conjointly and severally for and with him. The word has, by custom, the "hen chicum ordinis," or of dedication: by which the creditor is obliged to defend the proper debtor, before he can unite for payment against the cautoner. Where a per-
C-au, in Geography, a river of the island of Cuba, which runs into the sea, 20 miles N.W. of Hayamo.

Cauturier, in Anatomy, a name given by the French writers to a muscle of the leg; called by the old writers, primum felodentum tibianum; and by the latter writers, Cowper, Albains, &c. Jartorius; by Rioli, Jaturius.

Cauver, in Geography. See Cauveri.

Caux, a country of France, in Normandy, so called before the revolution, about 50 leagues in circumference, lying between the Ocean and the Seine. Vexin, Normandy, Picardy, and the country of Bray. The land is fertile in grain, hemp, fruits, &c. The coal abounds with fish, and the forests with game. Cauver is the capital.

Cavy, in Zoology. See Cavia.

Cavy, myq, of Pennant's quadrupeds, is the Mus pilores of Pallas, and other late writers. See Mus pilores.

Cavy, Cape of Pennant, is Hyrax capensis, which see.

Cawpoor, in Geography, a town of Hindoostan, in the Soukab of Oude; 37 miles S.W. of Lucknow, and 98 N. W. of Allahabad.

Cawood, a town in the well riding of Yorkshire, England, seated on the banks of the navigable river Ouse, over which there is a ferry from this town into the east riding. Here was formerly a castle, some ruins of which still remain. This was given by the Athenians to the archbishops of York, and was the birth-place of bishop Mountaine, who is buried in the church at this place. The castle suffered materially in the civil wars. Here are a weekly market on Wednesdays, and two fairs yearly. The town contains 247 houses, and 1,025 inhabitants, the greater number of whom is employed in agriculture. Cawood is situated 12 miles S. of the city of York, and 187 N. from London.

Cawston, a small market town of Norfolk, England, is held by the Duchy of Lancaster in free socage. It is situated on the river Bure, and has a small market on Wednesdays, and three annual fairs, one of which is well supplied with sheep. Cawston is eleven miles N.W. of Norwich, and 112 miles N.E. from London. Here are 176 houses and 846 inhabitants.

Cax, in Commerce, a little coin made of lead, mixed with c мира of copper; struck in China, but current chiefly at Bantam, in the room of the island of Java, and in some of the neighbouring islands.

It is somewhat smaller than the French double, and has a square hole through the middle: by means whereof, several of them are hung on the same string: this string, which they call fanta, usually contains two hundred caxas, equivalent to nine French deniers, or somewhat less than three farthings English. Five caxas tied together, i.e., a thousand caxas, make a fajpanor. Nothing can exceed the brittleness of the caxa; a string never falls to the ground without breaking at least ten or twelve pieces. Leaving them at night deepened in salt-water, they clung so firm to one another, that they are not to be separated without breaking one half of them. The Malays call them cac; and the fajpanor.

The caxas are of two kinds: great and small; the small are those which we have been speaking of: three hundred thousand whereof are equal to fifty-six lives five pounds, French money. The large are old caxas; fix thousand whereof are equal to the piece of eight, or four shillings and six pence English. There are near 2,000 pieces with the caxas of China, and the caxas of Japan.

Caxa Mino, an appellation distinguishing those mines of gold and silver in the province of Quito in South America, which are contained and confined, as it were, between two natural walls; in contradiction to those in which the metals are found dispersed and mingled with earths of different species. In these mines, generally speaking, the silver and gold are intimately united with other bodies; and, therefore, it is necessary to separate the grains from the earth by running conduits of water. After having undergone the operation of the quicksilver, which their quality renders indispensible, the fulness is washed in order to separate the remaining filth. After the last operation the amalgama is pure, confining entirely of quicksilver, and gold or silver, according to the species which has been worked.

Caxamaraca, in Geography, a jurisdiction of South America, in the country of Peru, and diocese of Truxillo, lying to the eastward of Truxillo, and extending along a vast interval between the two Cordilleras of the Andes. This jurisdiction is fertile in all kinds of corn, fruit, and excellent vegetables, and also in cattle, sheep, and especially hogs, of which they sell a great number to the farmers in the valleys, who, after fattening them with maize, sell them to the markets in the large towns. The farmers of the valley of Chinea, and others, in particular, carry on a considerable trade in these creatures at Lima, Truxillo, and other flourishing places. The Indians throughout this jurisdiction weave cotton for ship-linen, bed-curtains, quilts, and other uzes, which are sent into the other provinces. Here are also some silver mines, but of little consequence. The principal town is of the same name, and was formerly a royal city, where the emperor Atalla was put to death, after having been defated and imprisoned by Pizarro: about 70 miles from the Pacific Ocean. S.lat. 8°, W. long. 76° 10'.

Caxamarquilla, or Cosamarquilla, called also Patera, a jurisdiction of South America, in the diocese of Truxillo. It lies among the mountains at a small distance S.W. from Caxamarca, and from its different situations has a variety of products; but it is particularly remarkable for gold mines. The chief commerce consists in exchanging that metal for current money, especially silver coin, which is the more esteemed here on account of its scarcity.

Caxatambo, a jurisdiction of South America, in the circuit of Lima, commencing 23 leagues N. of Lima, and extending about 20 leagues, and partly among the mountains, so that the temperature of the air is very high; but the whole territory is very fertile in grain. It has also some silver mines, which are wrought; and the Indians have manufactories of guns, which constitute part of the trade of this jurisdiction.

Caxcaxtototi, of Ray, in Ornithology. See Sturmis mexicanus, Cand.

Caxines, Cape, or El Acen-natar, in Geography, a cape on the north coast of Africa, in the Mediterranean, forming the west point of the bay of Algiers. N. lat. 37° 15'; E. long. 3° 30'.

Cauxou, in Metallurgy, a word used to express a chalk of ores of silver, or any other metal, that has been burnt, ground, and washed, and is ready to be refined.

Caxton, in Biography, devolves to be recorded as the first person, who, according to some writers, introduced the art of printing into England, or who, according to others, improved and perfected it by the use of fustie types. He was born about the latter end of King Henry the IVth's reign, who died in the year 1412, in the Weald of Kent; and, after having been well instructed by his mother in reading and writing, he was apprenticed to Mr. Large, an eminent mercer in London, lord-mayor of the city, in 1430, with whom he resided till his death. In the year of his master's death, 1441, he was sent abroad by the mercers' company, as their agent and factor in the Low Countries, where he continued in the management of their concerns for about 23 years. His conduct in this department of public trust had been so satisfactory to his employers, and so highly reputable to himself, that he was joined
in a very honourable commission, granted by king Edward IV, in 1494, for the purpose of continuing and confirming the commercial treaty subsisting between his majesty and Philip Duke of Burgundy, or, if necessary, of negotiating and establishing a new treaty. Afterwards he appears to have held some office in the household of lady Margaret of York, the sister of king Edward, who, in 1468, was married to the duke's son, Charles, then duke of Burgundy. By his long residence in these countries, as well as by an inquisitive and industrious disposition, he became acquainted with the new invention of printing, which was then practised in Holland and Flanders; and he seems to have been actuated by the laudable ambition not only of acquiring the art, but of introducing it into his own country. At the instigation of the duchess of Burgundy, by whom he was probably employed in some literary department; having attained by his diligent application a competent knowledge of the Latin and French languages, he translated from the French a work, which he entitled "The Recuyell of the Hystorys of Troye," the first book suppos'd to have been ever printed in the English tongue. Having laboured for three years in the translation of this work, which he began at Bruges, in 1468, and finished at Cologne, in 1471, he undertook the task of printing it in this city, having, as he himself says, "practised and lerned at my grete charge and dispence, to ordyne this sayde book in prynte." Its date is 1471. After having published "The Book of Troy," he proceeded in printing others; and, at length, having provided himself with presses, types, and all other printing materials, he came over to England, in 1472; and, in a printing-room at the entrance of Wellminter Abbey, whence a printing-room is to this day called a "chapel," he produced, in 1474, the first book that was ever printed in this country, which was the translation of a French work, and entitled "The Game and Play of the Cheffe," &c. For other claims to the introduction and practice of printing in England; see the article PRINTING. The next works, printed by Caxton, in the order of time, were "The Hystory of Jafon," suppos'd, though without a date, to have been printed in 1473; "The Dicts and Sayings of the Philosophers," printed at Wellminter in 1477; "The Moral Proverbes of Chrylyme of Par," printed in the following year; "The Corday," printed in the same year; and after printing began to make its first appearance at Oxford in 1479, three books, entitled the "Image of the World," "Ovid's Metamorphoises," and the "Chronicles," with a "Description of England," all printed in 1480. Such was his indefatigable industry, even in the decline of life, that in the space of 20 years he produced between 50 and 60 specimens of his skill and labour, most of them being translations, by himself, from the French, and judiciously selected with a view to the promotion of a taste for literature, and of good morals. Caxton died in 1491, and was buried in St. Margaret's church, Wellminter. Although Caxton had no great pretensions to literature, nor to the reputation of an original writer, and though he does not appear to have made any improvement in the typographical art, he is entitled to respect and gratitude for the share he had in introducing and establishing an invention of the highest importance in his own country, and in facilitating and extending the practice of it. He printed, and in some cases translated, what he had undoubtedly great merit in, and contributed in a very considerable degree, not only to the perfection of the art of printing, but to the diffusion of useful knowledge. The specimens of his talents and performances as a poet are found in the rhyming introductions and epilogues, with which he frequently decorates his books, and in a poem of considerable length, entitled the "Work of Sapience." This comprehends not only an allegorical fiction concerning the two courts of the castle of Sapience, in which there is no imagination, but a system of natural philosophy, grammar, logic, rhetoric, geometry, astronomy, theology, and other topics of the fashionable literature. Although Caxton appears, by the preface, to be the author, yet Mr. Warton, (Hist. of Poetry, vol. ii. p. 194,) thinks it not improbable, that he might on this occasion employ some professed versifier, at least as an assistant, to prepare a new book of original poetry for his preëx. The writer's design is to describe the effects of wisdom from the beginning of the world; and the work is a history or knowledge or learning. Bkg. Brit.

CAXTON, in Geography, a small market town of Cambridgeshire, in England, has no other claim to publicity than from having been the birth-place of that respectable old historian, Matthew Paris, and the supposed birth-place of William Caxton, who introduced the art of printing into England. This ancient printer, we are informed by himself, was a native of Kent. In his "Recuyell of the Histories of Troye," he thus informs us. "In France was I never, and was born and learned myne English in Kente in the Weald, where English is spoken broad and rude." This town is fested on a Roman road, and at present derives its principal support from being situated on a modern public road. The houses are small and mean, and the inhabitants mostly occupied in husbandry. It has a small market on Tuesdays, and two fairs annually.

CAY, a town of China of the second rank, in the province of Pe-chë-leh; 125 miles S.S.W. of Peking. N. lat. 39° 3'. E. long. 115° 20'.

CAY, in Geography, a river of Spain, which runs into the Guadaisa, near Badasco.—Also, a river of Spain, in Catalonia, which runs into the Mediterranean, near Tamarit.

CAYAHOGA, or CAYUGA, a river of North America, in the state of Ohio, which discharges itself, by a mouth 83 yards wide, into the lake Erie at the fourth bank, 40 miles easterly of the mouth of Huron; having an Indian town of the same name on its banks, 30 miles S. of lake Erie. N. lat. 41° 30'. W. long. 81° 20'. It is navigable for boats 60 miles to the portage, which is 7½ miles to the head-waters of the Tuckarawa branch of the Mahoning; and it is also navigable for sewers for fifteen miles without any falls or rapids; but at the mouth there is a bar like that of Grand river. In the vicinity of this river are fine uplands, extensive meadows, oak and mulberry trees fit for ship-building, and walnut, chestnut, and poplar trees adapted to domestic uses. Near the mouth of this river are the celebrated rocks which project over the lake. They are seven miles in length, and rise 40 or 50 feet perpendicularly out of the water. Some parts of them consist of several strata of different colours, lying in a horizontal direction, and so exactly parallel that they resemble the work of art. The view from the land is grand; but the water presents the most magnificent prospect of this sublime work of nature; it is attended, however, with great danger, for
for, if the leaf from arised, the force of the sun is such, that no vessel can cleanse being dashed against the rock. The heathen Indians, when they pass this impending danger, offer a facsimile of tobacco to the water. Part of the boundary line between the United States of America and the Indians, begins at the mouth of Cayahoga, and runs up along the same to the portage between that and the Tul- carawa branch of the Maumee.

The Cayuga Indian, confiding of 500 persons, 200 of whom are warriors, 40 being resident in the United States, and the rest in Canada, receive of the State of New York an annuity of 2,500 dollars, besides 50 dollars granted to one of their chiefs, as a consideration for lands sold by them to the State, and 500 dollars from the United States, agreeably to the treaty of 1784.

CAYAMBE, a village of South America, in the province of Quito, and jurisdiction of Otabolo, seated in the middle of a spacious plain, about 12 leagues N. of Quito. In this place M. Couplé, one of the French mathematicians deputed to measure the length of an arc of the meridian, died on the 17th of September, 1736, after an illness of two days.

CAYAMBURO, a mountain of South America, in the province of Quito, seated at the extremity of the plain of Cayambe, about 12 leagues N.E. from Quito. It is one of the largest mountains of the Cordilleras in this part of the country, being nearly equal in height to that of Chimborazo, that of the latter above the ocean being 19,395 English feet, and that of the former 19,391 feet. Its altitude is so great that it may be seen from the city of Quito. Its summits are covered with snow and ice; and its vicinity renders the whole plain of Cayambe cold, which is increased by the violence and continuance of the winds. It exhibits no appearance of having ever been a volcano, nor is there any tradition to that purpose. Several rivers flow from it, from which those from the west and north run either into the river of Emeralds or that of Mira, but all fall into the South Sea; while those from the east discharge themselves into the river of the Amazonas.

CAYANG, in Botany, a leguminous plant, cultivated in the Mogul dominions for food. It is a kind of coarse pulse, of which the Europeans use great quantities on shipboard in the East Indies. It is a species of the cajifer, called by the Indians tiffy. Pol. Déc. Com.

CAYAO, or CALAO, in Ornithology, a name by which the Linnean cuceros bicorns, or Philippine hornbill, is described in the Transactions of the Royal Society, v. 23, p. 1794.

CAYBOBO, in Geography, a town of the island of Ceram, in the East Indian Sea.

CAYBOROUGH, a river of America, being one of those rivers, which fall into the channel of Amerys, or north-west branch of the river Amazon; but, though navigable, it is useless for want of towns and inhabitants to trade.

CAYEAC, a sweet scented wood which grows in Siam; the Siamese and Chinese burn it in their temples. It is one of the commodities exported from Siam for China.

CAYENNE, or French Guiana, in Geography, a province of South America, is noted, but erroneously, for the island of Cayenne, which was not only an uncomfortable part of it, but bounded N. and E. by the Atlantic Ocean, S. by a line not altogether; and W. by Dutch (now French) Guiana, and Surinam. It extends from the mouth of a small river called Arama, W. to another called Ara- cama, E., though an attempt was lately made to extend the limits at the expense of the Portuguese, to the ciphers of the Maranon; its whole extent not exceeding 370 British miles in length by 245 in breadth. The French formed their first settlement in Guiana about the year 1645; and having abandoned it soon after, they were succeeded by the English; but again took possession of the country about the year 1664, and retained it ever since. The coast is low and marshy, and subject to inundations from the number of rivers, which run down the mountains with great impetuosity. The soil of this colony is in many parts uncommonly fertile; and the productions are on the whole of an excellent quality, and it is easy to gain a subsistence. The Cayenne pepper is a noted produce of this country, and the inhabitants using it to excess, a considerable quantity is always imported from Peru. The other products of the colony are sugar, cocoa, coffee, and indigo, which, with maize, cassia, and vanilla, form the chief anti lies of its commerce. The interior parts, though much neglected, and remaining obstruted by thick forests and underwood, feed, not seldom, a great number of horses, sheep, goats, and cattle, which roam at pleasure: the beef and mutton are reckoned excellent. The climate is much more salubrious than that of any of the Antilles; but as the situation of the town is ill chosen, in a swampy fcl. its disadvantages have been lately ascribred to the whole territory. The opinion that has been entertained of the unhealthfulness of this climate partly took its rise from the unfortunate expedition to Kourou, 12 leagues below Cayenne, which between 30 and 40 years ago was undertaken by command of the late duke of Choiseul, then prime minister of France; who sent 10,000 persons, very much unp诱导ed with the most necessary articles, and in the most rainy season of the year, to people the immense deserts of French Guiana. This multitude of new colonists, after encountering in their voyage, and on their arrival, numberless inconveniences and hardships, pretleness vanished, falling victims, as it was, to the inhuman climate. Hence an erroneous opinion prevailed in France, which ruined the colony of Cayenne, by preventing the government from paying the least attention to that country, and discouraging a number of European inhabitants of the West Indian islands from settling in Guiana. In this colony there are, properly, only two different feaons, the dry and the rainy season. The former generally continues from the beginning of June until the end of September, during which time the heat is very oppressive: the air is almost always serene, and leared, a few drops of rain descend to purity and cool the atmosphere. The heavy falls of rain begin in the month of October, and are very frequent in December, January, February, and March, at which time they begin gradually to decrease until the dry season sets in. During the rainy season, that is, for seven or eight months, the heat is as moderate as can be expected to near to the equator; they, the negroes sometimes complain of cold; and, upon the whole, the state of health is as good there as in Europe. However, at the time when stagnat waters are dried up and corruated by the heat, fevers prevalent for about two months, which, though not contagious, prove very destructive. The inhabitants of French Guiana are principally occupied with all the requisites of a good life, but they generally prefer salt meat to fresh provisions. Being also much addicted to the use of every kind of food that is highly seasoned, they cultivate certain sorts of pepper for culinary purposes, however bad, and purgatif they may be. The Caribs prefer the calabash, which is a large round cake, about three lines thick, made of coarse flour of manioc and highly baked on a tin plate, to the salt and fresh sorts of bread. Besides
Besides the other articles of subsistence common to Guiana and other colonies, they have a dish called "catatoli," which is prepared of the fruit of a plant denominated "Combua," which is in frequent use. At every meal a negro prefers to the guests a glass of rattia, as soon as the first course is removed. This liquor is as transparent as Cayenne: it is purest spring-water; it is very wholesome, and acquires a more pleasant flavour the older it grows; especially since the colonists have applied themselves to distil it over newly gathered cinnamon. The dregs of the male sex confits in white pantaloons and a linen jacket, and the women spend most of their time in a hammock, a piece of furniture much valued in Guiana, and serving both for ornament and convenience. All hammocks are made of cotton; they are in general from five to seven feet in length, and nearly as broad; they are fastened on both ends by a number of small cotton fringes; which join, at each end, a large rope of the same stuff. The whole burden is supported by these ropes, which are fastened to the walls of the room by means of large hooks. The hammocks are commonly suspended in the corners of the room, where they hang, like swags, in the form of a garland. Very fine hammocks are made at Cayenne; but the most beautiful are imported from Peru in Brazil, situated on the right banks of the river Amazon. The latter are made of variegated cotton, after various designs, ornamented with borders, tussels, and fringes, and sold about 50 dollars.

CAYENNE, the capital of the above colony, which is the seat of government, and of the courts of justice and the military. It is seated close to the sea, on the right bank, and near the mouth of a river of the same name, which is there about a league in width. The town is small; the houses are badly constructed of wood; and it is surrounded by a swampy moat, and wretched walls, which form a fort of irregular hexagon. The fort, which commands the town, is constructed of earth, and tolerably strong towards the sea, especially for this reason, that, from the want of depth of water, ships of a middle size only can approach it within gun-shot. The palace of the government, and the ancient mansion of the Jefuits, are the only buildings which deserve particular notice. They form two large temples, forming the place of parade, which presents a pleasing prospect. Cayenne, on a hill, with two rows of orange trees of the largest size, which exhale an exquisite fragrance, and are crowded with colibris skimming from branch to branch. The population of the town of Cayenne, having of late years increased, and its circuit not admitted of a proportionate enlargement, a new town has been built on the neighbouring savannah, separated from the former merely by a ditch. This new town, which is already more considerable than the ancient city of Cayenne, and is daily increasing, is constructed on a regular plan: the streets are wide, admitting the free access and circulation of air, and contain some elegant houses, the beautiful appearance of which becomes more striking from the obvious marks of poverty and wretchedness exhibited by every thing about them. Cayenne, the metropolis of the whole colony, is also the capital of the island of the same name. Cayenne is celebrated on account of the experiment made by M. Richer, by order of the Academy of Sciences at Paris, in 1772, upon the pendulum; for an account of which, see Pendulum. N. lat. 4° 56'. W. long. 56° 15'.

CAYEUX, a town in France in the department of the Somme, and district of Abbeville; 34 leagues N. of Montdidier.

CAYUCOS, a town of Spanish America, in the province of Tabasco; 30 miles N. of Tabasco.

CAYLAR, Le. See CAILAR.
CAYLOMA, or CALLOMA, a jurisdiction of South America, in the country of Peru, and district of Aracuana, at the distance of about 30 leagues east from the city of Aracuana, famous for a mountain of the same name, and the silver mines it contains. The produce of these mines has been very considerable; and in the principal cities of the same name there are a governor and offices appointed for receiving the king's fifths, and sending the quicksilver to the metalliferous department. The cold in the greater part of this district is so intense, that the inhabitants are obliged to have recourse to the neighbouring provinces for the fruits of the earth. In some parts there are wild alleys.

CAYLUS, ANN-CLAUDE-PHILIPPE DE TUBIERS, DE GRIMMOARD, DE PETITIE, DE LEVY, prefect of, in Biography, an illustrious amateur of the arts, was descended from one of the most noble families of France, and born at Paris in 1692. Having entered at an early age into the military service, he distinguished himself in Calabria in 1711, and at the siege of Fribourg in 1713. But the peace of Rastadt terminated his military career; and from this time he devoted himself to those antiquarian researches, to which his love of the arts powerfully prompted him. In 1715 he joined the train of the French ambassador to the Porte, and visited the ruins of Ephesus, Colophon, and other places in Asia Minor and Greece. Availing himself by his garb and effort of those measures for his security, which prudence suggested, he viewed scenes that had been rarely contemplated by Europeans, and returned to France, in 1717, with a rich collection of drawings and descriptions. He afterwards visited London and other countries of Europe. Having concluded his foreign rambles and researches, he devoted himself to the inedited study of the elegant arts in all their branches. He was a practitioner in music, drawing, painting, and engraving; and the labours of the pencil and graver were aided by his pen in the illustration of classical antiquities. By his encouragement the public obtained a magnificent work, describing the sculptured gems in the king's cabinet, with the figures by Bouchardon, and the explanations by Marquet. In 1731, he was admitted a member of the Academy of Painting and Sculpture; and in return for this honour he composed the lives of the principal artists that had belonged to it; and he collected in three works all the new subjects for painting, which had occurred to him in his perusal of the writers of antiquity. He also founded an annual prize for the best drawing or model after nature of a head, expressing some particular passion; and he also, at his own expense, caused to be engraved the beautiful coloured drawings of Pietro Santo Bartoli, made at Rome after ancient paintings. In 1740, he was appointed one of the honorary members of the Academy of Inscriptions and Belles Lettres: and thus distinguished he was led to prosecute diligent inquiries into the Egyptian mode of embellishing, the preparation of the papyrus, the transportation of enormous blocks of stone from one extremity of Egypt to the other, and several other curious subjects of ancient art. He also elucidated many difficult passages in the elder Pliny, relative to the arts, and by the affilation of a chemist revived the secret of tinging marble and of encaustic painting, which he. His academical dissertations amounted to more than 40 in number; and he instituted a prize for a disputation, explaining the callotums of antiquity from monuments, with a view to the improvement of artists in the knowledge of costumes. By his various labours he acquired a reputation which extended throughout Europe, and which induced the principal learned academies to associate him with their members. He was justly deemed the Maximus of talents and literature; and by his own eccentric mode of living, he was enabled to indulge his taste both as a collector and a patron. His moral character was amiable: cheerful, good-humoured, polite, briskly just, an enemy to flattery, and indifferent to honour, he was a true practical philosopher. His health was preserved to an advanced period; and he died at Paris, after a short confinement, in 1674, aged 77 years. His principal work is a "Collection of Egyptian, Etruscan, Greek, Roman, and Gothic Antiquities," 7 vols. 8to. of which the last appeared in 1705, with an eloge of the author by Mr. le Peau. Of his other works are, "The History of the Techean Hercules, taken from various Authors," 8vo. 1758; "A Discourse on Ancient Pictures," and several romances and fairy tales, the productions of his hours of relaxation. Now. Dict. Hist. Gen. Biog.

CAYLU, in Geography, a town of France, in the department of the Lot, and chief place of a canton in the district of Montauban. 7 leagues N.E. of Montauban. The place contains 5131, and the canton 10,473 inhabitants; the territory comprises 1555 kilometres and 9 communes.

CAYMAN, in Zoology, the common name of the alligator in America. Bonitus, in his History of Java, calls it Crocodylus caimanum. See Alligator, see Alligator.

CAYMANS, in Geography, three small islands of the West Indies, in the bay of Honduras, 55 leagues N.W. of the island of Jamaica, called Great Caymans, Little Cayman, and Cayman Brock. The former is the most southerly, about 11 miles long, and a mile broad, and inhabited by about 160 persons, descendants of the old Buccaneers. It has no harbour for ships of burden, and only a tolerable anchoring place on the S.W. The climate and soil are very fabulous; and the people, who are vigorous, live to a great age. The produce is more than sufficient for the use of the inhabitants. Their chief employment is that of piloting vessels to the adjacent islands, and felling for turtle; with which they supply Port Royal and other places in great quantities. It is situated in N. lat. 19° 20'. W. long. 81° 40'. The other two islands are uninhabited.

CAYMANUM LAPIS, in Natural History, the name of a stone found in the beds of rivers in many parts of America, and of a yellowish colour, veined with red and white. The Indians have an idle tradition, that it is originally found in the Romach of a crocodile, which, in their language they call caymenes; and hence authors have named it lapis caymanum. The natives of America pretend that it has great virtues in medicine, and particularly that it cures quartans by being applied to the warts; and, to enhance its value, they pretend to take it from the crocodile.

CAYMITES, in Geography, three islands near the coast of St. Domingo, in the West Indies, the largest being about 12 miles in circumference; 56 miles W. from cape Donna Maria.

CAYNE, a river of Wales, which runs into the Severn, 4 miles W. from Newtown in Montgomeryshire.

CAYO, or, a town of the island of Cuba; 80 miles E. of Santo Santo.

CAYONNE, a river of the island of St. Christopher, in the West Indies; which falls into the sea from the W.S.W. near Little Bay, half a mile S.E. of Madan's point.

CAYOPOLLIN, a town of Boulin, and Fernand. Nov. Hisp., in Zoology, a quadruped of the Didelphis genus, described by Peninnat under the name of the Mexican opollon. Sprecher calls it Didelphis cayopollin, which fece.

CAYRES, in Geography, a town of France, in the department of the Upper Loire, and chief place of a canton in the
the district of Le Puy; 8 miles S.S.W. of Le Puy. The place contains 638 and the canton 3556 inhabitants; the territory includes 130 kilometres and 6 communes.

CAYS, a general denomination applied in the West Indies to small islands or rocks, or other banks above water. The English feamen improperly give them the name of Keys.

CAYSTER, in Ancient Geography, now Minderfonte, and called also by the Turks Couteaux-mindre, that is, the Little Meander, or the Black Meander, a river of Asia Minor, which had its two sources N. and S. of the mount Tmolus, and having bathed Lydia, and traversed the plain between the mountains Galleius and Corillus, it discharged itself into the Igean sea near Ephesus. This river was celebrated by the poets for the swans that frequented its banks, and the lakes formed by it on the plain. To this purpose Virgil says:—

"Jam varias pelagi volucres, et quae Asia circum,

Dulcis in italicis rimantur prata Caylirii."  

Georg. i. i.

It is also said to have almost as many windings as the Meander itself. From this resemblance several of our modern travellers have been led to mistake the one for the other.

CAYSTRUS CAMPUS, or CAYSTRUM, a plain of Asia Minor, in Ionia, between mount Galleus to the north and mount Corillus to the south, on which was seated the city of Ephesus. The Cayfer traversed it from the city to the sea, a distance of 36 miles. Pliny says that this plain was formed by the successive depositions of the river.

CAYSTROPEDUM, a very populous city of Asia, in Phrygia; where Cyrus remained five days and was joined by Epyaxa, wife of Synneas, king of Cilicia.

CAYUGA, in Geography, a beautiful lake in Onondaga county and state of New York, in America, from 33 to 36 miles long, about 24 miles wide, in some places 6, abounding with salmon, bass, catfish, eels, &c. It lies between Seneca and Oswego lakes, and at the north end empties into Cayuse river, which is the south-eastern part of Seneca river, whose waters run to Lake Ontario. The reversion lands of the Cayuga Indians lie on both sides of the lake at its northern end.

CAZAL, a town of Arabia, 80 miles N.E. of Medina.

CAZALLA. See CAZALLA.

CAZALS, a town of France, in the department of the Lot, and chief place of a canton in the district of Cahors; 3 leagues S.W. of Gourdon. The place contains 1000, and the canton 7974 inhabitants; the territory comprehends 1424 kilometres and 7 communes.

CAZARES, a town of Mexico. See ANGELO.

CAZ Aubon, a town of France, in the department of the Gers, and chief place of a canton in the district of Condom; 6 leagues W. of Condom. The place contains 3275, and the canton 12174 inhabitants; the territory includes 2875 kilometres and 18 communes.

CAZ-DAGLI, or CAZ-DAGLI, a district of Asia Minor, lying between Anatolia and Caramania, which the Turks believe to have been the country from which the English first drew their origin, and on this account, it is said, that they never fail to claim kindred with the English wherever they meet, especially if they stand in need of their aid.

CAZEA, in Ancient Geography, a maritime town of the Tauric Chersonesus, between Panticapae and Theodosia, according to Arrian. Vol. VII.

CAZEMATE, in Fortification. See CASEMATE.

CAZENOVA, in Geography, a new and thriving township of America, in Herkimer county and state of New York, 45 miles westward of Whitefield. By the late census of 1790, 374 of its inhabitants are electors.

CAZERES, a town of France, in the department of the Upper Garonne, and chief place of a canton in the district of Muret; 2 leagues S.W. of Rieux. The place contains 2023, and the canton 10978 inhabitants; the territory comprehends 2242 kilometres and 20 communes.

CAZERMES, in Fortification. See CASEMATES.

CAZES, Peter-James, in Biography, an eminent French painter, was born at Paris in 1670, and having discovered an early inclination for design, he was placed under the instruction of P. Bertin and afterwards of Houasse senior. The mode of Houasse being too mechanical for his taste, he received lessons of Boulogne the elder, and became his fellow scholar. He had obtained several academical prizes. In 1703 he became a member of the Royal Academy of painting, and from this time began to distinguish himself. His first performances were fabulous subjects in the gallery of the marquis de Clerambaut; but his reputation was established by a large picture displayed at the church of Notre Dame every 1st of May, representing the Woman with an Urn of Blood. He then opened a school, which was much frequented. Being of mild and polished manners, and of an enlarged understanding, he acquired the friendship of several persons of taste. By the Academy he was so much noticed, that he was advanced through the gradations of adjutant, professor, governor, and director, to that of chancellor. His particular work of painting was that of history; and his compositions are grand and well-flushed, derived from elevated conceptions, large and flowing draperies, correct drawing, and a good style of colouring. In his church pictures there is much dignity, and grace in his fabulous subjects; and he equally excelled in great and small works. He is principally deficient in expression, and in some of his later pieces, especially the coldness of age is perceptible. He lost his faculties some time before his death, which happened in 1754. His works are numerous in Paris, and its vicinity, and they are also found at Amiens, Montauban, and other places. His easel works are met with in several cabinets. The king of Prussia has two excellent ones, which for their beautiful finish are compared to the works of Correggio and Argenville. Gen. Biog.

CAZES de MENDONARD, in Geography, a town of France, in the department of the Lot and district of Montauban; 3 miles S.E. of Lauzerte.

CAZIC, or CAZIQUE, a general title given by the Spaniards to the petty kings, princes, and chiefs of the several countries of America, excepting the emperors of Peru, who are styled CAITARAT. The French call them CAESIERS, a denomination which they also give to the chiefs of the Tartarian hordes.

The cazies in some places do the office of physicians, and in others of priests, as well as captains. The dignity of cazie among the Chichis, a people of South America, does not descend to children, but must be acquired by valour and merit. One of the prerogatives annexed to it is, that the cazie may have three wives, while the other people are only allowed one. Mexico comprehended a great number of provinces and islands, which were governed by lords called CAZIQUE, dependent on and tributary to the emperor of Mexico; thirty of these CAZIQUE or valess are said to have been so powerful, that they could each of them bring an army of an hundred thousand men into the field.
CAZIMI, among the Aralim Africani, denotes the
dice of the fun. A planet is said to be in causim, when it is
not distant from the center of the sun more than 16°, the
semidiameter of the fun's dice.

CAZOLS, in Geography, a town of France, in the de-
partment of the Herault, and district of Beziers; 5 miles
N.W. of Beziers.

CAZZOLA, a small island in the Adriatic, near the
coast of Dalmatia. N. lat. 43° 8'. E. long. 16° 44'.

CAZZONI, in Rural Economy, a term provincially ap-
plicated to signify the dried dung of cattle, which is employed
as fuel. It is a fort of fuel frequently made use of in some
parts of Yorkshire, as about Holkerness.

CEA, in Geography, a town of Portugal, in the province
of Beira, 7 leagues S.S.E. of Vifho.

CEADAS, or CEADAS, in Ancient Geography, a name
given by Paulianus and Strabo to a place of Peloponnesus,
in the vicinity of Sparta, in which was a deep cavern, into
which they precipitated those who were condemned to
death for very atrocious crimes.

CEANIDES, or CEANTIDES, in Natural History, a
name given by many of the ancients to the thorne more gene-
 rally known under the name of encehjumites. It was
the same with our sparry incrustations on the walls and roofs
of subterranean caverns: and, from the opinion of the times,
that these stones brought forth young ones, which was
founded on their finding little ones daily produced among
them, it became a custom to give this internally to women
in labour, as a thing that would, by a fort of lymphody,
hail the time.

CEANMIARRA, in Geography, a hill in the Scots
island of Tiree, remarkable for numerous caves, to which
sea-fowl, eagles, and ravens retort; some of the caves are
more than 35 yards deep.

CEANOPHUS, in Botany, xanthiob, Gr. a name given
by Theophrastus to a prickly plant, supposed by Columba
to be ferrugina arvensis of Linnaeus, but by Adanson to be
Ord. Dunoa; Linn. Rhamn.; Juss. Rhamnoidae; Vent.

Gen. Ch. Cal. Perianth one-leafed, top-shaped, perma-
nent, five-cleft; segments acute, nearly closed. Cor. Petals
five, equal, clawed, awl-shaped, inserted into the calyx be-
tween its divisions. Stam. Filaments five, awl-shaped, erect,
opposite to the petals, the length of the corolla; anthers
roundish. Pfl. Germ superior, trigonous; style cylindrical,
semitrifid, the length of the flaments; stigma obtuse. Peric.
Capule (dry berry; Linn.) obtruse, three-grained or three-
celled. Seeds solitary, egg-shaped.

Eff. Ch. Calyx five-cleft. Petals five, clawed, cowled,
opposite to the flaments. Capsules three-grained, three-
celled.

Willd. 1. Lam. Ill. pl. 129. fig. 1. Garot. tab. 106. fig. 4.
(Celastrus; Gr. Vinr. 23. Evonymus; Com. Hort. tab.
86. Pluk. alm. tab. 28. fig. 6.) New Jersey tea. "Leaves
egg-shaped, acute, serrated, three-nerved at the base; pan-
cles axillary, on long peduncles." A shrub, three or four
feet high. Stems several, slender; branches cylindrical,
smooth, reddish. Leaves alternate, deciduous, on short
petioles. Flowers small, white, very numerous. Capsules
about the size of a pepper-corn. A native of New Jersey,
Virginia, Carolina, and other parts of North America.
An infusion of the dried leaves is used by the common people
instead of tea; particularly in the southern states, where,
from its Indian name, it is commonly called goongee tea.
It flowers from July to October, and from the profusion of
its blossoms is a very ornamental shrub. 2. C. macrocarpus
Willd. 2. Cav. i. 3. p. 38. tab. 276. "Leaves cordate-
rondish, obtuse, three-nerved; corlybms axillary." Fruit
noding, large. Sufficently diffused from the preceding, and
both, in its influence, and its leaves. A native of New Spain.
3. C. mucrophyllus, Lam. Illfl. 2681. "Leaves oblong-
epipetals, dilated toothed, small; petiole terminal, com-
poced of alternate peduncled cymes." Stems about nine
inches high, flender, much-branched. Found by André
Mart. 2. Lam. Enc. 2. Illfl. 2682. Pl. 129. fig. 2. Willd. 3.
(Rhamnus africicus; Poiret in Eneeye. Art. Nerprun. Gouilfa-
Burn. zeych. iii. tab. 48. Kattap; Rheed. Mal. tab.
Fert. prod. 111. gen. p. 33. tab. 17.) "Leaves egg-
shaped, somewhat serrated, three-nerved at the base; pedun-
cles axillary, branched, many-flowered, shorter than the
leaves." Lam. A shrub of a moderate size. Branches fluff,
cylindrical, perfectly smooth. Leaves alternate, obliquely
nerved, veined, smooth. Flowers in axillary racemes; most
of them abortive. A native of the Eait Indies, and the
isle of France. 5. C. reclinatus, Mart. 4. Lam. Illfl.
Hort. Kew. R. venetus; Poir. Enceye. 25. R. inermis;
Swartz. prod. 50. Fl. ind. 1. p. 457. R. arboreocephal;
Brown Jam. 172. tab. 29. fig. 2.) "Leaves egg-shaped,
quite entire; branches dependant; cymes axillary, shorter
than the leaves." Lam. A shrub. The young branches,
petioles, peduncles, and calyxes cloathed with light yellow-
ish down. Leaves alternate, acute; a little villous under-
neath when young; smooth and bright green above.

Flowers in small, axillary corymb; peduncles branched
at the summit into thort, thick pedicels, petals shorter than the
divisions of the calyx, almost linear. A native of Jamaica
and St. Domingo. 6. C. cubensis, Linn. Illfl. 2684.
(Rhamnus cubensis; Linn. Sp. Pl. 8. Mart. 16. Poiret
R. arboreocephal; Brown Jam. 2. p. 176. Arbor baccifer;
Com. Hort. 1. p. 175. tab. 90.) "Leaves elliptical, quite en-
tire; petioles, peduncles, and calyxes cloathed with a ferra-
ginous down." Lam. A tree, twenty feet high in moun-
tain woods; only seven or eight in coppices on the coast.
Branches spreading horizontally. Leaves alternate, acute,
smooth and shining above. Flowers greenish, in short ax-
illary racemes. A native of the West Indies, called by the
French bois couleenre, or frake-wood. In Cuba, according
to Jacquin, the down is stillery, but in the other islands it is
always ferruginous. 7. C. cubensis, Lam. Illfl. 2685.
Willd. 15. Jacc. Hort. 3. tab. 49.) "Leaves egg-shaped,
obtuse, quite entire, wrinkled, tomentous on both sides;
cymes axillary." A small upright tree seven feet high, in
habit approaching to viburnum lantan. Leaves alternate,
petioled. Petals, examined under a magnifier, ciliated.
Cliff. 73. Alaternus; Pluk. tab. 126. fig. 1. Alaternoides;
Comm. prael. 6t. tab. 11. Ricinoides; Sek. Thef. 1. p. 35.
fig. 22. fig. 6.) "Leaves lanceolate, obtuse, serrated; liti-
pules roundish." Lam. A shrub from fix to nine feet high,
evergreen. Branches smooth, reddish brown. Leaves al-
ternate, smooth, flowering, dark green above, on very short
petioles; flippces embracing the item. Flowers small, in
axillary and terminal racemes. Fruit about the size of a
large
large pea, globular, surrounded on its lower part by the calyx, which, having lost its divisions, resembles a little cup. A native of Africa. C. circumcissiflora, Mart. 5. Gart. tab. 106. fig. 4. (Rhamnus circumcissiflora; Linn. jun. Sup. p. 152. Poir. in Ence. 10. Wildl. 32. Lyciun. Pluk. Amst. tab. 426. fig. 3.) *Prickly; leaves nearly opposite, in two rows; prickles solitary, recurved opposite to the leaves.* A shrub. Branches simple, opposite, widely spreading, angular, with an even surface. Prickles solitary, opposite, fixed, horizontal, recurved, permanent. Leaves petioled, irregularly heart-shaped, obtusely toothed; stipules two, very minute, caducous. Flowers small, lateral, in axillary corymbs; pedicels four or five, very short, thick, placed near the summit of the peduncle; calyx campanulate, with five small sharp teeth, which fall off as the fruit advances, and leave the body of the permanent calyx apparently cut round; petals of a beautiful white colour, nearly heart-shaped, ciliated, involving the anthers; filaments a little shorter than the calyx; anthers upright, oblong, style short, permanent; stigma, maroon. Fruit three-celled; Linn. jun. two-celled, two-seeded in the specimens sent to La Marche by Sonnerat. A native of the East Indies and Ile de France. We have followed Garré in referring this plant to the present genus, on account of its having a dry fruit opening with pressure by two or three regular valves, although La Marche has left it under Rhamnus. 10. C. effusiflora, Mart. 5. Lam. III. Forli. Flor. Aufl. p. 18 n. 212. *Leaves ovate-cordate, acuminate, serrated; capsules three-valved.* Forli. A native of Oatheie.

Propagation and Culture. The first species was cultivated in England, by bishop Compton, at the beginning of the last century. It was soon lost, but, in Mr. Miller's time, was re-imported from America, and is now not uncommon in nurseries. It may be raised either from seeds or by layers of the young branches; but the first method is to be preferred. The seeds should be sown in autumn in small pots, which must be kept during the winter in an old hot-bed, and well sheltered from frost, but occasionally exposed to fresh air in mild weather. In March the pots should be plunged into a moderate hot-bed, and when the plants have gained a little strength, they should be exposed in a sheltered situation till autumn, but must be placed under a hot bed frame to screen them from the frosts of the ensuing winter, with a free allowance of open air in mild weather. In the following spring, they should be transplanted before they begin to shoot, come into separate pots, and others into the nursery bed in a warm situation, where they may remain for a year or two, and then be removed to the places where they are designed to remain. They require a dry soil and a sheltered situation; in stiff cold land they put out late in the spring, and their young shoots are consequent ly so full of sap in the autumn, that they are commonly hurt by the first frosts, and die nearly down to the ground. When propagated by layers, the young shoots should be laid down in autumn, and the surface of the ground covered with decayed manure taken from an old hot-bed, to fence them from frost, and to prevent the winds from drying the mould too much in the spring. In a light soil they will put out roots in about a year; but as the shoots are tender, they are apt to rot if they be more than very moderately watered.

The fourth species may be propagated either by layers or cuttings, but requires the protection of the bark-dove.

The seeds of the fifth species should be sown on a hot-bed in the spring; and when the plants are fit to remove, they should be placed separately in small pots, filled with light sandy earth, and treated like other tender exotic plants.

The eighth species is best propagated by cuttings, which should be planted in spring, in pots filled with good kitchen garden earth, and plunged into a very moderate hot-bed. In about two months, if only moderately watered, they will have taken root, and may be treated like the other species. Miller.
which does not seem to be consistent with the tenets of the
cSocratic school. Scornful, he mentions the Peripatetic
school, which arose in Greece long after the time of Cebes;
and, thirdly, he uses several expressions, which, as Meiners
thinks, were not in use among the early Socratic writers.
The learned Brucker, in his account of Cebes, (Hist. Crit.
Philol. t. i. p. 573. ed. 2. 1767,) has made several obser-
vations, which, if they do not entirely remove these objec-
tions, diminish, at least considerably, their force. Some
interpolations have been supplied by the learned to have got
into the text, perhaps from marginal notes in the MS.; and
the passage from which professor Meiners deduces his first
and most important objection, has, with no faint appearance
of evidence, been confided by Fabricius as corrupt and
skeptical. The professor, however, maintains, that this
passage is not closely connected with what precedes and what
follows, that the insertion of any addition or interpolation is
entirely groundless. Be that as it may, all the learned
ancients, with one voice, attribute this philosophical table
of Cebes, and, most certainly, both with respect to beauty of
composition and excellence of matter, it is worthy of the
manner flourishing period of Athenian philosophy and litera-
ture. The editions of this table in various languages have
been innumerable. The first complete edition of it was
published from a MS. in the king of France's library by
J. Gronovius, in 1687. 8vo. It is now usually printed
with the Enchiridion of Epictetus, as a manual for students
Bib. Græc. t. i. p. 591.

CEBESSUS, in Ancient Geography, a town of Asia, in
Lybia.

CEBESTUS, a town of Asia Minor, in Lybia, according
to Quintus Curtius.

CEBRENA, a town of Asia Minor, in the Troade, and
in the country named Cebrenia, a level country below,
and parallel to, Dardania. It is mentioned by Strabo, Thucy-
dides, Plut. and Sevay.

CEBRINUS, a river of Asia Minor, in Cebrenia, men-
tioned by Herodius.

CEBRUS, a place of Lower Lybia, according to the
Itinerary of Antoninus. It was situated to the north-west,
on the right bank of the Damub, below Ritharia, at the
mouth of a river of the same name.

CEBU, in Geography, an island of the East-Indian Ocean.
See ZEBA.

CEBU, SEBO, or SUTO, a river of Africa, in the em-
pire of Morocco, which runs from mount Atlas, through
the provinces of Fez and Algar, and in its course cuts its
way through two deep rocks of prodigious height near
the mountain of Beni-yazga, and falls into that sea near Manor,
a city destroyed by Almanzor, about 20 miles N. of Saller.
The mountaineers convey themselves from one side of this
dreadful wall to the other, by leaping themselves in a
strong balist, that runs by a pulley along a float cable,
which is fastened at both ends to two beams fixed in the
rock, and is drawn by the people on the opposite side; so
that if the balist or any of the tackle chance to break, as
it has sometimes done, by the weight of the passengers,
they fall into the river from a height of above 1500 fathoms.
This river is reckoned the largest in Mauritania, and
abounds with excellent fish, which has been harnessed by the
emperor at above 20,000 ducats.

CECCO, D'ASCOLI, whose proper name was Fran-
cisco de gli Stabilis, in Biography, was born at Ascoli,
about the year 1557; and acquired eminence, according to
the age in which he lived, in poetry, theology, medicine,
and mathematics. By his mechanical skill, he proposed to
the people of Ascoli to bring the Adriatic under their wall,
through an interval of six leagues. He seems to have had
for some time an intimacy with Dante, which was inter-
rupted by his free remarks on the Commedia of that author;
and it is probable that by the severity of his criticisms and
by other parts of his conduct he made himself many ene-
gies at Florence. He was invited to Avignon by pope
John XXII. in order to be his first physician; though his
medical reputation probably depended chiefly on his pro-
posed skill in astrology. In 1322, he was appointed
professor of astrology and philosophy at Bologna, and
there published his "Commentaries on the Sphere of John
de Sacrobosco." An accusation against him before the in-
quisition of Bologna was founded on this work, because he
had taught that Invocation and certain other wonderful feats
might be effected by means of demons inhabiting the sphere;
and the inquisition pulled a sentence enjoining penance, and
depriuing him of the right of ever again reading lectures on
astrology. From Bologna he removed to Florence, and
became astrologer and physician to Charles, duke of Cala-
bria, who governed that city. Here again the inquisition
took cognizance either of his pretended prophecies or heret-
ical opinions concerning the influence of the stars on the
human character and conduct; and the power of his ene-
gies prevailed against him to such a degree, particularly
that of Dino del Garbo, a famous physician, who had
attacked his commentaries, and who was probably jealous of
his influence at court, that he was capitally condemned
and brought to the stake at Florence in 1337. Dino himself
died a few days after, distressed by the reflection that he had
been instrumental in promoting this cruel event. Cecco
was vain, fraudulent, and superstitious, and licentious in his
practice. Besides the commentaries which occasioned his
condemnation, he wrote a poem in Sylvia, called "L'acerba,"
which was a medley of physics, morals, theology, and judicial
astrology, without much poetical merit; and yet the temporary
reputation of the author caused it to pass through 19 editions;
and the last year of its publication was 1546. Tarabosteh.

CECIL, William, lord Leithage, an eminentstates-
man, was son of sir Richard Cecil, master of the robes to
Henry VIII. and was born at Born in Lincolnsire in 1520.
from St. John's college, Cambridge, where he completed
his education, he was removed to Gray's-Inn, for the study
of the law. In consequence of a dispute with two Irish
priests concerning the power of the pope, which he con-
ducted with credit, he was introduced to the king; who
conferred upon him the reversion of the place of "Culfos
Brivium"; and he was then encouraged to push his fortunes
at court. His first wife was the sister of sir John Cheke, who
recommended him to the favour of the earl of Hertford,
afterwards so powerful in the reign of Edward VI. under
the title of the duke of Somerset. Soon after the com-
 mencement of that reign, having left his lady, he married
the daughter of sir Anthony Cook, director of the king's
studies; and thus supported, he rose in 1548 to the post of
master of requests, and in 1548, to that of Secretary. Some
court intrigue occasioned his loss of this place, and his being
committed, with some others of the duke of Somerset's
friends, to the Tower; whence, however, he was soon liber-
ated. In 1551, he was reinstated in his office, with an in-
crease of favour, knighted, and sworn a member of the privy
council. So wary was his conduct amidst the collis-
ion of parties, that he fled secrer when his patron, the
duke of Somerset, fell; and such was his personal influence
with the young king, that the haughty duke of Northum-
berland treated him with respect. Upon the death of Ed-
ward he pursued the fame cautious conduct, and thus secured a favourable reception from queen Mary; but refusing to change his religion, he forfeited his office. In 1555, he attended Cardinal Pole and other commissioners to the conclave in order to treat of a peace with France. On his return, he was deputed to parliament by the county of Lincoln, and distinguished himself by his opposition to a bill brought in for confining the estates of fugitives or account of religion. His prudent counsels were also of singular service to the princess Elizabeth in her critical situation; and they were duly acknowledged on her accession in 1558, when, in the arrangement of her first ministry, he was appointed privy councilor and secretary of state. The settlement of religion was one of the first acts of the new reign, in which Cecil took the lead, and in which he manifested great prudence and moderation; and in the recovery of the coin from its debased state he also successfully engaged. With regard to foreign affairs, it was his great object to guard against the dangers impending from the catholic powers; and with this view he thought it of great importance effectually to guard the reformed religion in Scotland. As he was one of the commissioners who accomplished the convention of Leith and the treaty of Edinburgh, which were eminently advantageous to the English interest, he was advanced, in recompense of this service, to the post of master of the wards in 1561. His systeim of politics, which was prudential and cautious, corresponded, in a considerable degree, with the inclinations of his mistrels; and he thus maintained a regular and permanent influence through the whole of his ministry. For his wisdom and activity in suppressing the northern rebellion, he was raised by Elizabeth to the peerage in 1571, by the style of Baron of Burleigh, and in the following year he was made knight of the garter and lord high treasurer. His lenient and clement opposition to the machinations of the papist party, drew upon him the rancorous hatred of the Jihuits, and emissaries of Spain; and their rancour was further inflamed by the part he took in the unhappy fate of Mary, queen of Scots; whom he is charged with having driven from the throne, and kept as a prisoner in England, and whom he considered as the invertebrate foe of Elizabeth, so that he never ceased urging her trial and condemnation. Burleigh shared with other actors in the catastrophe of her execution the stained remembrance of Elizabeth, and it was with some difficulty that he recovered his former credit. At the time of the threatened Spanish invasion, he drew up the plans of defence, and his eldest son served on board Lord Howard's fleet. Soon after this period he sunk into a state of melancholy, in consequence of the death of his wife, to whom he was affectionately attached, and wished to withdraw from public business. However, he was persuaded to retain his employments, and he was diligent to the last in fulfilling the various duties of his station, so that he was regarded as at the head of Elizabeth's councilors. One of the last services in which he engaged was an effort to bring about a peace with Spain; but being vehemently opposed in his proposed scheme of pacification by the earl of Essex, he contented himself with pointing out to his lordship in a prayer-book the following words, "Men of blood shall not live out half their days." Having attained an honourable age, Lord Burleigh died in 1588, after having completed his 77th year. Cecil may be justly reckoned the animating soul of queen Elizabeth's ministrv, and to his counsels may be attributed, in a very great degree, the singular prosperity of that period in the history of our country. Possessing no distinguished genius, he had other qualities, such as the knowledge of mankind, the wisdom of experience, invincible resolution and indefatigable application, which qualified him for encountering the difficulties and performing the services, which the critical circumstances of the times presented. Particular emergencies demanded corresponding measures of policy; and it must be allowed, that they offer an apology for some of those adopted by lord Burleigh, who always approved himself a faithful servant of his royal mistress. In his character as a courtier he combined that degree of probity which could not infrequently be found in him, of that learning, piety, and decorum, which in that age usually accompanied elevated stations. His manner of living was splendid and yet economical; and though he raised a considerable fortune, it was by no means greater than the various ports which he occupied might justify. His whole life was that of a busy statesman; and therefore he had not much leisure for literary avocations. However, he is said to have been the author of a few Latin verses, and of moral and historiical tracts. Several of his letters on buisines are still extant. Diog. Brit.

CECIL, ROBERT, earl of Salisbury, was the second fon of the former, and born about the year 1550. As his constitution was feebler and his form distempered, he received the first rudiments of learning at home, under his learned mother and an excellent tutor, and finished his education at St. John's college, in the university of Cambridge. By his father, however, he was instructed in the arts of an accomplished courtier and statesman. He began his political career as attain'd to the earl of Derby, embassador at the court of France, and in 1595, was appointed by queen Elizabeth second secretary of state with Sir Francis Walsingham; and when that minister died, he became principal secretary, which post he occupied as long as he lived. He acquired also other offices of profit and honour, for which he seems to have manifested a greater degree of industry than his father. His advancement, indeed, was enormously opposed by the earl of Essex; and for this reason he was a principal instrument in the disgrace and unfortunate end of that eminent nobleman. By the regular correspondence which he attentively maintained with foreign courts, he was enabled to counteract and defeat many conspiracies against his sovereign and his country. Whihl he contributed to support the declining years of Elizabeth by his vigour and prudence, he was not regardless of the favour of her successor. Accordingly he held a secret correspondence with him, and adopted the necessary measures for his quiet inheritance of the crown at the queen's demise; and for these services he was continued as prime minister at the acception of James; who advanced him to the peerage; creating him baron of Efiffden in 1623; viscount Cranbourn in 1624, and earl of Salisbury in 1625. In this last year he was appointed chancellor of the university of Cambridge, and admitted to the order of the garter. His politics were altogether adverse to the Spanish interest, which was powerful at court; he steadily opposed the papist party, and placed himself at the head of the protestant cause, in much that he was reproached with the appellation of puritan. He was indispensably necessary to James; and therefore, though the king did not love him, he was chosen, in 1609, as the fittest person to succeed the lord high treasurer, the earl of Dorset, at his death. The king's profession rendered his post very delicate and trying; and in order to fulfil the royal office, he is said to have had recourse to various methods that have been deemed arbitrary and opprobrious. The good of the nation was, however, the object at which he aimed; and he justly merited the praise of the ablest minister in that reign. By his application to business, he injured his health; and as he had a weakly constitution, his life terminated by a decline, in 1612. He died at Marlborough in his return fromloth, and was buried...
buried at his magnificent seat at Hatfield in Hertfordshire; which manor he had obtained from the crown, in exchange for his seat of Thetford near Cheffam.

Lord Salisbury is characterized as a man of more subtle and acute genius than his father; and he was thus led, as some have said, to pursue a more crooked and treacherous system of policy, so that those who were concerned with him in public affairs could repose no confidence in him. The death of Sir Walter Raleigh is a great degree charged upon him; and he is also reproached with having adopted arbitrary maxims of government, in order to gratify himself with his weak mullet. He was also selfish and avaricious in making lucrative bargains with the crown, and thus aggrandizing his own fortune. His natural temper was mild, gentle, and courtly; and though in the height of power, he met death with philosophical tranquillity. "Easie and pleasant," said he in his last illness, "quae to hear of death; but my life, full of cares and miseries, deitribre to be dissolv-ed."

As a writer, he was the author of a work against the papists, of several letters, dispatches, and parliamentary speeches, and of some notes in Dr. Dees discourse on the reformation of the calendar. Biog. Brit.

Cecil, in Geography, a county of America, in the state of Maryland, situated on the shore of Chesapeake-bay, and containing, by the estimate of the population in 1792, 77,949 inhabitants. — Also, a township of Washington county in the state of Pennsylvania.

Cecilia, Saint, in Biography. Musical historians have found it very difficult in the lives and legends of saints, to authenticate the claim which this holy personage has to such divine honours and annual celebrations from the wicked foes of Apollo, the divinity whom she had abandoned.

It was natural to expect to find in the "Legenda Aurea" of Jacobus Januensis, and in Chaucer's account of this saint in his second "Nonestale," that some mention would have been made of her musical powers and promise of protection to the art; but neither in Chaucer, nor in any of the histories or legendary accounts of this saint, which we have been able to consult, does any thing appear that can authorize the religious veneration which the votaries of music have so long paid to her; nor is it easy to discover whence it has arisen.

Chaucer's account is almost literally translated from the life of St. Cecilia, in the "Legenda Aurea" of Jacobus Januensis. Bede, in his Ecclesiastical History (lib. v. cap. 2), mentions her church at Rome, as the place where Vitaliod was ordained pope in 666; and in his Martyrology, he tells us, that her intended spouse, Valerian, and his brother Tiburtius, suffered martyrdom in the time of the emperor Alexander Severus. Mabillon (De Liturgia Gallicana, p. 175.) has proved, that the festival of this saint was celebrated in France before the time of Charlemagne, by a Gallican Mifiai, which he has published, and which must have been in use before the Gregorian chant was received in that country. (Cardinal Bona, "De divina Poffition," says, that the MS. of this mass, which was in possession of the late Chirifina, queen of Sweden, had belonged to the learned Petrusius, and was written in the 6th century, as it was discovered by the learned from the square form of the letters, and the capitals.) Fortunatus of Potiers (lib. vii. cap. 4.), the most ancient author who speaks of her, says, that she died, or rather suffered martyrdom in Sicily. Fortunatus wrote at the end of the 6th century; but even this was at too remote a period from that in which tradition tells us the saint lived, as Alexander Severus reigned from 194 to 211.

There was a great festival at Rome in 1599, during the pontificate of Clement VIII., for the finding the body of St. Cecilia among other relics. Cardinal Baronius, who was himself a witness of this translation, has left an ample account of it. (Voyez la Vie de Saints, tom. 51. 3 edit. fol. p. 60, Par. 1715.)

The earliest notice of her as the titular saint and protector of music seems to have been in the works of the great painters of the Italian school, some representing her in performing on the harp, and others on the organ. Raphael, in his celebrated portrait of the saint, has placed in her hands a column of organ pipes, or rather the front of a portable instrument called the "Regale," which in Roman Catholic times used to be carried by one person and played by another in processions. But when her birth-day first began to be celebrated by assemblies of musicians, we have been able to discover no instance earlier than the latter end of the 17th century, when there was a rage among the votaries of music for celebrating the birth-day of this saint, not only in London, but in all the considerate cities and provincial towns in the kingdom where music was cultivated.

We meet with no such constant annual celebrations of this feast on the 2d of November in other countries. In the "Dramaturgia" of Leo Allatius, indeed, 13 dramas, tragedies, and oratorios are recorded, of which this female saint is the heroine.

The first composition expressly produced for a music meeting in England on St. Cecilia's day, was called "A musical entertainment performed November 22d, 1683, on St. Cecilia's day," printed in score by John Playford, with a dedication to the gentlemen of the musical society, and particularly the stewards, written by Henry Purcell, composer of the music."

But whoever wishes to trace the celebration of this pious patroness of music in our country from this period, will find an ample account detailed in the life of Dryden, by the diligent and accurate Mr. Malone, who has not only gone over the same ground as the musical historians, but taken a much wider range in search of materials for the life of this saint, and the honourable titles conferred upon her by the sons of Apollo.

The history of this nominal patroness of music is involved in some obscurity, it not very clearly appearing how she became entitled to this honour. She is supposed to have been born in the reign of the emperor M. Aurelius Antoninus, and to have suffered martyrdom in that of Septimius Severus, in the beginning of the third century; and, according to the legend, she was a noble Roman lady of distinguished piety, who from her infancy had been bred in the Christian faith; notwithstanding which, she was married by her parents to a young Pagan nobleman, named Valerianus, who, on claiming the rights of a husband, was told by her, that she was venerated nightly by an angel, who was enamoured of her, and would destroy him if he presumed to approach her. He replied, that he would do it, if he were permitted to behold his rival, and he should prove an angel; but if he were a mere mortal, as he feared, he would put them both to death; to which Cecilia answered, that he should be indolent in what he desired, provided he became a convert to Chrifianity. To this requisition Valerianus agreed; and after having been baptized by bishop Urban (afterwards pope Urban I.), repaired to his wife's chamber, where he found her at prayer, with the angel by her side, in the form of a beautiful youth, clothed with celestial brightness. The angel had in his hand two crowns, or wreaths, the one of lilies, the other of roses, which he had brought from Paradise; one of them he presented to Cecilia, and the other to her husband, informing him at the same time, that as a reward for his piety, whatever he asked should be granted him. Valerianus replied, that he had a brother named Tiburtius, whom he wished to be made par-

Cec
taker of the same grace which he had received. The angel having granted his request, told him that they both should be crowned with martyrdom; and then vanished. They accordingly were put to death for their faith; but Cecilia was informed, that she should be spared, if she would offer sacrifice to Jupiter. Not choosing to preserve her life on such conditions, she suffered martyrdom, by being flung up in a dry bath, beneath which a large fire was made for the purpose of slowly consuming her. (According to other accounts, she was thrown into boiling water. Fortunatus of Poitiers, who lived in the sixth century, says, the sufferer martyrdom in Sicily.) Finding, however, that the fire had no effect, her tormentors put her to death. Malone's Life of Dryden, vol. i. pt. tit. p. 255.

"If (says Mr. Malone, as Dryden and others seem to have thought, she had been the inventress of the organ (obi supra, p. 257) an instrument to happily adapted to religious worship, that circumstance might have entitled her to a place, though not to so extraordinary an elevation, among the improvers of the musical art.

All this adoration of the faint seems "to have arisen from a tradition that she was a skilful musician, and that the angel who visited her was drawn from the mansions of the blessed by the charms of her melody; a circumstance to which Dryden has alluded in the conclusion of his ode."

Mr. Malone has been at the trouble of tracing all the great Cecilian festivals held in London, from the year 1683 to about the year 1743. And Mr. M. in his very agreeable book has given a chronological list of all the odes written expressly for the celebration of this faint, specifying by whom they were written, and by whom set to music.

Cecilia, in Ancient Geography, a town of Syria, near the Euphrates, according to Ptolemy; probably the same with Ceciliana.

Cecilia Gemellina, a town placed by Ptolemy in Lusitania; perhaps the same with Ceciliana, or Cairo Cecilia.

Cecilian, a town of Alia in Syria, seated on the western bank of the Euphrates, S.E. of Hierapolis.

Cecilonicum, a place of Spain, marked in the Itinerary of Antonine, between Capara and Ad Lippus.

Cecina Fluvius, a river of Italy in Etruria, which ran from the coast to the well and discharged itself in the sea.

Gen. Ch. Malo. Calyx common. Spathe egg-shaped, burbling, caduous; containing many fusculated, cylindrical aments, imbricated with numerous flowers. Cal. proper. Scales top-flapped, compressed-quadrangular, obtuse, with a double perforation at the tip. Cor. none. Stam. Filaments two, capillary, very short, from the perforations of the scales; anthers oblong, quadrangular. Female. Cal. common. Spathe oblong, obtuse with a point, burbling longitudinally, deciduous; containing four cylindrical, imbricated aments. Cal. proper funnel-flapped, oblong, erect, bifid at the tip; segments roundish, obtuse, concave, erect, small. Cor. none. Stam. none; but there are two very small, caduous bodies on the divisions of the calyx, which have the appearance of barren anthers. Pist. Germs numerous, imbricated, compressed, quadrangular, obtuse; styles solitary, very short; stigma somewhat capitate, lacerated. Peric. Berry the form of the germ, one-celled, one-seeded. Seeds oblong, compressed.

Sp. C. peltata, trumpet-tree, or snail-wood; Linn. Sp. Pl. Lxxiu. n. 272. Jacq. Obf. 2. tab. 46. fig. 4. Amer. piæt. 126. tab. 262. fig. 66. (Ambaba; Marq. bras. 91. Pfl. brus. 147. Yaroum Oviedi; Sloan jan. tab. 88. fig. 3. tab. 89. Ficus furaminata; Pluk. alh. tab. 243. fig. 5. C. ilotapalus; Brown jan. n. 1.) A tree, about thirty feet high. Trunk a foot in diameter, hollow, flapped from space to space with membranous flaps, which form wing, annular marks on the surface, branched only at the summit. Leaves in clusters at the ends of the branches, large, peltate, green and seafellow above, downy-white underneath, deeply divided into nine or ten oblong lobes, on long petioles. Berries in flavour somewhat resembling the common raspberry.

The wood when dry easily takes fire by attrition; and is employed by the native Indians for kindling their fires in the woods. The bark is strong and fibrous, and used for cordage. The smaller branches, when cleared of their membranous divisions, are employed for wind instruments. Both trunk and branches yield a great quantity of fixed fat, with which the French distill and granulate their sugars. A native of the West Indies, Guiana, and other parts of South America. It may be propagated by seeds brought from its native country in sand, and requires the same treatment as other tropical plants.

Cecropia, in Ancient Geography, one of the first names given to the citadel of Athens, and also to the whole city. See Athens.

Cecropia, a burgh of Greece in Attica, between Mount Cegalus and the village of Acharnes, according to Thucydides. A tribe of the same name belonged to it.

Cecropius Mons, a name given by Seneca the tragedian to a mountain of Greece, in Attica, in the vicinity of Athens; probably the eminence on which was erected the Acropolis, which afterwards bore the name of Cecropia.

Cecrops, in Biography, the first king of Athens, whose holy life ascends into the fabulous times, is said to have been an Egyptian by birth, and to have brought a colony from the city of Sais in Egypt, whom he conducted after a tedious voyage to the shores of Attica, and settled on the rock, that became afterwards the site of the city of Athens. The period to which this point is referred is, according to the Egyptian chronicle, about 1556 years B.C. On this spot Cecrops built a fortres, called Cecropia; and having taken possession of a country inhabited by a barbarous people, divided it into districts, introduced laws, agriculture, and the arts, social polity, and religion; and, on this account, deserved to be reckoned the founder of the Athenian state. Such was the beneficial effect of the regulations which he established, that Attica was soon peopled by 20,000 inhabitants, who were divided into four tribes. From respect to his memory, the Athenians affirmed the appellation of "Cecropides," which they retained to the time of Erechtheus. Cecrops died after a reign of 50 years. He had espoused Agraulis, the daughter of Aegeus, one of the principal inhabitants of Attica, by whom he had a son, who died before him, and three daughters to whom the Athenians afterwards decreed divine honours. His tomb was long preferred in the temple of Minerva; and his memory was perpetuated in the foundation of Aquarius, which was consecrated to him. After Cecrops, reigned 17 princes, during an interval of about 565 years, the seventh of whom was called Cecrops, and the last Codrus. Travels of Amacharys, vol. i. See Attica.

CECRY-
CECYPHALEA, in Ancient Geography, a prominent of Peloponnesus, near which the Athenians gained a naval combat against the Eginetans, according to Diodorus Scullus and Thucydides. This has been tempered to be the site of Cecypaethus, which Pliny has placed near the Peloponnesian Epitaurus. Part of the sea which bathed the island and prominent of this name was called "Cecypaethos mare."

CEDAR, Barbados bearded, in Botany. See Cedrela.

CEDAR, bardard. See Bueronia Guineana.

CEDAR, Bearnian. See Juniperus Bemudiana.

CEDAR, Carolina. See Juniperus.

CEDAR of Lebanon. See Pinus Cedroides.

CEDAR, Lyrian. See Juniperus Lyra.

CEDAR, Phenician. See Juniperus Phoenicia.

CEDAR, red, or Virginian. See Juniperus Virginiana.

CEDAR, white. See Cupressus Thyoides.

CEDAR, or Kedar. In Ancient Geography, a portion of Arabia, near Judea. The Arabs in this district had black tents. See the Song of Solomon, ch. 1, ver. 5.

CEDAR, in Geography, an island of America, on the coast of Virginia. N. lat. 37° 57'. W. long. 76° 43'.

CEDAR, a river of Canada which runs into the lake Michigan. N. lat. 47° 36'. W. long. 86° 57.'

CEDAR, a lake of North America. N. lat. 52° 30'. W. long. 100° 5'. The entrance into this lake is through a small channel on the left, formed by an island. Banks of rocks appear at intervals, in the approach to it on either side; the rest of the country is low. This is the cote along the fourth bank of the lake and the islands, which is the north is level throughout. This lake runs first west four miles, then as much more W.S.W. across a deep bay on the right, then five miles to the Point de Livre, and across another bay again on the right; then N.W. 6 miles across a still deeper bay on the right; and 7 miles parallel with the north coast, N.N.W. through islands, 5 miles more to Fort Bourbon, situated on a small island, dividing this from Mud lake. The Cedar lake is from 4 to 12 miles wide, especially of the bays. Its banks are covered with wood and abundant in game, and its waters produce plenty of fish, particularly the sturgeon. The river Saltkatchewi will probably, in a course of time, by the depopulation of earth and land, convert the whole of the cedar lake into a forest.

Mackenzie's Voyages, Intro. p. 68.

CEDAR, cast, a fall spring in the state of Tennessee, America, 19 miles from Nashville, 4 from Big Spring, and 6 from Little Spring.

CEDAR, Point, a port of entry in Charles county, Maryland, on the coast side of Patowmac river, about 12 miles below Port Tobacco, and 60 by W. of Baltimore. Its exports are chiefly tobacco and Indian corn, and in 1704 amounted in value to 15,393 dollars. Also a cape on the west side of Delaware bay, in St. Mary's County, Maryland.

CEDAR-cups, a sort of wooden ware brought from the West Indies. They are made out of the wood of the bastard cedar, and appear of a very close and firm grain; but they are really so porous, that when any liquor is poured into them, it runs out at the bottom.

CEDEBRATUS, in Ancient Geography, a town of Asia Minor in Lydia.

CEDEYRA, in Geography, a town of Spain, in the province of Galicia; 5 leagues north of Ferrol.

CEDIAS, in Ancient Geography, an episcopal town of Africa.

CEDILLA, in the Spanish and French languages, denotes a sort of small $, to the bottom of which is affixed a kind of virgula, as $, to denote that it is to be pronounced like $.

CEDOGNA, in Geography, a town of Naples, in the province of Principato Ultra, the site of a bishop, fullranged of Conza, at the foot of the Appenines, in a decayed state: 12 miles N.W. of Melito.

CEDRELIA, in Ancient Geography, a town of Asia Minor in Caria. Steph. Byz.

CEDREI, CEDRENS, or CEDERNIANS, a people of Arabia Deferta, in the vicinity of the Nabateans, mentioned by Pliny. They dwelt in tents, and commonly occupied the southern part of Arabia Deferta, north of Arabia Petraea and Arabia Felix.

Gen. Ch. Col. Perianth one-leaved, campanulate, very small, fattedoth, withering. Cor. petalopalous, funnel-shaped; tube belted below; petals linear-oblong, obtuse, erect, adnate to the receptacle a third of their length. Stam. filaments five, awl-shaped, seated on the receptacle; shorter than the petals, adnate to the receptacle. Lam. short, culitise. Jull. united into a tube half their length. Vent. : anthers oblong, bent outward at the tip. Pet. Receptacle proper, five-corned; germ globular, (elevated on a yellowish receptacle which rises within the flower. Lam. placed at the top of a flaps which has the flaments inserted into its upper part and the petals into its lower, Jull. supported by the tube formed by the union of the flaments, Vent.) style cylin- drical, the length of the flaments; stigma capitulate, de- pressed. Peric. capule woody, roundish, five-celled, five-valved; valves deciduous. Schreb. Lam. (dihcuteent from the tip, fixed at the base, not ceduceous, Gert.) Seeds numerous, fleshy, imbricated downwards, terminated by a membranous wing. (Compressed; upper ones elliptical; middle ones oblong-ovate; lower ones obovate-lanceolate; all of a ferruginous-cinnamon colour, with a ruellus at the top, and a membranous wing beneath, Gert.) Receptacle central, very large, woody, pentagonal, five-angular.

Sp. C. odorata, Linna. Sp. Pl. Brown. Jam. tab. 10. fig. 1. Lam. III. 313. (Cedrus barbadeniun, Pluk. aln. tab. 155. fig. 1. Pruno forte affinis. Sloan Jam. 162. hilm. tab. 225. fig. 2. Acasajoyer apalanches, Nicol. St. Dom. p. 15.) "Flow- ers paniced." "A straight tree feventy or eighty feet high. Wood folt, light, reddish, of a pleasant smell; bark smooth and ash-coloured when young, rough as it advances in age; having, when fresh, an unpticatle taste and very offensive smell resembling that of affodita. Leaves sometimes near the foot long, wings with fifteen or eighteen pairs of leaves without an odd one, with a smell like that of the bark. Flowers whitish flesh-colour, small, very numerous, in much-branched racemes or panicles: branchlets alternate,
in embalming was forced out of it by fire, and called in Syria corium. His words are, “Cuius tanta vis ebullit in Egypto corpora hominum defunctorum co perfusa ferventur.” Diodorus calls it the life of the dead, ropa man. See Phil. Trans. vol. iv. p. 12.

CEDRINUM (Tremus), cedar wine; of which there are several sorts, whose qualities are said to be heating, ductile, and gently adjointing; but the laurusmum, or bay-tree wine, is remarkably heating.

CEDRIPPA, in Ancient Geography, a place of Spain, in Betic.

CEDRIS, a river of Sardinia, which flowed towards the East into the sea.

CEDRON, or Kedron, a town of Palestine, on the borders of the Philistines, in the way to Jerus. It was rebuilt by Cæcubens, according to the book of the Maccabees.

CEDRON, Kidron, or Kedron, a brook or torrent of Palestine, in a valley on the east side of Jerusalem, buttwixt it and mount Olives, which discharged itself into the Asphaltite lake. Our blessed Lord passed over this brook into the garden where he was betrayed. (John, xvi. 1.)

David also, when he fled from Absalom, crossed this brook, (2 Sam. xxv. 27.) See also Jer. xxxi. 40. Jerome calls it a torrent or valley, and Josephus denominates it a deep valley. Into this valley was conveyed the blood poured out at the foot of the altar, which, as the blood made the river look black, derived its name from this circumstance, the word "Kidder," denoting blackness. Others deduce its name from the cedar-trees planted on each side, whence, say they, it is still named in the plural, as by the LXX, (Jer. xxxi. 40.), in cepha, from these cedar-trees.

CEDRONELLA, in Botany, Comm. Hort. See Dracaena.

CEDROPELUS, in Ancient Geography, a country of Thess, where, according to Aristotle, they trained hawks for the chase.

CEDROSIAS. See Cedrosia.

Sp. C. guianensis, Mart. Wild. (Aniba guianensis, Aubl. Gen. tab. 126. Lom. Illust. fl. 268.) A tree, forty feet high, two feet thick. Wood yellowish, aromatic, heavy when green, becoming light when dry; bark thick, unequal, wrinkled, full of clefts. Branches near the top of the trunk, numerous. Leaves about seven inches long, two broad, either opposite, or in whorls of three or more together, oval-acuminate, entire, thin, smooth, on short pedicles. Flowers small, green, loosely racemed, on a long, weak, axillary peduncle; pedicels slender, generally bearing three sessile flowers. A native of the forests of Guiana. The inhabitants call it cedar-wood, and use it for making their pipes. It is said also to be fit for nails.

CEDRUS. See Cedrela, Juniperus, Pinus, and Swietzria.

CEDRUS, or CEBRUS, in Ancient Geography, a small river of Myia, according to Dion Callus.

CEESTER, in Geography, a town of Germany, in the duchy of Holstein; 12 miles W. of Pinnenberg.

Vol. VII.
CEI

CERESTER-MHlle, a town of Germany, in the duchy of Holstein; 13 miles W. of Pinnenberg.

CEFALENSIS, in Ancient Geography, an episcopal see of Africa, in the Proconulinar province.

CEFALU, in Geography, a sea-port town of Sicily, in the valley of Demona, on the north coast of the island, the site of a hilltop, the ruins of Messina. The harbour will not contain more than 30 or 40 vessels. The number of inhabitants is about 5000; 14 miles E. of Termini. N. lat. 38° 5' E. long. 14° 5'.

CEGINUS, in Astronomy, a fixed star of the third magnitude, in the left shoulder of Bootes, marked γ by Bayer.

CEGLIA, in Geography, a town of Naples, in the province of Bari; 5 miles S.S.E. of Bari.

CEGLIAE, in Natural History, a name by which some authors have called the lapis Judaeicus, or Tegolis of the ancients.

CEILOTL of Ray, in Ornithology, the Mexican pigeon, celebrated by Gmelin under the title of columba mexicana, which fee.

CEIBA, in Botany, Plut. tab. 32. See Bombax celiu.

CEILA, or KEILAH, in Ancient Geography, a city of Pala
tine, in the tribe of Judah. Joshua, xv. 44. It was attacked by the Philistines in the time of Saul; but refused by David. Eueelius places it 17 miles from Eileutheropolis, on the side of Hebron. Szechmen says, that the tomb of the prophet Habakkuk was found in this place.

CEILANEOSE GODS. See Budn and Sarrade-wenda.

CEILING, in Architecture, the upper part or interior covering of any room or apartment.

Ceilings are in general composed of a coating of laths and plASTER, or flucco applied upon the under side of a vault or timber framing; accordingly they are either flat or coved in various manners; they are also either plain or ornamented. The usual method of ornamenting ceilings is to dispose them into compartments or panels forming various geometrical figures, either flat or into the ceiling, or being flush with its surface, and surrounded with one or several moldings. The compartments frequently receive ornaments of various kinds, foliage, figures, or grotesques, and executed in relief with flucco or plaster, or painted in colours, or chiaro oscuro. Thus the ceilings have frequently constituted the greatest ornament of palaces, and other splendid buildings, and have employed the talents of the greatest artists.

In England, the custom of ornamenting ceilings has greatly declined, and indeed is fearely at all practised in private buildings. The use of an inferior covering to the flooring-timbers of a house is considerable, as it preserves a greater equality of temperature in the apartments, and prevents the transmission of sound from one story to another. These advantages are so well understood in this country, that we see none but the oldest and meanest habitations unprovided with plaster ceilings.

Ceiling, in Sea Language, denotes the inside planks of a ship.

CEIMELIA, from κειμέλιον, to lie lat' up, in Antiquity, denotes choice, or precious pieces of furniture or ornaments, reserved or laid up for extraordinary occasions and uses.

In which sense, sacred garments, vellies, and the like, are spoken of the ceimela of a church. Medals, antique figures, manuscripts, records, &c. are the ceimelia of men of letters.

CEIMELIARGHUM, the repository or place where ceimelia are preferred.

CEIMELIOPHIALAX, from κειμελιόπηλαξ, τος, the keeper or curator of a collection of ceimelia; sometimes also denominated ceimelarchi.

The ceimelarchi, or ceimelosphialax, was an officer in the ancient churches or monasteries, answering to what was otherwise denominated chartophylax, and &iopis archibiborum.

CEINTURE, MILITIARE, a military cincture, girdle, belt, or loath. This term, however, has been generally employed to denote a broad leather belt, which was worn round the waist, and was ornamented with gold and silver plates. The chevaliers put on in even jewels and precious stones, as is manifest from the representations of their chevaliers on ancient tombs and monuments. These cinctures must have fatigue them, and particularly their sides, and much have required good handles to support them, when furnished with all their military appendages and trusses; for there were attached to this cincture the two swords for combat, the great epees, or rapier, and the bracquier, or strong short cutting sword; as also the shield or buckler, when the cavaliers were not in the act or attitude of fighting.

The marshal de Bourgogne, in 1441, left by his will to the church of St. Vincent de Chalons two cinctures, one of gold and the other of silver, to be wrought up into sacred vases. These ferts of cinctures, which ceased to be in use after armour of hammered or beaten iron made its appearance, constituted part of the cavalier's armament of honour.

The armament d'honneur, or armament of honour, consisted of those pieces of a warrior's armament, to the loss of which shame or disgrace was attached. A cavalier who lost through cowardice or misconduct in battle his sword or his buckler, was disgraced or dishonoured. Dishonour was equally attached to his losing his military cincture.

The conqueror in disposing his adversary of his cincture thereby manifested a complete victory over him. It was the mark or token of liberty as long as it was carried by one under arms, to which it was very that of servitude or slavery succeeded. For he who deprived another of it had power or authority to bind him with it.

Honour was so much attached to the military cincture, that the grand fiers took it much delight in enriching them, and among the other ceremonies observed at the degradation of a chevalier, that of depriving him of the cincture was one.

Cinctures were in use before the time of Charlemagne. A young chevalier, on first taking that ornament, received it from the hands of an old one. The ceremony observed on such an occasion was a sort of introduction to the profession of arms. When cinctures came to be laid aside, they were succeeded by silies, bands, and bandoliers.

CEINTURE, in Ornithology, the French name of the yellow lark, Alauda flavus. Ceinture de prêtre ou alunoz de Sibérien, Buffon. The plumage of this bird is rufius, varied with fuscous grey above; beneath white; front, chin, and throat yellow; tail-feathers black, edged with grey; the exterior ones edged with white. Length five inches and three quarters. Inhabits Siberia, and is very rare.

CEINTURE d'argent, in Ichthyology, the name given by French authors to the fish called by Linneus Thaenius lepturus, which see.

CEINTURON, a waist-belt generally of leather, which succeeded the bandier, or shoulde belt, and was smaller and lighter than it. The cinturon a d bandier have, indeed, at times, replaced each other. The shoulde-belt is most common, and certainly gives the folder a more military and graceful appearance than the waist belt.

CEIRI,
CEIRA. in Ancient Geography, a cavern in the country of the Getæ, in the vicinity of the Danube. Dion Cassius says, that Caestius stopped the avens of this cavern in order to compel the inhabitants of the country who had taken refuge in it, to surrender.

CEIRA, in Geography, a town of Portugal, in the province of Beira; one league S.E. of Coimbra.

CEIRA, a river of Portugal, which runs into the Mondego, about a league S.E. of Coimbra.

CEIXUPIERA, in Ichthyology. The fish described by Mareograte under this name cannot easily be ascertained from the account left us by that writer. He says it is a native of the American seas, and is esteemed a fine and delicate fish, though of an enormous size. Its growth to nine or ten feet long, and to the thickness of a man's body, but is chiefly eaten while young. The body is oblong; and the head flattened. The mouth is small for the size of the fish, and it has no teeth in the jaws, but the whole mouth is thickly set with small tubercles. Its back and sides are black, and the belly of a fine bright white. Its fins are all black except the belly ones, which are white, with a rim of black at their edge.

CEIZERIAT, in Geography, a town of France, in the department of the Ain, and chief place of a canton in the district of Bourg. The place contains 1106, and the canton 8865 inhabitants; the territory comprehends 140 kilometres, and 14 communes.

CELADON, in Ancient Geography, a small river of Peloponnesus, in Arcadia; which had its source in Mount Lycon, and discharged itself into the Alpheus, according to Pausanias.

CELADONE, a town of Greece, in the Locride.—Allo, the name of a small river of Spain, called also Celadus or Celandus.

CELADUSA, one of the names of the small island of Rhenea, situated in the vicinity of that of Delos.

CELADUSSE, an island of the Adriatic Sea, mentioned by Mela and Pliny.

CELÆNE, a large town of Aetia, in Phrygia, where Cyrus had a palace and a park filled with wild beasts. The river Meander traveled this town, and also the Marisias. Xenicles retired to Celaena after his defeat, and built the castle and fortresses. Xenophon mentions this city. Cyrus the younger sojourned here 30 days, and was joined by Clearchus, when exiled from Lacedæmon.—Allo, a place of Greece, on the confines of Attica and Boeotia. Sinsus.

CELÆNUS, a mountain of Aetia, placed by Ptolemy in Galatia. It was also called Celenus tumulus.

CELAMA, a village of Africa, in Mauritania Caesariensis. It lay in the interior of the country, S.W. of the grand promontory, and S.E. of Artigata.

CELANIDINE, in Botany. See Chelidonium majus.

CELANDINE. See Ranunculus ficaria.

CELANTINE tree. See Bocconia.

CELANO, in Geography, a town of Naples, in the province of Abruzzi Uitra, seated near the north shore of a lake of the same name, and the head of the earldom that comprehended at one time the greatest part of the country of the Maris. This was the ancient name of the people that inhabited the environs of the lake, allowed by the Romans to be the most intrepid soldiers of their legions, when in friendship, and the most formidable of their enemies, when at variance. It was a common saying, that Rome could neither triumph over the Maris, nor without them. In the 662d year of Rome, B. C. 92, they put themselves at the head of the Social war, one of the most obstinate and dangerous oppositions ever made to the progrefs of the Roman power, which was terminated by a grant of the privileges for which they contended. Their name still subsists in that of the diocese, for the prelate is styled bishop of the Maris. In ancient times, the Lake was called Fucinus, and was under the protection of a god of the same appellation, whose temple stood on its banks. According to the testimony of ancient authors, it was subject to extraordinary incendes and decrepit. The actual circumference is 47 miles. (more than 30 miles, says Sir William Hamilton, ubi infra;) the breadth, in the width for the bay, it is covered, 41 its depth, on an average, 12 feet. But these measures have been subject to great variations. Two miles up the plain, beyond Avezzano, the fragments of boat, shells, and other marks of its ancient extent, have been casually discovered; and, on the contrary, there are people who remember when it did not flow nearer than within two miles of Avezzano. An immense tract of land is lost at every increase of its level; and if any means could be devised for draining it, or, at least, reducing its size, the value of the ground recovered for cultivation would be more than an equivalent for any expense incurred in the works. Round this lake rises a circle of grand mountains covered with snow, some of which are the highest in Italy, if we except the Alpes; the most elevated is the Rocca di Cambo. At the foot of these are many villages, and rich, well-cultivated farms. In summer this country must be a delightful residence, for the environs of the lake are well enclosed, and the sides of the hills covered with fine woods; its waters abound with fish of various kinds, though not of the best quality, and hitherto, at the Walter leasons, repair innumerable flights of wild fowl. In the shallow water on the borders of the lake, Sir W. Hamilton saw thousands of water-faunes, porpoising and playing upon a little fish like our thornbacks, but much better armed, though their defensive weapons seemed to avail them but little against such ravenous foes. The necessaries of life are good, plentiful, and cheap. About 1 mile from the town is the emigration or opening made by order of Claudius Caesar for the discharge of the waters into the Liris, now the Garigliano, which runs in a deep valley on the other side of the hills. In a line from it, now choked up, up the slope, are six perpendicular wells, and two oblique grooves to the canal, which was driven into the hill into the opposite valley, and there had a vent at Capitrelli, two miles from the lake. As the swelling of this lake was attended with incredible damage, the Maris had often petitioned the senate to drain it; Julius Caesar would have attempted it, if his life had been prolonged. His successor declined the project, till, at length, Claudius, who delighted in expulsive, difficult enterprises, undertook it. During the space of eleven years he employed 30,000 men in digging a passage through the mountain, and when every thing was ready for letting off the water, he exhibited a superb naval spectacle on the lake, consisting of an engagement between condemned criminals, who, in separate fleets, acted the parts of Rhodians and Sicilians, and who destroyed one another for the amusement of the court, and of a multitude of spectators that covered the hills. When the emigration was opened, at the close of this savage diversion, the emperor himself, with difficulty escaped being hurried away and drowned by the sudden rushing of the waters towards this vent. However, through either the ignorance or negligence of the engineers, the work did not answer expectations, and Claudius did not live long enough
C E L

enough to complete it. Sir W. Hamilton went with torches into the eminence of Claudius as far as he could. It is a covered under-ground canal, three miles long, and great part of it cut through a hard rock; the other parts supported by masonry, with wells sunk to give air and light. In its present state, though filled up with rubbish and earth in many parts, and of course useless, it is a magnificent monument of antiquity. Nero abandoned the scheme projected and partly executed by Claudius, through envy. Adrian is said to have let off the waters of the Pecunus; but none now escape except through hidden channels formed by nature, but liable to frequent obstructions. As three considerable streams run into the lake, the old oblong to a discharge main raise the level. Swinburne’s Travels, vol. iv. p. 374. Phil. Trans. vol. lxxxv. p. 503.

CELANO, a river of Italy, which runs into the sea of Tarento, 1 miles from its mouth.

CELERANT, in Logic, a denomination given by the Peripatetics to the Galenicus synolytix; otherwise called 

CALENTES.

CELERANT, among Logicians, a mode of syllogizing, wherein the major and conclusion are universal negative propositions, and the minor an universal affirmative. L. gr. CE

None whereunder understanding is limited can be omniscient.

LA

Every man’s understanding is limited.

RENT

Therefore no man is omniscient.

Obf. Gartnur affirms that there is no solid generic distinct between this genus and evonymus, a difference in the number of cells and valves being, in his judgment, of no consequence, except to the mere carpologist.

* Without thorns.

† Leaves entire.

†† Leaves ferrated or toothed.

CEL.
Callery's Sycamore

Leaves egg-shaped, acute, remotely toothed, petioles, flowers axillary. A native of the Canary Islands, flowering in August and September, introduced into England by Maffin in 1779.

† Leaves serrate or toothed.

Celastrus sagamosus, See Senacia sagamoides.

Celastrus myrtifolius, Wild. See Senacia myrtifolia.

Celastrus, in Gardening, comprises some plants of the evergreen, and deciduous shrubby kinds, as the fluted or evergreen Virginia flax-tree (C. bullatus); the climbing flax-tree, or baldwood euonymus (C. scandens); the pyracantha-leaved flax-tree, or Athiopian box-thorn (C. pyracanthus); and the box-leaved flax-tree (C. buxifolius); of which the first in its native situation rises to the height of eighteen feet, but in this climate few of these shrubs are much more than half that height. It generally puts out two or three stems from the root, which divide upward into several branches being covered with a brown bark: the flowers come out in loose spikes at the end of the branches, and are white; the capsule is of a scarlet colour, let full of small protuberances. It flowers in July, but seldom produces good seed here.

In the second foot several woody flasks are sent out which are inedible, and twill themselves round trees and shrubs, or round each other to the height of twelve and fourteen feet or more, girding trees so closely as in a few years.
years to a bow. They are about three inches long, of a lively green above, but pile on the under side; the flower, produced in small bunches towards the end of the branches, are of an herbaceous colour, and succeeded by roundish three-cornered capsules, which are red when ripe, spreading open and disclosing their seeds in the same manner as the spindle-tree. It flowers in the beginning of June, and ripens its seeds in the autumnal fallow.

The third rife, with an irregular stalk, three or four feet high, issuing out of several side branches covered with brown bark; the leaves are about two inches long, and more than half an inch broad, some pointed and others obtuse; they are quite free, of a rich green, coming out irregularly from the branches in loose tufts, many from one point, on long peduncles, and of an herbaceous white colour; the fruit is of a fine red colour, opening into three cells, containing an oblong hard seed. It flowers the greatest part of the summer.

The last rife, with a slender woody stalk to the height of ten or twelve feet, is full of joints, armed with long spines, upon which grow many small leaves; the branches are slender, armed also with spines at every joint; but the whole plant is so weak as to require support: the leaves come out in clusters without order, are shaped somewhat like those of the box-tree, but longer, and of a looser texture; the flowers are on peduncled cymes from the axils, and the fruit globular. It flowers in May and June, and sometimes a little later.

Method of Culture. The two first sorts are capable of being raised either by seeds or layers, but the latter is the more ready method. And in the first mode, the seeds should be sown upon light sandy earth, either in beds or pots, as soon as they are procured from abroad, keeping them perfectly free from weeds till the plants are of sufficient growth to be planted out in nursery beds, watering them occasionally when the weather is dry. They are mostly fit for this in about two years. But in the latter method, layers from the young shoots should be laid down in the autumn, setting them at a joint on the under sides. They may sufficiently root and be taken off and planted out in the nursery rows by the succeeding autumn. The latter of these sorts succeeds better on a moister loamy soil.

In the last two sorts the culture may be in the same methods; but they should be in pots in order to their being placed under the protection of frames or other contrivances, when the weather is severe. After they have had a twelvemonths’ growth, they may be removed into other pots separately. And cuttings made from the young shoots in all the sorts may likewise be sown in the early spring months in pots exposed to a hot-bed heat. These may be planted out in the following autumn, either in pots separately, or where they are to remain according to their kinds. But these sorts should not be treated too tenderly, as they are apt to be rendered weak in their branches and leafy verdant.

The first two sorts are of a hardy nature, being well adapted to the borders and clumps of pleasure-grounds in mixture with other shrubs of the more tall growths. The first should, however, have a warm aspect and rather dry soil. The latter succeeds in wilderness quarters, under the shade of tall trees where it wind: itself about them to a great height, producing a fine effect in the autumn by the fine colour of its fruit.

The other two sorts are more tender, requiring to be kept in pots, as has been seen, to have the protection of the greenhouse in winter, where they afford variety in embellishment with other plants of the more hardy nature.

CELA, in Military Antiquity, from the Latin word celatus, signifying concealed. It is of the same import as kamae, which is derived from the German, and was used to denote a helm, casque, or helmet for covering not only the head, but also the whole face, having an opening only opposite to the eyes, which were secured by cross-bars or lattice-work of iron, forming a sort of visor. It has served for several centuries as an ornament on arms armorial, and is still preferred in heraldry as a distinguishing mark of nobility. It was worn not only by the chevaliers or knights when they went to war, but also at tilts and tournaments. Various applications have been given to this piece of armour, such as laclierement de tete, or covering for the head, casque, helmet. Under Francis I. it was distinguished by the name of armet. At tournaments it was assigned as the prize to him, who behaved best on the part of all those who presented themselves at the barrier of a tournament, and held against all those that might enter the lists, as the first piece of defensive armour: in the same manner as the sword was given to him, who distinguished himself most on the side of the assailants, as the first arm of offence. Formerly they used to label, call, or cry out an armet, as they now do aux armes.

CELOV, in Geography, a town of the department of Lianme (island of Corfica) and chief place of a canton in the district of Ajaccio. The canton contains 4060 inhabitants.

CELAVIA, in Ancient Geography, a small island of Greece, on the coast of the Peloponnesus. It belonged to the Troezentians, and was situated before the port called "Pagon" by Strabo. In this island was a magnificent temple of Neptune; and the tomb of Demosthenes, who lived here, is not one of the least of its ornaments. His memory was long held in great veneration on this island, and, in the time of Paulyasian, strangers, as well as the inhabitants of the island, rendered distinguished honour to this illustrious defender of the liberty of Greece.

CELEBRIDGE, in Geography, a small town of the County of Kildare, Ireland, pleasantly situated on the river Liffey, where the cotton manufacture has been carried on extensively; and also a manufacture of ship hats, which was for some years much encouraged. It is 10 miles west from Dublin.

CELECIKENS, in Ancient Geography, a people of Spain, who inhabited the town of Celica, seated on the banks of the Ebrus, according to Piny.

CELE, in a general sense, denotes any tumour, but more particularly that proceeding from a rupture or hernia.

CELE, in Ancient Geography, a town of Sicily, S. of Phlius. Here were celebrated in every fourth year, the mylerics of Ceres, who had a new pine at every return of the festival, so that the priesthood lasted only four years. In a temple of this city was suspended from the roof a car, which was said to be that of Pelops.

CELEBANDICUM jugum, a promontory of Spain, in the Mediterranean sea.

CELEBATE, or CELEBACY, the state of a person who lives out of marriage.

Scaliger derives the word from the Greek κοφάον, bed, and λαγός, lingua, i. e. have; others say, it is formed from cella, a little cell, q. d. the chambers of honey.

Among the Spartans, though very weighty reasons might persuade them not to marry, yet in old age they could not expect to be treated with the same respect as the other citizens. As a proof of this X nopi' (1. Hist. Gr. l. 3. p. 42., as also Plut. in Lycurg. T. 1. p. 48.) relates an anecdote of Dercyllidas, who had commanded some with so much glory. That general came one day into the assembly,
bly, when a young man said to him: "I shall not rise to you, because you will leave no children who may one day rise to me." Those who lived in celibacy were also subject to other humiliations. They were not allowed to be present at the exercises in which the girls engaged half-naked: the magistrates might also, in the midst of winter, command them to strip off their clothes, and go round the forum, flogging lascivious verses on themselves, in which they acknowledged that their disobedience to the laws merited the chastisement they suffered.

The ancient Romans used all means imaginable to discourage celibacy. Nothing was more usual than for the censors to impose a fine on old bachelors. Dionysius Halicarnassius mentions an ancient constitution, whereby all persons of full age were obliged to marry. But the first law of that kind of which we have any certainty, is that enacted under Augustus, A. U. 752, called "Lex Julia de maritandis ordi-
nibus." It was afterwards denominated "Papia-Poppaea," and more usually "Julia-Papia," because of some new function and amendments made to it under the consuls Papia and Poppaeus. By this law, divers prerogatives were given to persons who had many children; penalties imposed on those who lived a single life, as that they should be incapable of succeeding to an inheritance, except of their nearest relations, unless they married within 100 days after the death of the testator; and that they should not receive an entire legacy. What they were thus deprived of in certain cases fell as an ephedra (caducum) to the exchequer or prince's private purse.

The celebate of the clergy, which is still rigorously kept up among the Romanists, is of a pretty ancient foundation. It was first proposed by the council of Nice, but without passing; it was, however, in some measure, admitted by the western councils of Elvira, Arles, Tours, &c. and enjoined by the thirty-third canon of the council of Elvira, held about the year 360, though it does not appear that it was either generally or rigorously observed. In the year 360 it was decreed in the council of Arles, that no man in- cumbered with a wife, should be admitted into holy orders, unless he promised, with his wife's approbation and consent, to abstain for ever from the conjugal duty. From these citations it appears, that those writers are mistaken who affirm, that celibacy was first imposed upon the clergy by Sycius; and that it was not required of the ministers of the gospel by any council, but by the popes, in appellation to all councils which allowed the priests to marry. Among the priests as-signed themselves on the faculty of conscience, took the hint; infomuch that, towards the close of the fourth century, there were few but made profession of a voluntary celebate.

Sycius issued a decree in 385, obliging all priests and deacons to observe celibacy: and it was soon after enjoined by the synods of each particular nation, and observed in most of the western churches. In 441, the council of Orange ordered those to be deposed who did not abstain from their wives; and Leo the Great, in a letter written about the year 442, extended the law of celibacy, which was confined by the decree of this council to deacons, and by the letter of Sycius to deacons and prebendaries, to sub-deacons likewise: but it was Gregory the Great, in 591, who first brought ecclesiastics to admit the celebate as a law. In the council of Trent, it was proposed to let the clergy at liberty again from the yoke of celebate; and this was even made an article of the Interim of V.; but the pope could not be induced to acquiesce.

In Britain the celibacy of the clergy does not seem to have commenced till the arrival of Antoninus in the 6th century. About the middle of the tenth century, in the reign of Edred, who surrendered himself to the guidance of Dunstan, commonly called St. Dunstan, abbot of Glastonbury, a new order of monks, called Benedictines, had sprung up in Italy, and was introduced into this country by Dunstan. These monks made a merit of the most inviolable chastity; and their principles and practices were greedily embraced and promoted by the policy of the court of Rome.

The Roman pontiff, who was every day making great advances towards an absolute sovereignty over the ecclesiastics, perceived, that the celibacy of the clergy alone could break off entirely their connection with the civil power, and depriving them of every other object of condition, engage them to promote, with unclosing industry, the grandeur of their own order. He was sensible, that so long as the monks were indulged in marriage, and were permitted to rear families, they never could be subjected to strict discipline, or reduced to that slavery under their superiors, which was requisite for procuring to the mandates issued from Rome a ready and zealous obedience. Celibacy, therefore, began to be extolled, as the indiennable duty of priests; and the pope undertook to make all the clergy throughout the western world renounce at once the privilege of marriage. The undertaking was difficult, as he had the strongest propensities of human nature to encounter; and it is therefore no wonder that this master-stroke of policy should have met with violent contradiction, and that the interests of the hierarchy and the inclinations of the priests, being now placed in this singular opposition, should, notwithstanding the continued efforts of Rome, have retarded the execution of that bold scheme during the course of near three centuries. In the year 1167, during the reign of Henry I., a synod was held by the mitigation of pope Pausal II. and archbishop Anselm, at Wellminster, which enjoined the celibacy of priests; and which enacted, that even laymen should not marry within the seventh degree of affinity. By this contrivance the pope augmented the profits which accrued to him from granting dispensations, as well as those from divorces. Another synod was convened at London in 1129, under the pontificate of Honorius, at which prefixed William archbishop of Canterbury, with the character of the pope's legate, and where all the bishops of the kingdom were present. This council was assembled chiefly for the purpose of enforcing the observance of the canons issued by the councils concerning the celibacy of the clergy, and of which many amongst the priests as- signed themselves on the faculty of conscience, took the hint; infomuch that, towards the close of the fourth century, there were few but made profession of a voluntary celebate.

CELEBES, called also Macassar, in Geography, an island of the East Indian Ocean, situated under the equator, between Boromo on the west, and the Molucca islands on the east; or between 1° 20' N. lat. and 5° 40' S. lat. and 119° and 124° E. long. The form of this island is very irregular, so that it is not easy to ascertain its dimensions, as to length and breadth,
C E L E B E S.

breadth, in miles; but it has been usually reckoned about 700 miles long, and 350 broad; taking those parts whose dimensions are of the greatest extent. It is divided into a number of small kingdoms and states, most of which however depend on the two great kingdoms of Macassar and Boni. The king of Tarutane also, has extensive powers, which occupy almost the whole of the northern and eastern part of Celebes. The two most powerful kings, those of Dutch, by the preponderance of their arms, assumed allies, are the kings of Macassar and Boni. The king of Tello and Sandakani are in alliance with the kingdom of Mantaya; and that of Sopping, Locho, and Tanete, is with that of Boni. Some small states, such as Wajo, Mandub, &c. are independent. Although the kings of Macassar and Boni are allies of the Dutch, they are always shown enemies to each other; and the policy of the Dutch has continued to derive great advantage from the discord of these eastern princes. The kingdom of Mantaya, or Goach, lies on the western side of the island, of which it occupies the greater part. The king of Goach, and that of Tello, both bear the title of Macassar, though each has a distinct kingdom; they sally the talks of Goach and Tello from their places of residence.

Celebes is surrounded by a variety of islands, all of which may be denominates the Celebrian isles. See Macassar, Goach, Telly, Boni, Sandakani, Sopping, Lephoi, Tanete, Mandbar, Cebelula, Wajo, Tophrette, Toulkadi, Cajeelie, Torokcian, Bonton, Sumbara, Maros, Lacsali, Galicmond, Bonton, Dolem, Comba, Beke, Salye, Bonapatte, Calalwe, Tanakeke, &c. &c. According to an ancient tradition, the Macassars, like many other nations, deduce the origin of their princes immediately from the gods. Once, they say, after the death of the first sovereign of the kingdom, a beautiful female descended from heaven, descended from a golden chain. This celestial beauty, named Toematoong, was immediately chosen by the Macassars to be their queen. She afterwards married a king of Bantam, and, after being pregnant three years, she brought forth a wonderful child, capable of speaking and walking as soon as it was born, but very ugly and deformed. This young prince was named Tooma-Salangabarang. When he attained to manhood, he broke the golden chain, which his mother had brought with her from heaven, and the mother and her husband instantly disappeared, and left to the son the kingdom, together with one half of the chain. This chain, which, as it is styled, was sometimes light and sometimes heavy, and sometimes appeared of a pale colour, was long preserved as a valuable part of the regalia of the crown, until it was lost, with various other rarities, during the warlike commotions which took place in this kingdom about the middle of the last century. This Tooma-Salangabarang is considered as the chief of the family of all the kings of Goach. The Dutch were involved in violent disputes with these sovereigns before they were able to establish themselves in their kingdom. In 1778, Goach, the capital, was taken by force and destroyed; and, in 1781, the sovereign Pundiraci Sir, Sultan Abdul Hadja, was placed on the throne by the government of Batavia. The king of Goach does not possess unlimited power, but is subject to certain laws, which he is obliged strictly to observe. He can undertake no measure of importance without the consent of his council; nor can he inflict arbitrary punishment on criminals, who must be punished according to the laws. His privy-councillors are called Tomani Calangs; and every village is under the direction of a particular chief or governor, distinguished by the title of Galarang. The Portuguese visited this island about the beginning of the 16th century, and obtained, from the sovereign then on the throne, (viz. in 1512,) permission to form an establishment. The face forms of this prince introduced the weights and measures now in use, fixed the prices of merchandise, manufactured gunpowder, and planted the first artillery on the walls of Goach. He also not only allowed the Malays to settle in his states, but to erect a Mahometan temple. This religion made rapid progress in the island, that, about the year 1527, disputes were set to bring from thence a brada or priest, to instruct the Macassars in the doctrine of Mahometanism, which, in 1565, was established throughout the whole kingdom, under the name of Sultan Allah Ouden; and three years afterwards they forced the people of Boni equally to subscribe to the doctrines of the Koran. The power of Macassar was at its height about the middle of the 17th century; when its princes not only ruled over almost the whole of Celebes, but had likewise subdued Lamo, Mandalay, Bima, Tabamba, Dempo, and Singar, tributary to them, and had conquered Bonton, Burgay, Gori, the Xiwi islands, &c. The advantages which the government of Batavia derived from the government of the Foelen, which had been given to Macassar by Basul Uddah, king of Terutane; they were in strict alliance with the inhabitants of Bali, and coined the first gold coins, which were probably the gold "Mas," of the value of sixty Dutch flours. About that time also, the alliance between Goach and Tello was renewed; and these two states were soon united together, that it was a common saying that there were "two lords, but one people." By the articles of union it was settled, that all taxes and contributions from conquered provinces, &c. should be divided into five parts, two of which were to be given to Goach, and two to Tello; while the fifth should fall to the share of the eldest of the two kings, that the eldest of the kings should always exercise the office of regent or prime minister, to his junior colleague; that they should both be equal in dignity; and, lastly, that they should both enjoy the title of "Sannabo," signifying as much as emperor. The empire of Macassar has lost by so much declined, under the influence of the powerful arms and artful policy of the Dutch company, that the king of Boni is now much superior to Goach, both in extent of territory and number of subjects; although in war a Macassar is better than three Boaghees, on account of their martial character, and undaunted courage, which, notwithstanding all the adverse events that have befallen them in the course of a century, were never subdued, till the year 1775; when a finishing stroke was given to the independence, and power of reliance, of Goach. A rebellion having been raised by the mother of the king, who governed during his minority, with a view of emancipating the country from the yoke of the company, her forces were vanquished, the city of Goach taken by assault, its fortifications razed; and the government new modelled, conformably to the views of the conquerors. The kings of Macassar have a new name given them after their death, and their successor must be nominated before their interment. The Dutch East India Company possesses the castle of Batavia, which is called, in the language of the country "Adjong Pandang," together with the surrounding district, in consequence of a treaty which they entered into with the prince of Celebes. But as the boundaries of their possessions were, perhaps, not accurately defined, the company always endeavoured to enlarge, and the Macassars, on the other hand, to confine them. The company possess also a peninsula extending from this place towards the north, and a large flat district, which, on account of its fertility, is con-
considered as the granary of Celebes, together with several places lying between this plain and the mountains, and likewise a great many villages among the mountains. These places border on each other, and are bounded on the west by the sea, on the north by the kingdoms of Tannets and Maros, on the east by Tamarri, and on the south by the kingdom of Macasser.

The road of Macasser is one of the most beautiful in India, and at the same time safe for ships at every season of the year. The islands of “Great Ly Ly,” and “Little Ly Ly,” with their reefs, defend it from south-west to north; and there is a safe anchorage close under “Great Ly Ly,” in the bad monsoon, and when the N.W. winds blow violently. The entrance of the road is between the above-mentioned island of “Ly Ly,” and a sunken rock, which lies half a quarter of a league S. of the point of the reef of “Ly Ly.”

The environs of Macasser are very pleasant. They consist of an extensive plain, reaching to the foot of a high range of mountains, situated seven or eight Dutch miles to the eastward, and dividing this part of Celebes, that lies to the westward of the bay of Boni, and south of the gulf of Tomini, into two parts. This range is called the mountains of Boni, because the southern part of it terminates in a group of that name. The plain is covered, as far as the eye can reach, with rice-fields and paddy grounds, which are interspersed, here and there, with small groves of fruit-bearing or shady trees, and watered by drains made out of the larger rivers, which descend from the mountains.

Captain Forrest (in his “Voyage from Calcutta to the Mergui, Archipelago, &c.”) informs us, that at a place called Kyly, or Kyela, N. of Macasser, and in the Mandhar division, there is a flat, a spacious harbour; and that near the harbour are hills free from wood, and covered with grass, where many sheep are bred; though they are generally scarce, whist goats are much more plentiful. There are also two or three harbours on the east coast of Celebes, and two on the north coast, Koandang and Amoran.

The seafaring in Celebes are the same as in Java. The S.E. monsoon continues from May till November, and is reckoned favourable; the N.W. monsoon, called the bad one, continues from November till May. During the former the sky is serene, and the weather dry; but continual winds and violent rain prevail during the latter. It is singular, however, that on the east side of the above-mentioned range of Boni mountains, the contrary takes place: for, when fine weather in the S.E. monsoon prevails on the west side of the mountains, hurricanes and rain are found on the east side; there the boundaries of summer and winter are other eight Dutch miles distant from each other.

As this island lies under the sun, the air is very hot; but the heat is moderated by frequent rains and cooling breezes, so that the climate is not upon the whole insalubrious. It abounds with mountains, but the soil is generally fertile. The chief production of the island is rice, on which it yields more than enough to supply its numerous inhabitants, although it is not so good as the Java rice. Cotton of excellent quality is likewise very much cultivated; and the inhabitants manufacture it for the women’s dresses, which are held to be the finest in all India. These garments are called “Cambas;” they are red-checked, mixed with blue, but dull-coloured; they reach from head to foot, and are often fold from 6 to 10 Spanish dollars apiece. The Bougineese often import cotton from the island “Bali,” both raw and spun into yarn. They also manufacture beautiful silk belts, in which they fix their krisis; also a kind of paper, from the inner bark of a small tree, in which they wrap their fine cambas; this paper they often dye of various colours, and export much of it to Manila, and several other places; it resembles the cloth of Othaitte. They make fire-arms, but cannot make gun-locks; they also cast small brass guns, which they call “ranteckx,” the larger being about six feet long, and carrying a half-pound ball. They are curious in silk-agree work, both in gold and silver. Captain Forrest was informed, that they failed in their Takuars, or pros, to the northern parts of New Holland, probably Carpentaria bay, to gather tea-faual (bieche de mer), which they fell to the annual Chinese junk, at Macasser; but they did also that gold was to be obtained there. In this island cocoa-nut trees, mangos, bananas, melons, and oranges are cultivated in abundance, together with yu, a root used as food, and horse, a kind of buck wheat, which formerly was the chief food of the Iavasche before they were acquainted with the use of rice. They have also plenty of horses, oxen, buffaloes, deer, wild swine, and birds of all kinds, particularly a variety of beautiful parrots. The Dutch carry hither opium, spirits, rice, coarse and fine cloths, &c. and receive in exchange rice, wax, flaves, and gold. Here, as well as in many parts on the coast of Africa, the unfortunate beings doomed to slavery, are not prisoners taken in war, or criminals, but in general persons who have been kidnapped for the purpose of being sold; and it often happens, that relations do not hesitate, for the sake of gain, to deprive their kindred of liberty. Most of the eastern settlements, Batavia and Java, are furnished with flaves from Celebes. About 100 flaves are annually purchased at Macasser by the Dutch company, for their own service, and conveyed to Batavia; the whole remainder of this iniquitous traffic is in the hands of private individuals, and free inhabitants of the above-mentioned two places.

The island is well peopled; on the coast of Celebes alone there are said to be 56,000 inhabitants, 17,000 of whom are capable of bearing arms. Of the various nations who inhabit Celebes, the Bonians or Bougineese, called in general Buggeles by the English, and the Macassers, are the most known: the latter are the most considerable of those who have been forced by the arms of the Company to enter into alliance with them, and their lands likewise lie near those of the Company, and they are, therefore, better known in history than the more distant kingdoms and nations. See Boni and Bougineese. Several of the inhabitants of Celebes find employment in the gold mines of this island; and were it better peopled, and the islanders more industrious, these mines might supply a greater quantity of the precious metal. But the Indians who inhabit these parts of Celebes which produce gold, content themselves, like those of other places, with pursuing the gold mines in a disorderly manner. Accordingly, they obtain the metal by collecting the small particles which have been carried down by the streams, or by washing the sand which they dig up, rather than by working the mines in a regular manner. The gold mines in this island are found in the kingdom of Loochoe, and in the eastern parts; and it is partly collected for the Dutch East India Company at Gontang. The mines commence on the southern side of Bali, and the northern side of Kotboca, or Mogondo, and proceed thence to Dondo on the south-west, and Tamperana on the north-west side, at the bay of Tomini. Every where between these two distinct gold is found in a greater or less quantity. Where the land of Celebes becomes so narrow, and the mountains so low, that a person can with ease pass from one coast to the other, in a few hours, the auriferous mountains end; and on the whole coast on the other side, as far as Macasser, a single gold mine is not to be found. The villages, however, in these gold-yielding mountains are very ill-peopled; and, besides, these treasures are neglected on account of the ignorant superstition

C. C. 

VOL. VII.
CELESTI, a river of Africa. In the kingdom of Algiers, supposing to be the ancient Carthage, which falls into the sea about 3 leagues W. of Algiers, after a short course of 15 or 20 leagues.

CELIGERI, in Ancient Geography, a people of Macedonia, according to Pliny.

CELEIA, a town of Norcia, mentioned by Pliny and Ptolemy, and appearing, by an ancient inscription of Gutter, to be the modern Cilicia in Lower Soria.

CELEATES, an ancient people of Italy in Liburnia, who, according to Livy (1. xxxii. c. 29), submitted to the Romans in the year of Rome 555, under the confidate of C. Cornelius and Q. Minutius.

CELEMANTIA, a town of Germania Magna, placed by Ptolemy in the vicinity of the Danube.

CELENDES, a burgh of the Argolid, towards the extremity of the peninsula S.E. of the Argolid, on the Saronic gulf.—Also, a sea-port town of Asia, in Cilicia.—Also, an episcopal town of Asia in Iauria, probably the same with that last mentioned.

CELENERTITIS, a small district of Asia, in Cilicia, deriving its name from Celenderis.

CELENAE, an ancient town of Italy in Campania, mentioned by Virgil in his Aeneid. It was a colony, according to a medal of Vespasian.

CELENZA, in Geography, a town of Naples, in the province of Abruzzo Citera; 12 miles E. of Civita Borelo.

CELENES, in Antiquity, a Latin word made use of to denote cavalry, so called on account of the quickness of their movements, and the swiftness with which their service was performed. They were a sort of light-horse, about 300 in number, formed by Romulus for his body-guard, chosen out of the rest of the cavalry, and approved of by the sagacity of the curie of the people, each of which furnished ten. In war they constituted the van-guard in advancing towards the enemy, generally beginning the engagement, and the rear-guard in retreating.

Though the celebes were a body of horse, yet they usually dismounted, and fought on foot: their commander was called tribune, or preifal of the celebes. They were divided into three troops, of one hundred each, commanded by a captain called centurio: their tribune was the second person in the kingdom. See Cavalry, &c.

Phutarch says, Numa broke the celebes: if this be true, they were soon re-established, for we find them under most of the succeeding kings: witness the great Brutus, who expelled the Tarquins, and who was the tribune of the celebes.

CELEBINA, in Ancient Geography, an ancient episcopal town, in the pre-Daroba Africa.

CELENUS, in Ichthyology, a name by which some authors have called the pilchard, clupea pilchardus; also aqua membras, and chalice.

CELEBRY, in Mechanics, is the velocity of a moving body; or that affection of a body in motion, whereby it is enabled to pass over a certain space, in a certain time. See Motion and Velocity.

CELEY, in Botany and Gardening. See Atrium.

CELEY, exult. Atrium anticarena, in Botany, was found in considerable quantities by Mr. (Sir Jof.) Banks and Dr. Solander on the coast of Terra del Fuego. It is like the garden celery in the colour and disposition of the flowers, but the leaves are of a deeper green. The taste is between that of celery and parsley. It is a very useful ingredient in the soup for leekens, because of its antiscorbutic quality. Hawe- worth's Voyages, vol. ii. p. 66, &c.
CELESTI, Andrea, called Cavalier Celesti, in Biography, a painter of history and landscape, was born at Venice in 1637, and acquired the principles of design and colouring from Cavalier Matteo Ponsoni. He was much applauded for a beautiful style of painting, in history as well as landscape; but he principally employed himself in the latter. His beautiful views about Venice, and other cities of Italy, were painted both in a large and small size; and his works are very highly prized, but not easily procured.

Two of his historical compositions are preferred in the chapel of Madonna della Pace at Venice; the one is St. Luke painting the portrait of the Virgin; and the other, the Adoration of the Magi, which are reckoned excellent performances. Another of his pictures in the chapel of S. Pietro, representing St. Jerome, with the Virgin and some faints, is well delineated, fault, and delicately coloured, but rather too redly. This matter used a purplish tint, referring the manner of Rubens; but he sometimes erred in the extreme. Pilkington.

CELESTIAL Globe. See Globe.

CELESTIAL Sphere. See Sphere.

CELESTINE, in Biography, the name of several of the popes.

CELESTINE I., a native of Rome and the son of one Prifus, was elected bishop of Rome, upon the demise of Boniface, in 422. Soon after his election an appeal was made to him against Anthony, appointed bishop of Tuffala in Africa by St. Aulfin; in consequence of which he concurred in the sentence of the prelates of Numidia, who deprived him of all jurisdiction on account of his scandalous conduct. On occasion of another appeal by Apiarius, prebendary of Siccia, against his bishop, who had degraded and excommunicated him for several crimes, of which he had been convicted, and which appeal had been made in a flate of fulpene during the pontificates of his two predecessors, the African bishops confirmed a canon that prohibited appeals beyond sea on any pretext, under penalty of excommunication; and Celefine thought it most expedient to give way for the present to the zeal with which they refuted the supremacy of the Roman see. In the year 428 he remonstrated, in a long letter addressed to the bishops of the provinces of Vienne and Narbonne against several abuses that prevailed in the churches of Gaul; and towards the close of the year 429 he concurred with the Gallican bishops, in sending two missionaries into Britain for the purpose of suppressing the Pelagian heresy. But the principal act of his ecclesiastical administration was the part he took in the condemnation of Neftorius. A violent dispute having commenced in 430, between Neftorius, bishop of Constantinople, and Cyril, bishop of Alexandria, concerning the distinction of two natures in Christ and the refusal of the title of mother of God to the Virgin Mary, an appeal was made by both the disputants to Celestine. The Roman bishop convened a council at Rome; which condemned the opinions of Neftorius, as heretical, degraded him from his episcopal office, and allowed him only ten days for recantation; on the failure of which he was to be deposed and excommunicated; and Cyril was appointed to be the vice-gerent of Celestine in the execution of this sentence. An ecumenical council was afterward summoned by the emperor Theodosius at Ephesus, in order finally to decide concerning the subject in dispute. To this council Celestine sent legates, and he approved its condemnation of Neftorius; upon which he wrote a preface letter to the emperor, requesting him to banish the heresieve Neftorius to some uninhabited place, where he would have no power to spread the infection of his doctrine.

For this instance of zeal on behalf of what was then deemed orthodoxy, Celestine has been ranked among the saints of the Romish church. In 431 the pope addressed the bishops of Gaul in a letter, warmly supporting the doctrine of St. Augustine concerning grace and free will. He also sent Palladius into Ireland, in order to propagate the Christian religion among the rude inhabitants of that island; and as this first mission was not attended with much success, he employed, after the death of Palladius, in the same mission, Succathus, a native of Scotland, whose name he changed into that of Patrick, and who arrived among the Iblevi in the year 432. The success and fame of this missionary are recorded in the annals of that country; and he has been acknowledged and honoured, under the appellation of "The Apostle of the Irish," as the father of the Hibernian church. Celestine died in 432. Several of his letters relating to the Neftorian controversy are extant; and others on various subjects of discipline have been falsely attributed to him. Bower's Hist. of the Popes, vol. i. Mafheim's E. H. vol. ii. p. s.

CELESTINO II. a Tuscan, cardinal of St. Mark, and in 1140 legate of the apostolic see in France, and called before his election to the papal chair Guido de Caffello, succeeded Innocent II. in 1143. The chief act of his administration was that of abolishing the king of France from the interdict which he had been put under by Innocent. He had been a disciple of Abelard, and was respected for his humanity and other good qualities. He died in 1144, after having been in possession of the see of Rome about half a year. Bower.

CELESTINO III. was elected to succeed Clement II. in 1191, in the 67th year of his age. His name was Hyacinth, and he had been cardinal-deacon for 65 years. After some delay he contended to crown Henry V. emperor of Germany, together with his wife Constanza, the emperor having previously stipulated on oath that he would give up the lands and territories that belonged to St. Peter, and restore Tuscum to the apostolic see. He cauited the enemies of William, bishop of Ely, and high chancellor of England, who had been appointed governor of the kingdom by Richard 1. on his departure to the holy land, to be excommunicated; and the bishop to be restored to the government from which he had been excluded; and he also excommunicated the duke of Austria for having imprisoned Richard on occasion of his shipwreck in his return from the crusade. As Philip Augustus, king of France, had married Engelburga, daughter of Canutus IV. king of Denmark, within the forbidden degrees of consanguinity, he divorced her under this pretext upon the confirmation of the marriage; and the divorce was declared lawful by the Gallican bishops. The decree of the bishops assembled in council was confirmed by the pope's legates; but it was afterwards reverted on a discovery of the fallacy of the king's plea, by the pope. Philip, however, disregarding the prohibition of the pope, took another wife, and Celestine gave him self no concern in the matter. Being informed that in Poland and Bohemia most of the clergy were either married or publicly kept concubines, he sent, in 1197, a cardinal legate to reform this abuse; and he succeeded in reforming celibacy in Poland, but the opposition in Bohemia was such as to endanger his life. On the death of the emperor Henry, he granted leave to crown his son Frederic as king of Sicily, on condition of the payment of 1000 marks of silver to himself, and the same sum to the cardinals. As his intimates increased, he wished to resign the papal chair, but the cardinals would not allow him to retire. At length he died in 1199, after a pontificate of nearly seven years. By a particular
C E L

icular bull, he absolved those who had been devoted, while children, to particular monasteries, from the obligation of confirming their vows at mature age. Bower.

Celestine IV. was elected, after a contile among the cardinals, to succeed Gregory IX. in 1241. His name was Godfrey; he was of the illustrious family of Caffioli of Milan, and his mother was the sister of Pope Urban III. From his retirement among the Cistercians, he was drawn into public life, and created cardinal by his predecessor. It was his declared wish to establish a lasting peace between the church and empire, but his death, on the 18th day of his pontificate, in a very advanced age, prevented his receiving an answer from the emperor to his pacific proposal. Bower.

Celestine V. was, before his advancement to the pontifical dignity in 1264, a poor hermit, called Peter de Marrone, from the name of a mountain near Magella, who was born at Iternum in 1215, and there lived a retired and ascetic life. When he was acquainted with his election, which took place at Perugia, he at first declined the pontificate; but by the urgent persuasion of Charles, king of Apulia, and his eldest son, Charles Martel, king of Hungary, enforced by Cardinal Latinius, he was prevailed upon to accept it, and made his entry into Aquila mounted on an ass, one of the kings on each side holding his stirrup. Soon after his consecration at Aquila, he made a promotion of 12 cardinals; and before he left the city he confirmed the constitution of Gregory X. by which the cardinals were directed, on a vacancy, to be shut up in conclave till they should agree in a new election. The place of residence was Naples, which, by the recommendation of Charles, he preferred to the papal dominions, though the old cardinals wished him to remove thither. Totally unfit by his former habits for the papal office, he was persuaded by cardinal Cajetan at the close of the year of his election to resign it. His resolution to this purpose was, however, strongly opposed by Charles and the people of Naples; and a doubt was suggested, whether or not a pope could abdicate. A constitution having been established, empowering all sovereign pontiffs to resign at their pleasure, Celestine availed himself of it; and after reading his act of renunciation, directed himself to the pontifical ornaments, removed his monk's habit, and sat down at their feet. Cajetan, who succeeded him under the title of Boniface VIII., fearing his future interference, restored his ecclesiastical regalia of returning to his solitude, and carried him to Rome. He contrived, however, to make his escape, and connected himself for some time with other hermits, in a wood in Apulia, till he found an opportunity of embarking in a small vessel for Dalmatia; but being driven back by contrary winds, he was arrested by the governor of Capitanata. From hence he was conveyed by order of Boniface to Anagni, amidst the blessings of the people, who crowded round him, and plucked the hairs of the ass upon which he rode, as relics. Boniface confined him in his palace at Anagni, and after some time committed him to close custody in the castle of Fumoni, where he died in 1265, aged 81 years. Clement V. canonized him in 1313; and the religious order which he established under the name of Celestini fell into ruin. The writings attributed to him are merely collections of passages from the Scriptures, the fathers, the popes, and the canons. Bower. Du Pin. Mollheim.

Celestines, in Ecclesiastical History, an order of religious, called also the congregation of St. Damian, reformed from the Bernardins in 1224, by pope Celestine V. then only Peter de Marrone, of Iternum in Naples; and established in 1264, by pope Urban IV. and confirmed by Gregory X. in 1274. They were introduced into France by Philip the Fair, who requested a dozen of them from the general of their order, by his ambassador at Naples, in 1300. This order still flourishes in France and Italy.—It is a kind of proverb with them Voix un plaisant Celestien.

Celestini, an excellent performer on the violin, whom the late duke of Dorset brought from Rome in the year 1770. His style was pleasing, elegant, and correct; and such were his manners and conduct: so that while he remained in England, he at once did honour to his noble patron, to his profession, and to himself.

Celestes, or Celeste, from kon, a race horse, in Antiquity, denote figure or saddle horses; by way of contradiction from thosc yoked or harnessed together, called gigas, quadrigraris.

The same denomination is also given to the cavaliers, or riders on horseback; and hence some deduce celebri, the name of Romulus's guard.

Celestrum, in Ancient Geography, a small town of Greece, in the north of Illyria, fated on a peninsula, with its walls encompassed by a lake.

Celette, in Geography, a town of France in the department of the Loire and Cher, and district of Blois; 4 miles south of Blois.

Celeusma, or Celeuma, in Antiquity, the shout or cry of the seamen, whereby they animated each other in their work of rowing.

The word is formed from κελεύω, to call, to give the signal. Celeusma was also a kind of tongue or formula recited or prayed by the master or others, to direct the strokes and movements of the mariners, as well as to encourage them to labour. See Celebres.

Aquinas, without much foundation, extends the celeusma to the military shouts in land armies.

When Christianity got footing, hymns and psalms were sung in vessels by way of celeusma, in which the words amen and allelujah were frequently repeated. See Celebres.

Celeusma, in Ancient Navigation, the boatswain or officer appointed to give the rowers the signal when they were to pull, and when to stop. See Celeusma.

He was also denominated epopeus, and by the Romans porticus; sometimes simply vortos.

Celeusus, in Ancient Geography, a place of Germany between Germanicus and Arufena, at the mouth of a small river which runs into the Danube.

Celezene, a country of Asia in Armenia, according to Strabo; called Celse and Celestena by Eutropius.

Cella, a town of Italy, situate in the interior of the Peucetian district, according to Ptolemy and Strabo: thought to be the present Celga.—Also a place of Italy in Campania, taken by Quintus Fabius, according to Diodorus Siculus.

Celliac Passion, in Medicine. See Coplic.

Cellibate. See Celebres.

Cellida, in Ancient Geography, a town of Africa, placed by Ptolemy in the Cyrenaica.

Cellidographia, the description of the spots which appear on the faces of the sun and planets.
The word is formed from κελ, μακουλα, δατ, and γραφω, I describe.

Signor Bianchini has published a cedographia, or description of the spots of the fun.

CELIMEOS, in Ancient Geography, an episcopal see of Afa, under the metropolis of Edessa.

CELIMIA, in the Matrit Abadia, a name given by the modern Greeks to the calamite, or láps calaminarion. The Arabians called this substance cimeia, and sometimes calamia; and cimeia was but a very small change from this.

CELL, Cell, in Ancient Writers, denotes a place or apartment usually under ground, and vaulted; in which were stored up some foots of necessaries, as wine, honey, wheat, and the like; according to which it was peculiarly denominated cella vinaria, aleria, mellaria, panaria, &c.

The word is formed from celer, to cover. See Cells.

Cell, in Botany, (loculo-centrum), the hollow part of a pericarp in which the seeds are lodged. According to the number of these, a pericarp is said to be one-celled, two-celled, &c.

CELL, in Ancient Writers, was used for the lodge or habitation of a common woman or prostitute, as being under ground; hence also denominated fornix.

"Intravit calidum vetern centone lupanar, Et cellam vacuum." Juv. Sat. vi. ver. 128.

On which place an ancient scholiast remarks, that the names of the whores were written on the doors of their several apartments, by which we learn the meaning of inscripta cella, in Martial, lib. xi. ep. 45.

Cella was also applied to the bed-chambers of domestics, and servants; probably as being low and narrow.

 Cicero, inveighing against the luxury of Antony, says, the beds in the very cella of his servants were spred with pompous purple coverlets.

Cella is also applied to the members or apartments of baths.

Of these there were three principal, called frigidaria, tepidaria, and caldaria. To which may be added a fourth, called cella affa, a d sometimes sudatoria. See Bath.

Cella was also applied to the adytum, or inmost and most retired parts of the temples, wherein the images of the gods to whom the edifices were consecrated, were preserved. In this sense we meet with cella jovis, cella Constantia, &c. Pub. Victor calls them dolabra; and Pliny, by a more comprehensive name, edes. Hil. Nat. lib. xxxv. cap. 10.

The Roman capital, we are told by Dionysius, had three rich cella, or chapels; the middle-most of which was sacred to Jupiter, that on the right hand to Minerva, and that on the left to Juno.

Cella, is also used for a lesser or subordinate fort of monastery, dependant on a great one, by which it was erected and continues still to be governed. The great abbeys in England had most of them cella in places distant from the mother-abbey, to which they were accountable, and from which they received their supersiors.

The alien priories in England were cells to abbeys in Normandy, France, Italy, &c.

The name cell was sometimes also given to rich and considerable monasteries not dependant on any other. Such was that called cella vetus, erected by Otth, furnished the Rich, marchis of Mifinia, in the middle of the twelfth century, the most splendid abbey in that country.

CELLE, in Ancient Geography, sometimes called Celle, a town of Africa, in Mauritania.—Alfo, another town of Africa in Byzace, upon the Lefter Syrtis; called by D'Anville "Celle Picentina."—Alfo, a town of Europe, in Three, upon the Hebrus, at a small distance E. from Philadelphia.

—Alfo, a place in Macedo, between Heraclea to the north, and Edessa to the south.

CELLAR, Cellarium, in Ancient Writers, denotes the name with cella, viz. a conservatory of estables, or drinkables.

Cellar differs from vault, as the latter is supposed to be deeper, the former being frequently little below the surface of the ground.

In which sense, cellarium only differed from panus, as the former was only a store-house for several days, the latter for a long time. Thus it is, the Bactriana, a fort of ancient Cyries, are laid by S. Jerome to carry their cellar about with them. Hieron. in Math. cap. x.

CELLARIA, in Zoology, a section of the Scutaria genus, including some species which have the item crullaceae, inclining to the nature of flone, and composed of rows of cells: no vehicules, but small globules instead.

CELLARUM, in Ancient Writers, denoted an allowance of bread, wine, oil, or other provision, furnished out of the cella, to the use of the governor of the province, and his officers, &c. In which sense, the word amounts to much the fame with anonna, which fee.

CELLARIUS, CHRISTOPHER, in Biography, was born at Smaladac in 1618, and having studied at various German Universitites, was invited at the age of 20, to teach moral philosophy and the Oriental languages at the college of Weiffenfel. In 1673, he became rector of the college of Weimar, and afterwards occupied the fame poft at Zeita and Merburg. At the univerity of Halle in Saxony, founded by the king of Prufia, he was professor of eloquence and history. His affiduous application, at length, brought on the disorder of the flone, with which he was long tormented. He died at Halle in 1707, in his 69th year. His numerous publications comprised original works and editions of ancient authors. Of the former are, "Notin orbi antiqui," 2 vols. 4to. Leips. 1701. 1706, 1731, and Camb. 1703, acknowledged the best work on ancient geography extant, which brings it down to the time of Constantine; "Atlas Caleells," fol.; "Hittoria Antiqua," Jen. 1698, 12mo. an abridgment of ancient history; "De Latinitate medice et infime zetatis." The works edited by Cellarius are "Ciceronis Epist. ad Familiare," "Plini Epif.," "Corn. Nepos," "Quintus Curtius," "Ennius," "Sextus Rufus," "Velleius Paterculus," "D. Panegy. An- tq.," "Lactantius," "Mentorius Felix," "St. Cyprian," "de Vanit. Idol.," "Sedulius," "Prudentius," "Silbus Italicus," "Pici Mirandul. Epif.," "Zoeusus," "Pana- nius," the "Thesaurus of Faber," with large additions. A collection of his letters, and some other pieces, was published after his death. Nouv. Dict. Hilt.

CELLARS, in Modern Buildings, are the lowest rooms in a house, the ceilings of which usually lie level with the surface of the ground on which the house is built.

Cellars, and other places vaulted under ground, were called by the Greeks hypogea; the Italians still call them fundi delle cafe.

As to the situation of cellars, for Henry Wotton says they ought, unless the whole house be cellared, to be situated on the north side of the house, as requiring a cool fresh air.

In order to estimate the number of cubic yards in the dig- ing of cellars, multiply continually together the three di- mensions of length, breadth, and depth in feet, and divide the product by 27, the number of cubic feet in a yard; and the
the quotient will give the cubic yards. Suppose the length 54 feet, the breadth 8, and the depth 8; then $54 \times 8 \times 8 = 2160; \quad \frac{2160}{27} = 80$.

CELLARER, or CELLERER, Cellerina, or Cellalaris, an officer in monasteries, to whom belong the care and procurement of provisions for the convent. The denomination is said to be borrowed from the Roman law, where cellarius denotes an examiner of accounts and expenses. Ulpian defines it thus: "Cellarius, id est, idea praeluditis ut rationes solvere fiat." The cellarius was one of the four obedienciarum, or great officers of monasteries; under his ordering was the pellitrium, or backhouse, and the brachium, or brewhouse. In the richer houses there were particular lands set apart for the maintenance of his office, called in ancient writings, ad cellam monotborum. The cellarius was a great man in the convent. His whole office in ancient times had a respect to that origin: he was to see his lord's corn got in, and laid up in granaries; and his appointment confided in a certain proportion thereof, usually fixed at the thirteenth part of the whole; together with a furled gown. The office of cellarer then only differed in name from that of bailiff and minister; excepting that the cellarer had the receipt of his lord's rents through the whole extent of his jurisdiction.

CELLERER was also an officer in chapters, to whom belonged the care of the temporalis, and particularly the distribution of bread, wine, and money to canons, on account of their attendance in the choir. In some places he was called cellarer, in others bursier, and in others currier.

CELLE, in Geography, a town of France, in the department of the two Sevres; and chief place of a canton, in the district of Melle; 10 miles S.E. of Niort. The place contains 1,103, and the canton 8,293 inhabitants; the territory includes 167½ kilometres and 12 communes.

Celle, or Mareen Celle, a town of Germany, in the duchy of Lower Sina, on the confines of Austria, with a celebrated abbey to which the empress Maria Theresa presented a silver image of the Virgin, after the birth of the emperor Joseph III.; 12 miles N. of Pruck.

Celle for Thiers, a town of France, in the department of the Puy de Dôme; 2 leagues E. of Thiers.

Cellefrouin, a town of France, in the department of the Charente, and district of La Rochefoucauld; 5 miles N. of La Rochefoucauld.

CELLENE, in Entomology. Cramer calls the Fabrician Papilio delila by this name.

CELLENSIS, in Ancient Geography, an episcopal see of Africa in the Byzacene.—Also, another in Mauritania Sitifensis.

CELLEPORA, in Zoology, a genus of zoophytes, the animal of which is an hydra, or polype, and the coral somewhat mammaceous, and composed of round cells. The eight following species of cellepora are described by writers.

CELLEPORA camulis. This species is dichotomous, fagiulosa; with round obtuse ramifications, and very crowded calyceal. Mili. Zool. Dan. Inhabits the North Sea.

CELLEPORA verrucosa. With ovate cells in a round mass; mouth usually with three teeth. Fabr. Tubipora verrucosa. Linnaeus. Inhabits the Mediterranean and Norway seas.

CELLEPORA puncta. Dichotomous, very brittle; nearly erect, with gibbous mammate crowded cells. Reclenia puncta fovea; inhabits the Indian, Atlantic, and European seas. Paleis, Ellis, &c.

CELLEPORA ciliata. With convex cell; mouth fringed with teeth.

Fabricius describes this foreries as having seven teeth in the mouth of each cell, and the like number is mentioned by Pallis; other writers speak of them as varying in point of number in different specimens. This kind is found in the Mediterranean and North Sea.

CELLEPORA hyalinata. Cells subglobular, and diaphanous; mouth oblique and simple, or unarmed. Fabr. F. Gren. Frequent in seas, and shells in the Northern seas of Europe.

CELLEPORA nitida. Cells subcylinndrical, pellucid, and annihilated; mouth terminal and simple, or unarmed. Fabr. Inhabits the Greenland Sea.

CELLEPORA annulata. Cells oval, ventricose and annulated; mouth distinct and armed with about four teeth. Fabr. Found attached to fuci, fomes, &c. In European seas.

CELLES, in Geography, a town of France, in the department of Jemappe, and chief place of a canton, in the district of Troumary. The place contains 3,520, and the canton 12,635 inhabitants. The territory includes 15½ kilometres, and 13 communes.

CELLIER, Romi, in Biography, a learned Benedictine, was born at Bar-le-Duc in 1628; and having cultivated in early life an attachment to literature and piety in the congregation of the Benedictines of St. Vincen and St. Hidelph, he assumed the habit of the order in more advanced age, and filled several offices in it, particularly that of titular prior of Flavigny. He died in 1761. His great work was written in French (though begun in Latin), and entitled "A General History of Sacred and Ecclesiastical Authors," in 23 vols. 4to, published from 1791 to 1793. It comes down no lower than to St. Bernard. This work is an useful compilation, but rendered tedious by its diffuseness. He also published "An Apology for the Morality of the Fathers, against Barbevray," 1719, 4to. His habits were florid and reticent, and his temper singularly mild and conciliating. Dic. Nour Hot.

CELLINI, Benciavuto, a celebrated artist, was born at Florence in 1503; and though he discovered an early talent for design, was obliged by his father to learn music. Afterwards he was bound apprentice to a jeweller and goldsmith; but his temper being reticent and ungovernable, he paused throughout various vocations, and at length settled at Rome, where he was taken into the service of pope Clement VII., both as a musician and goldsmith. In the latter department he practised drawing, seal-engraving, damask-making, medallion, working in grotesque, and a variety of other ornamental arts. He was also an expert engineer, and was enticed by the pope with the promise of the castle of St. Angel, when Rome was sacked by the confederate Bourbon. On this occasion he claims the honour of having shot the contable while scaling the walls, and of directing the cannon which killed the prince of Orange. As he was employed by Clement in making lamps for the Roman mint, the coins of that period are reckoned singularly beautiful. His medals, and jewellery works, are also highly
highly extolled as the finest specimens of the art. At the
death of the pope, he returned to Florence, and was patron-
nized by the grand duke Alexander. The coins which
were struck from the heads of this duke prepared by Cellii-
ni for the mint at Florence have been held in such esteem,
that they have been preferred by the curious like ancient
medals. The raving disposition of this admirable artist led
him to visit France; but being tired of that country, not-
withstanding the gracious reception of Francis I., he
returned to Italy. At Rome he was committed to prison under
a charge of having robbed the castle of Angelo of considerable
treasure, while the Spanish army was in that city; and through
he made his escape in a wonderful manner, he was retaken,
and again confined, till at length he was delivered from the
hardships he endured by the intercession of the cardinal of
Ferrara. On his return to France, he entered into the ser-
vice of Francis, and employed himself in sculpture, and in
calling large figures of metal, by which he obtained great
reputation. But by his turbulent and quarrelsome dispo-
tion he incurred the displeasure of the favourite Mad. d'Es-
tampes, and was obliged, after a residence of 5 years, to quit
the country and return to Florence. In the service of the
grand duke Cosimo, he displayed his almonying genius, not
only by smaller works, but by some large pieces of sculpture,
particularly a statue of Pericles and Andromeda, and a cru-
cifix, which placed him on a level with the best sculptors.
In this art he had received instructions from the greatest
genius of his time, Michael Angelo Buonarroti. He wrought
in marble as well as in metal, and as he was a powerful com-
petitor to the famous Baccio Bandinelli, there subsisted be-
tween them a great degree of mutual jealousy and hatred.
He died at Florence in 1570. In 1568 Cellini published two
treatises; one on the goldsmith's art, the other on sculp-
ture, and the casting of metals. He also composed the his-
tory of his own life, which has been translated into English
by Dr. Nugent, in 2 vols. 8vo. 1771. In this work he de-
lineates his own character without disguising his faults,
whilst he makes a boastful recital of his bravery, address, and
professional skill. In the latter respect, the testimony of his
contemporary, Vafari, places him among the most ingeni-
ous men of that flourishing period of the arts. Life of Be-

CELLINO, in Geography, a town of Naples, in the
province of Abruzzo Ultra; 7 miles E. of Ternano.

CELLITES, CELLITE, in Ecclesiastical History, an order
of religious, founded at Antwerp in the beginning of the
fourteenth century, whose patron was Ambrosius, a Roman;
and therefore, in Italy they are called Alexians; but in Ger-
many, and the Low Countries, where they have monasteries,
are called people inhabiting cells. See LOLLARDS.

CELLON, in Ancient Geography, a canton of Aisa, in
the Palmyrene territory, mentioned in the history of Judah.

CELLONEZENES, a people of Scythia, mentioned by
Phavorinus.

CELLS, CELL, CELLULAR, little houses, apartments,
or chambers; particularly those wherein the ancient
monks, solitary, and hermits, lived in retirement. Some
dervise the word from the Hebrew נינ, i.e. a
prison, or place where any thing is shut up.
The same name is still retained in divers monasteries.
The dormitory is frequently divided into many cells, or lodges.
The Carthusians have each a separate house, which serves
them as a cell.
The hall wherein the Roman conclave is held is divided,
by partitions, into divers cells, for the several cardinals to
lodge in.

CELLS are also the little divisions, or apartments, in honey-
combs, where the honey, young bees, &c. are distributed:
these are always regular hexagons.

CELLULAR ADIPOSE, in Anatomy. See CELLULAR
SUBSTANCE.

CELLULAR, in the colon, a sort of spaces wherein the ex-
crements continue some time before they are voided.

CELLULANUS, a monk inhabitant, or resident in a
Cell, or cella. He is also denominated conciliarius, and cel-
lifer, by which are imported the relation of fellow-monks,
or those who live in the same cell or convent.

CELLULAR SUBSTANCE, in Anatomy, or cellular mem-
bbrane, tela cellulosa, or mucosus, of Latin writers, tela mucu-
ose of the French, is the medium which connects and supports
all the various parts and structures of the body. It is com-
posed of an assemblage of fibres, and laminae of animal matter;
connected to each other, so as to form immovable cells, or
small cavities, from which its name of cellular is derived.
This substance pervades every part of the animal structure.
By joining together the minute fibrils or of muscle, tendons or
nerve, it forms obvious and visible fibres; it collects these
fibres into larger fascioul; and by joining such fasciculi to
each other, constitutes an entire muscle or nerve. It thus
forms an investment common to the whole muscle, and be-
flows on each bundle of fibres, say, on each fibre, down to
the most minute threads, peculiar sheets, delicate and tender
in proportion to the fibribity of the fibre. It joins together
the individual muscles, and is collected in their intervals.
It surrounds each vessel and nerve in the body; often connect-
ing these parts to each other by a firm kind of capsule; and
in a looser form joining them to the neighbouring muscles, &c.
When condensed into a firm and compact structure, it con-
stitutes the various membranes of the body; which, by long
maceration in water, may be resolved into a cellular texture.
Its general consolidafion on the surface of the body con-
stitutes the cutis, or true skin. In the bones, it forms the
bals and groundwork of their fabric; a receptacle, in the
interfaces of which the earth of bone is deposited. Macer-
ation in diluted acid diffuses this earth, and leaves, if one
may use the expression, a skeleton of the bone, representing
its figure, its procusses, and its texture, in a kind of cellular
fubstancce. The only parts of the body in which the cellular
texture prevails, are the proper subfiance of the brain, the
crystalline lens, enamel of the teeth, and the insen-
tible integuments of the body; viz. the epidermis, nails,
and hair. As the cellular subfstance is entirely soluble in
boiling water, it is asberbed by chemicals to the peculiar mo-
dification of animal matter, termed gelatine. Its watery
solution sluitens, when cold, the appearance of jelly; and, after
a particular mode of preparation, confluents glue.
The interfaces of the cellular subfstance are lubricated and
moistened by a serous or watery fluid, poured out from the
exhalent arteries, and again taken in by the absorbents. It
thus acquires a pliancy and softness, which adapt it particu-
larly to serve as a connecting medium for parts, which have
motion on each other. The importance of this property will
be felt understood by observing the effects of its loss.
Inflammation or abscess often causes an induration and con-
solidation of the cellular texture, by which the inter-
guments are fixed to the muscles; the muscles are firmly united to each
other, and to the surrounding parts; in short, a kind of an-
cystolous fubstancce, by which the motions of the whole are con-
iderably impaired.

From the universal extent of this cellular texture, two
conclusions may be drawn. 1st. It forms the bals of the
whole animal fabric, in such a way, that if we conceive every
part removed, except this, the form of the whole would still
be expressed in cellular subfstance. 2dly. It forms a connexion

CEL
tion and passage between all parts of the body, however remote in situation, or dissimilar in structure. For the cells of this substance everywhere communicate; as we may collect from facts of the most common and familiar occurrence. The air in emphysemata spreads rapidly from the chest to the most remote parts of the body; it has been known in such a case to gain admissio into the eye-ball. (Lettre in Mem. de l'Acad. des Sciences an. 1742.) A similar diffusion of this fluid may be effected by artificial inflation, which is commonly practised by butchers on the carcasses of calves. In anasarca, or prerenal accumulation of fluid in the cellular substance, the most depending parts are the most loaded; and sclerelastic in the same drain the water off from the whole body.

The structure of the cellular substance varies considerably in different parts; it is very delicate, and possesses peculiarly short fibres, where it unites the different coats of the hollow visceras of the body; also where it joins the minute fibres of muscular fataculi. It is very loose in the serosa, and integuments of the penis; and it is found in every intermediate stage. In these various states of density and looseness, it bellows upon every part the required degree of firmness and strength, and gives its form, and determines its mobility.

A peculiar power of contraction is attributed to the cellular substance; and it is mentioned by Blumenbach, under the term contrafluitas. (Institut. Physiol. Sect. 4.) This is widely different from irritability, and confints in a flow and gradual motion, which is exemplified in the corrugation of the serosa, and in the similar effect produced by cold on the surface of the body in general.

The cells of the cellular substance, in many parts of the body, are divided for the reception of a fluid termed fat, adipos, or adip us viscellae. This fluid is of a viscous nature, inodorous, lighter than water, usually inodorous, and generally transparent, similar to the vegetable oils. In addition to the carbon and hydrogen, which it possesses in common with these oils, it abounds with oxygen, and a peculiar acid termed the fatty acid. It is white in young animals, and becomes yellower as they advance in age. It is always more or less fluid in the living subject; in carnivorous animals and in man it retains much of its oily appearance after death; but in herbivorous animals it constantly assumes a concrete form.

Dr. Hunter gave the name of adipose to that portion of the cellular substance which contains the fat; and distinguishes the rest by the term reticular.

As the fat is deposited in cells, it assimiles, in general, a kind of granular form. It varies considerably in consistence. That of the orbit is the softest in the body. The fat about the kidneys becomes particularly hard after death, and is called fett; the globules or portions of this are very large, and it contains on the whole less cellular substance than any fat in the body. There is, generally speaking, a layer of fat under the skin; whence a membrana adiposa has been sometimes enumerated as one of the common integuments of the body. This is connected to the subjacent muscles by a portion of the reticular substance. Some parts of the body never contain fat; even in subjects, who have the greatest accumulation of this fluid. This is the case with the serosa, the integuments of the penis, and the eyelids; it is obvious that the functions of these parts must be completely destroyed, if they were subject to the enormous accumulations of fat, which occur in the other parts of the body. Several of the vissera also never contain any of this substance, probably for the same reason, viz. the brain and lungs.

The quantity of fat varies according to the age, the state of health, and the peculiar habit or disposition of the individual. It is not found in the early periods of fetal existence; and cannot be distinguished with any certainty, sooner than the fifth month after conception. In the fetus, and for some time after birth, the fat is confined to the surface of the body; it is only found in a fluid under the skin. It begins, however, gradually to be deposited in the intervals of the muscles, and on the surface of some vissera. In old subjects, however thin they may seem on an external view, there is always much fat, penetrating even the substance of the muscles; the bones are greasy throughout; the heart is more or less loaded, as are also the parts in the abdomen. Hence a young subject should always be inspected for field anaatical preparations. There is considerable difference in the quantity of fat in different individuals; and in some there is a propensity or disposition to its accumulation. A sedentary life, copious food, and tranquil state of the mind are particularly favorable to the increase of fat, which sometimes proceeds to such a pitch, from the continuance of these causes, that it must be considered as a disease, and is attended with the greatest inconvenience to the individual. General diatheses of the frame are commonly attended with an absorption of the fat from the cellular substance: acute diseases cause a very rapid emaciation. In no case is the adipous substance more completely removed from the whole body than in anasarca, where its place is supplied by a ferous fluid.

Dr. Hunter thought that the fat was contained in cells peculiar to itself and different from those which are distributed by water in anasarca; and he distinguishes the two kinds of cells by the names of adipous and reticular cellular substance. C. A. a Bergen had already made a similar distinction (Diff. de Membrana Cellularis in Haller's Diap. Anat. tom. 3.) He observes, in proof of this opinion, that fat is never accumulated in certain parts of the body, which parts are the most particularly dilated by the water of anasarca. He thinks that the cells of the adipous substance do not communicate together like those of the reticulum; because the fluid fat does not drain into the depending parts like the water of anasarca; nor does the skin pit where fat is collected under it.

The fame great anatomist also thought that there was a glandular apparatus for secreting the fat. "Wherever there is fat in the human body, I apprehend that there is a particular organization, or glandular apparatus super-added to the reticular membrane, consisting of vessels, or bags for lodging the animal oil, as well as vesicles fitted for its secretion; so that I would compare the narrow in the bones to the glandular or follicular parts of the fat or adipous membrane; and the network of bony fibres and laminae, which support the narrow, to the reticular membrane, which is mixed with, and supports the adipose." (Medical Obs. and Inquiries, vol. ii. p. 33.) Malpighi terms to be the first who ascribed the secretion of fat to a glandular apparatus: he has described the follicles or cells, in which this structure resides; and even tubes, which he considers as excretory ducts of his glands. (De Omento et adipos DEuctibus.) His opinions were adopted in a greater or less extent by several anatomists; as Glisson, Havers, Perotin, Fonton, Littre, and even Morgagni. It appears to us more probable, that the fat is a simple secretion from the arteres, like the fercous fluid of the cellular membrane. We cannot differ anything deserving the name of gland in the adipous substance of the body. We subscribe, in short, to the opinion of Haller: "Simplicissima et facilissima secretions adipose historia.—Inter arterias, et adiposos loculos, nullum alium receptaculum interesse. Neque oculus, aut microscopium in tenuissimis laminis cellulosis efficiat.
CELI

"silquum particularum different, quam pro glanduli habet." (Elem. Physiol. tom. i. lib. i. sect. 4.) We see preter-
natural collections of fat, (forming fatty tumours,) in those parts which are naturally the most free from adhes; can we suppose that glands are formed or created in this case? Is it not more congenial to our opinions on the formation of

tumours in general to ascribe the phenomena to a peculiar

action of the arteries?

The ues of the fat seem to be, in part, common to it with the cellular substance: it connects contiguous parts, and at the same time prevents their coalition. It admits of their moving on each other with freedom and facility. Its deposition under the integuments gives a roundness and convexity to the surface, on which the beauty of the human form principally depends. Indeed, its accumulation in particular situations immediately influences the outline of the part; viz. the orbit, the cheek, and the buttocks. The effect of its loss is most disagreeably manifested in the jowl cheek and hollow eye of an emaciated patient. The fat is also said to defend the surface of the body from cold; and, indeed, it is accumulated very copiously under the integuments of fuch animals, as are exposed to the rigour of high northern latitudes; as the whale, the seal, &c. It has been likewise supposed that the fat, which is absorbed under cer-
tain circumstances, is applied to the nutrition of the body.

When we consider the extent and importance of the cell-
ular substance in the animal body, we shall perhaps be sur-
prised that there have only been ascertained within a com-
paratively short period of time. With the exception of a few vague notices in preceding writers, Malpighi, Ruyfch, Dougla5, and Winlow, gave the first correct descriptions of this substance in particular parts. It is to Haller that the merit belongs, of first giving the whole of the facts which it has in the composition of the body in general, and particu-
larly in the formation of membranes. The reader will per-
fume with advantage on the whole of this article, the first book of Haller's "Elementa Physiologiae." He may likewise confute "Bordeau Recherches sur le tilia muqueux et l'orgecellulaire," Paris, 11mo.

CELI, in Geography, a town of Spain, in the province of Galicia, on the river Lima; 6 leagues south of Montef-

tura.

CELIUS, in Ancient Geography, a river of Britain, mentioned by Ptolemy, and supposed to be the river Spay, in the shire of Elgin.

CELON, a town of Asia, supposed to have belonged to the Persian empire, and to have been situated towards Media.

CELONIA, in Geography, a town of Naples in the prov-

ince of Capitanata; 5 miles N.W. ofVolturara.

CELORICO, a town of Portugal, in the province of Beira, containing three churches, and about 1100 inhabi-

tants; three leagues N.W. of Guarda.

Gen. Ch. Cel. Perianth of two or three leaves, lance-

olate, acute, dry, thinning, permanent. Car. Petals five, lance-

olate, acuminate, erect, distinct, rigid, resisting the leaves of the calyx. Nect. surrounding the germ, quinquelocular. Stam. filaments five, awl-shaped, conjoined at the base to the plaited nectary; authors verificate. Fil. Germ globular; fstyle awl-shaped, sliglraigh, the length of the filaments; ligla-

mas one, two, or three. Peric. Capsule globular, surrounded

by the corolla, one-celled, separating transversely into two

parts (circumferentially). Stalk several, roundish, crumglate.

Eff. Ch. Calyx two or three-leaved; leaves similar to

those of the five-petalled corolla; laminas conjoined at the

base to the plaited nectary; capsule opening horizontally.

Obst. Juffieu, Ventenat, La Marek, and Gartner under-

stand the fructification differently. According to them the

plants of this genus have no corolla, a five-leaved calyx, and

an involucrure of two or three scales resembling the leaves of

the calyx. It is nearly allied to Amaranthus and Gom-

phrena; differing from the former chiefly in its hermaphro-

dite flowers, and from the latter in having more seeds than

one.

lanceolate; filipules somewhat falcate; peduncles angular; spikes scarious." 6. "Leaves nearly linear." Thera bel-

utta, Rheed. tab. 79. Root annual, whitish, fibrous. Stems

alnicl-woody, green, smooth, fissured; branches, slender. Leaves alternate, narrow, often very acute, entire, smooth, narrowed into a petiole; filipules caducous, narrow. Flowers in a terminal, oblong spike, either simple or closely branched, of a white silvery colour, sometimes reddish at the summit; leaves of the calyx thin, transpar-

ent, shining; anthers red. Seeds three or four in each capsule, small, obicular, flattened, smooth, shining. A native of China and the coast of Malabar. 2. C. al-

65. tab. 25. fig. 1.) "Leaves linear-lanceolate; item without filipules; spikes egg-shaped; bracteoles the length of the corolla." Poiret doubts whether it is sufficiently different from the preceding, and supposes that by bractes Willdenow means the leaves of the calyx. A native of the East Indies. 3. C. margaritacea, Linn. Sp. Pl. 2. Mart. 2. Poiret 2. Willd. 3. (Amaranthus simplici panicula, Bach. pin. 12.) "Leaves egg-shaped; filipules falcate; pedicels angular; spikes scarious." This also is scarcely more than a variety of C. argentea. It has thicker stems, broader and shorter leaves, and shorter spikes; in other respects not different.

Gart. tab. 128. fig. 8. Lam. Illi. Pl. 108. fig. 1. (Amaran-

thus panicula conglomerata; Bach. pin. 22. A. vulgaris,

Rumph. ambit. 5. tab. 84.) Cock's comb. "Leaves lance-

olate-egg-shaped, recurved, somewhat waved; pedicels angular; spikes oblong, crenated." Root annual. Stems angular, fissured. Leaves alternate, acute, various in breadth in differ-

ent plants, narrowed into a petiole at the base, sometimes a little curved. Spikes sometimes branched at the base, vari-

ous in their form and size as well as colour, which is yellow, or yellowish white, red, or purple, and sometimes va-

riiegated with two or three colours. A native of Asia. 5.

"Spike cylindrical, cometa; leaves lanceolate." Stem up-

right, naked, branched. Leaves quite entire, smooth. Spikes
cylindrical, barren in the upper part, often much divided, con-

fining of minute, imbricated bractes. Flowers solitary, longer

than the bractes, riling among them at some distance from each other. Style slightly trifid, permanent, twice as long as the petals. Capsule obovate, containing two seeds. A

native of the Eail Indies. 6. C. paniculata, Linn. Sp. Pl.

major farmentosa, Brown Jam. 1779.) Blitum album majus

scandens, Sloan jam. 49. illuf. i. tab. 91. fig. 2. "Leaves

evate-oblong; item rising, panicked; spikes alternate, ter-

minal, remote." Root annual. Stems leafless, prostrate, cy-

lindrical,
Ichneumon, branched. *Leaves* alternate, acuminate. *Flowers* alternate, distinct; filaments shorter than the corolla; stigma tridentate.* A native of dry rocky ground in Jamaica. 7. *C. nitida*, Wildl. 7. Vahl. Symb. 2. p. 44. (Amaranthus fruticosus erectus, Sloan. illus. 1. tab. 91. fig. 1.) "Leaves ovate-deltoid, attenuated; spikes terminal, branched; flowers distinct; stamens somewhat whitish." In habit resembling *Achyranthes* spinifera, but placed by Vahl under colophon, on account of its calyx, corolla, and the number of its seeds. A native of the West Indies. Poiret suspects that it is one and the same plant with the preceding. But his doubt appears to have arisen from a blunder made by Willdenow, in quoting at full length, as a synonym of both, the *amaranthus fruticosus erectus*, spica virida lata & drigola of Slane, which belongs only to the present species; Linnéus having referred the preceding to another of Slane's plants. Willdenow indeed under nitida refers to pl. 91. fig. 5, not fig. 1. as it stands in Vahl, but this, as Poiret observes, must be an error of the press, there being no fig. 5 in that plate. 8. *C. coccinea*, Linn. Sp. Pl. 5. Mart. 5. Poir. 5. Wildl. 8. (Amaranthus punctatus incurva, Balf. p. 131.) Scarlet or China oak's comb.* Leaves* egg-shaped, flat, not auriculate; stem furrowed; spikes manifold, ciliated.* Root* annual. *Stems* four or five feet high, branched. *Leaves* very large, narrowed into a petiole, ending in a long point, a little waved at the edges, smooth, entire, soon falling off. *Spikes* axillary and terminal, large, branched, tufted, of a beautiful scarlet colour; filaments shorter than the corolla. A native of the East Indies. 9. *C. crenifera*, Linn. Sp. Pl. 4. Mart. 6. Poir. 6. Wildl. 9. (Amaranthus crenatus; Cam. Epit. 792. A. minor. Barrelle ex. tab. 1192. Bocc. Misc. 2. tab. 69.) "Leaves lanceolate-ovate, marked with lines, very much acuminate; stipules falcate; spikes ciliated." *Root* annual. *Stems* erect; branches axillary, almost from the bottom to the top of the stem. *Leaves* alternate, petiolate, smooth, marked underneath with reddish veins; stipules two, sessile, embracing the stem. *Spikes* slender, axillary, sometimes a little branched. A native of the East Indies; leaves beautiful than many of the other species. 10. *C. monophylla*, Wildl. 10. Poir. 10. Mart. 12. Hort. Kew. 1. p. 288. Retz. Obsf. 2. p. 13. (Illecebrum monophylla; Linn. jun. Suppl. 161. Amaranthoidea; Pluk, alm. tab. 334. fig. 4, Amal. tab. 357. fig. 4.) "Leaves awl-shaped, whorled; item branched; spatulate, ciliate, compact, cylindrical." *Root* annual. *Stems* prostrate, branched, ending in more elongated branches, s'pan long, and hoary. *Leaves* a small crowd into a tuft. *Spikes* opposite and terminal, reddish and whitish, very beautiful. A native of the East Indies. 11. *C. cynoides*, Linn. Sp. Pl. 7. (excluding; according to Willdenow, the last two synonyms, which belong to *Achyranthes* corymbosa.) Wildl. 11. Retz. Obsf. 2. p. 13. (Paronychia; Burm. zeyl. tab. 65. fig. 2.) "Leaves linear, whorled, smooth; flowers corymbous-dichotomous." *Root* perennial. Willdenow affirms that it may easily be distinguished from *Achyranthes* corymbosa by its item ascending at the base, by its broader leaves and longer stipules, and by its flowers; but Poiret is of opinion that the difference is very problematical. 12. *C. trigyna*, Linn. Mant. 212. Mart. 7. Poir. 6. Wildl. 17. Jacq. Hort. 3. tab. 5. Lam. Illust. 168. fig. 2. "Leaves egg-shaped, acuminate, flat; item herbaeaceous; raceme loose; bracts scarious; petifil trilobium." *Root* annual. *Stems* a foot and a half high; erect, simple; somewhat angular, striated, stiff. *Leaves* alternate, petiolate, even, acute; stipules in pairs, cresent-shaped, horizontal, embracing the stem. *Flowers* in terminal racemes, a few clustered together at different distances, white, on short peduncles; bracts silvery, egg-shaped, dillant; calyx two-leaved; petals egg-shaped, acute, scarios, permanent; filaments purplish, only slightly connate at their base, shorter than the petals; germ globular; style very short; filaments longer than the style, purple. *Cypsiella globularis.* Seeds three. A native of Senegal. 13. *C. cayacata*, Wildl. 12. Vahl. Symb. 2. p. 21. (Amaranthus paniculatus; Forstl. 2. p. 48. "Leaves egg-shaped; racemes compound, loose, very long; petifil bifid; item without stipules." Poiret thinks it only a variety of *C. trigyna.* A native of Arabia Felix. 14. *C. virgata*, Poir. 11. Wildl. 14. Jacq. loc. cit. 2. tab. 339. Collec. 2. p. 279. "Leaves egg-shaped, acuminate, waved; item somewhat whitish; raceme loose; bracts membranous; petifil trilobium." *Root* perennial. *Stems* four feet high, almost woody, smooth, preferring its various all the year; branches slender. *Leaves* four or five lines long, petiolate, alternate, quite entire; upper ones falcate, lanceolate; stipules acute, falcate. *Flowers* greenish, in short axillary and terminal spikes; bracts resembling the foliages of the calyx, which are shorter than the corolla, whitish, and end in a blackish point; petals lanceolate, acute, a little concave. *Cypsiella membranous.* Seeds about six, lenticular. After impregnation the calyx and corolla unite to make the fruit, giving it a conical form. Native country unknown. 15. *C. papillaris*, Forstl. 14. Poir. 13. Wildl. 17. Retz. Obsf. 2. p. 13. "Leaves egg-shaped, item truncate, item ciliated, item spinulose, item long-pilose, item loose, item trisegmentose, item spinulose, item jucundus; flowers trigynous." *Root* perennial. *Stems* herbaeaceous, item upright, item filiform. *Leaves* obtuse, petiolate, alternate, falcatus; *Racemes* consisting of alternate, remote, sessile, even, generally two-flowered, little chilid. *Cypsiella* pitcher-shaped, with a contracted mouth covered by a lid, longer than the calyx, many-seeded. 16. *C. madagascariensis*, Poir. 14. "Seeds somewhat fornmentosus, item lanceolate, item concave, item obtuse, item flowers raceme-spiked." *Stems* furrowed, item branches dilatate. *Leaves* petiolate, item alternate, item smooth. *Flowers* small, cinnereous white. Gathered in the isle of Madagascar by Commeron and J. Martin, and describec from a dried specimen in the herbarium of La Marek, but too imperfectly preferred to make it quite certain that the plant belongs to this genus and not to *Achyranthes.* 17. *C. bacata*, Mart. 14. Poir. 15. Wildl. 16. Retz. Obsf. 5. p. 23. "Leaves heart-shaped, acuminate, item racemes spiked, item, flowers trigynous, item fruit berried." *Stems* upright. *Leaves* alternate, item. *Flowers* small, on very short peduncles; calyx-leaflets two, small; petals oval, a little concave; stipules dilated at the base, entirely surrounding the germ. *Fruit* a blackberry kind; not corresponding with the generic character. *Seeds* three, large, item, convex, item concave, item on the other. A native of the East Indies. 18. *C. ghaphthaecus*, Mart. 9. Wildl. 17. Linn. jun. Suppl. p. 161. "Shrubby, woolly; leaves opposite, ebook-shaped, white underneath; head globular, pedunculated. Found by Thouin in Brazil. Poiret suspects it to be an *illecebrum.* 19. *C. madagascariensis*, Linn. Sp. Pl. 8. Mart. 10. Poir. 12. Wildl. 18. Retz. Obsf. 4. 24. p. 75. Jacq. Hort. tab. 98. (Amaranthoidea; Burm. zeyl. tab. 5. fig. 5, Pluk. Alm. tab. 153. fig. 2.) "Leaves wedge-shaped, item rather acute, item spikes globular, lateral." *Root* annual. *Stems* angular, grooved, even. *Leaves* like those of *pumila,* obtuse with a point, item entire, smooth, on very short petioles. *Spikes* solitary, item petiolate, item pedunculated; item peduncles commonly shorter than the leaves. Instead of the calyx there are from one to three linear bracts; item filaments fixed to the nectary at the base; stigma twin-capsitate. *Seed* single; item lens-shaped. It varies 1. with oblong leaves and peduncled heads; 2. with short roundish leaves ending in a point and sessile heads; the frill from Sumatra; the second from Malabar. Retz. According to this.
this description it is surely an achyranthes. It is also a native of the island of Crete.

_Celosia lanata_, Linn. Sp. Pl. 7. See _Illecebsum jervicarium._

_Celosia procumbens_; Murray Jac. See _Comptrella interrumpa._

_Celosia_ Grown. _viz._ See _Ireece celsofides._

_Celosia_, in Gardening, comprehends some flowery ornamental annual plants, as the amaranth, or cock's-comb.

The species commonly cultivated are the crested amaranth, or cock's-comb (_G. crflata_); the pearly-spiked celosia, or cock's-comb (_G. margaritacea_); and the feckled celosia or Chinese cock's-comb (_G. coccinea_); and the woolly celosia (_C. lanata_). Of the first sort there are many varieties, differing in form, magnitude, and colour, from the same seed. In the dwarf kinds, they vary, with large purple heads of flowers, with red heads, with scarlet heads, and with yellowish heads; in the giant kinds, with very large purple heads, with red heads, with scarlet heads, with yellowish heads, with white heads, and with variegated heads; and in the branching kinds, with purple, with red, and with buff-coloured flowers. And the able editor of Miller's Dictionary has raised great varieties from seeds from China and other countries, but generally found them after a few years, notwithstanding great care was taken in sowing the seeds. The principal colours of their heads were red, purple, yellow, and white, but he has had some white heads that have been variegated with two or three colours. He also raised some, he says, from seeds from Peria, whose heads were divided like a plume of feathers, and were of a beautiful scarlet colour, but which degenerated in a few years. Linnæus has found it to vary, with narrow and broad leaves; and Thunberg affirms that the crests or heads of flowers are often a foot in length and breadth in Japan, and extremely beautiful, but that they degenerate in other situations.

In the second sort there are varieties with oblong spikes of equal thicknesses, with pyramidal spikes, with entire white spikes, and with white and red spikes of flowers.

The third kind also varies, with crested spikes, with incurved crested spikes, and with plumed spikes of flowers.

Method of Culture.—It is observed that in order to produce fine flowers of this sort, it is necessary to be particularly careful in collecting the seed, so as to have it good and well ripened. In regard to the method of raising all the different sorts, it is by sowing the seeds of each separately in the early spring, as in the beginning of March, either upon a hot bed, or in pots to be planted in one; in the first case, the surface being covered with fine, light, dry mould; four or five inches in thicknesses. When the plants have attained a few inches in growth they shoild be carefully taken up, and pricked out upon another hot-bed prepared and moulded for the purpose, at the distance of six inches; and should remain in this situation till they begin to be crowded, which is molly the case in six or seven weeks. At this period another hot-bed should be put in readiness, with very deep frames.

Where the plants have been raised without pots on the beds, as many as are necessary should now be put in pots, care being taken to remove them from the former bed, with good balls of earth about their roots, by means of a trowel, placing one in each pot without disturbing the mould about them, filling up the spaces about them with good rich earth. Some water should then be given, and the pots be plunged to their rims in the bed, and as close together as possible, the openings between the pots being filled up well with mould to prevent the rising of Ream so as to injure the plants.

And the glasses in these cases should be so managed as to preserve the heat in such a frame as may keep the plants in a constant vigorous state of growth, being matted up in the night, and having linings applied when there may be occasion for it from the state of the weather. When the weather is fine and calm, air should, however, be admitted freely by lifting up the ends of the frames, and water be moderately sprinkled over them as there may be occasion for it.

For the large sorts, the frames should have sufficient depth to draw them up to three or four feet in height, being raised, when necessary, as the plants advance in growth; but for the dwarf kinds the common frames are sufficient, as their heads should be constantly kept near to the glasses. See _Hot-bed and Garden Frame._

As the summer advances the plants should be gradually hardened by more free admission of air, till the glasses are wholly removed, and the plants set out where they are to remain, in which it is proper to support the top forms by handsome sticks. In this situation water should be freely given every day, to prevent the leaves from shrivelling and keep the flower-heads full and fine. It is remarked that plants of these sorts may be removed from the second hot bed into the beds, clumps, or borders; but that they never grow so strongly as in the above method.

The seeds in all different species become in a state of perfection about the beginning of the autumn, when attention should be had to select them from the best and finest plants of each kind, sheltering the heads when necessary from rains, &c. and keeping the different sorts of seed separate and in a dry situation.

The perfection of the cock's-comb chiefly consists in its having a regular, upright, straight stem without any side branches, but well furnished all the way with leaves, and large flower-head erect, close, and regular, in its form. These are all plants of the fine ornamental kind, which have a good effect in the more conspicuous parts of gardens or pleasure grounds in mixture with others of the flowery kinds. The cock's-combs are well calculated to be placed in the courts and other places about the house, from the variety of effect which is afforded by their fine showy heads of flowers.

_Celosia_, in _Ancient Geography_, a town of Hither Spain, towards the south-west, leated on the Iberus. It was a Roman colony, and had a port on this river. Ptolemy says erroneously placed this town at the foot of the Pyrenees.

_Celosia_, in _Geography_, a town of Naples, in the province of Principato Cita; 25 miles S.W. of Cagnano.

Gen. Ch. _Cel._ Perianth five-parted; segments lanceolate, permanent. _Cor._ monopetalous, wheel-shaped; tube very short; border flat; segments roundish, unequal. _Stam._ Filaments four, capillary, a little inclined, unequal, bearded; anthers roundish. _Pf._ Germ superior, roundish; style filiform, the length of the filaments; stigma obtuse. _Per._ Capsule, roundish, compressed at the tip, acuminate, furrowed at its base by the calyx, two-valved, two-celled; partition simple, contrary to the valves. _Seeds_ numerous, small, angular.

Sp. 1. C. orientalis. Linn. Sp. Pl. Mart. 1. Lam. 1. Wild. 1. Gard. ed. 3. p. 56. 7. Linn. Hort. Pl. 53. (Verbascum Sphagianum) Tournefort. Linn. Syst. 8. Buxb. Cent. 5. p. 17. Blattaria; Buxb. Cent. 1. tab. 26. "Leaves bipinnate." Linn. Root annual. Stem a foot and half high, upright, lvs. bipinnatifid, simple or furnished with short branches, hairy from the bottom. Leaves alternate, scattered, bipinnatifid, not bipinnate as they are described by Linnaeus in the specific character, green, entire smooth; segments slender toothed: those from the root oblong, finely divided almost to the midrib, lying flat on the ground. Flowers pale yellow, small, solitary, sessile, axillary; segments of the calyx narrow, sometimes broad or trifid. A native of the Levant, flowering in June, is not far from Paris from Armenia by Tournesfort, in 1719, and cultivated in Chelsea-garden in 1739. 2. C. arcturus, Murray Syll. Veg. p. 460. Vahl symb. 5. p. 79. Mart. 2. Lam. 2. Wild. 2. (Verbascum arcturus; Linn. Sp. Pl. v. humble cicutum: Buxb. pin. 240. Alp. exot. tab. 123. Colum. cephr. p. 88. "Root-leaves lyrate; upper ones oblong; peduncles longer than the bracteas; segments of the calyx linear, quite entire." Vahl. Root biennial. Stem a foot high or more, slender, weak, often simple, leafy, villous. Leaves generally alternate, sometimes opposite, petioled, toothed, a little viscid, dark green. Flowers yellow, in a loose spike on the upper part of each stem: peduncles from thin to bare, moss long; filaments covered with red or purple hairs. A native of Campania, first cultivated at Kew about 1753. 3. C. campanulaeefolia, Wild. 3. Vahl Symb. 5. p. 79. "Root-leaves lyrate; lvs. one-shaped peduncles shorter than the bracteas; segments of the calyx linear-oblong, quite entire. Root annual. Flowers distinct about the size of those of C. arcturus. A native of the East Indies. 4. C. recta. Linn. Synth. Veg. p. 46. Linn. jun. Supp. p. 281. Mart. 3. Lam. 3. Wild. 4. (Verbascum; Mill. Ic. tab. 273. Blattaria; Mor. 2. 488.) "Root-leaves lyrate; lvs. one-oblong; flowers nearly febly, the length of the bracteas; segments of the calyx egg-shaped, fertilar." Vahl. Root biennial. Stem two feet high, herbaceous, simple, upright, cylindrical, pubescent. Leaves alternate, embracing the stem, wrinkled, fertilar, pubescent underneath. Flowers large, yellow, with a conspicuous spot at the base of each of the upper divisions; in a long terminal raceme; bracteas heart-shaped, acuminate, somewhat acutely fertilar, one-florewed; segments of the calyx pedicellate on the outside; two upper lvs. very short, with a dark purple board, and kidney-shaped anthers; two lower ones the length of the corolla, smooth, inclined, with linear anthers. A native of Campania and the East Indies. 5. C. barbatus, Wild. 5. Desf. th. 2. p. 38. (Blattaria; Dodart. ic. Shaw afr. 4. 38.) "Leaves ovate-oblong, wrinkled, febly, lvs. angulate, shorter than the pedicellae." Root biennial. Stem two or three feet high, erect, somewhat hairy, generally branched; branches slender, bearing the flowers. Leaves alternate, smooth or slightly hairy, obtuse, usually ovate, slightly hairy, obtuse, often pilose near the base; upper ones febly, embracing the stem, lanceolate, acute, toothed. Flowers yellow, with a dark purple spot at the base of each of the two upper divisions; segments of the calyx egg-shaped, acute, nearly equal, fertilar or entire; two upper lvs. shorter, hairy; two lower ones smooth, decumbent, incurved upwards. Capsule roundish, covered with the calyx. A native of warm ground about Algiers.

Propagation and Culture.—If the seeds of the first species be sown on a warm border as soon as they are ripe, the plant will come up and live through the winter provided the soil be poor but in rich ground they are generally destroyed by the first frosts, or rotted in rainy seasons. They do not bear transplanting, and require only to be thinned, and kept free from weeds. Plants grown in the spring seldom produce ripe seeds. The second and the fourth species require the protection of the green house. Millar.

Celsina, in Ancient Geography, an island situate between Italy and Sicily, according to the Itinerary of Antonius.

Celsinus Mons, a mountain supposed to have been in the isle of Chios.

Celsia, a small town of Spain, in Bética.

Celsitan, a people placed by Pliny in the island of Sardinia.

Celsus, in Biography, an early admirer of Chrillianity, is supposed to have been the chief of the reign of Emperor, who died A. D. 159; and is placed by Dr. Lardner, with his friend Lucian, in the year of Christ 176, not far from the end of the reign of Marcus Antoninus, who died in March, A. D. 160. Although he sometimes recites to Plutonic and Stoic modes of reasoning, he is expressly ranked by Lardner, who incribed to him as Alexander, or "Pseudamans," as well as Origens, who wrote against him, among the Epicureans; and this supposal bell accounts for the violence with which he opposed the Chrillian religion; for an Epicurean would of course reject, without examination, all pretensions to divine communications or powers. The book which he wrote against the Chrilians was entitled sapg, or "The True Word." Of this work we have no other remains besides the quotations made by Origens in his repetition of it. The extracts from his writings, prefixed by Origens, have given occasion to various opinions concerning his talents as an author toCHRILLIANITY. Celsus, says Molesheim, was a trifling cavalier, as is manifest from the anfwer of Origens; nor to his writings against Christianity serve any other purpose than to show his malignity and illiberal turn of mind. Cave observes, that Origens has powerfully refuted the futile cæsarsius and arguments of Celsus; On the other hand, Dc Pin reckons him one of the most artful and acute of the opponents of Chrillianity; and Brucker says, that while the extracts of Origens prove him to have been an inveterate enemy to Chrillianity, they shew that he was not destitute of learning and ability. The answer of Origens was written at the desire of his friend Ambrose; and was published, as some think, in the year 350, and according to others 249. It was greatly esteemed and celebrated, as an excellent work, not only by Eusebius and Jerome, but also by many judicious moderns, particularly De Pin; who says, it is polite and philosophical; not only the best work of Origens, but the complete and best written apology for the Chrillian religion, which the ancients have left us. Origens's apology consists of eight books, which have been divided by the Benedictines into sections for the convenience of perusal and reference. As Celsus, performing a Jew, undertook a labourous argument against the Chrilians, and wrote lately as the time of Marcus Antoninus, when the Chrilians were openly persecuted, and their affairs were better known by the perfection itself, and by the apologies then made for them; we may reasonably expect to find in his work many things that are useful to us in the vindication of our religion; and his testimony to the books of the New Testament is peculiarly valuable. From several paffages in Celsus, it appears, that the Jewish expectation of a Messiah was a thing well known; and that this
this expectation fulfilled before the appearance of Jesus in the world. And, indeed, they having such an expectation in the time of Celsus, is an argument that they had it before the coming of Jesus; for they would not have taken up such a notion from his followers. Many passages are cited by Lardner from Celsus, which contain references to the books of the New Testament. To the cavils of Celsus, grounded on the passages which he has cited, Origen has given very satisfactory answers. To the facts recorded in the New Testament, Celsus has borne testimony; though he has misrepresented and perverted them. With regard to the miracles of our Lord, it is not easy to determine whether Celsus believed them or not. But it is not more easy to see how he could disbelieve them; and he was at a loss how to account for them. "I think," says Dr. Lardner, "Celsus could not or would not allow our Lord's great works to have been done by the power of God, because he would not admit the consequence, which was, that Jesus had a divine commission, and acted by authority from heaven; and rather than admit that just and necessary conclusion, he has recourse to shifts and evasions, which are absurd and inconsistent." Accordingly, Origen says, "Celsus not being able directly to deny the great works which Jesus is recorded to have done, alberth them, and calls them juggling tricks." With regard to the moral doctrine of the New Testament, it appears, from passages of Celsus, that no just exception could be made to it. Although he does not allow it to have any superior excellence above the doctrine of the philosophers, he does not deny it to be like their doctrine, and equal to that of the best part of the philosophers. From other passages it sufficiently appears, that Celsus allowed the progress and spread of the Christian religion; and that he acknowledges the sincerity and steadiness of those who embraced it amidst the difficulties and hardships to which they were subject. As to his charge of magic against the Christians, this affords an argument, that there were some uncommon things done by them at this time, as Origen and other ecclesiastical writers have often asserted, but not to the detriment of mankind, as Celsus infinuates, but for their benefit. From passages relating to Christian worship, it appears, upon the authority of Celsus, that they worshipped the one God, creator of all things, and had a high veneration for Jesus Christ; nor would they worship demons, or join in the public festivials and festivals of heathen people. Celsus likewise speaks of Christian preachers; though they had not then any altars, or temples, nor other impassioned buildings to meet in. He also reproaches them with holding their religious assemblies privately, and contrary to law; nor was it without reason that they aimed at privacy; for, as he owns, they were then fought for to be put to death. Celsus appears not to have been unacquainted with the absurd opinions of some who went under the Christian name; whom he introduces with a view of calling the greater reproach on those who were more rational in their behalf. All the attacks of Celsus are against the more sober part of the believers: those others were fought for in order to disparage and expropate them, if possible. It is well known, that, soon after the rise of Christianity, the followers of Jesus were loaded with many calamities: they were said to kill infants, and eat them; and when the lights were put out, to pratique profanecious lewdness in their assemblies. Celsus, in whose time these charges were not extint, seems, however, to have thought them absurd and incredible; and to mention them with any marks of countenance and approbation, he suppos'd would be a prejudice to his argument. But though he has omitted these, he has introduced divers in-
perfect knowledge as he appears to have had of the dressas of the different sects of physicians, or would have been able to
describe the diseases he treats of with much accuracy, or
laid down the most approved methods for curing them that
were then known. All this he has done; it is therefore
reasonable to suppose he practised the art, in which he was
so complete a proficient. Friend, whose opinion we may
safely follow in every thing relating to the early history of
medicine, and its professors, produces, as a proof that he
practised surgery, a passage from that part of his work, where
he treats "De Oculorum Vitius," reproducing the method used
by Heracleides in curing adhesion of the eyelids; "Ego feci
restitutum effe neminem munus."

Friend agrees with Le Clerc, that Celsius was a Roman by
birth, probably of the Cornelian family; that he was born in
the latter part of the reign of Augustus Caesar, and was
living in the time of Caligula. The work by which he has
been rendered famous is entitled "De Medicina Libri Oeto." The great number of editions this book has passed
through sufficiently indicate the high esteem in which it is
held. It contains, in an epitome, every thing that is valuable
in the works of Hippocrates. In medicine he seemed to
have approved and followed the doctrine of Alcmaeonides; but
the most valuable part of the work is that which treats of
surgery, in which we find methods of practice laid down, and
modes of performing several operations described, in the man-
ner usual. The language also in which the precepts are
contained, is so pure and elegant, as to have contributed in
no small degree to the celebrity of the work. He is said to
have written on rhetoric and on other subjects, but his works
on those subjects, if they ever existed, are lost. Le Clerc,
Ant. Circ. Med. in which most of the editions of the
"De Med. Medicina Libri..." are noticed. The earliest was
at Florence, 1478, fol. One of the best is Almeloveen's,
edited at Padua, 1722, 8vo, by Vulpius, and reprinted in
1750. There have been also translations of Celsus into
French, English, and other modern languages. The short
abridgment of rhetoric, which has been attributed to him by
some, was printed at Cologne in 1560.

CELTES, CONRAD, named also PROTUCUS, and ME-
ISSEL, a modern Latin poet of some eminence, was born at
Schweinfurt, in Franconia, in 1439. After having acquired
a large stock of literary and scientific knowledge in his
studies at Cologne and Heidelberg, he visited many of the
German universities, and supported himself as a private lec-
turer. He was thus enabled to make a tour for improvement
through all the principal cities and universities of Italy. The
reputation he thus gained was the means of introducing him
to the elector of Saxony; and the emperor Frederic III.,
whom he was recommended by the elector, conferred upon
him the poetical laurel at Nuremberg in 1491. Having ter-
minated his rambles, he settled at Vienna; where he was
made professor of eloquence and poetry, and librarian to the
emperor Maximilian. Here he died in 1508. Celtes de-
serves to be ranked among the refiners of polite literature in
Germany. Of all the various writings which he left, the
poetical were the most distinguished. Whilst he possessed
fanciful vigour of imagination and brilliancy of expression,
he was deficient in good taste and correct judgment. Some
of the best of his pieces, containing amatory elegies, odes, ep-
graves, &c., were published at Stralsburg in 1515, by the
care of a literary society of which he was the founder. He
wrote also a poem on the manners of the Germans, on the
river Vistula, an historical account of the town of Nuremberg,
the collography of Ariostello and Apulius, orations, and

CELTI, in Ancient Geography, a place of Spain, between
Albita and Regiana, according to the Itinerary of Antonine.
Pliny makes it the chief of the towns in the jurisdiction
of Hispaliu.

CELTIBERIA, the ancient name of a country of Spain,
in the Parragonenides, and to the eall of Carpentania,
according to Pliny and Ptolemy. The latter places in it 18
towns. It was originally of large extent; but the wars of
the Romans reduced it to a narrower compass.

CELTIBERIANS, a powerful and celebrated people
who occupied the greatest part of the interior of Spain.
Polybius, when he relates that T. Gracchus had subdued
300 towns in this country, seems to have exaggerated
the number, in order to flatter the vanity of Gracchus, who
had made this conquest in the year of Rome 575. Livy makes
the fame report; but Strabo very justly oberves, that these
authors had raised mere villages to the rank of towns.
According to this author, Celtiberia produced a great
number of plants, the roots of which served the purposes of
dyeing. He adds, that the part of it which was near the Medi-
terranean abounded with vines, olives, figs, and other trees
which yielded excellent fruits. Their principal towns were
Catalanum, Turiafo, Bilbilis, Ergovica, and Valeria. The
Celte-
berians, according to Diodorus Siculus, were a people com-
posed of two nations, the Ilbians and the Celtes. Accord-

CELTI, in Ancient Geography, a place of Spain, between
Albita and Regiana, according to the Itinerary of Antonine.
Pliny makes it the chief of the towns in the jurisdiction
of Hispaliu.
CELTICA, a spacious country, which, according to Plutarch, extended from the ocean and the northern climates as far as the Palus-Mecedotes to the call, touching on one side on Pontic Scythia.

CELTICI, a people of Spain, who, according to Strabo and Pliny, dwelt on the confines of Lusitanian.

CELTICI Mirbregienses, were, according to Pliny, the inhabitants of Mirbridge, a town of Spain.

CELTICO Nereus, a people of Spain, placed by Pliny on the promontory of Nereus, the present Finisterre.

CELTICO Praevenarii, a people of Spain, in whose country were the rivers Tamaris and Sars.

CELTICUM Promontorium, a name given to the promontory of Artabrum, called allo Nerion, on the western extremity of Spain, to the N.W., now Finisterre.

Gen. Ch. Hermaphroditic. Cal. perianth one-leaved, five-parted; segments egg-shaped, spreading, withering. Cor. none. Stam. filaments live, very short, at frift concealed by the anthers, but after the shedding of the pollen growing longer; anthers oblong, thickish, quadrilateral, marked with four furrows. Pijl. germ superior, egg-shaped, at least as large as the calyx; styles two, spreading, variously inflexed, awl-shaped, pubefcent, very long; filaments free or bident.

The two kinds of flowers are sometimes separate, and sometimes on the same raceme; in the former case the male flowers are situated below the others.

A tree. Trunk from 40 to 50 feet high; branches numerous, spreading, long, flexible, pubefcent near the summit. Leaves near four inches long, and about two broad in the middle, dark green, serrate, obliquely narrowed, veined, rather scabrous above, slightly villous on both sides, especially when young; stipules rather long, linear, narrow, caducous. Flowers axillary all along the branches, small, an herbaceous colour, perishing before the leaves have attained to half their size; pedicels solitary, generally simple, about three-fourths of the length of the young leaves; stigmas villous, bifid. Fruit about the size of a small cherry, blackish, round, a little flabby. A native of the north of Europe. The flowers open at the beginning of April. The fruit comes to maturity in the ensuing January, and continues on the tree till the sap rises in spring; it is rather astringent, and is eaten not only by birds, but by children, in Spain. Its wood is of a dark colour, remarkably hard, compact, and heavy; tough and flexible, and therefore excellent for making the shafts of carriages and hoops of barrels and tubs; next to ebony and box in durability, strength, and beauty; capable of receiving a fine polish, and, when sawed obliquely, is said to be a good substitute for the fattening wood of America. The ancients used it for flutes and other musical instruments, and as it is not subject to crack, it is particularly fit for the purposes of the carver. The root is less compact than the trunk, but of a darker colour, and suitable for the shafts of knives and other utensils. Sapodilla obtained from the express feeds an oil with a flavour similar to that of oil or sweet almonds. As an ornamental tree, it merits the attention of the planter, having a fine regular spreading head of a cheerful green colour, coming out in early March, and retaining its leaves late in the summer. It has not, however, been much cultivated in England, and is less common than the next species. 2. C. occidentalis, Lam. Sp. Pl. 3. Mart. 2. Lam. 2. Gartt. tab. 77. fig. 3. Lam. Illuf. Pl. 844. fig. 1. (C. fruticu fructufruits.) "Leaves obliquely egg-shaped, serrate, acuminate; fruit solitary. B. "Leaves more slender, less acuminate." A tree. Trunk straight; in young trees even, and of a dark colour; in older ones rough, and lighter green; branches spreading. Leaves alternate, broader and florifer than those of the preceding species, tender, quite entire at the base and tip, serrate in the middle, obliquely serrated, veined; pedicels slightly villous from three to six lines long. Flowers opposite the leaves; segments of the calyx oblong, obtuse, concave, spreading, pointed at the edges; flaminas nearly the length of the calyx; germ conical, surrounded at its base by a ring of fine, short, whitish hairs, which continue on the young fruit Fruit the size of a small cherry, oval, appearing like a berry, of a deep purple colour and sweet taste; stone globular, not dividing, white, hard, a little wrinkled. A native of Pennsylvania, first brought into England by John Tradescant; flowering in May, and ripening its fruit in October. There are many large trees of this latter species in the English gardens, which, in favourite climates, ripen a great quantity of fruit; and there are few years in which the fruit is not sent from America. It comes out late in the spring, but retains its leaves longer than any other deciduous tree. Its wood is tough and pliable, and esteemed by joiners and plategenerators for the frames of their carriages. The variety a is a native of Louisiana, and was cultivated in the royal garden at Paris, but as it was killed down to the root every winter by the frost, La Marec never saw its fruit or flowers, and, therefore, could not determine whether it be merely a variety or a distinct species. 3. C. crassifolius, Lam. 3. "Leaves somewhat heart-shaped, serrate, acuminate; pedicels often with two flowers." Branches woody, cylindrical, pubescent in the young shoots, with a reddish brown bark. Leaves in young plants five inches long, and three or a half broad, alternate, petiolated, generally enlarged on each side with a kind of roundish edge, as to appear somewhat heart-shaped, but, with the inequality, observable in the other species, rough on both sides, with short hairs, especially on the upper surface; pedicels short, slightly villous. Pedicels axillary, generally two or three-flowered, longer than the petioles. Fruit round, smooth, about the size of a small cherry. A native of North America: cultivated at Paris; and described by La Marec from a living plant. 4. C. americana, Mart. 4. Plum. Cat. 18. "Leaves oblong-egg-shaped, obtuse, serrate, smooth above, brown underneath. Trunk near twenty feet high, covered with a grey bark, and divided at the top into many branches. Leaves near four inches long, two and a half broad, rounded at their extremity, of a thick texture, very smooth on their upper surface, and on their under, of a lucid golden colour. Fruit round and red. Found by Pluemer in the French West India islands, and by Houtlon in Jamaica, and cultivated by Miller. Nearly allied to the preceding, if not the same species, differing chiefly in the surface of the leaves. 5. C. Tournefortii, Lam. 4. (C. orientalis minor, Tour. Cor. 41. Voyage, vol.
about branches from Lam. moderate panicles fertile very small, 26. native Loti clothed, loufl petioles Rhamnus villous fome.

"Leaves ovate-lanceolate, finely ferrated, very fbruous; racemes axillary, small." Branches cylindrical, cinctuous, smooth; smaller ones clothed with numerous, up-right, awl-shaped, short hairs, which render their surface a little feabrous. Leaves an inch and half or two inches long, about half an inch broad, alternate, on short peduncles, narrow, acute, conicous, firm, light green; sprinkled on both surfaces, but especially on the upper one, with a multitude of small whitish tubercles, each terminated by a short stiff hair, which render their surface as rough as a file or the skin of a shark; the intervals between these tubercles are smooth and shining, appearing as if they were varnished. Flowers very small, on short pedicels; in axillary, nearly simple racemes, either solitary, or two or three together, furnished at each of their divisions with a short bracte. Fruit, when young, green, smooth, surrounded at the base by the permanent calyx. Described by La Marek from a dried specimen sent from Martineau by Joseph Martin. The identity of Swartz's plant appears dubious. According to him it is fifteen feet high. Trunk straight, with a smooth, reddish or light brown coat, and several branches spreading towards the top. Leaves alternate, innately decurrent, indistinct from each other, two inches long, and half as broad near the base, dark green, petiolar. Flowers axillary, small, greenish. Fruit orange-coloured, not bigger than a pin's head, oval, insipid, having an orange-coloured pulp and a black round stone within. 9. C. trimorpha, Lam. 8. "Leaves egg-shaped, ferrated, three-nerved, nearly smooth; flowers fascicled; fertile one with a longer pedicel." Branches cylindric, greyish, slightly villous at the extremities. Leaves two inches, or two inches and a half long, little more than an inch broad, alternate, slightly acuminate, soft, thin, of a fine green colour; petioles about two lines long, pubescent. Flowers small, greenish; from three to fix together, on a common axillary, solitary peduncle, much shorter than the petiole; generally only one fertile flower in a fascicle; fr axes scarcely longer than the calyx; styles slightly villous. A native of St. Domingo. 10. C. integrifolia, Lam. 9. "Leaves roundish, ovate, acuminate, quite entire; styles hid." Branches alternate, cylindrical, slightly villous. Leaves about two inches and a half long, an inch and half broad, alternate, firm, thickish, slightly feabrous above, green on both sides but paler underneath; with four or five elevated, branched, longitudinal nerves proceeding from their base; clothed, when young, with a few short hairs, which gradually disappear, and finally remain only on the nerves; petioles a quarter of an inch long, villous like the nerves, slightly channelled on the upper side. Flowers small, greenish; in dichotomously branched panicles, solitary, or one or two together from the axil of the leaves; the male ones with very short pedicels. Fruit when young villous. Brought from Senegal by Adanson. 11. C. acutata, Mart. 6. (Rhamnus rigidus, Jacq. am. 74. 1. strictus, Jacq. 1. ziziphus swartzii, Mart. 1.) "Leaves cordate-egg-shaped, blunt at the tip, almutit entire, very smooth; branches prickly; styles hid." An insipid little tree. Branches very long, plant, reclining, not much divided, frequently with alternate, dilith branches the whole length; the upper ones gradually shorter. Leaves commonly three or four, sometimes eight inches long, alternate, dilith, smooth, petiolar. Spines in the axils of the leaves and branches, awl-shaped, very sharp, strong, and short, recurved, solitary, or in pairs. Flowers small, yellow; in small axillary racemes, growing one, two, or three together; segments, with hardly any tube and no scales; in the male flowers instead of the pithil, there is an oblong truncate body only half the length of the calyx. Fruit yellow, double the size of a pea, containing a sweet pulp.
pulp which is eaten by the natives; bone or nut wrinkled, thick, bony, white, once-celled. A native of the Caribbean islands, and the neighbouring continent. Swartz observes that Rhamnus ignatinus of Linnaeus should be placed in this genus on account of its calyx without petal-like scales, its two styles, and its fruit; but he doubts whether it be the ignatinus of Jacquin here described. It derived its trivial name from its growing in rocky places frequented by the Iguana.

Propagation and Culture. These trees are all propagated by seeds, and most of them are hardy enough to endure the open air in England, when they are become strong; but for the first two winters after they come up from seeds they require to be protected from frost. It is best to sow the seeds in autumn soon after they are ripe; and they ought by all means to be sown in pots or boxes, that they may be shifted into different situations according to the season. In the following spring they may be removed into nursery beds prepared for the purpose, in a sheltered situation, and if possible in a gentle loamy soil. If the surface of the ground be covered with old man or rotten dung, it will keep it moist, and prevent the drying winds from penetrating to the roots of the plants. After the plants have remained in the nursery beds two years they may be transplanted to the situations where they are intended to remain.

CELTO-GALATIA, in Ancient Geography, a name given by Ptolemy to Celtic Gaul; and which he divided into four provinces, viz. Aquitania, Lugdunensis, Belgica, and Narbonensis. See Gallia.

CELTO or CELTS, a marsh or lake which seems to have been loft in the Euxine sea, according to Lycophron. Ortelius conjectured, that it was one of the marshes at the mouth of the Danube.

CELTS, or CELTS, in Ancient History, the name of a very ancient people, whose descendants were the aboriginal inhabitants of Gaul and Britain. It was, however, more particularly given to a part of the Gauls, whose country, called Gallicia, was situated between the Seine and Marne and the Garonne.

The remoteness of their early history, and the obscurity in which it rests, make every effort to elucidate the first origin of the Celts of no avail. The opinions both of the ancient and the modern writers who have mentioned them, are equally vague and indeterminate; and it is perhaps enough to say, they appear to have been the most ancient inhabitants who can be traced in this quarter of the globe. Herodotus (II. 145), speaking of the Danube, says, "it commences with the Celts, who, except the Cynetes, are the most remote people in the west of Europe.

The little knowledge which the earlier Greek and Roman writers had of the barbarous nations round them, and the small pains they took to gain accurate information about their peculiar differences and distinctions, led many of them to confound the Celts, the Gauls, and the Sarmatians. Strabo (Geogr. lib. ii. p. 95) particularly states, that the writers before his time were both ignorant and uncertain in all that they related of those countries which formed the more immediate residence of the Celts. Nor can we allow more credit to the writers of a later date, who have rather guessed at the ancestry of the Celts, than given authentic materials for their history. One of the earliest on the continent was Ptolemy, whose work "De Prima Cels copia," appeared at Paris in 1556. The next writer of authority was Reinecke, who, in the second volume of the "Hisoria Julia," treated amply of them, as far as they were supposed to be related to the Gauls and Germans. Van Steeck was the next, who in the early part of the 17th century wrote ex-prefaly on their origin. Another writer was Peizton. The hallucinations, errors, and etymologies of the generality of those who followed, with the exception perhaps of Keyser, appear almost to have involved their history in fable. It was refuted by Pelautier. Yet though some of the most authentic and curious particulars in this article are obtained from his work, we cannot acquiesce in one of his leading features. This will appear presently.

The great source of mistake and confusion to many learned writers on the history of Europe has been the idea that the ancient Gauls and Germans, Britons and Saxons, were originally but one and the same people; thus confounding the antiquities of the Gothic and the Celtic nations. This idle opinion was long maintained with uncommon exhibition. Cluverius, in his "Germania Antiqua," and Keyser in the "Anti-quitates Selectae Septentrionales," etc., incautiously adopted it, and even Pelloutier, in the last and bell work which has appeared on the history of the Celts, has endeavoured to confirm it with great diligence and skill. In short, Bayle, bishop of Percy (Pref. to the North, Antiqu. p. 84), so much learning and ingenuity have fearfully ever been more perfectly or erroneously applied, or brought to adorn and support a more groundless hypothesis.

The ancient and original inhabitants of Europe, according to these writers, consisted only of two distinct races of men; the Celts and the Sarmatians. The Sarmatians, or Sarro- matics, they make the ancestors of the Sclavonian tribes; and represent the old inhabitants of Gaul, Germany, Scandinavia, Britain, and Spain, as the uniform descendants of the Celts. The last they state were all included by the ancients under the general name of Hyperboreans, Scythians, and Celts; having all the same common language, religion, laws, customs, and manners.

From Herodotus we have already shewn, that the source of the Danube, in the Black Forest, in Subbia, was originally among the Celts; and it seems probable that at that remote period the Sacae and the Maflagatae, the probable ancestors of the Saxons and the Goths, had not penetrated so far westward as they did afterwards. The Sarmatians are spoken of by the same writer as a Persian people (in Asia). It may likewise be worthy of observation, that, having mentioned the commencement of the Danube, he adds, "This river passes directly through the centre of Europe, and by a certain inclination enters Scythia." In this passage he seems expressly to distinguish the Scythians from the Celts; although it is no proof they were not confounded by frequent historians, or that the fluctuation of opinion might prove a consideration which would in fact reconcile the different information.

Cluverius, Keyser, and Pelautier have uniformly supported their hypotheses by obscure quotations from ancient authors, and arguments derived from etymology, leaving the precise and positive testimony of Cæsar relating to the Celts, and of Tacitus, relating to the Germans, almost entirely neglected. Cæsar, in the very first page of his Commentaries, expressly affirms us that the Celts, or common inhabitants of Gaul, in his time, differed "in language, customs, and laws" from the Belgae, on the one hand, who were a Teutonic people, and from the inhabitants of Acquitania on the other, who, from their vicinity to Spain, were probably of Iberian race. His words are remarkable: "Gallia est omnis divisa in partes tres: quarum unam incolumem Belgas, ab aqua Aquitanica, tertiam, qui ipsorum lingua Celtis, nolit Galli appellantur. Hi omnibus, linguas, institutis, legisibus, inter se different. Gallos ab Aquitanis, Garamum, Belgas ab Aquitanis, et Sequana dividit." The text here quoted is Oudendorp's; but in a note subjoined, Cæsar's words corrected, and the theory of Cluverius admitted. T. D.
But in the sixth book of his Commentaries, Caesar is still more particular; and his remarks are worth minute attention. He draws the characters of both nations at length, in an exact and well finished portrait, and states every essential difference by which the Gauls were distinguished in their laws, their customs, and their religion from the Germans; and closes with an observation, which we cannot but repeat, as we gain from it by inference that both nations had a separate origin. There was a time, he observes, when the Gauls were inferior to the Germans in valor; when through the increase of their tribes or the fecundity of land they sent colonies across the Rubicon. (Cesar de Bella Gallico, lib. vi. c. 24.)

Such appears to be the true history of the Celts. The love of what is ancient, however, or the belief of fable, has led the historians of almost every period into the labyrinths of more remote antiquity. They have considered Celts as the generic name of a vast people, known in different tracts of territory by a variety of names and characters. Of Cymmerians, Cyprians, or Carmarians, by which they relate them to have been sometimes called in the north of Europe, they have made Goemarians, and pretend to trace them even to Genier, the grandfoul of Noah. (See Pezron Antiquites de la Nation et de la Langue des Celtes. Ancient Univ. Hist. vol. iv. p. 180. Davies’s Celtic Refereches.) The folly and the fallacy of such inquiries need hardly be exposed; they are only equalled by the history of their migrations from Asia to Europe; and the chronology of the Titan princes. They who would indulge their curiosity farther on the subject may consult Mr. D. Jones’s translation of Pezron, published in this country, 1766; whence it may not only be learnt “that Saturn, the son of Uranus, was the first king of the Titans;” but “that the Titans were true Celts.”

In the difference of opinions which has been already mentioned, it is not easy to fix the exact boundaries which have at all times divided the Celts from the other inhabitants of Europe: it is on this account that we cannot but consider the work of Pelloulier, otherwise so excellent, as a perpetual source of mistake and confusion: in consonance with this idea he confines [liv. i. ch. vii. &c.] not only the Germans, but all the people settled along the banks of the Danube to the Black Sea, the Goths, the Dacians, Baffatians, (or Germans beyond the Vistula) Visigoths, Huns, and other tribes, to have been Celts. The ancient inhabitants of Greece, according to him, were either Celts or Scythians; under the same denomination he includes the Ligurians and the people between the Alps and Apennines. The Venetians, he says, were originally Gauls; and the Romans half Celts, half Greeks.

After such affirmations, we shall probably err very little in confining ourselves to the testimonies of Caesar, and a few of the more rational historians; who, without torturing etymology, afford us facts; and, though they may confine the territory of the Celts, at least give us something which may be relied upon as history.

Mr. Pinkerton, in his “Difleration on the Origin and Progress of the Scyphians and Goths,” has discriminated them from the Celts in a very clear and manly manner. Cluverius, Keyler, and Pellouier, have undoubtedly made many quotations from the ancient classics, which seemed to give their theory indisputable countenance. To produce all their authorities would be to fill a volume. From Herodotus to Caesar, passages may be found with very little trouble, which shew the uncertain and confused ideas of the ancients, in regard to the nations which lay round them. Arrian (book i. ch. 1) particularly mentions the warlike tribes on the banks of the Danube; ter mina Kelatica, “and especially the Celts.” But he describes them in a manner which shews he included the Tustiae tribes; and expressly enumerates the Macedonians and the Quadi, so particularly spoken of by Tacitus. (De Morib. Germ. cap. xli. xlii.) Snidas also, who lived so late as the 1st century, makes Kelt to have been the general appellation of the German tribes. There is a passage, however, in Dio- dorus Scaliger, one of the best informed and most judicious of the Greek historians, (who not only wrote after Caesar, but profited by his biographers,) which the modern antiquaries on the continent ought to have consulted. He tells us (De juxt. Scil. lib. v. p. 354, ed. Woffeling), “it is particularly necessary, in describing the Gauls, to make a distinction, of a high the generality of the world court ignorant.” That the people who inhabited the country from above Mareilles, and at the Alps, and then on the side the Pyrenean mountains, were called Celts. But that those who inhabited beyond this region and the parts towards the south, and situated on the ocean, and those toward the Hercynian mountains, and all onward, even to Scythia, were called Gauls; a name, he adds, which the Romans gave generally to all those nations.

We give the passage in the original. Χρησμον, δε λογισθείς το περί τοις προσφερομένοις τάξεσιν και τούς Τάτας, επι τον ταύτας ατύπους, επι τον ταύτας εμπεσομένους, ΚΕΛΑΤΟΥΣ ορισθέντες το αυτό της τετράκης της Κέλαιας: το τρίτον άδυνα τουτής μεγάλη της τον κατά τινα έπερεικα, κατά τινα δε μεγάλη, Σεγατών, ΓÅΛΛΑΤÇS πληρώθηκαν και τον Ρώμην παλιν παλιν τον έτη πληρώθηκαν και τον έτη των μεγάλων Σκοτών, ΚΕΛAIÀS ακολουθήσας, κατά της τούτης θελήσας, Σκοτών, ΓÅΛΛΑΤÇS πληρώθηκαν και τον Ρώμην παλιν παλιν τον έτη πληρώθηκαν και τον έτη πληρώθηκαν κατά της τούτης θελήσας, Σκοτών, ΓÅΛΛΑΤÇS ακολουθήσας.

Diodorus, says Mr. Pinkerton, (Duffett, on the Scyth. p. 125,) no doubt knowing that the Celts were not those Gauls celebrated in Roman history, but quite a different people, posifting the inner or further part of Gaul, with propriety puts them as different nations. Indeed Polybius, by the very enumeration of the different tribes, which one Rome was pilled over Bremen, convinces us that those Gauls were Belgium; and that their irruptions have nothing to do with any history of Gallia Celta. Caesar, observes Mr. Pinkerton, (Duffett, p. 125,) by showing the Celts to be confined to such small bounds, palpably marks that other nations had gained ground on them, so as to confine them to such a contracted space. Of their early history then, we are still in that uncertainty which we seem to have inherited from the first writers among the Greeks and Romans; and excepting what we gain from Caesar and Diodorus, we know but little of their manners. The region they retained at that period was small. And even in Britain, an island which may, perhaps, rank among their earliest possessions, they seem to have been in part exterminated by their Belgic neighbours. The Belgic, as Caesar shews, had all the south end of present England. (See Caesar de Bella Gallico, lib. v. c. 12, and Pinkerton’s Dufett, p. 121.)

After these preliminaries, we proceed to their more special history, as it is detailed by Caesar. In the account of his second expedition into Germany (lib. vi. c. 7,) he draws the contrail we have already mentioned between the Germans and the Celts: a picture which, with the addition of a few touches from the pens of other masters, will be found the most correct, in regard to the Celts, we are poffed of. Previous to his time we have nothing that can be called authentic information.

The Gaul, says Caesar, are, every where, from provinces to families, divided into factions. On his first arrival the Amuonis, wi whom the Autouonis, and the Seguni, who lived in
in Upper Burgundy, were at variance. The latter had always been the weakest, and the former the strongest tribe: "quod summa auctoris antiquitas erat in Adiuli."

(Bell. Gall. lib. vi. c. 12.) But the Sequani, assisted by the Germans, defeated their opponents; while the Adiuli sought the friendship of the Romans. Caesar changed the face of affairs. He restored the Adiuli to their lost preponderance, and, by artfully employing one faction against another, was enabled to reduce them all. This, upon his own authority, is the introduction to the contraband.

Throughout Gaul, he says, (and it was the fame in Britain,) there were only two orders of men in any high degree of honour or esteem: the Druids and the Nobles. The common people were nearly all upon a level: fo submissive to the will, and fo dependent on the power of the nobles, that their condition was little better than that of slaves. In the lowest rank, were such as had been taken in war, or by some other means reduced to actual slavery. These persons were the property of their respective masters.

The Druids had the supreme and sole direction in everything relating to religion. By them, as the favourites of the Gods, and the depositories of their councils, the people offered all their sacrifices, thanksm and prayers; they educated the greater part of the youth; were held in the highest honour; and determined all causes and controversies, whether of a public or a private nature. (See also Diod. Sic. lib. v. § 31.) If any crime was committed, or a murder perpetrated; if any disputes arose either about the division of inheritances, or the boundaries of cities; they alone dispensed both rewards and punishments. Whoever refused to submit to their decrees, whether tribes or individuals, were interdicted from the sacrifices: and the interdict of the Druids was most dreadful. They against whom it was pronounced, were held in universal detestation, as impious and abominable; their company was avoided as dangerous and contaminating; they were declared incapable of any trust or honour; put out of the protection of the laws; and exposed to injury of every kind.

Over all these Druids, one, who had the greatest authority, presided. On the demise of the Arch-Druil, if there was any one more eminent than the others in the ordinary chais, he succeeded: but, in general, the high priest was elected from among the remaining Druids by a plurality of votes: though sometimes this office was an object of ambition; not obtained but by the force of arms. Once in the year, at a certain appointed time, they assembled on a conflagrated spot, in the country of the Carnutes (the Paits Chastreis), which was thought the centre of Gaul. Hither all who had law-suits came, and implicitly submitted to the decision of the Druids.

The doctrines of Druidism, it was the received opinion, had their origin in Britain; and were thence transferred to Gaul. And even in Caesar's time, they who were delirous of becoming adepts in its mysteries, went to Britain for the purpose.

The Druids were exempted from taxes and military services; and enjoyed many immunities. Numbers, allured by the honours and privileges of the profession, embraced the discipline of their own accord; while many more were dedicated to it by their parents. The Druids were fain to commit an infinite multitude of verses to memory; and some of them paled no less than twenty years in becoming living repositories of their doctrines; since it was not lawful to entrust them to writing; though, in almost all other public transactions, and private accounts and computations, they made use of Greek letters.

The immortality of the soul, and its transmigration into other bodies, were among their leading doctrines; by which they excited an undiminished courage, and a sovereign contempt of death. Before these, they entered into disquisitions and disputations in their schools, concerning the stars and their motions, the form and magnitude of the universe in general, and the earth in particular; on the operations of nature; and on the powers of the immortal gods.

The second description of men, enumerated by Caesar, were the Nobles, who, in war time, appear to have assumed the command of their respective tribes. They were skilled in the arts of fighting, and were readily followed by their dependants into actual service.

From the mention of these, he proceeds to the religious principles and opinions which the Celts maintained. Gaul, as a nation, he says, was addicted to superstitious. They who laboured under diftance, or expected to be called to battle, either offered, or promised the future sacrifice of human victims. For it was an article in their creed, that nothing but the life of man could atone for the life of man.

For this purpose they used the minister of the Druids. At more important times, however, they formed colossal images of warriors, filled them with victims, let fire to them, and destroyed the whole. On these occasions, such as had been guilty of theft, robbery, or other crimes, were deemed the most acceptable offerings to the gods. But when criminals were fearss, the innocent supplied their place.

Mercury, according to Caesar, was regarded as their chief deity; they honoured him with images, and ecstatic him as the inventor of arts, and as the protector both of the public ways and commerce. After him, Apollo, Mars, Jupiter, and Minerva were worshipped; of whom their notions, he says, were much the same with those of other countries. They considered Apollo as the curer of diseases; Minerva as the guardian of works of art; Jupiter as the governor of heaven; and Mars as the god of war. To Mars, before they entered on a war, they usually vowed a great part of the expected spoil; and when they had sacrificed all the animals taken, they deposited the rest apart. In many of their flates, says Caesar, these flopes are seen piled in heaps in their consecrated groves. Nor did it often happen that any one neglected the performance of his vows, or secreted his flare of spoil, or having once devoted it, withdrew it. Such persons were punished with the severest tortures.

The Gauls considered themselves as the progeny of Dis, to the common people were told by the Druids; and on this account they reckoned time not by days but nights. In the institutions of ordinary life, they differed materially from other nations in this respect; that till their children arrived at a manly age they were not suffered to appear in public before their parents. It was accounted a shame for a father to be seen in company with his son.

Whatever fortune the wife brought, the husband was obliged to equal; and the principal and produce of both were laid up for the survivour. The husband had power both of life and death, not only over his children but his wife. When any one of distinction died, his nearest relations were assembled, and if there appeared any cause of fulmination as to his death, they had power to put the wife to the same torture as the meanest slave, and if found guilty, she was burnt to death in the most execratory manner. The funerals of the Gauls, he adds, considering their circumstances, were sumptuous and magnificent. It was their custom to throw into the funeral pile on which the body was burnt, those things, and even those animals, in which they deceased had most delighted; at a remoter period, however, they throw into the flaming pile such of his servants and friends as had been
CEITS.

been his greatest favourites, and all were reduced to ashes together in the same fire.

With those flates which were esteemed the belt admis-
tered, it was a law, that whoever should receive intelligence from any neighbouring state, of public importance, should communicate it only to a magistrate; lest they who might be alarmed by rumours, should, by rash resolutions, raise a ferment. The magistrates concealed what part of the in-
ligence they pleased; informing the public of the rest. Except in the general assembly, it was not allowable to talk of
state affairs.

Thus far we have the direct words of Cæfar. From a
few other writers we obtain additional points of information, which throw as much, if not more light upon a large portion of the early inhabitants of Britain, as upon the Celtics in gen-
eral. The particular history of the Druids will form a
separate article hereafter. Helius, according to Boxhorn (Orig. Gall. c. i. p. 41.), was the name by which Mars was
worshipped by the Gauls and Britons, although there appears some reason to believe, that he does not mean the Cætus but the
Belie Gauls. Didst answer to the Pluto of the Greeks. The
fun is said to have been worshipped under various names, prin-
cipally expressive of the nature and properties of light and heat.
To this object of idolatrous worship, the circles of stones de-
terred by Dr. Stukeley and others, are supposed to have been
chiefly dedicated. Saturn, of the worship of whom in the west-
etern parts of Europe we have the evidence of some of the clas-
cic writers, is flated to have been another of their deities (see
Henry's Hist. of Britain, vol. i. p. 107,); and others are in-
ditinctly mentioned by Roman apppellations, of whose history
we have no clear intelligence. It is to be regretted that
Cæfar did not give us the Celtic names of the several deities
worshipped in Gaul, as well as the names in use among the
Germans. In some resemblance of the attributes ascribed to
Helius and Tereuta, the Greeks and Romans saw Mars and
Mercury, and thence inferred that their own modes of
worship extended to barbarous nations. "The Greek and
Roman travellers and conquerors," says Mr. Hume (Hist. of
Natural Religion), "without much difficulty found their
own deities every where; and said, this is Mercury, that
Venus; this is Mars, that Neptune; by whatever title the
strange gods might be denominated."

What were the hymns either of the Gauls or Britons we
are ignorant. The Druids, as we have already seen, in-
structed their disciples in a poetical system of divinity; but as
their verses were never committed to writing, they were lost.
Their offerings, which constituted so important a part of
their religion, have been described by Cæfar; and their arts
of devotion, with some minuteneus, by Diodorus Siculus
(lib. v. c. 35). Pliny, in his Natural History (lib. xvi. c. 44),
says, the Druids held nothing so sacred as the milletoe of the
oak. As it was very scarce, when any of it was discovered
they went with great pomp and ceremony on a certain day
to gather it. When they had got every thing in readines-
under the oak, both for the sacrifice and the banquet which
they made on this great festival, they began by tying two
white bulls to it by the horns. Then one of the Druids,
clothed in white, mounted the tree, and with a knife of gold
cut the milletoe, which was received in a white flagon. This
done, they proceeded to their sacrifices and fealtings. The
Druids, he adds, had so high an esteem for the oak, that they
did not perform the leaf religious ceremony without being
adorned with garlands of its leaves. They believed that
every thing that grew upon it came from heaven, and that
God had chosen that tree above all others. There are,
however, one or two circumstances which lead us to doubt
whether Pliny here describes the Celtic Druids.

The sacred groves in which their religious ceremonies were
performed, was surrounded by a ditch or mound, to prevent
the intrusion of improper persons. In the centre of this, a
regular area was inclosed with one or two large rows of
columns. This was the temple. Close at hand was the car-
rue, or sacred mount; the cromlech, on which the sacrifice
was prepared; and all other things which were necessar-
for their worship. Stonehenge, if it really was a Druid
 temple, is the most magnificent of all that are remain-
ing.

In regard to the state of society and government among
the Celts, we find that both Gaul and Britain were divided
into petty states, each composed of two, three, four, or even
more clans or tribes. The king of which was commonly
the head of the chief clan of which the state was composed.
(See Henry's Hist. of Britain, vol. i. p. 161.) Thofo into
which Britain was divided need hardly be enumerated here.
The rule of succession to the throne is supposed to have been
hereditary; as well among the Celtic as the Belgic Gauls.
(Compare Cæfar de Bell. Gall. lib. v. c. 20. Stien. Vit.
Calig. c. 44. Tacitus Hist. lib. iii. c. 45. and Dio Cassius,
l. ix.) And the chief prerogative of the Celtic kings was
that of commanding the forces of their respective states in
time of war. In every thing else they seem to have been in-
ferior in their power to the Druids.

The little knowledge which we have of their theology,
philosophy, and jurisprudence, is gathered with difficulty,
and only from the scattered notices of ancient writers.
Strabo informs us, (lib. iv. p. 157,) that it was one of their
physiological opinions that the universe should never be
entirely destroyed or annihilated, but should undergo a suc-
cession of great changes and revolutions, which were to be pro-
duced sometimes by the power and predominance of fire, and
sometimes by that of water. They were acquainted with a
year, apparently exact enough for the purposes of life, but
not fitted for astronomical calculations. Pliny (Nat. Hist.
lib. xvi. c. 44,) says, "they began both their months and
their years not from the change, but from the sixth day of the
moon." The particulars and extent of their knowledge in
this part of astronomy are not farther preferred. If they
used Greek letters in their ordinary calculations, as Cæfar
has recorded, we must conclude they were acquainted with
arithmetic; and the rockings-stones alone are sufficient to
evince that they had some knowledge of mechanics. The
houses of the Britons, as Cæfar faw them, are particularly
described to us in the Commentaries. (De Bell. Gall. lib. v.
c. 2.) They were like those of the Gauls, though little
more than wretched cabins. (Zonaras, p. 189.) Their
clothing was usually a fawn (Bell. Gall. lib. v. c. 14,) cast
about the shoulders like a mantle. "Thofo," says Diodorus
Siculus (lib. v. p. 147,) "whom dwell near the promontory
Belorium (or Land's end), are very hospitable, and, by their
great intercourse with foreign merchants, much more civi-
lised in their way of living than the other Britons. They dig
tun ore out of their mines, and prepare it with great dexterity
and art. Though this ore is naturally of a hard substance,
like stone, yet it is mixed and incorporated with much earth,
from which they separate it with great care, and then melt and
cast it into blocks or ingots of a square form like dice." This
was the only metal they were acquainted with as the produce
of the island. In the art of war all the young men among
the Celtic nations were regularly trained; and their troops,
though they appeared, were chiefly composed of infantry.
The military cars of Britain (the Effides of Cæfar, and the
Covini of Tacitus) feem rather to have belonged to the Belgic
than the Celtic inhabitants. War-chariots, says Mr. Pinkerton,
were not known among the Celts. Their early trade was with
with the Phenicians (the foreign merchants spoken of by Diodorus Siculus), who appear to have laboured with a very anxious care to conceal the knowledge of their commerce. A singular anecdote of their jealousy of this exclusive trade is mentioned by Strabo. Afterwards, however, the Greeks, and latterly the merchants of Gaul, obtained a share, whose information finally led to the Roman expeditions. Polybius, who was by birth a Greek, and flourished near 200 years before the Christian era, is said to have written a distinct work concerning Britain; which appears to have been first described, about 130 years earlier, by Pythis of Marseille. What was the general medium of exchange, or what were the coins of the Celtic nations, it is impossible at this period to say. The principal of those which are acknowledged by our antiquaries as British, are not of Celtic but Roman origin. They have almost all the Roman letters, and many

of the Roman deities. Of the manners, virtues, vices, remarkable customs, or diversions of the Celts, our information is extremely scanty. Nor are we certain that the peculiar characteristics of the Britons, spoken of by Cæsar, attach either inclusively or exclusively to the Celtic population of the island.

The last subject to be mentioned here is the language of the Celts, which is now no longer doubted to have been one of the original dialects of Europe. What it was at a remote period we have no means to ascertain, but we are assured by Tacitus that, even in his time, the ancient British differed very little from the Gaulish. Sermo haud multis diversus. (Vit. Agr. cap. xi.)

Bishop Percy, in the Preface to Mallet's Northern Antiquities (p. xxx.), has given the following genealogical table of the languages descended from the Celtic.

Bishop Percy, in the Preface to Mallet's Northern Antiquities (p. xxx.), has given the following genealogical table of the languages descended from the Celtic.

**CEM**

CENTIC.

The study of the Welsh language was first encouraged in this country by Henry VIII. But the best body of materials for the knowledge of the Celtic dialects will be found in Llwyd's Archaeologia Britannica.

CELYDNUS, in Ancient Geography, a river of Macedonia, in the Oreliide territory. It had its source in the Cecroceanian mountains, and served as a boundary between Oreliide and Chaonia, according to Ptolemy.

CEMA, a mountain of the Gauls, forming a part of the chain of the Alps. "Annae Varus," says Pliny, "ex Alpium monte Cemá profusus." The mountain whence this small river flows, is at present called Cailole.

CEMAS,
CEMATES, Cema Setenian et Herodoci, in Zoology, synonymous with Antipe Rupicabra of modern writers, Bochart, &c. Belon conceives the Cemas, or Cemias of the Greeks to be this species.

CEMBALO, Italian, in Music, at present implies a harpsichord; but in the time of Boccaccio, it was the title given to the tambour de buffe: *infrumento da donne*; which in the Cufca dictionary is defined, *infrumento da fiore*; because a cercu d'alle fottile alla largozza d'un rumino, &c.—covered with parchment like a drum, surrounded with bells or bits of tin, and beaten with the hand.

Madonna, *Più offio un Cembalo, in dire, &c.*

We not only meet with *Arpiera* and *Clavizicula* in Zarino, 1566, but among keyed instruments, described by Ottomar Lutamino in 1574, under the three several Latin names of *Clericiiuthem*, *Claviziculum*, and *Clavizicula*; but in the courts wooden cants by which he represents them, the shape seems only that of a spinet or virginal; which for.

In Varchi, the contemporary of Zarino, the harpsichord is called *Gravicembalo*. And in another Italian writer of a more early period, we are told, that Tintoret the painter had a daughter called Marietta, who, besides other accomplishments, played on the *Gravicembalo*, or harpsichord, and painted extremely well. See *Organs, Harpsichord, Spinet*, and *Piano Forte*.

CEMBANI, in Ancient Geography, a people of Arabia Felix, who dwelt in the vicinity of the Agreens, according to Piny.

CEMBRA, in Botany. See *Pinus Cembra*.

CEMELANUM, or *Cemenelum*, or *Cemenelium*, or *Cemelum*, and *Cemiers*, in Ancient Geography, a town of Gallia Narbonensium, N. N. W. of Nicaea, and near it. It continued to be the capital of the Maritime Alps to the close of the 4th century, and was very considerable for the number and quality of its inhabitants, and the beauty of its edifices. The first officers of this province made this the place of their residence. It had three colleges, one of which was probably that of the priests; and a senate which allowed an assembly for deliberating on the conclusion of a monument in honour of M. Aurelian Meculus, president of the Maritime Alps. This Roman had supplied the city with corn in a time of famine, and re-establish the ancient aqueducts, the ruin of which had occasioned a want of water. The town of Cimiez was destroyed by the Lombards towards the year 737. The inclination of its amphitheatre is still in good preservation. It was the capital of the Vedastus, and was situated on the Aurelian way. M. D'Aunville discovered this ancient name in that of the church, called *Notre-Dame de Cimiez* to the right of Paillon, and 1/2 mile N. of Nice.

CEMENTATION, in Chemistry. *Cementiren*, Germ. This term is applied to a procéd in the dry way, similar to digestion in the moll, and means the exposure of any substance to a regular furnace-heat in a crucible, if stratified or otherwise covered with some kind of powder which is intended to produce a chemical change. Thus iron bars are converted into steel by being cemented with a powder of bone, and other materials: copper into brass by cementation, with a powder of calamine and charcoal; and the like. The powder is, in this case, called *Cement powder*.

CEMENT-COPPER. The copper procured from the sulphur by precipitation with iron is so called. See Copper.

CEMENTS and LUTES. Under this article may be mentioned the receipts for preparing some of the most useful substances of this kind, that are required in common chemical operations.

The use of lutes and cements are either to close the joints of chemical vessels to prevent the escape of vapours and gases during the processes of distillation, sublimation, and the like, or to protect vessels from the action of the fire which might crack, or fuse, or calcine them; or sometimes to repair flaws and cracks, and for a variety of other smaller purposes.

The subject of *calcareous cements*, such as mortar, tarsas, and other substances used to close the joints of bricks or flumes in buildings, will be mentioned in the following article.

When a lute is applied over the whole surface of a vessel, (as to a gale retort when it is intended to be heated red hot) the procéd is termed, *luteum; or luting*. Iron furnaces are also lined or coated on the inside with earth, to prevent the iron from being destroyed by the conductive action of the fire.

From the vast variety of receipts for lutes and cements of different kinds, the following may be selected, which will answer most of the purposes of the experimental chemist.

To prevent the escape of the vapours of water, spirit, and liquors not corrosive, the simple application of slips of moistened bladder will answer very well for glass, and paper with good paste for metal. Bladder, to be very adhesive, should be soaked some time in water moderately warm, till it feels clammy; it then sticks very well. If smeared with white of egg, instead of water, it adheres still closer.

Another very convenient lute is linseed meal, moistened with water, to a proper consistence, well beaten, and applied pretty thick over the joints of the vessels. This immediately renders them tight, and the lute in some hours dries to a hard mass. Almond paste will answer the same purpose.

The use of the above lute is so extensive, that no other is required in closing glass vessels in preparing all common distilled liquors; and it will even keep in ammonia, and acid gases, for a longer time than is required for most experimental purposes. It begins to sear and spoil at a heat much above boiling, and therefore will not do as a fire lute. It is still firmer, and dries sooner when made up with milk, or lime water, or weak glue.

A number of very coheitive cements impervious to water and most liquids and vapours, and extremely hard when once solidified, are made by the union of quick-lime with many of the vegetable or animal mucilaginous liquors. The variety of their is endless. We may best mention the following, as it has been extensively employed by chemists for centuries. Take some whites of eggs with as much water, beat them well together, and sprinkle in sufficient flaked lime, to make up the whole to the consistence of thin paste. The lime should be mixed by being once dipped in water and then suffered to fall into powder, which it will do speedily with great emission of heat, if well burnt. This cement should be spread on slips of cloth, and applied immediately, as it hardens or sets very speedily. While hardening it may be of use to sprinkle over it some of the lime in fine powder. This cement is often more firmly and as conveniently managed, by smearing slips of linen on both sides with white of egg, and when applied to the joining of the vessels shaking some powdered lime over it. It then dries very speedily.

Another lute of the same kind, and equally good, is made by using a strong solution of glue to the lime instead of the white of egg. It sets equally soon, and becomes very hard. A mixture of liquid glue, white of egg, and lime, makes the
the lut d'aer, which is so firm, that broken vessels united with it, are almost as strong at when found. None of these lutes, however, will enable these vessels to hold liquids for any great length of time. Milk or flarch, with lime, make a good, but his firm lute.

A very firm and singular lute of this kind is made by rubbing down some of the poorer skimmed milk cheese with water, to the confidence of thick soups, and then adding lime, and applying as above. It answer extremely well. Lime and blood, with a small quantity of brick-dust, or broken pottery, flinted in, is used in some places as a very good water cement for cellars and places liable to damp.

Paris-plaster, mixed with egg, milk, glue, flarch, or any mucilaginous liquor, also makes a good lute.

Some artists mix other earths with the above materials. Thus a very good cement is made with equal parts of clay and lime, about $\frac{1}{2}$ of flour and white of egg; or, as is used by many of the aqua fortis-makers, a mixture of colchoal lime and white of egg.

All the above-mentioned cements, with lime, become very hard, by drying, insomuch that they cannot be separated from glas vessels without the help of a sharp knife and some violence; and hence delicate vessels, and long thin tubes cemented with it, are apt to break, when the apparatus is taken down, and sometimes even by the mere force of contraction in firing. It is a great advantage, however, that they may be applied immediately to any accidental crack or failure of the lute already on, notwithstanding a stream of vapour is bustling through; and in large dilutions it is of advantage always to have some of the materials at hand.

These lutes will not confine very corrosive acid vapours perfectly, for a great length of time, but will answer for other purposes, particularly where a complicated apparatus is to be kept readily united and air tight. They will bear nearly a red heat without material alteration.

Another kind of lute, which is the most perfect for confining acid vapours for any length of time, and which never hardens to an inconvenient degree, is the fat lute, as it is called. This is made by taking any quantity of good clay, tobacco-pipe clay, for example, thoroughly dry, but not burnt, powdering it in an iron mortar, mixing it gradually with a little fine oil, and beating them together for a long time to the confidence of thick palm. Much manual labour is required, and it should be continued till the mass no longer adheres to the pelle. Then make the edges of the glas or other vessel, where it is to be used, perfectly dry, and apply the lute carefully, and it will stand the longest prows without failing. This grows firm enough to retain its place, and to hold the vessels together, but may readily be separated by a knife. This lute much improves in adhesiveness by long keeping, which should be in a covered pan in a cool cellar. When wanted, it regains sufficient ductility, merely by beating for a minute or two, or by the help of a few drops more of the oil. Good glassers pity, which is made of chalk, beat up with drying linseed oil, much resembles the fat lute in quality.

Another species of lute is that which is commonly applied round glas retorts, when distillation with a full red heat is wanted, to protect them from the sudden action of the fire, and to give them firmness, and to enable them to bear this heat without flattening or falling together, when red-hot, or melting with the fuel. A glas vessel, to be prepared, with a thick earthen coating, may be considered as an earthen vessel glazed on the inside. The substance used is a mixture of sand, with just sufficient clay to make it adhere together, beat up with some kind of fibrous matter, so as mechani-}

ically to increase the tenacity. A natural earthy mixture of the kind is Windsor-lime, or an equally good one may be formed with coarse sand and clay, or better with fragments of pottery coarsely ground, (the fine part being separated by sifting, and rejected,) mixed with more or less clay, according to the quality, so that it will just mould together when wet. For the porous matter, some use horse-dung, which appears to be the best, others chopped straw or chaff, others chopped horse, or cow-hair, or tow, all of which answer the same purpose. A small quantity of these will suffice. Beaumé recommends about an ounce of cow's hair to five pounds of the earthy mixture. A good deal of water should be added, when the materials are mixed, and much manual labour is required to diffuse the heat equally through the mixture. To apply it to a glas vessel, a retort, for example, take a sufficient quantity of the lute, spread it out flat on a table, lay the bottom of the retort on the middle of the mass, and then turn up the edges of the flat cake, and bring it over the roll of the glas, pressing it down with the fingers, till it applies uniformly and closely. By this method the lute is without seam, and is much more likely to dry in the fire without cracking. Or else, bring the lute, with sufficient water, to the confidence of thick soups, dip the retort in, and it will come out thinly coated. Turn it round before the fire, and, when dry, dip it again in the lute, to give a second coating, and so on, to the required depth of thickness, which may be from $\frac{1}{2}$ to $\frac{1}{4}$ an inch. A lute similar to this is used as a lining to iron furnaces, to confine the fire, and prevent the iron from consuming by the constant heat. This lute is just so fusible as to begin to amalgamate in a full red heat; and hence, if it remains found till thus hot, it will form an impermeable coating to the glas within, from which it cannot afterwards be detached. The covers of crucibles and other vessels intended to bear fire may be luted with this earthy mixture. It is rendered still less liable to crack on the fire-heating, if, when thoroughly dry, it is smeared with linseed oil.

Sometimes, however, a still more fusible compound is wanted, particularly where very volatile and penetrating substances are distilled from an earthen vessel. These vessels are necessarily porous, to a certain degree, independent of any casual cracks, from which the larger earthen vessels are seldom entirely free. When phosphporus, for example, is prepared, by strongly heating charcoal and phosphoric acid in one of these retorts, the vapour of the phosphporus penetrates through the pores, when thoroughly red hot, and much of it is boil. Nor will the latt-mentioned luting entirely prevent this, so that it is a great favour to cover the retort with a thin coat of a fusible glazing, which will melt on the surface as soon as red-hot, and close every opening. This glazing may be made by a variety of fluxes added to the proper dose of clay and earth, and mixed into a thin paste and applied to the retort with a brush. The following management is recommended by Mr. Willis, a practical chemist, (Repertory, Vol. i.) in dilution with large earthen retorts. Dilute one ounce of borax in half a pint of boiling water, and add as much fluxed lime as will make it into a thin paste. Spread it over the retort with a brush, and, when dry, apply over the whole a lute of fluxed lime and linseed oil, beaten till it is perfectly plastic. This becomes dry in a day or two, and is then fit for use. Stone retorts may thus be used several times with safety, (always renewing the oil and lime-lute); whereas, in the common way, and even with the clay and hair-lute, they generally crack when cooling, or on being heated a second time. If, during the operation, the retort should crack, Mr. Willis advises to spread some of the oil compulsion thickly on the part,
part, and sprinkle some flaked lime over the whole, which will prevent the further escape of the penetrating vapour of phosphorus, and may be applied even when the retort is red hot. When prepared somewhat thicker, it is very proper as a general lute for a variety of purposes, and will never harden so as to break the vessel.

Often a lute is required to join the covers to crucibles, or for similar purposes, so as to keep them air-tight when hot. A very valuable composition of the kind is made of glafs of borax, brick-dust and clay finely powdered together, and mixed with a little water when used. No very great nicety is required in the proportions, but about a tenth of borax is quite sufficient to bring the earths to that state of firmness or viscosity which is desired. Litharge may also be used instead of borax, but the latter is by far the best, as it promotes that thin spreading fusion which is best calculated to be equally applied over an uneven surface; and besides, if a portion of the litharge lute were to drop into the crucible it might possibly be reduced, and lead introduced into the results of the experiments.

A cement, said to be useful to stop cracks of iron vessels intended to be strongly heated, is made of six parts of clay, one of iron filings, and linseed oil enough for the mixture.

Another species of cement is what is termed by the French Magisth chaud, and consists of different kinds of oily and resinous substanse, liquid when hot, and which become more or less solid by cooling. They are useful for a variety of miscellaneous purposes, for experiments with gasses over water or mercury, and others where only a very moderate warmth is used, and where it is of importance to keep out air and water. There will also confine acid vapours, but not the vapours of alcohol, turpentine, or essential oils, which diffuse most resinous substanse. Most of them will stick very well to glafs. Common feeling-wax is one of the most useful of these cements. A cheaper and less brittle cement is made simply by melting bees wax with about one eighth of common turpentine. This may be made up into flicks to be used when wanted, being filled melted or spread evenly with a hot iron. A greater proportion of turpentine renders this lute softer and more flexible, but somewhat pliable.

A very firm cement is made by four parts of rosin, one of bees wax, and when melted, one part of fine brick dust, stirred in. This adheres with extreme firmness. Table knives are cemented to their handles by this mixture, and turnips are a familiar composition in some fine works to fix them to the lath.

Chapital found, after many trials, that the penetrating vapours of sulphurous acid in the manufacture of alum were completely confined in a wooden chamber lined very carefully with a mixture of equal parts of pitch, turpentine, and wax boiled till all the effluent oil was diffipated (which was known by the effusion of the bubbles) applied melted to the wood, and spread with a hot trowel over the joints. Vintners stop leaks in their casks with melted fat rubbed over when cooling with fitted wood ashes, or previously mixed with the ashes in melting.

The use of gum arabic dissolved in water, for cementing paper labels to bottles, and a great variety of miscellaneous purposes, is known to every one. A still better cement for the same use is glass dissolved in vinegar to a pretty thick consistency when warm. This congeals on cooling, and before it is used it should be gently warmed.

Many of the varnishes and oil paints are employed in rendering vessels air and water tight. Thus when car vas bags are fastened to a stop-cock tube for air-holders, the joining is made perfectly tight by tying over it flaps of cloth or bladder soaked in spirit varnish.

The following cement is said to be very useful in joining together glafs or text. Take of mallich five or six bits as big as peas, dissolve in as much alcohol as will render them liquid. In another vessel dissolve as much filings (previously soaked in water) in brandy or rum, as will make two ounces by measure of a strong glue, warm it, and incorporate with it by rubbing two or three small bits of gallnut or ammoniacum and then the mallich solution. Keep the cement in a bottle well stopped, and gently warm it before use.

Those fusible metal compounds used to unite pieces of metal form another totally distinct species of cements. These are termed Solders, under which they will be described. See CEメント.

CEMENTS. calcarceous. In this article it is proposed to give an account of the various cements used in building, into which lime enters as an essential constituent part; and in order to treat the subject with a degree of clearness, in some measure corresponding to its importance, it will be advisable to arrange every kind of calcarceous cement under one or other of the following three divisions: first, simple calcarceous cements: secondly, water cements: thirdly, mallich and malth.

§ 1. Simple calcarceous cements.

This section includes those kinds of mortar which are employed in buildings on land, and generally consist of lime, sand, and fresh water.

It is well known that calcarceous earths are converted, by burning, into what is called quick lime, which substanse being wetted with water falls into a powder with great extrication of heat, and then acquires the property of uniting with sand, and various other substanse, and forming a solid mass which becomes as hard and durable as most building flones. We have no means of ascertaining by whom, or at what time this valuable property of lime was discovered; but among the nations of antiquity the Romans appear to have made the most use of it, and to have been most skilful in cementitious building.

The various kinds of marble, chalk, and lime-stone, as far as regards their use in cements, may be divided into two species; the first being pure or nearly pure carbonat of lime; the second containing besides from $\frac{1}{4}$ to $\frac{1}{3}$ of clay and oxvd of iron. Previous to burning or calcination, there are two extraneous substanse by which the simple lime-flones can be distinguished from the argillo-ferruginous ones; but the former, whatever may have been their colour in a crude flate, become when calcined of a white colour, while the latter possess more or less of a light ochre tinge. The brown lime is by far the best for all kinds of cements; but the white varieties being more abundant, and allowing of a larger proportion of sand, are generally made use of. It was an opinion of the ancients, and is still commonly received among builders, that the hardest lime-flone, ceteris paribus, furnishes the best lime; but mortar was laid to grow as hard as the lime-flone of which it was composed, and hence marble was considered as superior to common lime flone, and this latter to chalk. The experiments of Dr. Higgins and Mr. Smeton, however, show that this is entirely a mistake; common chalk, and the hardest Plymouth marble, when similarly treated, affording cements of equal firmness.

When carbonated lime has been thoroughly burnt, it is deprived of its water, and of all, or nearly all of its carboinic acid; if, in this state, it is plunged into water, and immediately taken out again, the water which it has absorbed will
CEMENTS.

will occasion the mass to crack and become excessively hot, and at length to fall into an impalpable powder, much of the water being carried off in the form of steam during the process. When lime has been thus flaked, if it is beaten up with a little water into a very stiff paste and allowed to dry, it will be found that the white limes, whether from chalk or marble, never acquire any degree of hardness, that the brown limes become considerably indurated though not so much as when mixed with sand, and that shell lime (procured by calcining sea shells), concretes into a firm, hard cement, well qualified for dry buildings, although it falls to pieces in water.

Lime-flone loses about 4 of its weight by burning, but shrinks in an inconsiderable degree; upon quenching, when fully burnt, it falls freely, and will produce somewhat what more than double the quantity of powder or flaked lime, in measure, that the burnt lime-flone confided of.

Quick-lime, by exposure to the air, absorbs carbonic acid with greater or less rapidity, as it is of a close and hard, or soft and spongy texture; thus it gradually loses its cementing properties and at length becomes totally unfit for the purposes of mortar. Hence, though lime-flone and chalk-lime are equally good, when perfectly burnt, and used fresh from the kiln, there is an important practical difference between them, as the chalk lime absorbs carbonic acid with much the greatest facility.

A proper selection of sand is of great importance in the composition of mortar; the sharper and coarser it is the better; as it requires a smaller proportion of lime, and makes a stronger cement than when fine-grained and round sand is used of. Sea sand requires to be well washed in fresh water to dissolve out the salt with which it is mixed, otherwise the cement into which it enters never becomes thoroughly dry and hard.

The most advantageous proportions of lime and sand in the composition of mortar is a point by no means settled. The Roman builders were accustomed to allow three parts of pit sand, or two parts of river or sea sand to one of lime. In general, it may be affirmed, that it will be advantageous to use the largest quantity of sand that can be introduced, preserving the necessary degree of placticity. Mortar, in which the sand predominates, requires less water in preparing, and therefore sets sooner; it is harder and also less liable to crack on drying than that in which lime prevails. Smecaton observes, that there is scarcely any but what, if well burnt and beaten, a load or measure of unfaked lime will take two loads or measures of sand. On pursuing this subject he soon found that, by good botating, the fame quantity of lime would take in one measure of tarras and three of clean sand, which seems to be the greatest useful proportion, for on a further increase of the quantity of sand, the mortar required so much more beating to bring it to a proper consistence and toughness, that the labour became of more value than the saving of materials. These observations agree very nearly with the experiments of Dr. Hutton.

The weakness of modern mortar compared to the ancient is a common subject of regret, and many ingenious men taking for granted, that the process used by the Roman architects in preparing their mortar is one of those arts which are now lost, have employed themselves in making experiments to recover it, instead of attending to the directions left us in the works of Pliny and Vitruvius, which, when illustrated by the actual practice of builders in various parts of Europe, seem to have little or no doubt on the subject.

The characteristics of all modern arts, builders among the rest, seems to be to spare their time and labour as much as possible, and to increase the quantity of the articles they produce, without much regard to their goodarts; and perhaps there is no manufacture in which this is so remarkably exemplified as in the preparation of common mortar, especially in London and its neighbourhood.

The peculiar badness of London mortar is to be attributed, both to the faulty nature of the materials, and the careless and hasty method of using them. The lime employed is the soft chalk-lime of Edex and Kent, which insufficiently burnt at first, is conveyed a distance of ten or twenty miles and kept many days, without any precautions to prevent the access of the external air; and thus before it is used, it has time to absorb so much carbonic acid as nearly to lose its cementing properties. It has been before observed, that though chalk, when perfectly burnt, is equally good as the hardest limestone, it possesses some practical disadvantages; it will fall into a coarse powder on the application of water, when it is only partially calcined, which lime-flone will not, and the cores or unburnt lumps may be broken down by a blow with the spade, and are therefore very seldom rejected as they ought to be.

Sand, which is scarce and dear in London, is equally defective. This is pit sand, but very different from the kind recommended by Pliny and Vitruvius; instead of being clean, large-grained, and sharp, it is composed of small round grains, and filled with a large mixture of clay. Its fine nerfs and smoothness cannot be amended, but by washing it well in running water the clay might unquestionably be got rid of, and this would be no trifling improvement, for Smecaton has shown, by direct experiment, that mortar of the best quality, when mixed with a small proportion of unburnt clay, never acquires that hardness and dryness which, without this addition, it would speedily have attained. Screened rubbish and the scrapings of the roads, consisting chiefly of gravel reduced to fine powder, are also used as substitutes for sand with still greater inappropriety.

The method of preparing common mortar is also extremely imperfect. The lime being flaked by the addition of water, and the unburnt lime being broken down and mixed with the rest, a quantity of dirty sand is added, and the whole being incorporated by means of a spade, is reckoned to be fit for use; thus the principal point in the making of mortar, namely, beating the ingredients together, so as to mix them thoroughly, is flung over in a hasty careless manner, and the refit, as might be expected, is a crumbling mass scarcely fit for use. The Roman builders, on the other hand, after they had mixed together the materials, employing for this purpose a smaller proportion of water than is customary at present, put the mafs into a large wooden mortar, and beat it till it ceased to adhere to the heavy wooden or iron paffle which was used on the occasion; a practice, which has long been followed by the Dutch with complete success, as will be shown in the next section.

Fresh made mortar, if kept under ground in considerable masses, may be preferred for a great length of time without injury; and the older it is before it is used the better; the builder taking the precaution to beat it up again, previous to using it; for it not only sets sooner, but acquires a greater degree of hardnes, and is less apt to crack. A fact related by Mr. Smecaton, remarkably illustrates these points. Having had occasion to take up a large flat stone of a cluse grain, of about five feet square, that had probably lain above a century at the bottom of a malt cistern, he found that it had been well bedded in mortar, which had become coagulated to the consistence of cheese; but having never come to a perfect dryness, it so far retained its natural humidity, that he found it might, with some pains, be beaten up to mortar without
CEMENTS.

Without any addition of water; and afterwards being suffered to dry in the air, it set to a flinty hardness, and appeared as good mortar as any which that part of the country produced. Pliny informs us, that the ancient Roman laws prohibited builders from using mortar that was less than three years old; and to this circumstance he expressly attributes the remarkable firmness of the oldest buildings in the city. A similar custom prevailed, and we believe still prevails in Vienna, requiring the mortar to be a year old before it is employed. But there is nothing which shows, in so striking a point of view, the advantage and necessity of beating mortar, and that the effect produced is owing to something more than a mere mechanical mixture of the ingredients, as the preparation of great, or liquid mortar. This differs from common mortar only in containing a larger quantity of water, so as to be sufficiently fluid to penetrate the narrow irregular interstices of rough stone walls, and is generally made by diluting common mortar with water, either cold or hot. It not unfrequently happens, that this great refuses to set, and at all times it is a long while in acquiring the proper hardness; but if, instead of common mortar, that which has been long and thoroughly beaten is employed, the mortar will set in the space of a day, and soon after acquires a degree of hardness much superior to what is made in the common manner.

§ 2. Water Cements.

Although a well made mortar, composed merely of sand and lime, if allowed to dry, becomes impervious to water, so as to serve for the lining of reservoirs and aqueducts; yet if the circumstances of the building are such as to render it impracticable to keep out the water, whether fresh or salt, a sufficient length of time, or the use of common mortar must be abandoned; for lime and sand, if mixed together in any proportions, and put, while soft, into water, will in a short time fall to pieces.

Among the nations of antiquity the Romans appear to have been the only people who practised building in water, and especially in the sea, to any great extent. The bay of Baie, like the fathomable watering places, was the summer retreat of all the wealthy in Rome; who, not content with erecting their villas as near the shore as possible, were accustomed to construct mole, and form small islands, in the more sheltered parts of the bay, on which, for the sake of the grateful coolness, they built their summer houses and pavilions. They were enabled to build thus securely in the water by the fortunate discovery, at the neighbouring town of Puteoli, of an earthy sublimate, which, from this circumstance, was called Puteolanus (powder of Puteoli.) Putulan powder, or as it is now denominated puzzolana, is a light, porous, friable mineral, of a red colour, and is generally supposed to derive its origin from concreted volcanic ashes. The source of it is near Veluvius, near to which mountinous district of Puteoli is situated. It consists chiefly of a ferruginous clay, baked and calcined by the force of volcanic fire, and when mixed with common mortar, not only enables it to acquire a remarkable hardness in the air, but to become as firm as stone, even under water. The only preparation which puzzolana undergoes, is that of pounding and fitting, by which it is reduced to a coarse powder; in this state being thoroughly beaten up with lime, either with or without sand, it forms a mass of remarkable tenacity, which speedily sets under water, and becomes at least as strong as good freestone.

It has been before observed, that a composition of pure lime and sand alone will not harden under water, but leaves containing a portion of clay possesses this property in a considerable degree, and are therefore generally used in water building. The cement used by Mr. Smecaton, in the construction of the Eddystone light-house, was composed of equal parts by measure of flaked Aberthaw lime and puzzolana. The peculiar difficulties of this undertaking, exposed to the utmost violence of the seas, rendered these proportions advisable; but for works that are less exposed, such as locks and basins for canals, &c., the quantity of puzzolana may be considerably diminished. A composition of this kind, which has been found very effectual, is 2 bushels of flaked Aberthaw lime, 1 bushel of puzzolana, and 3 of clean sand; the whole being well beaten together will yield 45 cubic feet of cement.

The Dutch have practised building in water to a greater extent than any other nation of modern Europe; and to them is due the discovery of a cement admirably well adapted for this purpose, and called tarras or trafs. This is nothing more than wakke, or cellular basalt, and is procured chiefly from Bockenheim, Frankfort on the Maine, and Anvers, whence it is transported down the Rhine in large quantities to Holland. This sublimate, being, by grinding and mixing, reduced to the consistence of coarse sand, is used in the composition of mortar, with the blue argillaceous lime from the banks of the Scheldt, in the following method. They take of the quick-lime about the quantity which will be wanted during a week, and spread it in a kind of bason in a stratum of a foot thick, and sprinkle it with water. It is then covered with a stratum of about the same thickness of tarras, and the whole suffered to remain for two or three days, after which it is very well mixed and beaten, and formed into a mass, which is again left for about two days; it is then taken in small quantities, as it is wanted for daily consumption, which are again beaten previous to using. Thus is composed the celebrated tarras mortar with which the mounds and other constructions for the purpose of protecting the lowlands of Holland against the sea are cemented.

Tarras is frequently used in this country, being imported from Holland for that purpose. The proportions of the materials of the tarras mortar generally used in the construction of the belt water works is the same as the Dutch practice. One measure of quick-lime, or two measures of flaked lime in the dry powder, is mixed with one measure of tarras, and both very well beaten together, to the consistence of a paste, using as little water as possible. Another kind, almost equally good, and considerably cheaper, is made of two measures of flaked lime, one of tarras, and three of coarse sand; it requires to be beaten a longer time than the foregoing, and produces three measures and a half of excellent mortar.

When the building is constructed of rough irregular stones, where cavities and large joints are to be filled up with cement, the pebble mortar may be most advantageously applied; this was a favourite mode of construction among the Romans, and has been used ever since their time in those works in which a large quantity of stones is required. Pebble mortar will be found of sufficient compactness if composed of two measures of flaked argillaceous lime, half a measure of tarras, or puzzolana, one measure of coarse sand, one of fine sand, and four of small pebbles, screened and washed. It is only under water that tarras mortar acquires its proper hardness; for if suffered to dry by exposure to the air, it never sets into a sublimate so firm as if the same lime had been mixed with good clean common sand, but is very friable and crumbly. Ash mortar is reckoned to be superior for works that are sometimes wet and sometimes dry, but tarras has the advantage when constantly under water. Tarras mortar when kept always wet, and consequently in a state most favourable to its cementing principle, throws out a

1. Sublimate
Substance something like the concretions in limestone caverns called stalactites, which substance acquires a considerable hardness, and in time becomes so exuberant as to deform the face of the walls.

Although the cellular basalt is the only kind admitted into the preparation of Dutch terras, yet it appears from some good experiments of Moreau on the subject, that the common compact basalt, if previously calcined, will answer nearly the same purpose. Great Britain is at a considerable annual expense in purchasing terras from Holland; it may be worth while, therefore, to point out some of our domestic treasures of the same material. The compact basalt abounds in all the districts where coal is raised, and may therefore be procured easily, and calcined with the refuse coal, so as to be sold at a cheap rate. The Calton hill, adjoining to Edinburgh, consists almost entirely of cellular basalt, and being shot from a short distance from the port of Leith, offers an inexhaustible abundance at a small cost.

In some parts of the Low Countries coal ashes are substituted for terras with very good effect; of which the valuable cendree de Tournay is a striking instance. The deep blue argillo-ferruginous limestone of the Scheldt is burnt in kilns with a flaky kind of pit-coal that is found in the neighborhood. When the calcination of the lime is completed, the pieces are taken out, and a considerable quantity of dust and small fragments remains at the bottom of the kiln. This refuse conglutining of coal ash mixed with about one-fourth of lime dust, is called the cendree, and is made into a mortar with lime in the following method. About a bushel of the materials is put in any suitable vessel, and sprinkled with water just sufficient to slake the lime; another bushel is then treated in the same way, and so on till the vessel is filled. In this state it remains some weeks, and may be kept for a much longer time if covered with moist earth. A strong open trough, containing about two cubic feet, is filled about two-thirds full with the cement in the above state, and by means of a heavy iron pelle, suspended at the end of an elastic pole, is well beaten for about half an hour; at the end of this time it becomes of the consistence of soft mortar, and is then laid in the shade from three to fix days, according to the dryness of the air. When sufficiently dry, it is beaten again for half an hour as before, and the often it is beaten the better will be the cement; three or four times, however, are sufficient to reduce the cement to the consistence of an uniform smooth paste; after this period it is apt to become refractory on account of the evaporation of its water, as no more of this fluid is allowed to enter the composition than what was at first employed to slake the lime. The cement thus prepared is found to possess the singular advantage of uniting in a few minutes so firmly to brick or stone, that still water may be immediately let in upon the work without any inconvenience, and by keeping it dry for 24 hours, it has nothing further to fear from the most rapid current.

A composition very similar to the preceding in materials, which are coal cinders and lime, though seldom prepared with any attention, is the blue mortar, commonly used in London for setting the coping of buildings, and other works much exposed to the weather.

A blue mortar is used in some parts of England. It is prepared by taking two bushels of freth burnt mangre lime, and mixing it accurately with three bushels of wood ashes; the mass is then tied into a bag and left to stand over night. In this state it will keep a considerable time without injury, and even with advantage, provided it is thoroughly beaten twice or thrice before it is used.

The scales of blast-iron, which are detached by hammering red-hot iron, and are therefore to be procured at the forges and blacksmiths' shops, have been long known as an excellent material in water cements; but we believe that Mr. Smeaton was the first person who made any accurate experiments on their efficacy, compared with other substances. The scales being pulverized and sifted, and incorporated with lime, are found to produce a cement equally powerful with puzzolana mortar, if employed in the same quantity. It is, however, to be used in greater proportions than either terras or puzzolana; two bushels of argillaceous lime, two of iron ore, and one of sand, being carefully mixed, produce 3½ cubic feet of cement fully equal to terras mortar. If the common white lime is made use of, it will be advisable to employ equal quantities of all the three ingredients.

With respect to the water used in the preparation of water cements, that of rivers or ponds where it can be had easily, is to be preferred to spring water; but for works exposed to the action of the sea, such as piers, light-houses, &c., it is usually more convenient and equally advantageous, in other respects to use salt water.

Pumice stone, brick, and tile dust, are also recommended for water cements, but their only advantage seems to be an absorbent quality, which causes the mortar made with them to set sooner, and therefore acquire a greater hardnèss in the same time, than mortar composed of sand and lime alone, for they have no power of hardening under water.

The Loriot mortar is a composition which has acquired considerable celebrity in France, and has been employed in some large works. It was invented about 40 years ago by Mr. Loriot, who imagines that he has discovered the process used by the Romans. The principle of this invention consists in adding to any quantity of mortar made in the usual way with lime and sand, but prepared rather thinner than usual, a certain proportion of quick lime, in powder. The lime powder being well incorporated with the mortar, the mass heats, and in a few minutes acquires a consistence equal to the best Paris plaster, and is as dry at the end of two days, as an ordinary cement after several months. It also, when the ingredients are well proportioned, sets without any cracks. The quantity of lime powder to be added, varies from 1/4 to 1/3 of the other materials, according to the quality of the lime; too much burns and dries up the mass, and with too little, it loses its peculiar advantages; thus the proportions, a point of the utmost importance, can only be determined by experiment. It is its speedy dehydration which renders the Loriot mortar useful as a water cement, for under water it has only the common properties of a composition of lime and sand of equal solidity; indeed for this purpose various substances, commonly used in cements, are recommended to be added, such as brick and tile powder, and forge scales. The following is an approved receipt. One measure of bricks exactly pounded, two measures of lime river sand, old blistered lime in sufficient quantity to make a mortar in the usual manner and sufficiently liquid to quench the lime powder which is added in about the same quantity as the pulverized brick. It is extremely extraordinary, that a proceeds, perfectly similar to that of Mr. Loriot, is described in a "Tentoon over Building in Water," by George Sempere, printed at Dublin, 1776. In describing the good qualities of the road-lime of Ireland, M.'s Sempere remarks, that, "it has some useful qualities not much known among the generality of workmen, as, for instance, our lime-stone will make exceeding good terras for water-works, for which purpose, you are
to prepare it thus. Get your roach-lime brought to you hot from the kiln, and immediately pound, or rather grind it, with a wooden maul on a dry, boarded floor, till you make it as fine as flour; then, without loss of time, sift it through a coarse hair or wire sieve, and, to the quantity of a hod of yoursetting mortar, (which, on this account, ought to be poorer than ordinary,) put in two or three handfuls full of this fine flour of the roach-lime, and let two men, for expedient sake, beat them together with such beaters as the platter make use of, and then fuse it immediately. This, I can assure you, will not only fland as well, but is really preferable to any tarras." The memoir of M. Loriot was published in 1774, only two years previous to this treatise of Semple, who appears to have been a man rather of practice and experience than of reading; and, besides, in the book quoted from, he expressly, though incidentally, mentions his ignorance of the French language.

We are justified therefore, in flattering, that the knowledge of the advantages of mixing quick lime powder in mortar was not confined to M. Loriot, though it might be an original invention in him, and he was the first who drew public attention to the process, and used it in any considerable works.

§ 3. Matsha, or Maslah.

Under this term we include those calcareous cements of a more complicated kind, whose hardens appears to depend on the oily or mucilaginous substances that enter into their composition. The use of thee is at present very limited, at least in Europe, but they were highly esteemed by the ancients, especially for stucco. The malta of the Greeks seems to have been more ample than that employed by the Romans architects; at least we are informed that Pammenes, the brother of Phidias, lined the inside of the temple of Minerva at Ellis with a stucco, in which the usual ingredients, sand and lime, were mixed up with milk instead of water, some saffron being also added to give it a yellow tinge. The Roman maltha, according to Pliny, was prepared in the following manner. Take fresh burnt lime, flake it with wine, and beat it up very well in a mortar with hog's lard and figs: this cement, if well made, is exquisitely tender and pliable, and, in a short time, becomes harder than stone the surface to which it is to be applied is to be previously oiled, in order to make it adhere. Another kind, almost equally strong, and considerably cheaper, was prepared by beating together fine flaked lime, pulverized iron- scales and bullock's blood.

In the preparation of malthas, as well as of every other kind of mortar, so much depends on the maniplation, and especially on the care which is taken to incorporate the ingredients by long beating, that those countries in which labour is of the least value polish, in general, the best mortar. Hence, no doubt, principally arises the unequalled excellence of the mortar made by the Timoanians and other inhabitants of the northern coast of Africa, which, according to Dr. Shaw, is prepared in the following manner. One measure of sand, two of woodashes, and three of lime, being previously sifted, are mixed together, and sprinkled with a little water; after the mass has been beaten some time a little oil is added: the beating is carried on for three days incessively, and, as the evaporation in that hot climate is considerable, the cement is kept at the proper degree of foment by the alternate addition of very small quantities of water and oil. The cement being completed, is applied in the usual manner, and quickly acquires a firm hardens. The half species of maltha that we shall mention is the celebrated chunam of India, where it has been used from time immemorial. The method in which it is prepared at Madras is as follows.

Take 1½ bushels of pit sand, and 1½ bushels of stone-lime; flake the latter with water; and when it has fallen to powder, mix the two ingredients together, and let them remain untouched for three days. In the mean time dissolve 2lbs. of malolates in water, boil a peck of gramm (a kind of pea), to a jelly, boil a peck of mirabolan also to a jelly, mix the three liquors, and incorporate part of the mixture very accurately with the lime and sand; so as to make a very fluid cement: some flour is now to be beaten very well into it, and it is then fit for use. The bricks are to be baked in as thin a layer as possible of this mortar; and, when the workmen leave off, though but for an hour, the part where they recommence working is to be well moistened with some of the above liquor, before the application of any fresh mortar. When this is used for stucco, the white of four or five eggs, four ounces of butter or felamum oil, and a pint of butter milk, are to be mixed up with every half bushel of cement, and the composition is to be applied immediately.

It is to be regretted, that no experiments have been instituted to ascertain the cause of the induration of calcareous cements. It is attributed by Dr. Higgins to the absorption of carbonic acid; but several circumstances contradict this supposition. In numerous instances the cement hardens long before the lime is satu rated: in the different kinds of maltha the lime combines with the albumen, mucilage and oil with which it is in contact, and in all probability takes up little or no carbonic acid; and, if it be true, that the lime in old mortar cannot by burning be re-converted into quick lime, this would imply a chemical union of the ingredients; and it may reasonably be questioned whether, even in the simple calcareous cements, carbonic acid acts so important a part as is usually attributed to it.

Cemetery, Cemeterium, a dormitory, or sacred place set apart for the burial of the dead.

Chorier observes, that under cemeterium, kameitrio, from κημήτρων, I sleep, anciently was comprehended, not only the strict dormitory, or place where the dead were disposed; but all the lands which accompanied the parish churches, and were contiguous to the real churches.—Perhaps it might be added, that all the church domains were comprised under this notion. There will be reason enough for that confusion of the cemeteries, charged on Valerian.

In the early ages, the Christians held their assemblies in the cemeteries, as we learn from Eusebius and Tertullian, the latter of whom calls those cemeteries where they met to pray, oeces. Valerian seems to have connoted the cemeteries and places defined for divine worship, which were restored again to the Christians by Gallien. In the reft of that emperor, which is preserved by Eusebius, cemeteries and places of worship are used as synonymous terms. It being here the martyrs were buried, the Christians chose those places to have churches in, when leave was given them by Constantine to build. And hence some derive that rule which still obtains in the church of Rome, never to consecrate an altar without putting under it the relics of some saint. See Burial.

The heathen writers frequently upbraid the primitive Christians for their meetings in cemeteries; as if they served other purposes besides those of religion. The council of Elvira prohibits the keeping of tapers lighted in cemeteria, during the day-time; and by another canon, the woman from passing the night, watching in cemeteria.

The practice of consecrating cemeteries is of some antiquity: the bishop walked round it in procession, with the crosier, or pallorial staff, in his hand, the holy water-pot being carried before, out of which aspersions were made.

Cemeninus, in Ancient Geography, the name of a mountain.
CEN

mountain, which, branching from the Pyrenees, advanced far into Gaul, according to Strabo. It was the mea of mountains which Prolemy calls "Commnen montes," and which, he says, was inhabited by the Seguani, found in that chain which formed the Cevennes.

CEPSI, a people of Spain, who occupied the foot of the Pyrenees, according to Dionysius Puegrietes.

CENA, a small river of Sicily, which at present bears the name of "Fiume della Cane."

CENABUM. See GENABUM.

CENAEUM, a promontory on the island of Euboea towards the west and opposite to Thermopylae, according to Strabo, Pliny, and Poltemy, fertilized on the Malinc gulf; now called Cape Litar, or Canina. It had a temple of Jupiter Cencus.

CENAPATAM, in Geography, a town of Hindoostan, in the country of Myfore; 34 miles N.E. of Seriingapatam, and 28 S.W. of Bangalore.

CENCHRE, a town of Apha Minor, in the Troade. Suidas says that it was the country of Homer.—Aifo, a town of Italy. Step. Byz.

CENCHRAMIDIA, in Botany, Pluk. See Clusia pectera, and Datura guineensis.

CENCHRES, in Ornithology, one of the names given by authors to the small busting, Embiriza nigrella.

CENCHREA, in Ancient Geography, a port of Corinth, situated on the bay of Saron. This was a fortress built on the frontiers of Arcadia, towards the source of Phryxus, and S.W. of Argos. It defended the way that led from Argos to Tegea. Near this place, towards the south-east, lay the tombs of those Argrians, who, according to Pausanias, challenged an army of Lacedemonians near Hybre, under the archonate of Pithirata.

CENCHREA, a port town of Corinth, which lay towards the east upon the Gulf. It derived its name from Cenchreas, the pretended son of Neptune, when his brother Lecheus had given his name to Lecheum. These were the only two havens; and indeed the only two cities of any note, next to Corinth, that belonged to this territory. They were so well situated for naval commerce, and so near the metropolis, that they made ample compensation for the barrenness of the soil. Thee two naval roads, which opened a way into the Ionean and Aegean seas, might easily have gained them a superiority, if not a command over all Greece, if this advantageous situation had not inclined them more to commerce than war. That Cenchreas was a distinct city from Corinth, at least in St. Paul's time, we may infer from Acts xviii. 18, and from his epistle to the Romans, ch. xvi. 1; though it had the epithet of Corinthiaca in the poets, from its being one of the havens of that little state, as Corinthiaca had that of Bimaris, from its being so conveniently situated between two seas. Upon the road from Cenchreas across the illithus there was a mile of Diana, and at Cenchrea a temple of Venus, with a fine statue. At the end of this road was a Neptune in bronze; and on the other side of the port were two temples, one of Neptune, the other of Isis. In the vicinity was a spring of hot water, said by Pausanias to be ful, and called the bath of Helena. The water fell from a rock, and precipitated itself into the sea. Along the coast, towards the north-east, there was another port, mentioned by Strabo and Poltemy. Pliny and Strabo lay, that it was situated in the most secure place of the illithus.

CENCHREA was also a name given generally to the illithus of Corinth, distant 70 furlongs from it, where were celebrated the Ithian games: whence the apollate in his epistle to the Corinthians so frequently alludes to these games. See 1 Epil. vi. 2 Epil. iv. 7, 8, 9.

CENCHRES, a small island of Greece, towards the bottom of the Saronic gulf, according to Pliny.

CENCHRES, in Ornithology, a name given by Gesner, Aldrovandus, and others, to the kind of hawk known in England by the title of Keffle, Stranel, or Windhover hawk, Falco Tinnunculus of Linnæus.

CENCHRES, in Zoology, the name of a species of Boa that inhabits South America, and which is distinguished by having 265 abdominal plates, and 57 caudal. Linn.—Boa flavipes ochelli olivoidi, ride grisea, Bodduert.

Boa cenchres is a species of large size, though inferior in this respect to either the boa constrictor, or the spotted boa. The prevailing color is yellowish-tawny, darkened on the back, where it is marked by a continued series of very large blackish circles extending from the head to the tail: the sides are marked with a number of kidney-shaped blackish spots, many of which are occluded with whitish: the head is of a lengthened form, and is marked by a black longitudinal and two lateral bands.

CENCHRIUS, in Ancient Geography, a river of Apha Minor, in Ionia, which had its course through the territory of the city of Ephesus, according to Tactius and Pausanias.

Gen. Ch. Col. involucre variously divided, often ciliated, containing from two to four flowers; or, if wanting, the defect compensated by ciliated calyx-glymes; calyx-glymes lanceolate, concave, acute, shorter than the corolla, generally about two-flowered; one of the flowers often male. Cor. Glumes concave, lanceolate, acuminate, awnless; one shorter than the other. Stam. filaments three, capillary, the length of the corolla; anthers arrow-shaped. Pfl. gam. roundish; style filiform, the length of the flaminus; style two, hairy, oblong, spreading. Scida roundish, enclosed in the permanent corolla.

Eff. Ch. Involucre variously divided, often ciliated; or, if wanting, the defect compensated by ciliated calyx-glymes; style one, biund.

* With an involucrum.

"Spice oblong, conglomerated." Root annual. Stems from eight to ten inches high, bent at the lower joints, smooth, flattened, compressed, almost angular. Leaves from four to five lines broad, long, smooth, fringed: leaves long, smooth, slightly tomentous at their office. Spike two or three inches long; simple, upright: spikelets on short peduncles, scattered or alternate, at a small distance from each other; involucres large, entire at the base, cut at the edge into several small, awl-shaped, fetaecous, yellowish or somewhat violet segments; flowers from two to four in each involucre, very small. Scidae almost elliptical, flat, a little convex, without a furrow. A native of Jamaica and the coast of Barbary, described by Poiré from a living plant in the botanic garden at Paris, cultivated in England by Doody, in 1691. It is one of the most common graves in the open purlieu of Jamaica, and is esteemed a wholesome and pleasant food for all sorts of cattle. 2. C. tribuloides, Linn. Sp. Pl. 5. Mart. 8.

CEN

**Without an involucre.**

12. *C. inflexus*, Poir. 9. “Leaves lanceolate, villous; racemes lateral, inflexed, on long peduncles; spikelets sessile, spiklets in aingle row.” Stems branched, cylindrical. Leavers entirely covering the stem, an inch and half long, about four lines broad at their base, lanceolate, almost heart-shaped, finely villous, most villous on the sheath and at the edges. **Peduncles from the axes of the upper leaves, five or seven inches long, simple, smooth; each terminated by a spike of sessile flowers, so curved at its insertion as to make nearly a right angle with the stem; spikelets lanceolate, narrow, very acute; calyx one or two-flowered; outer ovary echiuated with spiiny points, ciliated at its edges, very acute; inner one short, villous, corolla one-valved, much shorter than the calyx, flat, smooth, obtuse. Seed naked, shining, oblong, cylindrical. A native of Cayenne. Described by Poiret from dried specimens in the herbarium of Jussieu and La Marck, but not so perfect as to make him quite certain that the plant may not more properly be referred to some other genus. On account of its one-valved corolla, it appears to us to be truly an alopecurus, and might have been placed very conveniently next to *A. monspesicus* of Linnæus, if that plant had not been described by Schrebcr and Dr. Smith to have really a two-valved corolla, and therefore removed to pleumum. Its racins resembles that of *paspalum*, 13. *C. ovatus*, Poir. 8. Lam. III. 838. fig. 2. “Leaves quite smooth, rather firm; spike densely egg shaped.” **Stems stiff, smooth, cylindrical. Leaves stiff, acute, rolled in at their edges; sheat cylindrical, long, narrow, enveloped at its orifice with a small tuft of fine whitish hairs. Flowers in a thick branched spike; outer calyx-valves echiuated with stiff, whitish hairs; flowers smooth, oval, mucronate; two or three in each calyx. Gathered by Sonnerat at the Cape of Good Hope, preferred in the herbarium of La Marck.” 14. *C. remotifolius*, Poir. 9. “Leaves tomentous-white on their upper fr., eflated underneath; spike obtuse, egg shaped.” **Stems upright, smooth. Leaves stiff, narrow, flat, a little...
a little rolled in at their edges; sheaths cylindrical, flattened. Spike very close, sometimes interrupted at its base; outer valves of the calyx echinate with short, stiff, unequal points; florets three or four in each calyx, oblong; valves very acute. A native of the Cape of Good Hope, preferred in the herbarium of La Mareck. 15. C. carthamnus, Wait. Flor. Car. p. 79. "Spike glomerate; glumes globular, muriated with spines, even."

Obf. In conformity with Poirret's ideas on the subject, we have extended the generic character so as to include the last four species, which would be excluded by it, as it was originally contrived by Linnaeus; without, however, being perfectly satisfied that they may not be better otherwise disposed of. 16. C. frutescent, Linn. Sp. Pl. 6. Mart. 9. Willd. to. (Arundo gracile, Linn. It. Alp. exot. tab. 164. Gram- men orientale, Echium fruticosum, Linn. spec. echinatus in capitulum congens; Tournefort, cor. 39.) "Heads lateral, fiddle; leaves mucronate; stem shrubby." Linn. Root perennial. A native of Armenia. La Mareck affirms, on the authority of Tournefort's speciments preferred in the herbarium of the museum at Paris, that its leaves have no sheaths, and that therefore it cannot be a gramineous plant. He has no doubt, notwithstanding the singularity of its habit, of its being really an eryngium. See Encyc. vol. iv. p. 756, and vol. vi. p. 53.

CENCRUS capitatus; Linn. Mart. Willd. Poir. See Echinaria.

CENCRUS lappaceus; Linn. Mart. Willd. Poir. See PANICUM lappaceum.

CENCRUS racemofus; Linn. Mart. Poir. See LAPAGO.

CENCRUS granularis; Linn. Mantilla. Mart. See MAISURIS.

As these four plants are destitute of an involucrum, they are improperly placed by Linnaeus under his cenchus; and as they have not an echinated calyx glume, they are equally excluded from our second section.

CENDEVA, in Ancient Geography, a marsh of Asia, in Phœnicia; placed by Pliny at the foot of Mount Carmel.

CENEDA, in Geography, a town of Italy, in the Trevisiana, belonging to the state of Venice, the eve of a bishop, suffragan of Udine, destroyed by the Huns and Goths; 20 miles of Trenigo.

CENDRILLARD, in Ornithology, the name given by Buffon to the St. Domingo Cuckow. Cuculus dominicus. Gmelin.

CENDRILE, the cinerous Lark, Alauda cinereus of Gmelin, is so named by Buffon in his Nat. Hist. d. Oise.

CENGOLD, in the Saxon Antiquities, an expiatory mullet, paid by one who had killed a man to the kindred of the deceased. The word is compounded of the Saxon eon, i.e. cognatio, relation, and gild, foliation, payment.

CENENOTLATOTLI, in Ornithology, the name by which Nieeremberg described the Polyglot or American mocking Thrush; a bird celebrated for the different modulations of its notes, which excel those of the nightingale in melody.

CENERIUM, in Ancient Geography, a small town of the Peloponnesus, in the Elide, according to Strabo.

CENEPOLIS, a name given by Polybius to a town of Spain.

CENESTAM, a town placed by Ptolemy towards the middle of the island of Corifica; which was an episcopal see.

CENETE, a town of Venetia, N. of Tarvisium.

CENGOTTO, in Geography, a small island in the Mediterranean; 24 miles N.N.W. of Candia. N. lat. 36° 1'. E. long. 4° 15'.
himself to them. That the inhabitants may not excite upon strangers, the king has fixed an order to regulate the price, which is generally stuck up in the poll-houses. From Laufnebourg to Novalea are two roads, the old and new; the last is the worst, but the shortest, and always chosen by those who travel on mules or in chairs. The Laufnebourg chairs are very active and expeditious in performing their labour; but notwithstanding their alertness and the extreme fatigue, that seems to attend it, they attain, in the use of the most simple diet, a considerable longevity. In order to betther to secure their footing, their shoes are without heels, and the soles are rubbed with wax and rosin. The machines in which travellers are carried down hill are a kind of draw chairs, with low back, two arms, and instead of feet a little board hanging down by a cord for supporting the traveller's legs. The feet, which is made of bark and hones twisted together, is looked to two poles, and carried, like a sedan, with broad flaps.

On the summit of mount Cenis is a plain, of rather a long uneven valley betwixt very high mountains, whose tops, even in summer, are covered with snow; and in winter and spring, when vast quantities of snow fall from the hills into the valley, the journey over mount Cenis is rendered not a little dangerous. There are lakes built up and down along the mountain for the herdmen, who come lither in summer with their cattle; fine grasses and several sorts of flowers being produced here, in the months of July, August, and September. This mountain, like some other parts of the Alps, abounds with chamois, wolves, marmottes, and hares. Half-way up the mountain is a lake about a league in circumference, which is said to be in the middle almost unattainable. In this lake is fine trout, some of which weigh 16 pounds. It is constantly fed up with water from springs issuing from the adjacent eminences, which are always covered with snow, and often with clouds; and out of it flows a river, which being augmented by other springs falls down in very delightful cascades; this river is by some called Senar, by others St. Nicholas; and near Suca it leaves itself in the Petite Doire or Dura. Kefler erroneously affirms, that the mountain of Roche-melon, on the left hand of Cenis, betwixt Pertiere and Novalea, is reckoned the highest of all the Italian Alps; it is 11,977 English feet above the sea; and little mount Cenis is 9,875; whereas mount Rosa exceeds 15,302, and mont Blanc is, according to Sir George Sackborough, 15,624; and according to De Luce 15,504. Kefler's Travels, vol. i.

Cenna, in Ancient Geography, a mountain of Africa, in Mauritania Cezariensis.

Cenning, Ceninga, or Ceninga, in our Ancient Books, denotes notice given by the buyer to him of whom he had bought, that the thing purchased was claimed by another, that he might appear and avow, or warrant his bargain. "The word is formed of the Saxon cennan, authore adducas; to call an author. Du Cange.

Ceno, or Zeno, in Geography, a river of Italy, which runs into the Tarso; 8 miles S.S.W. of Parma.

Cenobite. See Coenobite.

Cenomani, in Ancient Geography, a people of Transalpine Gaul, belonging to the Aulerci, whose country corresponded to the diocese of Mans. The Cenomani also were a people who originally came from Gaul, where they inhabited the country called by moderns le Maine, and settled themselves in Italy, a little after the year 600 B.C. Their principal towns in Italy were Brixia, Cremona, Mantua, and Verona.

Cenotaph, composed of κένο, empty, and τάφος, tomb, an empty tomb, or a monument without a body under it; erected only by way of honour to the deceased; and distinguished from sepulchre, in which a corpse is actually deposited.

Cenotaphs are honorary tombs, erected either to perform buried in another place, or to those who have received no burial, and whose relics cannot be found, as being killed in battle, lost at sea, or the like. Among the ancients the same privileges and religious regard were allowed to these common tombs & honoraria, as to real tombs. Card. Norris has a treatise express on the cenotaphs of the Cenars, Cains, and Laurus, which are still seen at Ptia. Lampud, in Alex. cap. 15.

Censal, in the Mediterranean parts, denotes a regula or established broker, authorized to negotiate between merchant and merchant.

Censer, in Antiquity, a kind of vessel where incense was burnt to the gods.

Censer is chiefly used in speaking of the Jewish worship. Among the Greeks and Romans it is more frequently called thurible, thuris, and auranum, which see.

The Jewish censer was a small sort of chafing-dish, covered with a dome, and suspended by a chain. Josephus tells us, that Solomon made twenty thousand gold censers for the temple of Jerusalem, to offer perfumes in, and fifty thousand others to carry fire in.

Censer, the same with Ara.

Censio, in Antiquity, the act or office of the censor. See Censor. Censio included both the rating or valuing of a man's estate, and the imposing of mulcts and penalties.

Censio balsarum, a punishment inflicted on a Roman soldier for some offence, as laziness or luxury, whereby his bals, or spear, was taken from him, and consequent his wages, and hopes of preeminence dropped.

Censitius, a person cenfled, or entered in the cenfual tables. See Census.

In an ancient monument found at Ancyra, containing the actions of the emperor Octavius, we read, "Quo ultero civium Romanorum Cenitae sunt capita quadragesima Centum milia & sexaginta tria.""
ceived at the census. M. Ruttilius was the first; who, having been twice consul and once dictator, in the year 402, demanded his census. The custom was to elect two, or the one of a patrician family, the other a plebeian; and upon the death of either, the other was discharged from his office, and two new ones elected; but not till the next lufrum. In the year 414, a law was made, when Publius Philo was dictator, appointing one of the cenfors to be always elected out of the plebeians; which held in force till the year 622, when both cenfors were chosen from among the people, viz. Q. Cæcilius Metellus, surnamed Macedonius, and Q. Pompeius; after which time, it was shared between the senate and the people.

The last cenfors, viz. Paulius and Planerus, under Augustus, are said to have been private persons; not, indeed, that they had never borne any public office before; but of a dilution from the emperor; all besides him being so called.

This office was so considerable, that none aspired to it till they had passed all the rei; so that it was looked on as surprising, that Crassus should be admitted censor, without having been either consul or praetor. The term of this office was at first established for five years; but that institution only lasted nine; M. Marcius Eumadius the dictator, in the year 325, made a law, restraining the censorship to a year and a half; which was afterwards observed very strictly. Thus, Rome was regularly without cenfors 33 years; for the lufrum did not cease by the end of the year. But this order was often interrupted, either by wars abroad, or domestic divisions, or some other particular reasons. Sometimes five years expired without the creation of any cenfors; on other occasions cenfors were created more than once during the space of a lufrum, if those who had been first chosen had not been able to complete the census.

The power of the cenfors was at first very limited; but afterwards it became very extensive. All the orders of the state were subject to them. Hence the cenfrian ship is called by Plutarch (in Cat. Maj.) the whim of all pretenders, "omnium honorum apex, vel fastigium;" and by Cicero (in P. 4.) "magistra pudoris et modelliz." The title of cenfor was esteemed more honourable than that of consul; as appears from ancient coins and statues; and it was reckoned the chief ornament of nobility to be sprung from a cenforian family.

The sentence of cenfors only affected the rank and character of persons; and it was therefore properly called "ingnomia," and in later times had no other effect besides putting a man to the blufis, or, as Cicero expresses it, "nihil feri damauto offerbatur prator ruborem." It was not fixed and unalterable, like the decision of a court of law; but might either be taken off by the next cenfor, or rendered ineffectual by the verdict of a jury, or by the suffrages of the Roman people. Thus we find C. Geta, who had been excluded the cenfor by the cenfors, A. U. 659, the very next lufrum, chosen himself cenfor. Sometimes the cenfors added force to the forbe sentence of the cenfors, by their decree, which imposed an additional punishment. When the cenfors acted improperly, they might be brought to a trial, as they sometimes were, by a tribune of the commons. Two things were peculiar to the cenfors: 1. No one could be elected a second time to that office, according to the law of C. Marius Romanus, who refused a second cenforship when conferred upon him, hence named "Conforinum." 2. If one of the cenfors died, another was not substituted in his room; but his surviving colleague was obliged to resign his office. The death of a cenfor was deemed ominous, because it had happened that a cenfor died, and another was chosen Vol. VII.

in his place, in that lufrum in which Rome was taken by the Gauls. Before the cenfors began to exercise their office, they swore that they would do nothing through favour or hatred, but that they would act uprightly; and when they resiged their office, they swore that they had done so. Then going up to the treasury, they left a bit of the same which they had made "ex ara." A record of their proceeding was kept in the temple of the Nymphs, and it is said to have been preserved with great care by their descendants.

The bufiness of the cenfors was, to register and value the effects, &c. of the Roman citizens; and to impose taxes, in proportion to what each person possessed. Cicero reduces their functions to the numbering of the people; the correction and reformation of manners; the eliminating of the effects of each citizen; the proportioning of taxes; the superintendence of tribute; the exclusion from the temples, and the care of the public places. They had also a right, senza eicere, to expel from the senate lurch of the members as they judged unworthy of the dignity; as well as to break and calum the knights who failed in their duty, by taking from them the public horfe, epum adinere.

There are many examples of cenfors expelled by the cenfors, generally for good reasons, yet sometimes through mere perversity, envy, or revenge: but in such cases, there was always the liberty of an appeal to the final judgment of the people. So that the cenforian power, properly speaking, was not that of making or unmaking cenfors, but of expelling only those whom the people had made; and of insulting their manners, and animadverting upon their vice; over which they had a special jurisdiction delegated by the people. Their rule of cenfuring feems to have been grounded on an old maxim of the Roman policy, rejoicing, "that the senate should be pure from all blemish, and an example of manners to all the other orders of the city;" as we find it laid down by Cicero in his "Book of Laws," which were drawn, as he tells us, from the plan of the Roman constitution.

Besides the talk of enrolling the cenfors, and inspecting their manners, it was a part likewise of the cenforian jurisdiction to let out to farm all the lands, revenues, and customs of the republic; and to contract with artificers for the charge of building and repairing all the public works and edifices, both in Rome, and the colonies of Italy. Now in this branch of their office it is certain that they acted merely under the authority of the people, and were prohibited by law to let out any of the revenues, except in the rostra, under the immediate inspection and in the very presence of the people.

In the general census and review of the city, held by them every five years, though every single citizen was particularly summoned and enrolled by name in his proper tribe, as a freeman of Rome, yet that solemn enrolment, as Cicero tells us, did not confirm any man's right to a citizenship, but signified only that he had palled for a citizen at that time, because the proper power of determining that right resided always in the people. (Cicer. pro Arch. 5. Jan. 52. Middleton of Rom. Sen. p. 50, 68, 70, 81, &c.)

When Rome had extended her conquests, and founded many colonies, or given the freedom of the city to many of her neighbours, the functions of the cenfors became proportionally more extensive. Officers, who were also called cenfors in those colonies, and municipal cities, gave the cenfors of Rome an account of the condition of those cities, of the number of their inhabitants, and of their riches; and their reports were registred in the books of the cenfors. The power of the cenfors continued unimpaired to the ...

bishops of Clodius, A. U. 695, who procured a law to be enacted, ordaining that no senator should be degraded by the censors, unless he had been formally accused and condemned by both censures; but this law was abrogated, and the powers of the censurship reverted soon after by Q. Metellus Scipio, A. U. 722.

The office continued to the time of the emperors, who allowed the authority of it to themselves, but without the name, calling themselves, instead of censors, magistri prefelli; though Vespasian and his sons took a pride to be called censors, and put among their other titles on their coins. Decius attempted to restore the dignity to a particular magistrate. After this we hear no more of it till Constantine's time, who made his brother censor: the last, who seems to have enjoyed the office.

The necessity of appearing at certain times before the tribunal of the censors, to give an account of their conduct, imposed universally on all the citizens, and from which neither birth, services rendered to the state, nor the most important offices previously exercised, as those of consul and dictator, exempted any one, must have been a powerful check upon licentiousness, and disorder. There are, says the author of "Confederations upon the Caesars and Declension of the Romans," bad examples, which are more pernicious even than crimes, and more states have been ruined by corrupting their manners than by violating their laws. At Rome, whatever might introduce dangerous innovations, change the sentiments or inclinations of the good citizen, and prevent their perpetuity; in a word, all disorders of a public or private nature were reformed by the censors. If luxury and avarice, the usual causes of the ruin of states, were introduced too late at Rome; if poverty, frugality, simplicity, and moderation in the table, buildings, furniture, and equipage, were so long in honour there, this extraordinary felicity ought, without doubt, to be ascribed principally, or in a great degree, to the inexorable severity of the censors, rigidly attached to the ancient manners of their country, from which they well knew how important it was not to depart. The authority of the censurship produced at Rome the same effect, in respect to manners, as the severity of the military discipline did in the armies with respect to the support of subordination and obedience. And there were the two principal causes of the Roman greatness and power. Whatevers victories are gained, whatever provinces are subdued, if purity of manners do not prevail in the different orders of a state; if the administration of justice, and the power of the government, be not founded upon invariable equity and a sacerore love of the public good, however powerful an empire may be, it cannot subsist long. (Val. Max. i. ii. c. 9.) The fanciety of oaths was no where so much respected as at Rome. This was, as Cicero remarks, (Offic. l. iii. c. 3.), because no crimes were so severely punished by the censors, as breach of faith and contempt of oaths. Upon the whole, we may observe, that upon the office of censurship depended, in a great degree, the good order, regulation, discipline, conformity of the manners, and administration of the revenues of the commonwealth. See on the subject of this article, Dion. Hal. Dion. Cassius. Livy. Cicero. Val. Max. Suetonius. Tacit. Annal. &c. &c.

The republic of Venice has at this day a censor of the manners of their people, whose office lasts six months.

Censors of books are a body of doctors, or other officers, established, in divers countries, to examine and give their judgment of all books, before they go to the press; and to see they contain nothing contrary to the faith, and good manners. In England we had formerly an officer of this kind, under the title of licenc of the press; but since the revolution the press has been open.

At Paris, the faculty of theology claimed the privilege of censuring, as granted to them by the pope; and it is certain they have been in possession of it for many ages: but in the year 1624, a new commission of four doctors was created, by letters patent, the sole public, and royal censers, and examiners of all books; and answerable for every thing contained therein. The faculty, however, still maintained their claim, by taking occasion, now and then, to give their approbation to books.

In the year 1678, when public censers were appointed without their consent, whom the faculty opposed, they flouted the antiquity of their right to be 300 years. For they said, "It is above 300 years since the doctors of Paris have had a right to approve books without being subjected but to their own faculty, to which they are not able for their decisions."

Many centuries before the invention of printing, books were forbidden by different governments, and even condemned to the flames. See Burning of Books. Authors, at this early period, submitted their works, before they were published, to the judgment of their superiors. This was principally done by the clergy; partly to secure themselves from censure or punishment, and partly to manifest respect for the pope or bishops. This, however, does not appear to have been, on their part, a duty, but a voluntary act. In 508, Ambrosius Autpert, a Benedictine monk, sent his exposition on the book of Revelation, to pope Stephen III., and begged that he would publish the work, and make it known. On this occasion, he says expressly, that he is the first writer who ever requested such a favour; that liberty to write belongs to every one who does not wish to depart from the doctrine of the fathers of the church; and he hopes that this freedom will not be leisened on account of his voluntary submission. Soon after the invention of printing, laws began to be made for subjecting books to examination; a regulation proposed even by Plato; and which has been wished for by many since. It is, indeed, very probable, that the apprehensions of the clergy, lest publications should get abroad prejudicial to religion, and consequently, to their power, contributed not a little to hale the establishment of book-censers. The earliest instance of a book printed with a reprobation from government is commonly supposed to occur in the year 1480; but professor Beckmann mentions two books, which were printed almost a year sooner than 1479, with the approbation of the public censor. The oldest mandate for appointing a book censor, that has occurred to him, is that issued by Berthold, archbishop of Metz, in the year 1486. In 1501, pope Alexander VI. published a bull, which contains several prohibitions and regulations, with regard to the printing of books, and decrees all catalogues and books before that period to be examined, and those which contained any thing prejudicial to the Catholic religion to be burned. In the council of Lateran, held at Rome in 1515, it was ordered, that in future no books should be printed but such as had been inspected by ecclesiastical censers. Beckmann's Hist. of Inventions, vol. iii.

CENSORIAL, Censorius, something that relates to the office of censor. In which sense we meet with cenforia nota, or animadverfio, cenforia virgula, &c.—cenforia lex, denoting a law palied or enacted by the censors:—bemo cenforius, a person who has borne the dignity, and served the office of cenfor:—virgula cenforia, which, among the ancient Grammarians, and Critics, denoted a note or mark of reproduction, affixed to those passages of a book or writing, which the critic disapproved or condemned.
CENSORINUS, in Biography, a learned grammarian, is supposed to have been of the Martian family, and to have been eminent at Rome in the times of Alexander Severus, Maximian, and Gordian. In the first year of the emperor Gordian, A.D. 238, he wrote his famous book "De Die Natali," which has been of great use to chronologers by connecting the principal years of various events of antiquity. It was dedicated to Q. Cerelius, of the equestrian order, and has been often cited with commendation by Sidonius, Cassiodorus, Priscian, and others. This work has passed through a great number of editions. It was printed at Hamburg, in 1614, with a perpetual commentary, by Lindenbroc; at Leyden, with additional notes, in 1642; at Cambridge in 1695; and by Havercamp in 1743. Censorinus also wrote a book "On Accents," Fab. Bib. Lat. vol. ii.

CENSUAL, Books, libri convenales, those wherein the census was taken down.

CENSUALES, in a substantive sense, denoted the clerks or public scrivens who wrote the censual books.

CENSUALES, in Ecclesiastical Antiquity, denoted also a class of the oblates, or voluntary slaves of churches or monasteries; or those who, for procuring the protection of the church, bound themselves to pay an annual tax or quit-rent out of their estates to a church or monastery. Besides this, they sometimes engaged to perform certain services. Robertson's Ch. V, vol. i. p. 326.

CENSURE, Censura, is popularly used for a judgment, whereby any book, person, or action is blamed or condemned; more particularly for a remand made by a superior, or perfun in authority.

Censure is also a custom, in several manors in Cornwall and Devon, whereby all the recipients above the age of sixteen are called to swear fealty to the lord, to pay two-pence per poll, and a penny per annum ever after, as rent-money, or common fine.

Censures, ecclesiastical, are the public menaces which the church makes, or pains and penalties incurred by disobeying what she enjoins; or rather the pains and punishments themselves; as interdiction, excommunication, &c.

Till the time of the Reformation, the kings of England were subject to the censures of the church of Rome; but the kings of France have always maintained themselves exempt from them.

The canonists distinguishes two kinds of censures; the one de jure, and the other de facto, or by sentence.

CENSUS, among the Romans, was an authentic declaration made upon oath by the several subjects of the empire, of their respective names, and places of abode, before proper magistrates in the city of Rome, called cenfori; and in the provinces, cenfrors, by whom the name were registered.

This declaration was accompanied with a catalogue, or enumeration, in writing, of all the estates, lands, and inheritances they possessed; their quantity, quality, place, value, tenants, domestics, slaves, &c.

Those who neglected to conform to this regulation were deprived of their estates, beaten with rods, and publicly sold for slaves, as persons who had deemed themselves unworthy of liberty.

The census was instituted by king Servius Tullius; to be held every five years; and this prince took the census four times during his reign. Tarquin the Proud neglected this useful institution. After the expulsion of the kings, the cenfors were charged with this care till the establishment of the censors. Each census terminated with a ceremony called lystrum, which fee.

There had been ten censuses, or lystra, before the first taken by the cenfori, which was the eleventh. See Censor. Servius, having by this regulation ascertained the valuation of the estates of the citizens, divided them into fix classes, and each class into a certain number of centuries. See Curty. By thus ascertaining the number of citizens and the value of their estates, Servius undertook to ease the poor by increasing the burdens of the rich, and, at the same time, to pleade the latter, by augmenting their power and influence. The census was taken anciently in the forum; but after the year 320, in the villa publica, which was a place in the Campus Martius; but the census was sometimes held without the concluding ceremony of the lystrum. The census comprehended all the ranks of people, though under different names; that of the common people was called census, or lystrum; that of the knights, censio, recensio, recognition; that of the senators, tetrio, rebellio. Hence, also, cenfus came to signify a person who had made such a declaration; in which sense it was opposed to insufficient, a person who had not given in his estate, or name, to be registered.

The census among the old Romans was held, as is commonly thought, every five years; but this must not be taken to be precisely true; on the contrary, Dr. Middleton has shewn, that both the census and lystrum were for the most part held irregularly and uncertainly, at very different and various intervals of time. See Lustrum.

The census was an excellent expedient for discovering the strength of the state; by it they learnt the number of the citizens, how many were fit for war, and who for offices of other kinds; how much each was able to pay of taxes towards the charge of the war.

The census, according to Salmusius, was peculiar to the city of Rome. That in the provinces was properly called prospeffio and propeffio. But this distinction is not everywhere observed by the ancients themselves.

In the provinces, the census not only served to discover the substance of each person, but where, and in what manner and proportion, tributes might be levied imposed.

Census was also used for the book or register wherein the professions of the people were entered. In which sense the census was frequently cited and appealed to, as evidence in the courts of justice.

Census is also used to denote a man's whole substance or estate.

Censura, the patrimony of a senator, which was limited to a certain value; being at first rated at eight hundred thousand sesterces, but afterwards, under Augustus, enlarged to twelve hundred thousand. Sueton. in Car. cap. 41.

Census equit. the estate or patrimony of a knight, rated at four hundred thousand sesterces, which was required to qualify a person for that order, and without which no virtue or merit was available. Suet. in Car. cap. 37. Hor. lib. i. sat. 30. vers. 57, 58, 70.

Censura was also used for a person worth an hundred thousand sesterces, or who was entered as such in the census tables on his own declaration. In which sense, cenfus amounts to the same with claflu, or a man of the first class; though Gellius limits the estate of those of these clafs to an hundred and twenty-five thousand sesterces. By the Vocijan law no census was allowed to give by his will above a fourth part of what he was worth to a woman. Aus. Celt. Not. Att. lib. viii. cap. 17. Cic. in Ver. 3.
**Census** was also used to denote a tax or tribute imposed on persons, and called also capitation. See Capita cens.

*Census dominicus*, in *Writers of the Lower Age*, denotes a rest due to the lord.

*Census decipher*, a double rent or tax, paid by vassals to their lord, on extraordinary or urgent occasions; as expeditions to the Holy Land, &c.

*Census ecclesiae Romanae*, was an annual contribution, voluntarily paid to the see of Rome by the several princes of Europe.

*Census focus*, that paid in money.

*CENT*, in *Commerci*, an abbreviation of the Latin *centum*, which properly signifies a hundred. It is applied when expressing the profit or loss upon any commodity.

*CENT* is also used in the trade of money, and signifies the benefit, profit, or interest of any sum of money which is laid out for improvement. Thus we say money is worth 4 or 5 per cent. upon exchange; that is, it brings four or five pounds profit for every 100 laid out.

*CENT* is also used with regard to the draughts or remittances of money, made from one place to another. Thus we say it will cost 2½ per cent. to remit money to such a city.

**CENTALLO**, in *Geography*, a town of Italy, in the principality of Piedmont; 2 miles N. of Conti.

**CENTAUREA**, in *Botany* (κένταυρες), or κένταυρος βάτος, herb centaur; κένταυρος, Theophr. Diocr. 4. 1. κένταυρος, Theophr. so called from Chiron the Centaur, who is said to have employed one of its species to care for himself of a wound accidentally received by letting one of the arrows of Hercules fall upon his foot.) *Linn. gen. 504. Schreb. 1771. Willd. 1789. Clays and ord. fingnenta polygamia fragrans. Nat. Ord. Compositae. Linn. Charophylla. Juss. Vent.*

Gen. Ch. *Centaurea*, common, imbricated, roundish; scales variously terminated. Cor compound, flaccular; florets differing in form; those of the disc florid, numerous; those of the ray fewer, looser, larger, funnel-shaped, constantly abortive; tube of the hermaphrodite florets filiform; border bellvory, oblong, erect, terminated by five linear erect segments; tube of the abortive florets tender, gradually enlarging, recurved; border oblong, obtuse, unequally divided. Stem. of the hermaphrodite floroes: filaments five, capillary, very short; anthers united into a hollow cylinder, the length of the petal; of the abortive florets none. Pyl. of the former: germ small; style filiform, the length of the filaments; stigma very obtuse, projecting in a point, in many species bifid; of the latter, germ very small; style scarcely any; stigmas none. Seeds of the fertile florets solitary; down in most species feathered or capillary; recept. briliy.

This extensive genus was formed by *Linnæus* as a kind of common receptacle for such plants as would have been placed under some other genus of compound capitae flowers, if they had not had a ray of abortive florets, which, by the principles of his system, obliged him to place them in this third artificial order, at a distance from their natural congers. It contains centaurea majus of *Tournefort*; *jacea* and *cyannus of Tournefort* and *Vaillant*; *celestrap*, *celestraposides*, *rhaponticum*, *rhaponticoides*, *amnerboi*, and *crucilum* of *Vaillant*. Molts of these have been revised by *Juddic* as separate genera, with some alterations, and are retained by Venticat.
CENTAUREA.

CENTAURIA.

rous, somewhat heart-shaped, on long pedicels; stem-leaves few, on short pedicle; sometimes pinnatifid. Flower purple, solitary, large, without any barren florets; La Marek on that account has discarded it from his genus, and Gart-ner has referred it to Scrophularia. 25. C. babylonica, Linn. 

Morif. hist. tab. 28. fig. 10.) "Calyxes conical, hard; 

seeds fix or seven feet high, simple, upright, winged, a little woody. Root-leaves very large, a foot and a half long, upright, petioled; stem-leaves diminishing in size from the bottom to the top, giving the plant a pyramidal form, rough to the touch. Flowers yellow, nearly sessile; in a very long, upright, terminal raceme, growing in bunches three or four together along the raceme; calyx almost smooth, made rough by the little expanding points which terminate the foliaceous. A native of the Levant. 26. C. alata, Lam. 10. 

Matt. 60. Wildl. 58. Vahl. symb. 22. "Calyxes egg-shaped, smooth, five, a few, somewhat curved at the tip; leaves greenish, deciduous, united; radical ones lyrate." Root perennial. Stems four feet high, smooth, a little angular, branched near the top, forming neither a spike, nor a raceme. Root-leaves considerably less than those of the preceding species, 

narrow, very little downy; stem-leaves narrow. Flowers bright yellow; calyx scales slightly saccate at the tip. Willdenow attributes it to ferrate; and Vahl, ciliated calyx-scales. Described by La Marek from a living plant, in the royal garden at Paris, where it had long been cultivated, supposing it to be a native of Tartary. 27. C. glafifolia, Linn. Sp. Pl. 33. Matt. 36. Lam. 11. Wildl. 71. Curt. Bot. mag. 62. (Centaureum majus incanum humile, capitae pinni, Tourn. 449. Jacca incana capitae pinni, Bauh. pin. 272. Morif. hist. tab. 29. fig. 19. Chamaeleon non aculeatum; Lob. ic. 2. p. 7. Stæhle, Barr. ic. 38.) "Leaves tomentose; root ones lanceolate; stem ones pinnatifid; stem simple. Stem fix or eight inches high, upright, frilled, cottony. Leaves greenish above, very white and cottony underneath. Flower very large, purple, terminal, branched; calyx shaped like a pine-cone, very taper at the top, where it closely surrounds the florets; only one a little above it: several fringed, transparent, the upper ones red. A native of the north of Europe. 29. C. membranacea, Lam. 16. Cucuru undi- 

flor, Linn.? "Calyces membranous; leaves pinnatifid, toothed." Nearly allied to the preceding. Stem a little taller. Leaves deeply pinnatifid. Flower large, purple; calyx shorter than in C. conifera; scales whitish with a pale brown tint, rounded at their fummat. Inerated at their edges. A native of Siberia. 111. Rhiptentica. Calyx-scales dry and saccate, ciliate-ferrat. (Khaponticum; Linn.)

3°. C. fulcérina, Wildl. 59. "Calyx scales egg-shap- 

ed, acuminate, ciliate-ferrate; leaves hoary underneath; root ones pinnatifid; stem ones lanceolate." Root perennial. Stem a foot high, quite simple, one-flowered, cylindrical, upright, tomentose. Root-leaves two inches long, petiolate; 

segments lanceolate, entire, terminal one very large; stem leaves an inch and half long, entire. Flower purple; the ray twice the length of the disc; lower calyx-scales snow-white; upper ones brownish. A native of the East. 31. C. Bulb- 

niflata, Lam. 26. Wildl. 51. (Carduus orientalis compl. hortennis folio; Tourn. Cor. 32. Itin. 2. p. 439.) "Calyces ciliate-fringed with straight, rigid, white bristles; leaves oblong, a little toothed; flower yellow, without a ray." Lam. "Seals egg-shaped, ciliate-ferrated, awned; leaves oblong, undivided, nearly entire, ferraceous, nucrinated. Wildl. Stem two feet high, frilled or angular, slightly villous, leafy; branches upright, one-flowered. Root-leaves oblong, acute, petioled; stem leaves scattered, feathery, lanceolate, a little toothed, whitish green. Flowers yellow, terminal; barren florets smaller than the fertile ones; calyx globular; scales beautifully fringed with rather long, stiff, whitish bristles. La Marek, from a living plant, in the royal garden at Paris, raised from seeds gathered by M. André in Syria or Armenia. Stem erect, cylindrical, smooth; very feathery. Leaves feathery, green; higher ones a little hoary; root ones oblong, acute; stem ones lanceolate-oblong; lower ones somewhat toothed, rather acute; upper ones quite entire, ending in a long bristle-shaped point. Flowers yellow, without a ray; calyx-scales yellowish, terminated by a long bristle, ciliate-ferrated at the edges. Wildl. from a dried spicemen. He quotes La 

Marek, but it appears dubious whether they have not referred different plants. 32. C. macrocephola, Wildl. 52. "Calyx-scales roundish-egg-shaped, ciliated; leaves oblong-lanceolate, undivided, very ferraceous, acute, ferrated." Branches the thickest of a swan's quill. Leaves three inches long, an inch and a half broad at the base, embracing the stem. Flowers yellow, without a ray. A native of 

Iberia. 33. C. calendulacea, Lam. 31. "Calyxes ciliate- 

hairy; inner scales ligulate, ferrate, ferrated at the tip; stem-leaves pinnate; those on the branches simple. Stem a foot and a half high, angular, frilled, much branched, panicled. Flowers yellow, terminal; fertile florets few, small; barren ones large, ligulate, flat, four or five toothed; inner calyx-scales long, narrow, toothed at the fummet; the other shorter, ciliated with long reddish hairs. A native of Armenia; discovered by M. André; described by La Marek from a living plant. 34. C. atrapurpurea, Wildl. 53. Wildl. 59. and Kitaib. pl. rar. Hung. 2. p. 127. tab. 116. "Calyx-scales ovate-lanceolate, ferrate-ciliated; leaves bipinnatifid; segments lanceolate." Flowers dark purple; calyx-scales black, fringed with white. A native of Hungary among calcareous rocks. 35. C. orientalis, Linn. Sp. Pl. 23. Matt. 27. Lam. 44. Wildl. 54. (Cyamus; Hall. Act. Angl. 1743. vol. 43. p. 94. tab. 4.) "Calyx-scales pinnatifid-ciliated; leaves deeply pinnatifid; segments linear-lanceolate." Lam. Nearly allied to C. lechobis, but distinguished from it by the color of the flower, and the structure of the calyx. Root perennial. Stem a foot and a half or two feet high, frilled, branched, downy near the fummet. Leaves petiolated, large, green. Flowers bright yellow, large, terminal; calyx-scales yellowish white, roundish, downy at the base, ciliated with long pinnatifid hairs. A native of Siberia and Tartary. 36. C. fimbriata, Matt. 72. Scop. infr. 38. tab. 32. "Calyxes ferrate ciliated; leaves dotted underneath, pinnate; pinnae lanceolate, scalaris, erect." Nearly allied to the preceding. Root perennial. Root-leaves entire. Flowers pale yellow, feathery; calyx-scales twice as large as in C. orientalis, not at all downy at the base; lacked all round; down of the seeds very apparent. 37. C. flavi- 

CENTAUREA.

fibrius; Curt. vol. ii, p. 383.) "Calyx scales egg-shaped, obulb.; ciliate; leaves downy on both sides, pinnatifid and undivided; stem declining." Root perennial. Stem from six to nine inches high, quite simple, rarely furnished with a single branch, somewhat furrowed, pubescuent. Leaves lanceolate; root ones generally pinnatifid; lobes turned upward, entire, terminal one very large; stem leaves mostly five or fix. the uppermost generally undivided. Flowers purple or flesh-colored, often single, with a large ray of barren florets; calyx, dwelling. A native of Siberia. 38. C. pefilitis Willd. 55. "Calyx scales ciliate-ferrated; flowers ciliate, leaves pinnatifid, hairy; stem none." Root perennial. Leaves an inch and a half long, petioloed; segments lanceolate, rather obtuse, quite entire in the upper part, arched toward the base with an oblong tooth; terminal one larger, egg-shaped, somewhat toothed. Flowers purple, five or fix. ciliate on the crown of the root, not at all pedunculated; calyxes oblong. A native of Armenia. 39. C. voragiza, Willd. 57. Schouboe Moroc. p. 199. "Calyx scales fearious at the tip, ferrated; leaves scarious at the edge; root ones oblong toothed; stem ones lanceolate, somewhat decurrent, quite entire." Root perennial. Flowers pale violet; side twice the length of the ray; calyx egg-shaped; lower leaves toothed at the tip, mucronated; upper ones encased with a fearious toothed scale. A native of Barbary. 40. C. fruticosa, Willd. 59. "Calyx scales ciliate; leaves linear, downy, fove-nerved, quite entire; stem erect." Stem downy; branches few, fagitate, one-flowered. Leaves an inch or an inch and a half long. Flowers purple. A native of Siberia. 41. C. nigrescens, Willd. 28. "Calyx scales fearious; root leaves oblong toothed; lower leaves somewhat toothed at the base, upper ones undivided, quite entire." Root perennial. It differs from C. nigra, in having a radiate flower, and calyx scales ciliate, not fothered; from C. jacea in having a ciliate calyx, root leaves often obliquely pinnatifid, and the lower stem ones often deeply toothed at the base. A native of Hungary and Austria.

IV. Cym. Calyx scales ciliate-ferrated, not fearious. (Cyanus and Jacc. Jull.)

42. C. Tryumfettii, Mart. 67. Willd. 29. Alib. ped. n. 379. (Cyanus; Triumf. Obfl. 26. Mcl. taur. 5. p. 68.) "Calyx ferrated; leaves foseille, downy, lanceolate, pinnatifidim" Willd. "Calyx ferrated, with white ciliate; leaves decurrent, deeply pinnatifid; pinnae generally two." Alibon. Root perennial. Stem simply or branched; branches one-flowered. Lower two inches long. Flowers purple. A native of mount Cenis. 43. C. ceterambifolia, Willd. 50. Phytoz. 12. n. 42. tab. 7. fig. 2. (Cyanus orientalis, angulifolius, incanus; filo magno, citrino; Tourn. Cor. 32.) "Calyx ferrated; leaves downy; root ones pinnatifid; stem ones foseille, linear, somewhat toothed; stem one-floree-ed." Root perennial. Flowers yellow, with a large ray; calyx scales fimbriated at the edges. A native of Armenia. 44. C. schraderi, Willd. 31. (Cyanus orientalis, flose maximo, citrino; Tourn. Cor. 32.) "Calyx ferrated; leaves oblong, ferrated, decurrent, and undivided." Root perennial. Flowers pale yellow, twice as large as those of C. montana. A native of mount Caucasus. 45. C. atrata, Willd. 32. (Cyanus orientalis folio fimbriato dentato; flore magno; Tourn. Cor. 32.) "Calyx ferrated, fimbriated; leaves lanceolate, foseille, smooth, toothed." Root perennial. Stem seven or eight inches high. Leaves an inch and a half long, green; younger ones woolly at the edge. Flowers blue; calyx scales black, with white teeth. A native of Armenia. 46. C. variegata, Lam. 29. (C. axillaris, Willd. 33. C. fennana, Villars delph. 5. p. 52. Suter helv. 2. p. 205.) "Calyx ciliated, variegated; leaves foseille, linear, downy; stem one-flowered." Lam. "Calyx ferrated, leaves hairy, lanceolate, decurrent; lower ones linear-toothed at the base; peduncles axillary and terminal." Wild. Root perennial. Stem from five to seven inches high, quite fimbriate, cymose. Leaves about three inches long, two lines broad, entire, a little umbellated, cymose, and whistled on both sides; flowers has a little fimbriated; upper ones shorter, more distant from each other. Flowers fine blue, large, terminal; calyx scales smooth, green at their base, blackish at their edges, furnished with large, palmated, brilliant, fimbriate ciliis. Lam. A native of mountains in the south of Europe. 47. C. montana, Linn. Sp. Pl. 13. Mart. 14. Lam. 28. Willd. 31. Pot. Mag. 77. (Cyanus, Bauh. pin. p. 273. n. 1. Bouq. D.S. 2. p. 25. tab. 2. Halli. helv. n. 192.) "Calyx ferrated; leaves fuscumfif; lanceolate, quite entire, decurrent; stem simple." Root perennial. Stems upwight, simple, when cultivated often a little branched, entire, decurrent, soft. Flowers blue, purple, or white, resembling that of the next species, but larger, terminal; calyx scales light green, black at the edges, with short, black ciliis; thole at the tip longer, brownish, a little recurved. A native of mountains in Germany, Switzerland, and the south of France. 48. C. Cyamus, Linn. Sp. Pl. 11. Mart. 15. Lam. 30. Willd. 35. Eng. bot. 277. Curt. Flor. Lond. Tab. 62. Mart. Flor. bull. 3. (Cyanus fegetum, Bauh. pin. p. 273. n. 2. Tourn. p. 440. Cyanus vulgaris, Linn. 1c. 340. Backw. tab. 275. Halli. helv. n. 191.) Corn blue-bottle. "Calyx ferrated; leaves linear, quite entire; lower ones toothed; stem branched, many-flowered," Lam. Root annual, fbruis, black. Stem erect, much branched, somewhat woolly. Leaves linear-lanceolate, acuminate, somewhat woolly; root leaves entire; lower stem leaves often pinnatifid or toothed; upper ones always entire. Flowers terminal, solitary, pedunculated; florets of the disc purplish red, angular; anthers black; florets of the ray funnel-shaped, always blue when wild, but when cultivated it varies with almost al colours except yellow; calyx egg-shaped; scales lanceolate. Seeds even; down many-leaved, unequal, scabrous, reddish. A well known weed growing in corn fields in the south of England and many other parts of Europe, and for its beauty often cultivated in gardens. A blue water-colour is easily prepared from the exprefsed juice of the neutral florets, mixed with a little cold alum water; but it is not durable if exposed to the action of light. A water is also distilled from them in France, which is said to remove inflammations of the eyes. 49. C. vingata, Lam. 37. Willd. 36. "Calyx ciliated, small, somewhat cylindrical; scales narrow-lanceolate, colored at the tip; branches slender, long, red-like," Lam. Branches somewhat scabrous, fimbriated. Leaves small, cinereous-green; lower ones half an inch long; segments narrow, linear, revolute at the edges, sometimes with one or two teeth; upper ones linear, entire. Flowers purple, small florets of the ray shorter than those of the disc. A native of Armenia. 50. C. ovina, Willd. 37. Pallas. "Calyx ciliated; scales oval-lanceolate, spreading at the tip; lower leaves pinnatifid, lanceolate-linear; upper ones pinnatifid; stem branched, divaricate." An intermediate species between the preceding and following. Whole plant green, woolly-pubescent. Florets of the ray longer than those of the disc. A native of Mount Caucasus. 51. C. paniculata, Linn. Sp. Pl. 15. Mart. 16. Lam. 36. Willd. 38. Jacq. Aufl. tab. 320. (C. meranthius, Gmel. it. 1. tab. 23. fig. 1. Stu,bc, Bauh. pin. p. 275. n. 3. Jaca folia calycanthus, Tourn. Inll. p. 444. Morii. hist. tab. 25. fig. 15.) "Calyx ciliated, egg-shaped; scales flat, clove-shaped; lower leaves pinnatifid; upper ones pinnatifid; stem branched, divaricate." Root annual. Stem a foot and a half high, angular,
Centauraea.

Angular, hard, slender. Flowers small, purple; petals white. A native of the utmost France, Austria, Italy, Spain, and Siberia. 52. C. maculosa, Lam. 39. Gmel. Sib. 2. p. 69. n. 79 and 83. Tab. 42. fig. 1. 2. "Calyxes ciliated, ovate-rounded, beautifully spotted; leaves flannel, bipinnatifid; flower a little pinnated." Stem from eight to ten inches high, spatulate, white. Lower whorl, more finely cut than the usual of the preceding species; lower ones oblong, bipinnatifid; upper ones larger, densely pinnatifid; segments linear.

V. Cyanoida. Calyx-scales bristly-ciliated; bristles recurved or erect. (Cyanus & Jacea, Jutt.)

68. *C. philoxia, Lam. Sp. Pl. 8. Mart. 7. Lam. 19. Wild. 15. (Jacea, n. 7. 8-9. Bauh. Pin. Cyanus. Hall. Helv. n. 188.) "Calyces recurved-flaethy; leaves oblong, undivided, febrown, mucronate-serrulatus." Root perennial. Stem a foot and a half high, somewhat hairy, angular, fringed, pubescent, branched towards the summit. *Leaves* greenish, rough to the touch; root-scales long, lanceolate, toothed, narrowed into a petiole towards the base; *stem* ones embracing the stem, lanceolate, toothed, with a longer tooth, appearing like an ear, at the base. *Flowers purpurea*, terminal, solitary; calyx-scales oblong, smooth, yellowish, in a brown, lanceolate lamina, two or thrice as long as the scales themselves, and two rows of frous cutie, having the appearance of a reflected leaf. A native of Germany, Switzerland, and the south of France. 69. *C. salisifolia, Wild. 16. "Calyces recurved-flaethy; stem long, pubescent, toothed, ending on once toothed, greenish, Mart. 5. Stem a foot and a half high; *Leaves* greenish, quite round, without a neutral ray; leaves hairy, lanceolate, remotely toothed." Root perennial. Stems simple, one-flowered, hairy. *Leaves* one to a half inch long, not downy, but clothed on each side with numerous, short, erect hairs. *Flowers purpurea*. The habit of the preceding species, but differs in the leaves and flowers. A native of Italy. 77. *C. trichoccephala, Wild. 23. Gmel. Sib. tab. 45. fig. 1, 2. "Calyxes recurved-flaethy, pubescent; leaves lanceolate, somewhat toothed, downy." Root perennial. Stem a foot and a half high, simple, cottony, one-flowered. *Leaves* narrow lanceolate, cottony, whitish, soft to the touch, some entire, others thinly toothed. *Flower* purple, large, terminal, febrown, surrounded by bracts at its base. A native of the South of Europe. 76. *C. floalba, Wild. 22. "Calyxes recurved-flaethy; flowers without a neutral ray; leaves hairy, lanceolate, removly toothed." Root perennial. Stem simple, one-flowered, hairy. *Leaves* one to a half inch high, not downy, but clothed on each side with numerous, short, erect hairs. *Flowers purpurea*. The habit of the preceding species, but differs in the leaves and flowers. A native of Italy. 77. *C. trichoccephala, Wild. 23. Gmel. Sib. tab. 45. fig. 1, 2. "Calyxes recurved-flaethy, pubescent; leaves lanceolate, quite entire, febrown." Root perennial. Stem febrown. Nearly allied to the next species, but larger. A native of Ruffia about the Volga. 78. *C. linifolia, Lam. Mant. 117. Mart. 19. Lam. 21. Wild. 24. (C. linifolia; Lam. 23. Jacea hispanica pura, leuca folio; Tourn. 445. Bar. ic. 162.) "Calyces recurved-flaethy, smooth, leaves linear; quite entire, hairy." Root perennial. Stems several, from six to eight inches high, more or less upright, much branched, panicled, hairy. *Leaves* acute, small, numerous, febrown, whitish, rough to the touch. *Flowers* purple, terminal, febrown, feitious, solitary. A native of Spain and Italy. The linifolia and linifolia of La Mare appear to be the same plant. He described the former from the living, but the latter from a dried specimen, and was doubtful to which the synonym from Tournabout should be referred. 79. *C. levypofolia, Wild. 23. Vahl. Symb. 1. p. 75. (Stebe, Barr. ic. 366.) "Calyces recurved-flaethy, pubescent; flowers without a neutral ray; leaves linear, quite entire; stem somewhat hairy." Root perennial. Stem about half a tooth high, cylindrical, somewhat febrown, branched from the bottom. *Leaves* febrown, crowded, half an inch long, flilf, pale green, spreading at the tip, ending in a white point. *Flower* purple, egg-shaped, nearly febrown, terminal. A native of Spain. 80. *C. coronafolia, Lam. 25. Wild. 26. (Jacea orientalis anara coronopus. floo flore luto; Tourn. Cor. 32.) "Calyces erect-flaethy; flowers without a neutral ray; lower leaves pinnatifid; upper ones linear; all quite entire; stem panicled." Root annual. Stem about a foot high, upright, slender, nearly smooth. *Leaves* clothed on both sides with short hairs. *Flowers* yellow, terminal, solitary; calyx-scales lanceolate, bristly-ciliated, ending in a long, flilf, expanding awn. A native of Spain. 81. *C. nigra, Lam. Sp. Pl. 11. Mart.
Centaurea.

Mart. 12. Lam. 18. Willd. 27. Eng. bot. tab. 178. Mart. Flor. Ruft. tab. 130. Flor. dang. 906. (Cyanus niger, Gart. tab. 161. fig. 4. Jacae nigra laciniosa, Bauh. pin. 271. Tourn. 443. Lob. ic. 541.) Common knap-weed, knobby, horse-knops, or hard-heads. "Calyxes erect-feathered; leaves oblong; root ones sometimes pinnatifid, item ones entire or slightly toothed." Root biennial. Linn. Lam. Willd. But in England it is certainly perennial, woody, and somewhat creeping; whole plant rigid, hard, febracious. Stem branched, angular. Lower-leaves often lyrate-angular or toothed, upper ones egg-shaped. Stalk annual. Calyx-calyx, two, terminal, solitary, fiddle, calyx glabrous; scales black, egg-shaped, entire, bristle-shaped, brown; inner scales unequal, all florets most generally equal, regular, all fertile. Seeds hairy; down short, confiding of numerous scales. Dr. Smith. In the north of England it is almost always without a ray of barren florets; but in the western counties it is said by Ray and other botanists, to be frequently found with it. According to La Mark it has always, in France, an evident ray of barren flowers larger than the others. Are there not two distinct species, one biennial with a ray, the other perennial without one?

VI. Stokes. Calyx-scales with palmated spines at the tip.

(Serolia; Jufa.)

82. C. jaceafolia, Linn. 35. Mart 38. Lam. 49. Willd. 73. (Carduus maritimus, Tourn. 441. Jacae laciniosa folia, Bauh. pin. 272. Pluk. tab. 39, fig. 1. 1. Pluk. tab. 94. fig. 1.) "Calyxes palaese-pinnatis; spines reflexed; leaves oblong, smooth, embracing the stem, half-dentured, repaid-toothed; teeth prickly." Root perennial. Stem a foot high, simple or sometimes a little branched, green, slightly downy near the top. Lower-leaves petioled, undivided, lanceolate-egg-shaped; upper ones fiddle, toothed towards the base; uppermost somewhat dentured, lanceolate. Flower purple, large, terminal, solitary; calyx-scales green; spines yellowish. A native of the coast of the Mediterranean.

83. C. feridus, Linn. 36. Mart 39. Lam. 50. Willd. 74. (Carduus hispanicus, Tourn. 442. Jacae foenis feridis, Bauh. pin. 272. J. Linn., Pluk. tab. 38. fig. 1.) "Calyces palaese-pinnatis; spines reflexed; leaves oblong, hoary, embracing the stem, half dentured, toothed, cut at the base; teeth rather prickly." Root perennial. Stem about a foot high, inclining a little branched. Leaves thick, fleshy; lower ones near a foot long, finnated like those of dandelion. Flowers very large, with a purple ray and whitish disk; calyx-scales nine or more, yellowish. A native of Spain. 84. C. farina, Linn. 37. Mart. 40. Willd. 75. (Jacea, Zan. hist. tab. 42. Cyanaus, Barr. rar. tab. 52.) "Calyxes palaese-pinnatis; leaves dentured, not prickly; root ones pinnatifid, terminal lobe very large." Linn. "Calyces palaese-pinnatis; spines reflexed; leaves lanceolate, fiddle, dentured, hairy, fuscous, not prickly, finely toothed; root-leaves lyrate." Root annual. Linn. biennial, Miller; perennial, Willd. Stems three feet high. Flowers large, red; calyx strongly armed with spines. Mill. A native of the Campania of Rome. Cultivated by Miller in 1768. 85. C. napuldana, Linn 40. Mart. 43. Lam. 51. Willd. 86. (Cyanus napuldana, Gart. Jacae, Herr. par. tab. 189. Pluk. tab. 94. fig. 2. Moril. hist. tab. 26. fig. 20.) "Calyces palaese-pinnatis; leaves dentured, finnated, somewhat prickly; root-leaves lyrate." Linn. "Calyces palaese-pinnatis; Rem-leaves lanceolate, toothed, dentured; root-leaves lyrate, obtuse." Willd. Root annual. Stems three feet high, branched. Lower-leaves not much unlike those of a turnip, rounded at the end, cut at the base into many segments, diminishing gradually to the top of the stem and winged. Miller. Stems a foot and half high, weak, much branched. Root-leaves lyrate; terminal lobe very large, roundish-oval, finely toothed; item-leaves small, oblong, narrow. Flowers purple, terminal, barbare flowers hole, large; calyx-scales small, very weak, always reflexed. Lam. from a living plant. A native of Candia. Cultivated by Miller in 1759. La Mark is of opinion that this and the preceding are the same species, and that one is not even a variety of the other. But as both are said to have been cultivated by Miller; and as Wilkenow appears to have formed his specific characters of both from living plants, we apprehend that this eminent French botanist must have fallen into an error, from having seen only one of them.

86. C. ferox, Willd. 76. Desfont. Atl. 2. tab. 242. "Calyces palaese-pinnatis; spines reflexed, larger than the calyx; leaves hoary, oblong, fiddle, dentured, pinnatifid; teeth not prickly." Root perennial. Stem procumbent. A native of the coast of Barbary. 87. C. foillisatia, Linn. 46. Mart. 55. Lam. 59. Willd. 77. Eng. bot. tab. 243. (Carduus illatius, Bauh. Pin. 387. n. 4. Tourn. 440. n. 7. Rai Sm. 166. n. 16. Jacca, Moril. tab. 34. fig. 20. Caletrapa, Hill. Helv. n. 153.) St. Barnaby's thistle. "Calyces palaese-pinnatis, terminal, solitary; spines straight; leaves lanceolate, dentured, not prickly; root ones lyrate." Root annual. Stems near two feet high, alternately branched, winged by the decurrent leaves. Leaves slightly cottony, whitish; item ones small, narrow, a little finnated or toothed; root-ones four or five inches long, deeply finnated or pinnatifid; with a large, more or less triangular terminal lobe. Flowers bright yellow, terminal, scarcely ruffled, calyx, like the rest of the plant, clothed with a cotton-like web; spines yellowish; the middle one considerably longer and stronger than the others. A native of the north of Europe, very rare in England. 88. C. vernum, Linn. 52. Mart. 56. Lam. 60. Willd. 111. Gouan Illust. 73. Jac. Ec. Rar. 1. tab. 178. "Calyces palaese-pinnatis; middle spine very long; lateral ones short; root-leaves finnated-pinnatifid; item ones lanceolate, quite entire, decurrent." Root annual. Stem from one to three feet high, upright, winged, with a few simple branches near the top. Lower-leaves lyrate. Flowers yellow, large, terminal, solitary, fiddle, fuscous, pubescent; spines yellowish. La Mark is inclined to consider it as only a variety of the preceding, although placed by Linnaeus and most other authors in a different division. 89. C. melitensis, Linn. 47. Mart. 51. Lam. 62. Willd. 78. (Cyanus melitensis, Gart. Carduus melitensis capitulis congestobatis, Tourn. 442. Jacae, Bosc. Sic. tab. 35. Moril. Hist. iii. p. 145.) "Calyces palaese-pinnatis; terminal ones cuttered, selliell; spines straight; leaves lanceolate, fuscous, decurrent, not prickly; lower item ones a little toothed; root ones finnated." Root annual. Stem from five to ten inches high, a little woolly, simple, or with only a few short branches. Leaves oblong, finnated, their terminal lobe obtuse, not angular, as in C. foillisatia; lower item-leaves not decurrent. Flowers yellow; axillary ones single; terminal ones cuttered, two or three together, nearly fuscous; calyx-scales brownish; the middle one not above one-third the length of that in foillisatia. A native of Malta and the south of France. This species was cultivated in the English gardens under the name of foillisatia, till Dr. Smith pointed out the mistake in the Linnean Transactons, vol. ii. p. 256. 90. C. Adami, Willd. 79. "Calyces palaese-pinnatis, solitary; spines straight; inner scales scarios at the tip; leaves downy, lanceolate, decurrent; lower ones finely toothed, pinnatifid at the base." Root annual. Stem a foot high, branched, near the top, hoary. Leaves hoary on both sides. Flowers yellow, terminal; calyx-scales egg-shaped, green;
middle spine longer than the others; florets of the ray shorter than those of the disc. A native of Iberia. 91. C. _falcis_, Lam. 43. Mart. 52. Lam. 65. Willd. 80. (Cardus melitenus cruce folio, Tourn. 44.) Jacea cichorii folio, Doc. Sie. 15. Morif. Hill. tab. 28. fig. 26.) "Ca-lyx palmate-flominous; spines spreading; leaves few- or _fem-leaves lanceolate_, a little embracing the stem, finely toothed; root _eves lyrate." _Root perennial. Stem a foot and a half high, angular, branched, slightly villous. _Flowers_ yellow, terminal; middle spine of the calyx longer than the others, brown. A native of Sicily. 92. _C. phae-rocephalus_, Lam. 38. Mart. 41. Lam. 5. Willd. 81. (Jacea, Morif. Hill. tab. 27; fig. 9.) "Ca-lyx palmate-flominous; leaves ovate-lanceolate, petioled, toothed._Linn. _Root annual. Stem_ from one to two feet high, feebly, dividing at the top into a few branches. _Leaves_ woolly; root ones petioled, a little flattened or laciniated, _fem_ ones sessile, oblong, simply toothed. _Flowers_ purple, terminal, solitary, often with one or two branches. A native of the coast of Barbary and Spain. 93. _C. caesifrons_, Lam. 75. Cyril Rar. Notp. tab. 8. Vahl Sym. ii. 93. "Ca-lyx palmate-flominous; leaves lanceolate, lower ones petioled, upper ones half embracing the stem." _Root perennial, woody, dry, perpendicular, black on the outside. Stem from one to two feet high, thickish, round, pubescent, frayed; dividing from the bottom into numerous procumbent branches. _Leaves_ slightly pubescent, teeth mucronate, but not prickly. _Flowers_ purple, terminal, solitary, of a strong disagreeable smell; surrounded at the base of the calyx with an involucre of four to six concea inflexed leaves, irregularly toothed, lanceolate-egg-shaped at the tip. A native of Italy, on the coast near Naples, forming thick tufts in the sand. Willdenow supposes this and the preceding to be one and the same species. 94. _C. hiardi_, Lam. 39. Mart. 42. Lam. 52. Willd. 82. (Caletraposoides, Bocc. Paris. 1719. tab. 9.) "Ca-lyx palmate-flominous, solitary, sessile; leaves lanceolate, a little embracing the stem, pinnaatifid-toothed. _Root perennial. Stem_ ascending, about a foot long, commonly square, hairy, furrowed, branched. _Lower leaves_ four or five inches long, scabrous, especially at the edges; lobes rather prickly; upper ones smaller, often entire, or a little toothed. _Flowers_ purple, terminal; calyx egg-shaped, smooth. A native of the island of Jersey, and other parts of the south of Europe. 95. _C. fricator_, Willd. 84. (C. proflora, Vahl. Hort. Cell. tab. 74. C. glomerata, Vahl Sym. ii. 93. C. acutifolia, Vahl. Descr. 153.) "Ca-lyx palmate-flominous, terminal, sessile, glabrous, leaves _fem_ petioled, pinnatifid, cut-toothed." _Root annual. Stemlefs in its natural wild state; but when cultivated it has a short stem. 96. _C. polyacantha_, Willd. 83. Ca-lyx palmate-flominous; leaves embracing the stem, runcinate, pinnaatifid, prickly toothed; root _eves lyrate." _Root annual. Stem fix or seven inches high, erct, slightly villous. _Root-leaves_ hispid-febraceous, lyrate; segments oblong, toothed; terminal one large, roundish. _Flowers_ purple; ray twice the length of the disc. Native country unknown. 97. _C. heterophyla_, Willd. 87. "Ca-lyx palmate-flominous; spines three; _fem-leaves linear-filiform, quite cutine; root ones lanceolate, toothed towards the base." _Root probably annual, simple, perpendicular. Stem fix or seven inches high, _erct_, scabrous, pubescent; branches simple. _Leaves_ hispid-febraceous; root ones rather acute, eltening into a pe-ctile; _fem_ ones alternate, rather crowded, revolute at the edges. _Flowers_ purple, rayed, terminal, solitary; calyx- _scales egg-shaped, close; spines yellow, awl-shaped, spreading, equal. A native of Spain. 98. _C. aspera_, Lam. 41. Mart. 44. Lam. 48. Willd. 88. (Stebe iquamis asperis, Baut. Pin. 27.) _Jacea, Bace. Muf. ii. tab. 26.) "Ca-lyx palmate-flominous; spines three or five; leaves lanceo- late, felate, toothed. _Root perennial. Stem_ from one to two feet long, procumbent when young, reddish, frayed, rough to the touch, branched, diffuse. _Root-leaves_ oblong, flattened; _fem_ ones small, narrow, rough. _Flowers_ bright purple, small; calyx-spines very small, yellowish, or reddish. A native of the south of France, Italy, Spain, and Por-ugal.

VII. Calitrapa. Calyx-flominous compound or branched. (Caletrapa, Jaff.) 99. _C. benedicta_, Lam. 43. Mart. 45. Lam. 54. Willd. 89. Woody Muf. Bot. tab. 42. (Canceus benedictus, Gartner. tab. 102. fig. 5. Cinclus veficifrons hurutous; five cardus benedictus, Bahl. pin. 378. Tourn. 490.) Bocc. tape. "Ca-lyx doubly flominous, woolly, involucrated; leaves half-decurrent, toothed-flominous." _Root annual, cylindric, white-fil. _Stems_ several, a foot and a half high, reddish, woolly, branched. _Leaves_ oblanceolate, toothed, villous, bright green, with a white rivever; lower ones flattened; almost runcinated. _Flowers_ yellow, terminal; involucre of ten leaves; five outer ones larger; calyx-spines pinнатed; yellowish; florets of the ray small, trid. A native of the south of France, Spain, and the Levant, flowering from June to September. This plant obtained the name of beneficent, or blessed, from its supposed extraordinary medicinal virtues. It has an intensely bitter taste, and disagreeable smell; and exclusive of the qualities attributed to other bitters, was thought, when taken inter- nally, to be peculiarly efficacious in malignant fevers, and applied externally to heal cancers and chronic bones. It has now lost much of its reputation, and does not seem to be es- sentially different from other simple bitters. An infusion of it was formerly employed to afflict the operation of emetics, but the flowers of chamomile are now substitituted for it with equal advantage. In lots of appetite, where the stomach has been injured by irregularities, its good effects have been fre- quently experienced. Cold water poured on the dry leaves extracts in an hour or two a light grateful bitterness; by standing long upon the plant the liquor becomes disagree- able. Rectified spirit in a short time extracts the lighter bitter, but does not take up the nauseous to cafficly as water. See Woodville’s Medical Botany. 100. _C. eupha_, Lam. 61. Willd. 92. Desf. Anat. 2, 360. (Carduus illinatus luteus, capitulo minus pinoo. Tourn. 441.) "Ca-lyx doubly flominous, globular, small; spines very short; root leaves lyrate, obtuse; _fem_ winged." _Linn. Root annual. Whole plant pubescent. _Stem_ about a foot high, branched. _Root-leaves_ lyrate-pinnatifid; terminal lobe oval-obtuse; _fem-leaves_ de- current, oblanceolate, rather narrow, entire or toothed. _Flowers_ yellow, terminal; calyx-spines three; middle one longer, branched. A native of Italy and the coast of Barbary. 101. _C. eriophora_, Lam. 43. Mart. 46. Lam. 55. Willd. 91. (Carduus illinaciex canecaneus, Tour. 441. Calitrapa, Vaas. Akt. 1718. p. 212. Cyannus eriophora, Gart. 2, 345. tab. 161. fig. 4.) "Ca-lyx doubly flominous, woolly; leaves half-decurrent, entire and flattened; _fem_ proflerosus." _Linn. Root annual. Stem eight or nine inches high, with several branches on its upper part, which often rife higher than it- self. _Leaves_ light green, obtuse, with a spicle-like point. _Flowers_ yellow, terminal, somewhat globular; barren florets four-clft, shorter than the others; inner scales of the calyx- simply acuminate; outer ones ending in a yellow, spreading spine, half an inch long, armed with prickles on each side. A native of Portugal 102. _C. aegyptia_, Lam. Mutl. 116. Mart. 47. Lam. 56. Willd. 92. "Ca-lyx doubly flominous, somewhat woolly; leaves felate, lanceolate, entire and toothed; _fem_ proflerosus." _Root annual. Stem a foot high, di diá.
diffuse, profusely branched, spreading; branches alternate, from the axis of the upper leaves. Leaves alternate, sessile, or enclosing the stem, somewhat pubescent, lowly pinnatifid; middle ones lyrated, blunted lanceolate. Flowers white, of the ray four to six, smaller than the others; calyx-pinnate; filaments white, with a terminal, little-shaped small filament on each side. A native of Asia. 102. C. sheffeldica, Linn. 41. Mart. 48. Lam. 57. Willd. 67. Eng. Bot. 1. 179. (Carduus Jellettus, f. his papaveris cerasiti, Buckl. p. 587. Tourn. 440. Calctrepa, Hall. beyl. n. 191. Hippophagum, Col. phy. tab. 24. Calactrepa hippophagnum. Gart. tab. 165. fig. 2. ) Common thistle. "Calyxes doubly pinnatis, sessile; leaves pinnatifid, toothed; stem divaricated, spreading, hairy." Smith. Root annual. Stem low, much branched, furrowed. Leaves pale green, sometimes alternate, sometimes from luxuriance clustered under the branches; teeth somewhat prickly. Flowers purple or white, lateral; sessile; flowers of the ray scarcely longer than those of the disc, nearly regular; calyx-pinnate yellowish, divaricating, pinnate, three times the length of the scale, pinnate at their base with smaller pinnate. Seeds with shaggy any down. A native of England and other temperate parts of Europe. The plant and root are both bitter, and are said to be sometimes used by brewers instead of hops. The leaves are eaten by the Jews with their parsnip lath. They are given by the French physicians in the way of extract, decoction, or powder in agues and fevers. A decoction of the root in the proportion of half an ounce to an ounce in six ounces of water, is said to be useful in disorders of the bladder and kidneys. 104. C. calcitrapoides, Linn. 45. Mant. Flora Brit. 1. 188. Lam. 94. (Carduus Jellettus, folios integris, ferratis, Monp. 252. Tourn. 447. ) "Calyxes of what doubly pinnatis; leaves embracing the stem, lanceolate, undivided, serrated." Nearly allied to the preceding, if not merely a variety. A native of the south of France, and of Syria.

VIII. Calctrepa. Calyx-pinnate, terminated by a simple spine. (Calctrepa; June.)

105. C. diastata. Mart. 71. Hort. Kew. 3. 261. "Calyxes clavate; scales acuminate, somewhat thorny; leaves oblong, pinnatifid; flowers of the ray longer than those of the disc. A native of the south of Europe. 106. C. nivinjiri, Mart. 74. Willd. 69. Allon. ped. tab. 74. "Calyces clavata-pinnatis in the tip; leaves oblong, embracing the stem, feathery, undivided, quite entire; root leaves egg-shaped, toothed. "Root biennial. Stems a foot and a half high, globose, angular, alternate branched. Flowers yellow; calyx-pinnate at the tip; spine short, stiff. A native of the neighbourhood of Nice. 1-7. C. Jucunda, Willd. 56. Ded. Bon. Atl. 2. tab. 244. "Calyxes clavata-pinnatis at the tip; leaves of the stem hydrate-pinnatifid; of the branches pubescent, lanceolate, somewhat toothed." A native of the coast of Barbary. 120. C. hybrida, Mart. 73. Willd. 97. Allon. ped. m. 54. "Calyces clavata-pinnatis in the tip; leaves horse, pubescent, quite entire; upper ones lanceolate. "Root biennial. Whole plant horse-pubescent. Root leaves pinnatifid, somewhat toothed. Flowers of the disc yellow; of the ray violet; calyx-pinnate lobed, yellow. A native of hills about Tunis. 2. "Tunis have been supposed to be a mule between C. foliisilius and C. paniculatus. 119. C. figurata, Willd. 95. "Calyces clavata-pinnatis, cylindrical; scales reflexed at the tip; leaves of the stem pinnatifid; of the branches lanceolate. "Stems a foot high or more, erect, branched, panicked; branches spreading. Flowers violet, solitary, or two together at the top of the branches. A native of the Levant. 110. C. parvijphyllum, Willd. 93. Desf. Atl. 2. 181. (C. diffusa, Lam. 70. Carduus orientalis calcitrape folio, flore minimo, Tourn. 51. ) "Calyces clavata-pinnatis, egg-shaped; scales reflexed at the tip; leaves horse; root leaves lanceolate; leaves one leaf. "Nearly allied to the preceding. A native of the Levant and of the coast of Barbary. 111. C. carvulifoto, Willd. 120. (G. cardui, Can. tab. 352. Calactrepa clavata-pinnatis, leaves of the stem pinnatifid, heart of the branches lanceolate. Stem a foot high, erect, smooth, pubescent near the top, furrowed, branched; branches few, erect. Leaves smooth. Flowers violet; calyx-pinnate; scales egg-shaped, obtuse, with a long spine; inner ones scarious at the tip. A native of Spain. 112. C. Jacobebus, Lam. 68. Willd. 101. "Calyces clavata-pinnatis; inner leaves scarious; root leaves deeply pinnatifid, laciniated, tormentous; stem nearly naked, one-flowered. "Stem fixed or seven inches long, simplex, angular, cottony. Leaves from the root, or the lower part of the stem, pedicled, short, whitish. Flower yellow. Described by L. March from a specimen in the herbarium of Justull. 113. C. refia, Lam. 67. Willd. 101. (Carduus orientalis, calcitrape folio, flore flavescence odoratifolino ) "Calyces clavata-pinnatis at the tip; spines of the lower scales reflexed; leaves pinnatis; spine linear; obtuse; root leaves bimarginated. "Stem about three feet high, erect, angular, deeply furrowed, branched. Leaves large. Flowers yellow, large; calyx-pinnate, ending in a long, ruff, straight spine; spines of the lower ones shorter, weaker, reflexed. A native of Armenia. 114. C. ornata, Willd. 1-7. "Calyces clavata-pinnatis; spines of the lower scales reflexed; leaves very feathery, pinnatifid, linear; spine linear, mucronate; root leaves bimarginated. Nearly allied to the preceding. Leaves smaller, hoary; calyx-pinnate, ciliated; inner ones with a feathery ciliate little scale at the tip. A native of Spain. 115. C. eyrudioides, Lam. 69. Willd. 124. (Carduus eyrudioides, caprino spinulosa, Alp. Exot. 1-78. ) "Calyces clavata-pinnatis; leaves pinnatis; spine oblong, lanceolate, toothed, or entire, mucronate at the tip. "Root perennal. Stem a foot and a half high, upright, simple, furrowed. Flowers purple, large, terminal; calyx-pinnate egg-shaped, with a strong spine half an inch long; inner ones with a small ciliate appendage at the tip. A native of the Levant. 116. C. centauroides, Linn. 49. Mart. 53. Lam. 64. Willd. 105. (Jacea lutea spinosa centauroides, Oudin. Pm. 27. Carduus centauri majoris, fasicule, capitulon longis & brevis aculis unnoto, Tourn. Cor. 51. ) "Calyces clavata-pinnatis; leaves lanceolate, pubescent, generally entire; terminal lobe large, toothed. "Stems two or three feet high, angular, branched, clothed with short hairs. Leaves large, rough, deeply pubescent. Flowers yellow, large, terminal; outer calyx-pinnate, toothed; inner ones oblong, scarious, without a spine. A native of Spain, Italy, and the coast of France. 117. C. carvulifera, Linn. 57. Mart. 54. Lam. 65. Willd. 1-70. (Jacea lutea, capitata spinulosa, Oudin. Pm. 272. Carduus luteus centauroides f. spinulosa, Tourn. 447. ) "Calyces clavata-pinnatis; stem-leaves pinnatifid; root ones bimarginated; segments lanceolate. "Root perennal. Stem two or three feet high, angular, nearly smooth, branched. Leaves large, greenish. Flowers yellow, rather large, terminal, solitary. La March thinks it scarcely more than a variety of the preceding, but its leaves are more deeply cut, and their terminal lobe is smaller. A native of Italy, Spain, and the coast of France. 118. C. cyp俵licus, Linn. 70. Mart. 55. Lam. 69. Willd. 1-7. (Jacea lacinata folia, Oudin. Pm. 272. Col. Exphr. 1. tab. 35. fig. 62. Mor. tab. 8. fig. 25. ) "Calyces clavata-pinnatis; stem leaves pinnatis; rachis-leaves bimarginated; spine linear-silhoulet. "Root perennal. Stem scarcely angular, but little branched. Calyx-pinnate weaker, shorter than the scale; inner leaves scarious. Nearly allied to the preceding. 119. C. pubescent, Willd. 1-70. (C. incana,
The natural history of the plant is described, including its leaf shapes, flower structures, and growth habits. The text also mentions a variety of related species, some of which are cultivated for their decorative or medicinal properties. The plant's distribution is noted, and its habitat preferences are discussed. The text concludes with a summary of the plant's characteristics and its significance in the natural world.
The first root has a strong perennial root, and a great number of long pinnate leaves, of a lucid green colour. spreading wide on every side proceeding from it; the peduncles are fl-anid, but very stiff, and divide at top into many smaller peduncles. These together with the flanks, rife five or six feet high, having at each joint one small pinnate leaf of the same form with the others: each of the peduncles is terminated by a single head of purple flowers, considerabiy longer than the calyx, whioe come out in July, and in warm situations, produce ripe seeds in this climate.

The second root has a perennial root, running deep into the ground; the stem is commonly single, upright, one-flowered: sometimes, especially in a cultivated state, it puts forth a branch or two; the leaves are quite entire, tenuiform; and the flower large and spacious. And these are varieties, with broad leaves, with narrow leaves, and the dwarf perennial blue-bottle.

In the third the stem is from one to two feet high, angular, slightly tenuiform, branched at top; the leaves are numerous, white underneath, with three parallel ribs; the branches are one-flowered, flowering from June to August. It varies with blue flowers, with blue and white flowers, with purple flowers, with purple and white flowers, with flesh-coloured flowers, with flesh-coloured and white flowers; with violet-coloured flowers, with violet and white flowers, with red flowers, with double blue flowers, with double purple flowers, and with double purple and white flowers.

The last root is annual, and sends up a round channelled stalk near three feet high, which divides into many branches with jagged leaves, of a pale green colour, smooth, and close to the branches; from the side of the branches comes out long naked peduncles, each terminating a single head of flowers, which have a very strong colour, so as to be offensive to many people, but to others very grateful; they are purple, white, or flesh-coloured. It varies with purple flowers, with white flowers, with flesh-coloured flowers, with purple fleshy flowers, with white fleshy flowers, with fringed flowers and fawed leaves, and with bright yellow fleshy flowers.

**Method of Culture.**—These are plants which are raised with little trouble or difficulty. The first root is capable of being increased by parting the roots, and planting them out in the early spring months or in the autumn, in beds or borders where they are to remain. And it, as well as the annual roots, may likewise be raised from seed, which in it and the second kind should be sown in the borders or chumps in March or the following month. The young plants being kept clean from weeds, and removed into other situations, when necessary, in the following autumn.

The two last roots and varieties are also propagated by sowing the seeds in the open ground, where the plants are to flower, in the above leafoil. They should be put in patches of six or seven seeds in a place, covering them lightly in to the depth of half an inch. The latter of which may also be sown in the autumn as soon as the seeds are fully ripened, by which means they will flower at a much more early period in the following year. And the last or sweet sultan kind, especially the yellow, which is rather tender, may also be rendered more forward by sowing the seeds under frames or glasses on gentle hot-beds in the early spring, removing the plants to the open ground when of sufficient growth, with hills of earth about their roots or in pots. They are all proper for ornamenting the chimps and borders of pleasure-grounds; the two first being placed more backward in them, as growing to the largest size.

**CENTAURIUM minores**, among Chelmis, a name given by some to the Panacea of antiquity, called also by Giau-

bar, purgas: universole; the preparation of which is given by Juncker.

**CENTAURIDES, in Medicine and Pharmacy,** the fame with Giauitha. Others give the denomination to the greater century.

**CENTAURPOLIS, in Ancient Geography,** a fortress of Greece in Thessaly; situated on Mount Ossa, near Tempe. The emperor Julian is said to have repaired its ruined walls.

**CENTAURS, in Mythology,** a kind of fabulous monsters, half men, half horses. The poets feign that the centaurs were the fonts of lyric and a cloud. The reason of which fancy was, that the cattle to which they retired was called N. 129, which signifies cloud. Pind. Pyth. Od. 2. This fable is differently interpreted.

The centaurs, in reality, were a tribe of Lapithes, who inhabited the city Peletrum, adjoining to Mount Pelion, and first invented the art of breaking horses; as is intimated by Virgil, Georg. lib. iv. ver. 115. Homer and Hesiod speak of centaurs. The fable of these poets in his liad (L. i. v. 367, and 1. ii. v. 420) and in his Odyssey (L. xx. v. 267) calls them savage, or monsters covered with hair. Hesiod describes the combat of the centaurs and Lapithes, and the latter of whom had helmets and cuirasses, whereas the former fought without any defensive armour. Pindar seems to have been the first of the poets who represented the centaurs as half men and half horses. These monsters (fayt. bi) were the ftrict of the amours of Centaurus, the son of Ion, with the marces of Thessaly; they resembled their father in the upper part of their body, and their mother in the lower. But upon the death of Cypresses, mentioned by Phaonius, and upon which characters were written in the year 578 B.C. in the bull-roden form, the centaur Chiron appears half man and half horse, but represented as a man indulging upon two human legs, and, with the group-flanks and two hinder legs of a horse attached to his loins; so that two feet of this centaur were those of a horse; so that it resembled a man leading a horse by the bridle rather than a cavalry mounted on horseback. M. Tieret (Mem. Litt. t. 23) suggests, that the centaurs were herdsmen, who for a long time occupied with their herds the valleys of Thessaly. Their name seems evidently to be derived from κτεινος, filinulo, with, or a. bull-frikeris, or ctenars. It is of this kind of persons that Homer speaks (v. 250) as inhabiting at first the environs of mount Pelion, and who, having been driven away by Perithous, fought a retreat in the country of the Cethici. Didymus, upon this and the following verses, observes, that, according to all the ancients, the centaurs of mount Pelion were of the same nation with the Perithous. Accordingly, the centaurs were the herdsmen of Thessaly. The more ancient sculptures represent them as persons who flood near horses to hold them; and in process of time, and by means of a poetic or picturesque licence, they came to be represented as half men and half horset.

**CENTAURUS, CENTAUR, from κτεινος, formed of κτος, partes, and κταινος, bull: q. d. bull-frikeris, in Achorus, a part or moiety of a southern constellation, being one of the 48 old constellations, in form, half man, half horse; usually joined with the Wolf, See Lycoris. According to the tale of the Greeks, this was Chiron the centaur, who was the tutor of Achilles and Asculapius, represented as half man and half horse, because he had applied the art of medicine to the benefit both of men and of horses. Others pretend that it is the symbol of pleasure, which reduces men to the similitude of beasts; but the origin of the allegory, which has placed
placed Centaurus among the constellations is unknown. His hands hold a bottle full of wine, as a symbol of the vintage, which occurs when the sun is near this constellation; and tending towards Hercules is represented by his triumph on a famous animal, because the sun in the sign of Aquarius causes the minotaur or monster of this constellation to disappear.

The stars of this constellation, in Ptolemy's Catalogue are 37; in Tycho's 3; and in the Britannic Catalogue, with Sharp's Appendix, 35. Among a great number of stars in the catalogue of La Caille, there is one, besides others of the first magnitude, which in 1750 had 21° 43' 26" of right ascension, and 59° 47' 8" of south declination. For an account of the comparative altitudes of some of the stars in this constellation by Dr. Herchel, see the Phil. Trans. for 1797, p. 314.

Centaur. See Chlora, Gentiana, and Centauraea.

Centaur, in Agriculture, is the name of a weed or plant, abundant in arable or other lands, and generally called blue-bottle. It is often very troublesome to extirpate from the lands on which it has established itself.

CENTELLA, in Botany, Linn. See Hydrocotyle glabrata, and vilifia.

CENTENARIENSIS, in Ancient Geography, an episcopal see of Acre in Numidia.

CENTENARIUS, or Centenier, in the Middle Ages, was an officer who had the government or command, with the administration of justice, in a village, or division, containing an hundred freemen. The centenari were under the jurisdiction and command of a superior officer, called the count or comte. We find them among the Franks, Germans, Goths, Lombards, &c. On account of the disorders that prevailed in the ninth century, and the acts of violence that were so commonly committed, as to be hardly confedered as criminal, the centenari were required to take an oath, that they would neither commit any robbery themselves, nor protect such as were guilty of that crime. Before the time of Charles the Bald, the titles of count, duke, vicar, centenier, or thungin, were not hereditary in families. They had the management of the revenue and administered justice in the provinces. They were at the same time magistrates and military men. They convoked the ban and arrière-ban, assembered and conducted the troops to the places of general rendezvous.

Centenarius is also used for an officer who had the command of a hundred men, more frequently called centurion.

Centenarius, in Monasteries, was an officer who had the superintendence of a hundred monks.

Centenarius was also used for a person worth a hundred thousand furtures; otherwise called census.

CENTENIER. See Centenarius.

CENTENINUM. See Egg.

CENTER, or Centre, in a general sense, denotes a point equally remote from the extremities of a line, figure, or body; or the middle of a line, or plane, by which a figure or body is divided into two equal parts; or the middle point so dividing a line, plane, or solid, that some certain effects are equal on all sides of it. The word is κέντρον, which primarily signifies a point; being formed from the verb κεντρίζω, pungeres, to prick.

Center, in Architecture. This term is used to denote a frame of timber constructed for the purpose of supporting the flumes or bricks forming an arch or vault during the erection. Thus the center serves as a foundation for the arch to be built upon, which, at the completion of the work, is struck or taken down, and then the arch will stand of itself from its curved figure.

The center of a large vault, such as that of a bridge, consists of turned ribs, formed like those of a roof, let in parallel vertical planes, at the distance of 5, 6, 7, or 8 feet, bridged over with horizontal parries. In great works, a bridging is laid for every course of arch flumes, with blockings between to keep them at proper distances. The flume-tones do not always immediately rest upon these blockings: planks are sometimes put between that they may afterwards be cut away, in order to separate the center from the vaults, which must now support itself by the reciprocal pressure of its parts.

If a center is truly constructed, every point of the vault to be built ought to be supported, without giving any transferable strain to the incumbent part of the center: but this is impracticable, for, as it would require such a multiplicity of joints, and, from the shrinking of the timber, it would be less sufficient than if composed of few pieces, supporting only a certain number of points disposed at judicious distances, leaving the intervals to be supported by timbers in which the superincumbent part of the arch will act transfervely, but will still present a sufficient resistance so as not to be materially bent or put out of form by the load of the arch above.

If the river over which a bridge is to be built is not navigable, the manner of constructing the center is so easy, that it would be unnecessary to give any examples here; but where the river is navigable, the center requires an opening in the middle for vessels to pass: this renders the construction more intricate by interrupting the horizontal tie, instead of which a number of tongs are therefore disposed around the polygon, forming the interior part of the center; but as in many practical cases the most judicious and well-fitted theorist might be deceived as to the equilibrium of the arch to be supported, or the points on which it has the most tendency to fall in, it would, therefore, be difficult to lay what are tics and what are fluttas; and even if the true pressure of the arch could be ascertained, the knowledge of this alone would not be sufficient; for the same parts of the vaults, in the process of execution, vary their pressure in every succeeding additional part, and what was a tie at one time, becomes sometimes a flutta, and a flutta, on the contrary, a tie at another, either in building, or at the completion of the vault. This ought to be well considered; and, where the pressure is doubtful, or any of the lengths of timber forming the center be ascertained to be in the two different flutes above mentioned, such timbers should be made to act in either cafe.

Though the timbers upon which the vault immediately rests cannot be supported transfervely throughout, the other pieces, which support the arch from the several pressing points, may all be made to act by a judicious arrangement, in a direction of their lengths. The abutting joints, which are prefixed, will be sufficiently refilled, when their shoulders are made perpendicular to the direction of their force, and with a very small tenant; but if the timbers are drawn in a direction of their length, the joints ought to be strapped.

The beauty of every truf is to have as few quadrilaterals as possible. All the openings should be triangles: the intersection of the timber should be as direct as possible. Oblique preffures exert prodigious strains, which require timbers of very large sections to withstand them, and which press upon the abutments so much as to make the whole trus fag by the compression of the intermediate joggles.

If proper attention be paid to these circumstances, and
the bearings of the timbers well ascertained, a center, con-
structed upon such principles, must answer its intended pur-
pose, provided that a proper climate be taken of the com-
municating forces during the execution of the vault, and
that the center be well secured at its abutment.
There are several principles of constructing the ribs of
centering; one of these may be that of a large truss, spanning
the whole opening, having its vertex supporting the summit
of the arch, and its rafters, or principal braces, supporting
other subordinate trusses which reful the profile of the arch
at other intermediate points.

Of this kind is that of the bridge of Orleans, by Mr.
Hupceau, one of the boldest centers ever executed in Eu-
rope. Another principle is that of two independent trusses,
one supporting the fids or haunches of the arch and the
other the crown. Of this construction was the centering
of the nave and transepts of St. Peter's church at Rome,
by Michael Angelo, and two centers by Pitot.
Another principle of centering is that of inscribed equilateral poly-
gons, that is, the exterior beams, supporting the curve, are
of equal lengths, and joined together in the form of a poly-
gon: another polygon is formed within this, having its ar-
gles in the middle of the fids of the former, and so on, al-
nernately until there are as many polygons inscribed as will
make the centering sufficiently strong or stiff: this mode of
centering may be of two kinds. One, when the angles are
fixed at their junction to the fids of the fall, with bolts:
double king-polls are put over the angles to prevent tran-
verse strain at that section of the beams where the two
pieces meet, and to support the curve above. The other
kind is, when the polygons act independently of each other:
these polygons are brought into action by king-
polls, which support the curve, and act upon the angular
points of each other's polygon. Of this kind were the cen-
tering of the bridges of Cravant, Nogent, Mayence, and
Neuilly, constructed by Perronet. Though these cen-
terings have been executed to very large spans, the fall
mentioned being 120 feet, their equilibrium is by no means
so secure as when the angles of the inner polygon are
fastened to that immediately preceding, as is evident from
the information given of the erection of these bridges by
the ingenious architect who has favoured the world with a
treatise on this subject.
Another principle of centering is that of Westminster and Blackfriars bridges, London.
The conflict of a series of trusses, each supporting a point in
the arch, the principal braces having their lower extre-
mities abutting below at each end of the centering, on the
fronking-plates, and at the upper end, upon apron pieces,
which are bolted to the curve that support bridgings for
binding the pieces which compose them together at their
junction. There is one disadvantage under which this
mode labours; that is the frequent interfeion of the prin-
cipal braces with one another: they must either be
halved, upon each other, otherwise they must be disconti-
ued, and made in various lengths. Both of these diminish
their lateral strength, and consequently make them much
more liable to buckle than when whole; but of the two
that of halving is to be preferred; as, by the braces being
in one length, there can be no faking occasioned by inter-
mediate joggles, and the braces may be rendered sufficiently
secure laterally, by running straps longitudinally across the
notched part on each fide, bolting these straps to the
braces.

Lately another mode of centering may be that of a num-
ber of quadrilateral frames abutting on each other, having
their joints radiating to a center, in the manner of the wedge-
frames of an arch in masonry. These frames should all be re-
folved into triangles by one or two diagonals, according to
the kind of frame, keeping in view that a piece, which is a tie
in one diagonal, is, in the other diagonal, of the same quad-
rilateral, a strut; but if the kind of frame on any frame is
not well ascertained, it would be better to place two diag-
ons halved upon each other. The frames are to be secured
to one another with keys or bolts; by this precaution each
frame will be rendered quite impmoveable.

Having now shown the principles upon which a good
center may be constructed, we shall proceed to give
some of the most approved examples.

Fig. 1. Plate LXVI of Architecture, is the manner of
forming the ribs for a center by two independent trusses;
in this form of centering there is no occasion for bridles, or
double king-polls, as in those of Pitot, of the same con-
struction.

Fig. 2. The manner of forming a center by two poly-
gons, of which the interior one is secured to the exterior:
in this there is no occasion for double king-polls, as the
parts of the inscribed polygon either act as struts, or ties to
that of the circumferencing one.

Fig. 3. is the manner of constructing a center with three
polygons, which are all secured to each other. In this,
king-polls become necessary, otherwise the angles of the
inner polygon would bend the fids of that part to it.

Fig. 1, Plate LXVII. is the manner of constructing a
center according to Perronet, with four polygons, indepen-
dent of each other, but with this improvement, that the
lower extremities of each ring of polygons are framed into
the two abutments; this gives a much firmer base than if
they were all to meet at the same place, and renders the
center much stronger, by making the angles more acute.
In this it becomes also necessary to have double king-polls,
otherwise the exterior polygon would only be effective.

Fig. 2, is the manner of forming a center, as used at
Westminster and Blackfriars bridges, by independent trusses,
confiding of two rafters. Whoever considers the principle
of this center, must evidently fee that there is no occasion
for the double king polls, as the pressure is directed to the
abutments, or to two opposite of the arch in the same
level. In this example, the interfeions are all suppoed
to be halved together, and firmly strapped across the notch-
ing-plates.

Fig. 3, is the manner of constructing a center with se-
parate frames, the fids of which radiate to a center, as has
already been intimated.

Fig. 1, Plate LXVIII. is the design of a center; its
principle is that of two roofs intersecting each other. In
this example, the forces which are communicated to the
various parts of the frame are refolved longitudinally, either
by compression or extension; and no force is exerted tran-
versely on any part, excepting the curved pieces in contact
with the boarding supporting the arch fones.

Fig. 2, is the design of a center: it is first framed in on
large trusses, like a common roof, with two principal rafters,
and a collar beam: each of the rafters becomes a tie for the
two small trusses above which are framed in the manner of
a roof with queen-polls and braces. The lower angles of
the principal rafters are braced from the lower queen polls
to the polls. This truss is free from transverse strains in all
its parts, except the curve, which supports the arch fones:
and, if well secured at the abutments, an arch of an immense
weight may be erected upon it.

Fig. 3, is the celebrated center used at Blackfriars bridge.
The names of the timbers are as follows:

A. Timbers which support the centering.
B, C, Upper and lower friking-plates caled with copper.
D, Wedge
D. Wedge between striking-plates for lowering the center.
E. Double king-polls to confine braces.
F. Apron pieces to strengthen rib of center.
G. Bridles laid on the back of the ribs.
H. Blocks between bridgings to keep them at equal distances.

I. Small braces to confine the ribs tight.

K. Iron straps bolted to king-polls and apron-pieces.

L. Ends of the beam at the feet of king-polls.

M. Principal braces.

In striking the center of a large arch, the belt method is to let it down a little all in one piece, by easing some of the wedges; it is there let to red for a few hours or days, to try if the arch makes any efforts to fall, or any joints open orrones crack, or crack, that the damage may be repaired before the center is entirely removed, which is not to be done till the arch ceases to make any visible efforts.

Center of Attack. In French centre d'attaque, or attaque du centre, in Military Language, is an attack on an extensive front, from the second parallel upon the works of a strong place that is besieged, according to the rules or principles of a regular attack.

Center of Attraction. See Center of Gravitation. Center of attraction. In Fortification, is the middle point of its gorge, or angular point of the interior polygon, or the point where the two adjacent curtains would meet when produced.

Center, or Center of a battalion on parade, in Military Language, is the middle of it, where an interval is left for the colours; and so on.

Center of cavity, in a ship, is the center of that part of the ship's body which is immersed in the water; and which is also the center of the vertical force exerted by the water to support the vessel. See Ballast.

Center of a circle is a point in the middle of a circle, or circular figure, from which all lines drawn to the circumference are equal.

Euclid demonstrates, that the angle at the center is double to that at the circumference; i.e., the angle made by two lines drawn from the extremes of an arch to the center, is double that made by two lines drawn from those extremes to a point in the circumference.

Center of a conic section is the middle point bisecting any diameter, or the point in which all the diameters intersect and bisect one another.

This point, in the ellipse, is within the figure; and, in the hyperbola, without, or between the conjugate hyperbolas; and in the parabola, it is at an infinite distance.

Center of conversion, in Mechanics, a term first used by M. Parent. Its signification is thus conceived: if a body be placed on flagrant water, and drawn by a thread fastened to it, so that the thread always makes the same angle with the body, the thread will be found to turn on one of its points which will be immovable; which point is termed the center of conversion. For the greater ease the thread may be conceived fastened to one end of the body.

This effect arises from the resistance of the fluid, and the manner wherein it divides: for, imagine the first moment of traction, it is certain, hence, the resistance of the parts of the fluid to be displaced tends to turn the thread around the point to which the thread is fastened, as on a center; so that in the present instance, the fluid would describe precisely the quadrant of a circle: after which the fluid would no longer bear the thread lengthwise; but in a particular motion, in such manner, that the free end of the fluid, and the parts nearest it, would describe larger arcs of circles than the rest, and have a greater velocity. The resistance, therefore, of the fluid, which tends to impress a circular motion on the body, around the point to which the thread is fastened, tends to impress a greater velocity on the parts next to the other extremity, or, which is the same thing, those parts acquire a greater velocity to surmount the resistance of the fluid, so that the fluid will not have that circular motion around the point to which the thread is fastened; or the resistance of the fluid is greater towards the free extreme of the fluid, and still lessens towards the other extreme.

Now all the columns, or threads of water, which resist the fluid, must be supposed of the same length or the same masts. One may therefore find on the fluid such a point, as that taking a great number of those threads on that side which resists the least, and a little number on that side where they resist the most, there will be an exact compensation, and the forces be equal on each side: this point is the center of conversion. And as the reasoning has place in all motions of traction made in the same manner, this center is always the same point. The grand question here arising is, to know precisely in what point the center of conversion is found: this M. Parent has determined by much laborious calculation. If the fluid drawn by one extremity be a straight line divided into twenty parts, reckoning from the thread, the center of conversion he finds will be nearly on the 13th. If it be not a line, but a surface or a field, there will be some change in the situation of the center of conversion, according to the force, or the field. See Mem. of the Acad. of Sciences, abridged, vol. 1. p. 131.

If in lieu of a body swimming in a fluid, we suppose it laid on a rough uneven plane: the resistance of this plane to the motion of the body will always be divided in the same manner, and determine the same center of conversion. This resistance is, precisely, what we call friction, so prejudicial to the effects of machines. See Center of rotation.

Center of a curve, of the higher kind, is the point where two diameters concur.

When all the diameters concur in the same point, Sir Isaac Newton calls it the general center. M. l'Abbe de Gua, in his "Ufges de l'Analyse de Descartes," has given a method for finding the general centers of curves, and suggested some important remarks on the definition of general centers given by Newton. The ingenious abbe calls the general center of a curve a point of his plane, such that all the right lines which pass through one side or other of this point equal portions terminated by the curve; and he observes: 1. That this definition corresponds with sufficient exactness to the ordinary acception of the word center: 2. That the definition of Newton is comprised in his own: and 3. That by adhering to his definition he has arrived at those conditions which Newton affirms to curves, which, according to him, have a general center; and hence it seems to follow that Newton had in view the definition of M. l'Abbe de Gua rather than his own, when he determined thee centers. M. Cramer, in his "Introduction a l'Analyse des Lignes courbes," gives a very exact method for determining their general centers.

Center of a dial, is that point where its gnomon or style, which is placed parallel to the axis of the earth, intersects the plane of the dial; and from thence, in those dials which have centers, all the hour lines are drawn. If the plane of the dial be parallel to the axis of the earth, it can have no center at all; but all the hour lines will be parallel to the style, and to one another; the center being, as it were, at an infinite distance.

Center of an ellipse, is that point where the two diameters, the transverse and the conjugate, and all other diameters, intersect each other.

Center of the equant, in the Old Astronomy, a point in the line of the apsides being as far distant from the center of
of the eccentric towards the aphelion, as the sun is from the center of the eccentric towards the perihelion.

Center of equilibrium, is the name with respect to body s suspended in a F. 1, as the center of gravity of two bodies in free space: or it is a certain point on which, if the body or bodies be suspended, they will rest in any position. More generally, in a system of bodies, it is the point about which they will be in equilibrium; or it is a point such that if the system of bodies be suspended or placed by, the instantaneous products of the weight of the body or bodies about that point, would remain in equilibrium. Thus, the barycentre is the centre of equilibrium. For a method of determining the center of equilibrium, see Emerson’s Mechanics, pp. 20, 121.

Center of friction is the point in the base of a body, on which it revolves into which, if the whole surface of the base and the mass of the body were collected, and made to revolve about the center of the given body, the angular velocity destroyed by its friction would be equal to the angular velocity destroyed in the given body by its friction in the same time.

To find the center of friction. Let FGH (Plate IV. Mechanics, fig. 21) be the base of a body revolving about its center C, and suppose about a, b, c, &c. to be indefinitely small parts of the base, and let A, B, C, &c. be the corresponding parts of the solid, or the prismatic parts, having a, b, c, &c. for their bases; and P the center of friction. It is manifest, that the decrement of the angular velocity must vary as the whole diminution of the momentum of rotation caused by the friction directly, and as the whole momentum of rotation or effect of the inertia of all the particles of the solid inversely; the former being employed in diminishing the angular velocity, and the latter in opposing that diminution by the endeavours of the particles to perpetuate in their motion. Hence, if the effect of the friction varies as the effect of the inertia, the decrements of the angular velocity in a given time will be equal. Now as the quantity of friction does not depend on the velocity, the effect of the friction of the elementary parts of the base a, b, c, &c. will be as a x aC, b x bC, c x cC, &c. and also the effect of the inertia of the corresponding parts of the body will be as A x aC, B x bC, C x cC, &c. Now when the whole surface of the base and mass of the body are concentrated in P, the effect of the friction will be as a + b + c + &c. x CP, and of the inertia as A + B + C + &c. x CP²; consequently a x aC + b x bC + c x cC + &c. = a + b + c + &c. x CP : A x aC + B x bC + C x cC + &c. = A + B + C + &c. x CP + and hence

\[ \frac{A + B + C + &c.}{A x aC + B x bC + C x cC + &c.} = \left( \frac{a + b + c + &c.}{a x aC + b x bC + c x cC + &c.} \right) \]

center of gravity. In Mechanics, is a point within a body, through which if a plane pass, the segments on each side will be equal in weight, i.e., neither of them can move the other. Hence, if the defcent of the center of gravity be prevented, or if the body be suspended by its center of gravity, it will continue at rest in equilibrium, in any position. The whole gravity, or whole matter, of a body may be conceived united in its center of gravity; and therefore, in demonstrations, it is usual for the body to figure out the center.

Through the center of gravity passes a right line, called the diameter of gravity: the intersection, therefore, of two such diameters determines the center. The plane wherein the center of gravity is placed is called the plane of gravity: so that the common intersection of two such planes determines the diameter of gravity.

In homopodal bodies, which may be divided lengthwise into similar and equal parts, the center of gravity is the same with the center of magnitude. If, therefore, a line be bisected, the point of bisection will be the center of gravity.

The center of gravity of a parallelogram, or cylinder, or any prism whatever, is in the middle point of the axis: and the center of gravity of a circle, or any regular figure, is the same as the center of magnitude. Also, if a line be so drawn as to divide a plane into equal and similar parts, that line will be a diameter of gravity, or will pass through the center of gravity; and it is the same as the axis of the plane. Thus, the line, drawn from the vertex perpendicular to the base of an isosceles triangle, is a diameter of gravity; and thus also the axis of an ellipse, or a parabola, &c., is a diameter of gravity. The centre of gravity of a segment or arc of a circle is in the radius or line perpendicular to bisecting its chord or base. Likewise, if a plane divide a solid in the same manner, making the parts on both sides of it perfectly equal, and in all respects similar, it will be a plane of gravity, or will pass through the center of gravity. Therefore, as the intersection of two such planes determines the diameter of gravity, the center of gravity of a right cone, or a spherical segment, or cone, &c. will be in the axis of the same. See the sequel of this article.

To find the center of gravity of a body. Let A, B, C, D, &c. (Plate IV. Mechanics, fig. 22) be particles of the body, and finding the centers of equilibrium, P, and G, of A and B, C and D respectively (see Balance and Levers); let A + B be placed in P, and C + D in G, and their center of equilibrium, G, will be the center of gravity of the particles A, B, C, D, &c. Because the force of gravity acts upon the particles in parallel directions, the efficacy of A to communicate motion to G is A x A G, and that of B is B x B G, or A x A P + B x B G, and B x B P + B G, which are equivalent to them, or A + B + P x G, since A x A P and B x B P are equal and opposite, and consequently destroy each other. The sum of the moments of C and D is found, by a similar process, to be the same as if they were placed in G: and consequently G, which is the center of gravity of A + B + C + D, placed in P and Q respectively, is the center of gravity of A, B, C, D, placed at the points A, B, C, D, &c. Hence it follows, that the particles of the body cannot be in equilibrium about any other point except G; for, if possible, let X be such a point, and it is plain that the efforts of A and B to move X = A + B x P X, and of C and D = C + D x G X; consequently the point X is kept in equilibrium by two forces, A + B x P X, and C + D x G X, not acting in opposite directions, which is impossible. Moreover, in every situation of the body composed of the particles A, B, C, D, &c. if the point G be supported, the body will be at rest; for the force of gravity acting always in parallel directions upon the particles, their momenta, or efforts to move G.
G, will always be as \( \Delta \times \Delta G \), \( B \times B C \), &c. which, by the forces used in this proposition, will always be reduced to two forces that are equal and opposite. Further, if \( A + B + C + D \), &c. be equal to \( Q \), and the pressure of each in parallel directions be equal to \( g \), a force, as \( Q \times g \), acting at the point \( G \) in a direction opposite to that in which the particles press, will remove their pressure. Or, if \( A, B, C \), &c. be definite of gravity, and only refill the action of a force by their inertia, a force at \( P \) acting at \( G \) will communicate equal velocities to every particle; because their refinaleness, being exerted in directions opposite to that of \( P \), and therefore parallel to each other, vary as their distance from \( G \), and consequently the sums of the refinaleness on each side of \( G \) are equal. And, vice versa, if \( Q \) be moving and without gravity, a force applied at \( G \) (the center of inertia) equal to the momentum of \( Q \), will destroy all motion.

The center of gravity of a ship is always before the point, which is the middle of her absolute length; for the fore part, having greater capacity than the after part, must of course have also greater weight: and, therefore, it is the center of gravity forward in proportion to its greater weight (which in large ships is from 30 to 50 tons), and also to the interval between every center of gravity of each particular part, both forward and aft. When a ship is at sea, and loaded, the center of gravity may well be supposed not to change, unless the cargo be moved. But experience shows, that the fore or after part of the bottom of a ship plagues and labours more and more, in proportion as the wind acts with more or less force on the sails: because ships are generally not milled according to the point velum; so that a ship which has the center of the effort of the sail ill placed, draws always more water forward or aft, when the impulsion of the wind upon her sails is very powerful, than when she is at ease under her burden. Obs. From the center of gravity of the floating line of a ship let a perpendicular be raised, and continued till it be intersected by the direction of the impulsion of the water on the bows, in failing directly before the wind; and, where these two lines cut each other, that point is the "point velum," and where the center of effort of all the forces shall be placed.

**Center, common, of gravity of two bodies, is a point so situated, in the right line joining the centers of the two bodies, as that, if the point be suspended, the two bodies will equiponderate, and rest in any situation. Thus, the point of suspension in a common balance, or in a Roman freely, where the two weights equiponderate, is the common center of gravity of the two weights.

When any number of bodies move in right lines with uniform motions, their common center of gravity moves likewise in a right line with an uniform motion; and the sum of their motions estimated in any given direction, is precisely the same as if all the bodies, in one mass, were carried on with the direction and motion of their common center of gravity. Nor is the center of gravity of any number of bodies affected by their collisions or actions on each other.

1. If one or more of the bodies, \( A, B, C, \) &c. (Plate IV, Mechanics, fig. 23.) move uniformly in the same right line, with velocities equal to \( a, b, c, \) &c. their common center of gravity will move uniformly. For, let \( A \) and \( B \) move uniformly in the same or an opposite direction, \( P \) be their center of gravity, and \( D \) their distance; then, because the motions of \( A \) and \( B \) are uniform, \( D \) either continues the same, or increases and decreases uniformly; but \( A \times B = \frac{D \times B}{A + B} \), and consequently varies as \( D \), and \( P \) moves uniformly. If another body, \( C \), move uniformly in the same right line, and \( R \) be the center of gravity of \( A, B, C \), the distance, \( C P \), either continues the same, or increases and decreases uniformly, because \( C \) and \( P \) move uniformly; but \( P R = \frac{A + B + C}{A + B + C} \); and consequently varies as \( C P \), or \( R \) moves uniformly. Hence it follows, that the velocity of the center of gravity is equal to \( \frac{A + B + C}{A + B + C} \); and for, let \( p, r, a, b, c, \) be contemporary positions of \( P, R, \) and the bodies, and (by what we shall demonstrate in the sequel of this article,) \( A \times \Delta p, \) or \( \Delta a + \Delta b - B \times Bp \) or \( \times \Delta b + \Delta b + \Delta b = A + B + Pp \), and \( Pp = \frac{A \times \Delta a + B \times \Delta b}{A + B} \), because \( A \times \Delta a - B \times \Delta b = 0 \). And, placing \( A + B + P \) in, and repeating the above process, it appears that \( \Delta R = \frac{A \times \Delta a + B \times \Delta b + C \times \Delta c}{A + B + C} \). Hence again it is inferred, that the velocity of \( R \) is uniform; because \( Aa, Bb, Cc \), are confinetal, and consequently their sum, or difference, multiplied into the same given quantities, or the velocity of \( R \), is always the same. Moreover, because \( A + B + C \times \Delta R = A \times \Delta a + B \times \Delta b + C \times \Delta c \), the velocity of the center of gravity is such as would be communicated to the sum of the bodies actuated upon by a force equal to \( A \times \Delta a + B \times \Delta b + C \times \Delta c \).

2. If one or more bodies, \( A, B, C, \) &c. (fig. 24.) move uniformly in right lines, either in the same or different places, their common center of gravity, \( S, \) will move uniformly in a right line. Let \( A \) describe \( Bb \) uniformly in the time \( T \), and \( P, Q, \) be, the centers of gravity of \( A \) and \( B \); and \( A + B : B : A \times B : A B : A B : A B : A B : QP \). By the above, \( PQ \) is parallel to \( Bb \) and equal to \( X \), and varies therefore as \( Bb \), or uniformly. Let \( A \) describe \( Aa \) uniformly in the time \( T \), either in the same plane with \( Bb \), or not, and \( R \) the center of gravity of \( A \) and \( B \) placed at \( b \); and \( QR \), the path of the center of gravity, will appear, by the same process with the above, to be parallel to \( Aa \), and equal to \( Aa \), and consequently it varies as \( Aa \), or increases uniformly. When both bodies move at the same time, the point \( P \) will have two motions, \( PQ \) and \( QR \): and will consequently describe the diagonal \( PR \) uniformly in the time \( T \). Let a third body be added, and the common center of gravity be \( S \), and \( CS \) produced will pass through the center of gravity of \( A \) and \( B \). Then, from the nature of the center of gravity, \( A + B + C : A + B + C : CQ : CQ : CP \). By the above, \( CQ : CT : CQ : ST \); and \( ST = \frac{A + B \times \Delta P}{A + B + C}, \) and varies as \( CQ \); or uniformly; and for the same reason \( TV \), the motion of \( T \) arising from \( A \) motions, is equal to \( \frac{Q R \times A \times B}{A + B + C} \), and therefore varies as \( QR \), or uniformly. When \( A \) and \( B \) move together, the motions \( ST, \) \( TV \), will be combined into one, \( SV \); and if \( C \) describe \( Cc \) uniformly in the time \( T \), the common center of gravity will describe \( YY \), and this new motion, combined with \( SV \), will make it describe \( SY \) uniformly in the time \( T \).

This proposition may be otherwise demonstrated in the following manner. Case 1. Let two bodies move, in the same plane, in the directions \( A, B \), (fig. 25.) and let \( D \) and \( E \) be, and \( B \), be contemporary positions, and \( K, \) the center of gravity in those positions, respectively; and taking two
CENTER.

B P = A D, joining E P, and drawing D L parallel to H K; D E : A B in the given ratio of the motions of the bodies; and, because the angle E D P is given, all the angles of the triangle E D P are given, and D P is to E P in a given ratio. Hence, all the angles of the triangle D P L are given, the angle P D L is given, and L is always in D L. By the nature of the center of gravity, D A : D H :: E B : E K :: P B or D A : L K; therefore D H = L K, and D H K L is a parallelogram, H K is parallel to D L, and the angle B H K is given, and the center of gravity K is always in the right line H K given in position. And, because all the angles of the triangles D P L, and D E are given, the lines D P, D E, D L, that is, A B, D E, H K, are in a given ratio, and consequently the point K moves uniformly in H K. The demonstration is the same if one of the bodies moves from B towards A.

Case 2. Let the paths of the bodies, A B and D E, (fig. 26.) be in different planes; and through A B draw a plane B d e parallel to D E, and through D E draw the plane D d e; perpendicular to B d e; produce B A to d, and let D d, E e, be perpendicular to d e, and the planes D d / A, E e / B, will be perpendicular to the plane c d / e. Let A and D, B and E, be contemporary positions of the bodies. If the body at D were to move in d e, the center of gravity would move uniformly in some line H K (case 1.); though H K does not the plane H K k e perpendicular to H B K. From similar triangles, the center of gravity of A B : D E :: A H : H d :: B K : K e :: B c : C e; therefore b k is the path of the center of gravity of the bodies moving in A B, D E. And, because D d : H b :: A d : A H :: B c : C e, D d = k e, H b = k e, and b k is equal and parallel to H K; therefore the center of gravity of the bodies, moving uniformly in A B, D E, moves uniformly in b k.

Case 3. The common center of gravity of two bodies and a third body is either at rest, or moves uniformly in a right line; for two may be placed in their common center of gravity, which was proved to move uniformly, and the center of gravity of the three or more bodies is proved, by the same process as before, to move uniformly.

From what has been above demonstrated, it is evident, that the path of the center of gravity, arising from the motion of any one body, is always parallel to that of the moving body: P Q and S T (fig. 24.) are parallel to B d e; Q R and T V are parallel to A a, and V Y to C c. Moreover, the centers of gravity of two, three, &c. bodies will describe polygons or curves similar to that of the moving body to which their motion is owing; and if the velocity of the body be variable, the velocity of each center will be variable according to the same law. Also, the velocity of the center of gravity of two, three, &c. bodies is the same as if they were placed in it, and acted upon by forces equal to the momenta of the moving bodies, in their respective planes and directions: for B x B c = A B x P Q, and A x A a = A B x Q R; and if A + B were placed at P, and acted upon by forces equal to B x B c and A x A a in the planes and directions of B c and A a, they would describe the diagonal B P.

1. The common center of gravity of two or more bodies is not affected by any action of the bodies upon each other. For, let A and B (fig. 27.) be two bodies in a field, acting upon each other, G their common center of gravity, and A a, B b, the velocities lost by A and gained by B respectively in opposite directions; and A x A a = B x B b, or A : B = B b : A a :: B G : A G :: t g, or A : B : B b’s distance from the center of gravity: A a’s distance from it; and consequently the same point, G, is still the center of gravity of A and B, or it has been immovable. What is proved of these two is true of every two bodies, and therefore of all. Hence, if two parts of a system, A and B, attract or repel each other, or moving with unequal rectilinear motions, disturb each other’s motion by the force of their inertia, the center of gravity will not be affected by their mutual action.

Center of gravity, laws of the. 1. In two bodies, whose masses of matter are equal, the center of gravity is equally distant from their two respective centers. For there are like two equal weights suspended at equal distances from the point of suspension; and in this case they will equilibrate, and rest in any position.

2. If the centers of gravity of two bodies, A and B, (Plate IV. Mechanics, fig. 28.) be joined by the right line A B, the distances, B C and C A, of the common center of gravity, C, from the particular centers of gravity, B and A, are reciprocally as the weights B and A. See this demonstrated under Balance and Lever.

Hence, if the gravities of the bodies A and B be equal, the common center of gravity, C, will be in the middle of the right line, A B. Again, since A : B :: B C : A C; it follows that A x A C = B x B C; whence it appears, that the powers of equilibrating bodies are to be estimated by the produce of the ma, multiplied into the distance from the center of gravity; which product is usually called the momentum of the weights.

Further, since A : B :: B C : A C; it follows, A B = B C + AC (or A B) = B : C + A : C = A : C (A B) = A C. Therefore the common center of gravity, C, of two bodies, will be found, if the product of one weight, A, into the distance of the separate centers of gravity, A B, be divided by the sum of the weights, A and B. Suppose, e. g., A = 12, B = 4, A B = 24; therefore B C = 12 x 16 = 18; and A C = 6. If the weight, A, be given, and the distance of the particular centers of gravity, A B, together with the common center of gravity, C, the weight of B will be found = to A x A C ÷ B C; that is, dividing the momentum of the given weight, by the distance of the weight required from the common center of gravity. Suppose, A = 12, B C = 18, A C = 6; then B = 6 x 16 = 18 = 4.

3. To determine the common center of gravity of several given bodies or points, a, b, c, d, (fig. 29.) in the same right line, A B. Find the common center of gravity of the two bodies, a and d, which suppose in F; conceive a weight, a + b, applied in F; and in the line, F E, if d the common center of the weights, a + b and e; which suppose in G. Lastly, in B G, suppose a weight a + b + e applied, equal to the two a + b and e, and find the common center of gravity between this and the weight d, which suppose in H; this H will be the common center of gravity of the bodies, a, b, c, d. And in the same manner might the common center of gravity of any greater number of bodies be found. Otherwise: take the distances of the given bodies from some fixed point, as V (fig. 30.), calling the distance V A = a, V B = b, V C = c, V D = d, and the distance of the center of gravity V S = x; then S A = x - a, S B = x - b, S C = x - c, S D = x - d; and by the property of the lever, A x x - a + B x x - b = C x x - c + D x x - d; hence Ax + Bc + Cx + Dx = Ax + Bb + Cc + Cb + Dd, and x = = A + B + C + D) = V S, the distance sought; which is consequently equal to the sum of all the moments, divided by the sum of all the weights in the bodies.
Or thus: when the bodies are not in the same straight line, connect them with the lines, A B, C D; then find, as before, P, the common center of A and B, and Q, the common center of C and D; and conceiving A and B united in P, and C and D united in Q, and S, the common center of P and Q, which will be the common center of the whole. Or, the bodies may be all reduced to any line, V A B. &c. drawn in any direction whatever, by perpendiculars, B B, C C, &c. and then the common center in this line, found as before, will be at the same distance from V as the true center is; and consequently, the perpendicular from s will pass through S, the real center. From the preceding general expression, viz. \[ x = \frac{Aa + Ba + Cc + \text{&c.}}{A + B + C + \text{&c.}} \]

for the center of gravity of any system of bodies, we may deduce a general method for finding that center; for A, B, C, &c. may be considered, as above stated, to be the elementary parts of any body, whose sum or mass is M = A + B + C + \text{&c.}, and Aa, Ba, Cc, &c. are the several moments of all these parts, viz. the product of each part multiplied by its distance from the fixed point, V. Hence then, in any body, if you find a general expression for the sum of the moments, and divide it by the expression of the body, and the quotient will be the distance of the center of gravity from the vertex, or from any other fixed point, from which the moments are eliminated. The application of this principle will appear in the sequel of the article. M. Lhuiller has, in the fourth volume of the New Acts of the Academy of Petersburg, given the demonstration of a very general theorem concerning centers of gravity; the following expression is a particular example of the general proposition: Let A, B, C be the centers of gravity of three bodies; a, b, c, their respective masses; and Q their common center of gravity. Let right lines, Q A, Q B, Q C, be drawn from the common center to that of each body, and the latter be connected by right lines, A B, A C, and B C; then \( QA^2 + a + QC^2 + b + QC^2 + c = AB^2 + \frac{ab}{a + b + c} + AC^2 + \frac{ac}{a + b + c} + BC^2 + \frac{bc}{a + b + c} \)

4. Two weights, D and E, \((\text{fig. 37.})\) being suspended without their common center of gravity in C, to determine which of them preponderates, and how much. Multiply each into its distance from the center of suspension; that side on which the product is greatest will preponderate; and the difference between the two will be the quantity wherewith it preponderates. Hence, the momenta of the weights, D and E, suspended without the center of gravity, are in a ratio compounded of the weights, D and E, and the distances from the point of suspension. Hence, also, the moment of a weight suspended in the very point, C, will have no effect at all in respect of the rest, D, E.

5. To determine the preponderation whereof several bodies, a, b, c, \(d, (\text{fig. 35.})\) are suspended without their common center of gravity in C. Multiply the weights, c and d, into their distances from the point of suspension, C E and C B; the sum will be the momentum of their weights, or the ponderation towards the right: then multiply the weights, a and b, into their distances, A C and C D, the sum will be the ponderation towards the left: subtracting, therefore, the one from the other, the remainder will be the preponderation required.

6. Any number of weights, a, b, c, \(d, (\text{fig. 35.})\) are suspended without their common center of gravity in C, and preponderating towards the right, to determine the point, P, from whence the sum of all the weights being suspended, the ponderation still continues the same as in their former situation. Find the momentum wherewith the weights, c and d, preponderate towards the right; since the momentum of the sum of the weights to be suspended in P is to be equal to it, the momentum now found will be the product of C F into the sum of the weights: this, therefore, being divided by the sum of the weights, the quotient will be the distance, C F, at which the sum of the weights is to be suspended, that the preponderation may continue the same as before.

7. The sum, or difference, of the products, which results from multiplying each particle, A, B, C, D, into its perpendicular distance from any plane, L N, as they are on the same or different sides of the plane, is equal to the product of all the particles multiplied into the distance of their center of gravity, G, from that plane. See figs. 32, 33, and 34. Let P and Q be the centers of gravity of A and B, C and D, and drawing right lines through P, Q, G, parallel to the plane, which intersect the perpendiculars drawn from those points respectively; and \( A : B = BP : BB \cdot PB = AP : MP - AA \); and \( A \times BP - AA = B \times BB - PP, \) or \( A \times \frac{Aa + Ba + Cc + \text{&c.}}{A + B + C + \text{&c.}} \) minus \( A \times \frac{Aa + Ba + Cc + \text{&c.}}{A + B + C + \text{&c.}} \) minus \( GQ \cdot P \cdot PP - G \cdot C, \) and \( A + B : C + D : QG : PG : \frac{G^2 + G^2 - GQ^2}{GQ} + XQ \); or, by transposition and substitution of equals, \( Aa + BA + Bb + Cc + \text{&c.} = C + D + \text{&c.} \) or, \( A + B : C + D : A \cdot PG = A + B + C + D \cdot Bg \); in which expression the higher or lower signs are to be used, as the bodies are on the same, or a different side, of the plane.

Hence it appears, that, if the particles be placed upon the same right line, or, \( (\text{as in fig. 35.}) Aa, Bb, Cc, \) &c.\(, \) become \( A + B, Cc, Dd, Gg \) respectively, \( A \times \frac{Aa + Ba + Cc + \text{&c.}}{A + B + C + \text{&c.}} \) and \( Bg + Cc + \text{&c.} = A + B + C + D + G \); i.e. the sum, or difference, of the products resulting from the multiplication of each particle into its distance from any point, \( g, \) as they are on the same, or a different side of that point, is equal to the product of their sum multiplied into the distance of their center of gravity from that point. Moreover, the whole momentum of a body, acting upon a lever, being equal to that of every particle, or to the sum of the products which results from the multiplication of each particle into its distance from the center of motion, is equal therefore to the product of the whole body into the distance of the center of gravity from the center of motion, and is consequently the same as if it were collected in the center of gravity. The demonstration of this proposition obtains therefore when \( A, B, C, D \) are collections of particles or bodies, whose centers of gravity are the points \( A, B, C, D. \) And to find the center of gravity of a system of bodies, it is evident that in the proposition, introducing this article, bodies, whose centers of gravity are \( A, B, C, D, \) &c. may be substituted for particles. Further, if \( A, B, C, \) \( D, (\text{fig. 33} \) and 34) be bodies acting upon any plane, L N, in parallel directions, the sum of their efforts to move it is the same as if they were collected in their center of gravity; for, if \( A, B, C, D \) be the respective centers of gravity of each body, this sum is equal to \( A \times AA + B \times BB + C \times CC + D \times DD = A + B + C + D + Gg \); or, if they be placed upon a lever, the sum of their efforts to make it rotate is the same as if they were placed at \( G. \) When the center of gravity, therefore, is in the plane, or at the fulcrum of the lever, the plane and lever are quiescent. And if any point, \( Z, \) be taken in \( N L, A \times AZ + B \times BZ + C \times CZ + D \times DZ = A + B + C + D + Gz, \) for if a plane passes through \( Z, \) the proof is the same as that of this proposition. Also, the distance
distance of any plane from the common center of gravity of 

\[ A_1, P, C, B, \text{ &c. or } G \text{ is equal to} \]

\[ A_1 \times A_2 + B \times B_2 + C \times C_2 + D \times D_2 \]

and its distance from a plane passing through any point, \( Z, \) is equal to

\[ A_3 \times Z_3 + B \times Z_3 + C \times Z_3 + D \times Z_3 \]

in which express the lower figures as to be used for the bodies whose center are not on the same side of \( Z, \) with \( A_1 \) and \( B. \)

It follows, that a right line drawn from \( A_1 \) through the center of gravity, \( G, \) of any number or bodies, \( A, B, C, D, \&c., \) will pass through the center of gravity of the remainder; for \( B \times B_1 + D \times D_1 = C \times C_1 \), and consequently the center of gravity of \( B, C, D \) in the plane passing through \( A_1 G \); and if this plane separate, their center of gravity is always in the plane passing through \( A_1 G \), and consequently it must be in the line \( A_1 G \) produced, which is the common intersection of the planes.

If \( r \) be this center, \( B + C + D + G \times r = A \times A_1 G, \) and if the bodies be equal, and \( n \) their number, \( A_1 G = \pi \times I \times G \).

It appears farther, that if a circle or sphere be described about the center of gravity, \( G, \) of any number of bodies, \( A, B, C, \&c., \) and any point, \( P, \) be taken in the periphery of the circle or surface of the sphere, \( PA^2 \times A + PB^2 \times B + PC^2 \times C, \) &c. is a given quantity; for, drawing \( G, \) and the perpendiculai to it \( A_1 B, C, A \times G_1 = B \times G_1 + C \times G_1, \) or by substitution of equals, \( A \times G_1^2 - PA^2 - G_1^2 = B \times PB^2 - G_1^2 - G_1^2 = AC^2. \)

8. If \( A, B, C, D, \&c. \) (fig. 38) be particles of a body urged by forces in parallel directions, whose magnitudes are \( A, B, C, \&c., \) the sum of their weights is equal to the weight of \( A + B + C, \&c., \) acted upon by a force whose magnitude is \( G \).

For the weights of \( A, B, C, \&c., \) be \( A \times A, B \times B, C \times C, \&c., \) the sum of their weights will be equal to \( A + B + C, \&c., \) but this product is the weight of \( A + B + C, \&c., \) acted upon by the force \( G \).

Hence, if the forces \( A_t, B_t, C_t, \&c., \) be equal to each other, \( G \) is equal to one of them, or if the particles \( A, B, C, \&c., \) be acted upon by the same force, their weight is the same as if they were collected in their center of gravity, and acted upon by that force.

The tendency, therefore, of a body to descend is the same as if it were collected in its center of gravity, and, consequently, if a line drawn from that center perpendicular to the horizon falls within the base of that body, it cannot fall; and if without the base, it cannot float. See Gravity.

9. If any number of bodies, \( A, B, C, \&c. \) (fig. 39) move in parallel directions, with any velocities, the center of gravity will describe a right line parallel to them. Let \( A \) and \( B, a \) and \( b, \) be contemporary positions of the bodies \( A \) and \( B, \) and \( G, \) their centers of gravity, and through \( G \) draw a line, \( x y, \) parallel, and consequently equal, to \( A \). From the nature of the center of gravity, \( A \), \( B \), \( P \) : \( P \) : \( G \), \( A \) : \( G \) : \( b_1 : a_1 \), \( y g : x g \), (by similar triangles); and the point \( P \) divides the parallel and equal lines \( A P, x y, \) in the same ratio, and \( G \) is a right line parallel to \( A P \) or \( B \).

If \( H \) be the center of gravity of \( A, B, C, \) it is proved in the same manner that it cuts the parallel and equal lines, \( G, C, \) &c., in the same ratio, and \( H \) is consequently a right line parallel to \( G C. \) Hence, if any number of bodies, \( A, B, C, \&c. \) (fig. 38) acted or deflected in parallel right lines, the sum of the products resulting from the multiplication of each body into the space described by it is equal to the product of their sum, and the space described by their center of gravity \( G, \) for, let \( a, b, c, \&c. \) be contemporary positions of \( A, B, C, \) and, drawing any plane \( M, A \times Am + B \times Bm + C \times Cm = A + B + C \times Gm; \) and \( A \times am + B \times bm + C \times cm = A + B + C \times Gm; \) and consequently by addition \( A \times a + B \times b + C \times c = A + B + C \times Gm, \) and moreover, if any number of bodies move in parallel directions with any unequal velocities, or they be placed upon the lever \( X Y \) (fig. 39, 39, and 40), and receive unequal impulses from any force at the same time in parallel directions, the center of gravity will, in the beginning of its motion, move uniformly in a right line parallel to itself, and its velocity is equal to the product of each body into its velocity, divided by the sum of the bodies; for the spaces \( Aa, Bb, Cc, Gd \) are described in the same time, and vary as the velocities; and \( Gd, \) or if \( G \) be the center of gravity, \( = \frac{A + B + C}{A + B + C}. \)

See Parkinson's System of Mechanics, &c. ch. ix.

10. To find the center of gravity in a right line \( A B \) (Pl. VI. Mechan. fig. 41). All the particles that compose this line may be considered as for any very small weights, each equal to \( \frac{m}{x}, \) which is therefore the fluxion of the weights, or of the line denoted by \( x. \) Multiplying therefore the small weight \( \frac{m}{x} \) by its distance from \( A, \) viz. \( x, \) and \( xx \) will be the momentum of that weight \( \frac{m}{x}; \) or, in other words, \( \frac{m}{x} \) is the fluxion of all the momenta in the line \( A B \) or \( x, \) and, therefore, its fluent \( \frac{x}{m} \) is the sum of all those momenta; which, being divided by \( x \) the sum of all the weights, gives \( \frac{x}{m} \) or \( \frac{1}{m} \) for the distance of the center of gravity \( C \) from the point \( A; \) that is, the center of gravity of an homogeneous line is in the middle of that line. In any body, having found a general expression for the sum of the momenta of all the parts, this be divided by the content of the body, the quotient will be the distance of the center of gravity from the vertex, or from any other fixed point, from which the momenta are estimated.

11. To find the center of gravity in a parallelogram and parallelepiped. Draw the diagonals \( A D \) and \( E G, \) (fig. 42.) likewise \( C B \) and \( H F; \) since each diagonal, \( A D \) and \( C B, \) divides the parallelogram \( A C D B \) into two equal parts, each passes through the center of gravity; consequently, the point of intersection, \( I, \) must be the center of gravity of the parallelogram. In the same manner, since both the planes, \( CBEF, \) and \( ADEG, \) divide the parallelepiped into two equal parts, each passes through its center of gravity; so that the common intersection, \( I, \) is the diameter of gravity, the middle whereof is the center.

After the same manner may the center of gravity be found in prisms and cylinders; it being the middle point of the right line that joins the center of gravity of their opposite bases.

The center of gravity of a parallelogram, &c. may be very easily found by the method of fluxions. Let the axis or length \( A B \) of the parallelogram (fig. 43.) be \( x, \) and its breadth \( DE = b, \) and if \( dc \) be drawn parallel and indefinitely near to \( DE, \) the area \( d E = b, \) will be the fluxion of all the weights, which multiplied by its distance \( x \) from
from the point $A$ gives $b \times \dot{x}$ for the fluxion of all the moments, and consequently the fluxion $\frac{1}{2} b \times \dot{x}$ is the sum of all those moments themselves; which, being divided by $b \times \dot{x}$ the sum of all the weights, gives $\frac{1}{2} x = \frac{1}{2} A B$ for the distance of the center $C$ from the extremity $A$, and is therefore in the middle of the axis, as we have above shown. The process and conclusion will be precisely the same for a cylinder, or any prism whatever, making $b$ to denote the area of the end or of a transverse section of the body.

12. In regular polygons, the center of gravity is the same with the center of the circumscribed polygonal.

13. To find the center of gravity of a cone and a pyramid. The center of gravity of a cone is in its axis $AC$ (fig. 44). If then $\Delta P = x$, $\angle AC = \alpha$, $\angle DC = \beta$, the periphery of the base is $\rho$, and $P N = \gamma$, we shall have, by the well known property of circles, $r : \rho :: y : r'$. The periphery of the circle, whose diameter is $MN$, which being multiplied by $\frac{v}{2}$ will give $\frac{r'}{2\gamma}$ be the area of the same circle. But, by similar triangles, $y : x :: r : \alpha$, therefore $y = \frac{r}{\alpha} x$, and $y^2 = \frac{r^2}{\alpha^2} x^2$; consequently the area of the circle, whose radius is $P N$, becomes equal to $\frac{\rho r^2}{2\alpha^2} x^2$; and therefore $\frac{\rho r^2}{2\alpha^2} x^2$ will be the fluxion of the mafs, or the content of the cone at the term $M N$, and $\frac{\rho r^2}{2\alpha^2} x^2$ will be the fluxion of the moment, whose fluxion is $\frac{\rho r^2}{2\alpha^2} x^2$, which, being divided by $\frac{\rho r^2 x^2}{2\alpha^2}$, the fluxion of the mafs, will give $\frac{x}{\alpha} \frac{\Delta P}{\gamma}$, for the distance of the center of gravity of the portion $AMN$ from the vertex $A$; and when $\Delta P$ becomes equal to $\Delta AC$, $x$ will be equal to $\alpha$; and therefore the center of gravity of the whole cone is distant from the vertex $\frac{\Delta AC}{\alpha}$ of $AC$. And in the same manner is found the distance of the center of gravity from the vertex of the pyramid $\frac{1}{3} \Delta AC$; and therefore all pyramids of the same altitude have the same center of gravity.

14. To determine the center of gravity in an isosceles triangle $BAC$ (fig. 45). Draw the right line $AC$, bisecting the base $BC$ in $D$, which will be also perpendicular to it; since $\Delta BAD = \Delta DAC$, each may be divided into the same number of little weights, applied in the same manner on each side to the common axis $AD$; so that the center of gravity of the $\Delta BAC$, will be in $AD$. To determine the precise point in that, let $AD = a$, $BC = b$, $AP = x$, $MN = y$; then will $\Delta AP : MN :: AD : BC$; or $x : y :: a : b$.

Hence, $y = \frac{b x}{a}$. Consequently $y \times \dot{x}$, which represents the fluxion of the mafs at the term $MN$, divided by $y \times \dot{x}$ expressing the fluxion of the area $AMN$, will be equal to $\frac{b \times \dot{x}}{a} = \frac{b \times \dot{x}}{a} = \frac{x}{\alpha}$; the fluxion of which quantity will be $\frac{1}{\alpha} x$, and at the term $BC$, when $x = A D$, $\frac{1}{2} \Delta AC$, and therefore the distance of the center of gravity of the $\Delta$ from the vertex, will be found $\frac{1}{2} a$.

In the very same manner the center of gravity of any other plain triangle will appear to be at $\frac{1}{2}$ of a line drawn from one angle to bisect the opposite side, or the diameter of gravity, from the vertex.

The same center may be otherwise ascertained without this process. Since a line drawn from any angle to the middle of the opposite side will pass through the center of gravity, the point of intersection of any two such lines will be the center of gravity. For that the center of gravity is in the line $AD$ (fig. 46), and it is also in the line $CG$ bisecting $\angle AB$; and consequently in the point of their intersection, $S$. In order to determine the distance of $S$ from any angle, as $A$, produce $CG$ to meet $BH$ parallel to $AS$ in $H$; then the two triangles $AGS$, $BGH$ are mutually equal and similar, because the opposite angles at $G$ are equal, and also the alternate angles at $H$ and $S$, and at $A$ and $B$, and the line $AG$ is $BG$; therefore the other sides $BH$, $AS$ are equal. But the triangles $CDS$, $CBH$ are similar, and the side $CB = 2 \times CD$; therefore $BH$ or its equal $AS = 2 \times DS$; that is $A S = \frac{1}{2} A D$, the same as before. And in like manner $CS = \frac{1}{2} CG$.

15. To determine the center of gravity of a tetrahedron. Divide the figure (fig. 47) into two triangles by the diagonal $AC$, and find the centers of gravity $E$ and $F$ of these triangles; join $EF$, and find the common center $G$ of these two by this proportion, viz. $\Delta ABC : \Delta ADC :: FG : EG$, or $\Delta ABC : \Delta ABD :: EF : EG$. In a similar manner, the center of gravity may be found in any other figure, whatever be the number of sides, by dividing it into several triangles, and finding the center of gravity of each; then connecting these centers together, and finding their common center as above; then connecting this and the center of a third, and finding the common center of these; and so on, always connecting the last found common center to another center, till all are included in the process; and thus the last common center will be that which is required.

16. For the center of gravity in a parabola (fig. 48). Let $A E = a$, $SH = b$, $AP = x$, $PN = y$. Then will $\frac{2}{3} y$, be the fluxion of the whole weight; but from the nature of the parabola, and the parameter being a constant quantity, $\frac{2}{3} x = y$; whence $x = \frac{2}{3} y$; substituting $2x\frac{2}{3} y$ instead of $2 y$ in the above expression, we shall have $2x\frac{2}{3} y$ for the fluxion of the mafs, whose fluxion $\frac{4}{3} \Delta x$ will be the moment of all the mafs itself. Then, multiplying $2x\frac{2}{3} y \times x$, we shall have $2x^2 \times \frac{2}{3} y \times x$ for the fluxion of the moment, whose fluxion $\frac{4}{3} \frac{x^2}{3} y$ will be the momentum itself. Divide this by $5$ for the whole weight, and the quotient $\frac{2}{3} x \frac{2}{3} y \frac{2}{3} y = \frac{2}{3} x y$, will be the distance of the center of gravity of the space $N A Z P$ from the vertex $A$; and when $AP$ becomes equal to $AE$, or $x = a$, $\frac{2}{3} a$, or $\frac{1}{3} AE$, will be the distance of the center of gravity of the whole parabolic space from the vertex $A$. Now $\Delta MN = \frac{1}{2} x$, being a general equation for all kinds of parabolas, we shall have $y = x \times n$ and therefore $x \times \dot{x}$ will be the fluxion of the whole mafs, and $\frac{1}{m} x$ the fluxion of the moment: the fluxion of this last expression, viz. $\frac{1}{2 m + 1} \times n$, being divided by the fluxion of $x \times \dot{x}$ or $\frac{1}{2 m + 1} \times n$, will give $\frac{m + 1}{2 m + 1} x$, for the distance of the center of gravity of the space $Z A N$ from the vertex $A$, and $\frac{m + 1}{2 m + 1} a$ will be the distance of the center of gravity of the whole parabolic space from $A$. When $m = 2$, as in the common
The center of gravity of a semi-circle, or of a circle, is the center of the circle. 

17. The center of gravity of the arc of a circle, as $ABD$ (fg. 49) is considered a plane line, having gravity.

It is evident that the center of gravity, $G$, of the arc, will be somewhere in the axis, or middle radius $BC$, $C$ being the center of the circle, which is considered as the point of fulcrum. Suppose $F$ indefinitely near to $A$, and $FH$ parallel to $BC$. Put the radius $BC$ or $AC = r$, the semi-arc $AB = z$, and the semi-chord $AE = x$; then $AH = x$, and $AF = z$, the fluxion of the weights, and therefore $CE = z$ is the fluxion of the momenta. But by similar triangles, $AC : r :: AE : z :: AH : x$; therefore $x = CE = z$, and consequently $y = 0$ is also the fluxion of the momenta; the fluxion of which is, and this, divided by $z$, the weight, gives $y = \frac{AC \times AE}{AB} = \frac{AC \times AED}{ABD}$.

$G$, the distance of the center of gravity from the center $C$ of the circle; and it is manifestly a fourth proportional to the given arc, its chord, and the radius of the circle. When the arc becomes the semi-periphery $ABK$, the above expression becomes $\frac{1}{3} \frac{r^2}{1 + \sqrt{3} r} = \frac{r}{1.5708} = .6366r$.

18. Let $ABCD$ (fg. 49) be a circular sector; and the center of gravity will be somewhere in the axis or middle radius, $BC$, as in the former case. With any lesser radius describe the concentric arc $LMN$, and put the radius $AC$ or $BC = r$, the arc $ABD = a$, its chord $AED = c$, and the variable radius, $C$, or $CM = y$; then $r : y :: a : \frac{r}{a}$.

and also by the last article the distance of the center of gravity of the arc $LMN$ is $\frac{CM \times LON}{LMN} = \frac{CM \times AED}{ABD}$.

$\frac{c}{a}$: hence the arc $LMN$ or $\frac{a}{r}$ multiplied by $y$ gives $\frac{c}{r} y$, the fluxion of the weights, and this multiplied by $r$ gives $\frac{c}{a} r$, the distance of the common center of gravity, gives $\frac{c}{a} c$ divided by $\frac{r}{a}$, the fluxion of the momenta; the fluxion of which, viz.

The centers of gravity of other bodies may be found in a similar manner. Thus the attitude of the segment of a sphere, or spheroid, or conoid, being $x$, the whole of the axis itself being $a$, the distance of the center of gravity in each of these bodies from the vertex will be as follows:

$4 a = 3 x$ in the sphere or spheroid.
$6 a = 4 x$ in the semi-sphere or semi-spheroid (as above).
$\frac{3 x}{2} a$ in the parabolic conoid.
$\frac{1}{4} a + \frac{3 x}{2} a$ in the hyperbolic conoid.

Thus, and such cases, however, are more or less, and also more uncommon, and we shall therefore refer for a more ample account of the center of gravity to writers on this subject; among whom we may reckon Archimedes, Pappus, Guidinus, Wallis, Caflus, Carle, Hays, Wolthus, Hodgson, Simpson, &c. &c.

To find the value of any surface or solid by means of the center of gravity; see Céserbary's Method.

20. To determine the center of gravity in any body mechanically. Lay the given body $H I$ (fig. 51.) on an extended rope, or on the edge of a triangular prism $F G$. bringing it thus and that way, till the parts on either side are in equilibrium; the plane, whose sides are $K$, parallel through the center of gravity. Balance it again, on the same, only changing its situation; then will the chord, or the edge $MN$, pass through the center of gravity; so that the intersection of the two lines $MN$ and $KL$, determine the point $O$, in the surface of the body required.

The frame may be drawn thus; on the horizontal table is near the
in two positions, lengthwise and breadthwise: the common
intersection of the two lines contiguous to the edge will
be its center of gravity. Or it may be done by placing
the body on the point of a file, &c. till it rest in equilibrio.
It was by this method that Borda found the center of
gravity in a human body to be between the nates and pubes;
so that the whole gravity of the body is there collected, where
nature has placed the generative organs, (says Wolffius)
the wisdom of the Creator, in placing the membro virile.
In that place which of all others is the most convenient for
copulation; nevertheless, this law does not take place in the
greater number of animals.

Or thus. Suspend the body by any point: then a plumb-
line hung over the same point will pass through the center
of gravity; because that center will always descend to the
lowest point when the body comes to rest, which it cannot
do except when it falls in the plumb-line. Therefore,
marking that line upon it, and suspending the body by an-
other point, with the plumbet, to find another such line, the
intersection of the two will give the center of gravity.

Otherwise. Hang the body by two strings from the fame
tack or nail, but fixed to different points of the body; then
a plummet, hung by the same tack, will fall on the center
of gravity.

Center of gyration, is that point of a body revolving
about an axis, into which, if the whole quantity of materie
were collected, the fame moving force would generate the fame
angular velocity in the body. This point differs from the
center of oscillation, because, in this latter case, the motion
of the body is produced by the gravity of its own particles;
but in the cafe of the center of gyration, the body is put in
motion by some other force acting at one place only. Let
a body, $p$, revolve about $C$, (Plate VII. Mechnica, f. 52.)
and let $A B$ be placed at $D$ to oppose its motion. Then
the momentum of $p$ varies, as $p$ x its velocity, or as $p$ x $p$,
which may be considered as a power acting at $p$, in oppo-
sition to the force at $D$; but this power acting at the dis-
cance, $p$, from the center of motion, its effer to oppose a
force at $D$ must (by the property of the lever), be as $p$ x $p$
$C$, which this power acting at its point, or, which is the fame, to prevent any change in its
motion, is called its "inertia."

To find the center of gyration of a body. Let a body be
conceived to be made up of the particles A, B, C, &c.
whose distances from the axis are $a$, $b$, $c$, &c. and let $x$ be
the distance of the center of gyration from the axis; then,
by the preceding observation, the inertia of $A$, $B$, $C$, &c.
will be as $a$ x $a$, $b$ x $b$, $c$ x $c$, &c. and the inertia of all the
materie of the distance $x$, will be as $A + B + C + &c.
x x$: and as the moving force is the fame in both cafes, the
inertia must be the fame when the fame angular velocity
is generated; hence, $A + B + C + &c.$ x $x^2$
$= A + a^2 + B + b^2 + C + c^2 + &c.$; and, therefore,
$x = \sqrt[3]{\frac{A + a^2 + B + b^2 + C + c^2 + &c.}{A + B + C + &c.}}$: that is, if $i$
be the fluxion of the body at the distance $x$, from the axis,
in $= \sqrt[3]{\frac{\text{flux of}}{x}}$.

E. G. 1. Let the direct line, CA, (fig. 53.) revolve
about $C$; and find O the center of gyration. Put $x$ = $p$,
then $s = s_1$, and $i = i_1$; and therefore $s + \frac{1}{2} s = s_1$, whole fluxion
is $\frac{1}{2} s^2 = (x = C A) \frac{1}{2} C A^2$; hence, $C O = \sqrt[3]{\frac{1}{4} C A^2}$
$= C A \sqrt[3]{\frac{1}{3}}$. Let a circle, A B, (fig. 54.) revolve in its
own plane about its center C; to find O, its center of gyration.
Put $p = 6.28: 518$, &c. the circumference of a circle
Vol. VII.
monstrate under Center of percussion it will appear, that in the center of gravity, or from a line passing through the center of gravity parallel to the axis of vibration, be divided by the product of the whole mass or body, multiplied by the distance of the center of gravity from the point of percussion, the quotient will be the distance of the center of oscillation, from the center of gravity; which being added to the distance of the center of gravity from the point of percussion, will be the distance of the center of oscillation from the point of percussion.

Let C A B (Plate V. Mechanics, fig. 56.) represent any form of body regular or irregular, suspended at C; G its center of oscillation; G O its axis of gravity; C O B its axis or right line, passing through the point of percussion, and centers of gravity and oscillation. This body may be conceived to consist of an indefinite number of extremely small parts or weights. Let W be one of those small weights, join W C and W G, and W F perpendicular to C O. Then the product of W, by the square of its distance from C, is $W \times C W^2$. But (Eucl. p. 47, B. i.) $C W^2 = W F^2 + G F^2$; and $G W^2 = G F^2 + W F^2$. (Eucl. p. 7, B. ii.) $C G^2 + G F^2 = 2 CG \times GF + C^2$; and by transposition $C G^2 = GF^2 + CG^2 - 2 CG \times GF$. Then by substitution (viz. by putting instead of $C F^2$ its equal $G F^2 + C G^2 - 2 CG \times GF$), the above stated equation becomes $C W^2 = W F^2 + G F^2 + C G^2 - 2 CG \times GF = (putting GF^2 for its equal $G F^2 + W F^2$) $W F^2 + C G^2 - 2 CG \times GF$. And multiplying both sides by W, we have the sum of all the products $W \times C W^2 = \text{the sum of all the } W \times GF^2 \text{ or } W \times CG^2 \text{ or } W \times 2 CG \times GF$. But by the nature of the center of gravity, the sum of all the $W \times GF^2$ is = C, for those which are on one side of the axis must balance those which are on the other side; and of course all the $W \times 2 CG \times GF$ also become = 0. Therefore there remains the sum of all the $W \times CG^2$ = the sum of all the $W \times W C W^2$ or of all the $W \times CG^2$ or of all the $W \times W G W^2$ or of all the $W \times CG^2$. Or, (taking away the sum of all the $W \times GF^2$ from both sides of the equation) the sum of all the $W \times CG^2$ = the sum of all the $W \times CG^2$.

Then $CO = \frac{\text{the whole body } \times CG^2}{\text{the whole body } \times CG}$ (by rule the $1\text{st}$) = $CG + \frac{\text{the sum of all the } W \times W G W^2}{\text{the whole body } \times CG}$; And lastly, $G O = CO - CG = \frac{\text{the sum of all the } W \times W G W^2}{\text{the whole body } \times CG}$; which is the rule of the $2\text{nd}$.

In the application of the above-mentioned rules, it is frequently very difficult to find the sum of the products of all the weights multiplied by the squares of their respective distances. The method of fluxions is undoubtedly the most extensive, as it may be applied to all such figures or bodies as have some regularity of shape, or such as may be expressed by an algebraical equation. But in some cases the irregularity of form is so very great, that the center of oscillation can only be found out by means of the mechanical method subjoined.

In order to find the sum of the weights, &c. you must consider an indefinitely small part, or increment, or fluxion, of the figure, as being a small weight, and multiply it by the square of its distance from the center of oscillation or axis of vibration, according to the rule the $1\text{st}$, or else multiply it by

| Rule 1. if all the bodies or parts of a body, that forms a pendulum, be multiplied each by the square of its distance from the point or axis of suspension, and the sum of the products be divided by the product of the whole weight of the pendulum, multiplied by the distance of the center of gravity from the point of suspension; the quotient will be the distance of the center of oscillation or percussion from the point of suspension.

| Rule 2. if the sum of the products of all the parts or weights, multiplied each by the square of its distance from the center of gravity, or from a line passing through the center of gravity parallel to the axis of vibration, be divided by the product of the whole mass or body, multiplied by the distance of the center of gravity from the point of percussion, the quotient will be the distance of the center of oscillation, from the center of gravity; which being added to the distance of the center of gravity from the point of percussion, will be the distance of the center of oscillation from the point of percussion. |
by the square of its distance from the center of gravity, or from a line passing through the center of gravity, and parallel to the axis of vibration, according to rule the 2d.; then the fluent of that expression will be the sum of the products of all the weights, multiplied by the squares of their respective distances, either from the axis of vibration, or from the center of gravity, &c. Lastly, this fluent must be divided by the product of the whole body (to be had by common mensuration) multiplied by the distance of the center of gravity, from the point of suspension; and the quotient will be the distance of the center of oscillation either from the point of suspension, or from the center of gravity, according as the operation was performed either by rule the first, or rule the second. Before we proceed to flate and apply another method for investigating the center of oscillation, it will be necessary to premise the following lemma.

Suppose two exceeding small weights, C and P, acting on each other by means of an inflexible line (or wire), PC, to vibrate in a vertical plane, ROC, POM, about the center O; and it be required to determine how much the motion of one is affected by the other. Let CH and PQ (Plate VII. Mechanics, fig. 57) be perpendicular to the horizontal line OR; and let PB and CS be perpendicular to OP and OC respectively. If the force of gravity be denoted by unity, the forces acting in the directions CS and PB, whereby the weights, in their descent, are accelerated, will, according to the resolution of forces, be represented by \( \frac{OC}{O P} \times \frac{OG}{O C} \) and \( \frac{OC}{O P} \times \frac{OP}{OC} \). Moreover, since the velocities are always in the ratio of the radii OC and OP, if the aforesaid forces were to be in that ratio, or that of P was to become \( \frac{OC}{O P} \times \frac{OG}{O C} \), instead of \( \frac{OC}{O P} \times \frac{OG}{O C} \), in that case it is plain, that the weights would continue their motion without affecting each other, or acting upon each other on the line of communication PC (or PB). Whence, the excess of \( \frac{OC}{O P} \times \frac{OG}{O C} \) above \( \frac{OC}{O P} \times \frac{OG}{O C} \) must be the accelerative force whereby the weight, P, acts upon the line (or wire), OC, in the direction OPB; which multiplied by the weight, P, gives \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \), for the absolute force in that direction; which, therefore, in the perpendicular direction NB, is \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \times \frac{OB}{OB} \); whereby the part acting upon C being to the whole as OB to OC, is truly defined by \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \times \frac{OB}{OC} \). If the hypothesis is supposing P to act upon C by means of FC (instead of PB) the conclusion will be in no respect different. For, let F denote the force \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \), in the direction PB, found above; then the action thereof upon PC (according to the principles of mechanics) will be expressed by \( P' \times \frac{PC}{PC} \times \frac{C}{C} \), which, therefore, in the direction SC, perpendicular to OC, is \( F \times \frac{SC}{SC} \times \frac{PC}{PC} \). Hence it follows, that if P D, P Y, &c. be perpendicular to OS, the numerator of the fraction, found above, will become \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \times \frac{GD}{GD} \), in the direction PO, &c. Consequently, the forces of all the particles destroying each other (by hypothesis), the sum of all the quantities \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \times \frac{GD}{GD} \), and \( P \times \frac{OC}{O P} \times \frac{OG}{O C} \), &c. &c. is equal to the content of the body, multiplied by the distance \( ON \), of the center of gravity \( G \), from the line LM (perpendicular to OC); whence \( O C \) is also \( = \frac{ON}{P \times \frac{OC}{O P} \times \frac{GD}{GD}} \), and \( \frac{G}{G} \times \frac{b}{b} \times \frac{ON}{ON} \times \frac{P \times \frac{OC}{O P} \times \frac{GD}{GD}} \). Hence the center of oscillation \( O C \) is, therefore, \( \frac{ radius }{radius} \times \frac{S}{S} \times \frac{PC}{PC} \).
it appears, that, if a body be turned about its center of gravity, in a direction perpendicular to the axis of the motion, the place of the center of oscillation will remain unaltered; because the quantities \( P \times G P^2 + \frac{P}{2} \times \frac{G P^4 + \text{sec. \&c.}}{G \times O G} \) are not way affected by such a motion of the body. It also appears, that the distance of the center of gravity from that of oscillation (if the plane of the motion of the body remains unaltered) will be reciprocally as the distance of the former from the point of suspension. Consequently, if that distance be found when the point of suspension is in the vertex, or so placed, that the operation may become the most simple, the value thereof in any other proposed position of that point will likewise be given by the single proportion.

In order to show these conclusions may be reduced to practice, let it be observed, that the product of any particle of the body by the square of its distance from the axis of motion is (here) called the force thereof, (to efficacy to turn the body about the said axis being in that ratio).

According to which, and the first general value of \( O C \), it appears that, if the sum of all the forces be divided by the product of the body into the distance of the center of gravity from the point of suspension, the quotient thence arising will give the distance of the center of percussion, or oscillation, from the said point of suspension.

In the following examples, let the distance of the center of gravity from the point of suspension be \( g \), and the distance of the center of percussion, or oscillation, from the same point, be \( C \).

1. To find the center of oscillation of a right line, \( O S \), (fig. 59.) perpendicular at one of its extremities. If the part, \( O P \), considered as variable, be denoted by \( x \), the force of all the particles at \( P \), will be expressed by \( x \times x^2 \); and \( 4 \times x \), the fluency of this quantity will express the force of all the particles in \( O P \), or the sum of all the products, under each particle, and the square of its distance from \( O \), the point of suspension. This quantity, when \( x \) becomes \( O S \), being divided by \( O S \times \frac{1}{2} O S \), according to the rule above stated, will give \( \frac{1}{2} O S^3 = \frac{1}{2} O S \) for the value of \( C \), the true distance of the center of oscillation (or percussion) from the point of suspension.

2. Let \( A B \), (fig. 60.) be a line, vibrating in a vertical plane, having its two extremities, \( A \) and \( B \), equally distant from the point of suspension, \( O \). If \( O G \), perpendicular to \( A B \), be put \( = a \), and \( A P \times \frac{1}{2} A \), the force of \( x \) particles at \( P \), will be denoted by \( x \times a \times x^2 = x \times O P \); and the fluency of this quantity, divided by \( a \times x \), or \( P G \times O G \), will give \( \frac{a^2 x + \frac{1}{3} x^3}{a^3} = \frac{O G + \frac{1}{2} G^2}{O G} = C \), when \( x \) becomes \( O C \).

3. Let \( A P S Q \) (Plate VIII. Mechanics, fig. 61.) be a circle, vibrating in a vertical plane; any diameter of which is \( P Q \). Thus \( O P^2 + O Q^2 = 2 \times O G^2 + 2 \times P G^2 \), the sum of the forces of two particles at \( P \) and \( Q \) (putting \( O G = a \), and \( A G = r \)) will be \( a^2 + r^2 \times 2 \); whence the sum of all the particles, in the whole periphery, will be expressed by their number, multiplied by \( a^2 + r^2 \), or by \( a^2 + r^2 \) periphery \( A P S Q \); which, if \( P \) be put \( = 3 \times a \), &c., will be \( a^2 + r^2 \times 2 \times 2 = 2 \times a^2 \times r + 2 \times r^2 \). Hence the force of the circle itself is also given, being equal to the fluency of \( 2 \times a^2 \times r + 2 \times r^2 \times x \times x = a^2 + \frac{1}{2} r^2 \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \times \time
a constant ratio, we have \( y = \frac{b x}{c} \) (supposing \( S F = b \), and \( AS = c \). Hence, \( C = \frac{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}}{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}} = \frac{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}}{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}} = \frac{\frac{\sqrt{a}}{a}}{\frac{\sqrt{a}}{a}} = 1 \). Then, \( \frac{\sqrt{a}}{a} \) is a constant, and \( a \) is known to be \( \frac{2}{x} \). We have \( C = \left( \frac{g + a \times y - a}{g} \right) = \frac{g + a}{g} = \frac{a + g}{g} \), where \( g = d + a \) = \( d + \frac{1}{a} \), and \( a \) being \( \frac{n + 2 \times x}{n + 2} \). If \( a \) is the constant \( \frac{n + 2 \times x}{n + 2} \), we also obtain \( C = \left( \frac{g}{a + 3} \right) = \frac{g + a}{a + 3} \), where \( g = d + \frac{n + 1 \times x}{n + 2} \). But with respect to the arc of the curve, \( \psi = \left( \frac{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}}{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}} \right) \) is \( \frac{Flu. y \times x}{Flu. y \times x} = \frac{\sqrt{a}}{\sqrt{a}} = 1 \); which, when the point of suspension is in the vertex \( A \), becomes \( \frac{Flu. y \times x}{Flu. y \times x} = \psi \), and consequently, \( C = \frac{a \times y - a}{g} \), as in the preceding case.

But with regard to the superficies of the solid, it is found (Art. 4, above) that the force of all the particles in the circular section \( b \), parallel to \( H \), will be expressed by \( O P + \frac{b}{d} \times PN \times \pi b \) or \( O P \times \frac{b}{d} \times PN \times \pi b \) (\( 1 \) being \( 3.14159 \)). In algebraic terms, \( \frac{d}{d} \times \frac{1}{2} \times \frac{a}{a} \times y \times y \), \( \pi b \) is \( \frac{d}{d} \times \frac{1}{2} \times \frac{a}{a} \times y \times y \). This will give the true value of \( C \) with respect to the curve surface \( Eb Ab F \), which, putting \( \psi = \frac{Flu. y \times x}{Flu. y \times x} \), is likewise expressed by \( g + \frac{a \times y - a}{g} \).

E. G. 1. Let \( E A F \) be considered as a cone, then, putting \( AS = f \), \( SF = b \), and \( AF = c \), we have \( y = \frac{b x}{c} \), and \( \psi = \frac{c}{f} \); and, therefore, \( C = \frac{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}}{Flu. \frac{d}{a} + \frac{1}{a} \times y \times \frac{\sqrt{a}}{a}} = \frac{20 d^3 + 30 d f + 3 d^2}{20 d + 15 f} \) when \( n = f \). But with respect to the convex superficies, \( C \) will be found \( \frac{12 d^3 + 16 d f + 6 d^2 + 3 b^2 + 20 d^3 + 30 d f + 3 d^2}{12 d + 8 f} \).
C. E. G. 2. Let the figure be a sphere, and the axis of vibration pass through $C$ perpendicular to its plane. Put $G = r_1$, $C = d$, $GO = r = \rho$, and $\omega = - \omega$, &c. Then

$$p = \rho_1$$

and the area of the circle $x = \frac{p}{2}$; and hence

$$C = d + \frac{p}{2}.$$ 

Hence it follows that the same must be true for a cylinder, whose axis is parallel to the axis of vibration. See Simpson's Fluxions, vol. i. p. 214, &c. Hodgson's Fluxions, p. 414, &c. Vincè's Principles of Fluxions, section 5. Cavallo's Elem. of Nat. and Exp. Phiol. vol. i.

Mr. Huygens, in his "Horologium Oscillatorium," was the first person who showed how to find the center of oscillation. Mercenarius, he says, first proposed the problem to him, and he was very young, requiring him to resolve it in the cases of circles or of two circles inscribed in the same circle. He further, inspired to try it by advancing the motion of the pendulums of my clock, I have overcome all difficulties, going far beyond Descartes, Fabri, and others, who had done the thing in a few of the most costly cages only, without any sufficient demonstration; and solving not only the problem proposed by Mercenarius, but many others that were much more difficult, and showing a general way of determining this center in lines, superficies, and solids. In the Leibnitz acta for 1691 and 1714, this doctrine is discussed by the two Bernoullis; and the same is also done by Hermann, in his treatise "De Motu Corporum Solidorum et Fluidorum." But it has been since more amply investigated in various treatises on the interc method of fluxions, in which it is introduced as one of the examples of that method by Hayes, Carré, Wollius, Simpson, &c. &c.

A specimen of the application of this method to several cases has been given above; from which it appears, that in a right line, or rectangle, or cylinder, or any other prism, whose constant section is $y$, or the constant quantity $x$; then $y = \frac{x(a)}{a}$, whose flux is $\frac{x}{a}$; also $y = x \frac{a}{a}$, whose fluent is $\frac{x}{a}$; and the quotient of the former $\frac{x}{a}$ divided by the latter $\frac{a}{a}$, is $\frac{x}{a}$ for the distance of the center of oscillation below the vertex in any such figure; namely, having every where the same breadth or section, that is, at two-thirds of its length. In like manner, the centers of oscillation are found for various figures, vibrating flatways, and are as they are expressed in the subjacent summary:

Nature of the figure, when subjected by the vertex.

Hofscles triangle $- \frac{2}{3}$ of its altitude
Common parabola $- \frac{9}{8}$ of its altitude
Any parabola $- \frac{m + 1}{n + 1}$ of its altitude

$m$ being 2 in the common parabola; 3 in the cubic parabola; 4 in the biquadratic.

The investigation of the center of oscillation in figures moved laterally or side-ways, or edge-ways, that is, about an axis perpendicular to the plane of the figure, is somewhat difficult; because all the parts of the weight in the same horizontal plane, on account of their unequal distances from the point of suspension, do not move with the same velocity.
In vibrating the pendulum, let the body be made to oscillate about its point of suspension, and hang up also a simple pendulum of such a length that it may vibrate or just keep time with the other body; then the length of the simple pendulum is equal to the distance of the center of oscillation of the body below the point of suspension. Or it may be still better found in the following manner: Suspend the body very freely by the given point, and make it vibrate in small arcs, counting the vibrations it makes in any portion of time, as a minute, by a good stop-watch; and let that number of oscillations made in a minute be called $n$; then shall the distance of the center of oscillation be $SO = \frac{140850}{n^2}$ inches. For, the length of the pendulum vibrating second, or 62 times in a minute, being $39\frac{1}{2}$ inches, or more accurately 39.1166 inches, and the lengths of pendulums being reciprocally as the squares of the number of vibrations made in the same time; therefore $n^2: 62^2:: 39\frac{1}{2}: \frac{140850}{n}$, the length of the pendulum which vibrates $n$ times in a minute, or the distance of the center of oscillation below the axis of motion. Or again: divide 60 seconds by the number of vibrations performed by the pendulous body in quinelle one minute; and the quotient is the time of one vibration. Square this time, and multiply its square by the length of the pendulum that vibrates second, viz. by 39.1166 inches, and the last product shews the distance in inches of the center of oscillation or percussion from the point of suspension in the proposed pendulum.

E. G. 1. Let a cylindrical flick about a yard long be suspended by one extremity, and caunted to vibrate. Let the number of its vibrations be 75 in a minute; divide 60 seconds by 76, and the quotient, or $0.79$ (79 hundredths of a second), is the time in which the proposed pendulum performs one vibration. Then, the lengths of pendulums being as the squares of the times of vibration, lay, as the square of one second, i.e. unity, is to the square of $0.79$, viz. 0.6241, so is the length of the pendulum which vibrates seconds, viz. 39.1166, the length sought; therefore multiply 39.1166 by 0.6241, and the product, 24.64, is the distance sought: so that the center of oscillation in the flick is 24 inches and 4 tenths distant from its extremity by which it is suspended; that is, about $\frac{1}{3}$ of its length.

E. G. 2. Let an irregular body, suspended by one end, perform 20 vibrations in a minute; and the time of one vibration is $\frac{60}{20} = 3$ seconds; the square of this is 9, and 39.1166 $\times$ 9 = 352.0704 inches, or nearly 29 feet, the distance of the center of oscillation from the point of suspension.

Center of percussion, in a moving body, is that point where the percussion is the greatest, in which the whole percutent force of the body is supposed to be collected: or about which the impetus of the parts is balanced on every side: so that it may be stopped by an immovable obstacle at this point, and rest on it, without acting on the center of percussion: or, the center of percussion is that point in the axis of a vibrating or revolving body, which, striking against an immovable obstacle, causes the whole motion, estimated in the plane of the body's motion, to be destroyed. It is obvious, that if the obstacle be opposed to the moving body at different distances from the point of percussion, the stroke or percussion will not be equally powerful: and it is evident, that this center of percussion does not coincide with the center of gravity. Let the body, AB. (Plate VIII. Mechanics, fig. 67.) consisting of two equal balls fastened to a stiff rod, move in a direction parallel to itself, and it is evident that the two balls must have equal momentums, since their quantities of matter are equal, and they move with equal velocities. Now if in its way, as at N. II. an obstacle C be opposed exactly against its middle E, the body will thereby be effecitively stopped, nor can either end of it move forwards, for they exactly balance each other, the middle of this body being its center of gravity. Now should an obstacle be opposed to this body, not against its middle, but nearer to one end, as at N. III. then the stroke being not in the direction of the center of gravity, is in fact an oblique stroke, in which case, agreeably to the laws of congres, a part only of the momentum will be spent upon the obstacle, and the body advancing the end A, which is fartherl from the obstacle, as shewn by the dotted representation, will proceed with that part of the momentum which has not been spent upon the obstacle; consequently in this case the percussion is not so powerful as in the foregoing. Therefore there is a certain point in a moving body which makes a stronger impression on an obstacle than any other part of it. In the present case, indeed, this point coincides with the center of gravity; because the two ends of the body before the stroke moved with equal velocities. But in a pendulum the case is different; for let the same body of fig. 67. be suspended by the addition of a line AB, fig. 68, which line we shall suppose to be void of weight and flexibility, and let it vibrate round the point of suspension S. It is evident that now the two balls will not move with equal velocities; for the ball B, by describing a longer arc than the ball A in the same time, will have a greater momentum; and of course the point where the forces of the two balls balance each other, which is the center of percussion, lies nearer to the lower ball B; consequently this point does not coincide with the center of gravity of the body AB; but it is that point wherein the forces of all the parts of the body may be conceived to be concentrated. Hence the center of oscillation and the center of percussion coincide; or rather they are exactly the same point, whose two names only allude, the former to the time of vibration, and the latter to its striking force.

If in fig. 67, the balls A and B be not equal, their common center of gravity will not be in the middle at E, but it will lie nearer to the heavier body, as at D, supposing B to be the heavier body; so that the distances, BD, AD, may be inversely as the weights of those bodies. Now when the above-mentioned body is formed into a pendulum, as in fig. 68, though the weights A and B be equal, yet by their moving in different arcs, viz. with different velocities, their forces or momentums become actually unequal; therefore in order to find the point where the forces balance each other, so that when an obstacle is opposed to that point, the moving pendulum may be effectually stopped, and
and no part of it may preponderate, in which case the obstacle will receive the greatest impulse; we must find first the momentum of the two bodies A and B, then the distances of those bodies from the center of percussion, or, of equal forces, must be inversely as those moments. Thus the velocities of A and B are represented by the similar arcs which they describe, and those arcs are as the radii \( \overrightarrow{SA}, \overrightarrow{SB} \). Therefore the momentum of A is the product of its quantity of matter multiplied by \( \overrightarrow{SA} \), and the momentum of B is the product of its quantity of matter multiplied by \( \overrightarrow{SB} \); consequently \( \mathbf{A \cdot D} \) must be to \( \mathbf{B \cdot D} \), as the weight of B multiplied by \( \overrightarrow{SB} \) is to the weight of A multiplied by \( \overrightarrow{SA} \). Then \( \mathbf{D} \) is the center of percussion. And when four quantities are proportional, the product of the two extremes is equal to the product of the two means; therefore if the weight of A multiplied by \( \overrightarrow{AS} \), be again multiplied by \( \mathbf{AD} \), the product must be equal to the product of the weight of B multiplied by \( \overrightarrow{BS} \), and again multiplied by \( \mathbf{BD} \).

Center of percussion, locus of the. — The center of percussion is the same with the center of oscillation, where the percipient body revolves round a fixed point, and is determined in the same manner, viz. by considering the impetus of the parts, so many weights applied to an insensible right line, void of gravity; i.e. by dividing the sum of the products of the forces of the parts, multiplied by their distances from the point of suspension, by the sum of the forces. What, therefore, has been above shewn of the center of oscillation, will hold of the center of percussion, where the percipient body moves round a fixed point; e.g. that the center of percussion in a cylinder is at \( \frac{1}{2} \) of its length from the point of suspension; or that a duck of a cylindrical figure, supposing the center of motion at the head, will strike the greatest blow at a point about two-thirds of its length from the head. See Center of oscillation.

2. The center of percussion is the same with the center of gravity, if all the parts of the percipient body be carried with a parallel motion, or with the same celerity: for the moments are the products of the weights into the celerities. Wherefore, to multiply equiponderating bodies by the same velocity, is the same thing as to take equiparallels; but the equiparallels of equiponderating bodies themselves equiponderate; therefore, equivalent momenta are disposed about the center of gravity: consequently the center of percussion in this case coincides with that of gravity; and what is shown of the one, will hold of the other.

To find the center of percussion of a body. Let \( \mathbf{A \cdot B \cdot D} \) (fig. 69.) be a plane passing through the center of gravity \( \mathbf{G} \) of the body, and perpendicular to the axis of suspension which passes through \( \mathbf{C} \); and conceive the whole body to be projected upon this plane in lines perpendicular to it, or parallel to the axis: then, as each particle is thus kept at the same distance from the axis, the effect, from the rotary motion about the axis, will not be altered, nor will the center of gravity be changed. Let \( \mathbf{O} \) be the center of percussion, and draw \( \overrightarrow{p} \) perpendicular to \( \mathbf{p} \), and \( \overrightarrow{w} \) perpendicular to \( \mathbf{p} \); also \( \overrightarrow{v} \) perpendicular to \( \mathbf{G} \). As the velocity of any particle \( \mathbf{p} \) is as \( \mathbf{p} \), the momentum of \( \mathbf{p} \) in the direction \( \mathbf{p} \) is as \( \mathbf{p} \times \mathbf{p} \), being as the velocity of the lever, the efficacy of this force to turn the body about \( \mathbf{O} \) is as \( \mathbf{p} \times \mathbf{p} \times \mathbf{C} \times \mathbf{O} \times \mathbf{w} \) (because \( \overrightarrow{O \cdot w} = \mathbf{C} \times \mathbf{O} \times \mathbf{w} = \mathbf{O} \times \mathbf{C} \times \mathbf{O} \times \mathbf{w} = \mathbf{C} \times \mathbf{O} \times \mathbf{w} = \mathbf{G} \). Now the efficacy of all the particles to turn the body about \( \mathbf{O} \) may be \( \mathbf{r} \), we must make the sum of all the quantities \( \mathbf{p} \times \mathbf{w} \times \mathbf{C} \times \mathbf{O} = \) sum of all the quantities \( \mathbf{p} \times \mathbf{C} \times \mathbf{O} = \) sum of all the \( \mathbf{p} \times \mathbf{C} \times \mathbf{O} \); hence \( \mathbf{G} = \mathbf{r} \times \mathbf{G} \). Therefore the sum of the moments of all the particles is equal to the product of the center of gravity and the axis of vibration in that plane, is also \( \mathbf{r} \). But this is a problem of more difficult solution. As the force acting at \( \mathbf{O} \) destroys the motion, let its suppoasive force to act at \( \mathbf{O} \) and to generate the motion back again; then it is manifest, that the body would return to the point of suspension, and the same circumstances in which its motion ceased; that is, it would begin its motion by revolving about \( \mathbf{C} \). In this case \( \mathbf{C} \) is called the center of spontaneous rotation: making the plane the point at which a force acts upon a body that can move freely the center of percussion, the center of spontaneous rotation coincides with the center of rotation corresponding to that center of percussion. Vinci's Principles of Dynamics, p. 125. Parkinson's System of Mechanics, &c., p. 194.

Center of a parallelogram, the point wherein its diagonals intersect.

Center of position, denotes a point of any body, or system of bodies, so selected, that we may properly estimate the situation and motion of the body or system by those of this point. It is evident that, in mechanical discussions, the point, by the position of which we estimate the position and distance of the whole, must be so determined, that its position and distance, estimated in any direction whatever, shall be the average of the positions and distances of every particle of the mass, estimated in the same direction. Accordingly this will be the case, if the point be so selected that, when a plane is made to pass through it in any direction whatever, and perpendiculars are drawn to this plane from every particle in the body or system, the sum of all the perpendiculars on one side of this plane is equal to the sum of all the perpendiculars on the other side. If there be such a point in the body, the position and motion of this point are the average of the positions and motions of all the particles. For if \( \mathbf{P} \) (Plate 1X. Mechanism, fig. 70.) be a point of transit, and if \( \mathbf{Q} \) be a plane (perpendicular to the paper) at any distance from it, the distance \( \mathbf{P} \) of the point from this plane is the average of all the distances of all the particles from it. Let for the plane \( \mathbf{A \cdot P \cdot B} \) be passed through \( \mathbf{P} \), parallel to \( \mathbf{Q} \). The distance \( \mathbf{D} \) of any particle \( \mathbf{C} \) from the plane \( \mathbf{Q} \) is equal to \( \mathbf{D} = \mathbf{D} \), or to \( \mathbf{D} = \mathbf{D} \). And the distance \( \mathbf{G} \) of any particle \( \mathbf{G} \), lying on the other side of \( \mathbf{A \cdot P \cdot B} \), is equal to \( \mathbf{G} = \mathbf{G} \). Let \( \mathbf{n} \) be the number of particles on that side of \( \mathbf{A \cdot B} \), half of which are nearest to \( \mathbf{Q} \), and let \( \mathbf{m} \) be the number of those on the remote side of \( \mathbf{A} \), and let \( \mathbf{m} \) be the number of particles in the whole body, and therefore equal to \( \mathbf{n} + \mathbf{m} \). It is evident that the sum of the distances of all the particles, such as \( \mathbf{C} \), is \( \mathbf{n} \times \mathbf{P} \), after deducting all the distances, such as \( \mathbf{D} \). Also the sum of all the distances of the particles, such as \( \mathbf{G} \), is \( \mathbf{n} \times \mathbf{P} \), together with the sum of all the distances, such as \( \mathbf{G} \). Therefore the sum of both facts is \( \mathbf{n} + \mathbf{m} \times \mathbf{P} + \mathbf{G} \). But the sum of all the \( \mathbf{D} \), or \( \mathbf{m} \times \mathbf{P} \), the sum of \( \mathbf{G} \), or \( \mathbf{G} \); but the sum of \( \mathbf{D} \), or \( \mathbf{m} \times \mathbf{P} \), the sum of \( \mathbf{G} \), or \( \mathbf{G} \).
by the supposed property of the point P. Therefore $m \times P_0$ is the sum of all the distances, and $P_0$ is the nth part of this sum, or the average distance.

Now suppose that the body has changed both its place and its position with respect to the plane $QR$, and that $P$ (fig. 71) is still the same point of the body, and $A \beta$ a plane parallel to $QR$. Make $p = \alpha P \beta$ equal to $P_0$ of fig. 70. It is plain that $P_0$ is still the average distance, and that $m \times P_0$ is the sum of all the distances of the particles from $QR$, and that $m \times P_0$ is the sum of all the distances.

Therefore $m \times P = \pi$ is the sum of all the changes of distance, or the whole quantity of motion elastically determined in the direction $n$. $P_0$ is the nth part of this sum, and is therefore the average motion in this direction. The point $P$ has therefore been properly selected: and its position, and distance, and motion, in respect of any plane, is a proper representation of the situation and motion of the whole.

It follows from the preceding discussion, that if any particle $C$ (fig. 70.) moves from $C$ to $N$, in the line $C S$, the centre of the whole will be transferred from $P$ to $Q$, so that $P Q$ is the nth part of $CN$; for the sum of all the distances has been diminished by the quantity $CN$, and therefore the average distance must be diminished by the nth part of $CN$, or $P Q = \frac{CN}{m}$.

But it may be doubted whether there is in every body a point, and but one point, such that if a plane passes through it, in any direction whatever, the sum of all the distances of the particles on one side of this plane is equal to the sum of all the distances on the other side.

It is easy to show that such a point may be found, with respect to a plane parallel to $QR$. For if the sum of all the distances $DC$ exceed the sum of all the distances $GH$, we have only to pass the plane $AB$ a little nearer to $QR$, but still parallel to it. This will diminish the sum of the lines $DC$, and increase the sum of the lines $GH$. We may do this till the sums are equal.

In like manner we can do this with respect to a plane $LM$ (also perpendicular to the paper), perpendicular to the plane $AB$. The point wanted is somewhere in the plane $AB$, and somewhere in the plane $LM$. Therefore it is somewhere in the line in which these two planes intersect each other. This line passes through the point $P$ of the paper where the two lines $AB$ and $LM$ cut each other. These two lines represent planes, but are, in fact, only the intersection of those planes with the plane of the paper. Part of the body must be conceived as being above the paper, and part of it behind or below the paper. The plane of the paper therefore divides the body into two parts. It may be so situated, therefore, that the sum of all the distances from it to the particles lying above it shall be equal to the sum of all the distances of those which are below it. Therefore the situation of the point $P$ is now determined, namely, at the common intersection of three planes perpendicular to each other. It is evident that this point alone can have the condition required in respect of these three planes.

But it still remains to be determined whether the same condition will hold true for the point thus found, in respect to any other plane passing through it; that is, whether the sum of all the perpendiculars on one side of this fourth plane is equal to the sum of all the perpendiculars on the other side. Theore.

Let $AGHB$ (fig. 72.) $A X Y B$, and $CDFE$, be three planes intersecting each other perpendicular in the point $C$, and let $C I K L$ be any other plane, intersecting the first in the line $C I$, and the second in the line $CL$. Let $P$ be any particle of matter in the body or system.

Draw $PM$, $PO$, $PR$ perpendicular to the first three planes respectively, and let $PR$, when produced, meet the oblique plane in $V$; draw $MN$, $ON$, perpendicular to $CB$. They will meet in one point $N$. Then $PMNO$ is a rectangular parallelogram. Also draw $MQ$ perpendicular to $CE$, and therefore parallel to $AB$, and meeting $CI$ in $S$. Draw $SV$; also draw $ST$ perpendicular to $VP$. It is evident that $SV$ is parallel to $CL$, and that $STRQ$ and $STPM$ are rectangles.

All the perpendiculars, such as $PR$, on one side of the plane $CDFE$, being equal to all those on the other side, they may be considered as coexisting each other; the one being considered as positive or additive quantities, the other as negative or subtractive. There is no difference between their sums, and the sum of both sets may be called $0$, or nothing. The same must be allowed of all the perpendiculars $PM$, and of all the perpendiculars $PO$.

Every line, such as $RT$, or its equal $QS$, is in a certain invariable ratio to its corresponding $QC$, or its equal $PO$. Therefore the positive lines $RT$ are compensated by the negative, and the sum total is nothing.

Every line, such as $TV$, is in a certain invariable ratio to its corresponding $ST$, or its equal $PM$, and therefore their sum total is nothing.

Therefore the sum of all the lines $PV$ is nothing; but each is in an invariable ratio to a corresponding perpendicular from $P$ on the oblique plane $C I K L$. Therefore the sum of all the positive perpendiculars on this plane is equal to the sum of all the negative perpendiculars, and the proposition is demonstrated, viz. that in every body, or system of bodies, there is a point such, that if a plane be passed through it in any direction whatever, the sum of all the perpendiculars on one side of the plane is equal to the sum of all the perpendiculars on the other side.

The point $P$, thus selected, may, with great propriety, be called the center of position of the body or system.

If $A$ and $B$ (fig. 73.) are the centers of position of two bodies, whose quantities of matter (or numbers of equal particles) are $a$ and $b$, the center of the straight line joining $A$ and $B$, and $AC : BC = b : a$, or its distance from the centers of each are invariable as their quantities of matter. For let $AC \beta$ be any plane passing through $C$. Draw $A \alpha$, $B \beta$, perpendicular to this plane. Then we have $A \alpha = B \beta$, and $B \beta = a : b$; and, by the similitude of triangles, $CA \cdot CB = a : b$.

If a third body $D$, whose quantity of matter is $d$, be added, the common center of position $E$ of the three bodies is in the straight line $DC$, joining the center of the third body with the center $C$ of the other two, and $DE : EC = a + b : d$. For passing the plane $DE$ through $E$, and drawing the perpendiculars $D \delta$, $C \chi$, the sum of the perpendiculars from $D$ is $d \times D \delta$; and the sum of the perpendiculars from $A$ and $B$ is $a + b + C \chi$, and we have $d \times D \delta = a + b + C \chi$, and therefore $DE : EC = a + b : d$.

In like manner, if a fourth body be added, the common center is in the line joining the fourth with the center of the other three, and its distance from this center and from the fourth is invariable as the quantities of matter; and so on for any number of bodies.

If all the particles of any system be moving uniformly, in straight lines, in any directions, and with any velocities whatever, the center of the system is either moving uniformly in a straight line, or is at rest.

For, let $m$ be the number of particles in the system. Suppose any particle to move uniformly in any direction. It is evident from the reasoning in a former paragraph, that the
the motion of the common center is the n-th part of this motion, and is in the same direction. The same must be said of every particle. Therefore the motion of the center is the motion which is compounded of the n-th part of the motion of each particle. And because each of these was supposed to be uniform and rectilinear, the motion compounded of them all is also uniform and rectilinear; or it may happen that they will be compensative each other that there will be no diagonal, and the common center will remain at rest.

Cor. 1. If the centers of any number of bodies move uniformly in straight lines, whatever may be the motions of each particle of each body, by rotation or otherwise, the motion of the common center will be uniform and rectilinear.

Cor. 2. The quantity of motion of such a system is the sum of the quantities of motion of each body, reduced to the direction of the center's motion. And it is had by multiplying the quantity of matter in the system by the velocity of the center.

The velocity of the center is had by reducing the motion of each particle to the direction of the center's motion, and then dividing the sum of those reduced motions by the quantity of matter in the system.

By the selection of this point, we render the investigation of the motions and actions of bodies incomparably more simple and easy, freeing our calculations from numberless intricate complications of motion, which would frequently make our progress almost impossible. That there is in every body such a point has been demonstrated in the manner above stated by Dr. Robiton (after Bodinovich) in his Elements of Mechanical Philosophy, &c. Svo. 1803, p. 76 &c.

The center of pressure, in Hydrostatics, is that point of a surface, against which any fluid pressure, in which the whole pressure may be conceived to be united; or, as Mr. Cotes has defined it, is that point, in which, if the total pressure on any plane were applied, its effect upon the pane would be the same as when it was distributed unequally over the whole; or again, it is that point to which, if a force were applied, equal to the total pressure, but with a contrary direction, it would exactly balance or still itself in the effect of the pressure, and keep the surface at rest.

Thus if be de (Plate IX. Mechanic, Fig. 74) be a vessel or water, and the fluid be supported upon a force equivalent to 20 pounds of water, this force is unequally distributed over a; for the parts near a being at a lesser depth, are press'd up more than the parts near c, which are at a greater depth, and therefore the efforts of all the particular pressures are united in some point as e, which is nearer to e than to a, and that point e is what may be called the center of pressure. If to that point a force equivalent to 20 pounds weight be applied, it will affect the plane ac in the same manner as before by the pressure of the water distributed unequally over the whole; and if to this same point we apply the same force with a contrary direction to that of the pressure of the water, the force and pressure will balance each other, and by contrary endeavours destroy each other's effects. Suppose at e a cord p q were fixed, which passing over the pulley p has a weight, we, of 20 pounds annexed to it, and that the part of the cord p q were perpendicular to a c; the effect of the weight we is equal, and its direction contrary to that of the pressure of the water. Now if e be the center of pressure, these two powers will be in equilibrium, and mutually destroy each other's endeavours.

To find the center of pressure of a plane surface. Let A B C D (fig. 75) be the surface of the fluid, V W the plane, in which produced, let c d be its intersection with the surface, P the center of pressure, and G the center of gravity; and conceive the whole plane to be divided into an infinite number of indefinitely small parts, of which one is x y draw P Q, G x, perpendicular to the surface, and P a, G n, x m, perpendicular to c d; and join Q n, a m, w m; then it is manifest that the triangles P Q a, G x, w m, are similar. Now the pressure on x perpendicular to V W is as x x w (being as the particle or number of particles x the depth); and its effect to turn the plane about c d is as x x w x x m; but, by similar triangles, G x : G n :: x x m : x w = x m x G x : G n ; hence the effect of the pressure at x to turn the plane about c d is as x x m x x m x G x : G n ; therefore the whole effect is as the sum of all the pressure on all the x x m x x m x G x : G n ; for if A = the area of V W, the pressure on V W is as A x G x; therefore the effect of that pressure at P to turn the plane about c d is as A x G x x P a. Hence A x G x x P a = the sum of all the x x m x x m x G x : G n. Consequently P a = sum of all the x x m x x m x G x : G n. Hence it appears, that P is at the same distance from c d as the center of periphery is from the axis of fulcrum.

They do not, however, in general lie in the same line, that is, in the line n G; for the efficacy of the point at x, to turn the plane about G, is as x x w x x m, or (since x w varies as x m) as x x m x m, but the sum of all the x x m x m x m is not generally as a; therefore the whole pressure will not necessarily balance itself upon the line G. The situation of the line A P must therefore be determined, by making the sum of all the x x m x m x m = a. The centers of pressure and periphery are not therefore in general coincident, taking the center of periphery a in its usual acceptation. Ob. The center of periphery has always been defined to be that point in the line n G at which all the motion of the body would be destroyed, estimating the motion of the body at the line c d; but the body, after its action against that center, may still have a tendency to turn about the line n G. If, therefore, we were to define the center of periphery to be that point at which the whole motion of the body would be destroyed, the centers of pressure and periphery would not, in general, coincide; in which case, the position of the line A P is determined on the same principle. See p. 75. Principles of Hydrostatics, p. 47. &c. Venetian Principles of Hydrostatics, p. 100.

The center of a regular prism, or regular body, is the same as that of the included or circumscribed sphere or circle.

The center of rotation, is that point about which a body, otherwise at liberty, revolves or tends to revolve, when it is acted upon equally at different points, or by a force in the direction of which does not pass through its center of gravity. M. L. Bernouilli was the first who published anything on this subject; and he first found the point about which a body at rest would begin to revolve, when struck by another body, and he called this point the "monumental center of rotation," to distinguish it from the center of linear rotation. He observes, however, that D. Bernouilli had discovered the same; he has also mentioned the curve described by that point in the progressive motion of the body, and has directed a method of inquiry by which the velocities of the bodies may be found after the stroke. Two years afterwards D. Bernouilli published an paper on progressive and rotary motion, containing not the more than what J. Bernouilli had before given. Euler has also investigated the velocities of the
the bodies after impact in a manner somewhat different, but
he has rendered it much more intricate by a fluxional cal-
culus. Mr. Vince has treated this subject much at large and
with great perspicuity in the Philosophical Transactions, vol.
lxxv. (for 1750) p. 519, &c. He begins with the most sim-
ples cases, and then proceeds to those that are more complica-
ted: and he comprehends the whole in a variety of dis-
tinct propositions.

1. Let A and B (Pl. IX, Mechanics, fix. 76) be two in-
definitely small bodies connected by a lever void of gravity: and
suppose a force to act at any point D perpendicularly to the
lever; and it be required to find the point about which the
bodies will begin to revolve.

By the property of the lever, the effort of the force act-
ing at D on the body is to the effect on B :: BD : AD; and
therefore the ratio of the spaces Am, Dm, deflected by the
bodies A and B in the first instant of their motion will be as
BD : AD :: AB : B; join mn, and produce it if necessary, and also
AB to meet in C, and this will be the point about which
the bodies begin to revolve. Hence from similar figures
BC : AC :: AD : BD (Ba) :: A : AB (Am) :: A : AD : BD ; or DC - DB : AD + DC :: A : AD :: BD : AD + BD ; and consequently DC = BD - AD - AD ; and therefore DC is the center of percussion or occlusion to
the point of fulcrum C. Hence, whatever be the magni-
tude of the stroke at D, the point C will remain the same.
Moreover, if the force acts at the center of gravity, G, the
bodies will have no circular motion; for in this case BD =
AD : A : AD = 0: and therefore DC becomes infinite.
Further, if the force acts at one of the bodies, the
center of rotation, C, will coincide with the other body.
Also, if the lever had been in motion before the stroke, the
point C, at the instant of the stroke, would not have been
disturbed.

2. Let a given quantity of motion be communicated to the
lever at D, to determine the velocity of the center of gravity, G. The
space Am is as DB
A
; and CG = CD - DG = CD -
AG + AD = A + AD + BD - A = BD - AD - AD = BD = BD - AD - AD ; also CA = CD + DA = BD + BD - AD = BD + BD - AD ; hence we have
B + BD - AD = A + AD + BD + AD = B + BD - AD - AD = A + AD + BD - AD - AD = AD + BD - AD - AD = A
or G = v, the velocity of the center of gravity: hence if the
motion be communicated at G, the velocity becomes
A + B.

Let the motion, supposed to be actually communicated to the
rod at D, be equivalent to the motion of a body whose magnitude is G, and moving with a
velocity v; then, if that motion be communicated at G, the velocity of the center of gravity will be

\[
\frac{G \times v}{A + B} = \frac{B + B \times G + A \times A + G}{A + B}.
\]

3. Let a given elastic body P, moving with a given velocity, be supposed to strike the lever at the point D, in a direction per-
pendicular to it; and it be required to determine the velocity of the
center of gravity G after the stroke. Suppose, first, the
body to be non-elastic, and let v be the velocity of the
center of gravity after the stroke, and V the velocity of the
striking body: then CG = CD = v :: CD = v =
the velocity of the point D, after the stroke, or of the body P;
for the same reason, \(\frac{v \times CA}{C + G} \) and \(\frac{v \times CB}{C + G} \) equal the velocities
of A and B respectively. Now, because in revolving bodies, the momenta arising from the magnitude of the bodies,
their distance from the center of rotation and velocity con-
jointly, remain the same after the stroke as before it, we shall have

\[
\frac{v \times CD}{C + G} = \frac{P \times V + DC}{P + V} + \frac{v \times CA}{C + G}.
\]

or

\[
A + B \times G + P \times DC = A + B \times G + P \times DC.
\]
hence if P be supposed an elastic body, we shall have

\[
A + B \times G + P \times DC = \frac{2 \times P \times V \times CG}{C + G}.
\]

4. Let a motion be communicated to the lever obliquely, and
it be required to determine the point about which the bodies begin to
revolve. Let F D (fig. 77.) represent the force communicating
the motion at the point D, and resolve it into two others, FH, HD, the former F H parallel to the lever, and the latter H D perpendicular to it. Let G be the
point about which the bodies would have begun to revolve, if the
force HD alone had acted, which may be found by
Art. 1; and suppose in this case \(m \approx n \) to have been the next
position of the lever after the commencement of the motion,
or that the bodies A, B, and center of gravity G, had been
carried to m, g, and n, respectively. But as the force
FH acts at the point D at the same time in the direction of
the rod, if we take G as FH; HD, then whilst the
center of gravity would have moved from G to g in
consequence of the force H.D, it will be by means of the force
FH be carried in the direction of the lever from G to g,
and also every other point of the lever will be carried in
the same direction with the same velocity; take therefore
A and B each equal to G; and complete the paral-
lelograms A, G, and B, and the bodies A, B, and
center of gravity G will, at the end of that time, be
found at a, b, and \(a \approx b \), respectively, and \(a \approx b \) will be the
position of the lever. Now it is evident, that C is not
the point about which the bodies begin to revolve, for

\[
\frac{1}{A + B}.
\]
(considering the lever to be produced to C) that point must have moved over a space CE equal to CGy, when the lever is come into the position a w b; draw CO perpendicular to CE, and G O perpendicular to GC; and O will be the center of rotation at the commencement of the motion. For conceive CO to be a lever, then the lever A B C has a circular motion about C, whilst that point is moving from C to E, and consequently the point O is carried forward in a direction parallel to CO by this motion; but as the lever CO is carried by a circular motion about C in a contrary direction, it is evident that that point of the lever CO must be at rest where those two motions are equal, as they are in contrary directions. Now the velocity of C in the direction CO : velocity of G about C :: CG:y : G O :: (by fim. triangle) CO : CG, and the velocity of the point G about C: velocity of the point O about C :: CG : CO; hence ex aequo the velocity of C in the direction G O, or of O in the direction O P parallel to CO, is equal to the velocity of the base point O in a contrary direction arising from its rotation about C, and consequently O being a point at rest, must be the center of rotation in ipso motu initio. Also, because m is equal and parallel to a b, a b must be equal and parallel to m n, therefore the angular velocity is just the same as if the force FH had not acted. The center O of rotation at the beginning of the motion being thus determined, every thing relative to the motion of the bodies after they are at liberty to remove freely, may be determined as in the proceeding propositions.

Cor. 1. Hence it appears, that whatever be the magnitude or direction of the force communicating the motion, or the point at which it acts, the center of gravity will move in a line parallel to the direction of the force, for the triangles F H D, G g w being similar, G w must be parallel to F D.

Cor. 2. The same is manifestly true for any number of bodies; for let (fig. 78.) E be a third body, and conceive it to be connected with the other two bodies A and B in their center of gravity G; then if F D represents the force acting at the point D, it is evident from the last Corol. and the second Prop. that the center of gravity moves with the same velocity and in the same direction, as if the same motion had been communicated at G in a line R G parallel to F D, and that the center of gravity has the same velocity communicated to it, as if the two bodies had been placed at G; conceive therefore the bodies A and B to be placed at G, and let the force act at D, and then from the last Corol. the center of gravity g, of the three bodies, will move in a line parallel to the direction of the force communicated. In the same manner it may be proved for any number of bodies.

The method here used for determining the point of rotation in ipso motu initio, when a single force acts at any point D, may be applied, when any number of forces act at different points at the same time. For let (fig. 79.) a, b, g, &c. represent the forces acting on the lever at the points D, E, F, respectively, &c. then from the same principles the effect of all the forces on A: the effect on B::

\[
\begin{align*}
\frac{A}{B} & = \frac{a}{b} + \frac{\beta}{\gamma} + \text{ &c.} = \frac{A D + A E + A F}{B D + B E + B F} + \text{ &c.}
\end{align*}
\]

which quantities put equal to P and Q respectively, and then the ratio \(\frac{P}{Q}\) :: A:m: B:n :: A C: B C, from whence it appears, that (putting G C + G A = A C and G C + G B = B C) the distance G C = \(\frac{A \times P + B \times Q}{A \times Q - B \times P}\). The same conclusion might have been deduced from this consideration: that if any number of forces act on a lever, the effect on any point of that lever is just the same as if a force, equivalent to the sum of those forces, had acted at their common center of gravity; and therefore their common center of gravity, and conceive a force equivalent to them all to be communicated to that point, and the problem is reduced to the case of the first proposition. If any of the forces had acted on the opposite side of the lever, such forces must have been considered as negative.

If there be any number of bodies placed on the lever, and a single force acts at D, it will appear from the same principles that the point C, about which they begin to revolve, will be the point of fixation to the center of percussion D; and the same conclusion will be obtained, if the bodies be not situated in a straight line.

5. If a force acts upon a body in any given direction not passing through the center of gravity; to determine the plane of rotation, the direction in which the center of gravity begins to move, and its motion after. Conceive a plane A y B Z (fig. 79.) to be supported upon a line A B passing through its center of gravity G, and suppose a force to act at any point D in that line, and in a direction perpendicular to the plane; then it is manifest, that such a force can give the plane no rotatory motion about A B. Imagine now the support to be taken away whilst the force is acting at D, then it is evident, that as the plane had no tendency to move about A B as an axis, and the taking away of the support can give it no such motion, it will, by Cor. 2. Art. 4. begin its progressive motion in the direction in which the force acts; and as the force is supposed not to act at the center of gravity, it must at the same time have a rotatory motion about some axis, and as it has no motion about A B, must be somewhere in the plane, and perpendicular to A B; and consequently in ipso motu initio the plane of rotation must be perpendicular to the plane A y B Z. Let L C M, perpendicular to A B, be the axis about which the plane begins to revolve, and A y, B Z be two equal particles of the plane similarly situated in respect to A B, also A y, B Z are perpendicular to L C M. Now the centrifugal force of p, or its force in the direction a p = p x a p, and that of q in the direction b q = q x b q; to determine now how these forces will affect the motion of the plane, we may observe, in the first place, that the force p x a p, acting at a in the plane, must tend to give it a motion about an axis perpendicular to the plane; but as an equal force q x b q acts at q to give it a motion in a contrary direction, it is evident that the two forces will destroy each other, so far as they tend to generate any motion in the plane about an axis perpendicular to it; and hence it is manifest, that if the parts of the plane A y B, A Z B, be similar, and similarly situated in respect to A B, the plane, after the commencement of the motion, will have no tendency to revolve about an axis perpendicular to it. Also, as the centrifugal force of each particle acts in a direction parallel to A B, it can give the plane no tendency to revolve about that line as an axis, and consequently the plane of rotation will be preferred as in ipso motu initio. Conceiving therefore the plane on each side the line A B to be similar, and similarly situated, suppose another plane to be fixed upon this, whose parts on each side A B are similar, and similarly situated, and the force to act as before, then it is manifest, that as each plane endeavours to prefer the same plane of rotation, the
two planes connected will also continue to move in the same plane of rotation, for the action of one plane on another, on each side the plane of rotation, being equal, cannot tend to disturb the motion in that plane; and as this must be true for any number of planes that similar and familiar situated, it is evident, that if a force should act upon a body, and each section, perpendicular to the direction of the force, should be similar on each side the plane passing through the direction of the force, and the center of gravity of the body, that plane would be the plane of rotation in which the body would both begin and continue its motion. It appears also, from what has been proved, that if every section on each side that plane had not been similar, the plane of rotation would not necessarily have continued the same after the commencement of the motion. Hence all bodies, formed by the revolution of any plane figure, will have the axis about which they were generated, a fixed axis of rotation; to determine, however, every other axis of a body about which it would continue to revolve, would be foreign to the present subject. Supposing therefore the plane of rotation to continue the same, imagine all the particles of the body to be referred to that plane orthographically, which supposition not affecting the angular motion of the body, the centrifugal force of all the particles, to cause the body to revolve about an axis perpendicular to that plane, will remain unaltered. Let L M N O (fig. 83.) be that plane, and suppose a force to act at A in the direction P A living in the same plane, which produce until it meets L N, passing through the center of gravity G, perpendicularly in D; then by Cor. 2. Art. 4. the center of gravity G will begin its motion in a line parallel to P A, or perpendicular to L N; and consequently the center C, about which the body begins to revolve, must lie somewhere in the line L N. Now the centripetal force of any particle P is \( p \times \frac{r^2}{R^2} \); let fall a perpendicular to L N, then the effect of that force at C, in a direction perpendicular to L N, will be \( p \times \frac{r^2}{R^2} \); and in the direction C L it will be \( p \times \frac{r^2}{R^2} \); but as the sum of all the quantities \( p \times \frac{r^2}{R^2} \), it follows from the same reasoning as in Art. 3. that the point G will continue to move in a direction perpendicular to L N; and also, as the forces \( p \times \frac{r^2}{R^2} \) act in a direction perpendicular to that in which the center of gravity moves, its motion must be continued uniform. In the following proposition, therefore, we suppose the axis to be fixed, after the commencement of the motion, to continue perpendicular to the plane passing through the direction of the force and the center of gravity of the body, and that the body itself is orthographically projected upon that plane; also in the case of the action of two bodies on each other, the plane passing through the direction of the striking body and point of percussion is supposed to pass through the centers of gravity of each body; that the axis of each body after it is fixed continues perpendicular to that plane, and that each body is reduced to it in the manner above described.

6. To determine the point about which a body, when struck, begins to revolve. Let L M N O (fig. 83.) represent the body, G the center of gravity, and P A the direction of the force acting at A, which produce till it meets L N, passing through G, perpendicularly in the point D; draw \( p b \) perpendicular to \( p c \), on which (produced if necessary) let fall the perpendicular D w; C being supposed the point about which the body begins to revolve, and which, from the last proposition, is somewhere in the line L N. Because the body, in consequence of the force acting at D, begins to revolve about C, and consequently if immediately after the beginning of the motion a force were applied at D equal to it, and in a contrary direction, the motion of the body would be destroyed. It is evident, that the efficacy of the body revolving about C, to turn the body about D, should any obstacle be opposed to its motion at that point, must be equal to nothing; for were it not, the body, when stopped at D, would still have a rotatory motion about that point, and consequently two equal and contrary forces applied at D would not destroy each other's efficacy, which would be absurd. Now the force of a particle \( p \), in the direction \( p c \), being \( p \times p c \), its efficacy to turn the body about the point D is \( p \times p c \times D w \); but by sim. trian.,

\[ D w = D b \times p \frac{a c}{p c} \]

and consequently the efficacy to turn the body about \( D = p \times D b \times p \frac{a c}{p c} \). 

Hence \( p \times p c \times D w = \frac{p c}{p c} \times D b \times a c \); and consequently the efficacy to turn the body about \( D = \frac{p c}{p c} \times D b \times a c \). 

Hence \( D w = D b \times p \frac{a c}{p c} \), and consequently the efficacy to turn the body about \( D = \frac{p c}{p c} \times D b \times a c \).
part of a long object glass were exactly in the middle, yet it may be a very good one when it is an inch or two out of it.

ject glass.

CENTESIMA, in Roman Antiquities, that wherein the inter-est in an hundred months became equal to the prin-
cipal; i.e. where the money is laid out at one per cent. per
month, answering to what in our line would be called 12 per cent. for the Romans reckoned their interest not by the
year, but by the month.

CENTESIMUM, in Ancient Geography, a piece of Italy,
in Umbria, S.W. of Nuceria. Its name indicates its dif-
tance from Rome.

CENTESIMATION, in Ancient Military History, a
punishment reorted to in cases of mutiny, defection or the
like, by which every one hundredth man only was executed
or punished with death.

CENTESMI, the 10th part of any thing.

CENTAVIUS, in Middle Age Writers, the same
with CENTAVRUS.

CENTIARE, in French Superficial Measure. 100 square
meters or 930.4 square feet. See Measure.

CENTIBAR, in French Measures of Capacity, the hun-
dredth part of a bar, called also decal, containing 10 cubic
decimeters of water, and weighing 20.444 French pounds.

See Measure.

CENTICAD, a bushel, 10 cubic decimeters, or 10.5
Paris pints, or .578 Paris bushel. See Measure.

CENTIGRAM, or dram, the hundredth part of a
Grave, weighing 2 gros, 44.41 grains. A piece of silver
coin weighing a centigrave, is denominated a Franc of silver,
and, according to the former standard, will be worth 40 sols
10\textdegree} deniers.

CENTIGRAV, contains 1,000 cubic decimeters, and
weighs 1.481 grain.

CENTILIOQUIUM, from centum, a hundred, and logor;
I speak, denotes a collection of an hundred Sentences, opin-
ions, or sayings.

CENTIME, in French Money, the hundredth part of
a livre. See Money.

CENTIMETRE, in French long Measure, is the hun-
dredth part of a metre or 4.444 lines. A cubic centimetre of
water is named a Gravit or Miller, and weighs 18.441
grams.

CENTINEL or Centry, in French Sentinelle, is a soldier
from a guard, placed at any poll for the security of the fald
guard, or any other body of troops, for watching the enemy,
preventing surprizes, and stopping those who might wish to
pass without orders, and without making themselves known.
All centinels ought to be very vigilant on their polls, should
avoid finging, smoking, making any noise themselves, or
suffering any to be made near them by others. They should
keep their arms in their hands during the whole time they
are on duty, should not sit down, or on any account go to
sleep, as on their attention and watchfulness depend the lives
of many; but should keep moving about, if the weather will
permit them. They ought never to move farther from their
polls in any directions, than to distances from which they
can have distinct views of them, as well as of the intervening
and intervening spaces. And should the weather be ever so bad,
they ought not to go under any other cover than that of their
centry boxes. Not one of them should be allowed to quit
his poll without leave from his commanding officer. And
in order to prevent defection, marauding, or other irregulari-
ties; they should be strictly charged to let no soldier pass
them.

CENTINEL perdu, in French Sentinelle perdu, is a soldier
placed at a very hazardous poll, or in a situation where he
is in constant danger of being attacked, taken, or killed
by the enemy without any prospect of aid, help (holp) or relief.
Hence the phrase fortun perdu, commonly pronounced forlorn
hope.

CENTINEL, Great and Little, in Geography, two islands
in the Indian Sea: the former five leagues from the Great
Andaman; and the latter seven leagues N.W. from the
Little Andaman.

CENTINODIUM, an official plant, popularly called
botanics polygium; reputed an allrin-
gent and vulnerary.

CENTIPES, CENTIPEDIL, in Entomology. See Scro-
lopendra.

CENTIUM, Putei, in Ancient Geography, a place of
Asia in Syria, situated on a large plain, and surrounded by
mountains.

CENLANCES, in Military Language, a name given to
a Scottish company of gendarmerie, established in 1422
by Charles VII. of France.

CENTILVRE, Susanna, in Biography, a dramatic
writer, was the daughter of Mr. Freeman, a gentleman of
Lincolnshire, who, being attached to the parliamentary
camp, took refuge in Ireland at the restoration. She
is supposed to have been born in Ireland about the year 1667.
Discovering an early propensity to poetry and a romantic
disposition, and being ill-treated by those who had the
care of her after the death of her mother, she resolved on a
visit to London; and in the course of her journey, which she
performed on foot, she was met by Anthony Hammond, eq.,
then a student at the University of Cambridge. This
gentleman caused her to assume a boy's garb, and took her
with him to college, where she spent some months in his
company, but fearing a discovery, he persuaded her to go
to London, where, being in her 15th year, she married a
nephew of Sir Stephen F. By having in about a year lost
her husband, she soon after married Mr. Carroll, an officer
in the army, whom she left in a duel about a year and a half
after their union. She then commenced her course as a
dramatic writer, and made her first attempt in tragedy.
Accordingly in 1700 her "Perjured Husband" was
performed at Drury-lane. She afterwards wrote several
comedies, which were chiefly translations from the French,
and which obtained temporary success. One of them,
etitiled "The Gameller," was honour'd with a prologue by
Rowe. She also made some trial, without rising to any
great reputation, as an actress. Under this character,
however, she performed before the court on the stage at
Windlor, and captivated the heart of Mr. Joseph Centlivre,
young man of the mouth to Queen Anne, whom she married
in 1756. Of the number of her comedies, which she
produced with great fertility, we may reckon "The Bufty Body,"
performed in 1708; "The Wonder, a Woman keeps a
Secret," in 1714; and "A bold Stroke for a Wife," in
1715. The licentiousness which at that time characterized
the English stage is too apparent in her productions. She
lived, however, on terms of friendship and familiarity with
most of the wits of that period, as Steele, Rowe, Farquhar,
and Bulstrode; but upon incuring the displeasure of Pope,
she was introduced into the Dunciad. Her person was
handsome, her conversation sprightly, and her disposition
friendly and benevolent. She died in 1753. Her dramatic
works were printed in 1761, in 3 vol. 12mo. Her verses
and letters were collected and published by Mr. Boyer.

CENTNER, or Dzensnog Hundred, in Metallurgy
and Assaying, is a weight divisible, first into an hundred, and
thence into a greater number of other smaller parts; but
though the word is the same, both with the assayers and
metallurgists,
metallurgists, yet it is to be understood as expressing a very
different quantity in their different acceptance of it. The
weights of the metallurgists are catly understood, as being of
the common proportion, but those of the affayers are a
thousand times smaller than these, as the portions of metals
or ores examined by the affayers are usually very small.
The metallurgists, who extract metals out of their ores,
sue a weight divided into an hundred equal parts, each part
a pound; the whole they call a centun or hundred weight;
the pound is divided into thirty-two parts, or half ounces;
and the half ounce into two quarters of ounces, and these
each into two drams.

These divisions and denominations of the metallurgists are
catly understood; but the same words, though they are
equally used by affayers, with them express very different
quantities: for as the centun of the metallurgists contains
a hundred pounds, the centun of the affayers is really no
more than one drachm, to which the other parts are propor-
tioned.

As the affayers' weights are divided into such an extreme
degree of minuteness, and are so very different from all the
common weight, the affayers usually make them themselves
in the following manner, out of small flaker, or fine folder
plates, of such a size, that the mark or their weight, ac-
cording to the division of the dram, which is the docimatic,
or affaying centun, may be put upon them. They first
make a half an ounce weight, being about two thirds of a
common dram; this they mark (63:8.) Then having at
hand some granulated lead, washed clean, well dried, and
fitted very fine, they put as much of it in one of the small
dishes of a fine balance, as will equipotence the 63:8. (as it
is called) just mentioned; then dividing this granulated lead
into very nice halves. In the two scales, after taking out the
first flaker weight, they obtain a perfect equilibrium between
the two scales; they then pour the granulated lead out of
one dish of the scales, and instead of it put in another flaker
weight, which they make exactly equiperpondent with the
lead in the other scale, and mark it (6:x.) If this second
weight, when first put into the scale, exceed by much the
weight of the lead, they take a little from it by a very fine
flake; but when it comes very near, they use only a whiteline
to wear off an extremely small portion at a time. When it
is brought to be perfectly even and equal to the lead, they
change the scales to see that no error has been committed,
and then go on in the same manner till they have made all
the divisions, and all the small weights. Then to have an
entire centun, or hundred weight, they add to the 63:8.
(as they call it) a 32:6. and a 4:8. and weighing against
then one small weight, they make it equal to them, and
mark it (10:6.) This is the docimatic, or affaying centun,
and is really one dram. Cramer, Art. All, p. 108.

CENTO, in Poetry, a work wholly composed of verses,
or paraphrases, promiscuously taken from other authors;
or disposed in a new form, or order: so as to compose a new
work, and make a new meaning.
The word is Latin, cento, which primarily signifies a
dress made of patches, and that from xenia.

Autonomus has laid down the rules to be observed in com-
posing cantors. The pieces, he says, may be taken either
from the same poet, or from several; and the verses may be
either entire, or divided into two; one half to be connected
with another half taken elsewhere; but two verses are never
to be taken running, nor is much less than half a verse to be
taken. Agreeable to these rules, he has made a pleasant
nuptial cento from Virgil.

Hvba Falconi has written the life of Jesus Christ in cantos
taken from Virgil: the like is done by Alex. Rolli, in his
Chriftidos; and by Stephen de Pleure, canon regular of

CENTOBRYCA, in Ancient Geography, a town of
Spain, in Celtiberia.

CENTON, a fortress of Thrace, in Lower Myria, the
walls of which were repaired by Justinian. Procopius.

CENTONARE. In Italy, a plagiarist in musical com-
position, where melody and harmony are mere patch-work;
it is said to centonar. Sometimes an opera consisting of airs
selected from the Mafoni, or by the fingers themselves from
the works of various composers, is called a cento. See
Pasticcio.

CENTONARI, in Antiquity, a sort of officers or
operators, whose business was to make centones, or coats
patched of leather and cloth, wherewith to cover the vince,
under which the bullies made their approaches, as well as
the towers and machines used to batter the place, and pre-
vent their being set on fire by the enemy.

In the Theodorian code we have a title De centonaribus
et denrobatibus. And in ancient inscriptions, the centonarii are
joined with the signarii, or carpenters, ferrarii, or smiths, &c.
who made but one company, under the denomination of collegium
fabrorum et centonariorum.

CENTONIER, French. See Centonare, Ital.

CENTO-POZZI, in Geography, a town of Naples, in
the province of Batn; three miles N. of Matera.

CENTORBI, the ancient Centoripa, a city of Sicily,
mentioned by Cicero in his oration against Verres. It is
situated on five points of rocks, and resembles a far-fish;
being very difficult of access, and incommodious for habitation.
Yet, in the time of the Romans, it was very populous;
but it retains no vestige of its ancient splendour, except a
few ruins. Its long fabums, terminated in a point, are
miserable and depopulated; and it is delirious of money and
commerce. The convent of the reformed Augustines is a
large building, but in as depopulated a state as the town.
To the wellward of the town there are considerable runs of
baths, built with beautiful marble, lined with marble in
the Roman style, like that of the baths of Baal. To the
east of the town is the ruin of a castle, called the castle of
Canradin. Frederic, the grandfather of this Conradin,
destroyed Centorbi about the beginning of the 13th century,
and razed its foundations. It was, however, again rebuilt,
with the castle; for in 1268, after the J. fest of Conradin,
Conrad Capetius, aspiring to become king of Sicily, and
finding himself abandoned by the Sicilians, who declared for
Charles of Anjou, that himself up in this fortress.
Montfort, having forced him to surrender, put out his eyes,
and afterwards hanged him; and then destroyed the city.
A greater number of gold and silver coins, precious stones of
every kind, vases, statues, cinerary urns, &c. have been
found at Centorbi than in any other place in Sicily.
A considerable part of the riches of the museum of the
 prince of Bicaris has been furnished by this town. The
number of inhabitants in this ancient and once large city is now
reduced to 3000, who are very poor and wretched. The
neighbouring country, planted chiefly with vineyards, pro-
duces an indifferent wine; and there are soft rocks of an
imperfect free-stone, mixed with a marine tufa, even to the
summit of the mountain. The soil in one part of the town
is formed of marine concretions, mixed with shells; and
under the vegetable earth lies tufa, with the fore-mentioned
concretions, and gritty stone; and at a greater depth,
found lavas, beneath which is a bed of grit. The
lava probably forms the basis of the mountain, and indicates,
by being covered with marine concretions to the depth of
600 feet below the present level of the sea, the antiquity of
the
the volcano that produced it. De Nola's Journey in Sicily and Malta, p. 85.

CENTRES, in Ancient Geography, a people of Scythia, mentioned by Valerius Flaccus.

CENTORIO, Accarnia, in Biography, an Italian writer of the 16th century, originally of Rome, and after his expulsion from this city, a resident at Milan. His profusion was military; but in the interval of peace he compiled "Military and Historical Memoirs," collected from his own knowledge and from the information of others. They were published at Venice in 1565 and 1579, in 2 vol. 4to. The first part contains an account of the wars of Transylvania; the second, of those of his own time. They are held in high estimation. Nov. Dict. Hist.

CENTRAL, something relating to a centre, or centre. Thus, we say, central eclipse, central forces, central rule, &c.

Central eclipse, is that in which the center of the luminaries exactly coincides, and are directly in a line with the eye of the observer. See Eclipse.

Central forces, are the forces which tend to or from some point or center; or they are forces which cause a moving body to tend towards the center of motion, or to recede from it. According they are divided into two kinds, with regard to their different relations to the center, viz., the centrifugal and the centripetal.

The doctrine of central forces, a very considerable branch of the Newtonian philosophy, has been much cultivated by mathematicians, on account of its extensive use in the theory of gravity, and other physico-mathematical sciences.

In this doctrine it is supposed, that a body at rest never moves itself; and that a body in motion never of itself changes the velocity or the direction of its motion; but that every motion would continue uniform, and its direction rectilinear, unless some external force or resistance affected it. Hence, when a body at rest always tends to move, or when the velocity of any rectilinear motion is accelerated or retarded continually, or when the direction of a motion is continually varied, and a curve line is described; these changes are supposed to proceed from the influence of some power that acts incessantly; which power may be measured either by the pressure of the quiescent body against the obelisk that hinders it to move, in the first case; or by the degree of acceleration or retardation of the motion, in the second; or by the flexure of the curve described, in the third; due regard being had to the time in which these effects are produced, and other circumstances, according to the principles of mechanics. Effects of the power or force of gravity of each kind fall under our cognizance observation near the surface of the earth; for the same power which renders bodies heavy while they are at rest, accelerates them when they descend perpendicularly, or retards them when they ascend, and bends the course of their motion into a curve line when they are projected in any other direction than that of their gravity.

But we can judge of the forces or powers that act on the celestial bodies by effects of the last kind only. And hence it is that the doctrine of central forces is of so much use in the theory of the planetary motions.

SIR ISAAC NEWTON has treated of central forces in book i. § 2, of his Principia; and has demonstrated this fundamental theorem respecting them, viz., that the arcs which revolving bodies describe by radii drawn to an immovable center, lie in the same inmoveable planes, and are proportional to the times in which they are described. Principi. lib. i. prop. 1.

A late eminent mathematician observes, that this law, which is originally Kepler's, is the only general principle in the doctrine of centripetal forces; but since this law, as Sir ISAAC NEWTON himself has proved, cannot hold whenever a body has a tendency by its gravity or force to any other than one and the same point, there seems to be wanting some law that may serve to explain the motions of the moon and satellites which have a gravity towards two different centers. The law he lays down for this purpose is as follows: namely, that where a body is urged by two forces tending constantly to two fixed points, it will describe, by lines drawn from the two fixed points, equal solids in equal times, about the lines joining those fixed points. See MACHIN, on the laws of the moon's motion, in the Phil. Trans. This short treatise is published at the end of the English translation of Sir ISAAC NEWTON's Principia. See a demonstration of this law by Mr. W. Jones in the Phil. Trans. vol. li. art. 12. p. 74. &c. The same subject has been elaborately discussed, when the motion respects, not two centers only, but several centers, by many ingenious authors; and practical rules have been laid down for computing the places, &c. of planets and satellites; as by La Grange, La Place, Waring, &c. See Berlin Memoirs, those of the Academy of Sciences at Paris; and the Philosophical Transactions of the Royal Society of London, and various treatises of astronomers.

M. de MONTUORE has given elegant general theorems relating to central forces in the Phil. Trans. and in his Mémo. Analyst. p. 321.

Let M P O (Plate X. Mechanics, fig. 81.) be any given curve in the perimeter of which a body moves; let P be the place of the body in the curve at any time; S the center of force, or the point to which the central force acting on the body is always directed; P G the radius of concurrency of curvature at the point P; and S T the perpendicular drawn from the center of force to the tangent PT of the curve in P, then will the centripetal force be everywhere proportional to the quantity S P.

Monseigneur Varignon has also given two general theorems on this subject in the Memoirs of the Academy. an. 1700, 1701, and has shown their application to the motions of the planets. See also the same Memoirs, an. 1706-1710. Mr. MACLAURIN has also treated the subject of central forces very fully in his Fluxions, from art. 426 to 429, where he gives a great variety of expressions for these forces, and several elegant methods of investigating them.

Central forces. Laws of 1. The following rule, for which we are obliged to the marquis de l'Hôpital, is very clear and comprehensive. Suppose a body of any determinate weight to move uniformly round a center, with any given velocity: find from what height it must have fallen to acquire that velocity; then, as the radius of the circle it describes is double to that height, so is its weight to its centripetal force.

Let v represent the body, or its weight or quantity of matter, o its velocity, and r the radius of the circle described, and g be = 10^2.45152 f屏障, the space fallen through in the first sec. of time, and z g will express the velocity acquired; then, since the squares of the velocities are as the spaces (see Acceleration) 4 g^2: g^2: o^2: or the height pertaining to the velocity v; and r: o^2: b: a: s: = f the centripetal force. Hence, if the centripetal force be equal to the gravity, the velocity acquired is equal to that acquired by falling through half the radius.

2. The central force of a body moving in the periphery of a circle, is as the verified sine of the indeterminate small arc, A E, or as the square of the said arc divided by the diameter, A B; or, as the square of the arc, A E, directly, and the diameter
CEN T R A L FORCES.

Let this be the distance which the body describes in a given particle of time; then, from the nature of the circle (of little being very small, and consequently nearly equal to its chord) 

\[ AE^2 = AB \times AM, \text{and therefore} AM = \frac{AE^2}{AB}. \]

Now AM is the space through which the body is drawn from the tangent in the given time; and though 2 AM is the proper measure of the central force, yet when the forces compared are all computed in the same manner, from the same, or indefinitely small subtenes of contemperaneous arcs, it is of no consequence whether we consider these subtenes, or their doubles, as the measures of the forces, since the ratio is in both cases the same. Since then a body, by an equable motion, in equal times describes equal areas \( AE \); the central force by which the body is impelled in the periphery of the circle is constantly the same.

3. If two bodies describe different peripheries by an equable motion, their central forces are in a ratio, compounded of the duplicate ratio of their velocities directly, and the reciprocal ratio of their diameters: because the ratio of the velocities is in this case the same with that of the arcs or spaces described in the same time; and the velocities are evidently in the subduplicate of the products of the diameters multiplied by the forces. Thus, \( F_1 : F_2 = \frac{v_1^2}{D_1} : \frac{v_2^2}{D_2} \) \( A \), \( E^2 \) \( A \) \( B \), and the velocity \( v \) is as the space \( AE \) uniformly described. Hence, if the velocities be equal, the central forces will be reciprocally as their diameters; and if the diameters \( A B \) and \( H L \) be equal, i.e. if each moveable proceed in the same periphery, but with unequal velocities, the central forces will be in aduplicate ratio of the velocities. Hence, if the radii or diameters be reciprocally in the duplicate ratio of the velocities, the central forces will be reciprocally in the duplicate ratio of the radii, or directly as the 4th powers of the velocities: that is, if \( V^2 : v^2 : r : R \), then \( F_1 : F_2 : R^2 : V^2 \) \( v^2 \), for \( V^2 = v^2 \) \( r \), and \( F = \frac{V^2}{R} : \frac{v^2}{r} \). \( V^2 : v^2 : r : R \).

If the central forces of the two bodies moving in different peripheries be equal, the diameters of the circles \( A B \) and \( H L \) will be in a duplicate ratio of the velocities. For in this case, \( \frac{V^2}{R} = \frac{v^2}{r} \) and \( V^2 = v^2 \) \( r \); therefore \( r : R :: \frac{V^2}{R} : \frac{v^2}{r} \).

4. The central forces are in a ratio compounded of the direct ratio of the diameters, and the reciprocal one of the squares of the periodic times. For the diameters are as the peripheries which are the spaces run in the periodic times; and these are in the compound ratio of their times and velocities directly: therefore, representing the times by \( t_1 \), \( t_2 \), the velocities by \( V \), \( v \), and the diameters by \( D_1 \), \( D_2 \) \( D :: \frac{V^2}{D} \times T \cdot v \times t \; \text{consequently,} \frac{V^2}{D} \times T :: \frac{v^2}{d} \times t \). \( t^2 \) \( d^2 \) \( D^2 \); and therefore by Art. 3. the central forces are in the proportion required; i.e. \( F_1 : F_2 = \frac{V^2}{D} : \frac{v^2}{d} \). \( t^2 \) \( d^2 \) \( D^2 \). And when the circles are equal, the central forces are reciprocally as the squares of the times, \( D \) being \( d \).

5. If two bodies, equal in weight, describe peripheries of unequal circles in equal times, their central forces are as their diameters \( A B \) and \( H L \). For \( F' :: t^2 \times D = T^2 \times d \); but \( T' :: t' \); \( F :: F' : D : d' ; R : r \). And hence, if the central forces of two bodies, describing peripheries of two unequal circles, be as their diameters, they pass over the same in equal times. For \( Fd = F' T^2 \times d \); and \( F' T^2 \times d = f' \times d' \times D ; \) therefore, \( T' = t' \) \( T :: t \).

6. If two bodies, moving in unequal peripheries, be acted on by the same central force, the time the larger is to that in the smaller, in a subduplicate ratio of the greater diameter \( A B \), to the less \( H L \); for \( F \) being \( F = \frac{V^2}{D} \times t = t' \times D, \) and \( T' :: t \). \( T :: T' \); wherefore, \( T' :: F' :: D : d \) the time of the diameters of the circles in whose peripheries those bodies are acted on by the same central force, are in a duplicate ratio of the times. Hence also the times wherein similar peripheries or arcs are run over by bodies impelled by the same central forces, are in proportion to their velocities.

7. If the times wherein the bodies are carried through the same entire peripheries, or similar arcs, be as the diameters of the circles, the central forces are reciprocally as the same diameters. For \( T :: T' :: D \times d \); and \( T' :: d' \times D' \); therefore, \( F' : F = \frac{r}{D} = \frac{R}{D} \).

8. If a body move uniformly in the periphery of a circle, with the velocity it acquires by falling from the height \( A F \); the central force will be to the gravity, as double the altitude of the circle \( A F \) to the radius \( CA \). If, therefore, the gravity of the body be called \( G \), the centrifugal force will be \( 2AF \times G \div CA \). See Art. 1.

9. If a heavy body move equally in the periphery of a circle, and with the velocity which it acquires by falling through a height equal to half the radius; the central force will be equal to the gravity. And again, if the central force be equal to the gravity, it moves in the periphery of a circle, with the same velocity which it acquires in falling a height equal to half the radius.

10. If the central force be equal to the gravity, the time it takes up in the entire periphery, is to the time of its fall through half the radius, as the periphery to the radius.

11. If two bodies move in unequal peripheries, and with an unequal velocity, which is reciprocally in a subduplicate ratio of the diameters; the central forces are in a duplicate ratio of the distances from the center of the forces, taken reciprocally. For \( F :: d^2 \div D^2 \); and \( F = \frac{V^2}{R} \div \frac{v^2}{r} \). \( d' \div D' \), or \( r \div R \).

12. If two bodies move in unequal peripheries, with velocities which are reciprocally as the diameters or distances from the center; their central forces will be reciprocally as the cubes of their distances from the center, or directly as the cubes of the velocities. Thus, if \( V :: r :: R \); \( F = \frac{V^2}{R} \div \frac{v^2}{r} \). \( \frac{R^3}{r^3} \); \( r^3 \div R \), or \( V^3 :: r^3 \).

13. If the velocities of two bodies, moving in unequal peripheries, be reciprocally in a subduplicate ratio of the diameters, or central distances; the squares of the times wherein they pass the whole peripheries, or similar arcs, are in a triplicate ratio of the distances from the center of the forces; wherefore, if the central forces be reciprocally in a duplicate ratio of the distances from the center, the squares of the times wherein the entire peripheries, or similar arcs, are passed over, are also in a triplicate ratio of the distances.

If \( V :: r :: d^3 \div D^3 \); or \( V^3 :: d :: D \); then \( T' :: t' \).

Vol. VII.
 CENTRAL FORCES.

14. However, the central forces differ from one another, they may be compared together; for they are always in a ratio compounded of the ratio of the quantities of matter in the revolving bodies, and the ratio of the distances from the center; and also in an inverse ratio of the squares of the periodical times. If then you multiply the quantity of matter in each body by its distance from the center, and divide the product by the square of the periodical time, the quotients of the division will be to one another in the said compound ratio, that is, as the central forces.

15. When the quantities of matter are equal, the distances themselves must be divided by the squares of the periodical times, to determine the proportion of the central forces: in that case, if the squares of the periodical times be to one another as the cubes of the distances, the quotients of the divisions, as well as the central forces, will be an inverse ratio of the squares of the distances.

From the foregoing theorems we may deduce the velocity and periodical time of a body revolving in a circle, by means of its own gravity, at any given distance from the earth's center. Let $g$ be the space through which a heavy body descends at the surface of the earth, in the first second of time, or $164$ feet, $= A M$, in the preceding figure; then $2g$ will be the measure of the force of gravity at the surface: and $r$ being allowed for the earth's radius, $A C$, the velocity in a circle at its surface, in one second, will be $v = \sqrt{2rg}$, or $\sqrt{2rA}$, &c., as Art. 2. Hence, if we put $c = 3.14159$, &c., the circumference of the earth is $2\pi r = 25,000$ miles nearly, or $132,000,000$ feet (in round numbers), we shall have $v = \sqrt{2gr} = \sqrt{2}\pi r = \pi r$.

The velocity of a body at the equator, or any other part of the earth, is $\pi r$, where $r$ is the radius of the earth, and $\pi$ is the number of the squares of a circle.

In order to apply this to the case of the moon, revolving about the earth at the distance of 60 semidiameters, let $R = 60r$, or the distance of the moon from the earth, and the above expressions will become $v = 26000 \sqrt{\frac{r}{R}}$, or $26000 \sqrt{\frac{r}{60r}} = 3557$ feet per second, or 3574 miles per minute, for the velocity of the moon in her orbit; and $T = 5078 \sqrt{\frac{R}{r}} = 236051$ seconds, or 27.3 days nearly for the periodical time of the moon in her orbit at that distance. This is nearly equal to what the astronomers reckon it, viz. 27\(\frac{1}{2}\) days; and it would have come out exactly like it, if the distances had been precisely stated, and other circumstances, omitted for the sake of brevity, had been taken into the account, which interfere with that period. Similar calculations may be instituted with respect to all the planets of our solar system, and the result of the calculations will be found to coincide, with surprising exactness, with the appearances; and this affords a strong confirmation of the Newtonian theory of universal gravitation.

Thus also the ratio of the forces of gravitation of the moon towards the sun and earth may be estimated. For, 1 year, or 365 days, being the periodical time of the earth and moon about the sun, and 27.3 the periodical time of the moon about the earth; and also 60 being the distance of the moon from the earth, and $23.2$ the distance from the sun, in semidiameters of the earth, we shall have (by Art. 4.)

$$\frac{F}{f} = \frac{R^2}{r^2} \times \frac{c^2}{t^2}$$

that is, the proportion of the moon's gravitation towards the sun is to that towards the earth, as 23 to 1 nearly.

Further, the mean distance of the moon from the center of the earth is $1,073,000,000$ feet, or about 60 semidiameters of the earth. Also, the force of gravity at different distances is inversely as the squares of the distances, and the radius of the earth is $210,000,000$ feet; therefore, as the square of $1,073,000,000$ is to the square of $210,000,000$, so is the force of gravity at the earth to the force of gravity at the distance of the moon; viz.

$$\frac{F}{f} = \frac{1,073^2}{210^2} \times \frac{c^2}{t^2}$$

or $1:5560$; so that the force of gravity at the surface of the earth is to the force of gravity at the moon as 1 to 0.6667; or as 10,000,000 to 274. And since the earth falling bodies pass over $16\frac{1}{2}$, or $16.57$ feet, in the first second of time; therefore we may say, 10,000,000: 274: 16.57: 0.0044 of a foot; which shows that the moon, if its velocity should cease at once, would fall towards the earth, and in the first second of time would descend through not more than $16\frac{1}{2}$ feet of a foot.

Again, we may hence compute the centrifugal force of a body at the equator, arising from the earth's rotation. The time of revolution, when the centrifugal force would become equal to that of gravity, as has been shewn above, is $5078$ seconds; and, by Art. 4. $86160$, which is the square of the number of seconds in 24 hours, 56 minutes, the time of the earth's entire rotation on its axis, is to $5078$, as the force of gravity, which may be denoted by unit, to $5560$, the centrifugal force required, which is the 28th part of gravity at the earth's surface. Simpson's Fluxions, vol. i. p. 240, &c.

Otherwise, it appears (by Art. 4.) that, when the distances from the center are equal, or in the same circle, the central forces are inversely as the squares of the periodical times; and we have above shewn, that the velocity, which near the surface of the earth is equivalent to gravity, is $26000$ feet per second nearly. Then if, as the square of the earth's diurnal rotation round its axis is to the square of the periodical time in the case above shewn, viz. $1:24\frac{1}{2}$, or nearly 85, is the force of gravity (e. g. i.) to the centrifugal force of bodies near the equator of the earth; i. e. $2073000$ (the square of 24 hours): $7225$ is the centrifugal force near the equator; i. e. the force by which bodies that are near the equator are attracted towards the center is to the force with which they endeavour to fly off, in consequence of the earth's diurnal rotation round its axis, as 1 is to 0.004385; or as 10,000,000 to 3495; or the former is almost 300 times more powerful than the latter.

By similar means we may determine the centrifugal force of bodies in different latitudes; for as the earth turns round its axis, it is evident that those bodies on the surface of it, which lie nearer to the axis, or, which is the same thing, are nearer
nearer to the poles, perform circles smaller than those which are nearer to the equator; though they are all performed in the same interval of 24 hours. Hence, the periodical times being equal, or the same, the central forces are as the radii of the circles, and as in different latitudes the radii are equal to the cosines of the latitudes, we may use the following proportion; viz. as the radius is to the cosine of a given latitude, so is the centrifugal force of bodies situated at the equator to the centrifugal force of bodies at that given latitude. Now as the cosines decrease in length the nearer they approach the poles, so the tendency of bodies to fly off from the surface of the earth is greatest at the equator, but diminishes in approaching towards the poles; and hence we perceive why the earth has been found, by means of unquestionable measurements and other observations, to be an oblate spheroid, whose polar diameter is the shortest. This circumstance furnishes a convincing evidence of the earth's daily rotation about its axis.

For another example of the application of the theory of central forces above stated, we may suppose A to be a ball of one ounce, whirled about the center C, so as to describe the circle ABE (fig. 82.) each revolution being made in half a second; and the length of the cord AC = 2 feet. Here \( r = \frac{1}{2}, \) r = 2; and as it has been already found that

\[
e = \sqrt[\frac{2}{3}] \frac{2R}{\varepsilon} = T \text{ is the periodic time at which the circumference of the earth, when the centrifugal force is equal to gravity; hence then, (by Art. 4.) } \frac{R}{T^2} = \frac{\varepsilon}{g}; \text{ and this proportion becomes } \frac{g}{2} = \frac{r}{t}; \text{ viz. as } \frac{2g}{r} = \frac{16\pi^3}{9} = \frac{16 \times 3 (1+16)^\frac{1}{3}}{16\pi^3} = 9.819 = \text{ the centrifugal force, or that by which the string is stretched, viz. nearly } 10 \text{ ounces, or } 10 \text{ times the weight of the ball. This central force may be called centripetal or centrifugal, according as it is applied to the tendency of the parts of the string, or to the force of the body; so that the body is said to be retained by a centripetal force } 9.8 \text{ times as great as the force of terrestrial gravity, or may be said, that the centrifugal force of the revolving body stretches the string as much as if a weight of } 9.8 \text{ pounds were simply suspend to it.}

Again, suppose the string and ball to be suspended from a point D (fig. 83.) and to describe in its motion a conical surface, AXB; then, putting DC = a, AC = r, and AD = b; and F = t, the force of gravity as before; the body will now be affected by three forces, viz. gravity acting parallel to DC, a centrifugal force in the direction CA, and the tension of the string, or force by which it is stretched, in the direction DA; hence these three powers will be as the three sides of the triangle ADC respectively; and, therefore, as CD or a : AD or b :: \( \frac{2g}{r} : \frac{1}{a} \); the tension of the string as compared with the weight of the body.

Also, CD or a : AC or r :: \( \frac{2g}{r} : \frac{1}{a} \); the general expression for the centrifugal force above found; hence \( g^d = 2a^2 \), and consequently \( t = e \sqrt[\frac{2}{3}] \frac{2a}{g} = 1.108 \sqrt{e} a \) is the periodical time.

When the force by which a body solicitated towards a point is not everywhere the same, but is either increased or diminished, in proportion to some power of the distance from the center; several curves will thence arise in a certain proportion according to that power. If the force decreases in an inverse ratio of the squares of the distances from that point, the body will describe an ellipse, which is an oval curve, in which there are two points called foci, and the point towards which the force is directed, falls upon one of them; so that in every revolution, the body once approaches to, and once recedes from it: and the eccentricity of the ellipse is greater or less, according to the projective force: and when the eccentricity is nothing, the curve becomes a circle, which may also be described, in certain circumstances, by a moving body. The body may also (by supposing a greater degree of velocity in certain proportions, describe the two remaining conic sections, viz. the parabolic and hyperbolic curves, which do not return into themselves; on the contrary, if the force increses with the distance, and that in a ratio of the distance itself, the body will again describe an ellipse: but the point to which the force is directed is the centre of the ellipse; and the body, in each revolution, will twice approach to, and again twice recede from, that point. In this case also a body may move in a circle, for the reason above mentioned.

In order to explain these particulars more at large, let ABC (fig. 84.) represent a circular orbit, A = S an elliptical, ADE a parabolic, and AKF an hyperbolic orbit: and let the bodies be supposed to move with certain velocities under the influence of a force at N, which is the center of the circle, and the focus of the conic sections. Let A B, perpendicular to A D, represent the velocity which is necessary to retain the body in the circular orbit, and let it be denoted by \( v \); as the standard with which the other degrees of velocity may be compared. Also, let a body be projected from A in the direction \( A \) with any other degree of velocity \( u \). It is now proposed to determine the nature of the curve, which will be described with this other velocity \( u \), or rather to ascertian what the value of \( u \) must be in order to produce each particular conic section. Draw \( m K \) parallel to \( A \) L, interseeting the circle as well as the other curvres. Let \( A N \) be denoted by \( z \); the semi-transverse axis of any of the conic sections by \( a \); the semi-conjugate by \( b \); and Am = B C = GZ = HZ = I K = \( x \) by \( x \). Then the ordinate m C in the circle will be \( z \), but the other ordinates \( m z \) of the ellipse, and \( m K \) of the hyperbola may both be represented by \( \frac{b \times z}{x} + \frac{x}{x} \). The fluxions of these ordinates are

\[
\frac{d}{dx} \left( \frac{1}{x^2} \right) = \frac{1}{x^3} \quad \text{and} \quad \frac{d}{dx} \left( \frac{1}{x} \right) = \frac{1}{x^2} \]

respectively; which fluxions are to each other as the velocities in every point of their respective curves in the direction A L; and in the like proportion are the quantities \( \frac{d}{dx} = \frac{1}{x^3} \quad \text{and} \quad \frac{b \times z}{x} + \frac{x}{x} \)

these quantities being the abovementioned fluxions divided by the same quantity. Now, when the point in the curve approaches the point A so near as to coincide with it, then Am vanishes, or \( x = ox \); and the above expressions become \( \frac{d}{dx} = \frac{1}{x^3} \quad \text{and} \quad \frac{b \times z}{x} + \frac{x}{x} \); so that at the point A the velocity which retains the body in the circular orbit is to the velocity which retains the body in the ellipse or hyperbola, as \( \frac{d}{dx} : \frac{b \times z}{x} + \frac{x}{x} :: \frac{1}{x^3} \quad \text{and} \quad \frac{b \times z}{x} + \frac{x}{x} \). Therefore

\[
n \times \left( \frac{1}{x^3} \right) = \frac{b}{a} \quad \text{and} \quad n \times \frac{b}{a} = \frac{b}{a} \quad \text{or} \quad an \times \frac{b}{a} = \frac{b}{a}. \quad \text{When}
\]

M = 2

\( x = \)
The central rule is chiefly founded on this property of the parabola; that if a line be inscribed in that curve perpendicular to any diameter, a rectangle formed of the segments of this line is equal to a rectangle made of the intercepted part of the diameter and the parameter of the axis.

The central rule has the advantage over Cartes's and De Latteres's methods of conducting equations, as both these are subject to the trouble of preparing the equation by taking away the second term. This we are freed from in Baker's method, which shews us how to construct all equations not exceeding the fourth power, by the intersection of a circle and parabola, without the omission or change of any terms. See Phil. Trans. No. 157.

CENTRALS Retina, in Anatomy, an artery, which is sent from the ophthalmic, and is chiefly distributed to the retina. See Arteries and Eye.

CENTREVILLE, in Geography, the chief town of Queen Anne's county, and on the east side of Chesapeake bay in the state of Maryland, in America. It lies between the forks of the river which runs into Chester river, 18 miles S. of Chester, 34 S. E. by E. of Baltimore; and 95 S. W. by S. of Philadelphia, N. lat. 39° 6'.

CENTRIFUGAL FORCE is that whereby a body revolving round a centre or another body endeavours to recede from it.

It is one of the established laws of nature, that all motion is of itself rectilinear; and that the moving body never recedes from its first right line, till some new impulse be superadded in a different direction: after that new impulse, the motion becomes compounded, but it continues still rectilinear, though the direction of the line be altered. To move in a curve, it must receive a new impulse, and that in a different direction every moment; a curve not being reducible to any number of finite right lines. If then a body continually drawn towards a center be projected in a line that does not go through that center, it will describe a curve; in each point whereof, the velocity is a quantity less than the square root of 2 (viz. less than the square root of twice that velocity which is requisite to retain the body in a circular orbit); then the values \( \frac{n}{2 - n} \) and \( \frac{n}{2 - n \frac{1}{2}} \), viz. of \( a \) and \( b \), will be positive; whereas, by the same substitution, the value \( \frac{n}{2 n - 2} \) becomes impossible; which shews, that when \( n < 2 \) the square root of 2, the curve can only be the ellipse.

But if we make \( n = 2 \) equal to any thing greater than the square root of 2; then the values of \( a \) and \( b \) for the hyperbola become positive, whereas those for the ellipse become impossible; and, therefore, in this case, the curve must be the hyperbola.

Central Rule, is a rule or method discovered by our countryman Thomas Baker, rector of Nympont in Devon, for finding the center of a circle designed to cut the parabola in as many points as an equation to be constructed had real roots. See the article Baker.

Its principal use is in the construction of equations; and he has applied it with good success as far as biquadratics.
CEN

he has given a few easy cases in bodies revolving in the circumstances of circles. But the doctrine was full fully difficult, especially in its reference to the comic sections, by Sir Isaac Newton. He was succeeded by several other writers upon the same subject; as Leibnitz, Varignon in the Mem. de l'Acad. Keil in the Phil. Trans. and in his "Physices," Bernoulli, Hennel, Cotes in his "Harmonia Mensurabilum," Malusian in his "Geometria Organica," and in his "Fluxions," and Euler in his book "De Motu," where he considers the figures described by a body acted on by centripetal forces tending to several points. The subject has also been illustrated by various writers on mechanics and astronomy. See Centrifugal Force, and Central Forces.

Centrifugal Machine, a curious machine invented by Mr. Erkine, for raising water by means of a centrifugal force, combined with the pressure of the atmosphere. This machine consists of a large tube of copper, &c. in the form of a crofs, placed perpendicularly in the water, and resting at the bottom on a pivot. At the upper part of the tube is an horizontal cog-wheel, which touches the cofs of another in a vertical position; so that by the aid of a double winch, the whole machine is moved round with very great velocity. Near the bottom of the perpendicular part of the tube is a valve opening upwards; and near the two extremities, but on the contrary sides of the arms, or crofs part of the tube, are two other valves opening outward. These two valves are kept shut, by means of springs, till the machine is put in motion; when the centrifugal velocity of the water forces them open, and discharges itself into a cylinder or reservoir placed there for that purpose. On the upper part of the arm are two holes, which are closed by pieces of screw that pierce into the metal of the tube. Before the machine can work, these holes must be opened, and water poured in through them, till the whole tube be full; by which means all the air will be forced out of the machine, and the water supported in the tube by means of the valve at the bottom. The tube being thus filled with water, and the holes closed by their screw-caps, it is turned round by the winch; when the water in the arms of the tube acquires a centrifugal force, opens the valves near the extremities of the arms, and flies out with a velocity nearly equal to that of the extremities of the said arms.

A perspective view of the centrifugal machine erected on board a ship, is exhibited in Pl. XI. Mechanics, fig. 93. ABC is the copper tube; D an horizontal cog-wheel, furnished with 12 cofs; E a vertical cog-wheel, having 36 cofs; FF the double winch; a the valve near the bottom of the tube: b, b, the two pivots on which the tube turns; c one of the valves in the crofs piece; the other at d, but invisible, as it is on the other side of the tube; e e the two holes through which the water is poured into the machine; G H the cylinder or reservoir; I I part of the ship's deck. The distance between the two valves, e e, is 10 feet; the diameter of these valves is about 3 inches; and that of the perpendicular tube is about 7 inches.

If the men who work the machine be supposed to turn the winch round in 3 seconds, the machine will move round its axis in one second; and con-fquently each extremity of the arms will move with a velocity of 18.8 feet in a second. A column of water, therefore, of three inches diameter will issue through each of the valves with a velocity of 18.8 feet in a second; but the area of the aperture of each of the valves is 7.14 inches; which, being multiplied by the velocity in inches = 135.6, gives 1610.784 cubic inches, the quantity of water discharged through one of the apertures in one second; so that the whole quantity discharged in that space of time through both the apertures is = 3221.568 inches; or 19720.68 cubic inches in one minute. But 60812 cubic inches make a tun, or measure; consequently, if we suppose the centrifugal machine to revolve round its axis in one second, it will raise nearly 3 tons 44 gallons in one minute; but this velocity is too great, at least to be maintained for any considerable time; so that, when this and other deficiencies in the machine are allowed for, two tuns are nearly the quantity that can be raised by it in one minute. As the water is forced up the perpendicular tube by the pressure of the atmosphere, it is evident that this machine cannot raise water above 32 feet high.

An attempt has been made to diminish this machine in the place of the pumps commonly used on board board; but the labour of working was found to be too great to render the machine inferior to the chain-pump; which fee. The machine might be improved by loading with a weight of lead the ends of the tubes through which the water issue; and thus the machine would be made to turn with much greater ease, as the centrifugal force of the lead would in some measure supply the place of a fly.

Centrifugal Wheel. See Wheel.

Centrina, in Ethnology, the specific name of a shark. See Squalus Centrina. The fish described by Ray, Aldrovandus, and various old writers, under the name of Centrina and Centrine is of this species. This shark has been also called Porcus Pfeptis, from its somewhat triangular figure, and elevated back, which rising into a ridge, bears a remote resemblance to that of a hog.

Centrina, a binominal name of Chimaera Mon- flia. Centrina prima, Centrina vera, Simia marina Danica. Aldrovandus.

Centrinæ, in Physiology, a species of insects hatched in the wild fig-tree, and used in caprification.

Centripetal Force is that by which a moving body is perpetually urged towards a center, and made to revolve in a circle, instead of a right line. Thus, the body impelled in the right line AG, (Plate X. Mechanics fig. 82.) is perpetually drawn out of its rectilinear motion, and forced to proceed in a curve. The centripetal force, therefore, is as the right line DE; supposing the arc, AE, indefinitely small. Hence, when a body revolves in a circle, the two forces, viz. the centrifugal and centripetal, are equal and contrary to each other, since neither of them gains upon the other; the body being, as it were, equally balanced by them. But when, in revolving, the body recedes farther from the center, then the centrifugal force exceeds the centripetal; as is the case in a body revolving from the lower to the higher apsis in an ellipse, and reflecting the focus as the center. And when the revolving body approaches nearer to the center, the centripetal force is less than the centrifital; as while the body moves from the farther to the nearer extremity of the transverse axis of the ellipse. For the proportion of the one to the other, fee the sequel of this article.

In the firft or nascent state of circular motion, the projective force infinitely exceeds the centripetal force. For, let the circle AEB, (fig. 82.) represent the orbit of the body A, moving uniformly along its circumference; this body, A, is impelled by a projective force in the direction AG, perpendicular to AC, and is at the same time constantly acted upon by an attractive or impelling force, in a direction towards the center, C: these two forces being fo adjusted, or bearing such proportion to each other, as to keep the body in the circular orbit, AEB. In the very small arc AE, the line AD is to the line AM (= DE) as the force of projection is to the centripetal force at the distance AC; for whilst AD represents the uniform or equitable
equable movement which arises from the projectile force in a certain time, $DF$ represents the deviation from that course, or the force by which the body is driven towards the center of force in the same time. $N:W:DF$ ($= AM$); $AE :: AE :: AB$; and when the arc $AE$ becomes indefinitely small, or is in its vincent state, then the diameter $AB$ becomes indefinitely greater than $AE$ and of course $AE$ or $AD$ (which in the state here supposed is nearly equal to it) becomes indefinitely greater than $DE$ or $AN$; i.e. the projectile force infinitely greater than the central or centripetal force.

If a body move in a curve line, and in such a manner that the radius $CB$ ($f_{g, 56}$) drawn from it to the fixed point $C$, placed in the same plane, describes areas $ABC, BCE, \&c.$ proportional to the times, or equal to any given time, it is solicited towards the point $C$ by a centripetal force. And also, if a body proceed according to the direction of the right line $AD$, and be solicited by a centripetal force towards a fixed point $C$, placed in the same plane; it describes a curve, whole cavity is towards $C$, and whose several areas, comprehended between the two radii $AC$ and $CB$, are proportional to the times. Moreover, the velocity of a revolving body, at any point, $Q$ or $R$, ($f_{g, 56}$) is inversely as the perpendicular $SP$ or $ST$, falling from the center of force, upon the tangent at that point. For, let two other bodies, $m$ and $n$, be supposed to move uniformly from $Q$ and $R$, along the tangents $QP$ and $RT$, with velocities respectively equal to those of the revolving body at $Q$ and $R$; then the distances $m$ and $n$, gone over in the same times, will be in each other as those velocities, and the area $QS$m and $RS$n, will be equal, being equal to those described by the revolving body in the same time (see Quadrature): whence $Qm$ and $SP$ being $= Rn$ and $ST$, it follows that $Qm = Rn = ST$.

1. To determine the law of the centripetal force tending to a given point $C$, ($f_{g, 77}$) by which a body may describe a given curve $AQB$. Let $QP$ be a tangent to the curve at any point $Q$: upon which, from the center $C$, let fall the perpendicular $CP$: put $CQ = t$, $CP = u$; and let the velocity of the projectile at $Q$ be denoted by $v$. Since $v^2$ is always as $\frac{v^2}{u}$ (by the preceding article), it is evident that if we take the fluxions of both quantities, $v^2$ will also be as $\frac{v^2}{u^2}$. But the centripetal force, whether the body moves in a right line or a curve, is always as $\frac{v^2}{u^2}$ (see Central force): consequently the centripetal force is likewise as $\frac{v^2}{u^2}$.

Otherwise, let the ray of curvature $QO$ be denoted by $R$; then, because the centripetal forces in circles are as the squares of the velocities directly and the radii inversely (see Central force); it follows that the force, tending to the point $O$, by which the body might be retained in its orbit at $Q$, or in the circle whose radius is $QO$, will be defined by $\frac{1}{u^2} \times \frac{1}{R}$; whence (by the resolution of forces) it will be $CP (u) = CQ (t) = \frac{1}{u^2} \times \frac{R}{R}$ (the force in the direction $QO$), the force in the direction $QC$, which, because $R = \frac{1}{u^2}$ (see Radius of Evolute), will be expressed by $\frac{1}{u^2} \times \frac{v^2}{u^2}$.

Hence it appears, that as the force, tending to the point $C$, is universally as $\frac{CQ}{CP} \times \frac{QO}{QO}$ (or $\frac{s}{u^2}R$), the force to any other point $c$ will, by the same argument, be as $\frac{CQ}{CQ} \times \frac{QO}{QO}$. Consequently, the forces to different centers $C$ and $c$ (about which equal areas are described in the same time) are to each other in the ratio of $\frac{CQ}{CQ}$ to $\frac{QO}{QO}$ inversely. Moreover, the ratio of the velocity at $Q$ to the velocity by which the body might revolve in a circle about the center $C$, at the distance $CQ$, is easily deduced from hence: for, since the velocity at $Q$ is that by which the body might revolve in a circle about the center $O$, and the forces tending to the centers, $O$ and $C$, are to each other as $u$ (CP) and $s$ (CQ); at therefore follows, if the ratio sought be assumed as $v$ to $w$, that $\frac{v^2}{w^2} = \frac{u^2}{s^2}$ (see Central force): whence also $\frac{v^2}{w^2} = u \times QO \times QO$.

For, let the centripetal force be given, the nature of the trajectory may be found; for since the force $(F)$ is universally defined by $\frac{1}{u^2}$, it is evident that $\frac{1}{u^2}$ will be the fluent of $F$; which, when $F$ is given in terms of $u$, will become known; and then the relation between $u$ and $x$ being given, the curve itself is known.

E. G. Let it be required to find the law of the centripetal force, by which a body, tending to the focus $C$, is made to revolve in the periphery of an ellipse $AQDB$ ($f_{g, 86}$).

From the other focus, $F$, draw $FK$ parallel to $CP$, meeting the tangent $PQ$ (at right angles in $K$, join $F$, $Q$; putting the transverse axis $A$ $B = a$, the semi-conjugate $O$ $D = \frac{1}{2} b$, and the parameter $\frac{b^2}{a} = b$: then, $CQ$ and $CP$ being denoted as before, we have $FQ = (A B - C Q)$, and property of the ellipse) $= a - x$; whence, by reason of the similar triangles $CQP$ and $FKQ$, it will be $x = u: a - x: FK = \frac{a - x + u}{i}$. But $FK \times CP$ is $= OD^3$ (by the nature of the curve). Hence we get $\frac{u - x \times u^2}{i} = \frac{1}{a^2}$; and consequently $\frac{1}{u^2} = \frac{4 a^2}{b^2} - \frac{1}{b^2}$; the fluxion of which being $\frac{-2 u}{u^2} = -\frac{4 a}{b^2} i$, we obtain $\frac{u^2}{u^2} (as before) = \frac{2 a}{b^2} \times \frac{i}{i} = \frac{2}{b^2}$, and $\sqrt{\frac{u^2}{i^2}} = \sqrt{\frac{2 \times a - i}{a} = v \times \Gamma_2}$. 

\[ \sqrt{\frac{FQ}{AQ}} \]  
Hence it appears, that the centripetal force is, in this case, as the square of the distance inversely; and the velocity at \( Q \) is to that by which the body might describe a circle at the distance \( CQ \), every where in the ratio of \( \frac{FQ^2}{AQ^2} \) to \( AO^2 \). If the curve had been a hyperbola, then 
\[ \frac{a + o}{s} \times u^2 \]  
instead of \( \frac{a - o}{s} \times u^2 \) would have been 
\[ \frac{1}{4} b^2 ; \]  
and for \( \frac{o}{s} = \frac{2 a}{b^2} \times \frac{1}{s} = \frac{2}{b^2} \), as before. If the 
curve had been a parabola, the equation would have been 
\[ \frac{a + o}{s} \times u^2 = 4 b^2, \]  
or \[ u = \frac{b^2}{4 a} \]; and the force, 
\[ \text{still, as } \frac{a}{s} \times u^2 \]. But the measure of the velocity 
\[ \sqrt{\frac{a^2 - 2 b^2}{a}} \]  
in this case becoming barely \( \sqrt{2} \), it 
follows that the velocity in a parabola is to that by which 
the body might describe a circle at the same distance 
from the centre, in the conflux ratio of \( \sqrt{2} \) to unity.

2. To determine the ratio of the velocities of bodies revolving 
in different orbits, about the same, or different centers; the orbits 
themselves, and the forces by which they are described, being 
given. Let \( A \) be any orbit, described about 
the center of force \( C \), and let the force itself at the 
principal vertex be denoted by \( F \); also let \( r \) stand for the 
semiparameter, or the ray of curvature at the vertex, and let \( C \) 
be perpendicular to the tangent \( Q \). Then, the celerity at 
\( A \) being, always, as \( \sqrt{rF} \) (by central forces), we have 
\[ \frac{C \times C}{A} : C : \sqrt{rF}, \]  
the velocity at \( Q \) (by a preceding article). This answers 
in all cases, let the values of \( \frac{C}{A} \) and \( F \) be what they 
may.

Hence, if the centripetal force be as the square of the 
distance inversely, or \( F \) be expressed by \( \frac{1}{AC^2} \), the velocity at 
\( Q \) will become 
\[ \frac{AC}{CP} \times \sqrt{\frac{r}{AC}}, \]  
or \[ \sqrt{\frac{r}{CP}} \]; whence 
the velocities, in different orbits, about the same center, are 
in the subduplicate ratio of the parameters, and the inverse 
ratio of the perpendiculars from the center of force to the 
tagents, conjunctly. Farther; if the celerity at \( Q \) be 
denoted by \( Q_1 \), and \( C \) be drawn; then, \( Q_2 \) being as 
\[ \sqrt{\frac{r}{CP}} \]; it follows that \( \sqrt{r} \) is as \( CP \times Q_1 \), or as the 
triangle \( Q \times C \). Consequently, the areas described about 
a common center of force in a given time, are in the subduplicate 
ratio of the parameters.

Moreover, since the area of the curve \( A \times H \), &c. 
when an ellipse, is known to be as \( (AO \times OD) \frac{A \times \sqrt{r}}{AO} \) (supposing 
\( O \) to be the center), if the same 
be applied to \( \sqrt{r} \), expressing the area described in a given 
part of time (by the last article), we shall hence have 
\[ A \times O \times \sqrt{AO}, \]  
or \( AO^2 \), for the measure of the time of 
one whole revolution. Whence it appears that the periodic 
times, let the foci of ellipse be what it may, are in the 
uequivalence ratio of their principal axes.

3. The centripetal force, tending to a point \( C \), being as 
the square of the distances reciprocally, and the direction and velocity 
of a body at any point \( Q \) being given; to determine the path in 
oblique the body moves, and the periodic time, in case it returns, 
(\( fig. 90 \)) The trajectory \( \Lambda Q B \) is a conic section, having 
the point \( C \) for one of its foci. Let \( F \) be the other focus, 
and upon the tangent \( PQ \) the let fall the perpendiculars \( CP \) 
and \( FK \), and let \( CQ \) and \( FK \) be drawn; also, put, the 
feminal focus axis \( AO = \alpha \), the given focal distance 
\( CQ = d \), and the sine of the angle of direction \( \angle FCQ \) (to 
the radius \( 1 \)) = \( m \) and let the given velocity at \( Q \) be to 
that by which the body might revolve in a circle about 
the center \( C \), at that distance, in any given ratio of \( a \) to unity: 
then it will be \( n : 1 : FQ : \Lambda O \) \( \frac{a}{2} \) (i.e. a preceding 
article); therefore \( n^2 = \frac{1}{2} \times (2 a - d) : \Lambda O \), etc.

whence \( \Lambda O = \) \( \frac{d}{2 - n^2} \). Moreover, since \( CP \times m \times 
CQ \), and \( FK = m \times FQ \), we have \( O D^2 \) \( = C \times 
FK^2 = m^2 \times CQ \times FQ \) \( = m^2 - n^2 \), whence 
the semi-conjugate axis (\( OD \)) is given likewise. Lastly, it 
will be (by a preceding article) as \( CT : \Lambda O \) \( \frac{a}{2} \) : \( P \) 
the periodical time in any given circle, whole radius is \( CT \), to 
\( \frac{(\Lambda O \frac{a}{2} \times P)}{\times \times} \) the required time of one revolution, when 
the orbit is an ellipse; that is, when \( n^2 \) is less than \( 2 \); for 
if \( n^2 = 2 \), the curve (as its axis \( \frac{a}{2 - n^2} \) becomes infinite) 
will degenerate to a parabola; and if \( n^2 \) be greater than \( 2 \), 
the axis being negative, it is then an hyperbola; whose 
principal diameters are equal to \( \frac{2 d}{m} \) and \( \frac{2 m n d}{n^2 - 2} \). Hence 
it follows, that, since neither the value of \( \Lambda O \), nor that of 
the periodic time, is affected with \( m \), the principal axis, and 
the periodic time, will remain invariable, if the velocity \( Q \) be 
the same, let the direction at that point be what it may.

The same solution might be obtained by first finding the 
principal parameter; for it is evident, that the area described 
by the body about the center \( C \), in any given time, is to 
the area described, in the same time, by another body revolving 
in a circle at the distance \( CQ \), as \( mn \) to unity; hence it will 
be, \( 1^2 : m^2 n^2 :: d : m^2 n^2 d \), the semiparameter: from which 
(proceeding as above) we get \( a \times m^2 n^2 d = (O D^2) = m^2 
\times \frac{2 a - d}{d} \); and consequently \( a = \frac{d}{2 - n^2} \), as before.

4. To find expressions for the centrifugal and centripetal 
forces, and to determine their proportion to each other. Let \( S \) 
(\( fig. 91 \)) be the center of force, \( PK \) the curve described, 
\( PT \) a tangent to it, \( SY \) perpendicular to \( PT \), and \( P \) an 
indefinably small arc; draw \( QW \) perpendicular to \( SP \), and 
with the center \( S \) describe the circular arc \( QX \); and let 
\( R \) be parallel to \( SP \), and \( PV \) be the chord of the 
circle of curvature. Let \( PQ \) represent the motion of the 
body in the curve in a given time; then \( P \) will represent 
that part of the motion which is directed towards the 
center, and by which alone the body would be found, at 
the end of the given time, at the distance \( S \); but on account 
of the motion \( Q \), it is found at the end of the same 
time at the distance \( S \) or \( S \); so that the perpendicular 
motion \( Q \) has made the body to recede from \( S \) through a 
space equal to \( Q \), which therefore represents the 
centrifugal force; and the centripetal force is represented by \( Q \) \( R \).

Now \( Q \times \frac{Q^2}{x} \) ultimately; but \( Q^2 \) varies as \( \frac{\text{area } S \times Q^1}{\times x} \), 
therefore \( Q \times \frac{x}{S} \) varies as \( \frac{\text{area } S \times Q^1}{\times x} \), which varies as 
\( \frac{x}{S} \).
...
hundred feet from it, who seemed determined to oppose their paffage. These were Armenians, Mygdolians, Chaldeans, and other auxiliaries, hired by Orontes, governor of that province. The only road which the Greeks could discover led upwards, and seemed to have been made by art; and the breadth of the river inducing them to believe it fordable, they attempted to pass it there; but they had not proceeded far before they found themselves obliged to return, and encamp on the banks of the river.

CENTRO. BARYC Method, from κέντρον and βάρος, heavy, in Mechanicis, is a method of measuring or determining the quantity of a surface or a solid, by considering it as formed by motion, and multiplying it into the way of its center of gravity.

The doctrine is comprised in the following theorem, with its corollaries.

Every figure, either superficial or solid, generated by the motion of a line or figure, is equal to the product of the generating magnitude into the way of its center of gravity, or the line which its center of gravity describes.

Demonstr. For suppose the weight of the whole generating magnitude collected in the center of gravity; the whole weight produced by its motion will be equal to the product of the weight moved into the way of the center of gravity. But when lines and figures are considered like homogenous, heavy bodies, their weights are as their bulk; and therefore the weight moved is the generating magnitude; and the weight produced that generated. The figure generated, therefore, is equal to the product of the magnitude into the way of its center of gravity. Q. E. D.

This kind of proof, furnished by Wallis, is very vague and unsatisfactory. But it is not difficult to supply one that is much better. Accordingly, let us suppose a lever loaded with two weights, and a fixed point in this lever. It is well known that the sum of the products of each weight by its distance from this point is equal to the product of the sum of the weights by the distance of their center of gravity from this point: then, if we imagine the lever to revolve round this fixed point, the circumstances will be proportion of the radii, and the sum of the products of each weight by the path or circumference which it describes will be equal to the product of the sum of the weights by the circumference described by the center of gravity. This demonstration, comprehending two weights, may be easily applied to any number of weights at pleasure.

Corol. 1. Since a parallelogram A B C D (Plate XI. Mechanicis, fig. 94.) is described, if the right line A B proceed according to the direction of another A C, with a motion still parallel to itself; and the way of the center of gravity E is equal to the line E F, perpendicular to C D, that is, to the altitude of the parallelogram: its area is equal to the product of the base C D, or the describing line here to the altitude E F. On this corollary we may observe, that A C is not, strictly speaking, the directrix of A B, although A B moves along A C; but this directrix is properly the line E F, which measures the distance of A B from C D; and the way of the center of gravity, by which we multiply the describing line, A B (or C D) is not the absolute way of this, but its way estimated with respect to the directrix or the way it describes in a line perpendicular to the describing line. This remark is necessary in order to prevent those paradoxes which might occur, in applying without precaution the foregoing rule to the measure of surfaces and solids.

Corol. 2. In the same manner it appears, that the solidity of all bodies, described by a plane defending according to the direction of any right line A C, is had by multiplying the describing plane by the altitude.

Corol. 3. Since a circle is described, if the radius C L, (fig. 95.) revolves round a center C, and the center of gravity of the radius C L be in the middle F, the way of the center of gravity is the periphery of a circle X, described by a subduple radius: consequently the area of the circle is equal to the product of the radius C L into the periphery described by the subduple radius C F.

Corol. 4. If a rectangle A B C D (fig. 96.) revolves about its axis A D; the rectangle will describe a cylinder, and the side B C the superficies of a cylinder. But the center of gravity of the right line B C is in the middle, F; and the center of gravity of the generating plane in the middle, G, of the right line E F. The way of this latter, therefore, is the periphery of a circle described by the radius E G, and that of the first the circumference of a circle described by the radius E F. Wherefore, the superficies of the cylinder is the product of the altitude B C into the periphery of a circle described by the radius E F, or the base. And the solidity of the cylinder is the product of the generating rectangle A B C D into the periphery of a circle described by the radius E G, which is subduple of E F, or of the semidiameter of the cylinder.

Suppose v. gr. the altitude of the describing plane, and therefore of the cylinder B C = a; the semidiameter of the base D C = r; then will E G = 2 r a and supposing the ratio of the semidiameter to the periphery = 1 : m, the periphery described by the radius 2 r = 2 m r. Therefore multiplying 2 m r by the area of the rectangle A C = a r; the solidity of the cylinder will be = 2 m r 2. But 2 m r 2 = 2 r x m r x a; and m r 2 is the area of the circle described by the radius E G. It is evident, therefore, the cylinder is equal to the product of the base into the altitude.

Corol. 5. In like manner since the center of gravity of the right line A B (fig. 97.) is in the middle M, and the surface of a cone is described, if the triangle A B C revolves about its axis; if PM = 1 2 BC; the superficies of the cone will be equal to the product of its side A B, into the periphery described by the radius PM, or the subduple of the semidiameter of the base BC.

Suppose v. gr. B C = r, A B = a, the ratio of the radius to the periphery = m; then will PM = 1 4 r, and the periphery described by this radius = 1 4 m r. Therefore multiplying 1 4 m r into the side A B, the product is the superficies or 1 4 a r. But 1 4 a r is also the product of 1 4 a and m r; therefore the surface of the cone is the product of the periphery into half the side.

Corol. 6. If the triangle A B C (fig. 98.) revolves about its axis, it describes a cone; but if C B be bisected in D, and the right line A D be drawn, and A O = 1 2 A D; the center of gravity will be in O. The solidity of the cone, therefore, is equal to the product of the triangle C A B into the periphery described by the radius PO; but A D = A O : BD : OP; and A O = 1 2 A D, and DB = 1 2 C B. Therefore, OP = 1 2 BD = 1 2 C B.

Suppose v. gr. B C = r, A B = a, the ratio of the radius to the periphery = m. Then will OP = 1 4 r, the periphery described by this radius 1 4 m r; the triangle A C B = 1 4 a r; and, therefore, the solidity of the cone 1 4 m r 1 4 a r = 1 4 a r 2. But 1 4 a r 2 = 1 4 r x m r x 1 4 a; or, the product of the base of the cone into the third part of the altitude. See Triangle.

Corol. 7. Let the semicircle D C A (fig. 99.) revolves about the diameter A D, and describe the surface of a sphere,
sphere. If there be taken DC : FC : FC : FH = \( \frac{4r^3}{c} \), putting \( r \) for the radius, and \( c \) for the whole circumference; \( H \) will be the center of gravity of the arc DCA; and consequently \( r \cdot c = FH \cdot 4r = \text{the line or circumference described by } H \text{ the center of gravity: and by the general rule } DCA \times \frac{4}{3} r = 4 \times 4 \times 3 \text{ r} = 2rc = \text{the surface of the sphere = the circumference into the diameter: as it ought to be by other principles. For the focality of the sphere, we shall have } \frac{1}{3} c = 2 \cdot r = \frac{3}{2} \cdot r = \frac{8}{9} r^3 = \text{the distance } FH \text{ of the center of gravity of the sphere } \text{from the diameter } AD \text{, which is two-thirds of the distance of the center of gravity of the arc } DCA \text{ from the same diameter } DA, \text{ in the former case: consequently, the line described by the center of gravity in this case will be two thirds of that in the former: but the describing line in the former case is to the describing space in this as } \frac{3}{2} \text{ r} \text{ to } \frac{5}{2} \text{ r}; \text{ therefore } i \cdot \frac{3}{2} \text{ r} = \text{surface of the sphere = solidity} = \frac{3}{2} \cdot \text{the content}, \text{ which is } \frac{3}{2} r^3 \text{ of the circumfered cylinder.}

Coroll. 8. For the focality of a parabolic spindle, put \( b = \text{the base, and } a = \text{the altitude or axis of the generating parabola, and } a = 5.855.8 \text{. It is known that } \frac{3}{2} \text{ r} \text{ is the distance of the center of gravity from the base, and consequently } \frac{3}{2} \text{ a} = \text{the line described by the center of gravity; but } \frac{3}{2} ab \text{ is the revolving area: therefore } \frac{3}{2} a \times \frac{3}{2} ab = \frac{3}{2} \text{ a} \cdot \text{ab} = \text{the content, which is } \frac{3}{2} r^3 \text{ of the circumfered cylinder.}

This elegant theorem, which may be ranked among the chief inventions in geometry of the 16th age, was taken notice of long ago by Pappus; but the justit Guldinus was the first who set it in its full light, and exhibited its use in a variety of examples. Several other geometers, after Pappus and Guldinus, have also used it in measuring solids, and surfaces generated by a rotation round a fixed axis: especially before the late invention of the integral calculus: and it may still take place in some cases where the integral calculus would be more difficult. M. Leibnitz has observed, that the method will hold, though the axis or center be continually changed during the generative motion.

CENTRON, in Geography, a village of Savoy in the Tarantaise, formerly a capital town of a people, called Centronii; 3 miles E. N. E. of Monther.

CENTRONES, in Ancient Geography, a people of Belgic Gaul, placed by Cassar in dependence on the Nervii. Some authors place them in the territory of Gand, others in that of Courtry, &c. D'Antville has not mentioned them. — Also, an ancient people of the Gauls, placed by Ptolemy in the Grecian Alps; and mentioned both by Cassar and Pliny. Many authors have supposed, and not improbably, that the Actavones, on the Alps, were the Centrones.

CENTRONIA, in Zoology, the name by which Dr. Hill distinguishes the crustaceous worms called Sea-cadets, and by Naturalists. Echinus. See Echinus.

CENTRUM, in Geometry, Mechanics, &c. See CenteR.

CEN

Gen. Ch. Cal. Periа-th four-cleft, spreading; segments lanceolate, acute. Cor. monopetalons; wheel-shaped; tube short, somewhat globular; border four-cleft; segments egg-shaped, spreading. Stam. Filaments four, naked, the length of the corolla; anthers simple. Pyi. Germ. superior, roundish, within the tube of the corolla; style filiform, permanent; stigma simple. Peric. Capsule globular, one celled, splitting horizontally; receptacle free. Seeds many, very small.

Eff. Char. Calyx four-cleft. Corolla wheel-shaped, four-cleft, filaments naked, capsule splitting horizontally, one-celled, many seeds. According to Jussieu it is sometimes petandrous with a five-cleft corolla, and then in its essential characters does not differ from Anagallis; but Dr. Smith is of opinion that the tubular form of the corolla, and the naked filaments, independent of the number, justify Dillenius in making it different.

Sp. C. minimus, Linn. Mart. Lam. Willd. Gart. tab. 50. fig. 2. Lam. Illud. tab. 83. Flor. dan. tab. 177. Curt. Flor. Land. tab. 11. Engl. bot. 531. (Anagallis, Waill. par. tab. 4. fig. 2. Meuntz. Pogil. tab. 7. Anagallidflorum, Mch. gen. tab. 18. fig. 2.) Baillart Pimpler, small Chaffweed. Root annual, fibrous. Stem one or two inches high, a little branched at the base, ascending, leafy, somewhat angular, smooth. Leaves alternate, sessile, spreading, egg-shaped, quite entire, smooth. Flowers solitary, axillary, sessile, little, white, expanded only in the most brilliant sunshine, foot withering, but permanent till forced off by the swelling capsule. Capsule globular, mucronate with the permanent style. A native of moist heaths in England, France, Italy, Germany, and Sweden, but often overlooked on account of its minuteness; it is most readily discovered by its capsules.

CENTUNCULUS, Scop. See Cerasium.

CENTURI, in Geography, a sea-port town of the island of Corfu.

CENTURIA, in Ancient Geography, or Pinturia, the name as it variously occurs in Ptolemy's geography, of one of the fortunate islands, in the Atlantic Ocean, near the coast of Africa.

CENTURIE, an episcopal city of Africa, in Numidia; probably the same with Centuriasens, or Centuriamens.

CENTURIAL INSCRIPTIONS, a denomination given by some to those inscriptions inscribed in the face of Severus's wall, which make mention of the centuries and cohorts by whom such parts of the wall are supposed to have been erected. In which sense, centurial inscriptions stand contradistinguished from legionary.

CENTURITÀ Comitia, in Antiquity, those assemblies of the Romans, wherein the people gave their votes by centuries. See Centuriis and Centurians.

CENTURIATORS, an appellation given to certain learned Germans of the city of Magdeburg, who in the early days of the Reformation composed a body of church history, divided into centuries of years.

Baronius is said to have written his Annals by way of opposition to the centurials of Magdeburg.

CENTURINUM, in Ancient Geography, a town or burgh, seated at the point of the most northerly promontory of the island of Corfu.

CENTURION, a military officer among the Romans, who with another officer of the same denomination, commanded a company or maniple, or one of the ten separate parts, into which the hattati, as well as the principles and triarii in each legion, were divided. From each of these descriptions of soldiers, ten men of the most approved and distinguished merit were first selected, and after them ten more. These were all called Commanders of companies or maniples. The first of these that was chosen or appointed was called primipilus, or centurio primipilus, and had a seat in the military council. Two of these centuries or captains of companies or maniples were appointed to each company. And when both were present, he that was first chosen led the right, and the other the left of the company; but when either of them was absent, he who remained, conducted the whole of it. In the choice of these captains or commanders of companies, those who were the boldest and most enterprising were not esteemed the best, but rather those who were nearest and fleeter, prudent and skilful in command. And it was not so much required of them that they should on all occasions be eager to begin an engagement, to force those themselves into action, as that when hard pressed or even overpowered by superior force and numbers, they should still maintain their posts, and rather die than desert their stations.

The twenty centuries or commanders of companies chose twenty two other men of distinguished conduct, prudence, and merit; two of whom were affiliated to each company to take care of its rear. Besides these, two of the bravest and stoutest among the soldiers were appointed by the centuries to carry the standards in each company. And it was not without very good reason indeed, that two captains or centuries were affiliated to each maniple or company, as well as two sub-captains or sub-centurions. For as it was impossible to know or ascertain beforehand what the conduct of an officer would be, or to what accidents he might be exposed; and as those of the affairs of war is inadmissible, that precaution and arrangement were necessary to prevent the company from being on any occasion without a leader.

A centurion is generally defined to have been a military officer, who commanded a hundred men. But this is a very erroneous definition. For when the Roman state was in its greatest vigour and perfection, which it was about the time of Hannibal's invasion of Italy, the two centuries in a maniple or company of the hastati or principles commanded twice as many men as the two centuries in a maniple of the triarii; as a maniple of each of the former then contained 120 men, whereas a maniple of the latter consisted only of sixty. The legion then consisted commonly of 4200 foot, and 300 horse. Of these 4200 infantry, 600 were triarii, 1200 were hastati, 1200 were principles, and the remainder were velites or light troops.

Anciently and before the war of Hannibal, it was the constant custom of the Romans to raise four legions annually, and to allow to each legion 4000 foot and two hundred horse, unless they were pressed by any great or unusual danger, in which case they increased the number of men composing it to 5000 foot and 300 horse. And prior to the battle of Cannae, they ordered eight legions of 5000 men each to be raised, independent of an equal number of the allies, an expedient, to which they had recourse before they had recourse in any of their wars. Whilst the number of foot in a legion thus varied between 4000 and 5000, the number of men commanded by a centurion in the hastati and principles also varied, though the number of those commanded by a centurion in the triarii continued invariably the same. For whatever number of men the legion consisted of, that of the triarii continued at 600, or the same, till it was augmented as equal that of the hastati or principles; towards the time of Julius Cæsar and the close of the mixed government of the Romans, during the continuance of which in its vigour and purity the numbers of men commanded respectively by a centurion in the hastati, or principles, and by a centurion in the triarii, were
were in a ratio that frequently varied. During the same period, there were, in every legion, sixty centurions or commanders of companies or maniples, sixty officers chosen by them to take charge of the rear of the companies, who might be denominated sub-centurions or sub-capitans, and sixty standard-bearers or enligns, who were appointed by the captains or centurions.

CENTURIONES, An, in Ancient Geography, a place of Gaul in the French.

CENTURIPS, Centuripri, now Canterbury; a town of Sicily on the south coast, at a small distance from Catania. This city was declared a capital, and, like Syracuse, received its liberty from Timoleon. Its inhabitants cultivated the fine arts, particularly sculpture and engraving. In digging for the remains of antiquities, coarse are no where found in such abundance as at Centuripii and its environs. The situation of the place is romantic; it is built on the summit of a salt group of rocks, which was probably chosen as the most difficult of access, and consequently the most proper in times of civil commotion. The remains of its ancient bridge afford evidence of its having been formerly a considerable city. Cicero speaks of it as such. It was taken by the Romans, plundered and oppressed by Verres, destroyed by Pompey, and restored by Octavius, who made it the residence of a Roman colony. Houel's Voyage Pittoresque des Isles de Sicile, de Malte, et de Lipari, &c. See CANTORI.

CENTURY, in French centuria, from the Latin word centuria, a derivative of centum, a hundred. Strictly speaking, it signifies one hundred of any thing, as a hundred years, a hundred men, &c.

The term centuria, century, was given to the Roman horsemen or equites that belonged to each tribe, and at first amounted only to a hundred. The term, however, centuria equitum was continued after that number was greatly increased. It was also, however, the custom of the Romans, in forming their legions, to choose their cavalry, and to add two hundred horsemen to every four thousand of their infantry. But in the time of Polybius, the citizens, of whom the cavalry was composed, were appointed by the censors according to the rate of their revenue, and were enrolled before the infancy; and three hundred of them were assigned to every legion.

When the Roman people were assembled in the Campus Martius for the purpose of choosing magistrates, establishing laws, or deliberating on public affairs, they were divided into centuries, and voted by centuries to facilitate the taking of their suffrages. These assemblies were called comitia centuriata.

The Latin writers sometimes made use of the word centuria, to denote a company or the number of men commanded by a centurion, whether it consisted of a hundred, or of more, or of less. Thus the phrase, pedes centuriant, means infantry divided into companies or maniples.

In chronology, century signifies a period of one hundred years. Church-history is generally computed by centuries commencing from the incarnation of Jesus Christ. In this sense of the word, we say, the first century, the fathers of the second century, the counsels of the third century, &c.

CENTUS, in Ancient Geography, a town of Arabia Felix. Ptolemy.

CENTUSIS, a Roman coin, containing a hundred asses. See AS.

CEPOL, or CEPOL, in Ancient Geography, now Zira, one of the Cyclades, an island of the Aegorean sea, lies opposite to the promontory of Aegina, called Sinumium, and is 50 miles in compass. This island is commanded by the ancients for its fertility and the richness of its pastures. If we may credit Pliny and Solinus, the first silk fluffs were brought in this island; and they were hence called the Cepolian manufacture. Cepos was also famous for its excellent figs. It is said to have been first peopled by Arioius, the son of Apollo and Cyrene, who, being grieved for the death of his son Acheron, retired from Thebes, at the perfusion of his mother, and went over with some Thebans to Cepos, at that time unoccupied. Diiodorus Siculus says, that he retired to the island of Cepos; but the ancients, as Servius (in Virg. Georg. lib. i.) observes, called both these islands by the name of Cepos. However this be, the island of Cepos became fo populous, that a law prevailed there, commanding all persons upwards of 60 years of age to be poisoned, that others might be able to labour; so that none above 60 years of age were to be seen in the island, being obliged, after they had attained that age, either to submit to the law or abandon the country, together with their effects. (See Strabo, lib x. Ælian Var. Hist. lib. i. c. 77.) In former times Cepos had four famous cities, viz. Julis, Corthea, Corephiis, and Praethylis. The two latter were, according to Pliny (l. xvi. c. 25), swallowed up by an earthquake. The other two flourished in the time of Strabo. Julis was seated on a rising ground, at the end of a valley, about 3 miles from the sea; and its situation agrees with that of the present town of Zira, whence the island derives its name. The ruins both of Corthea and Julis are still remaining; those of the latter occupy a whole mountain, and are called by the modern inhabitants "Polis," that is, the city. Near this place are the ruins of a small temple, with many pieces of broken pillars, and statues of most exquisite workmanship. The walls of the city were of marble, and some pieces are still remaining. About 12 feet in length. Julis, was, according to Strabo, the birth-place of Simonides, Bacchylides, Eratosthenes, and Ariton. We learn from the Oxford marbles, that Simonides, the son of Leep gepis, invented a sort of artificial memory, the principles of which he explained at Athens; and that he was defended from another Simonides, who was a poet no less renowned than himself. One of these two poets invented those melancholy versicles which were sung at funerals, and are called by the Latins "Nemesis." (Hor. I. ii. 1.) Strabo says, that the Athenians having besieged the city of Julis, raised the siege upon advice that the inhabitants had resolved to murder all the children under a certain age, that useful persons might not be employed in taking charge of them. Cepos, with the other Greek islands, subdued by the Romans, and belowered upon the Athenians by Marc Antony the triumvir, together with Æginæ, Timos, and some other adjoining islands, which were all reduced to one Roman province by Vespasian.

CEPA, in Botany. C. Bauh. Tourn. See ALLIUM.

CEPA, Rumph. See Pancreatium anchoifae.

CEPA, in Gardening. See ALLIUM.

CEPÆA, in Botany. C. Bauh. See Sedum Cepæa.

CEPARUM PRIMONTORIUM, in Ancient Geography, a promontory of the island of Cyprus, extended into the sea directly towards the north, near the town of Sol, according to Strabo and Ptolemy.

CEPASILE, in Geography, a town of Italy, in Venetia, N. of Plavis and W. of Æpitergyium.

CEPEDE, De La, Count, in Biography, a French writer on music, who published, in 1785, a treatise entitled "La Poétique..."
P.S.C. P.

Poezie de la Musique," which contains many excellent reflections and precepts for a young composer of lyric dramas, particularly French, from which the author draws all the illustrations of his principles. The work is extended to 2 vols. 12mo.; is well written and well printed, but contains few precepts to which the present musical critics at the Institute, or ferous opera, will subscribe. The tale of music at Paris, from all we can gather in conversing with good judges of the lyric drama, is so much improved since the time of Rossini, and the orchestra so well disciplined by the performance of German symphonies, that, with a better language for the emission of sound, and better fingers, would be very high in the scale of the melodrama.

CEPHALOÆDIS, Cefalu, a town on the northern part of Sicily.

CEPHALALGIA, in Medic. from κεφαλή, head, and αἰθή, pain, is the technical term for the disorder, which is, in common language, called head-ache. By some authors this term is applied only to a recent or flight head-ache, or to one which is partial or confined to a particular part of the head; and they employ the word CEPHALÆA, κεφαλαία, to denote the complaint, when it is of longer standing, or more obstinate, or when the whole of the head is affected. These definitions, however, are generally overlooked at present, and from two terms are used synonymously. Other denominations are also given to head-aches, which are accompanied by other peculiarities of symptoms; thus when they return at regular periods, with certain intervals of cafe, they are termed intermittent head-aches, and by the vulgar, aches in the head; and as in these infures it usually happens that one half of the head only suffers, they are technically described under the term Hemianalia (from ἡμι-, half; and ἀνάλη, the skull); see HEMICRANIA. When the pain is confined to a particular point in the face, namely, to the situation of a small hole, through which a nerve passes to the integuments, it has been denominated by the French Tie Douleurs. A local and violent pain also occurs occasionally in some part of the head, in hyphema, an animal, which is laid to resemble the senation of a nail driven into the head, and has hence been denominated Clavus hystericus. See HYSTERIA.

Head-ache is a symptom of almost every febrile complaint, as well as of many others of a chronic nature; inform much that Dr. Cullen has not included it among the genera of idiopathic disease, in his nosology. Although it be, however, in a great majority of infures, symptomatic of a disease in some other part of the body, or of a general febrile state, yet it is frequently the concomitant of some morbid state of the contents, or of the integuments, of the skull.—An acute pain of the head is one of the most obvious marks of inflammation of the brain or its membranes, which is termed phrenitis, or phreny; as well in its common acceptance, as in that form of the disease, which terminates by an effusion of serum into the ventricle of the brain, and is then denominated hydrocephalus. It also accompanies the various organic diseases, which take place in the different parts of the brain, as may be found among the accounts of febicides, detailed by Morgagni, Haller, Lieutaud, &c. Thus after death, which had been preceded by severe and obilinate head-ache, tumours and abscesses have been found in, or adhering to, certain portions of the cerebrum or cerebellum; the different membranes of the brain have been found thickened; the arteries or membranes partially converted into bone; bony projections from the cranium have been discovered piercing or pitting on the brain; and effusions of blood or serum producing pressure on the external surface, or in the internal cavities, of that organ. Pain in the head is also the consequence of that influx of the vessels of the head, which gives rise to lethargic, apoplectic, and paralytic affections, by prehure on the brain, or by the subsequent rupture of the vessels, and effusion of blood. In persons of full habit of body, therefore, with short neck, large head, and fluid complexion, the head-ache is usually one of the forerunners of an apoplectic attack.

Further, there are infures of idiopathic head-ache, in which the brain itself does not appear to be affected, but in which the morbid condition is confined to the skull, or its integuments. The integuments of the cranium appear to be not unfrequently the seat of rheumatic inflammation, which gives rise to a head-ache, tedious and distressing as rheumatic fevered in the membranes surrounding the joints, or in other parts of the body. The poison of the venereal disease, when the syphilis becomes thoroughly imbued with it, is liable to excite a peculiar inflammation in the periosteum, or membrane investing the skull, and even in the skull itself, which excites a severe head-ache, accompanied by a great forense and tenderness of the integuments.

The most frequent infures of head-ache, however, are those in which it is symptomatic of disease in some other part of the body, or arises in consequence of the sympathy which exists between the brain and some other organ. These sympathies are numerous, and one of the strangest is that which takes place between the head and the alimentary canal, but especially between the head and the stomach. Hence with almost every derangement of the stomach, the head is liable to suffer. Such is the origin of that common complaint, especially among the high-feeding ranks of society, which is usually termed a sick head-ache, and which has been well described and commented on by Dr. Pothergill. (See Medical Obs. and Inquir. vol. vi. p. 103.) This learned physician has remarked, that the patients, affected with this species of head-ache, awake early in the morning with a pain, which seldom affects the whole head, but one particular part of it only; most commonly the forehead, frequently over one, and sometimes over both eyes. Sometimes it fixes itself about the upper part of the parietal bone of one side only; sometimes, and not unfrequently, the back part of the head, or occiput, is affected: sometimes it darts from one to another of these places. With this is joined more or less of sickness, which is dull barely, in many people, not sufficient, without ailanscence, to excite vomiting. If this pain comes on, as is usually the cafe, early in the morning, and before any meal is taken, seldom any thing is thrown up but this phlegm, unless the inflammation is severe, when some bitter or acid bile is brought up. In this case, the disease begins soon to abate, leaving a forense about the head, a squamativeness at the stomach, and a general measiness, which induces the sick to wish to repose. Perhaps, after a short sleep, they recover perfectly well, being only a little debilitated by their sufferings.

The duration of this paroxysm is different in different persons: in some it goes off in two or three hours; in others it will last twenty-four, or longer, and with a violence scarcely to be endured, the leaf light or noise seeming to throw them on the rack. Its returns are very irregular, as must be the case, since the disease for the most part proceeds from accidental causes. It occurs in persons of almost every habit and complexion; chiefly in the early and middle stages of life, and among the middle and upper ranks in society. Those who use but little exercise, and are inattentive to their diet, both as to the kind and the quantity, are the greatest sufferers.

This,
CEPHALALGIA.

This, or a similar species of head-ache, is frequently an attendant on a constricted state of the bowels; so that those who are habitually colicky, are frequently subject to habitual head-aches, which are really removed by laxative medicines, or cease on the suppression of a laxity of the intestines from any other cause. Even in the febrile state, when the head-ache may be considered as originating from other circumstances, dilatation of the bowels tends to aggravate it greatly. Hence the necessity for the practitioner to attend to the state of the bowels in all cases of head-ache.

A pain in the head frequently occurs, in consequence of its sympathy with the utile organs, more especially as a symptom of retention or suppression of the catamenia. In the latter case, indeed, it may perhaps be considered as the effect of an increased quantity of blood distributed to the head, rather than a sympathetic pain, since a general pleurisy is induced by the suppression of an accutened evacuation. In the same way head-ache is the consequence of the suppression of other habitual discharges, such as old ulcers, and ulcers, the bleeding piles, or the omission of periodical blood-letting.

Head-ache is a symptom of almost all acute febrile complaints, as well of intermittent as of continued and convulsive fevers. It likewise occurs in certain atheritic or debilitated conditions of the body, when it has been called a nervous head-ache. This species of head-ache takes place, as Dr. Willan has remarked, "unconnected with any particular febrile disease, from sorrow, fatigue, watching, and from sudden changes of temperature in summer as well as in winter. It is attended with a whiteness of the tongue, and a sensation of weakness or languor. A sharp and quick pulse, in this complaint, produces a throbbing at the temples, and an acute pain through the whole head. When the pulse is slow and feeble, the pain is described as dull and heavy, sometimes girding round the head, sometimes fixed at the nape of the neck. In persons who have constitutionally a very languid circulation of the blood, the latter species of head-ache recurs on every light occasion, and often becomes periodical, returning every day, or every other day, without any manifest exciting cause." Reports on the Diseases in London, p. 239.

It is obvious, then, that the causes of head-ache may be considered under three heads; namely, whatever comprizes or in any manner irritates the contents or the integuments of the cranium itself; whatever irritates or injures those parts with which the head is connected by sympathy, especially the organs of digestion; and, lastly, whatever tends to induce a state of fever or of morbid irritability in the constitution at large. It is frequently extremely difficult, particularly at the commencement of the disease, to ascertain the nature of the cause from which the pain originates. If it arise from inflammation in the brain or its membranes, indeed, it will be easily distinguished by the acute fever, with a quick and hard pulse, the intolerance of light, delirium, and other symptoms of phrensy; and if these occur in children, a termination in hydrocephalus, or dropsy in the head, may generally be anticipated. When the pain attacks those persons who exhibit the marks of phthisis before described, and who are affected with great drowsiness, or slight loss of memory, there can be no doubt that the fullness of the vefels of the brain is the immediate cause of the head-ache. And when symptoms of Hercynia, or of rheumatism, in other parts of the body, have preceded or accompanied the head-ache, it may be pronounced phthisical or rheumatic according. But it is not only extremely difficult, if not impossible, to determine what the internal organic cause of the head-ache is, or in what part of the brain it is situated, but also to ascertain whether the cause be really organic, or whether it may arise from sympathy with some other organ, or from the state of the constitution in general. The duration and perniciousness of the pain are often the only source of conjecture as to its organic origin.

With respect to the sympathetic head-aches, the absence of the diagnostic symptoms just enumerated; the obvious condition of the functions of the stomach, bowels, &c.; the known circumstances as to irritability of diet, &c. which may have preceded the attack; and the fact, the mode, and time of its occurrence, as has been already stated, will contribute to inform us of the nature and origin of the head-ache. And if there be any obvious general debility, languor, or low spirits, with occasional giddiness, tremors, and sensations of faintness about the precordia; and, more especially, if grief, watching, fatigue, or such debilitating causes have been acting, the asthenic head-ache, before described from Dr. Willan, may be presumed to exist.

After all these circumstances have been duly investigated and considered, the method of treatment to be adopted will readily suggest itself, if the conclusion as to the origin of the complaint be satisfactory. Where the symptoms of phrenetic inflammation are present, general and local blood-letting, blunting, purging, the application of cold, and the whole of the anthroplogistic regimen, must be referred to. See Phrenitis. Where there is apparently some internal organic cause, the nature and seat of which cannot be ascertained, the attempt to cure can only be pursued upon general principles; and therefore, upon the supposition that some morbid or preternatural enlargement of some part is taking place, the impetus and quantity of the blood carried to the brain, and the increased action of its vessels, must be diminished by the local extraction of blood, and the application of blisters; which view will also be further accomplished by the administration of some febrile medicine, such as digitalis, or ciauta; or with the intention of exciting the activity of the absorptive vessels, by which any morbid growth may be diminished, the use of mercury may be also referred to. The bowels, in such a case, must be kept regularly open; and every thing which can accelerate the circulation, whether stimulating food or drink, or corporeal exertion, should be carefully avoided. Where the head-ache is apparently phthisical or rheumatic, it is scarcely necessary to mention that the remedies, which are useful in other forms of phthisis and rheumatism, may be administered with success.

The "feck head-ache," which depends on a disordered condition of the stomach and bowels, occasioned by irregularities of diet, may be readily removed or relieved by emptying the stomach of its ed-digested and noxious content, by means of an emetic or mild cathartic: but the same paroxysm will be again repeated, unless the cause be avoided. Some persons prefer to little f.d.-command, and are so much habituated to indulge in the gratification of the palate, that they pass a great portion of their lives in the constant succedaneum of such attacks. The stomach, however, may be strengthened, and its digestive powers aided, by the use of bitter stomachic medicines, joined with alkalies or preparations of fucul; and the remora of the food may be in some degree avoided by the use of rhubarb and magnesia, or the astrigent pills, in moderate quantities. But, as Dr. Fothergill has very judiciously remarked, "whatever proceeds the physician's judgment leads him to pursue, there is one object that will defer his attention, and will require that of the patient. This disease is not the effect of any sudden accidental cause; it is the effect of reiterated errors in diet, or in conduct, which, by weakening the powers of digestion,
Where the head-ache is a concomitant of general fever, the treatment peculiar to that modification of fever which may be present must be necessarily employed. See Fever.

Gen. Ch. Col. common perianth none: capsules receptacle globular, villose, collecting numerous florets into a head; superior perianth superior, small, one keeled, funnel-shaped, angular; border quadrifid. Proper monopetalous, funnel-shaped; tube flender, longer than the calyx; bowl quadrifid. Stem. filaments four, inserted into the corolla, shorter than the border; anthers globular. Pet. germ inferior; stile longer than the corolla; stigma globular. [Peric. none. Seeds solitary, long, attenanted at the base, pyramidal, wooly. Linn.] Peric. capsule inferior, crowned with the permanent calyx, inverely pyramidal, four-celled; cells one-seeded, separating from each other as the seed ripens, but without valves, and not opening spontaneously; two of them generally abortive. Seeds oblong. Garr. Lam.

Gen. Ch. Flowers aggregate, fixed to a globular receptacle. Calyx proper superior, quadrifid. Corolla tubular. Capsule four to two-celled, dividing into four or two parts. Sp. 1. C. occidentalis, Linn. Sp. Pl. Mart. 1. Lam. 1. Willd. Gart. tab. 86. fig. 7. Lam. ii. tab. 59. (Sect. mila, Pluk. tab. 72. fig. 4.) "Leaves opposite alternate: heads terminal, forming a kind of raceme." Lam. A shrub, from five to seven feet high. Stem a little branched, weak, cylindric, greyish, leathy, almost its whole length. Leaves petiolate, egg-shaped, acute, entire, soft, smooth above; the nerves of the lower surface, as well as the petioles, sometimes bifet with short hairs. Flowers white, in small peduncled heads which terminate the stem, three, five or seven together, and form what La Marek calls a kind of raceme, but which, from the terms of his own description, as well as from his figure, is rather an umbel. A native of swamps, in Carolina. A decoction of the wood or root is used as a cure for the bite of venomous animals, and is said to be efficacious in venereal complaints. 2. C. angustifolius, Mart. 2. Linn. Cochin. "Leaves lanceolate, linear, opposite." A middle-sized tree, with ascending branches. Leaves quite entire. Flowers pale, in small terminal heads; common receptacle oblong, villose; segments of the proper calyx awl-shaped, hairy, beket with shining, coloured, peduncled glands. Fruit a small compound berry; the acini or component parts roundish, crummed, flacid, two-celled, inferior; cells one-seeded. A native of Cochin-China. 3. C. procumbent, Mart. 3. Linn. "Stem procumbent; leaves ovate-lanceolate, alternate." A thick shrub, with many long filiform branches. Leaves large, quite entire, tomentose, petiolate. Flowers violet-coloured, dioecious; in long, interrupted, terminal racemes; the females in a naked globular receptacle, without any perianth, either proper or common; corollas five-cleft, inferior, very many, on long pedicules, forming a ball or head; stile capillary, equal to the corolla; stigma simple. Seed fagine, egg-shaped, compressed, naked. A native of Cochin-China. 4. C. montanus. "Leaves egg-shaped, crenate, alternate." A large tree, with a hempen bark and spreading branches. Leaves acuminate, petiolate, rough above, tomentose underneath. Flowers dioecious, green, on solitary axillary peduncles, forming roundish...
in heads, on a naked globular receptacle; the female
without a corolla; proper perianth almost closed, four-cleft,
superior. Sex fiddle, compacted, with a subpappose ring,
periphere from the lacinated tube of the calyx. A native
of China. 5. C. Reticula, Mart. 5. Four. Leaves
laciniate, laciniate-linear." A middle-sized tree, with ascending
branches. Leaves by threes, quite entire, smooth. Flores
white, collected into a ball, with a small egg-shaped receptacle;
no common perianth; proper perianth inferior, with
four awl-shaped segments; corolla superior, with a four-cleft
reflexed border, four nearly sessile anthers, a long style, and
one naked style. A native of Cochin-China.

We have followed professor Martyn in taking up the last
four species from Loureiro, that they might not be entirely
omitted; although Loureiro himself confesses that they differ
very much from each other, as well as from Linnaeus's
generic character. The description given by Linnaeus
of the fruit of his sole cephalanthus is certainly founded on a
misconception, and, according to Gartner, appears to have
been made when he was only half awake: fructus negligenter & quasi ex infimo descript. It is, therefore,
titled to no authority in fixing the generic character. But
Loureiro's descriptions of his new species are also in several respects so confused, that it is not easy to determine what
he means. If, by the fruit of the second species, which he
calls a compound berry, we are to understand, as is probably
the case, the aggregate fruit of all the proper flowers, it
may belong to this genus. What he calls the single naked
seed of the fifth, may possibly be a pericarp with three abortive
cells, and may not contradict any essential part of the
generic character. But the third and fourth seem too refractory to obtain admission. In Morm, in the Encyclo-
pedic, has added to the C. occidentalis of Linnaeus, two other
species, which he calls euripus and philodera, both
communicated by Sonnerat: the former he supposed might
be found not to differ from nauclea orientalis of Linnaeus,
but he had then no doubt of its being a real cephalanthus.
As, however, he has not infected them in his subsequent illu-
lusions, he appears to have changed his opinion. See
Nauclea.

Propagation and Culture. The first species only has been
cultivated in England. It has been raised by cuttings and
layers, but is chiefly propagated by seeds. These should be
sown before Christmas, and will then come up in the next
spring; but if they be sown in spring, they generally remain a
year in the ground; in which case, the pots should be
placed in the shade during the summer, and sheltered under
a common frame to protect them from frost in the ensuing
winter. The third year, after they come up, they should be
shaded from the sun in hot weather; and as they naturally
grow in moist ground, should be regularly watered. In
the autumn they may be transplanted into sheltered nur-
series beds, where they may remain a year or two, according to
the progress which they have made; and should be finally
transplanted in October.

CEPHALAS, in Ancient Geography, a promontory of
Africa, mentioned by Strabo, situate at the commencement
of the great Syrin. He adds, that it was elevated, and
covered with wood. Ptolemy also mentions it. It is thought
to be the present cape Mejana.

CEPHALE, a burgh of Greece in Attica, between
Prophyta and Aphydne, at some distance from the coast of
the Saronic gulf. The Dioecuri, viz. Caistor and Pollux,
were highly respected in this place, that they were ranked in
the number of the great gods, according to Pausanias.
This burgh belonged to the Acrampite tribe.

CEPHALENIA, or Cephalenia, an island of the
Ionian seas, now called Cephalonia, which see. It was
known in the time of Homer (Odyssey) by the names of Olym-
peus and Black Epirus, or Epirus Melana; and had an-
ciently four cities, one of which bore the name of the island,
although Ptolemy mentions only two. Strabo tells us, that
in his time there were only two cities remaining; but Pliny
(L. iv. c. 12.) speaks of three; adding, that the ruins of Same,
which had been destroyed by the Romans, were still in being.
Same was the metropolis of the island, and is supposed to
have flood in the place which the Italians call "Porto Gir-
cardo." The names of the four cities were, according to
Thucydides (lib. ii.) Same, Prone, Craioni, and Pale.

This island was subdued by the Thebans, under the con-
duct of Amphytrion, who is said to have killed Pterelas,
who then reigned there. While Amphytrion was carrying on the
war in Cephalonia, then called Samos, one Cephalus, a man
of great distinffion at Athens, having accidentally killed his
wife Procris in shooting at a deer, fled to Amphytrion, who,
pitying his fate, not only received him kindly, but made him
governor of the island, which from that time was called Cep-
halonia. After it had been long in subjection to the The-
bans, it fell under the power of the Macedonians, and was
then taken from them by the Athenians, who held it till it was reduced by
M. Fulvius Nobilior, who having gained the metropolis
after a four months' siege in the year 169 B. C., fold all the
citizens for slaves, adding the whole island to the dominions of
his republic. Liv. i. xxxviii. c. 29. 29.

CEPHALICUS, in Medicine, from κεφαλή, the head,
a term given by the older writers on the materia medica,
to the organs which receive the disorders of the head. Under
this term were chiefly included certain fragrant, aromatic,
and stimulant substances, which, whether applied as odours
to the organs of smell, or used as inebriating, or taken into the
flomach, afforded a speedy relief to nervous or ascen-
taneous headaches, giddiness, and faintness. In such a condi-
tion of the body all cordials would operate as cephalics.
The symptoms arise from a languor of the circulation in the
veils of the head, which is accelerated by the general flui-
mus of cordials taken into the flomach, or the local flui-
mus of odours or inebriating applied to the organ of
smell, and the headache or giddiness necessarily ecede. The
term is now seldom used.

CEPHALIC vein, in Anatomy, one of the large superficial
veins of the upper extremity. See Veins.

CEPHALOIDES, a denomination given by some writers,
who discover virtues in plants from their signatures, to
those which bear any resemblance to a human head; such
are the poppy, poppy, and like.

CEPHALOMANTIA, from κεφαλή, and μάντις, divi-
nation, an ancient species of divination, or method of foretell-
ning futurity by a dead man's skull.

CEPHALONIA, in Ancient Geography, one of the ancient
names of the city of Rome.

CEPHALONIA, or Cephalonia, in Geography, a con-
 siderable island of the Levant, in the Mediterranean, near
the coast of Livadia to the north-east, and near the coast
of Morocco to the south-east, opposite to the gulf of Lepanto;
about 150 miles in length, and from 80 to 90 its greatest
breadth; anciently called Cephalonia, which see. Venice
acquired the sovereignty of this island, as a gift from Gaido
to lord, in 1224; though it was taken by the Turks in 1479,
and held by them for about 20 years. On the fall of Venice,
it was seized by the French; and by the fourth article of the trea-
ty of Campo Formio in 1797, renewed and confirmed by the
third article of the treaty of Lunville in 1801, so that the
French republic hold posses, in full sovereignty, the ci-

devant Venetian islands of the Levant, viz. Confl. Zante, Cephalonia, St. Maure, Cerigo, and other islands dependent theron; together with Butrinto, Larta, Voaizia, and in all the cis-vant establishments in Albania, which are situate lower down than the gulf of Lodrino.

The chief articles of commerce in Cephalonia are oil, molasses, and a species of grapes called currants. The air of this island is very warm; the trees are covered with flowers through the winter, and bear ripe fruit twice a year, in April and November; but those which grow in the latter month are smaller than the others. Corn is sown in the winter, and reaped in June. N. lat. 38° 10' to 38° 54'. E. long. 20° 15' to 21° 52'.

Cephalonia, the capital of the island of the same name; the seat of a bishopric united to Zante. N. lat. 38° 30'. E. long. 28° 40'.

Cephalonnesos, in Ancient Geography, an island of the Exune sea, in the Cariamite gulf, according to Pliny. It belonged to European Sammtica, according to Ptolemy. CEPHALONANTICIA, composed of κεραῖον, head, κοιλιον, and μυχαίνα, division, a method of division, or revealing secrets, by means of an αία's head broiled on the coals. After muttering a few prayers, the name of several persons suspected of a theft, or the like, were repeated over; he at whose name the αία's jaws made any motion, or the teeth began to chatter, was held for convicted.

CEPHALOPHANYGEUS, in Anatomy, a term applied by some writers to the middle constriction of the pharynx. See CONSTRUCTIORES PHARYNGIS.

Eff. Ch. Receptacle naked, hemispherical; down chaft-like, many-leaved; calyx many-leaved, reflexed.

CEPHALOPODY, from κεφαλή and ποτίς, pain, a denomination given by home to the cephalophora, or head-ache.

CEPHALOTOEM, in Ancient Geography, a people of Asia, placed by Pliny towards mount Caucas, and on the borders of the Exune sea.

CEPHALUS, a town of the island of Cyprus, watered by the river Areus.

CEPHALE, in Mythology, the name given by Aristotle, Aelian, Appian, and others to the mullet, muced cephalus, which fee.

CEPHALE, in Ancient Geography, a country of Armenia, more generally called Sophort.

CEPHENES, a name anciently given by the Greeks to the Persians.

CEPHENIA, a name which, according to Agathæneus, was given to Euphratea, and which seems to have been derived from the fabulous Cepheus.

CEPHESIAS, a lake, so called by Strabo, situated on the coast of Africa.

CEPHESUS, in Astronomy, a constellation of the northern hemisphere, being one of the 45 old altitutins; whose stars in Ptolemy's Catalogue, are 15; in Tycho's, 12; in Hevelius's, 51; in the British Catalogue, 55.

Dr. Herchel has given an account of the latitude of the 35 stars in this constellation, in his third catalogue of the comparative brightnesses of the stars; (Phil. Trans. for 1797; pt. ii. p. 314.) and he observes that the 15th, in the neck of Cepheus, marked by Bayer, consists of two stars. Mr. Goodricke infers from a series of observations on the star α Cephei, that it has a periodic variation of 5' 8° 37', during which it undergoes the following changes; viz. it is at its greatest brightness about one day and thirteen hours; its diminution is performed in about one day and eighteen hours; it is at its greatest obscurity on about one day and twelve hours; and it increases about thirteen hours. In the fift point, it appears as a star of the 2d and 4th magnitude, though its relative brightness does not seem always to be quite the same. In the third point it appears as a star of between the 4th and 5th magnitude, if not nearer the 5th; and its relative brightness is as follows: nearly equal to; and ɛ Cephei, and considerably less than 7 Lacertae. The relative brightnees and magnitude of these stars with which the variable one was compared are as follow: ɛ Cephei, the brightest, is between the 3d and 4th magnitude; ɛ Cephei, the next brightest, is between the 4th and 3d; 7 Lacertae, is less than ɛ Cephei, and of about the 4th magnitude; ɛ Cephei is between the 4th and 5th magnitude; and ɛ Cephei, which is a little less than ɛ, is between the 5th and 4th. The variation of the star ɛ was corroborated by the observations of Mr. Pigott. Phil. Trans. vol. lxxvi. p. 43. &c.

Cepheus, in Fabulous History, a king of Ethiopia, father of Andromeda by Calliope. See ANDROMEDA. Cepheus was one of the Argonauts, and after his death, became a constellation. There was another Cepheus, prince of Arcadia, and favoured by Minerva, who transferred to his head a lock from the head of Medusa, by which he was rendered invincible. He is mentioned by Apollodorus as the son of Leucorus, and hunter of the Caledonian boar. A third Cepheus is said, by the same author, to have been the son of Aeius, an Argonaut, king of Tegen, father of Sterope, and an oracle of Hercules, in opposition to Hippocoon.

CEPHISSIA, in Ancient Geography, a village of Greece, in Attica, near Athens.

CEPHISSUS, a fountain of Attica, according to Pliny.

CEPHISSUS, or COPIS HIBIUS, a lake of Brontia, which took its name from the river Cephissus, which discharged itself into this lake. Its name, Copis, was formed from the town of Copes, seated upon its banks. Pausanias says (l. ix. Boetiae, c. 74.) that there were two towns on this lake, viz. Athens and Eleutis, which had been swallowed up by its inundations.

CEPHISSUS, or CEPHISUS, a river of Greece, which had its source in the mountains that separated Phocis from Thessaly, which range of mountains was called Octa. Its course was from north-west to south-east. In its progress it received several rivers, such as the Lilea, the Fundus, and the Chalceus; and before it entered Brontia, it ran at the foot of a mountain, where was the district called Patopotamus. In Brontia it received the Hermon and the Melas; and at the south of Orchomene it discharged itself into the lake Copis, or Cephissus. This river was celebrated in fabulous history; as the graces delighted to bathe in it, and were thence flyed the goddesses of the Cephissus. This river, or rather river god, is said to have been enmoured of several nymphs, all of whom flew his passion. 

In Attica there were two rivers of this name, one, which
was the most easterly and the most considerable, commenced north of Decelia, ran towards the south as far as Cephalis, and to the south-west on the north of Athens, near the northern wall of the Pireaus, and discharged itself in the port of Phalerum. See Athens. The other river commenced N. of Phyla, and flowed into the Saronic gulf, near Sceius. Near its mouth were found several statues, and one in particular of a young man, who cut his hair in order to consecrate them to the river, according to the custom of the ancient Greeks. Paulmus, in Attic. c. 37. — Cepheus was also the name of a river of the Pecoponousus in the Argolid, according to Pausanius. — Ortelius mentions a river of this name in the island of Samos; a river of Grecia in S. Crema, and another of the same name in the island of Iesus.

CEPHIRO, or Kephiro, a village and desert of Egypt, at the entrance of the desert of Libya; to which were banished Democritus of Alexandria, St. Marcellus, &c.

CEPIUS, or Cephus, in Orbacon, the name by which the black-headed gull has been described by some writers. See Lib. ed. Holboed. See Cepus.

CEPHYRA, or Typhon, daughter of Oceanus, who is fabulously reputed to have deceived Neptune.

CEPI, in Ancient Geography, a maritime place of Asia Minor, placed by Strabo near the island of the Medeans. Also, a town in the island of Cocoscondia, upon the Euxine sea, at the entrance of the Cimmerian Bosphorus, according to Pliny; who says, it was a colony of the inhabitants of Miletus. Strabo calls it Cepus; and it is denominated Cepus by Mala and Diodorus Siculus.

CEPE, in Lavo, a nation made by the sheriff, upon a capias, or other process to the like purpose; signifying, that he hath taken the body of the party.

CEPLANA, in Ancient Geography, a town of Spain belonging to the Celts of Lusitania.

CEP, in Geography, a town of Ithria; 4 miles S. of Pelena.

CEPION, in Antiquity, the name of a particular air, invented by a disciple of Terpander, and designed to be played on the cithara.

CEPIONIS TURRI, in Ancient Geography, a place of Spain, in Bética.

CEPIONITES Turr, in Ancient Geography, a place of Spain, in Bética.

CEPITAS, in Natural History, a name given by Pliny, and other ancient writers, to a species of fish, seeming to approach to the nature of the Jasper. Pliny tells us that there were many kinds of it, some more peculiar than others, and some colourless; others variegated with green and the other colours of the jaspers and agates: they were all used in the ornamentation of houses; and the best beautiful furred, when well polished, to make speculums of.

CEPITES, in Natural History, a name used by the ancients to express a gem which gave the representation of the several chalets of plants and flowers in the beds of a garden, with naked veins, expressing the walks between. The common text of Pliny is unintelligible, where he gives the description of this stone; but Schaffius has restored it from some old copies, so as to make it finite, and expressive of this meaning. The stone was probably not of another peculiar kind of that agate which the ancients called dimwrits, and we the molca flaves.

CEPOLA, in Ichthyology, a genus of theracae fishes, which have the head roundish, and compressed; teeth curved, and placed in a single row; gill membranes fixed; body elongated, naked; belly rather shorter than the head.

CEPULATIS, with cadulian tapering, wCdc; and head very obtuse. It is a native of the Mediterranean sea, and is sometimes found of the length of three, four, or five feet, but more commonly does not exceed two feet in length. The head is short and rounded; mouth large, and the lower jaw rather exceeding the upper one in length. Both jaws are armed with sharp curved teeth, placed in a single row in the upper, and in a double row in the lower jaw. The tongue is broad and long; the eyes very large, with silvery sides, and black pupil, and placed vertically in the head. The abdomen scarcely longer than the head; body remarkably long, gradually tapering to the tail, and of extreme thickness in proportion to the length, whence it obtained the name of a fish or band-fish among ancient ichthyologists. The general colour is very, huory on the back, and the sides, and after a month, marked with rather large reddish spots; a lateral line is wanting, and the fins reddish. This fish is confined to the neighbourhood of the shores, in other more rarely to obtain its food, which consists principally of crabs, and other crustaceous animals. The flesh is extremely edible.

CEROLA, or Cepola, a Cadulian tapering; jaws sharp, pinnate, Limn. Ophiomus macropsia, Ruff., Sync. nat. Tama fipps in the river of Cephisus.

Support, as Gemm and others be to be, perhaps, a variety of the preceding; it is smaller, and of a pale red and hour yellow, hout. It inhabits the Mediterranean, and has been lately discovered on the coast of Devonshire. Vide Limn. Trans. and Donov. Brit. Tiges.

CERAL, or Cepola, a head tapering; both jaws arched; fins pinnate, forked, and rough.

Found in the Adriatic. The lateral line in this species is straight, with a single row of scales.

The hermanian band-fish, cedula hermaniana of Dr. Shaw's zoology, appears to differ from such particulars from the true cedula, that we are of opinion with Cepede, that it ought to form a genus altogether distinct from them.

CEPOLAPITES, in Natural History, a name given by aee to the fish properly called cypites, a kind of moccia agate.

CEPES. See CEPUS.

CEPHULA, in Ichthyology, a name by which Gefeir and some other authors have called the common ribb. fish. It is derived from the Italian word cepole, the familiar name of the same fish in the markets of Rome. This is the cepola tania of modern naturalists.

CEPUS, or CEPUS, in Zoology, a name affixed indiscriminately by old writers to several monstes of the smaller kind that have more or less green among them other colours. The only monstes so named by modern naturalists is the monstes. flamme, fitua cepus of Schreiber.

CERA prima et extrina, in Roman Antiquity, were terms applied to wands and tawettes, from the circumstance of their being usually written on tables covered with wax, because in them a person could easily erase what he wished to alter. Hence cera is put for tabula cerata or tabula tawettea, (Juvenal, i. 63.) and primus cera is used for prima tabs tabulate, the first part of the wall, (Hor. Sat. ii. p. 53;) and cera extrina or ima for the last part, (Cic. Ver. r. 56. Suet. Juvenal, 8. 4.)

CERACE, in Ancient Geography, a town of Macedonia, so called by Pylus, seated near the lake Lichonides.

CERACHATES, in the Natural History of the Ancients, the name of a species of agate of a plain yellow colour, and very much resembling yellow wax. We have it from the East Indies, as also from New Spain, and some other parts of America; and our jewellers sometimes work it into toys of small value.

CERAM,
CERAM, in Geography, one of the spic islands in the East Indian Sea, about 100 miles in length, and 40 in breadth; low towards the shore, and in the interior parts, which are little known, very mountainous. Several chains of mountains run parallel to one another, in the direction of east and west, and are separated by fertile valleys that support a luxuriant vegetation. Its high mountains, some of which are at least 1,200 toises in perpendicular elevation, and yet frequented by the natives, afford effectual protection to their inhabitants; so that the Dutch have only been able to attach to its government of Ambon a comparatively small number, settled on the lower parts of the island, near the sea.

This island is said to contain 30,000 fighting men. It produces clove trees, which the policy of the Dutch has induced them to destroy along the coasts, to which their influence extends; and it has also large forests of the fago-tree, which furnishes a valuable article of exportation. S. lat. about 3°. E. long. about 128° to 131°.

CERAM-LAOUT, an island of the East Indian Sea, near the island of Ceram, above five miles long, and nearly three broad; mountainous, and uninhabited. It has a bay on the north coast.

CERAMBYX, in Entomology, a genus of insects in the order Coleoptera.

The generic character of the Cerambyces is variously defined by different writers. Linneus describes it as having the antennæ composed of articulations, which gradually diminish in size as they approach towards the extremity: thorax either gibbous laterally, or armed with spines; wing-cases linear, or of equal breadth throughout; and the feet confiding of four joints.

This Linnean definition of the genus applies to such a vast number of insects, which, in other particulars, possess an evident generical dissimilarity, that later authors have found it absolutely requisite to divide the Linnean Cerambyces into several distinct genera. Linneus was himself aware of the inconvenience of retaining many of his Cerambyces in this genus; but in order to comprise them, divided the genus into five distinct sections. Thoese families, or sections, as far as they relate to the few species known to the Linnean philosopher, may, perhaps, be found sufficiently comprehensible by the Linnean entomologist; but when we reflect on the vast number of new species, described by the indefatigable Fabricius, by Olivier, and other skilful writers, not to mention the many species that are to be yet found in our cabinets, that have not been described by any author, thoese subdivisions will at once appear incompetent for their arrangement. We must constitute new genera for their reception, or if we are to follow in servile imitation, we cannot dispense with the inattention, at last, of several new subdivisions, to comprise them. The Linnean subdivisions of the Cerambyx genus stand in the following order:

1. Thoese which have the thorax armed on each side with moveable spines—This is exemplified in Cerambyx Longimanus. Linn.
2. Thoese in which the thorax is margined, and armed at the fides with spines—As in Cerambyx pinosus. Linn.
3. Thoese having the thorax round, and armed with fixed spines—As in Cerambyx futor. Linn.
4. Thoese with the thorax unarmed and somewhat cylindrical—As in Cerambyx punclatus. Linn.
5. Thoese with the thorax unarmed, roundish, somewhat globose, and flattened on the upper side—As in Cerambyx violaceus. Linn.

Two writers of respectable quality, Geoffroy and Schaffier, form several new genera of the different kinds of Linnean Cerambyces. Their genus Prionus consists of those which have serrated antennæ placed in the eyes, or surrounded and embraced at their base by the eyes. The true Cerambyces, according to these authors, are such as have the antennæ gradually tapering from the base towards their extremity, and are placed in the eye, and have the thorax armed with spines. Thoese Linnean Cerambyces, which have feticose antennæ placed in the eyes, and the thorax cylindrical and unarmed with spines, are referred to their genus Lepultura; and their genus Speritus comprehends thoese which have the antennæ tapering towards the extremity, but have their base originating before the eyes; and the wing-cases diminishing in breadth towards their point. This last genus Speritus is divided into two families, each of which only belongs to the Linnean Cerambyces, being such as have the thorax armed with spines; the other to the Linnean Lepultura, having the thorax delimitated of spines. Sco-poli likewise has made some alterations in the Cerambyx and Lepultura genera; his character of the first is, however, vague and indefinite; he assigns it the power of emitting a sound or noise by the friction of the thorax, where it lies close to the body, as a character of the genus, and has, by this means, placed several of the true Cerambyces, which have not this property, among his Lepultura. The remainder of the Linnean Cerambyces he separates into two divisions, the first containing those which have the thorax armed with spines, and the other those which have the thorax delimitate of spines.

Olivier found it requisite to divide the Linnean Cerambyces into several genera; La Marck and Latreille have done the same; but the most important innovations that have been made on the Linnean genera are to be found in the different entomological publications of Fabricius. Contrary to the Linnean method, his characters of genera are taken from parts of the mouth, which cannot readily be so examined as thoese which Linneus has taken, or it would be impossible to deny the manifested superiority of the Fabrician genera over thoese of Linneus. Notwithstanding that Fabricius confines so many genera of the Linnean Cerambyces, and that his characters are so dissimilar, thoese genera appear so natural and well selected, that other characters, seen after the Linnean method, may be applied with propriety to nearly the whole of them. This is in particular obvious in the genus Prionus, as well as Lamia and Speritus, each of which poises Linnean characters, if they may be so expressed, different from those which characterize the true Cerambyces, although in the system left us by Linneus, they could not be referred to any other genus. In a work recently published, on the entomology of New Holland, and the contiguous islands, we have endeavoured, under this persuasion, to reconcile the Fabrician genera, Prionus, Lamia, Stenocorus, and Speritus, to the Linnean arrangement, by allying each to a new general definition after the manner of Linneus; and conceiving there can be neither difficulty, nor impropriety, in reconciling many other of the Fabrician genera to the Linnean method in a similar manner. As subdivisions of the Linnean genera, the Fabrician genera might be eminently useful. Should increasing the number of new genera be thought objectionable. It must be regarded as no inconsiderable improvement, in the last edition of the Systema Naturae, that Cimelie has availed himself, in a great measure, of the Fabrician genera as subdivisions of his genus Cerambyx.

The genus Cerambyx comprehends an amazing number of the larger and most beautiful of all the coleopterous insects. In the larger races they resemble the oblong, slender worms, with a heavy head, furnished with strong jaws, and
and fix feet on the anterior part. They live, principally in trees, the inner part of which they bore through, reducing the wood to powder, and undergo their change from the larva to the pupa, and thence to the perfect state, in the cavities which they bore. In the larva state, they are sometimes eaten; in the West Indies these larvae are collected by the negroes as an article of luxury for the tables of their owners, and are in great esteem. Many of these insects possess a powerful odoriferous smell similar to that of the European species Molochatus. The antennae, in many of the species, are longer than the body.

In describing the species of the genus Cerambyx, we shall mention those first which stand as true Cerambyces in the Fabrician, as well as Linnean, systems; the other genera Prionus, Lamia, &c. will be introduced under the present article for the sake of brevity.

Genus Cerambyx.

Antenna fetcaceous: feelers four: thorax spinous or gibbous: wing-cases linear: jaw obtuse and armed with a single tooth. Feelers four, bifid: wing obtuse, with one tooth: antenna fetcaceous. Fabr.

Cerambyx virgatus, black: thorax unarmed, elongated, with transverse rugose fibras: wing-cases feathery at the base, and smooth towards the apex. Donov. Inf. N. Holland.

Cerambyx nigritus, black: antennae fetcaceous, long, flattened in the eyes; feelers four, equal: eyes crescent-shaped: jaws bidentate. La Mare.

Cerambyx circatus, black: thorax unarmed, elongated, with transverse rugose fibras: wing-cases feathery at the base, and smooth towards the apex. Donov. Inf. N. Holland.

This species is found on the willows in European countries, and is generally known in England by the name of Goat-chaffer, or milk-beetle, which last it merits particularly, the insect emitting a powerful smell of musk when alive.

Length, including the antenna, about three inches.

This is a native of Jamaica; the larva is found in the trunk of the amys balumafa. Dr. Schwartz. It is observed of this species, by Fabricius, that it varies in having the antenna longer or shorter than the body, and the thighs toothed or unarmed. These suppos'd varieties are most probably distinct species.

Nitens. Thorax rounded and somewhat spinous: spinning green: thighs elevated, the club of the four anterior ones rufous. Cerambyx nitens of Olivier. Habits Africa.

Muft. Donov. Described by Fabricius from the Bankian cabinet. The antennae are twice the length of the body, and of a black colour: the body fuscous green and shining: legs black: posterior femurs compressed. Fabr.

Afr. Thorax rounded and spinous: body green: antenna and legs rufous. Fabr. This is Cerambyx of the Linnean manta 5:2: the front is obtuse: antenna scarcely longer than the body, and rufous: thorax rugose: wing-cases attenuated: four anterior teeth elevated.

Vittatus. Thorax spinous, fuscous green: thorax and wing cases linedate with black. Fabr. This is Cerambyx of the Linnean manta 5:2: the front is obtuse: antenna scarcely longer than the body, and rufous: thorax rufous: wing-cases attenuated: four anterior teeth elevated.

Festivus. Thorax spinous and green: wing-cases violaceous, greenish at the base: thighs ferruginous, and armed with a foot's tooth. Fabr. Discovered by Mr. Mears in the banks of the river Gambia. The antennae are of moderate length, black, with the first joint rufous: two obtuse spines on each side the thorax: thighs ferruginous: hairs brown.

Voluta. Thorax spinous and black: with a deep black stripe. Fabr. The antennae of this insect are of a moderate length: the body black: wing-cases obtuse, with the dorsal stripe velvety: posterior femurs compressed, and spinous at the apex. This kind inhabits America. Dr. Schinz.

Sericeus. Thorax spinous, body black and filiform: future and stripe on the wing-cases greenish: thighs rufous. Fabr. This insect inhabits South America. The antennae are black: head and thorax deep black, velvety, and spotted with shining green.

Described by Fabricius from the Hunterian cabinet. It inhabits South America. The abdomen is black, beneath bluish and glosy: legs black: thighs clavated: posterior femurs yellowish, and covered with a blackish sable.

Elegans. Thorax spinous, and, with the head, brassy green and glosy: wing-cases dusky: antenna long and rufous: legs rufous. Fabr. Habits America. The antennae in this species are twice the length of the body.

Interruus. Thorax spinous, deep black: wing-cases with three linear white spots: antenna short. Fabr. Described by Fabricius from the museum of Olivier. The antennae are shorter than the body, which last is black: posterior femurs longer than the red, and with the hairs compressed. Native place unknown.

This species is described by Olivier, under the name of Cerambyx torridus. It inhabits Africa. The antennae are long and black, with the third, fourth, fifth, and sixth joint spinous at the tip: thorax black, with three tubercles on each side the face, the lateral ones obtuse: legs black: thighs clavated.

Atrix. Thorax somewhat spinous, black: antenna moderate, and anulated with rufous and black. Fabr. Olivier, &c. Inhabits the Cape of Good Hope. This is much less than the last mentioned species. The body is black: head crimson and glosy: legs black: thighs at the base reddish: posterior femurs long.

Ferrugineus. Thorax armed with sharp spines, rufous.
CERAMBYX.

gold and black; wing-cases ferrugineous; antennae long. Cerambyx ferrugineus. Linn. Inhabits the East Indies. Cerambyx gigas of the Fabrician Monarch.

AELFINUS. Thorax spinous; head, and four spots on the wing-cases; black; antennae long. Linn. Found in some parts of Europe, not hitherto discovered in England. Its size is rather less than that of Cerambyx Mecophus, or Mofh Beetle.

SCALARIS. Thorax spinous and fuscous, with a white longitudinal line; antennae long. Fabr. A native of South America, described by Fabricius from the Bokian cabinet. The antennae are three times the length of the body; head fuscous; orbits of the eyes, and dorsal line white; thorax armed with acute spines, fuscous, with a dorsal line of white; wing-cases fuscous with a white dot in the middle and indented future.

EBULINUS. Thorax spinous, green and brassy; wing-cases telfaceous; antennae short. Fabr. This kind inhabits Africa, and was first described by Fabricius, from a specimen in the collection of Dr. Hunter. The antennae are ferrated; thorax uneven, and without spots.

MARGO. Thorax furnished with two spines, rugose and black; antennae long and ferrugineous. Fabr. From the same cabinet, as the preceding. This species inhabits Cayenne. The antennae are twice the length of the body, cylindrical, and ferrugineous, with the first and second joint cutiled black, and the three next black at the base; thorax rugose; with two spines on each side, the posterior one of which is larger; wing-cases smooth, impressed at the base, and at the tip truncated.

KAHLERI. Thorax spinous, black; wing-cases ferrugineous, with a black spot. Linn. Found in the south of Europe, and varies in being sometimes without the black spot on the wing-cases, and sometimes marked with a rufous lateral spot. Wing-cases notched at the extremity.

LUNDII. Thorax spinous, fuscous, antennae, tips of the wing-cases, abdomen, and legs black. Fabr.

Described by Fabricius from the cabinet of Lund, who received it from Tranquebar. Size of C. Kahlern. Antennae short and black; thorax gibbous, spinous, fuscous, and without spots; scutell black; breast ferrugineous; abdomen black, with acute rugous tubercle between the second pair of legs; thighs slightly elevated.

SUCINCENTUS. Thorax rugose, with two spines; wing-cases banded with yellow; antennae very long and compressed. Linn. Inhabits America and Brazil, and is mentioned by de Geer under the title of Cerambyx fuscles-oalitaec. [i. 113. &c.

DESFONTAINI. Thorax spinous, fuscous, spotted with black; wing-cases ferrugineous and black at the tip and base; antennae very long. Fabr.

In the collection of Desfontaines. This kind inhabits Barbary. The head is black; wing-cases smooth, with a small black spot at the base, and an larger one at the apex; thorax black and without spots.

STRIATUS. Thorax somewhat spinous, rugose, ferrugineous; wing-cases impunctate with yellow; antennae long. Oliver. Fabr. &c. Inhabits Cayenne. Described from the Hunterian collection. The antennae are cylindrical, twice the length of the body, ferrugineous, and black at the tips. Head ferrugineous with three vertical black spots; thorax rugose, with two spines on each side, and dotted with black; scutell black at the tip; wing-cases ferrugineous with four yellow bands; thighs black at the tips.

RUTIPES. Thorax robust, and armed with two spines; wing-cases smooth and black; antennae long. Fabr. A native of South America. The antennae are longer than the body, and yellowish, with the tips of the joints ferrugineous; posterior thoracic spine large; wing-cases glabrous, with a large impressed dot at the base; legs yellowish with the tips of the thighs black; abdomen black.

DIMICATUS. Thorax armed with two spines, and rugose, yellow with black spots; wing-cases black, yellow at the base; antennae moderate. Fabr.

The head of this insect is yellow, with three vertical black spots; posterior spine on the thorax large, and yellow with black dots; wing-cases glabrous, black, with the future and base yellow; body yellow with half the abdomen black; legs yellow.

BICOLOR. Thorax armed with two spines, tuberculated and ferrugineous; lower half of the wing-cases, and the body black. Olivier. &c. Inhabits Cayenne; first described from the cabinet of Von Rohr. The antennae are moderate, ferrugineous at the base, in the middle yellow, and at the extremity ferrugineous; head ferrugineous; throat prominent and acute; a large impressed dot at the base of the wing-cases; legs ferrugineous.

DEPRESSUS. Thorax armed with many spines, depressed, black, variegated with cinerous; wing-cases pointed; antennae long. Olivier. Vest. &c.

The head is black with cinerous villous impressed spots; thorax befeet on each side, with about four or five short spines; wing-cases striated; legs black.

FASCICATUS. Thorax spinous, azure; wing-cases banded with yellow; antennae moderate; yellow, blue at the base and tip. Found in Tranquebar by Dr. Koenig. The antennae are compressed, and blue; the last four joints but one yellow; the last blue; legs blue, the posterior ones compressed. Olivier, Dallas, &c.

BARBICORNIS. Thorax spinous; four first joints of the antennae bearded with black; body telfaceous, variegated with black. Fabr. This species inhabits the East Indies.

NEBULOSUS. Thorax spinous; wing-cases dotted and striped with black; antennae long. Linn. Inhabits the trunks of pine trees in Europe, and is found in England. Donov. Brit. Inf. Length half an inch.

OBSCURUS. Thorax spinous, villous and fulvous; wing-cases black, with a villous fulvous spot behind; antennae moderate. Fabr.

Size of the preceding; antennae length of the body; wing-cases somewhat feabrous; legs black with yellowish flanks. Inhabits the Cape of Good Hope. Lund.

KLASSICUS. Thorax spinous and fulvous; wing-cases smooth with grey bands dotted with black; antennae very long. Fabr.

This species inhabits Germany (Loewenfkiold.) It bears a great resemblance to Cerambyx Nebulous but is larger, and has the antennae three times the length of the body. The head and thorax are fuscous, very slightly spotted; wing-cases with a dirty band at the base, and another in the middle, and also the tip cinceroes dotted with black; body cinceroes; thighs dotted with black; flanks black at the tip.

COSTATUS. Thorax spinous, grey; wing-cases with elevated lines dotted with black at the tips fulvous; antennae very long. Fabr.

Size of the last. The antennae twice the length of the body, black, with the joints whitish at the base, head and thorax grey, the latter armed with a single spine; wing-cases grey at the base with four elevated lines; legs grey.

HISPIDUS. Thorax spinous; wing-cases whitish at the base, and indented at the tip; antennae of moderate size and hairy. Linn. Le capricorne à écus denté. Geoffr. Cerambyx falsiculatus. De Geer. Inhabits Europe, and is found...
CERAMBYX.

fond in England. Donor, Brit. Isf. This insect is small, of a general colour diverse; forehead black with white, and an ovoid oval into the middle of the wing-cases with white.

**BALTUS.** Thorax spinous; wing-cases entire, with three forked legs; antennae moderate and hairy. Pauser., Hymen. &c. Inhabits Germany. The head and thorax of this species are fuscose; wing-cases pale at the base; legs grey.

**Pilosus.** Thorax armed with two spines; wing-cases grey with a single tooth at the tip; antennae moderate and hairy. Olivier.

This kind is found in Saxony. Hymen. It is smaller than Cerambyx hirsutus; wing-cases grey, pale at the base.

**RUGICOLLIS.** Thorax unarmed, very rough and black; antennae moderate, and with the legs pithy. Fabr. Inhabits Tranquebar, (Hymen.) The antennae are compript: wing-cases black, obtuse at the tip, and nearly truncated; legs pithy.

**BIMACULATUS.** Thorax unarmed and rufous; wing-cases tealtaceous with a black spine; antennae short. Fabr. Found in the East Indies. This is of the middle size; the antennae are villous, rufous, and shorter than the body; head and thorax villous, rufous and immaculate; thorax tuberculated, and very finely spined; wing-cases dotted; legs tealtaceous. Muf. Lund.

**SPLENDIDUS.** Thorax somewhat spinous and rufous; wing-cases tealtaceous, black-blue at the base; antennae short. Fabr. Described from the cabinet of Lund. The species inhabits Tranquebar. It resembles C. bimaculatus; the antennae are rufous at the base, tealtaceous in the middle, and brown at the tip; head punctured, rufous, and without spines; thorax rounded, dotted and armed with a small spine, obtuse spine on each side: wing-cases with three smooth elevated frises; body villous; abdomen rufous, with a prominent tooth beneath, and correspondent lateral groove in the thorax; legs rufous.

**LONGICORNIS.** Thorax unarmed; back flat; body varied with grey and fuscose; antennae very long. Fabr. Inhabits the coast of Coromandel. Antennae thrice the length of the body; black, the joints cinereous at the base; head cinereous, bafe and lateral line black; thorax flat above, and much impressed, brown and cinereous varied; wing-cases with punctured frises; body cinereous. From the Bankian cabinet.

**MARGINALIS.** Thorax unarmed; wing-cases somewhat tealtaceous, and surrounded with a black margin. Fabr. A native of the Cape of Good Hope. Antennae moderate, and pithy; head brown; thorax ovate, fuscose, bordered behind and in front with black; wing-cases smooth; legs blackish.

**BREVICORNIS.** Thorax unarmed, green; wing-cases dusky; antennae short and black. Olivier &c. From the Bankian cabinet.

Obf. The head is green; antennae compript; thorax dotted, green and shining; wing-cases smooth, and greenish; legs black, thighs elevated; the four anterior ones rufous, posterior greenish.

**JEUNUS.** Thorax unarmed, and rufous; wing-cases pointed, black, with brown down; antennae very long. Linn. inhabits America.

**HOLOCERUS.** Thorax unarmed, rufous, gricous; wing-cases armed with a single tooth, fink, with a brown and cinereous hue; antennae moderate. Fabr.

Inhabits the East Indies. Head grey; body beneath shining. Olivier &c.

**CINEREUS.** Thorax unarmed, and somewhat rugose, cinereous and without spots. Fabr. From the cabinet of Lund. This is a native of Tranquebar.

**GNOTUS PRIORUS.**

Antennae ficateous; eyes reniform, embracing the base of the antennae; thorax flat, and marginate, the margin often very imbricated; body oblong, and depressed. Donov. Inf. N. Holland.

**GNOTUS PRIORUS.** Feels four; filiform; jaw cylindrical and acute; lip short and membranaceous; antennae ficateous. Fabr.

**P. LONGICORNIS.** Thorax armed with moveable spines; wing-cases with a single tooth at the base, and bidentated at the tip; antennae and fore legs very long. Fabr. *Cerambyx Longicornis* Linn. This is an insect of large size, the body exceeding three inches in length, and having the antennae, and tarsal part of legs remarkably long in proportion; the colour is pale whitish grey varied with yellow and orange, and a number of black interrupted lines. It is a beautiful species, and inhabits South America.

**LEPIDOPTERUS.** Pitchy, rufous; wing-cases with grey villous spots and three elevated longitudinal lines; base gibbous, tip truncated. Donov. Inf. N. Holland. *P. lepidus* Hybner. Tranquebar. This insect is of a large size; the species is named Lepidopterus from the villous spots on the wing-cases, which, when attentively examined, appear clothed with a fort of feathy down, or feathering, most exactly resembling that which we observe on the wings of lepidopterus insects.

**FASCATUS.** Thorax somewhat marginated, and unarmed; black, downy; wing-cases chefsuot clouded with yellow, and rounded at the tip, with four elevated lines. Donov. Inf. N. Holland. A new species lately discovered in New South Wales.

**FULIGINOSUS.** Thorax with crenated margin, armed with one tooth, and marked with an impressed dorsal line; wing-cases with crenated teeth at the tip. Fabr. Described from a specimen in the British Museum, received from America.

**ROSTRATUS.** Thorax marginated, armed with one tooth and rufous; jaws inflected and acute; sternal spinous. Fabr.

This species, which is very large, inhabits Siam. The head is black, and grooved; antennae shorter than the body, the last joint much serrated; thorax glabrous; wing-cases black and obtuse; breast and legs rufous.

**BIDENTATUS.** Thorax somewhat marginated, unarmed, black and downy; wing-cases chefsuot clouded with yellow, and bidentated at the apex, with four elevated lines. Donov. Inf. N. Holland.

**LINEATUS.** Thorax with crenated margin, and a single lateral tooth on each side; black, striped with white; wing-cases crenated with teeth at the apex. Fabr. *Cerambyx lineatus* Linn. This species inhabits America.

**NITENS.** Thorax with crenated margin and single lateral tooth each side; braly azure; wing-cases coppery. Fabr. Described from the Hunterian Museum. Inhabits Brazil. The antennae are long and blue; head grooved, and braly greem; wing-cases punctured, and obtuse; abdomen braly green.

**FABR.** Thorax marginated with a single spine on each side; wing-cases pitchy; antennae moderate. Fabr. *Cerambyx Faber* Linn. Schaeffer &c. This is a rare species and inhabits Europe; the thorax of the male has the crenated edges, but is destitute of the tooth.

**MUCRONATUS.** Thorax marginated, and bidentated; wing-
CERAMBYX.

wing-cafes mucronated and rufulous. Fabr. Inhabits America. The front is retuse; antennae short and compressed; thorax with two tubercles on the back; wing-cafes velvety and pointed.

Desparius. Thorax somewhat margined, arried with a single tooth, and downy; body blackish; antennae short and red. Fabr.

Described from a Swedish insect in the cabinet of Ziechuck. It is the Cerambyx desperius of Linn.

Scabriicoris. This thorax somewhat margined, and armed with a single tooth; somewhat villous, blackish with fusous wing-cafes, and two elevated lines; antennae moderate. Fabr. Cerambyx fabricioris, Olivier, and Pfeu! Prionus fabricioris of Scopoli. Leptura Geoffroy. A native of the southern parts of Europe; the body is very narrow; thorax very slightly margined, and in one sex nearly unarmed.

Arcaarius. This thorax bidentate; teeth arched and black; wing-cafes obtuse and tettaceous. Fabr. Inhabits Van Diemen’s land. Described from the Bankian Museum.

Maculatus. Thorax margined and three-toothed; black; wing-cafes with cerinseous spots. Fabr.

Described from Senegal, derived from a specimen in the museum of the late king of France. This is a large species; the jaws are exerted and dentated; antennae length of the body and black; thorax armed with three sharp spines; wing-cafes much variegated with grey. Muf. Donov.

Cevicornis. This thorax margined, with three teeth each side; jaws advanced and armed outwardly with a single spine; antennae short. Fabr. Cerambyx cevicornis. Linn.

This insect is an inhabitant of America; the larva is eaten by the Indians, and is esteemed a delicacy.

Spinicornis. Thorax armed on each side with three teeth; black, glossy; antennae short; exterior joint fpinosus at the tip. Fabr. Native country unknown. Muf. Brit. Obf. This does not appear distinct from Prionus buphthalmus of the fame author, and Hypsarius Ceylonensis of Voet. Fabricius describes both specifically in the same words “Thorax utrinque tridentato ater nitidus, antennae brevissimae, articulis ultimis apecte spinosis.”

This is an European insect, and is scarcely found in England. Donov. Brit. Inf. Lives in the trunks of decayed trees. Fabricius fooposes the Cerambyx imbricarius of Linneus (Syl. Nat. 2. 634. 5.) to be only a variety of this insect, and entertains a similar opinion with regard to the Laccanus trigint unus of Linnæus. 5yl. Nat. 2. 560. 5.

Giganteus. Thorax armed with two teeth on each side; body black; wing-cafes ferrugineous; antennae short. Fabr.

The Fabrician Prouus giganteus is Cerambyx giganteus of the Linnean maitilla; this kind is of a large size, as its name implies, and inhabits Cayenne.

Cylindricus. Thorax margined, three-toothed, and dusky; breast and abdomen ferrugineous; antennae short. Fabr.

This is the Cerambyx niticolor of Drury; inhabits North America. Blackburn. The antennae are comprefsed; head and thorax black; wing-cafes pitchy.

Armillatus. Thorax margined, with four spines on each side; wing-cafes ferrugineous with black margin. Fabr.

This is of a very large size, and inhabits India. It is the Cerambyx armillatus of Linnæus. The front is retuse; jaws emarginate; thorax ruifulus at the sides; wing-cafes pointed at the tip.

Luciouris. Thorax margined with many spines; jaws advanced, armed with a single tooth, and blifu apex; anterior legs elongated. Fabr. A native of South America, described by Petiver. The antennae are of moderate length, and black, with the second, third, fourth, and fifth joint margined beneath; thorax black, ciliated at the edge with twelve spines; wing-cafes mucronate, pale ferrugineous, and slightly punctuated at the base; anterior legs rough and prickly beneath.

Serrifis. Thorax margined, with many spines; jaws advanced, and tridentated at the tip; legs spinous and ferruginate. Fabr. A native of Africa.

Danicornis. This thorax margined, and denticulated; jaws advanced, bidentate; antennae short. Fabr.

This is Cerambyx danicoriis of Linnæus (Mant. 532.) It inhabits America; and the larva is eaten.

Bifasciatus. Thorax margined and denticulated; body black; wing-cafes red, with two black bands; antennae short. Linn. Inhabits America, and is the Cerambyx bifo- ciatis of Linnæus.

Thone. Thorax with crenulated margin; body black; wing-cafes glutinous and ferrugineous; margin pale yellow. Fabr. Cerambyx Thone. Acta Soci. Berol. This is native of the isle of St. Thomas in America; wing-cafes rounded at the tip.

Spinibarbis. Thorax with crenated margin; head spinous below the jaws, which are armed with three teeth. Cerambyx spinibarbis. Linn.

This is a native of South America; the jaws are large, thick, three-toothed within, with the tip emarginate.

Palmatus. Sides of the thorax ferruginous, with many teeth; posterior tooth palmedate; antennae short. Fabr. Inhabitans Guinea. The head is grooved and black; antennae comprefsed and dusky at the tip; thorax flat and glossy; wing-cafes smooth, piceous, and mucronated on the future at the tip; legs ferrated within.

Maxillosus. Thorax with crenated margin; jaws advanced, hairy within, and armed with four teeth. Fabr.

This is the Cerambyx maxillosus of Drury, and Prionus maxillosus of Olivier. It inhabits South America. The colour is glossy black.

Canaliculatus. Thorax with crenated margin and a villous white groove down the back; antennae short. Fabr. Muf. Hunter, and Donov. A native of the American islands. The antennae are short, comprefsed, and black; head without spots; cutel white and villous; wing-cafes rather rough; legs black.

Melanopus. Thorax with denticulated margin; jaws advanced and armed with many teeth; wing-cafes mucronated. Fabr. Cerambyx melanopus. Linn. Cerambyx cama- nOPSIS. Drury. From the same country as the last.

Spinosus. Thorax armed with many teeth, and black; wing-cafes tettaceous and one-toothed. Fabr. Inhabitans Tranquebar. Muf. Hybr. The head of this insect is grooved; the antennae short, comprefsed, and black; thorax very slightly margined, cincuous-downy beneath; back grooved.

Barbatus.
CERAMBYX.

Barbatum. Thorax with entire mac in; jaws ferrugineous; antennae very long; legs moderate. Fabr.

Descended from the Bankian cabinet. This is a native of South America. The antennae are rough, the lab joint conical and with the wing-cases picaceous, abdomen villous and white; legs black.

Pectinicornis. Thorax unarmed, tectaceous; antennae short and pett"hard. Olivier.

This inhabits Central America. The antennae are shorter than the body, and greatly pettinulated; jaws exerted, with a single tooth in the middle.

G P H Lamia.

Antennae frugicos and elongated; head large, obtuse, declivous; eyes reform, and produce the base of the antennae; thorax cylindrical and uncinus; wing-cases as long as the abdomen, body cylindrical. Donov. Lat. N. Holland.

Genus Lamia. Feders four, filiform; jaw bravy, and bind; tip chit and horn; antennae feticus. Fbr.

Vermicularis. Thorax somewhat tuberculatus, black; wing-cases ptericro with numerous minute white vermicular characters. Donov. Lat. N. Holland.

Lamia vermiculata is a new species lately discovered in New South Wales, and described amongst the insects of New Holland. It is of the middle size, and entirely black, except the vermicular marks.

Obliga. Thorax dentated, cinereous; wing-cases fuscous, emarginate at the tip, and marked obliquely behind with a whitish band. Donov. Lat. N. Holland.

This is a small but elegant species, general e four pale tectaceous and whitish varie with brown, and begett with numerous small denticulations.

Gigas. Thorax armed with sharp spines, and rugous; wing-cases cinereous, with a black marginal sp., rough with two tubercles at the base; antennae long. Fbr. Oliv.

This insect, which is of a large size, inhabits the coast of China, and of the middle size, and entirely black, except the vermicular marks.

Tribulus. Thorax four-spined; felted and wing-cases fuscous; antennae longer than the body. Fabr.

Found on the banks of the river Gabun in Africa. Muf. Donov. &c. The antennae are longer than the body, brown, with the base of the joints cinereous; head and thorax brown and cinereous variegated; tips on the fevital two, and short; wing-cases fuscous as the thorax, and pointed at the tip with a short desticule; a small tubercle at the end of the middle shanks of the legs.

Petcornis. Thorax and wing-cases fuscous; anterior thighs coimated. Fabr.

Distinguished from the Bankian cabinet. This is a native of New Holland. The colour of the head grey; antennae vil-

lus and moderate; thorax grey, rounded, with rick dorso erect fuscous; wing-cases grey, with unate, marginal, cinereous spot red variegated in the middle, and at the base many erect black spots; horns on the anterior thorax long, sharp and curved.

Pimenta. Thorax fuscous; a projecting recurved notch behind on front; antennae long. Fabr. Cerambyx zonatus. Dryx. I f. Inhabits the Cape. The antennae are long, and brown, and have the joints black at the tips; head brown, with black mandibles; thorax fuscous, rather rugous, brown with a broad white line on each side beneath; wing-cases brown, with a few elevated dots at the base, two ocellated black spots in the middle, and a larger whitish one behind; abdomen and legs fulvous.

Hystrix. Thorax armed with five spines; wing-cases with tufts of hairs; antennae moderate and ferrugineous. Olivier, Fabr. &c.

This insect is a native of the Cape of Good Hope. The antennae are hairy, deeply ferrugineous towards the extremity, with the joints Tufts at the tips; two raised tubercles below the middle spine on the thorax; wing-cases with fuscous and brown; body small and cinereous.

Crypta. Thorax armed with sharp spines, grey; wing-cases with a compressed tridenticulate tubercle at the base. Fabr.

Discovered in New Zealand by Sir Joseph Banks. The antennae are very little longer than the body, cinereous, the joints tinged with black; on each side below the lateral spine a fuscous dot. a small oblique black line on the posterior part of the wing-cases. thorax; thighs emarginated and black, the club grey; thanks grey with black tips.

Ambulacrum. Anterior part of the thorax furnished with two spines on each side; body elongated. Fabr.

Descended by Petiver as a native of America. The antennae are of a moderate length; thorax and wing-cases clouded with cinereous and cirrus.

Clepsidra. Thorax fuscous, black; wing-cases with a cinereous lunular fillet, and marginal dot; antennae long. Fabr.

Native country unknown. The body is long, and of a ducky black colour; antennae twice the length of the body; on each side of the thorax an oblique fuscous transverse line in the middle of the exterior margin of the wing-cases a small dot; legs blackish.

Vaginata. Thorax fuscous, rugous, and black; wing-cases ferrugineous and emarginated; antennae moderate. Fabr. Inhabits the Balkan lands. The antennae are compressed and ferrugineous, fuscous cinereous, and fuscous, smooth, fuscous, cinereous, at the base, with emarginated tips; beneath cinereous and fuscous.

This insect is rather larger than the body, and black; heat black with a green stripe, black on the side crossing the eyes; wing-cases armed with two elevated tridenticulate tubercles; body variegated with black and green; two black dots; almost in each.

Regalis. Thorax fuscous, mixed with green; wing-cases speckled with green, and three oblong spots on each. Fabr. &c.

This is a species of considerable beauty, and in size and general appearance bears a living resemblance to the last; and it also inhabits the same country. The antennae are longer than the body, and black; head black, variegated with green, and marked by each joint with a fuscous spot; thorax black, with three in profile green bands; wing-cases somewhat flattened, and black; body grey beneath; on each side of the abdomen a row of fuscous dots.

Native country unknown. Size of the 1. regalis. Antennae longer than the thorax, and black.

Irregulara. Thorax fuscous, and ferrugineous variegated; wing-cases black, speckled with ferrugineous; antennae moderate. Fabr. Obst. &c. Cerambyx irregulara. Gmel. Inhabits the East Indies. Antennae moderate, grey-
in; head fuscos, and ferruginous; mandibles black and glossy; feeted ferruginous; wing-cafes pointed at the tip.

ÆDILIS. 

Found in the trunks of trees in the northern parts of Europe, and is found, though rarely, in England. Donov. Brit. Inf. p. 72. The antennæ are rather more than three times the length of the body, measuring about three inches, the body better than three fourths of an inch. This species is most frequent in Germany.

ANNULARIA. 

Thorax spinous, tuberculated, and cinereous; wing-cafes fuscos variegated, with black elevated dots; antennæ long. Fabr. Cerambyx annularius. Gmel.

According to Smidt this insect inhabits Germany. It resembles ædilis, but is rather smaller. The antennæ are as long as the body, cinereous and black variegated; thorax spinous, with four tubercles on the back; wing-cafes with four raised lines meeting behind, and sprinkled with black dots; body cinereous, fleckled with black.

VARIATA. 

Thorax spinous, and tuberculated; body variegated with black and cinereous; thighs elevated; antennæ moderate. Fabr. Inhabits the south of Europe. Zschuck. Cerambyx variatus. Gmel.

The antennæ are cinereous annulated with black; head brown; wing-cafes rounded; body dark brown beneath; tians black annulated with cinereous.

ARANEIFORMIS. 

Thorax spinous and tuberculated; wing-cafes porous; antennæ long, with a single tooth on the fifth joint. Linn. Sloane, &c. Inhabits South America.

PUNCTATA. 

Thorax spinous, fuscos, with white dots. Olivier. Cerambyx punctatus. Gmel. A native of Cayenne. Antennæ of moderate length, and black; head black, with two white dots above the tip, and two others placed vertically; thorax tuberculated, with two larger marginal white dots, and two smaller dorsal ones; wing-cafes black speckled with white. Resembles lamia ædilis.

CANCERIFORMIS. 

Thorax befig with many denticulations; back flat; wing-cafes and anterior tians with a single tooth. Fabr. Cerambyx canceriformis. Drury. Inhabits Jamaica. The antennæ are long; the first joint one-toothed behind the tip; thorax cinereous, with five or six small teeth on the margin disposed in two series; wing-cafes cinereous, sprinkled with brown elevated dots; thighs elevated.

NODOSA. 

Thorax spinous; wing-cafes cinereous, with black spots; antennæ very long, with the third joint gibbous at the tip. Fabr. Cerambyx nodosus. Gmel.

Described from a specimen in the British Museum, received from Maryland. The antennæ are four times the length of the thorax; wing-cafes flat, rounded, and dotted at the base.

TUBERCULATA. 

Fabricius refers for this species to the Hunterian Museum. It inhabits Jamaica. The body is grey, with an angulated white band on the wing-cafes; antennæ fuscos, the joints cinereous at the tips; jaws black; thorax rough, with numerous elevated obtuse dots; wing-cafes befig with many spines, which are sharp and black; legs black, the tians with a white annulation.

HISPANA. 

Thorax armed with a sharp tooth, and bica- rimated on the back; wing-cafes cinereous, frilled, and spotted with fuscos. Fabr. Cerambyx hispana. Gmel. Found in South America. Antennæ short and black. Thorax cinereous, with a thick and sharp spine on each side; two elevated lines on the back, black and glabrous; wing-cafes rounded, cinereous, with the future and three fine brown, and between them numerous spots; legs cinereous. Cabinet of Dr. Hunter.

HORRIDA. 

Thorax acutely spinous, cinereous; wing-cafes spinous; antennæ long. Fabr. Cerambyx horridus. Olivier. Inhabits Cayenne, and is rare. Muf. Donov. The antennæ are long, greyish, with the joints black at the tip; thorax greyish, with a thick, somewhat bent, and sharp-pointed spine; wing-cafes spinous and grey.

PRAEMORSA. 

Thorax ferruginous; wing-cafes granulated tubercles; antennæ length. Fabr. Cerambyx præmorso. Fabr. Man., &c. Inhabits South America. antennæ short, cinereous, with the joints black at the tip; thorax cinereous, the four spines on the thorax black at the tip; wing-cafes cinereous, veined, with black granulated tubercles; legs short.

GLAUCA. 

Thorax armed with five spines, and glaucescent; wing-cafes muralated, the sides and band black; antennæ long. Fabr. Cerambyx glaucus. Linn. Degeer, &c. This species inhabits America.

Obs. The extremities of the wing-cafes are furnished each with a single tooth.

BIDENTATUS. 

Thorax somewhat spinous; wing-cafes bidentated, rough, cinereous, variegated with fuscos. Fabr. Cerambyx bidentatus. Mant. Gmel. &c. Inhabits America. The antennæ are long; thorax unequal, and armed on each side with an obtuse spine; wing-cafes rough, with acute elevated dots; thighs clubbed.

SCABRA. 

Thorax spinous, and armed with three tubercles; wing-cafes eubrous, with bidentated tip; antennæ very long. Fabr. Olivier, &c. Cerambyx scabrer. Gmel. &c.

Described by Fabricius from a specimen in the British Museum. The antennæ tesselacous, at the base of the tip cinereous; wing-cafes tesselacous at the base, with elevated glabrous dots; body cinereous; thighs elevated.

PREMORSA. 

Thorax tuberculated; wing-cafes dotted, cinereous, tip fuscos and bidentated; antennæ long. Fabr. Cerambyx premorsa. Gmel. &c. Inhabits Guadaloupe. Cabinet of de Radier. One of the smallest insects in the lamia family. Antennæ twice the length of the body; thorax cinereous, with three dorsal tubercles, and two black spots on each side at the base; a few elevated dots on the wing-cafes; thighs elevated.

SPINIFERA. 

This is about the middle size. Antennæ longer than the body, and dusky grey; scutellum yellowish; wing-cafes smooth; body villous and grey. Inhabits South America. Muf. D. PIg.

GRISATOR. 

Thorax unarmed, and greyish; two tubercles at the base of the wing-cafes; apex spinous; antennæ short and villous. Fabr. Inhabits Tranquebar. Schian-buchel.

ÆDIFICATOR. 

Thorax spinous and tuberculated; cinereous; wing-cafes with two tubercles at the base; antennæ moderate. Fabr. Inhabits the East Indies. Muf. Lund.

AMPUTATOR. 

Thorax spinous; wing-cafes cinereous, sprinkled with black, and numerous tesselacous spots. Fabr. Inhabits the American islands, and is reported to gnaw round and cut off the larger branches of trees.

STERNUTATOR. 

Thorax spinous; wing-cafes porus at the
CERAMBYX.

the bafe; antennae moderate. Fabr. A native of Barbadoes.

Obl. The antennae are blackish, the extreme joint acute; thorax unequal; wing-cases obtuse and black; beneath covered with yellow hair.

Spinator. Thorax spinous, and, with the base of the wing-cases, finely wrought; apex grey; antennae moderate. Fabr. Inhabits the Cape of Good Hope. Muf. Lund.

An African insect, described from the British Museum. The head is telateous, marked with a black longitudinal line; thorax telateous, with a transverse ridge in the middle; wing-cases obtuse, speckled with yellow, and a few elevated red dots at the base.

Nebulosa. Thorax unarmed, ferruginous, lined with black; wing-cases varied with fuscous and ferruginous, and a marginal cinereous spot; antennae moderate. Fabr. &c. Inhabits Europe, and is found in England. Cerambyx nebulosa.

Variator. Thorax spinous and linedate; wing-cases fuscous, with a ferrugineous white line. Fabr. Inhabits the Indies. Antennae longer than the body; thorax fuscous, with white declivous and lateral line.

Sutor. Thorax spinous; wing-cases black, with fuscous spots; apex pale yellow; antennae very long. Fabr. Cerambyx sutor. Linn. Cerambyx atomarius. De Geer. Inhabits the woods of Europe. The species has been found in England, according to Harris; (Vide Donov. Brit. Inf. &c.) but is very rare.

Sartor. Thorax spinous, black, with yellow feate; wing-cases immaculate; antennae very long. Fabr. This resembles the last, but is larger, and has the front between the antennae, deeply grooved. Found by Ziehuck on the horse-chestnut, &c. in the vicinity of Dresden.

Dentator. Thorax spinous, varied with fuscous, and cinereous. Fabr. This resembles lamia sutor, and inhabits Carolina. The antennae are thrice the length of the body, and of a fuscous colour, but black at the base.

Reticulator. Thorax spinous, black; thorax fulvous, and linedate with black; wing-cases fulvous and reetated with black. Olivier. Donov. Inf. China, &c. This very rare species inhabits China, and the bordering parts of India. The body is black, and without spots; antennae of moderate length, and ferruginous. The extant joint at the base black, the second gibbous at the base and tint, yellow and black. Length of the body about an inch and a half.

Scalator. Thorax armed with acute spines, and black; wing-cases with numerous interrupted white lines; antennae moderate. Fabr. A native of Louisiana. Size of the leaf. The head is black; hand above the hill and orbits white; sides of the thorax and two broad lines white; shells black and glossy, the edge and future ramifying into numerous interrupted dents; body cinereous and downy.

Molitor. Thorax somewhat spinous, dusky, cinereous, with fuscous spots; wing-cases rufous at the tip. Fabr. Inhabits Cayenne. The antennae are of moderate size and fuscous; head cinereous, rufous in front; thorax rufous on the anterior and posterior margins; wing-cases obtuse; abdomen pale, rufous.

Titillator. Thorax spinous; wing-cases cinereous, clouded with glaucous, and brown; antennae very long and rufous. Fabr. This is a native of Carolina. The antennae are red, with the third joint fuscous; on the anterior part of the thorax two very small tubercles; wing-cases punctured, cinereous, with irregular brown and glaucous spots; tips of the legs rufous, the second pair with a flight gibuosity.

Vittator. Thorax spinous; wing-cases cinereous, and finely speckled or powdered, with two yellow stripes, and black margin. Fabr.

This is the Cerambyx incanus of Forster. Nov. Sp. It is described by Olivier and Petiver, and has been found on the shores of Campaspe. The antennae are of moderate size, varied with cinereous and fulvous; head cinereous, powdery, with two glibrous black lines; thorax cinereous, with three glibrous, black, longitudinal lines; wing-cases with a few black spots at the base.

Oculator. Thorax spinous, black; wing-cases with four subocculated spots; antennae long. Fabr. Cerambyx oculatus. De Geer. Inhabits the Cape of Good Hope. Thorax marked before and behind with two thin, yellow, impressed lines; wing-cases somewhat disrated, with four yellow spots encircled by a white ring, that nearly the base large and rounded, the second placed near the anterior margin, the third in the middle, and the fourth near the tip. This is an insect of large size, and very beautiful.

Cerastes. Thorax armed with two spines; black; wing-cases with four rufous bands; antennae moderate. Fabr. Cerambyx capensis. Linn. This, as its name implies, is a native of the Cape of Good Hope.

Hottentotta. Thorax spinous and rufous; wing-cases black, with a band and two marginal spots, fangouineous. Fabr. Cerambyx hottentotta. Gmel. Cerambyx huttentotta. Brown's Illust. The antennae are moderate; thorax ferruginous, dusky, rufous; wing-cases with a brassy tinge; legs black.

Ferrugator. Thorax spinous, dusky, ferruginous; wing-cases dusky, greenish, with an interrupted fangouineous stripe; antennae long. Fabr.

Deferred from the cabinet of Spengler as an inhabitant of the Cape of Good Hope. The antennae are black; thorax somewhat rugged, with a small denticate on each side; wing-cases punctured, dusky, greenish, and glibrous; exterior margin fangouineous, head, body, and legs ferruginous, the latter with black tails, and the flanks of the middle legs slightly toothed outwardly.

Humeralis. Thorax spinous; wing-cases yellow, fuscous, with black, and morscinated anteriorly. Fabr.

This elegant species is described by Fabrancus from a specimen in the cabinet of the late Mr. Drury, now in Mus. Donov. The native country is unknown, but supposed to be South America. The antennae are larger than the body, and black; head yellow, with four black lines; thorax yellow, with three black bands; the base emargiante at each side; wing-cases yellow, with confluent bands; femora advanced, and bidentate at the tip.

Disfasciata. Thorax spinous, and fuscous behind; wing-cases yellow, with two bands and rhombic spot of black. Fabr. Inhabits Jamaica. Muf. Brit. The antennae are rather longer than the body, and black; head yellow, with the orbits of the eye blue; thorax yellow, with blue posterior band; scutell at the bafe and tip blue; legs pale yellow, with blue thighs.

Trifasciata. Thorax somewhat spinous, black; three yellow bands on the wing-cases; antennae moderate. Fabr. Cerambyx trifasciatus. Gmel. The thorax slightly tuberculated on each side; yellow bands on the wing-cases broad; legs black, the flanks of the middle ones tuberculated at the tip.
Cerambyx.

Tip. This is a native of Sierra Leone. Herbst, Olivier, &c.

5. Fasciculata. Thorax armed with two spines, and black; wing-cases with five red bands; antennae moderate. Fabr. Inhabits the coast of Guinea. Mus. Dr. Hert. The antennae of this species are black; thorax fuscous, black, with short spines on each side; wing-cases fuscous at the base; body black.

Nobilis. Thorax spinous and black; margin yellow; wing-cases black, with three yellow bands, and two white dots. Fabr. A native of Cayenne. The antennae are of moderate length, and black; head black, with yellow frontal spots, and two dots between the eyes; thorax velvety, black with yellow margin, and white at the base; spine near the base black; wing-cases velvety, black, with an interrupted yellow band at the base, the middle band innate, that at the tip abbreviated; the two white dots situated between the second and third band.

Athiops. Thorax spinosus, black; wing-cases with two yellow bands and a dot at the tip; antennae moderate. Fabr.

The antennae are black; head grooved; thorax rather rough; wing-cases velvety, black, with two yellow bands; the dot at the tip very small, and sometimes wanting; legs compresed and black. Mus. Brit. Inhabits the Cape of Good Hope.

Vasiator. Thorax spinosus and cinereous; thorax and wing-cases varied with brown; antennae long. Fabr.

From the Bankian cabinet. Found in Africa. The antennae are fuscous; head, thorax, and wing-cases with an intermixture of brown and cinereous; mouth black.

Lisca. Thorax spinosus, rough, black sprinkled with ferruginous; at the base of the wing-cases a large black ocular spot; antennae very long. Fabr. Cerambyx fuscus. Gmel.

This inhabits Siam. The antennae are black; head blackish, with a few ferruginous dots; thorax somewhat rough, black, with a few ferruginous dots on each side; wing-cases obtuse, and nearly truncated; legs black; thanks of the middle pair armed with a single tooth on the back.

Lucuris. Thorax acutely spined and black; wing-cases rough, with obsolete ferruginous; antennae very long. Fabr. Cerambyx lucuris. Gmel. Inhabitats Italy, Schlabenth. The antennae are twice the length of the body, and black; body black; legs black, with a small elevated obtuse tooth at the extremity of each of the four anterior tarsus.

Tristis. Thorax spinosus, fuscous, with rough wing-cases; with two black spots; antennae moderate. Fabr.

It is found on the cypresses in the south of France. Olivier. The antennae in one cross is twice the length of the body, in the other the same length as the body.

Fenesta. Thorax spinosus, fuscous; wing-cases smooth with two black spots; antennae short. Fabr.

Lives in the north of France, chiefly on the Elder. Dr. Broussonet. This is only half the size of the preceding species.

This kind inhabits China, and has been described under several names by different writers: it is the Cerambyx farinosus of Drury. Cerambyx punctator. Olivier. Cerambyx chinensis. Forster. nov. Sp.—Obs. The antennae are black, with the joint at the base pale; wing-cases rough at the base; legs black.

Fasciculata. Thorax spinosus and hairy; wing-cases tufted with hair. Fabr. Lamia fasciculata. Olivier. Cerambyx fascicularis. Gmel. A native of Cayenne. This species is of the middle size. The antennae are of moderate length, black, with the first articulation yellow and villous; thorax armed with short spines, and thickly covered with pubescent hairs; wing-cases fuscous, with one or more whitish dots; black elevated furcular line, three tufts of hair near the base, and two contiguous pairs near the apex; legs variegated.

Rotator. Thorax spinosus and cinereous; wing-cases somewhat fasciated; antennae moderate. Fabr.

The joints of the antennae are cinereous with fuscous tips; head furrowed, cinnereous, with black feelers; wing-cases cinereous, and somewhat banded with brown. This species inhabits India.

Glucyrrhize. Thorax spinosus, black; wing-cases bicinctured and incised with white; legs ferruginous; antennae short. Fabr. &c.

Discovered by Pallas in Siberia. Described by Subzzer under the name of Cerambyx ovatus. Head black, with a whitish daub at the base; antennae short, black, the first joint ferruginous and black at the tip; three white lines on the thorax; future white; legs ferruginous and white at the tip.

Cruciata. Thorax spinosus, black, a white cross in the middle of the wing-cases. Fabr.

The antennae of this insect are short and black; head black; thorax black, with a dusky white line; legs black. Inhabits the southern part of Russia. Becker. Cerambyx cruciatus. Pallas, Lem. &c.

Fuliginator. Thorax somewhat spined, and black; wing-cases grayish; antennae short. Fabr. Cerambyx fuliginator. Linn. Geoffr. &c. Inhabits the south of Europe. This insect is said to become gradually darker as it advances in age.

This is a native of Russia, and is about half the size of the preceding species.

This is a Siberian species, described from a specimen in the Bankian cabinet. The antennae are short, thick, and black; head and thorax punctured with impressed middle line; wing-cases obtuse; body beneath whitish.

Coquus. Thorax slightly spined, and hisitary; wing-cases obtuse, furrowed, black, with the anterior part ferruginous; antennae moderate. Linn. A native of North America. The thoracic spines are very minute.

Ruscator. Thorax spinosus, brown, with two fuscous dots; wing-cases brown, variegated with cinereous. Fabr. Inhabitats Africa. The antennae are moderate, and fuscous; head fuscous; facel ferruginous; wing-cases obtuse and dotted; body brown.

America. The antennae are black; head rufous with an elevated black dot at the base of the antennae; thorax obtutely spined at the sides, rufous with four black dorsal dots; body beneath black changeable to cinereous.

Bankii. Thorax spinous grey; wing-cases sprinkled with ferruginous, with two cinereous bands. Fabr. This kind inhabits the Cape of Good Hope. It is of a small size. Antennae moderate, varied with fuscous and cinereous; thorax with two short spines at the anterior part on each side, and sprinkled with ferruginous.

Saltator. Thorax unarmed, greyish; with two abbreviated white bands, composed of three or four white spots, and a white punctured streak behind; antenna short. Fabr.

Native country of this species unknown. This is of a small size; thorax with a white dorsal line; wing-cases dotted, obtuse, faceted, and spotted with fuscous white.

Illicitro. Thorax unarmed and yellowish, sprinkled with numerous fuscous-white dots; antenna short. Fabr. Inhabits Tranquebar. Muf. Lund. The antennae are short and greyish; head punctured, yellowish with obsolete whitish spots; thorax rounded, unarmed, dull, yellowish, with many distinct fuscous dots; wing-cases punctured, yellowish, with numerous fuscous dots; body yellowish.

Testator. Thorax spinous, with a short recumbent horn; body tesselate; antenna short with black tip. Fabr.

The body of this insect is short, villous and tesselate; head large, and flat in front; thorax with a short broad recumbent horn in the middle having the tip retuse; wing-cases villous, fimbriated, and without spots.

Pedestri. Thorax spinous and black, with an entire white stripe; antenna moderate. Fabr. Cerambyx pedifris. Linn. Inhabits the south of Europe.

Ruppes. Thorax spinous, black, future of the wing-cases white; base of the antenna and legs rufous. Fabr. Inhabits Hungary. Refembles L. pedifris in size and appearance. The antennae are compresse and black, except the first joint at the base which is rufous; head and thorax rufous and without spots; wing-cases smooth and black, with white future; legs rufous.

Morio. Thorax spinous, black; wing-cases of one colour; antenna short. Fabr. Inhabits the south of Germany, Zilchuck. Rather larger than Lamia pedeliris; the elytra of one colour, sometimes black, sometimes tesselate; antennae black, with the first joint usually tesselate.

Lineata. Thorax spinous black; margins of the wing-cases, and two longitudinal lines, that unite at each end, white. Fabr. Cerambyx Scolapi. Herbst. Inhabits Germany. Head and thorax black with a white line on the back; legs black.

Molitor. Thorax spinous, and fuscous, with three entire white stripes; antenna moderate. Fabr. Inhabits India. Described from a specimen in the British Museum. The body is brown above, with three white lines, extending from the head to the extremity of the wing-cases, a small line between the broader one at the base of the latter; thorax with a lateral tubercle.

Tuberculata. Thorax unarmed, grey; wing-cases with two tubercles at the base, and two common white spots; antenna short. Fabr.

The antennae are cinereous; tubercles on the wing-cases comprised near the future; anterior spot large.

Mutator. Thorax unarmed, cinereous, with a pale line on each side; body villous; antenna and legs tesselate. Fabr.

Inhabits Otaheite. From the Bankian cabinet. The antennae are of a moderate length; wing-cases punctured and obtuse.

S. maculatus. Thorax spinous and bimaculated; wing-cases spotted with white; at the base rough and maculated; tip bidentated. Fabr.

Nearly allied to L. Rufus, of which it is supposed by some to be a variety. The antennae are longer than the body, rough and black; thorax unequal, acutely spined, with two large impressed yellowish dorsal lines; scutellum whitish; wing-cases cinereous, and rough, with black raised dots at the base; in the middle four whitish spots, the second of which is largest, the fourth small and rounded; side white.

Spinicornis. Thorax spinous and rough; wing-cases truncated and grey; antenna compressed, joint at the tip spined. Fabr.

A native of Africa. The antennae are moderate, and compressed, joint at the tip acutely spined outwardly; head black; thorax rough and grey; wing-cases smooth, truncated, and somewhat spined.

Scapductor. Thorax spinous, somewhat tesselate; wing-cases with rough black dots at the base. Olivier, &c.

Antenne moderate, with the joint at the tip black; wing-cases somewhat emarginate at the tip, and pointed at the future. Inhabits the East Indies. Bankian cabinet.

Spengleri. Thorax spinous, and tesselate; cinereous; wing-cases rough, with two lateral black spots. Fabr.

From the cabinet of Spengleri. A native of South America. The antennae are long, cinereous, with the joints fuscous at the tip; thorax obtusely spined on each side, with three dorsal tubercles.

Fuscator. Thorax armed with two spines, and tuberculated; wing-cases three-toothed at the tip, and griseous, with a cinereous band. Fabr.

Inhabits Tranquebar. This is of the middle size. The antennae are rather shorter than the body, and greyish; thorax unequal, with two spines, the anterior one largest, recurved, and above them a large obtuse tubercle; wing-cases cinereous, or griveous, sprinkled with numerous ferruginous dots; legs grey.

Bidens. Thorax acutely spinous, grey; wing-cases bidentated at the tip. Fabr. This species inhabits New Holland. The antennae are long and fuscos, and the legs unarmed.

Crantor. Thorax unarmed, cinereous with black dots; wing-cases pale tesselate; tips bidentated, cinereous, with black spots. Fabr.

Inhabits China. Cabinet of Schlumbergh. The antennae moderate and black; head cinereous with two dots, and small black line at the base; scutellum black, with cinereous margin; wing-cases pale tesselate, dotted at the base, and bidentated at the tip, cinereous, with a black spot; body and legs black, with cinereous down.

Leprosa. Thorax spinous; wing-cases variolous at the base, with a large lateral spot of black; antennae long. Fabr. Cerambyx leprous. Gmel.

A native of America. The antennae are dusky and rufous; thorax uneven on the back; wing-cases with large impressed dots at the base; behind smooth and cinereous, with a small spot in the middle; on each side, at the base of the abdomen, a snowy spot; legs cinereous.

5. Solander.
CERAMBYX.

SOLANDRI. Thorax somewhat spinous and black; wing-cases bidentated, sprinkled with fulvous and cinereous. Fabr. Inhabitst New Holland. The antennae are moderate and black; thorax somewhat rough, and black with a small acute anterior spine each side; scutell black; wing-cases dotted, black sprinkled with cinereous; gibbous at the shoulder, and bidentated at the tip; legs black, with thefoles of the feet fulvous.

CORNUTOR. Thorax obtusely spinied; jaws cornuted at the base; antennae very long. Fabr. Inhabits America. It is figured by Olivier from a specimen in the British Museum. The antennae are black; head grooved and black; jaws advanced, sharp pointed, with a thick horn-shaped elevated tubercle at the base; thorax black and without spots; wing-cases dotted, black, with yellow spots, small inflected spine at the base; tip rounded and unarmed.

UNGARICA. Black; head and thorax spinous; longitudinal line, future, and three lines on the wing-cases white. Herb. Cerambyx Ungaricus. Gmel.

TRIFASCIATA. Thorax spinous; wing-cases convex, black, with three interrupted scarlet lines; narrow towards the apex; antennae long. Gmel.

DAVIESI. Black, thorax spinous, with numerous fulvous dots and spots; wing-cases somewhat triangular. Swederus. Nov. Act. Stockh. This inhabits the bay of Honduras.

Genus Stenocorus.

Antenna long and filiform; eyes reniform, embracing the base of the antennae; thorax round; wing-cases length of the abdomen, frequently with two teeth at the apex; body somewhat cylindrical. Donov. Inf. N. Holland.

Genus Stenocorus. Antennae four, anterior ones filiform, posterior elevated; antennae facetous. Fabr.

SEMIPUNCTATUS. Thorax spinous, and fuscous; anterior part of the wing-cases rough, with dots, and banded with yellow; posterior part smooth; apex bidentate with three yellow spots. Donov. Inf. N. Holland. From the same country as the preceding.

LAMED. Thorax pubescent; wing-cases fuscous, livid, with a dusty finate stripe down the middle. Fabr. Cerambyx lamed. Linn. This inhabits Europe.

CYANEUS. Thorax somewhat spinous, azure, with the wing-cases yellow at the base. Fabr.

This is an Indian species, first described by Forster under the title of Cerambyx pallorius. The antennae are short and blue, with elevated joints; thorax narrow in front, behind somewhat spinous.

BIGOTTATUS. Thorax without spines, and ferrugineous; anterior part of the wing-cases rugose with dots, and spotted with fuscous; posterior part smooth, bidentate, and marked with a yellow spot. Donov. Inf. N. Holland.

GARGANICUS. Thorax spinous; wing-cases bidentated, and greyish, with a yellow spot; antennae very long. Fabr. Defended by Fabricius from a specimen in the British Museum. It is a native of Maryland.

FESTIVUS. Thorax armed with two teeth each side; wing-cases bidentated and greenish, with a yellow lateral line. Fabr. Cerambyx fusticus. Linn. Common in America.

OBSCURUS. Thorax rugose, spinous, fulvous; anterior part of the wing-cases rough, with dots; posterior part smooth, fuscous, and bidentated at the tip. Donov. Inf. New Holland. A new species.

MARYLANDICUS. Thorax depressed, tuberculated, unarmed; wing-cases bidentated, clouded with fulvous and cinereous; antennae moderate. Fabr.

This insect inhabits Maryland. The antennae are somewhat spinous; body entirely varied with cinereous and fulvous.

SPINICORNIS. Thorax unarmed, tuberculated; wing-cases bidentated; joints of the antennae with two spines; body variegated. Fabr.

Inhabitst America. The body is cinereous with raised fulvous dots.

IRRORATUS. Thorax unarmed and unequal; wing-cases bidentated and sprinkled with white; antennae long and aculated. Fabr. Cerambyx irroratus. Linn. A native of America.

GLABRATUS. Thorax unarmed and cinereous, with a glabrous brown line; wing-cases bidentated. Fabr.

The antennae of this species are moderate, brown with three joints spinous; wing-cases varied with grey, and brown. Inhabitst South America. Rohr.

FARINOSUS. Thorax spinous, pitchy; wing-cases sprinkled with powdery dots; antennae long. Fabr. Cerambyx farinosus. Linn.

6-MACULATUS. Thorax spinous, and ferruginous; wing-cases pointed, with three yellow spots. Fabr. &c. Cerambyx fex-maculatus. Olivier. This insect inhabits Cayenne. The antennae are moderate, villous, and ferruginous; thorax ferruginous, with a small black spine on each side; wing-cases with three large, oblong, yellow spots, and black spine at the apex.

5-MACULATUS. Thorax somewhat spinous, and rufous; with four yellow spots; wing-cases bidentated and rufous; two spots and line at the apex white; antennae very long. Fabr.

This insect inhabits the island of Guadaloupe. Dr. Fert. The antennae are ferruginous; head ferruginous with the orbits of the eyes cinereous; thorax rough with lateral line and four dorsal spots pale; scutell whitish; wing-cases ferruginous with whitish spot, and double yellow pupila: body beneath whitish.

4-MACULATUS. Thorax spinous, and rufous; wing-cases bidentated, with two pair of glabrous spots. Fabr. Cerambyx quadriscutellatus. Linn.

A native of South America. Obs. The four posterior thighs are spinous.

MACULATUS. Thorax spinous, and fuscous; wing-cases bidentated with two pair of glossy spots; antennae moderate and black. Fabr. Cerambyx maculatus. Olivier.

The head is fuscous with ferruginous lip; thorax spinous, fuscous, and without spots; wing-cases pale; legs black with rufous thighs.

GENINATUS. Thorax unarmed, black, with rufous spot on each side; wing-cases black; with two pair of glabrous spots; antennae very long. Fabr.

A native of Sierra Leona. Pfugl. The antennae are black; head rufous with a black dot in front; wing-cases truncate at the tip, and gibbous with cinereous; legs black; thighs rufous; the four posterior ones spinous at the tip.

PELLENS. Thorax unarmed and pale; wing-cases with a single spine and three black dots; antennae long. Fabr.

This kind inhabits South America. It is of the middle size. The antennae are long, and pale, and cinereous; eyes palish.

STREPENS.
CERAMBYX.

The antennae are compossed, moderate, and ferruginous; head grooved; wing-cases finou, pale yellowish, and immaculate; body ferruginous. Olivier describes this insect as a native of Provence, and observes that it flies by night with a buzzing noise.

This kind inhabits Africa. The antennae are moderate, red black; head yellow, with three black lines; thorax black above, beneath yellowish; wing-cases dotted at the base; abdomen tesselated with a yellow spot on each side of the base, and black tip.

It is particularly described, Thorax rounded, unarmed, griscous, with tesselated legs. Fabr.

The country of this species is unknown. The fize is small; antennae moderate; villous, and cinereous; head and thorax grey, without spots; wing-cases grey, with two longitudinal abbreviated black lines; legs tesselated with very thick plumes.

The antennae are ferruginous, with the third, fourth, and fifth joint annulated with white; head fuscose with two white lines; thorax grey with four white lines; wing-cases grey, with fuscose tip and white margin, truncated and fingle toothed; legs fuscose, with cinereous rings.

Lineola. Thorax spinous, ferruginous; wing-cases pointed and tesselated, with three small glossy yellow lines. Fabr. Cerambyx brasiliensis. Gmel. A native of Brazil.

The head is ferruginous; antennae longer than the body, black, with the first joint ferruginous; wing-cases armed with a fingle spine at the tip; legs black; thorax yellow, the four posterior ones armed with a thick black spine at the tip.

Varius. Thorax somewhat spinous; wing-cases bidentated, cinereous, fuscose, and yellow variegated; the base at the angle compressed. Fabr. Cerambyx taylorinae. Gmel.

This is an insect of small fize. The general colour is cinereous; antennae longer than the body, cinereous, with the joints fuscose at the tip; thorax black, with yellowish lines and dots; wing-cases emarginated, and bidentated at the tip.

Purpurascens. Thorax spinous, and black; wing-cases with a fingle spine at the tip, base tesselated; antennae long. Fabr. Cerambyx purpurascens. Olivier. A native of Cayenne. This species is small; the antennae are longer than the body, black and spinous at the joints; thorax spinous and tesselated.

Durius. Thorax somewhat spinous; wing-cases truncated, bidentated, ferruginous, with cinereous bands; antennae short. Fabr.

Described from a specimen in the cabinet of Drury. The antennae are shorter than the body, and pecoous; thorax armed with a small spine on each side, and marked with a few raised transverse lines; wing-cases truncated at the tip, bidentated, the outer spine large, ferruginous, with three cinereous bands, which unite at the fracture; base ferruginous, with two large white spots on each side; abdomen with three white dots on each side. Muf. Donov.

Undatus. Thorax spinous, cinereous; wing-cases bidentated, with two waved black lines. Fabr. Habits America. The head is cinereous; eyes black; antennae, moderate, villous, black, with the joints cinereous at the tip; thorax cinereous, with a few dorsal black glutinous spots; wing-cases dotted, cinereous, with two large waved black bands, the posterior one of which is largest.

Rusticus. Thorax spinous, ferruginous brown; wing-cases bidentated and pale; antennae very short. Fabr.

An insect of middle size, that inhabits India. The antennae are longer than the body and fuscose; head and thorax dusky, ferruginous and downy; wing-cases smooth, paler and bidentated at the apex. Cerambyx ferrugineus. Gmel.

Quadriguttatus. Pale tesselated; thorax somewhat spinous; wing-cases two-spined, with two yellow spots on each side; thorax cinereous and unarmed. Sweeds Nov. Act. Stidh. Habits Honduras.

A native of Europe.

Ferruginosus. Blackish; wing-cases ferruginous; antennae spinous inwardly. Rauzer Jour. de Phy. A native of America.

Hirudinaceus. Beneath brown; head and thorax woolly, with a bare space on the back; wing-cases black, glabrous, with five bluish white dots, and tesselated future on each side. Pals. This species inhabits woods in the northern parts of Siberia.

Perforatus. Above covered with a whitish powder, beneath with yellowish down; five black dots on the middle of each wing-case. Pals. Habits the same country as the preceding, which it readily resembles.

Genus Callidium.

Antennae fuscous; head ovate-obtuse and inferted; eyes lateral, reniform, and bearing the base of the antennae; thorax flat, with rounded and rather prominent margin; wing-cases rigid; length of the abdomen; body flat; somewhat depressed, and often pubescent; legs elongated and formed for running; tigulis con elavated.

Genus Callidium. Feelers four, elevated; jaw membranaceous and bifid; lip two-leafed; antennae fuscous. Fabr.

Oscenurum. Thorax somewhat villous, fuscose; wing-cases tesselated, varied with cinereous; antennae moderate. Fabr.

The antennae are pubescent and fuscous; wing-cases dusky at the base; legs tesselated.

CERAMBYX.

Found on plants in Africa. Vahl. The antennae are moderate, ferruginous, with the first joint thick, and black; body black; wing-cases smooth, violaceous and glisting; thighs clavated.

Aeneum. Fuscous, thorax and wing-cases brassy green; thighs ferruginous. Fabr. From the Hunterian museum.

The antennae are black; thorax without tubercles, pubescent and brassy; wing-cases pubescent, and glisting; body black; legs black, thighs somewhat compressed and rufous, with the knees black. Inhabitts India.

Fulcratum. Thorax naked and glisting; body black; wing-cases rufous; antennae moderate. Fabr. Inhabitts Saxony. Hybner. Obs. All the thighs are compressed.

VioLACEUM. Thorax somewhat pubescent; body violaceous; antennae short. Fabr.

Linnaeus describes this insect under the name of Cerambyx violaceus. It inhabits woods in Europe, and is rarely found in England. Donov. Brit. Inf. This kind is highly detrimental to timber, especially fir, that has been felled some time, and has not been directed of the bark, beneath which it bores terpine cavities in the wood in various directions. Tranf. Lin. Soc.

Femoratum. Thorax naked; body black and opake; thighs red; antennae moderate. Fabr. This is Cerambyx femoratus. Linn. Inhabits Germany.

Spinosum. Thorax spinous, naked, black, antennae short. Fabr. Inhabitts Hungary. Hybner. The antennae are black; head grooved; thorax flat, naked, smooth, black and without spots, with a sharp spine each side; wing-cases smooth, glisting and black; legs black, thighs thick. 

Amethystinus. Pubescent, azure, with rufous legs; thighs clibbed and black. Fabr.

This insect is small, pubescent, azure, and glisting; antennae short, black, and rufous at the base; legs ferruginous, with all the thighs clavated; club large and black.

Biplicatum. Thorax pubescent, black; wing-cases with two rufous bands.

Described from a South American insect in the Bankian cabinet. Fabr. The antennae are moderate, with the joints two-fined at the tip; thorax with two tubercles; legs black; thighs somewhat clavated.

Acuminatum. Thorax warded and blackish; wing-cases pointed and greenish. Fabr. A native of the Cape of Good Hope. The antennae are moderate, fuscous, with the tips of the joints spinous; thorax rounded, black, with many elevated tubercles; wing-cases greenish, with blue future, tip sharp-pointed; legs black; thighs clavated, the club red.

Rusciicum. Thorax warded, black, wing-cases tellacous, with a black spot in the middle, and black tip. Fabr. Inhabitts Russia. Head black, antennae moderate; legs unarmed and black.

Tenebrosum. Thorax tuberculated, dullky, rufous, with black dorfl lines; wing-cases cinereous, deprefled, with two elevated black lines. Fabr. Inhabitts Cayenne. Olivier.

VITTATUM. Thorax rounded, naked; wing-cases ferruginous, with a black stripe in the middle; antennae long as the body. Fabr.

The antennae are ferruginous, second joint long, incurved, and somewhat spinous at the tip; body dusky; thighs clavated.

STIGMA. Thorax dotted; body black; wing-cases smooth, with a white fignitate spot. Cerambyx stigma. Linn. A native of America.

Fugax. Thorax hairy, fuscous; joints of the antennae rufous at the base. Fabr.

Found in Provence. Olivier. The head is small, entirely black and fuscous; thighs clavated, thanks tellacous.

This kind inhabits Italy, and has been found in England; antennae longer than the body, and yellow; thighs clavated.

Fulvicolle. Thorax unarmed, fuscous, black, with very long antennae. Fabr. Inhabitts Surinam.

Hirtum. Thorax rounded and hairy, wing-cases pointed, and pale tellacous. Fabr.

Described from the Bankian cabinet. The antennae are compressed, and black; legs black.

Pubescens. Thorax rounded, pubescent, and tellacous; wing-cases greenish, and at the base tellacous. Olivier, &c. A native of the Cape of Good Hope.

Barnatum. Thorax rounded, beneath each side a downy ferruginous spot, antennae very long and bearded. Olivier. This insect inhabits Tranquebar. Dr. Koegig.

Inhabitts Siam. Described from the Bankian Cabinet. The head, thorax, wing-cases, and body are smooth; abdomen tellacous; thighs much compressed.

Variegatum. Back of the thorax glabrous, black, with four white lines, and the wing-cases sprinkled with yellow. Fabr. Olivier, &c.

The antennae are of moderate size, black, with the two extreme joints ferruginous; head black, with two whitish lines, and transverse streaks; sides of the thorax sprinkled with yellow; three lines on the wing-cases rather raised, black, and thickly sprinkled with yellow dots; abdomen black, and speckled with yellow on both sides; legs blackish, with elongated thighs, the posterior ones ringed with white. Bankian Cabinet. Inhabitts New Holland.

Linetum. Thorax with two white lines, and four on the wing-cases, the middle ones uniting, and abbreviated. Fabr. Olivier, &c.

Antennae short, with the first joint ferruginous; lip whitish, with three black lines; feutel whitish; wing-cases obtuse; abdomen whitish in the middle black; legs ferruginous, with black joints. A native of New South Wales. Cerambyx angulis. Gmel. &c.

Sulcatum. Thorax downy cinereous; wing-cases white, firiated with black. Olivier.

This is a native of New Zealand. The antennae are short and...
and fuscous; head clavate, with a black, frontal, elevated line; lines on the wing-cases elevated and glossy; legs grey.

Sanguineum. Thorax somewhat tuberculated, and, with the wing cases, fuscous; antennae moderate. Fabr. "Le touches velocee couleurs de feu." Geoffr.

A Linnæan species, Cerambyx sanguineus of that author. Inhabits European woods; once met with in Wales. Muf. Donov.

Pileum. Thorax somewhat tuberculated and ferruginous; wing-cases tesselate; antennae moderate and villose; thighs elevated. Fabr.

Inhabits South American islands. This is of the middle size; head ferruginous; wing-cases smooth; legs tesselate, with the thighs much compressed.

Perhaps a variety of the Linnæan Cerambyx testaceus. The antennae are moderate, fuscous at the tip; thighs elevated.

Ligustum. Thorax tuberculated, villose, and black; wing-cases red, with spot and tip violaceous. Fabr.

The body is black; thorax flat, villose, black, with glosby elevated tubercles; legs black, with compressed thighs. Schulz.

Flaviss. Thorax rounded, pubescent, ferruginous; legs tesselate. Fabr.

A native of the Cape of Good Hope. This is small; antennae rather longer than the body, and ferruginous; head ferruginous, with the eyes black; thorax rounded, downy, somewhat tuberculated, and ferruginous; wing-cases rather paler.

The antennae are fuscous; legs black, with short, thick, and compressed thighs.

4. Maculatum. Thorax villous, fuscous; wing-cases with two ferruginous spots each; antennae long. Fabr.

A native of the island Candeloup, and described by Fabricius from the cabinet of Dr. Caudri. This is of a small size, and dusky; antennae longer than the body, somewhat ferruginous, and dusky at the base; head and thorax villous and fuscous; legs dusky, ferruginous, with elevated thighs.

Hainnense. Thorax somewhat villous and black, with four white lines, the inner ones abbreviated. Olivier, Fabr. &c. Cerambyx hainnense. Linn. Inhabits Europe.

Inhabits Germany. Muf. Hattorff. Antennae fuscous, and, at the base ferruginous; head and thorax smooth, violaceous, and glossy; body braily: legs violaceous, with fuscous flanks; posterior thighs elevated, and fuscous at the base.

Striatum. Thorax glabrous; body black; wing-cases frayed; antennae short. Fabr.

This is the Linnæan Cerambyx striatus. A native of Europe; is said to have been found in England.

Bicolor. Thorax glabrous and yellowish; head and wing-cases greenish; antennae moderate and black. Fabr.

Inhabits South America. Smaller than the last; thorax flat, smooth, and yellow; wing-cases smooth, green; legs black.

Lyncium. Thorax rounded, somewhat fuscous, villose, and black; wing-cases with a somewhat double fuscous spot. Fabr. Cerambyx lyncium. Olivier.

A native of the Cape of Good Hope. Thorax armed on each side with a small spine.

Inhabits Europe, and is found on willows. Antennae short and rufous; wing-cases slightly frayed; abdomen and legs rufous.

Cyanum. Thorax flat, tuberculated, villose, and violaceous; half segment but one ferruginous; antennae moderate. Fabr. Inhabits Italy. Cerambyx cyanus. Gmel.

Flavum. Thorax fuscous at the base; body yellow; thighs elevated; antennae moderate. Fabr. Inhabits America, Off. The antennae are yellow; eyes black; all the thighs thickly elevated.

Varius. Thorax rounded and fuscous; wing-cases fuscous at the base, with two white bands. Fabr. Inhabits North America.

Flexuosum. Thorax rounded, with yellow bands; wing-cases with seven yellow bands, the anterior ones curved upwards, the posterior downwards. Fabr. Leptura rubrolinea of Forster. Leptura pilosula. Drury. A native of America. Olivier, &c.

Florale. Thorax globose, and banded with white; the white bands on the wing-cases, the second and third of which are removed.

Aestival. Thorax globose, with cinereous spots; wing-cases black, with whitish dots, and posterior, fuscous, whitish line. Fabr. Inhabits Saxony.

Gazella. Thorax rounded, black; wing-cases black, with yellow bands, the second bent; legs ferruginous; thighs black. Fabr. A native of Europe.

Mucronatum. Thorax rounded and spotted; wing-cases mucronate and black, with three bent yellow lines and ferruginous base. Fabr. Found in America.

Angulatum. Thorax rounded, and mucronate; wing-cases mucronate, with three dorsal spots, and two yellow spots in the middle. Fabr. Country unknown.

Erythrocephalum. Thorax rounded, somewhat fuscous; wing-cases bidentate and fuscous, with four yellow bands; thighs compressed and elevated. Olivier. A native of America.
GLAUCUM. Thorax rounded, black; wing-cafes glaucous, spotted at the base with black. Olivier. Inhabits India.

SEX-FASCIATUM. Black; thorax with two, wing-cafes with four yellow bands. Fabr. Described from a specimen in the British Museum.

TRIFASCIAI. Thorax globose, ferruginous; wing-cafes black, with three white bands, the first annular. Fabr. A native of Europe.

ORNATUM. Thorax rounded, fasciated with black; wing-cafes greenish, with three entire black bands, the first annular. Fabr. Callidium ornatum. Herb. Stenocerae du-

plex. Scopoli. Inhabits Germany.

ANNULARE. Thorax rounded, and spotted with black; wing-cafes bidentated, and somewhat greenish, with three black bands, the first of which is annular. Fabr. Callidium annulare. Olivier. A Siame species.

EGYP'TIACUM. Thorax rounded and ferruginous; wing-cafes greyish, with three fuscous bands, the first annular. Found in the East Indies. Forthahl.

VIRENS. Thorax rounded, greenish, with black antennae, and telfaccean legs. Fabr. Inhabits Barbary.

GIBROSUM. Thorax rounded, black; wing-cafes fasciated with cincereous; at the base tuberculated, and pointed at the tip. Fabr. Inhabits Italy. Daldorf.

UNIFASCIAI. Thorax rounded, brown; wing-cafes black, with a snowy band in the middle; base chefun. Olivier, &c. Inhabits Provence.

PICIPES. Thorax globose, black, with an oblique streak on the wing-cafes.

GÉNUS CALOPUS.

Antennae filiform; feelers four, anterior ones elevated; posterior filiform; jaw bifid; thorax gibbous; wing-cafes linear. Gmel. &c.

GÉNUS CALOPUS. Feelers four, anterior elevated, posterior filiform; jaw bifid; lip membranaceous and bifid; antenafiliform. Fabr.

HISPICORNIS. Somewhat fuscous; joints of the antena with a small spine behind. Gmel. Doubtful if of this genus.

GÉNUS RHAGIUM.

Antennae setaceous, elongated, approximate, and infert between the eyes; feelers four, capitata; jaw armed with a single tooth; eyes rounded; thorax narrow, cylindrical, and spinous each side; wing-cafes rigid; legs formed for running; feet formed of four joints.

GÉNUS RHAGIUM. Feelers four, capitata; jaw single toothed; lip membranaceous, and bifid; antennae setaceous. Fabr.

MORDAX. Thorax spinosus, grey; wing-cafes clouded, and somewhat banded with telfacceous. Fabr. Inhabits Germany.

INQUISTOR. Thorax spinosus, and black; wing-cafes clouded, and subfasciated with telfacceous. Fabr. Cerambyx insqustor. Linn. Remembtes the last but is rather smaller. Inhabits Europe; not uncommon.

INDAGATOR. Thorax spinosus, cinereous; three elevated lines on the wing-cafes; specklings and two bands black. Fabr. DeGeer, &c. An European species.

CINCTUM. Thorax spinosus, and black; wing-cafes somewhat ferruginous, with a yellow band; posterior thighs with a single tooth. Fabr. Inhabits Germany.

NOCTIS. Thorax spinosus, and black; base of the antena ferruginous. Fabr. Linn. &c. Bears some affinity to Rhegium Curfor, but differs in being entirely black. Inhabits northern Europe.

BIFASCIAI. Thorax spinosus; wing-cafes with two oblique yellow spots. Fabr. &c. An European species.

CLATHRATUM. Thorax somewhat spinous; black; wing-cafes somewhat reticulated with yellow; legs rufous. Fabr. A native of Austria. Schneider.

ORNATUM. Thorax spinosus, and black, wing-cafes with a broad yellow band. Fabr. Inhabits Pennsylvania.

MINUTUM. Thorax spinosus; wing-cafes with elevated frise, cinereous, waved with black. Olivier, &c. A native of Europe.

MENTICUM. Thorax unarmed, rufous, with two black spots; wing-cafes fuscous, with rufous flax, and bidentated at the tip. Fabr. Found in Sweden. Obs! This is small. The head is cinereous; antena brown annulated with white at the base; wing-cafes somewhat dotted; body cinereous; legs ferruginous.

GÉNUS SAPERDA.

Antennae setaceous; eyes lunate, and embracing the base of the antennae; thorax short, somewhat cylindrical, and unarmed; head retracted; wing-cafes rigid and as long as the abdomen; body elongated, cylindrical, and marginate. Donov. Inf. N. Holland, &c.

GÉNUS SAPERDA. Feelers four, filiform; jaw membranaceous and bidentate, with heart-shaped and truncated; antena setaceous.

NIGROVIRENS. Blackish-green; thorax with rufous characters; wing-cafes rough, with a telfaccean spot at the base; sides yellow; tip truncated and bearded. Donov. Inf. N. Holland. A species lately discovered in New South Wales.

COLLARIS. Black, thorax encircled with four white rings; sides of the wing-cafes, spot at the tip, and body beneath covered with white down. Donov. Inf. N. Holland. This also is a new species from the same country as the preceding.

CANDIDA, white; thorax and wing-cafes fuscous, with two white stripes. Fabr. From the Hunterian Museum. Country unknown.

DETRIVA. Black with cinereous hairs, and white dorsal line, and a white stripe on the wing-cafes; antennae short. Fabr. Inhabits Barbary.

MODESTA. Black; head, thorax, and vent ferruginous. Fabr. Inhabits Africa.

ATRICORNIS. Ferruginous; antennae and tip of the abdomen above black. Fabr. Inhabits China. Schefeldt. Obs! The head and thorax are smooth, glabrous, rufous, and immaculate;
immaele; wing-cases frillated with dots, dusky and emarginate at the tip; wings ferruginous; with black tip.

Tricolor. Ferruginous; wing-cases bidentated, frillated with dots, and greenish; antennae moderate and black. Fabr. A native of the East Indies. Muf. Schell. Off. The head is rufous with black eyes; thorax rufous with 3 small dots at the base; body rufous; the legs black at the apex.

Hirta. Ferruginous with green hairs; frillated and obtuse at the eyes fulvous. Fabr. Inhabits New Zealand. Head greyish with four yellow spots at the base; wing-cases covered with grey hairs; and obtuse at the tip.

Unicolor. Tectaceus; antennae and legs same colour; antennae long. Fabr. Described by Fabricius from a specimen found in Amsterdam Island.

Nigrispect. Cylindrical, black, with two lines on the thorax and scutellum cinereous; legs black. Fabr. Inhabits Hungary.

Cyindrica. Cylindrical, black, with the anterior legs pale yellow. Fabr. Cerambyx colombianus. Linn.

Triplunctata. Cylindrical, black; thorax ferruginous above, with three black dots. Fabr. Inhabits Virginia. Off. The antennae are moderate, villous, and black; wing-cases frillated with dots.

Melaenochlata. Thorsx rufous, body black; legs rufous. Fabr. Inhabits Africa. Vahl. The antennae are moderate and black; and head and body black.

Plicicornis. Violaceous, with the first and second joint of the antennae chubbed, and hairy. Fabr. Inhabits South America. Hybr. 

Barnicornis. Head and thorax rufous; wing-cases azure; antennae moderate, and bearded before the tip. Fabr. Native country unknown. This is of the middle size.

Ruficollis. Thorax villous, rufous; antennae and wing-cases fulvous. Fabr. A native of Virginia. Off. The head is rufous, antennae moderate and black; thorax villous, rufous, and immuculate; wing-cases villous and fulvous.

Fasciata. Thorax somewhat spinous, azure; with two yellow bands on the wing-cases. Fabr. Inhabits Siberia. Off. The antennae are moderate and black; body entirely violaceous, slightly glossed with cinereous.

Clavicornis. Green, with three yellow spots on the wing-cases. Fabr. Inhabits the Cape of Good Hope. From the Bankian cabinet.

Latipes. Black; thighs clavated and violaceous at the tip; posterior flanks compressed; antennae long. Fabr. From the same country as the preceding.

Off. The antennae are longer than the body, the first and second joint thick and black, the rest rufous with black tips, except the last joint which is entirely black; four anterior legs rufous with clavated thighs.

The body of this insect is small, black, glossed with blue; wing-cases rough; legs blue with all the thighs clavated.

Lyncia. Thorax black, with a ferruginous dot on each side; wing-cases grey and pointed. Fabr. A native of New Zealand. Off. The head is black; antennae ferruginous; wing-cases gray, frillated at the base; body black; abdomen with four ferruginous dots on each side; legs fulvous; thighs clavated.

Grisea. Greyish; margin of the scutel, and small lines on the wing-cases yellowish. Fabr. Inhabits New Zealand. Off. The antennae are fulvous; wing-cases somewhat villous; legs fulvous with clavated thighs.

Analis. Tectaceus; tip of the wing-cases and vent black. Fabr. A native of Africa.

Bidentata. Thorax rounded; with four dots of black; wing-cases bidentated at the tip. Fabr. Inhabits Guiana. Dr. Hert. This is small; antennae length of the body, with the third and fourth joint yellow; body and legs yellow.

Nigricornis. Fuscous; thorax linear; scutellum yellow; antennae long. Fabr. Cerambyx Cardii. Linn. Found on thistles in southern Europe. The body is fulvous sprinkled with yellow; lines on the thorax three in number.

Annulata. Thorax rounded, lined, greenish; wing-cases pointed, with white future. Fabr. Found on plants in Africa. Vahl. The antennae are moderate; joints white at the base and black at the tip, the first entirely black; head dusky.

Lineata. Thorax rounded and somewhat spinous; joints of the antennae white at the base. Fabr. Inhabits South America.

Teistis. Thorax rounded, black, with white lines; wing-cases clavated, tectaceous with whitish lines. Fabr. This kind inhabits Transcaucas. The antennae are short and fulvous; wing-cases smooth.

Populnea. Thorax lined with yellow; wing-cases with four yellow dots; antennae moderate. Fabr. Cerambyx populneus. Linn.

Tremula. Green, with two black dots on the thorax, and four on the wing-cases. Fabr. A native of Germany.

Punctata. Green, with numerous black spots; antennae moderate. Fabr. Cerambyx punctatus. Linn. Inhabits the south of Europe.

Vellecens. Thorax villous and cinereous; wing-cases somewhat attenuated and green. Fabr. Inhabits Italy, Dr. Allioni, and France. Broutefont.

Longicornis. Fuscous; legs tectaceous; antennae very long and black with a white ring. Fabr. Inhabits Austria. Bankian cabinet.

Femorata. Anterior part of the thorax fulvous, posterior tectaceous; three alternate bands of black, and tectaceous on the wing-cases; antennae very long. Fabr.

Volvulus. Above black; thorax and wing-cases margined with cinereous. Fabr. Inhabits Cayennne.

Brunnea. Thorax rather spinous, ferruginous; antennae
CER

CER

CER

ceramic and legs fuscous colour. Inhabits Germany. Helwig, &c.

Testacea. Black with tellteaceous wing-cases. Fabr.

A native of Germany.

Violacea. Body violaceous and immaculate. Fabr. Obs. The antennae are moderate and black; thorax somewhat pubescent; wing-cases rough; legs black.

Ephippium. Black; dorso line on the thorax and feint cinereus; thighs ferrugineus. Fabr. This inhabits Hungary, Hungary.

Picea. Fuscus; antennae and legs ferrugineus. Fabr. A South American species of final size.

Scutella. Thorax somewhat spinosus, black; antennae wing-cases and legs greyish; ventral white. Fabr.

A native of Germany. The antennae are shorter than the body, greyish, with the joints ferrugineus at the base; and black at the tip, the frst entirely black; head black; wing-cases smooth, and cinereus; thanks dusky ferrugineus.

Lincola. Black; dorso line on the thorax. and thighs fuscous at the tip. Herbst, &c. Inhabits Italy.

Genus Clinetus.

Antennae fuscous; eyes redinforn, and embracing the base of the antennae; thorax gloes, and broad as the wing-cases; elytra rigid; length of the abdomen; legs long and furmed for walking; thighs comprised; four joints in the feet. Donov. Inf. N. Holland.

Silmaculus. Black; thorax covered with fivory down; wing-cases with three yellow spots, and somewhat emarginate at the tip. Donov. Inf. N. Holland.

Ceramicus, the name of a burgh in Greece, in Attica, belonging to the Acmantole tribe; which was the place called by others the Oster Ceramicus.

Ceramicus, in Botany, a genus formed by Roth for some species of sea weed arranged by Linnaeus and other authors under either focus or conferva, with the following generic character: fronds membranous-corticifolious, somewhat geniculatis; epithelia with generally one seed scattered on the conferva of the branches. His generic character of focus, in contradistinction from the preceding, is, vehicles, aggregate, imbedded in the substance of the frond, furnished with micelluous pores; and of conferva, small tubes, or herbaceous elements, with granae of fructification scattered on the inndo coats of the tube. The same name was given by Stackhouse in the first Faciehin of his "Neres Britannica," to another falcation of plants from the genus Focus, which is afterwards called palmaria. See Neres Brit. Introil. p. 15. 24. 31. 32. See Palmaria.

Ceramium, share in measure, answering to what was otherwise called amphora and cadus.

Ceramorum, in Ancient Geography, a town of Asia Minor, which, according to Xenophon, was situated on the confines of Myia.

Ceramus. See Ceramicus.

Ceramus, or Ceramusa, or Ceramunus, an ephical fee of Africa, in Numidia, and near Mrica.

Cerane. A town of Phrygia, according to Pliny.

Ceranga, a town of Italy, placed by Ptolemy on this side of the Ganges.

Ceranthus, in Botany, Schrebr. Gen. 27. See Chionanthus hieracifolius.

Cerasus affinis, fruitu coccineo. Sloan. Jam. See Cera

Cerasus affinis, fruitu fuscus, Sloan. Jam. See Er

Cerasus affinis, Bauh. Pin. See Prunus maloab.

Ceraso, in Ancient Geography, a Greek town, situated in the territory of Calchis, on the coast. It was a colony of Sampe, according to Xe

Cerasus, or Cerason, an ephical fee of Asis, under the metropolis of Bostra.

Cerasus, one of the names of the isle of Cyprus, according to Pliny. Some say that it bore this appellation on account of the ferocious manners of its inhabitants. Others say that it was called Cerastes (from κερατον, horned), or horned, because it was surrounded with promontories, which projected into the sea, and exhibited the points of rocks at a distance, appearing like horns.

Cerasus was also the name of a people who inhabited this island, who had an altar dedicated to Jupiter, the Hospitable, and which was always invested with the blood of strangers. Venus, offended at this inhumanity, changed them into bulls.

Cerasus, in Zoology, the horned shafe. See C clarify.

Cerasus was also the name given by the ancient Greeks to a flag when at its full growth, or at the end of its fourth year.

Gen. Ch. Cal. perianth five-leaved; leaves ovate-lanceolate, acute, spreading, permanent. Cor. petals five, fuid, obtuse, erect-spreading. Stam. filaments generally ten, filiform, shorter than the corolla; alternate ones shorter;

and
CERASTIUM.

...
CERASTIUM.

** Capsules roundish.

Raf. pl. 1051. Col. Phyta. tab. 71. Myrofoss. Hall. helv. n. 891.) "Leaves linear, tomentuous, hoary; peduncles branched, form what perianth." Lam. Root perennial, creeping. Stems five or six inches long, cottony, branched near the bottom; outer branches procumbent, more abundantly hairy or barren. Leaves white, from six to eight lines long. Flowers white, large, on branched peduncles; calyx cottony, half the length of the corolla. *Catnioniera, L. ob. aid and 21. native I she torn opal.

CERASUS, Cerasus, Cherries. - The word Cerasus is derived from *Cerastia, Cassine virginiana, Rait. denc. See Cercis canadensis.

CERASUS, or Cera, is the name of two mountains of Greece, which were the scenes of the operations of Megara and Athens, according to Strabo. Dictam Surcul, and Plutarch. See Ceratium.

Ceratia flagrata, L. B. See Ceratonia flagrata.

* Ceratia argafla, vitis, Rait, denc. See Ceris canadensis.

CERATIAE, quidam modo affinias, Plut. See Mimosa ligustica.

CERATIAS, among Ancient Naturalists, denotes a horned comet. The word is formed from κέρας, a horn. Such is that said to have appeared when Xerxes passed his army into Greece.

CERATINUS, Jamiw, in Biography, a learned Dutchman of the 16th century, whose family name was Tryggs, but who assumed the name Ceratinus, of Greek etymology, from κέρας, the appellation of his native place, Horn or Hoorn. He combined singular modesty with distinguished attainments in Greek and in the Latin literature, for which he is highly commended by Erasmus. Such was his extreme disinterestedness, that, upon being examined for priest's orders, a question was put to him from the Latin grammar, to which he ingeniously replied, that he did not recollect a single rule by heart. The consequence was his rejection; but when he acquainted a friend with the reason of it, the friend immediately repaired to the examiners, and told them, that they had discovered the most learned man in Louvain, who had given ample evidence of his erudition by an elegant Latin translation from Cytrofson's works. Upon receiving this information, they set him for a second time, and armed him with many apologies for their former rejection of him. Being obliged by the war to quit a professorship which he held at Tournoy, he became a private teacher of Greek at Louvain; and afterwards, on the recommendation of Erasmus to George elector of Saxony, he was chosen to succeed Moellanus in the university of Leipsic. But returning to Louvain, he died there in 1530, in the prime of life. His works were "A Translaction of Cytrofson's Treatise concerning the Priesthood," an improved edition of the "Greek-Latin Lexicon," printed in 1524, with a preface by Erasmus; and a treatise " De Soni Grecorum Literaturum," printed in 1529. Gen. Dict. See Ceratinus Sinus, in Ancient Geography, a gulf of the Thracian Bosphorus.

CERATION, Ceratio, in Cenocracy, the operation of waxing.

CERATITIS, a name given by many authors to the substance more usually called by authors wax. See Ceratia flagrata, and found in great plenty in the coverts of Hartz forest in Germany.

CERATIUM, or Ceration, a name given by the Ancient...
Ancient Physicians to a small weight. The curation is properly the name of a tree called the carob, or *ficus delici*, the sweet pipe-tree: this tree bears a long pod, in which are contained several seeds among the pulp: these seeds are also called *ceratod* and *fumut* by the Arabians; and being dried, they were used as a weight to proportion the dose of medicine. Thus the small weight which took its origin from them, was called curation; as that small weight, which took its origin from a grain of barley, was called granum.

**Ceratodium** was also a small silver coin, the third part of an obolus, and the fame with what the Romans called follis.

Gen Char. Male flowers. Cal. perianth one-leaved, tubular, wider at the top, thin, coloured, smooth (two leaved, Gartt., Cor. none. Stam. filamente, capsillary, scarcely longer than the calyx, inserted into the receptacle; anther two-celled, oval, upright. Female flowers. Cal. perianth one-leaved, inerfely egg-shaped, compressed, keeled on both sides, permanent, two-horned; hornis straight, awl-shaped, divaricat. Cor. none. Pyft. germ oblong, superior; filis two, capillary; ligules simple, standing out between the horns of the calyx. Peric none, except the permanent enlarged calyx, including and cluily adhering to it. Seed simple, oblong, keeled at the bottom, compressed.

**Ceratocephalus**, in Botany, bulbous folio, Vail. See Spilanthes acmela.

**Ceratocephalus folis ordalitis, Vail.** See Biddies there.

**Ceratocephalus folis lanceolatis, Vail.** See Cotula Spilanthes.

**Ceratocephalus delphini folis, Vail.** See Coreopsis coronata.

**Ceratoglossus**, in Anatomy, is that part of the hyoquollus muscle which arises from the cornu of the os hyoides, and which is described by some anatomists as a distinct muscle. See Tongue.

**Ceratoide, in Botany, orientalis fruticos, Tourn.** See Anxri, ceratoide.

**Ceratoide orientalis major & minor, Tourn.** See Ceratocarpos.

**Ceratomalaga**, a sere or cerylcloth.

Gen. Ch. Hesperaphrodite, male and female flowers each on a different plant. Male. Cal. perianth small, open, with five divisions. Cor. none. Stam. filaments five, rarely fix or fcent, awl-shaped, very long, expanding, oppoite to the division of the calyx, proceeding from the margin of the fibrous disk, which occupies the middle of the flower; anthers large, furred, two-celled.

Female. Cal. perianth one-leaved, divided by five tuberules. Cor. none. Pyft, germ superior, in the centre of the fibrous disk or receptacle which covers the inner part of the calyx; style long, terminal; stigma capitate. Peric. lemma long, obtuse, flattened, tetrangular when dry, smooth, coriaceous, not opening by valves, divided by transverse partitions into many cells. Seeds one in each cell, bedded in a succulent pulp, roundish, compressed, hard, shining.

Obsev. Fafano, in Act. Neap. 1787, calls the fibrous disk or receptacle of other authors a permanent corolla.

Sp. C. filipes, Linn. Sp. Pl. Matt. Lam. Illus. Pl. 859. Fafano Act. Neap. tab. 18. fig. 2. Gartt. tab. 146. fig. 1. Del. Pempt. 787, fig. 1. (Silisca eurium, Bauh. Pl. 149. Blackbl. tab. 190.) Carob-tree, St. John’s bread, Pr. Carobum. An evergreen tree of a considerable size. Trunk rugged. Branches crooked, spreading like those of the apple tree. Leaves winged, without an odd one; leaflets in six or eight pairs, three inches broad, roundish, entire, thick, rigid, nerved, dark green above, paler beneath. A native of the south of France, of Naples, Spain, Egypt, and the Levant. Its fruit, when ripe, has a tolerably pleasant sweetish taste, and is eaten in times of scarcity by the country people, but is apt to purge and give the hovels. It is commonly given to cattle. As a medicine, it has the same properties as calffia, but in a lesser degree. The pulp, which has the confidence of a blackish syrup, mixed with licorice-root, dry raffins, and several other kinds of fruit, forms the herbet of the Turks. It was long supphed to have been the food of John the Baptist in the wildernefs; but a better acquaintance with natural histry has now rendered it very unlikely that the *axenic*, or bocul of the evangelic history, is the wealf-known delusive insect of that name. It is much more probable that the shells of the carob tree were the hovels intended by our Saviour in the parable of the prodigal fig. Its leaves are of an alltrange nature, and may be used as a substitute for oak-hark in the tanning of hides. Its wood is esteemed in the south of Europe equal to that of the evergreen oak, and is used for the same purposes.

**Ceratonia**, in Gardening, contains a plant of the evergreen, exotic, thorny kind; of which the species cultivated is the carob-tree, or St. John’s bread, (C. filipes), which rifes with an upright, thick, woody stem, to the height of 15 or 20 feet in its native situation; the head being divided into many branches; the leaves are pinnate, of a dark green colour, three inches in breadth, and rather more in length; and the flowers small, and of a dark purple colour. It is a native of Syria, &c.

**Method of Culture.** These plants are increaset by laying the seeds produced from their native situations in pots of light earth in the spring, plunging them in moderate hotbeds; and after the plants have attained sufficient growth, removing them into separate pots, shade, water, and earth being occasionally given, and the pots continued in the hotbed. As soon as the weather becomes fine in the summer, they should be gradually hardened by exposure to the free air, and be placed out till the approach of autumn, when the protection of the green houle will be necessary to preserve them during the winter feason, free air being given in fine days as much as possible; and afterwards they require only to be managed as other green-house plants, in which situation
tion they have a good effect by the variety which they afford.

Gen. Ch. Male. Cal. perianth with many divisions: divisions awl-shaped, equal. Cor. none. Stam. filaments double the divisions of the calyx, from sixteen to twenty, very short; authors oblong, erect, longer than the calyx.

Female. Cal. and Cor. as in the male. Pet. germ egg-shaped, compressed; flyle none; stigmas obtuse, oblique. Peris. nut small, with a thin, somewhat conicinous rind, hard, one-celled. Seed attached to the bottom of the shell.

**CERATOFORUM**, in *Ancient Geography*, an episcopal see of Afia Minor, in the Pactian Phrygia, according to the acts of the council of Ephesus.

**CERATOSANTHES**, in *Botany*, (compound of κεράς and σανθης, denoting a horned flower). Jaffieu, p. 396. Vent. vol. iii. p. 518. A genus formed out of the Tricho- santhes of Linnæus, for such species as have a four-celled fruit and the inner segments of the calyx not ciliated, but divided at the summit into two revolute horns.

**CERATOSPERMUM**, (compound of κεράς, and σπερμον, denoting a horned seed), Lam. Encyc. Mich. nov. gen. 125. Tab. 56. fig. 1. Hal. helv. n. 2212. Clas and ord. Cryptogamia Alge. A plant acknowledged to be very rare, and to have been seen by few botanists.

It is said to grow on the bark of trees, and to consist of numerous cruraceous, orbicular, distinct warts, charged with a fugacious powder, and containing, in small cavities, oblong, curved capsul with embossing little horns. But Dillenius suspects that Micheli imagined more than he saw, and that his 'cerato' is no other than Lichenoides verrucosum and rugosum, curium album of the Hiliora Muscorum; Lichen pertusus of Linnaeus. Deprerata, quinquies poterit; fiores Michelii visos, tab. 56. lit. A, B, C, D. Quidam plus videt, quam ait, quoniam nempe imaginato perit. Hilt. Muic. p. 139.

Gen. Ch. Cal. Perianth top-shaped, five-cleft; segments large. Cor. concav, tubular-cylindrical; border five-cleft, erect. Stam. ten, situated on the calyx; filaments short; authors very long, attenuated at the tip, and ending in two horns. Pet. stigmas one. Pet. Capsule crowned with the segments of the calyx, somewhat downy, five-cleft, many-seed.

**CERATUM**, in the *Medicinae.* a kind of stuff unguent or liniment; made of oil and wax, with other ingredients; used externally in several diseases, especially those of the skin.

It takes its name from its capital ingredient, wax, called in Latin cera.

Its consistence is thicker than that of a liniment; the last having usually two ounces of wax to two oz. oil; but the cerate four of wax to two of oil; yet it is thinner than a phial.

There are cerates of various kinds, refrigerativa, glammatic, &c. cerates de sulfur, of sanufors, refirgentes cerate de brics, divine cerate, &c.

There is a particular one, called the refrigerativa cerate of Galen, made of white wax and oleum rostit. amphiun.

**CERATUM euphoricum**, a name given to a late London Dispelting to the composition commonly called Turner's cerate, called in the late London Pharmacopea "Ceratum lapides cauinariam," and ordered to be made in this manner: take olive oil a pint; yellow wax and prepared calamine, of each half a pound; melt the wax in the oil, expo it to the air, and when the mixture begins to congeal again, sprinkle in the powder of calamine, and continue stirring it till the whole is cold.

**CERATUM cantharidid is prepared by mixing fix drams by weight of cerate of spermaceti softened by the fire, and one dram by weight of finely powdered cantharis." This may supply the place of the "Epithelium vegetans of the former dispensatory; and in order to quicken its action, an addition of pulv. cantharid, may be made at discretion.

**CERATUM lithargyri aceti compositum**, or compound cerate of acetated litharge, is composed of 2 oz. ounces by measure of water of acetated litharge, four ounces by weight of yellow wax, nine ounces by measure of olive oil, and half a dram by weight of camphor. Rub the camphor with a little of the oil: melt the wax with the remaining oil, and when the mixture begins to thicken, pour on gradually the water of acetated litharge, stirring it till it is cold; and then mix in the camphor, which was before rubbed with the oil.

**CERATUM reina fluxa**, or cerate of yellow resin, is prepared by melting together half a pound of ointment of yellow resin with one ounce by weight of yellow wax.
CERATUM socotri, or soap-cerate, is composed of the following ingredients; viz. 8 ounces by weight of soap, 1 ounce by weight of yellow wax, one pound of powdered laurel, one pint of olive oil, and one gallon of vinegar. Boil the vinegar with the laurel, or, as means of a slow fire, constantly fuming, till the mixture unites and thickens; then mix in the other ingredients in order to form a cerate.

CERATUM Sperrmanni Ceti, or cerate of spermaceti, is prepared by mixing together half an ounce by weight of spermaceti, two ounces by weight of white wax, and four ounces by measure of olive oil, and allowing it till the mixture becomes cold.

CERATUM mercurialis, a form of medicine prepared in the late London Pharmacopoea, and ordered to be made in the following manner: take yellow wax and twice logo's lard, of each half a pound; quicksilver, three ounces; simple balsam of sulphur, a dram: melt the wax and lard, and then add to them gradually the quicksilver, first well divided by the bal- 

CERATUS, or CERATUS, in Ancient Geography, a small river of the island of Crete, which, according to Siraiob, ran near the town of Gaius.

CERERIA, in Antiquity, a kind of musician, who blows or plays on the horn.

In which sense, the word amounts to the same with the Latin cornicen.

CERANIA, in Ancient Geography, a town of the Peloponnesus, in Achaia, according to Polybius. It was one of the twelve cities which formed the Achaean league.

CERANIA, now Cerone, an ancient town on the north coast of the island of Cyprus; which, like Paphos, exhibits nothing but ruins, as a testimonio of its past grandeur.

CERANIAS, CERANIAS; of CERANIAS lupitae, in Natural History, a sort of flinty figured stone of no certain colour, but of a pyramidal or wedge-like figure; popularly supposed to fall from the clouds in thunder-storms, and to be possessed of divers notable virtues; as of promoting sleep, preferring from lightning, &c. The word is formed from κέρανιον, a thunder bolt. The ceramia is the name with what is otherwise called the thunder-flone, or thunder-bolt; and sometimes also ≤γινιτα, or arrow's head, on account of its shape.

The ceramia are frequently confounded with the ombria and brontia, as being all supposed to have the fame origin.

The generality of naturalists take the ceramia for a native fomite, formed among pyrites, of a silane, concrete, mineral juice. Mercutus and Dr. Woodward assert it to be artificial, and to have been fashioned thus by tools. The ceramia, according to these authors, are tinsels, or heads of the ancient weapons of war, in use before the invention of iron; which, upon the introduction of that metal, growing into disuse, were dispersed in the fields through this and that neighbouring country.

Mr. Dohrke has found, among the worn fomes of the Mediterranean shore, javelin-heads of pyhophyr, Jasper, horn-flone, fchell, varoite, &c. probably fabricated by the ancient inhabitants, the Gauls. These javelin-heads, made of Jasper, &c. on account of their excelle hardnes, of which even the savages of Canada have availed themselves in the confection of such weapons, are commonly known by the name of thunder-flomes, and are distinguished by the Litho-

gulls by the name of Ceramites or Ceranias.

CERANIAS albus, a name given by Pliny to a gem or precious flone, of the nature of the alieria, but somewhat inferior to it in beauty. Pliny tells us that it was a very bright gem, of a crytalline appearance, but

with a cat of blinis; and that it was found in Caramania. Solinus gives us much the fame account, but makes Ger-

many the place of its origin. It is, indeed, written Ger-

mania in several of the old copies in Pliny, but the most correct have it as in printed, Caramania; and Caramania was a country from which the Romans had many gems.

CERANII, in Ancient Geography, a people of Illyria, who, according to Pliny, were divided into 124 decures. They are also mentioned by Ptolomy.

CERANIA, See ACERANIA. Pomponius Mela gives this name to a part of mount Taurus, which proceeded from the coast of the Euxine sea, the Palus Mountis and Tania.

CERANIAE, or CERANAE, a town of Italy, which Diodorus Siculus places in the country of the Semnites; and which, he says, was taken by the Romans.

CERANITIES, in Natural History, a name given by several writers to the seminates.

CERANUS, or Fulminator, in Mythology, an epitaph of Jupiter.

CERANUS, in Ancient Geography, a river of Asia, in Cappadocia, according to Pliny.

CERANUS, a mountain of Peloponnesus, in Arcadia; which, according to Pausanias, formed a part of mount Lyceum.

CERBALITANUS, an episcopal see of the proconfular Africa.

CERBALUS, now Ceravo, a river of Italy.

CERBANI, a name given by Pliny to an ancient people of Arabia Felix; called Cerdanite by Steph. Byz.

CERBANUM, a town of Italy, mentioned by Procopi.

Gen. Ch. Cal. Perianth five-leaved, or five-cleft. Cor. monopetalous, funnel-shaped; tube elevated, longer than the calyx; orifice pentangular, nearly closed by five converging teeth; limb large, five-cleft; segments oblique, obtuse, more gibbous on one side. Stam. filaments five, awl-shaped, in the middle of the tube; anthers erect, converging. Pijf. germ roundish; style filiform, short; stigma capitulate, two-lobed. Peric. drupe large, roundish, felthy, hollowed on one side by a longitudinal furrow. Seed, a nut, containing one, two, or four kernels.

Sp. 1. C. Aboun, Linn. Sp. Pl. 1. mart. 1. Willd. 1. Lam. 1. Illuf. Pl. 170. Bat. Mag. Pl. 737. (Ahousi, Thev. Antarct. 65. Tourn. Infl. 658. tab. 434.) Thevetia, Linn. Hort. Chlf. Arbor Americana, folis pinnatis, fructis triangularibus, Daud. pin. 454.) "Leaves egg-shaped, acute." A tree, ten feet high, yielding in all its parts a poisonous milky juice. Stem and branches irregular and crooked. Leaves three inches long, one and a half broad, thick, succulent, bright green, smooth. Flowers in clusters at or near the extremity of the branches, cream-coloured; calyx divided half way down into five acute reflexed segments; tube of the corolla dilated in the upper part; stamens five, twisted, marked with five deep furrows; segments of the limb, oval, oblique, with undulated margins; anthers on short filaments, enclosed in the inflated part of the tube; stigma bident, top-shaped, surrounded at the base by a circle of greenish glands, which secrete a colourless, very sweet honey, perfectly free from any acrid or nauseous taint. A native of Brazil and the West Indies. Cultivated by

Mr.
Mr. Miller, in 1759. It flowers in July and August, but never produces fruit in England. Its wood has a very offensive smell; and its kernels of the nuts are a deadly poison. 2. C. obtusa, Willd. 2. Cavan. 1c. in. p. 35. tab. 470. "Leaves elliptical, obtuse." Leaves feathery, nearly sessile. Flowers terminal, about five together. A native of New Spain. 3. C. theovis, Loudon. Sp. Pl. 2. Mart. 3. Lam. 2. Willd. 6. Jacq. Amer. 38. tab. 34. Herb. 20. tab. 47. Lam. Ill. Pl. 170. "Leaves linear, very long, crowded." An elegant shrub, from twelve to fifteen feet high. Stem round, subangular in a poisonous milky juice, diluting at the top into numerous weak branches; branches imparipinnate, leaves so small, marked with the scars of fallen leaves. Leaves on short petioles, scattered, narrow, linear, acuminate. Four or five inches long, full of a milky juice. Flowers yellow, large, odoriferous, generally solitary, nodding, axillary, and terminal; pedicels shorter than the leaves; teeth of the tube dilated; filaments very short; germ free, brown, interspersed with a yellow, fleshy, mealy-ovate, yellowish seed. Fruit greenish, round, oblong, milky, containing an obscurely three or four-corrugated nut, which opens by a kind of furrow on one side. A native of Cayenne and the West Indies. Received by Mr. Miller in 1759, by the name of French physic-nut. 4. C. manghas, Loudon. Sp. Pl. 2. Mart. 2. Lam. 3. Willd. 4. Obs. l. 91. Petiv. tab. 16. fig. 4. (Manghas fruitu venenato, Bauh. P. 442. Burm. Zel. 150. tab. 70. fig. i. Arbor lactacea, Rumph. Ambr. ii. p. 243. tab. 51. Odolom. Rheed. Mal. i. p. 71. tab. 39.) "Leaves lanceolate; nerves transverse." A milky tree, from eighteen to twenty feet high. Wood white and tender; bark even; branches rather spreading, crooked, cylindrical, marked with scars of fallen leaves. Leaves alternate, but scattered near the ends of the branches, ten or twelve inches long, and three broad, on short petioles, quite entire, smooth even, above, furnished underneath with transverse parallel nerves, which proceed from the midrib, and terminate in a nerve-like cord at the border of the leaf. Flowers white, in terminal, branched, unequal, racemose; calyx five-lobed; leaflets lanceolate, spreading, coloured, deciduous; tube of the corolla longer than the calyx; anguly oval within; lobes of the border egg-shaped, large; filaments very short, inserted into the upper part of the tube; anthers egg-shaped, covered with the down of the tube; germ brown; style filiform, somewhat shorter than the tube; stigma egg-shaped, cloven. Fruit egg-shaped, the size of a goose's egg, green, marked with small white spots, compressed on one side, with an obsolete furrow; including two large seeds which resemble chestnuts, and have a poisonous, vomiting quality. A native of the East Indies, and of the Society islands. In the island of Ambuina its bark is used as a purgative.

Swartz has observed that this species would form a genus distinct from the two preceding, if it were not defirable not to multiply genera without absolute necessity. Gartner affirms that on account of the difference in the structure of the fruit it cannot be associated with them under the same genus. He maintains moreover, that the Arbor lactacea of Rumphius and the Odollam of Rhedoe, quoted by Linnaeus as synonyms, are distinct species strongly marked by the characters of the fruit. He gives the following description of the former from a specimen in the collection of Mr Joseph Banks, and of the latter from a specimen preserved in the museum at Amsterdam. C. manghas, Tab. 123 and 124. fig. 1. Paric. Drupe two, dry, large, ovate-oblong, gibbous and obliquely truncated behind, more even with a slightly deprected furrow before; outer cuticle membranous, thin, dark brown; flesh fleshy, resembling the dried pith of elder, intermingled with the filaments of the putamen or shell; putamen woody; confining of round fibres proceeding from the inner part in a radial manner towards the circumference, and there changing into new, rather even, longitudinal fibres which form a peculiar woody kind of bark; embalmed by means of a delusive fruit in the anterior part, and continued to the middle of the back; oneelled, but divided into two chambers by a movable membranous partition placed between the valves. Seed one, (the other constantly abortive) large, ovate-oblong, lenticularly compressed, attenuated at the tip, of a dull nutty colour.

5. C. obsidolem, tab. 124. fig. 3. Drupe generally single, elliptico-oblong, very convex on one side, greenish yellow; cortical layer of fibres as in the preceding, woody; fibres broader, more branched and frequently reticulated on the hinder part; putamen embalmed, one celled, but divided into two chambers; partition free, double, rising from a woody curved pedicle, each part clothed on its inner side (that towards the axis of the fruit) with an irregular sheath of crooked fibres, and on its outer side bearing the seed. Seed one in each chamber, ovate-accuminate, on one side remarkably convex, flat on the other, and so closely adnate to the partition as to leave only the tip free. Gartner describes also a seed communicated to him by a friend which appears to belong to another distinct but unknown species. He calls it 6. C. playf. frons, tab. 124. fig. 2. Putamen woody, egg-shaped, muriated on all sides by multiform upwardly incurved fibres, nearly two-valved by means of a future extended to the base, divided into two very compressed chambers by a movable partition; partition coriaceous, confining of two laminæ opposite to the future of the valves. Seeds two in each chamber, foliaceous-compressed, free on both sides, unequal; one larger, ovate-lanate superior; the other smaller, somewhat kidney-shaped, inferior. 7. C. parvispero. Willd. 3. Forth. prod. 121. (Ochofria borbonica; Genel. Syllab. nat. p. 459.) "Leaves filiform, irregularly egg-shaped." A native of the Friendly Islands and of Savage Island in the Pacific ocean. 8. C. maculata, Willd. 5. (Ochofria borbonica;焦耳. O. maculata; Jacq. croc. rar. 2. tab. 341. Dryand. in Linn. Trans. 2. p. 227.) "Leaves lanceolate, dark green, spotted; cymes axillary, branched, disarticulated." It differs from the preceding in the form of its leaves. A native of the Isle of Carbon, 9. C. falatis, tab. 35. Linn. Cochin. 156. (C. crassifolium, Lam. 9. Lat. falatis; Rumph. Amb. 3. tab. 255. tab. 54.) "Leaves and fruit oval." A middle-sized tree, with a milky juice, and spreading branches. Leaves oblong-oval, obtuse, quite entire, shining, crowded at the ends of the branches, on short petioles. Flowers white, inodorous, in small nearly terminal racemes; calyx five-cleft; segments awn-scaled, long, erect; corolla falcat-shaped, with a long incurved tube; segments of the border oblong, fleshy, spreading, not contorted; germ egg-shaped, very small; style longer than the filaments, thick, curved, always turbinated on the side of the corolla; stigma smooth, vertically compressed, truncate. Drupe oval, large, with a smooth skin, yellow on one side, red on the other, containing a fibrous-woody nut, with a single kernel, not poisonous. The want of a contorted corolla renders its genus dubious. A native of Cochin China near the coast, and of the Moluccas. 10. C. mumculformis, Lam. 5. (Fructus mumculiformes; Rumph. Amb. 2. Append. 165. tab. 63.) "Fruit mumculiform." Leaves alternate, pinnate, petiolated, ovate-oblong, obtuse, smooth furnished with lateral transverse nerves, from six to eight inches long and two broad.

Flowers

Flowers in a simple raceme, according to Rumphius resembling those of C. manghas, but smaller. Fruit oblong, acute, full of a milky juice like the leaves and all other parts of the plant, about three inches long and one broad, a little compressed laterally, with a longitudinal furrow, having firm flesh, and containing two or three irregular kernels. The empty dried shell is half split in two on the upper part and bears some resemblance to a muscle. A native of the Moluccas and the Sunda isles. La Maree judges this as well as the preceding to be a doubtful species.

Propagation and Culture. These plants may be propagated by seeds procured from their native countries, and require the same treatment as other tropical trees and shrubs, but as they abound in milky juice, they should be sparingly watered, especially in the winter season.

CERBERUS, in Astronomy, a small northern constellation near Hercules, confining, in Hevelius’s Catalogue, of four stars, which are enumerated under Hercules in the British Catalogue.

CERBERUS, among Chemists, denotes Mercury.

The name CERBERUS is also given by some to a famous purging powder, more usually called pulvis cornachines, and pulvis comitis Harracense. See Cornachina powder.

CERBERUS, in Mythology, a name which the ancient poets have given to a dog with three heads and mouths, born of Typhon and Echidna, and stationed at the gate of hell. Those who entered were cared for by him; but to such as would return he was more terrible than hell itself; except in the influences of Bacchus and Hercules, and Mercury and Orpheus. The “dog of darkness” of the Edda bears, in some respects, a resemblance of this monster.

Some have supposed that CERBERUS is the symbol of the earth, or of all-devouring time; and that its three mouths represent the present, past, and future. Accordingly they derive the name from *κερίς, καρνοφόρος, carnivorous; it being the property of the earth to devour dead bodies. The victory obtained by Hercules over this monster, denotes the conquest which this hero acquired over his passions. The Platonists consider him as the evil demon, who, as Porphyry expressed it, is found in the three elements, air, water, and earth; whence they derive his three heads. In a monument, preferred by Montauro, CERBERUS is represented on a box, with one head of a man, another of a dog, and the third of an ape; and two serpents twining round him bind together his legs. This figure was brought from Egypt. Heraclides gives to CERBERUS 50, and others 100 heads; but he more commonly appears with three. He is said by SOME to have had the tail of a dragon; and instead of hair a skin, flagged over with scales, whence probably is derived the epithet Medusaean.

Dr. Bryant supposes that CERBERUS was the name of a place, and that it signified the temple of the Sun; deriving it from Kûr-Abor, the place of light. This temple was also called Tor Caphel, of which it was changed to *τυρακόπους, and hence CERBERUS was suppos’d to have had three heads. It was likewise called Tor-Korin, Turris Regia; whence *τυρών, of a, from *τιμων, three, and ἄπων, head. Anal. of Mythology, vol. i. p. 439, ccc.

CERBIA, in Ancient Geography, a town of the island of Cyprus.

CERBICA, Sleekhal, a town of Africa, situate 18 leagues S.W. of Capsa, according to Ptolemy. In this place are found some vestiges of the Romans.

CERBOLE, in Geography, a small island, or rather rock, in the Mediterranean, near the coast of Tuscany, a little to the north of the island of Elba.

CERAPHUS, in Ancient Geography, a mountain of Afa Minor, in Ionia, near the town of Colophon.

CERCARIA, in Zoology, a genus of animals, defined by writers vermis nudus ocult insconsuerus, pellicidas, candidus. Gmel. Vermis insconsuerus, pellicidas, candidus, Müller, &c. A worm, invisible to the naked eye, pellicid, and furnished with a tail.

The animals of this tribe which, from their extreme minuteness, can only be discovered by the assistance of a microscope, are found in vegetable and animal infusions of water, in stagnant waters of every kind, in salt-water, even in pure water, and in spermatic fluids, according to some French writers. The most copious history of these anamnelves is to be found in Müller’s Hist. Vermin, Havniae, 1786. Om insurrectiones dysenterae forplantifer-ciliata, &c. The following are the principal species of this genus.

* Depressid.

PLEURONECTES. Orbicular, the tail consisting of a single bristle. Müll. Gmel. This is membraneous, rather round, and white; not the entire tail of the latter is blackish, but the middle orbicular interlines of various sizes, the larger of which appears remarkably bright. When swimming, it is observed that one edge of the lateral membrane is upwards, and the other folded down. It is found in water that has been kept several months. Müll. Adams, &c.

TENAX. Membraneous, anterior part rather thick and truncated; tail three times as short as the body. Müll. This appears an oval pellucid membrane, the anterior part thick, and truncated, the posterior acute, or terminating in a short tail; its motion in the water is circular, whirling about in various directions with great velocity.

CYCLIDUM. Oval, somewhat emarginate behind, with an exsertile tail. Müll. Found frequently in pure water. The body is oval, smooth, membraneous, pellucid, with a black margin; the posterior part is somewhat notched, and furnished with a tail which it thrusts out at pleasure. The interlines are remarkably pellucid vehicles.

** Subregional.

TRIPUS. With a pointed, reflected arm on each side. Müll. This kind was discovered in sea-water by Müller. The body is of a somewhat triangular form, with a straight tail.

LEMMIA. Changeable, somewhat flattened, with an annulated tail. Müll. Remembles, in some respects, the proteus of Baker, though altogether different. The body is capable of being contracted or extended, changing from oblong, or the shape of a pear, to kidney-shape. The tail is short, thick, and annulated. It vibrates, when stretched out, with so much velocity, that it appears double. The interlines are not very dilated. Near the apex is a small pellucid globule, which Müller supposes to be the mouth. Adams, &c. Inhabits stagnant water.

LUPUS. Cylindrical, thick, and elongated: tail terminating in two spines. Müll. Lives in stagnant waters. This is one of the largest species of its genus. It is full of muscles, which are capable of being contracted or extended. The head is larger than the body, with the apex bent down like a hook. The two spines at the extremity of the tail are very bright, and moveable.

PODURA. Cylindrical, posterior part pointed, and slightly

clit
of tail, level, river of air, though, e. months cake, pointed. It body. Also, arm, Gyrinus. Gibba. Inquieta. CERCEAU, terminating and swimming, gelatinous, with ventral turns and long is. This one form Adams. Rarely found. Inhabitants eat water. Hirta. Anterior part, what truncated; lower obtuse, and terminating in two small points. Adams. This also is found in salt water.

Crumena. Cylindrical and ventricose; anterior part obliquely truncate; tail linear, and ending in two diverging points. Adams, &c.

Verticillata. Cylindrical, annulated, with projecting front; tail two small points, Adams.

Luna. Orbicular; tail two short points; anterior part inflated, or crescent-shaped. Cercestis, Adams.

CERCAS, in Ancient Geography, a town of Greece, near Adas, mentioned by Suidas.

CERASAROPOLIS, a town of Egypt, seated on the left bank of the Nile, at the place where this river divides to form the Dikta. It is mentioned by Herodotus and Pompimus Mela. Its eastern branch is the Pelusian arm, and the western, the Canopian. Strabo calls this town Cerephora, and places it on the side of Libya.

CERCI, in the Eastern History, are a body of horse in the service of the grand vizier.

CERCEAL, John Anthony Duc, in Biography, was born at Paris in 1750, and entering at the age of 18 years among the Jeffins, distinguished himself in their society by the vicinity of his talents. Having indulged his taste for Latin poetry, he published a collection of pieces in 1755, which gained him a considerable degree of reputation. He afterwards applied to vernacular poetry, and became an imitator of Miró. But, retiring to a life of leisure and study, he resumed his former pursuits; and, after a long illness, he was enabled to pursue his studies in peace. He died in 1775, and was buried in the church of St. Stephen, where a monument was erected in his memory. His works were published posthumously, and were received with great applause.

CERCEI, in Hisbelion, one of the nymphs called Oceanides, the daughter of Oceanus and Theis. Hesiod. Theogon. v. 55.

CERCEI, in Ancient Geography, a town of Egypt, placed by Diodorus Siculus towards the western ocean; called the Atlantides. CERCEASCO, in Geography, a town of Piedmont, in the marquisate of Salsus; 21 miles S.S.W. of Turin.

CERCEI, in Ancient Geography, a people who dwelt to the south of Mount Caecina and the Esiae sea, according to Strabo.

CERCI, in Modern Geography, the mountains of Thessaly, according to Pausanias. They are named "Mons Cercestis," by Ptolemy, and "Mons Cerasti" by Lyc. CERCLITICUS Sins, a small place, said to be called by the ancient coast of the Esiae sea, to the east of the Ades.

CERCIUS, a mountain of the island of Samos; Strabo seems to make it a part of mount Amphias.

CERESARO, in Geography, a town of Naples, in the province of Calabria Citta; 6 miles N.E. of Capo di Farno.

CERCHIARO, a river of Naples, which runs into the sea of Tarentum; 9 miles N.E. of Capo di Farno.

CERCI, in Ancient Geography, an island of the Mediterranean, placed by Ptolemy in Asia Minor, on the coast of India.

CERCHI, a people of Italy, who were forced by the Romans into a colony under the consulate of Lucius Varus and A. Munatius. Diod. Sec.

CERCEI and CERCI, now Kraukol, two vast and contiguous islands of Africa, situate to the S.E. of Capo-podis, at the distance of five leagues. Strabo and Pliny say, that they were joined by a bridge. Poleni mentions also a town of the name of Cercina. A great stream, Strabo, and other ancient geographers, fix the beginning of the Iberian Syrtes at these islands; though, from circumstances
CERCIS, a mountain of Macedonia, between Peonia and Sotica, according to Thucydides.

CERCINE, a town of Macedonia, at the mouth of the river Pontus in the lake called "Cerciniths palus," which was a marsh extending from west to east, between the town of Cercine and the place called Myrcineus.

CERCINTIS. See CERCINE.

Gen. Ch. Col. Parnath one-leaved, very short, bilobed, gibbous below, meiferous, with five erect obverse teeth. Cor. Petals five, inserted into the calyx, phyllonoceous; wings bent upwards, affixed by long claws; standard roundish, shorter than the wings, and placed beneath them; keel two-petalled, converging into a heart-shaped form, and containing the stamens and pistil; neasty a style-shaped gland beneath the germ. Linn. (a cavity between the insertion of the stamens and of the pistil. Linn.) Stam. Filaments ten, not united, avul-shaped, curved, slightly downy on the inner side of their base, unequal, inserted into the calyx; anthers oblong, incumbent, rising upwards. Pyl. Germ linear-lanceolate, pedicilled, smooth; style the length of the stamens; stigma obtuse, rising upwards. Peric. Legume oblong, obliquely acuminate, one-celled. Seeds several, roundish, attached to the upper future.

Eff. Ch. Calyx five-toothed, gibbous below. Cor. phyllonoceous; standard short, placed beneath the wings; fruit, a legume.

Sp. 1. C. Siliqua trium. Common Judas-tree. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Wild. 1. Lam. Pl. 328. (Siliqua fylhebra rotundifolia; Dast. Pin. Arbor Judae; Dast. Ræ. hill.) "Leaves orbicular-heart-shaped, smooth." A tree, from twenty to thirty feet high. Trunk upright, with a dark-green bark; branches irregular, spreading. Leaves alternate, petiolated, quite entire, thickish, pale green above, greyclad underneath, deciduous, with diverging leaves proceeding from the extremity of the petiole; stipules oblong, membranous, opposite, caduous. Flowers red, or bright purplish rosy-colour, sometimes white, appearing before the leaves in lateral racemes on the branches, and sometimes on the trunk of the tree. Legumes five or six inches long, near an inch broad, resembling the cave of a knife, whence their French name is derived. The flowers are grateful to birds, especially parrots, who often make great havoc among them and prevent the fruit from coming to perfection. On account of their agreeable pungency they are used by the French as an ingredient in salads, and are sometimes pickled. A native of the southern parts of Europe, flowering in April and May. Cultivated by Gerard in 1597. 2. C. canadensis, Linn. Sp. Pl. 1. Mart. Lam. Wild. (Ceratia gigantea macrozona folio, Pluk. Alm. 95.) "Leaves acuminate-heart-shaped, pubescent." Common in Japan and American Territories. Resembling the preceding in habit, but smaller and less beautiful. La Mareck affirms that its leaves, as well as those of the common kind, are quite smooth: A native of most parts of North America. Cultivated by Miller in 1790.
